Complementary Therapies and Integrative Health

OBJECTIVES

- Differentiate between the use of therapies as complementary versus alternative treatments.
- Describe integrative health as applied to nursing practice.
- Describe the clinical applications of relaxation therapies.
- Discuss the relaxation response and its effect on somatic ailments.
- Identify the principles and effectiveness of imagery, meditation, and breathwork.
- Describe the purpose and principles of biofeedback.
- Describe the methods of and the psychophysiological responses to therapeutic touch.
- Discuss the principles and applications of acupuncture.
- Describe safe and unsafe herbal therapies.

KEY TERMS

With few exceptions, the general health of North American people has steadily improved over the course of the past century, as evidenced by lower mortality rates and increased life expectancies. Changes in knowledge, technology, science, and health care have altered the course of many illnesses. Although **allopathic or biomedicine** (conventional Western medicine) is quite effective in treating numerous physical ailments (e.g., bacterial infections, structural abnormalities, and acute emergencies), it is generally less effective in decreasing stress-induced illnesses, managing symptoms of chronic disease, caring for the emotional and spiritual needs of individuals, and improving quality of life and general well-being. As a result, patients continue to seek complementary (non-biomedical) treatments in increasing numbers, integrating these therapies with biomedicine.

The most recent comprehensive national survey estimates that between 33.2% and 50.6% of the US population integrate complementary and biomedical treatments to reduce symptom burden and improve overall well-being (Clarke et al., 2015). In part, this use corresponds to (1) a desire

for less invasive, less toxic, “more natural” treatments; (2) lack of satisfaction with biomedical treatments; (3) an increasing desire by patients to take a more active role in their treatment process; (4) beliefs that a combination of treatments (biomedical and complementary) result in better overall results; (5) the increased number of research articles in journals such as *Journal of Alternative and Complementary Medicine* and the *Journal of Holistic Nursing*; and (6) beliefs and values that are consistent with an approach to health that incorporates the mind, body, and spirit or a holistic approach (Koithan, 2018).

Complementary and Integrative Approaches to Health

The National Institutes of Health/National Center for Complementary and Integrative Health (NIH/NCCIH, 2018) identifies complementary and integrative approaches as an array of health care approaches with a history of use or origins outside of mainstream or conventional medicine.

Complementary therapies are therapies used together with conventional treatment recommended by a person's health care provider. As the name implies, complementary therapies complement conventional treatments. Many of them, such as therapeutic touch, contain diagnostic and therapeutic methods that require special training. Others, such as guided imagery and breathwork, are easily learned and applied. Complementary therapies also include relaxation; exercise; massage; reflexology; prayer; biofeedback; hypnotherapy; creative therapies, including art, music, or dance therapy; meditation; chiropractic therapy; and herbs/supplements (Lindquist et al., 2018). Another term that is used to describe interventions used in this fashion, particularly by licensed health care providers, is **integrative therapies** (Kreitzer and Koithan, 2019).

When nonpharmacologic therapies such as exercise, chiropractic, and herb supplements are used in place of conventional pharmacologic or other medical procedures, they are considered **alternative therapies** (NCCIH, 2018). These therapies then become primary treatments, replacing biomedical care. For example, most of the time a person with chronic pain uses yoga to encourage flexibility and relaxation at the same time in which nonsteroidal antiinflammatory or opioid medications are prescribed. Both sets of interventions are based on conventional pathophysiology and anatomy while acknowledging the mind-body connection that contributes to the physiological pain response. In this case, yoga is used as a complementary intervention. However, when that same patient decides to use a meditative practice that includes yoga and other lifestyle changes rather than medication, yoga now becomes an alternative therapy and is perceived as more helpful than an allopathic approach for chronic pain. Some patients, particularly those from different cultural backgrounds, may choose to use **whole medical systems** such as **traditional Chinese medicine (TCM)**, Ayurveda, or naturopathy as alternative systems of care to biomedicine. When used in this fashion, these approaches are always considered alternative because they are based

on completely different philosophies and life systems than those used by allopathic medicine. [Table 32.1](#) presents types of complementary therapies.

TABLE 32.1**Complementary Therapies**

Types	Definitions
Biologically Based Therapies	
(Natural products)	
Dietary supplements	Defined by the Dietary Supplement Health and Education Act of 1994 and used to supplement dietary/nutritional intake by mouth; contain one or more dietary ingredients, including vitamins, minerals, herbs, or other botanical products
Herbal medicines	Plant-based therapies used in whole systems of medicine or as individual preparations by allopathic providers and consumers for specific symptoms or issues
Macrobiotic diet	Predominantly a vegan diet (no animal products except fish); initially used in the management of a variety of cancers; emphasis placed on whole cereal grains, vegetables, and unprocessed foods
Mycotherapies	Fungi-based (mushroom) products
Orthomolecular medicine (megavitamin)	Increased intake of nutrients such as vitamin C and beta-carotene; treats cancer, schizophrenia, autism, and certain chronic diseases such as hypercholesterolemia and coronary artery disease
Probiotics	Live microorganisms (in most cases, bacteria) that are similar to beneficial microorganisms found in the human gastrointestinal system; also called <i>good bacteria</i>
The "Zone"	Dietary program that requires eating protein, carbohydrate, and fat in a 30:40:30 ratio—30% of calories from protein, 40% from carbohydrate, and 30% from fat; used to balance insulin and other hormones for optimal health
Energy Therapies	
(Use or manipulation of energy fields)	
Acupuncture	Traditional Chinese method of producing analgesia or altering the function of a body system by inserting thin needles along a series of lines or channels, called meridians; direct needle manipulation of energetic meridians influences deeper internal organs by redirecting <i>qi</i>
Healing touch	Biofield therapy; uses gentle touch directly on or close to body to influence and support the human energy system and bring balance to the whole body (physical, spiritual, emotional, and mental); a formal educational and certification system provides credentials for practitioners
Reiki therapy	Biofield therapy derived from ancient Buddhist rituals; practitioner places hands on or above a body area and transfers "universal life energy," providing strength, harmony, and balance to treat a patient's health disturbances
Therapeutic touch	Biofield therapy involving direction of a practitioner's balanced energies in an intentional manner toward those of a patient; practitioner's hands lay on or close to a patient's body
Magnet therapy	Bioelectromagnetic therapy; devices (magnets) applied to the body surface, producing a measurable magnetic field; used primarily to alleviate pain associated with musculoskeletal injuries or disorders
Manipulative and Body-Based Methods	
(Involve movement of body with focus on body structures and systems)	
Acupressure	Applying digital pressure in a specified way on designated points on the body to relieve pain, produce analgesia, or regulate a body function
Chiropractic medicine	Manipulating the spinal column; includes physiotherapy and diet therapy
Craniosacral therapy	Assessing the craniosacral motion for rate, amplitude, symmetry, and quality and attuning/aligning the spinal column, cerebrospinal fluid, and rhythmic processes, releasing restrictions or abnormal barriers to motion
Massage therapy	Manipulating soft tissue through stroking, rubbing, or kneading to increase circulation, improve muscle tone, and provide relaxation
Simple touch	Touching the patient in appropriate and gentle ways to make connection, display acceptance, and give appreciation
Mind-Body Interventions	
(Honor connections between thoughts and physiological functioning using emotion to influence health and well-being)	
Art therapy	Use of art to reconcile emotional conflicts, foster self-awareness, and express patients' unspoken and frequently unconscious concerns about their disease
Biofeedback	Process providing a person with visual or auditory information about autonomic physiological functions of the body such as muscle tension, skin temperature, and brain wave activity through the use of instruments
Breathwork	Using a variety of breathing patterns to relax, invigorate, or open emotional channels
Guided imagery	Concentrating on an image or series of images to treat pathological conditions
Meditation	Self-directed practice for relaxing the body and calming the mind using focused rhythmic breathing
Music therapy	Using music to address physical, psychological, cognitive, and social needs of individuals with disabilities and illnesses; improves physical movement and/or communication, develops emotional expression, evokes memories, and distracts people who are in pain
Tai chi	Incorporating breath, movement, and meditation to cleanse, strengthen, and circulate vital life energy and blood; stimulate the immune system; and maintain external and internal balance
Yoga	Focuses on body musculature, posture, breathing mechanisms, and consciousness; goal is attainment of physical and mental well-being through mastery of body achieved through exercise, holding of postures, proper breathing, and meditation
Movement Therapies	
(Eastern or Western approaches to promote well-being)	
Dance therapy	Intimate and powerful medium because it is a direct expression of the mind and body; treats persons with social, emotional, cognitive, or physical problems
Feldenkrais method	A complementary therapy based on establishment of good self-image through awareness and correction of body movements; integrates the understanding of the physics of body movement patterns with an awareness of the way people learn to move, behave, and interact

Types	Definitions
Pilates	Method of body movement used to strengthen, lengthen, and improve the voluntary control of muscles and muscle groups, especially those used for posture and core strengthening; awareness of breathing and precise movements are integral components
Whole Medical Systems	

(Complete systems of theory and practice that have evolved independently from or parallel to conventional biomedicine)

Ayurvedic medicine	One of the oldest systems of medicine, practiced in India since the first century AD. There are eight branches of Ayurvedic medicine, including internal medicine; surgery; treatment of head and neck disease; gynecology, obstetrics, and pediatrics; toxicology; psychiatry; elder care and rejuvenation; and sexual vitality. Treatments balance the doshas using a combination of dietary and lifestyle changes, herbal remedies and purgatives, massage, meditation, and exercise.
Homeopathic medicine	Developed in Germany and practiced in the United States since the mid-1800s. It is a system of medical treatments based on the theory that certain diseases can be cured by giving small, highly diluted doses of substances that in a healthy person would produce symptoms like those of the disease. Prescribed substances called <i>remedies</i> are made from naturally occurring plant, animal, or mineral substances and are used to stimulate the vital force of the body so that it can heal itself.
Latin American traditional healing	<i>Curanderismo</i> is a Latin American traditional healing system that includes a humoral model for classifying food, activity, drugs, and illnesses and a series of folk illnesses. The goal is to create a balance between the patient and his or her environment, thereby sustaining health.
Native American traditional healing	Tribal traditions are individualistic, but similarities across traditions include the use of sweating and purging, herbal remedies, and ceremonies in which a shaman (a spiritual healer) makes contact with spirits to ask their direction in bringing healing to people to promote wholeness and healing.
Naturopathic medicine	A system of therapeutics focused on treating the whole person and promoting health and well-being rather than an individual disease. Therapeutics include herbal medicine, nutritional supplementation, physical medicine, homeopathy, lifestyle counseling, and mind-body therapies with an orientation toward assisting the person's internal capacity for self-healing (vitalism).
Traditional Chinese medicine (TCM)	An ancient healing tradition identified in the first century AD focused on balancing yin/yang energies. It is a set of systematic techniques and methods, including acupuncture, herbal medicines, massage, acupressure, moxibustion (use of heat from burning herbs), qi gong (balancing energy flow through body movement), cupping, and massage. Fundamental concepts are from Taoism, Confucianism, and Buddhism.

Because of the increased interest in complementary therapies, many institutions, including medical and nursing schools, have integrated conventional “biomedical” education with programs that incorporate complementary therapy content. These integrative health care programs graduate practitioners who recommend a full spectrum of possible treatments, both biomedical and complementary. In an integrative health care system consumers are treated by a team of providers consisting of both biomedical and complementary practitioners. More fully defined, **integrative health care** emphasizes the importance of the relationship between practitioner and patient; focuses on the whole person; is informed by evidence; and makes use of appropriate therapeutic approaches, health care professionals, and disciplines to achieve optimal health (Rakel, 2018).

Nurses have historically practiced in an integrative fashion; a review of nursing theory (see Chapter 4) reveals the values of holism, relational care, and evidence-informed practice. Until recently, nursing identified its practice as holistic rather than integrated. Holistic nursing treats the mind-body-spirit of the patient, using interventions such as relaxation therapy, music therapy, touch therapies, and guided imagery (Dossey and Keegan, 2016). The American Holistic Nurses Association maintains Standards of Holistic Nursing Practice, which defines and establishes the scope of holistic practice and describes the level of care expected from a holistic nurse (AHNA/ANA, 2013).

Kreitzer and Koithan (2019) challenge the profession to embrace its long-standing roots of integrative care, standing alongside colleagues to help transform the current health care system and operationalize our collective

wisdom to offer whole person care that is patient-centered, relationship-based, and supported by evidence that incorporates the best of all possible interventions. Grounded in six principles, **integrative nursing** is defined as “a way of being-knowing-doing that advances the health and well-being of persons, families, and communities through caring-healing relationships. Integrative nurses use evidence to inform traditional and emerging interventions that support whole person/whole systems healing” (Kreitzer and Koithan, 2019).

Increasing interest in integrative health care is evident in the increased number of publications in respected health care journals and the continued support of research. The mission of the National Institutes of Health/National Center for Complementary and Integrative Health (NIH/NCCIH) supports the investigation of the benefits and safety of complementary interventions. Although the body of evidence about complementary therapies is growing, limited data make it difficult to establish the benefits of specific therapies. Reasons are varied but reflect the growing and developing nature of the science. More research is needed. Therefore nurses need to weigh the risk and benefits of each intervention and consider the following when recommending complementary therapies: (1) the history of each therapy (many have been used by cultures for thousands of years to support health and ameliorate suffering); (2) nursing’s history and experience with a particular therapy; (3) other forms of evidence reporting outcomes and safety data, including case study and qualitative research; and (4) the cultural influences and context for certain patient populations.

This chapter discusses several types of complementary therapies, including a description, the clinical applications, and the limitations of each therapy. The therapies are organized into two categories. The first are nursing-accessible therapies that you can begin to learn and apply in patient care. The second category includes training-specific therapies such as chiropractic therapy or acupuncture that a nurse cannot perform without additional training and/or certification.

REFLECT NOW

Reflect on your own life experiences. Do you personally use a variety of therapeutic strategies (e.g., massage for a sore back or neck), and do your own practices influence your acceptance of this approach to care?

Nursing-Accessible Therapies

Some complementary therapies and techniques are general in nature and use natural processes (e.g., breathing, thinking and concentration, presence, movement) to help people feel better and cope with both acute and chronic conditions (Box 32.1). You can learn about these techniques and integrate them into your independent nursing practice with patients. Ongoing assessment and evaluation of response to these interventions will determine both the appropriateness and usefulness of these complementary therapies. Sometimes changes to physician-prescribed therapies, such as medication doses, are needed when complementary therapies alter physiological responses and lead to therapeutic responses (Ringdahl, et al., 2018).

Box 32.1 Evidence-Based Practice **Pain in Hospitalized Children**

PICOT Question: Do complementary therapies versus biomedical therapies safely and effectively reduce pain and discomfort in hospitalized children?

Evidence Summary

Pain is a complex phenomenon for children, involving psychological, biological, and sociological factors. Hospitalization and pain are often linked in the minds of children. Despite advances in pediatric pain management, recent studies demonstrate that many children continue to have uncontrolled moderate-to-severe pain when they are in the hospital. Several systematic analyses focusing on the use of complementary therapies to control pain show that many complementary and nonpharmacological therapies, such as relaxation, repositioning, distraction, focused breathing, art therapy, and humor, are effective in reducing discomfort in children who are hospitalized (Buratti et al., 2015; Kahsay, 2017; Thrane et al., 2016). Barriers to the use of complementary therapies included nurses' heavy workloads and the need for further education about how to use these techniques.

Application to Nursing Practice

- Children who are hospitalized often respond positively to complementary therapies, experience reduced pain, and need fewer

medications to control their pain.

- Instructing parents on specific complementary therapies used for their child's pain control (e.g., breathing techniques, art therapy) allows the parents to use these techniques.
- Nurses need to learn about and use complementary therapies such as breathing techniques and distraction to alleviate the pain associated with painful and stressful procedures, especially among children.

Complementary therapies teach individuals ways to change their behavior to help alter physical responses to stress and improve symptoms such as muscle tension, gastrointestinal discomfort, pain, or sleep disturbances. Active involvement is a primary principle for these therapies; individuals achieve better responses if they commit to practice the techniques or exercises daily. Therefore, to achieve effective outcomes, therapeutic strategies need to be matched with an individual's lifestyle, his or her beliefs and values, and the context within which the care is to be delivered (acute or community-based).

Relaxation Therapy

People face situations in everyday life that evoke the **stress response** (see [Chapter 37](#)). The mind modifies the biochemical functions of the major organ systems in response to feedback. Thoughts and feelings influence the production of chemicals (i.e., neurotransmitters, neurohormones, and peptides) that circulate throughout the body and convey messages via cells to various systems within the body. The stress response is a good example of the way in which systems cooperate to protect an individual from harm. Physiologically, the cascade of changes associated with the stress response causes increased heart and respiratory rates; tightened muscles; increased metabolic rate; and a general sense of foreboding, fear, nervousness, irritability, and negative mood. Other physiological responses include elevated blood pressure; dilated pupils; stronger cardiac contractions; and increased levels of blood glucose, serum cholesterol, circulating free fatty acids, and triglycerides. Although these responses prepare a person for short-term stress, the effects on the body of long-term stress may include structural damage and chronic illness such as angina, tension headaches, cardiac arrhythmias, pain, ulcers, and atrophy of the immune system organs ([Voss and Kreitzer, 2018](#)).

The **relaxation response** reduces generalized cognitive, physiological, and/or behavioral arousal. The process of relaxation elongates the muscle

fibers, reduces the neural impulses sent to the brain, and thus decreases the activity of the brain and other body systems. Decreased heart and respiratory rates, blood pressure, and oxygen consumption and increased alpha brain activity and peripheral skin temperature characterize the relaxation response. The relaxation response occurs through a variety of techniques that incorporate a repetitive mental focus and the adoption of a calm, peaceful attitude (Bee et al., 2018).

Relaxation helps individuals develop cognitive skills to reduce the negative ways in which they respond to situations within their environment. Cognitive skills include the following:

- Focusing (the ability to identify, differentiate, maintain attention on, and return attention to simple stimuli for an extended period)
- Passivity (the ability to stop unnecessary goal-directed and analytic activity)
- Receptivity (the ability to tolerate and accept experiences that are uncertain, unfamiliar, or paradoxical)

The long-term goal of relaxation therapy is for people to continually monitor themselves for indicators of tension and consciously let go and release the tension contained in various body parts.

Progressive relaxation training teaches the individual how to effectively rest and reduces tension in the body. The person learns to detect subtle localized muscle tension sequentially, one muscle group at a time (e.g., the upper arm muscles, the forearm muscles). In doing so the individual learns to differentiate between high-intensity tension (strong fist clenching), very subtle tension, and relaxation (Bee et al., 2018). A person practices this activity using different muscle groups. One active progressive relaxation technique involves the use of slow, deep abdominal breathing while tightening and relaxing an ordered succession of muscle groups, focusing on the associated bodily sensations while letting go of extraneous thoughts. When guiding a patient, you may decide to begin with the muscles in the face, followed by those in the arms, hands, abdomen, legs, and feet. Conversely you may also guide a patient to tense and relax muscles, beginning with the feet and working up the body.

The goal of **passive relaxation** is to still the mind and body intentionally without the need to tighten and relax any particular body part. One effective passive relaxation technique incorporates slow abdominal breathing exercises while imagining warmth and relaxation flowing through specific body parts such as the lungs or hands. Passive relaxation

is useful for persons for whom the effort and energy expenditure of active muscle contracting leads to discomfort or exhaustion.

Clinical Applications of Relaxation Therapy

Research shows relaxation techniques effectively lower blood pressure (Nagele et al., 2014) and heart rate, decrease muscle tension, improve well-being, and reduce symptom distress in persons experiencing a variety of situations (e.g., complications from medical treatments, chronic illness, or loss of a significant other) (Golding, et al., 2016; Meyer et al, 2016).

Research also indicates that relaxation, alone or in combination with imagery, yoga (Fig. 32.1), and music, reduces pain and anxiety while improving well-being (Charalambous et al., 2016). Other benefits of relaxation include the reduction of depression (Pospos et al., 2018) and breathlessness in persons with chronic respiratory illnesses (Brighton et al., 2018).

FIG. 32.1 Yoga is a discipline that focuses on muscles, posture, breathing, and consciousness.

Relaxation enables individuals to exert control over their lives. Some experience a decreased feeling of helplessness and a more positive psychological state overall. For example, relaxation also reduces workplace stress experienced by nurses working on nursing units. Deep-breathing exercises, centering, and focusing attention often lead to improved staff satisfaction, staff relationships and communication, and workload perceptions (Clarke et al., 2009). Nursing units that incorporate

relaxation activities into daily routines experience reduced turnover and improved patient satisfaction scores (Kreitzer and Zbrowsky, 2018).

Limitations of Relaxation Therapy

During relaxation training individuals learn to differentiate between low and high levels of muscle tension. During the first months of training sessions, when the person is learning how to focus on body sensations and tensions, there are reports of increased sensitivity in detecting muscle tension. Usually these feelings are minor and resolve as the person continues with the training. However, be aware that on occasion some relaxation techniques result in continued intensification of symptoms or the development of altogether new symptoms (Dossey and Keegan, 2016).

An important consideration when choosing any type of relaxation technique is the physiological and psychological status of the individual. Some patients with advanced disease such as cancer or acquired immunodeficiency syndrome (AIDS) seek relaxation training to reduce their stress response. However, techniques such as active progressive relaxation training require a moderate expenditure of energy, which often increases fatigue and limits an individual's ability to complete relaxation sessions and practice. Therefore, active progressive relaxation is not appropriate for patients with advanced disease or those who have decreased energy reserves. Passive relaxation or guided imagery is more appropriate for these individuals.

REFLECT NOW

Reflect on a time when you were experiencing a substantial stress response. What physical and mental/cognitive sensations did you feel? What strategies (passive or progressive) did you use to relax or reduce this stress response?

Meditation and Breathing

Meditation is any activity that limits stimulus input by directing attention to a single unchanging or repetitive stimulus so that the person is able to become more aware of self (Gross et al., 2018). It is a general term for a wide range of practices that involve relaxing the body and stilling the mind. Although meditation has its roots in Eastern religious practices (Hinduism, Buddhism, and Taoism), conventional health care practitioners began to recognize its healing potential in the early 1970s (Gross et al., 2018). According to Benson (1975), the four components of meditation are (1) a quiet space, (2) a comfortable position, (3) a receptive attitude, and (4) a focus of attention. He described meditation as a process that anyone can use to calm down; cope with stress; and, for those with spiritual inclinations, feel one with God or the universe.

Meditation is different from relaxation; the purpose of meditation is to become “mindful,” increasing our ability to live freely and escape destructive patterns of negativity. Meditation is self-directed; it does not necessarily require a teacher and can be learned from books or audiotapes (Kabat-Zinn, 2018). Most meditation techniques involve slow, relaxed, deep abdominal breathing that evokes a restful state, lowers oxygen consumption, reduces respiratory and heart rates, and reduces anxiety (Hilton et al., 2017).

Clinical Applications of Meditation

Several studies support the clinical benefits of meditation. For example, meditation reduces overall systolic and diastolic blood pressures and significantly reduces hypertensive risk (Park and Han, 2017). It also successfully reduces relapses in alcohol treatment programs (Wilson et al., 2017). Patients with cancer who use mindfulness-based cognitive therapies often experience less depression, anxiety, and distress and report an improved quality of life (Carlson, 2017). Patients who have posttraumatic stress disorders and chronic pain also benefit from mindfulness meditation (Cushing and Braun, 2018). In addition, meditation increases productivity, improves mood, increases sense of identity, and lowers irritability (Bee et al., 2018).

Considerations for the appropriateness of meditation include the person’s degree of self-discipline; it requires ongoing practice to achieve lasting results. Most meditation activities are easy to learn and do not require memorization or particular procedures. Patients typically find mindfulness and meditation self-reinforcing. The peaceful, positive mental state is usually pleasurable and provides an incentive for individuals to continue to meditate.

Limitations of Meditation

Although meditation contributes to improvement in a variety of physiological and psychological ailments, it is contraindicated for some people. For example, a person who has a strong fear of losing control will possibly perceive it as a form of mind control and thus will be resistant to learning the technique. Some individuals also become hypertensive during meditation and require a much shorter session than the average session of 15 to 20 minutes.

Meditation may also increase the effects of certain drugs. Therefore monitor individuals learning meditation closely for physiological changes with respect to their medications. Prolonged practice of meditation techniques sometimes reduces the need for antihypertensive, thyroid-regulating, and psychotropic medications (e.g., antidepressants and anti-anxiety agents). In these cases, adjustment of the medication is necessary ([Gross et al., 2018](#)).

Imagery

Imagery or visualization is a mind-body therapy that uses the conscious mind to create mental images to stimulate physical changes in the body, improve perceived well-being, and/or enhance self-awareness. Frequently imagery, combined with some form of relaxation training, facilitates the effect of the relaxation technique. Imagery is self-directed, in which individuals create their mental images, or guided, during which a practitioner leads an individual through a particular scenario ([Fitzgerald and Langevin, 2016](#)). When guiding an imagery exercise, direct the patient to begin slow abdominal breathing while focusing on the rhythm of breathing (see [Chapter 44](#)). Then direct the patient to visualize a specific image such as ocean waves coming to shore with each inspiration and receding with each exhalation. Next instruct the patient to take notice of the smells, sounds, and temperatures that he or she is experiencing. As the imagery session progresses, instruct the patient to visualize warmth entering the body during inspiration and tension leaving the body during exhalation. Individualize imagery scenarios for each patient to ensure that the image does not evoke negative memories or feelings.

Imagery often evokes psychophysiological responses such as alterations in gastric secretions, body chemistry, internal and superficial blood flow, wound healing, and heart rate/heart rate variability ([Pincus and Sheikh, 2009](#)). Although most imagery techniques involve visual images, they also include the auditory, proprioceptive, gustatory, and olfactory senses. An

example of this involves visualizing a lemon being sliced in half and squeezing the lemon juice on the tongue. This visualization produces increased salivation as effectively as the actual event. People typically respond to their environment according to the way they perceive it and by their own visualizations and expectancies. Therefore you need to help patients individualize imagery based on their preferences and expectations (Fitzgerald and Langevin, 2016).

Creative visualization is one form of self-directed imagery that is based on the principle of mind-body connectivity (i.e., every mental image leads to physical or emotional changes) (Gawain, 2016). Box 32.2 lists patient teaching strategies for creative visualization.

Box 32.2 Patient Teaching Creative Visualization

Objective

- The patient will demonstrate skills in creative visualization.

Teaching Strategies

- Set mutual goals the patient can meet. Success leads to confidence and increased self-esteem.
- Create a clear image. Although it is sometimes difficult to develop a visual image, if the patient views the goals of the imagery with clear thoughts and in the present tense, the patient will be more successful in creating an effective image.
- Have the patient frequently visualize the image. Have him or her perform this visualization during relaxing states and throughout the day but particularly before bedtime or on wakening, when his or her mind usually is more relaxed.
- Have the patient repeat encouraging statements while focusing on the image. This alleviates any doubts about his or her ability to achieve established goals.

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- Describe when you plan to use visualization.
- I want to be sure I described this therapy well. Please explain to me the steps you are going to take to practice visualization.

Clinical Applications of Imagery

Imagery has applications in a number of pediatric and adult patient populations. For example, it helps control or relieve pain, decrease nightmares, and improve sleep ([Pincus and Sheikh, 2009](#)). It also aids in the treatment of chronic conditions such as asthma, cancer, sickle cell anemia, migraines, autoimmune disorders, atrial fibrillation, functional urinary disorders, menstrual and premenstrual syndromes, gastrointestinal disorders such as irritable bowel syndrome and ulcerative colitis, and rheumatoid arthritis ([Fitzgerald and Langevin, 2018](#)).

Limitations of Imagery

Imagery is a behavioral intervention that has relatively few side effects ([Fitzgerald and Langevin, 2018](#)). Yet increased anxiety and fear sometimes occur when imagery is used to treat posttraumatic stress disorders and social anxiety disorders ([Bisson et al, 2013](#)). Some patients with chronic obstructive pulmonary disease (COPD) and asthma experience increased airway constriction when using guided imagery ([Volpato et al., 2015](#)). Thus you need to closely monitor patients when using this therapy.

Training-Specific Therapies

Training-specific therapies are complementary treatments that nurses administer only after completing a specific course of study and training. These therapies require postgraduate certificates or degrees indicating completion of additional education and training, national certification, or additional licensure beyond the registered nurse (RN) to practice and administer them. Several training-specific therapies (e.g., biofeedback and acupuncture) are very effective and often recommended by conventional health care practitioners (NIH/NCCIH, 2018; Qaseem et al., 2017). However, others (e.g., homeopathy and naturopathy) have not been adequately studied, and their effectiveness in many conditions has been questioned (National Health and Medical Research Council, 2015; NIH/NCCIH, 2018). Although many of these complementary therapies elicit positive effects, all therapies carry some risk, particularly when used in conjunction with conventional medical therapies. Therefore, you need advanced knowledge to effectively talk about them with patients and provide education about their safe use.

Biofeedback

Biofeedback is a mind-body technique that uses instruments to teach self-regulation and voluntary self-control over specific physiological responses. Electronic or electromechanical instruments measure, process, and provide information to patients about their muscle tension, cardiac activity, respiratory rates, brain-wave patterns, and autonomic nervous system activity. This information, or feedback, is given in physical, physiological, auditory, and/or visual feedback signals that increase a person's awareness of internal processes that are linked to illness and distress. Biofeedback therapies are used to change thinking, emotions, and behaviors, which in turn support beneficial physiological changes, resulting in improved health and well-being. For example, patients connected to a biofeedback device sometimes hear a sound if their pulse rate or blood pressure increases out of their therapeutic zone. Practitioners then help patients interpret these sounds and use a variety of breathing, relaxation, and imaging exercises to gain voluntary control over their racing heart or their increasing systolic blood pressure (Good and Zauszmiewski, 2016).

Biofeedback is an effective addition to more traditional relaxation programs because it immediately demonstrates to patients their ability to control some physiological responses and the relationship among

thoughts, feelings, and physiological responses (fig. 32.2). It helps individuals focus on and monitor specific body parts. Biofeedback helps patients control the physiological functions that are most difficult to control by providing immediate feedback about which stress relaxation behaviors work most effectively. Eventually patients notice positive physiological changes without the need for instrument feedback.

FIG. 32.2 A patient using biofeedback can visually see how relaxation affects physiological functions.

From Okeson JP: *Management of temporomandibular disorders and occlusion*, ed 8, St Louis, 2020, Elsevier.

Clinical Applications of Biofeedback

Biofeedback in a variety of forms has application in numerous situations, with evidence supporting its effectiveness dating back to the 1980s. Initial studies suggest that it may be helpful in stroke recovery, smoking cessation, attention-deficit/hyperactivity disorder (ADHD), epilepsy, headache disorders, and a variety of gastrointestinal and urinary tract disorders (Secic et al., 2016; Stanton et al, 2011, 2017). One of the most critical components of any behavioral program is adherence to the treatment regimen. Patients who adhere to the treatment regimen have more positive results.

Limitations of Biofeedback

Although biofeedback produces effective outcomes in many patients, there are several precautions, particularly in those with psychological or neurological conditions. During biofeedback sessions the repressed emotions or feelings for which coping is difficult sometimes surface. For this reason, practitioners who offer biofeedback need to be trained in more traditional psychological methods or have qualified professionals available for referral. In addition, long-term use of biofeedback sometimes lowers blood pressure, heart rates, and other physiological parameters. As with other biobehavioral interventions, monitor patients closely to determine the need for medication adjustments.

Traditional Chinese Medicine

Traditional Chinese medicine (TCM) is a whole system of medicine that began as an ethnic healing system approximately 3600 years ago. Chinese medicine views health as “life in balance,” which manifests as lustrous hair, a radiant complexion, engaged interactions, a body that functions without limitations, and emotional balance. Health promotion encourages a healthy diet, moderate regular exercise, regular meditation/introspection, healthy family and social relationships, and avoidance of environmental toxins such as cigarette smoke.

Several concepts and principles guide the TCM system of assessment, diagnosis, and intervention. The most important of these is the concept of **yin and yang**, which represent opposing yet complementary phenomena that exist in a state of dynamic equilibrium. Examples are night/day, hot/cold, and shady/sunny. Yin represents shade, cold, and inhibition, whereas yang represents fire, light, and excitement. Yin also represents the inner part of the body, specifically the viscera, liver, heart, spleen, lung, and kidney, whereas yang represents the outer part, specifically the bowels, stomach, and bladder. Harmony and balance in every aspect of life are the keys to health, including yin/yang balance. Practitioners believe that disease occurs when there is an imbalance in these two paired opposites (Holland, 1999). Imbalance occurs as excess or deficiencies in three areas: external (six “evils” linked to weather and climate, including wind, cold, fire, damp, summer heat, and dryness), internal (originate in emotions and affect different organs, such as anger [liver], joy [heart], or fear [kidney]), or neither internal nor external (congenital weak constitutions, such as birth defects, trauma, overexertion, excessive sexual activity, poor-quality diet, and poisons). Imbalance ultimately leads to

disruption of vital energy, *qi*, which then compromises the body-mind-spirit of the person, causing “disease.” Disruptions in *qi* along the meridians can be systematically evaluated and treated by TCM practitioners.

TCM is an individualized treatment system based on a very specific assessment process. Practitioners use four methods to evaluate a patient’s condition: observing, hearing/smelling, asking/interviewing, and touching/palpating. In TCM, outward manifestations reflect the internal environment. For example, the color, shape, and coating of the tongue reflect the general condition of the internal organs. The pulses provide information about the condition and balance of *qi*, blood, yin and yang, and internal organs. Therapeutic modalities include acupuncture, Chinese herbs, tui na massage, **moxibustion** (burning moxa, a cone or stick of dried herbs that have healing properties on or near the skin), **cupping** (placing a heated cup on the skin to create a slight suction), **tai chi** (originally a martial art that is now viewed as a moving meditation in which patients move their bodies slowly, gently, and with awareness while breathing deeply), **qi gong** (originally a martial art, now viewed as a series of carefully choreographed movements or gestures that are designed to promote and manipulate the flow of *qi* within the body), lifestyle modifications, and dietary changes.

Clinical Applications of Traditional Chinese Medicine

In spite of widespread use of TCM in Asia, evidence about its effectiveness as a whole system of care is limited. Most research in this field focuses on the study of individual treatment components of TCM such as acupuncture and herbal therapies. However, some evidence shows that TCM is helpful in treating fibromyalgia (Deare et al., 2013) and in addressing symptoms associated with menopause (Taylor-Swanson et al., 2015).

Limitations of Traditional Chinese Medicine

TCM is not currently regulated in most states, although acupuncture is. The federal government recognizes the Accreditation Commission for Acupuncture and Oriental Medicine (ACAOM) as responsible for accrediting schools that teach acupuncture and TCM, and approximately one-third of the states that license acupuncture require graduation from an ACAOM-accredited school. The National Certification Commission for Acupuncture and Oriental Medicine (NCCAOM) offers a certification

examination for acupuncture and Chinese herbal and manipulative therapies. Refer patients requesting TCM to a qualified practitioner found at <http://www.nccaom.org/find-a-practitioner-directory/>.

There is some concern about the safety of Chinese herbal treatments that are used in teas, remedies, and supplements. The US Food and Drug Administration (FDA) does not regulate, inspect, or ensure that the ingredients of these herbs are safe and without toxins. Recent reports about these products suggest that many Chinese herbs are contaminated with drugs, toxins, or heavy metals or that their ingredients may not be clearly listed or labeled. Further, these herbs can be very powerful, interacting with drugs and causing serious complications. When assessing a person using TCM, you always need to ask about the full complement of therapies, including the types of herbs that the patient is using. Some patients consider these as teas or dietary additives, powders, or supplements and not as over-the-counter medications.

Acupuncture

As a key component of TCM, **acupuncture** is an ancient practice shared by other Asian systems of care. When applied outside the system practice of TCM, acupuncture is viewed as a mind-body therapy and is referred to as medical acupuncture. In the United States, medical acupuncture is often provided as an individual treatment by conventionally trained physicians, nurses, chiropractors, dentists, and acupuncturists for many chronic conditions. Many states now have regulations and licensure requirements to practice as an acupuncturist.

Acupuncture regulates or realigns the **vital energy (*qi*)**, which flows like a river through the body in channels that form a system of pathways called meridians. Twelve primary and eight secondary meridians are used by medical acupuncturists. An obstruction in these channels blocks energy flow in other parts of the body. Acupuncturists insert needles in specific areas along the channels called **acupoints**, through which the *qi* can be influenced and flow reestablished. Application of heat or weak electrical currents enhances the effects of the needles.

Clinical Applications of Acupuncture

Current evidence shows that acupuncture modifies the body's response to pain and how pain is processed by central neural pathways and cerebral function (NIH/NCCIH, 2018). Acupuncture is effective for low back pain, myofascial pain (e.g., temporomandibular joint disorder and trigeminal

neuralgia), hot flashes, simple and migraine headaches, osteoarthritis, plantar heel pain, and chronic shoulder pain (Frisk et al., 2014; Reinstein et al., 2017). It is also used to treat sinusitis, gastrointestinal disorders, chronic pruritus, perimenstrual symptoms, menopausal symptoms, clinical depression, smoking, and other addictions with varying effectiveness (NIH/NCCIH, 2018).

Limitations of Acupuncture

Acupuncture is a safe therapy when the practitioner has the appropriate training and uses sterilized needles. Although needle complications occur, they are rare if the practitioner takes appropriate steps to ensure the safety of the equipment and the patient. Reported complications include infections resulting from inadequately sterilized needles or those that are left in place for an extended length of time, broken needles, puncture of an internal organ, bleeding, fainting, seizures, and posttreatment drowsiness.

Caution is necessary when using acupuncture with pregnant patients and those who have a history of seizures, are carriers of hepatitis, or are infected with human immunodeficiency virus (HIV). Treatment is contraindicated in persons who have bleeding disorders and skin infections. Further, semipermanent needles should not be used with patients who have valvular heart disease because of the increased risk of infection. Electroacupuncture is not recommended for persons with a pacemaker and those who have cardiac arrhythmias or epilepsy or are pregnant (Fontaine, 2018).

Therapeutic Touch

Therapeutic touch (TT), developed in the 1970s by Delores Krieger and Dora Kunz, is one of the “touch therapies” identified by NCCIH. It affects the energy fields that surround and penetrate the human body with the conscious intent to help or heal (Dossey and Keegan, 2016). Other touch therapies include acupressure, healing touch (HT), and reiki. Blending ancient Eastern traditions with modern nursing theory, TT uses the energy of the provider to positively influence the patient’s energy field.

TT consists of placing the practitioner’s open palms either on or close to the body of a person (Fig. 32.3). It occurs in five phases: centering, assessing, unruffling, treating, and evaluating. To begin, the practitioner centers physically and psychologically, becoming fully present in the moment and quieting outside distractions. Then the practitioner scans the body of the patient with the palms (roughly 2 to 6 inches [5 to 15 cm] from

the body) from head to toe. While assessing the energetic biofield of the patient, the practitioner focuses on the quality of the *qi*, identifying areas of accumulated energetic tensions, uneasiness, sluggishness, or congestion that manifest as sensations of congestion, pressure, warmth, coolness, blockage, pulling or drawing, or static or tingling. The practitioner then redirects these energetic patterns to harmonize distressed areas or to stimulate movement of *qi* in areas that are stuck and congested. Using long downward strokes over the energy fields of the body, the practitioner touches the body or maintains the hands in a position a few inches away from the body. The final phase consists of evaluating the patient, reassessing the energy field to ensure that energy is flowing freely, and determining additional outcomes and responses to the treatment (Krieger, 1975, 1979).

FIG. 32.3 During a therapeutic touch session, the practitioner intentionally directs energy to facilitate the patient's healing process.

Clinical Applications of Touch Therapies

The evidence supporting the effectiveness of touch therapies, including therapeutic and healing touch, is inconclusive, although it may be effective in treating pain in adults and children, dementia, trauma, and anxiety during acute and chronic illnesses (Baldwin and Trent, 2017). Box 32.3 summarizes the importance of touch in older adults.

Box 32.3 Focus on Older Adults **The Importance of Touch**

- Touch is a primal need, as necessary as food, growth, or shelter. Touch is like a nutrient transmitted through the skin, and “skin hunger” is like a form of malnutrition that has reached epidemic proportions in the United States, especially among older adults (Fontaine, 2018).
- Older adults need touch as much as or more than any other age-group. However, older adults often experience “skin hunger.” Older adults often have fewer family members or friends to touch them at a time when simple touch may enhance communication, especially when other senses are reduced (Dossey and Keegan, 2016).
- Simple touch helps older adults feel more connected to and accepted by those around them and more in tune with their environment. Touch enhances self-esteem and sense of worth.
- Nurses who react adversely to skin changes caused by aging often find it difficult to touch older adults. This reluctance communicates a negative message to the older adult (Dossey and Keegan, 2016). Therefore be aware of your own reactions to touch when caring for older adults to ensure a therapeutic approach to patient-centered care.
- Be mindful of a patient’s own acceptance of touch. Ask permission to hold a hand or give a hug. Once you form a relationship with a patient, touch can usually be more spontaneous.

Limitations of Touch Therapies

Although touch therapies cause very few complications or side effects, they may be contraindicated in certain patient populations. For example, people who are sensitive to human interaction and touch (e.g., those who

have been physically abused or have psychiatric disorders) often misinterpret the intent of the treatment and feel threatened and anxious by it. Determining if your patient has experienced trauma is important before using touch therapies (see <https://www.samhsa.gov/trauma-violence> for additional information). Other patients, including pregnant women, neonates, patients with cardiovascular and neurological instabilities, or patients who are dying, sometimes are sensitive to energy repatterning. Sessions with these populations need to be time limited and particularly gentle (Umbreit and Johnson, 2018).

Chiropractic Therapy

Chiropractic therapy, a manipulative or body-based therapy, was developed in 1895 in Iowa. Chiropractors graduate from well-established postbaccalaureate educational programs similar to medical schools. The central belief of the chiropractic profession is that body structure (primarily that of the spine and spinal cord) and the ability of the body to function normally are closely related. Thus when the spine is misaligned, energy flow is impeded, and the innate healing abilities of the body are impaired. Chiropractic therapy aims to normalize the relationship between structure and function by a series of manipulations. Practitioners use their hands or a device to provide manipulation, which is the application of a controlled, sudden forceful movement to a joint, moving it beyond its passive range of motion. Often manipulations are combined with additional therapeutic modalities, including ice and heat, electrical stimulation, deep tissue massage, joint immobilization, lifestyle counseling, and medications.

Chiropractic care is a popular form of complementary therapy in the United States; 8.4% of the adult and 3.3% of the pediatric population visit chiropractors each year, representing almost 20 million health care visits (Clarke et al., 2015). Compared with other forms of complementary therapies, chiropractic care is often covered by insurance plans, including Medicare, Medicaid, state workers' compensation plans, health maintenance organizations (HMOs), and private insurance plans. Licensure is regulated by individual state governments, and scopes of practice and prescriptive authority vary from state to state.

Clinical Applications of Chiropractic Therapy

The basic goals of chiropractic therapy focus on restoring structural and functional imbalances. Chiropractors believe that structure and function

coexist with one another and that alterations or distortions in structure ultimately lead to abnormalities in function. A major structural problem that chiropractors treat is vertebral (neck/back) subluxation with its accompanying symptom of pain.

Chiropractic therapy improves acute pain and disability in some patients. This therapy is also sometimes effective over longer periods to reduce acute and subacute low back pain and joint pain caused by osteoarthritis (Globe et al., 2016). Chiropractic care may also enhance the effects of conventional treatments in pediatric asthma (Gleberzon et al., 2012). Chiropractic interventions are also used to treat headaches, dysmenorrhea, vertigo, tinnitus, and visual disorders (Bryans et al., 2014).

Limitations of Chiropractic Therapy

Although chiropractic therapies are safe for a variety of conditions, chiropractors do not treat several diseases or conditions with manipulation. Bone and joint infections require pharmaceutical or surgical intervention because the structural integrity of the bone is compromised if excessive force is used. Other contraindications include acute myelopathy, fractures, dislocations, rheumatoid arthritis, and osteoporosis.

Some risks are associated with chiropractic therapy. A variety of injuries, ranging in severity from mild adverse responses (e.g., mild transient headache, increased pain and stiffness) to more serious injuries (e.g., vertebral artery dissection), have been reported (Shekelle et al., 2017). Degree and risk of injury depend on the type of manipulation performed, location of the manipulation (cervical spine is more susceptible to serious injury), overall health of the patient, and expertise of the provider. When educating patients about chiropractic care, you need to include educational and licensure credentials of qualified chiropractors, typical treatments, and possible complications.

Natural Products and Herbal Therapies

It is estimated that approximately 25,000 plant species are used medicinally throughout the world. It is the oldest form of medicine known to man, and archeological evidence suggests that herbal remedies have been used for over 60,000 years. Herbal medicines are a prominent part of health care among indigenous populations worldwide. Interest in natural products also continues to increase in countries where biomedicine is dominant (Clarke, et al., 2015).

Nonvitamin, nonmineral natural products are used by 18% of the US population to prevent disease and illness and to promote health and well-being (Clarke et al., 2015). A natural product is a chemical compound or substance produced by a living organism and includes herbal medicines (also known as botanicals), dietary supplements, vitamins, minerals, mycotherapies (fungi-based products), essential oils (aromatherapy), and probiotics. Many are sold over the counter as dietary supplements. The most frequently used products are fish oil/omega-3 fatty acids, glucosamine, probiotics/prebiotics, melatonin, coenzyme Q10, echinacea, cranberry, garlic, ginseng, and ginkgo biloba (Clarke et al., 2015).

Herbal medicines are not approved for use as drugs and are not regulated by the FDA. For this reason, many are sold as foods or food supplements. The Dietary Supplement Health and Education Act (1994) allows companies to sell herbs as dietary supplements as long as there are no health claims written on their labels. Natural products in the United States are prepared primarily from plant materials. They are provided as tinctures or extracts, elixirs, syrups, capsules, pills, tablets, lozenges, powders, ointments or creams, drops, and suppositories.

Clinical Applications of Herbal Therapy

A number of herbs are safe and effective for a variety of conditions (Table 32.2). Cranberry juice has been sometimes used to treat urinary tract infections for decades. The effectiveness evidence supporting cranberry supplements to prevent urinary tract infections is mixed although clinicians continue to cite case studies that suggest its effectiveness, particularly in postmenopausal women with incontinence because cranberry molecules bind with the iron that bacteria need to grow and reproduce and substances in cranberry block adherence of bacteria to the walls of the bladder (Wang, et al., 2012). Curcumin is a yellow plant substance associated with turmeric as well as ginger. A polyphenol, curcumin appears to have a potent antiinflammatory effect, with suggested use in cancer prevention and progression as well as other chronic conditions. Clinical trials have recently found that curcuminoids are effective in lowering fasting blood sugars in persons with dysglycemia, including prediabetes and other metabolic syndromes (Melo et al., 2018).

TABLE 32.2**Safe or Effective Herbs Determined By Non–United States Regulatory Authorities**

Common Name and Uses	Effects	Potential Drug Interactions
Aloe		
Skin disorders, including burns, inflammation and acute injuries (used topically)	Acceleration of wound healing	Furosemide (Lasix) and loop diuretics
GI ulcerations, including Crohn's disease and ulcerative colitis (taken orally)	Unknown mechanism, although there is a known laxative effect	May enhance the effects of laxatives when taken orally
Chamomile		
Inflammatory diseases of GI and upper respiratory tracts	Antiinflammatory	Drugs that cause drowsiness (alcohol, barbiturates, benzodiazepines, narcotics, antidepressants)
Generalized anxiety disorder	Calming agent	
Echinacea		
Upper respiratory tract infections	Stimulant of immune system	Anti-rejection and other drugs that weaken immune system May interact with antiretrovirals and other drugs used in the treatment of HIV/AIDS
Feverfew		
Wound healing	Antiinflammatory	Warfarin and other anticoagulants
Arthritis	Inhibition of serotonin and prostaglandins	Aspirin and ibuprofen
Garlic		
Elevated cholesterol levels	Inhibition of platelet aggregation	Warfarin and blood thinners
Hypertension		Saquinavir and other anti-HIV drugs
Ginger		
Nausea and vomiting	Antiemetic	Warfarin and anticoagulants Aspirin and NSAIDs
Ginkgo biloba		
Alzheimer's disease and dementia	Memory improvement, although these effects are now in question given results in two recent clinical trials	Warfarin and anticoagulants Aspirin and NSAIDs
Ginseng		
Age-related diseases	Increased physical endurance, improved immune function	Warfarin and anticoagulants Aspirin and NSAIDs MAO inhibitors
Licorice		
GI disorders, including gastric ulcers and hepatitis C	Unknown	Corticosteroids and other immunosuppressive drugs Digoxin Antihypertensive drugs
Saw palmetto		
Benign prostatic hyperplasia	Prevention of conversion of testosterone to dihydrotestosterone (needed for prostate cell multiplication)	Finasteride and antiandrogen drugs
Chronic pelvic pain	Unknown mechanism	None known
Valerian		
Sleep disorders, mild anxiety and restlessness	Central nervous system depression	Barbiturates and other sleep medications Alcohol Antihistamines

AIDS, Acquired immunodeficiency disease; *GI*, gastrointestinal; *HIV*, human immunodeficiency virus; *MAO*, monoamine oxidase; *NSAIDs*, nonsteroidal antiinflammatory drugs.

Data from National Institutes of Health/National Center for Complementary and Integrative Health: *Herbs at a glance*, 2018.

Limitations of Herbal Therapy

Simply because a product is “natural” does not make it “safe.” Although herbal medicines provide beneficial effects for a variety of conditions, a number of problems exist. Because they are not regulated, concentrations of the active ingredients vary considerably. Contamination with other herbs or chemicals, including pesticides and heavy metals, is also problematic. Not all companies follow strict quality control and manufacturing guidelines that set standards for acceptable levels of pesticides, residual solvents, bacterial levels, and heavy metals. For this reason, teach patients to purchase herbal medicines only from reputable manufacturers. This means that labels on herbal products need to contain the scientific name of the botanical, the name and address of the actual manufacturer, a batch or lot number, the date of manufacture, and the expiration date. Using natural products that have been verified by the US Pharmacopeia (USP) is another way to ensure product safety, quality, and purity. Look for the USP Verified Dietary Supplement mark on product labels when buying or recommending natural products.

Some herbs also contain toxic products that have been linked to cancer. [Table 32.3](#) lists several unsafe herbs. Some herbal substances contain powerful chemicals. As with any other medication, examine herbs for interaction and compatibility with other prescribed or over-the-counter substances that are being used simultaneously.

TABLE 32.3**Unsafe Herbs**

Common Name	Effects	Comments
Calamus (Indian type most toxic)	Fever Digestive aid	Contains varying amounts of carcinogenic <i>cis</i> -isoasarone Documented cases of kidney damage and seizures with oral preparations
Chaparral	Anticancer Used for bronchitis in traditional healing systems (Native American and Hispanic folk medicine) Found in “natural” weight-loss products	No proven efficacy Induces severe liver toxicity in some cases Severe uterine contractions
Coltsfoot	Antitussive	Contains carcinogenic pyrrolizidine alkaloids Hepatotoxic
Comfrey	Wound healing and acute injuries Used for antiinflammatory effects in osteoarthritis and rheumatoid arthritis	Contains carcinogenic pyrrolizidine alkaloids May induce venoocclusive disease Hepatotoxic
Ephedra (ma huang)	Central nervous system stimulant Bronchodilator Cardiac stimulation Weight loss	Unsafe for people with hypertension, diabetes, or thyroid disease Avoid consumption with caffeine
Life root	Menstrual flow stimulant	Hepatotoxic
Pokeweed	Antirheumatic Anticancer	Do not use with children, but many websites state that it is safe with observation and monitoring and proper dosing; often used with folk remedies and in Native American healing

The Integrative Nursing Role

The interest in complementary therapies and an integrative approach to care continues to increase, fueled in part by the explosion in opioid addictions, the increase in chronic disease, and the need to consider nonpharmacological treatment options ([National Academies of Sciences, Engineering, and Medicine, 2017](#)). In North America and Europe, professional groups increasingly support the use of complementary therapies and monitor research in this area. The American College of Physicians issued new clinical practice guidelines for the management of acute, subacute, and chronic low back pain in 2017, recommending the use of nonpharmacological interventions that include tai chi, yoga, and other mind/body techniques ([Qaseem et al., 2017](#)). In January 2018, The Joint Commission ([TJC, 2019a](#)) implemented new pain assessment and management standards, requiring accredited hospitals to offer nonpharmacological (complementary) therapy to effectively manage patients' pain. All providers, including nurses, need to encourage open, honest dialogue with patients about the use of complementary therapies. Providers also need to actively engage patients to accept integrative care to prevent disease, manage illness, and improve whole person well-being by employing the full spectrum of possible therapeutics rather than relying solely on surgery or drugs.

The integrative approach to health care is consistent with nursing's patient-centered, relationship-based legacy, which is focused on whole person well-being and health. Nurses have the potential for becoming essential participants in this type of health care delivery system. Many nurses already practice the use of touch, relaxation techniques, imagery, and breathwork and practice using the principles of integrative nursing ([Kreitzer and Koithan, 2019](#)). Familiarize yourself with the evidence in each modality that you incorporate into your practice. Know which patient is most likely to benefit from each therapy, when to use the various therapies, which complications might occur, and which precautions are needed when using these therapies.

In addition, you need enough knowledge to discuss the full range of biomedical and complementary therapeutic options so that you can help patients make informed health care decisions. Always ask patients directly about their use of complementary therapies, including self-care activities such as yoga, meditation, or dietary supplements. Be knowledgeable about the evidence for different complementary therapies so that you can make appropriate recommendations about which therapies are possibly useful

for patients. Know about the different credentialing processes and how to refer patients to competent providers. Understand thoroughly the potential benefits and risks so that information is clearly and fully disclosed. Be knowledgeable, so you can give advice to patients about when to seek conventional care and when it is safe to consider complementary care services. For example, if a patient has right lower abdominal pain, nausea, and vomiting, be suspicious of conditions such as appendicitis or colitis and recommend consultation with a health care provider. However, if the patient has a chronic gastrointestinal disorder and has a diagnosis of irritable bowel syndrome, the patient may benefit from relaxation and herbal therapy. Be aware of the safety precautions for each complementary therapy, and incorporate these in your teaching plans. Finally, understand your state Nurse Practice Act with regard to complementary therapies and practice only within the scope of these laws.

Nurses work very closely with their patients and are in the unique position of becoming familiar with the patient's spiritual and cultural viewpoints. They are often able to determine which complementary therapies are more appropriately aligned with these beliefs and offer recommendations accordingly. Being knowledgeable about complementary therapies will help you provide accurate information to patients and other health care professionals.

Building Competency in Patient-Centered Care

You are caring for a 48-year-old woman, Carmen, with stage 3 breast cancer who has returned to the hospital after being discharged after a mastectomy. She developed an infection in her suture line and around her drain site. Just before changing her dressings, you notice that she is more withdrawn and unwilling to speak more than one or two words and only to answer direct questions. When you question her further, she states that she can't stop thinking about her future and fears that "this will be how it's going to be ... one hospital visit after another." She also says that she's concerned about the amount of pain medication that she's taking and that she's "tired of feeling drowsy and out-of-it" when her family comes to visit but doesn't know how else to manage her fear and pain. Which techniques could you offer Carmen to alleviate her suffering? Are there strategies that would help address her fears of the future and begin to view it in a more positive light?

Key Points

- Integrative health care programs use the full complement of treatment approaches (biomedical and complementary) to provide patient-centered care to patients.
- The stress response is an adaptive response that allows individuals to respond to stressful situations.
- A chronic stress response is often maladaptive, leading to chronic muscle tension, mood changes, and immune changes.
- Complementary therapies require commitment and regular involvement by the patient to be most effective and have prolonged beneficial outcomes.
- Choose complementary therapies appropriately according to a patient's overall health status, presenting symptom severity and distress, beliefs and cultural values, access to health care options, and insurance coverage/ability to pay.
- Continuously evaluate a patient's response to complementary therapies, as medication doses may need to change based on physiological responses.
- Complementary therapies accessible to nursing include relaxation, meditation and mindfulness techniques, and imagery. Evidence supports their use to decrease the effects of stress and improve overall patient well-being.
- Many complementary therapies require additional education and certification, including biofeedback, touch therapies (therapeutic touch, reiki, and healing touch), and acupuncture.
- Although there is increasing evidence to support the use of complementary therapies, additional research of sufficient quality and rigor is needed.

Reflective Learning

- You are completing an admission assessment for a surgical patient. What types of assessment questions would you ask to determine whether your patient is using any natural products or complementary therapies?
- Reflect on a recent clinical experience. Were there situations when the integrative approach to care would be helpful or perhaps inappropriate? For example, think about whether an integrative approach would be just as useful in the emergency department as it is in hospice care?
- Reflect on a couple of relaxation techniques discussed in this chapter. How could you use these techniques to help you prepare for your current courses and clinical experiences?

Review Questions

1. When planning patient education, it is important to remember that patients with which of the following illnesses often find relief in complementary therapies?
 1. Lupus and diabetes
 2. Ulcers and hepatitis
 3. Heart disease and pancreatitis
 4. Chronic back pain and arthritis
2. Which complementary therapies are most easily learned and applied by a nurse? (Select all that apply.)
 1. Therapeutic massage therapy
 2. Traditional Chinese medicine
 3. Progressive relaxation
 4. Breathwork and guided imagery
 5. Therapeutic touch

3. While planning care for a patient, a nurse understands that providing integrative care includes treating which of the following?
 1. Disease, spirit, and family interactions
 2. Desires and emotions of the patient
 3. Mind-body-spirit of patients and their families
 4. Muscles, nerves, and spine disorders
4. In addition to a thorough patient assessment, when a nurse uses one of the nursing-accessible complementary therapies, he or she must ensure that which of the following has occurred?
 1. The family has provided permission.
 2. The patient has provided permission and consent.
 3. The health care provider has given approval or provided orders for the therapy.
 4. The nurse has received specialized training in the therapeutic technique.
5. A nurse is caring for a patient with chronic arthritis pain. The patient wants to add some complementary therapies to help with pain management. Which therapies might be most effective for controlling pain (Select all that apply):
 1. Biofeedback
 2. Acupuncture
 3. Therapeutic touch
 4. Chiropractic therapy
 5. Herbal medicines
6. A nurse is caring for a patient experiencing a stress response. The nurse plans care with the knowledge that systems respond to stress in what manner? (Select all that apply.)
 1. Always fail and cause illness and disease
 2. Cause negative responses over time

3. React the same way for all individuals
 4. Protect an individual from harm in the short term
 5. Tolerate the stress response indefinitely
7. Meditation may intensify the effects of which of these medications? (Select all that apply.)
1. Steroid medications
 2. Insulin
 3. Thyroid-regulating medications
 4. Cough syrups
 5. Antihypertensive medications
8. Which of the following statements best explains therapeutic touch (TT)?
1. Intentionally mobilizes energy to balance, harmonize, and repattern the recipient's biofield
 2. Intentionally heals tissue damage or corrects certain disease symptoms
 3. Is overwhelmingly effective in many conditions
 4. Is completely safe and does not warrant any special precautions
9. Traditional Chinese medicine (TCM) is used by many patients. Which statement most accurately describes intervention(s) offered by TCM providers?
1. Uses acupuncture as its primary intervention modality
 2. Uses many modalities based on the individual's needs
 3. Uses primarily herbal remedies and exercise
 4. Is the equivalent of medical acupuncture
10. The nurse manager of a community clinic arranges for staff in-services about various complementary therapies available in the

community. What is the purpose of this training? (Select all that apply.)

1. Nurses play an essential role in the safe use of complementary therapies.
2. Nurses are often asked for recommendations and strategies that promote well-being and quality of life.
3. Nurses learn how to provide all of the complementary modalities during their basic education.
4. Nurses play an essential role in patient education to provide information about the safe use of these healing strategies.
5. Nurses appreciate the cultural aspects of care and recognize that many of these complementary strategies are part of a patient's life.

UNIT 6

Psychosocial Basis for Nursing Practice

OUTLINE

33. Self-Concept

34. Sexuality

35. Spiritual Health

36. Loss and Grief

37. Stress and Coping

Self-Concept

OBJECTIVES

- Discuss factors that influence the components of self-concept and self-esteem.
- Identify stressors that affect self-concept and self-esteem.
- List the components of self-concept as related to psychosocial and cognitive developmental stages.
- Explore ways in which a nurse's self-concept and nursing actions affect a patient's self-concept and self-esteem.
- Discuss evidence-based care for patients with identity confusion, disturbed body image, altered self-concept, low self-esteem, and role conflict.
- Examine cultural considerations that affect self-concept and self-esteem.
- Apply the nursing process to promote a patient's self-concept.

KEY TERMS

Body image, p. 692

Identity, p. 692

Identity confusion, p. 694

Role ambiguity, p. 695

Role conflict, p. 695

Role overload, p. 695

Role performance, p. 693

Role strain, p. 695

Self-concept, p. 690

Self-esteem, p. 693

Sick role, p. 695

Self-concept is an individual's view of self. It is subjective and involves a complex mixture of unconscious and conscious thoughts, attitudes, and perceptions. Self-concept, or how a person *thinks* about oneself, directly affects self-esteem, or how one *feels* about oneself. Although these two terms often are used interchangeably, nurses need to differentiate the two so that they correctly and completely assess a patient and develop an individualized plan of care based on a patient's needs.

Patients face a variety of health problems that threaten their self-concept and self-esteem. A loss of bodily function, decline in activity tolerance, and difficulty in managing a chronic illness are examples of situations that change a patient's self-concept. You will help patients adjust to alterations in self-concept and strengthen components of self-concept to promote successful coping and positive health outcomes.

Scientific Knowledge Base

The development and maintenance of self-concept and self-esteem begin at a young age and continue across the life span. Parents and other primary caregivers not only influence the development of a child's self-concept and self-esteem, but research suggests that self-concept clarity is transmitted from parents to children (Crocetti et al., 2016). In addition, individuals learn and internalize cultural influences on self-concept and self-esteem in childhood and adolescence. There is a significant emphasis on fostering a school-age child's self-concept. In general young children tend to rate themselves higher than they rate other children, suggesting that their view of themselves is positively inflated (Thomaes et al., 2017). Adolescence is a particularly critical developmental period when many variables, including school, family, and friends, affect self-concept and self-esteem (Rosenberg, 1965). The adolescent experience can adversely affect self-esteem, often more strongly for girls than for boys (Bleidorn et al., 2016). Boys often have better overall self-concepts than girls, particularly in physical and social domains (Agrahari and Kinra, 2017). Some adolescent girls are more sensitive about their appearance and how others view them (Vartanian et al., 2018). It is during adolescence that the search for an enduring sense of self turns into a core developmental task impacted by biological changes (e.g., puberty) and psychosocial changes (e.g., new interactions with peers and modifications in parent-adolescent relationships) (Erikson, 1963). During adolescence, individuals may rethink their previous sense of self and experiment with new roles and life plans. Thus, it is important to assess changes in identity formation and self-esteem among early, middle, and late adolescence because changes in self-concept occur over time (Fig. 33.1).

FIG. 33.1 Adolescents' participation in group activities can foster self-esteem.

[iStock.com/hraun](https://www.istock.com/hraun).

Most individuals cope with the transition from childhood through adolescence to adulthood successfully and become healthy and productive adults (Kann et al., 2018). Job satisfaction and overall performance in adulthood are also linked to self-esteem. Self-enhancing opportunities such as exploring new ideas, solving problems in creative ways, and learning new skills predict job satisfaction and commitment and promote self-concept clarity and self-esteem (Touhy and Jett, 2016). Sometimes when individuals lose a job, their sense of self diminishes, they lose motivation to be socially active, and they even become depressed. They lose their job identity, altering their self-perceptions and self-care practices. Establishing a stable sense of self that transcends relationships and situations is a developmental goal of adulthood.

Cultural variations in self-concept and self-esteem across the life span can impact health behaviors. In adolescent girls, culture, class, and self-esteem serve as protective factors against risk-taking behaviors, including unhealthy sexual behaviors (Kerpelman et al., 2016; Wilkins and Miller, 2017). Similarly, cultural identity of older adults is one of the major elements of self-concept and a key aspect of self-esteem (Touhy and Jett, 2016). Be aware of the cultural perspectives of aging when providing

patient care. Sensitivity to factors that affect self-concept and self-esteem in diverse cultures is essential to ensure an individualized approach to health care.

There is a close relationship between how individuals view themselves and their perception of their health. Lower self-esteem is a risk factor that leaves one vulnerable to health problems, whereas higher self-esteem and strong social relationships support good health (Halter, 2018). A patient's belief in personal health often enhances his or her self-concept. Statements such as "I can get through anything" or "I've never been sick a day in my life" indicate that a person's thoughts about personal health are positive. Illness, hospitalization, and surgery affect self-concept. Chronic illness often affects the ability to provide financial support and maintain relationships, which then affects an individual's self-esteem and perceived identity and roles. Negative perceptions regarding health status are reflected in such statements as "It's not worth it anymore" or "I'm a burden to my family." Chronic illness affects identity and body image as reflected by verbalizations such as "I'll never get any better" or "I can't stand to look at myself anymore."

What individuals think and how they feel about themselves affect the way in which they approach self-care physically and emotionally and how they care for others. A person's behaviors are generally consistent with both self-concept and self-esteem. Individuals who have a poor self-concept often do not feel in control of situations and worthy of care, which influences decisions regarding health care. Patients often have difficulty making even simple decisions, such as what to eat. Knowledge of variables that affect self-concept and self-esteem is critical to provide effective treatment.

REFLECT NOW

Reflect on a statement a patient made recently about identity, body image, role performance, or self-esteem for which you felt unprepared to respond.

Nursing Knowledge Base

When providing evidence-based patient care, incorporate professional nursing knowledge developed from the humanities, sciences, nursing research, and clinical practice. A broad knowledge base allows nurses to have a holistic view of patients, thus promoting quality patient care that best meets the self-concept needs of each patient and family.

Understanding a patient's self-concept is a necessary part of all nursing care (Halter, 2018).

Factors Influencing the Development of Self-Concept

The development of self-concept is a complex lifelong process that involves many factors. Erikson's psychosocial theory of development (1963) remains beneficial in understanding key tasks that individuals face at various stages of development. Each stage builds on the tasks of the previous stage. Successful mastery of each stage leads to a solid sense of self (Box 33.1).

Box 33.1 Self-Concept: Developmental Tasks

Trust versus Mistrust (Birth to 18 Months)

- Develops trust following consistency in caregiving and nurturing interactions
- Distinguishes self from environment

Autonomy versus Shame and Doubt (18-24 Months to 3 Years)

- Begins to communicate likes and dislikes
- Increasingly independent in thoughts and actions
- Appreciates body appearance and function (e.g., dressing, feeding, talking, and walking)

Initiative versus Guilt (3 to 5 Years)

- Identifies with a gender
- Enhances self-awareness
- Increases language skills, including identification of feelings

Industry versus Inferiority (6 to 11 Years)

- Incorporates feedback from peers and teachers
- Increases self-esteem with new skill mastery (e.g., reading, mathematics, sports, music)
- Aware of strengths and limitations

Identity versus Role Confusion (12 to 18 Years)

- Accepts body changes/maturation
- Examines attitudes, values, and beliefs; establishes goals for the future
- Feels positive about expanded sense of self

Intimacy versus Isolation (Late Teens to Mid-40s)

- Has stable, positive feelings about self
- Experiences successful role transitions and increased responsibilities

Generativity versus Self-Absorption (Mid-40s to Mid-60s)

- Able to accept changes in appearance and physical endurance
- Reassesses life goals
- Shows contentment with aging

Ego Integrity versus Despair (Mid-Late 60s to Death)

- Feels positive about life and its meaning
- Interested in providing a legacy for the next generation

Learn to recognize an individual's failure to achieve an age-appropriate developmental stage or his or her regression to an earlier stage in a period of crisis. This understanding allows you to individualize care and determine appropriate nursing interventions. Self-concept is always changing and is based on the following:

- Sense of competency
- Perceived reactions of others to one's body
- Ongoing perceptions and interpretations of the thoughts and feelings of others
- Personal and professional relationships
- Academic and employment-related identity
- Personality characteristics that affect self-expectations
- Perceptions of events that have an impact on self
- Mastery of prior and new experiences
- Cultural identity

Self-esteem usually increases in early and middle childhood, fluctuates or remains constant in adolescence, increases strongly in young adulthood, continues to increase in middle adulthood, and peaks between ages 60 and 70 years. Depending on self-concept clarity, self-esteem diminishes or stays constant in old age with a sharp drop in very old age ([Orth et al., 2018](#)). Although this pattern varies, in general it holds true across gender, socioeconomic status, and culture. Children often report high self-esteem because their sense of self is inflated by a variety of extremely positive sources, and periodic declines may be associated with shifts to more realistic information about the self. Adolescence is a time of marked maturational changes and shifting levels of self-esteem that set the stage for rises in self-concept from adolescence to young adulthood ([Bleidorn et al., 2016](#)).

[Erikson's \(1963\)](#) emphasis on the generativity stage explains the rise in self-esteem and self-concept in adulthood (see [Chapter 11](#)). The individual focuses on being increasingly productive and creative at work while at the same time promoting and guiding the next generation. On the basis of Erikson's stages of development, a decline in self-concept in later adulthood reflects a diminished need for self-promotion and a shift in self-

concept to a more modest and balanced view of self. Many report a decline in self-esteem in later adulthood caused in part by physical and emotional changes associated with aging, but older adults with self-concept clarity demonstrate psychological well-being (Touhy and Jett, 2018). When aging is associated with deterioration of health, nursing interventions must focus on health behavior changes to promote self-care and self-concept (Touhy and Jett, 2016). Identifying specific nursing interventions to address the unique needs of patients at various life stages is essential.

Components and Interrelated Terms of Self-Concept

A positive self-concept gives a sense of meaning, wholeness, and consistency to a person. A healthy self-concept provides a high degree of stability, which generates positive feelings toward self. The components of self-concept are identity, body image, and role performance.

Identity

Identity involves the internal sense of individuality, wholeness, and consistency of a person over time and in different situations. It implies being distinct and separate from others. Being “oneself” or living an authentic life is the basis of true identity. Children learn culturally accepted values, behaviors, and roles through identification and modeling. They often gain an identity from self-observations and from what individuals tell them. An individual first identifies with parenting figures and later with other role models such as teachers or peers (Hockenberry et al., 2019). Relationships with parents, teachers, and peers have unique and combined effects on young children’s general, academic, and social self-concept. To form an identity, a child must be able to bring together learned behaviors and expectations into a coherent, consistent, and unique whole (Erikson, 1963).

The achievement of identity is necessary for intimate relationships because individuals express identity in relationships with others (Halter, 2018). Sexuality is a part of identity, and its focus differs across the life span. For example, as an adult ages, the focus shifts from procreation to companionship, physical and emotional intimacy, and pleasure seeking (Touhy and Jett, 2018). Gender identity is a person’s private view of maleness or femaleness; gender role is the masculine or feminine behavior

exhibited. This image and its meaning depend on culturally determined values (see [Chapters 9](#) and [34](#)).

Cultural differences in identity exist ([Box 33.2](#)). Cultural identity develops from identification and socialization within an established group and through the experience of integrating the response of individuals outside the group into one's self-concept. Differences in cultural identity exist through identification with traditions, customs, and rituals within one's cultural group. When cultural identity is central to self-concept and is positive, cultural pride and self-esteem tend to be strong. In contrast, internalization of prejudice and devaluation of one's racial minority group can result in social isolation, which can negatively influence self-concept ([Benninger and Savahl, 2017](#)). An individual who experiences discrimination, prejudice, or environmental stressors such as low-income or high-crime neighborhoods can conceptualize himself or herself differently than an individual who experiences privilege. One's perception of social class also affects self-esteem ([Wilkins and Miller, 2017](#)).

Box 33.2 Cultural Aspects of Care Promoting Self-Concept and Self-Esteem in Culturally Diverse Patients

Cultural identity is an essential component of a person's self-concept and self-esteem. Early in growth and development an individual develops this identity within the context of family (Crocetti et al., 2016). As an individual matures, the cultural aspects of his or her self-concept are reinforced through social, family, or cultural experiences. In addition, a person's self-concept is strengthened or questioned through political, social, or cultural influences experienced in the home, school, and workplace environments. Positive or negative cultural role modeling, identity, and past experiences influence self-care, self-concept, and self-esteem. Social media also has a significant impact on the development of self-concept and identity (Eleuteri et al., 2017). Bullying, including cyberbullying, is one type of youth violence that threatens young people's self-concept and well-being. Nationwide, electronic bullying is rising, particularly among youth of color, including through e-mail, chat rooms, instant messaging, websites, or texting (Kann et al., 2018).

Implications for Patient-Centered Care

- Develop an open, nonrestrictive attitude for assessing and encouraging cultural practices to improve patients' self-concept.
- Understand that the relationship among self-esteem, stress, and social support can facilitate the development of nursing strategies to promote effective coping in culturally diverse adolescents (Bleidorn et al., 2016).
- Ask patients what they think is important to help them feel better or gain a stronger sense of self.
- Encourage cultural identity and pride by individualizing self-care practices and offering treatment choices to meet patients' self-concept needs.
- Facilitate culturally sensitive health promotion activities that address at-risk behaviors identified through evidence-based practice (e.g., smoking, vaping, drinking, eating disorder risks, premature sexual experiences, excessive and violent video gaming) (Eleuteri et al., 2017).
- When completing a social history, a priority nursing action is the assessment of child and adolescent coping strategies, conflict resolution, and stress management as it relates to the use of social media and texting (Kann et al., 2018).

Body Image

Body image involves attitudes related to the body, including physical appearance, structure, or function. Feelings about body image include those related to sexuality, femininity and masculinity, youthfulness, health, and strength. These mental images are not always consistent with a person's actual physical structure or appearance. Some body image distortions have deep psychological origins, such as the eating disorder anorexia nervosa. Other alterations occur as a result of situational events, such as the loss or change in a body part. Be aware that most men and women experience some degree of dissatisfaction with their bodies, which affects body image and overall self-concept. Individuals often exaggerate disturbances in body image when a change in health status occurs. The way others view a person's body and the feedback offered are also influential. For example, a controlling, violent husband tells his wife that she is ugly and that no one else would want her. Over the years of marriage she incorporates this devaluation into her self-concept.

Cognitive growth and physical development also affect body image. Normal developmental changes such as puberty and aging have a more

apparent effect on body image than on other aspects of self-concept. Hormonal changes during adolescence influence body image. The development of secondary sex characteristics and the changes in body fat distribution have a tremendous impact on an adolescent's self-concept. For both male and female adolescents, appearance comparisons can result in a negative body image that impacts health behaviors, including disordered eating and exercise (Vartanian et al., 2018). For example, an adolescent girl may have a distorted body image and view herself as fat, which signals an eating disorder. Your assessment may reveal that an adolescent engages in self-harmful behaviors such as cutting; self-mutilation can indicate self-concept and self-esteem issues that warrant nursing intervention (Halter, 2018). A threat to body image and overall self-concept can affect adherence to recommended health regimens, including diet, exercise, health screening practices, and taking medications as prescribed. Changes associated with aging (e.g., menopause; wrinkles; graying hair; and decrease in visual acuity, hearing, and mobility) also affect body image in an older adult (Touhy and Jett, 2018).

Cultural and societal attitudes and values influence body image. Culture and society dictate the accepted norms of body image and influence one's attitudes (Fig. 33.2). Cultural background plays an integral role in body satisfaction in adolescent girls and is reflected in differences in body satisfaction among groups. Body image is more favorable in cultures in which girls describe more reasonable views about physical appearance, report less social pressure for thinness, and have less tendency to base self-esteem on body image. Low self-concept clarity increases vulnerability to body image issues as a result of the internalization of the thin ideal and appearance-related social comparisons (Vartanian et al., 2018). Values such as ideal body weight and shape and attitudes toward piercing and tattoos are culturally based. American society emphasizes youth, beauty, and wholeness. Western cultures have been socialized to dread the normal aging process, whereas Eastern cultures view aging positively and respect older adults. Body image issues are often associated with impaired self-concept and self-esteem.

Role Performance

Role performance is the way in which individuals perceive their ability to carry out significant roles (e.g., parent, supervisor, partner, or close friend). Normal changes associated with maturation result in changes in role performance. For example, when a man has a child, he becomes a father. The new role of father requires many changes in behavior if the man is going to be successful. Roles that individuals follow in given situations involve socialization, expectations, or standards of behavior. The patterns are stable and change only minimally during adulthood.

Ideal societal role behaviors are often hard to achieve in real life. Individuals have multiple roles and personal needs that sometimes conflict. Successful adults learn to distinguish between ideal role expectations and realistic possibilities. To function effectively in multiple roles, a person must know the expected behavior and values, desire to conform to them, and be able to meet the role requirements. Fulfillment of role expectations leads to an enhanced sense of self. Difficulty or failure to meet role expectations leads to deficits and often contributes to decreased self-esteem or altered self-concept.

Self-Esteem

Because how one thinks about oneself (self-concept) affects how one feels about oneself (self-esteem), you need to understand both concepts. **Self-esteem** is an individual's overall feeling of self-worth or the emotional appraisal of self-concept. It is the most fundamental self-evaluation because it represents the overall judgment of personal worth or value. Self-esteem is positive when one feels capable, worthwhile, and competent. A person's self-esteem is related to his or her evaluation of his or her effectiveness at school, within the family, and in social settings. The evaluation of others also is likely to have a profound influence on a person's self-esteem.

Considering the relationship between a person's actual self-concept and his or her ideal self enhances understanding of that person's self-esteem. The ideal self consists of the aspirations, goals, values, and standards of behavior that a person considers ideal and strives to attain. In general, a person whose self-concept comes close to matching the ideal self has high self-esteem, whereas a person whose self-concept varies widely from the ideal self suffers from low self-esteem (Halter, 2018). Once established, basic feelings about the self tend to be constant, even though a situational crisis can temporarily affect self-esteem.

Factors Influencing Self-Concept

A self-concept stressor is any real or perceived change that threatens identity, body image, or role performance (Fig. 33.3). An individual's perception of the stressor is the most important factor in determining his or her response. The ability to reestablish balance following a stressor is related to numerous factors, including the number of stressors, duration of the stressor, and health status (see Chapter 37). Stressors challenge a person's adaptive capacities. Changes that occur in physical, spiritual, emotional, sexual, familial, and sociocultural health affect self-concept. Being able to successfully adapt to stressors is likely to lead to a positive sense of self, whereas failure to adapt often leads to a negative self-concept.

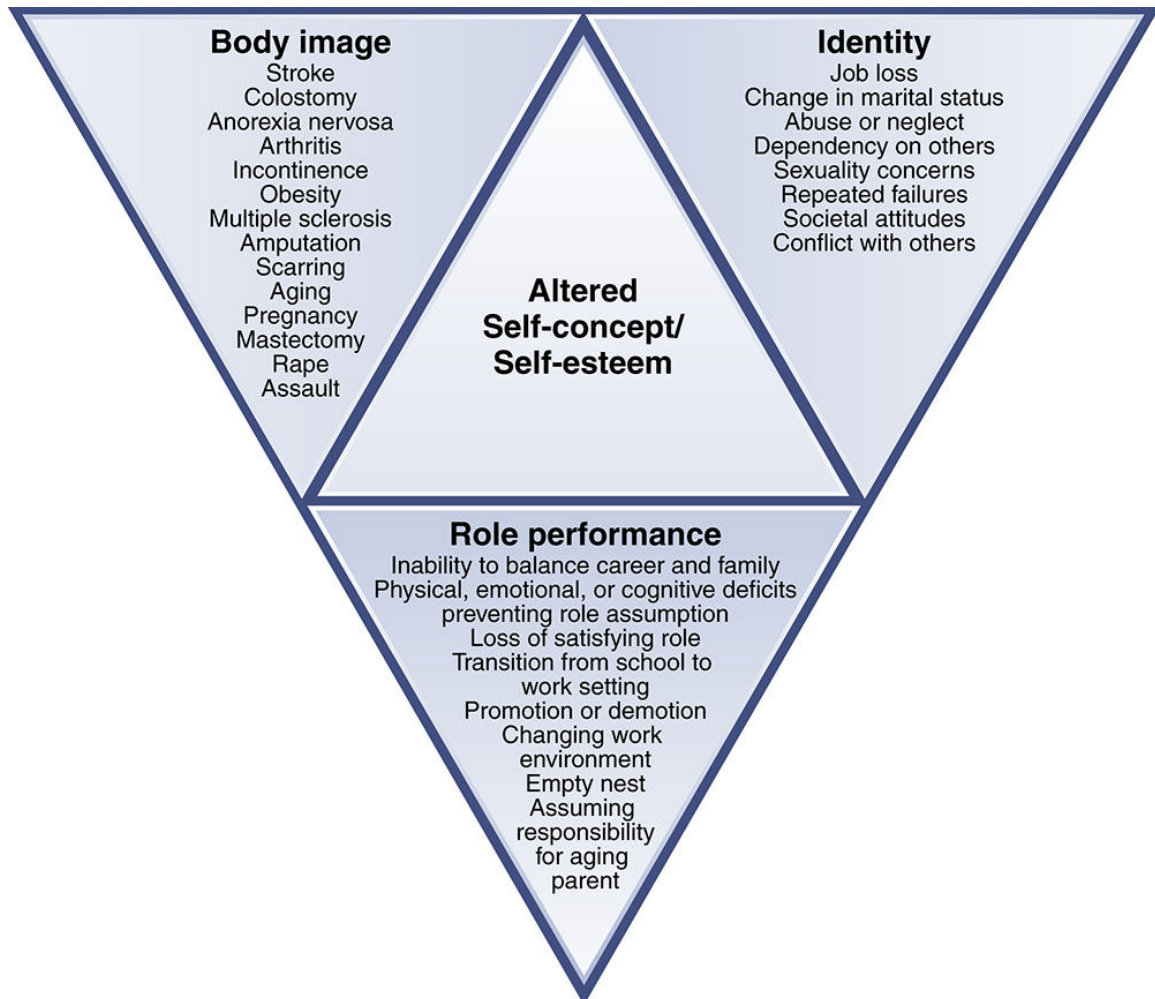

FIG. 33.3 Common stressors that influence self-concept.

Any change in health is a stressor that potentially affects self-concept. A physical change in the body sometimes leads to an altered body image, affecting identity and self-esteem (White and Taliaferro, 2016). Chronic illness often alters role performance, which changes an individual's identity and self-esteem. An essential process in the adjustment to loss is the development of a new self-concept. A loss of a partner can lead to a loss of identity and a lower self-esteem. Unlike the loss in self-esteem shown in vulnerable older adults, the resiliency demonstrated in some older adults may reflect more sophisticated cognitive strategies to manage losses (Touhy and Jett, 2018).

The stressors created as a result of a crisis also affect a person's health. If the resulting identity confusion, disturbed body image, low self-esteem, or role conflict is not relieved, illness can result. For example, the diagnosis of cancer places additional demands on a person's established living pattern. It changes his or her appraisal of and satisfaction with the current level of

physical, emotional, and social functioning (see [Chapter 37](#)). Assess self-esteem, effectiveness of coping strategies, and social support in all patients. During self-concept crises, supportive and educational resources are valuable in helping a person learn new ways of coping with and responding to the stressful event or situation to maintain or enhance self-concept.

Identity Stressors

Stressors affect an individual's identity throughout life, but individuals are particularly vulnerable during adolescence. Adolescents need to adjust to the physical, emotional, and mental changes of increasing maturity, which results in insecurity and anxiety. Adolescents also develop academic and psychosocial competence at this time. The use of social media affects identity development as adolescents attempt to navigate relationships and express themselves in a way others will accept and like ([Eleuteri et al., 2017](#)).

Compared with an adolescent, an adult generally has a more stable identity and thus a more firmly developed self-concept ([Orth et al., 2018](#)). Cultural and social stressors rather than personal stressors have more impact on an adult's identity. For example, an adult has to balance career and family or make choices regarding honoring religious traditions from one's family of origin. **Identity confusion** results when people do not maintain a clear, consistent, and continuous consciousness of personal identity. Inability to adapt to identity stressors can result in identity confusion regardless of stage of life.

Body Image Stressors

A change in the appearance, structure, or function of a body part requires an adjustment in body image. An individual's perception of the change and the relative importance placed on body image affects the significance of a loss of function or change in appearance. For example, if a woman's body image incorporates reproductive organs as the ideal, a hysterectomy needed because of a diagnosis of uterine cancer is a significant alteration and can result in a perceived loss of femininity or wholeness. Changes in the appearance of the body such as an amputation, facial disfigurement, or scars from burns are obvious stressors affecting body image. Mastectomy and colostomy are surgical procedures that alter the appearance and function of the body, yet the changes typically are not apparent to others when the individual is dressed. Although potentially undetected by

others, these changes significantly impact the individual. Even some elective changes such as breast augmentation or reduction affect body image. Chronic illnesses such as heart and renal disease affect body image because the body no longer functions at an optimal level. The patient has to adjust to a decrease in activity tolerance that impacts his or her ability to perform normal activities of daily living. In addition, pregnancy, significant weight gain or loss, pharmacological management of illness, or radiation therapy changes body image. Negative body image often leads to adverse health outcomes.

The response of society to physical changes in an individual often depends on the conditions surrounding the alteration. Some social changes have allowed the public to respond more favorably to illness and altered body image. For example, the media frequently present positive stories about people adjusting in a healthy manner to serious injuries, debilitating illness, or chronic disease (e.g., surfer Bethany Hamilton with her loss of a limb, actor Michael J. Fox with Parkinson's disease, and singer and actress Selena Gomez with lupus). These stories change public awareness and the perception of what constitutes a disability, and provide positive role models for individuals undergoing self-concept stressors and their families, friends, and society as a whole. In view of the growing epidemic of obesity in Western cultures, parents and health care providers need to address weight-management issues without causing further injury to body image. Providing a social environment that focuses on health and fitness rather than a drive for thinness for girls or muscularity for boys can potentially increase adolescent satisfaction with their bodies.

Role Performance Stressors

Throughout life a person undergoes numerous role changes. Situational transitions occur when parents, spouses, children, or close friends die or people move, marry, divorce, or change jobs. It is important to recognize that a shift along the continuum from illness to wellness is as stressful as a shift from wellness to illness. Any of these transitions may lead to role conflict, role ambiguity, role strain, or role overload.

Role conflict results when a person has to simultaneously assume two or more roles that are inconsistent, contradictory, or mutually exclusive. For example, when a middle-age woman with teenage children assumes responsibility for the care of her older parents, conflicts occur in relation to being both a parent to her children and the child of her parents. Negotiating a balance of time and energy between her children and parents creates role conflicts (see [Chapter 13](#)). The perceived importance of

each conflicting role influences the degree of conflict experienced. The **sick role** involves the expectations of others and society regarding how an individual behaves when sick. Role conflict occurs when general societal expectations (take care of yourself, and you will get better) and the expectations of co-workers (need to get the job done regardless of illness) collide. The conflict of taking care of oneself while getting everything done is often a major challenge.

Role ambiguity involves unclear role expectations, which makes people unsure about what to do or how to do it, creating stress and confusion. Role ambiguity is common in the adolescent years. Parents, peers, and the media pressure adolescents to assume adultlike roles; yet many lack the resources to move beyond the role of a dependent child. Role ambiguity is also common in employment situations. In complex, rapidly changing, or highly specialized organizations, employees often become unsure about job expectations.

Role strain combines role conflict and role ambiguity. Some express role strain as a feeling of frustration when a person feels inadequate or unsuited to a role such as providing care for a disabled child or a family member with dementia or terminal cancer (see [Chapter 14](#)).

Role overload involves having more roles or responsibilities within a role than are manageable. This is common in an individual who unsuccessfully attempts to meet the demands of work and family while carving out some personal time. Often during periods of illness or change, those involved either as the one who is ill or as a significant other find themselves in role overload.

Self-Esteem Stressors

Individuals with high self-esteem generally are more resilient and better able to cope with demands and stressors than those with low self-esteem. Low self-worth contributes to feeling unfulfilled and disconnected from others. Decreased self-worth potentially can result in depression and unremitting uneasiness or anxiety. Illness, surgery, or accidents that change life patterns also influence feelings of self-worth. Chronic illnesses such as diabetes, arthritis, and cardiac disease require changes in accepted and long-assumed behavioral patterns. Female children and adolescents with chronic illness are particularly vulnerable to low self-esteem. The more the chronic illness interferes with the person's ability to engage in activities contributing to feelings of worth or success, the more it affects self-esteem.

Self-esteem stressors vary with developmental stages. Perceived inability to meet parental expectations, harsh criticism, inconsistent discipline, and unresolved sibling rivalry reduce the level of self-worth of children. A developmental milestone such as pregnancy introduces unique self-esteem stressors and has significant health care implications. Self-esteem and health behaviors are intertwined (Tonsing and Ow, 2018). Self-concept guides health behaviors and organizes health-related actions. Stressors affecting the self-esteem of an adult include failure in work and unsuccessful relationships. Self-esteem stressors in older adults include health problems, declining socioeconomic status, spousal loss or bereavement, loss of social support, and decline in achievement experiences following retirement (Box 33.3).

Box 33.3 Focus on Older Adults Enhancing Self-Esteem in Older Adults

In some older adults, self-esteem can be negatively affected due to a number of life changes. However, in other individuals aging promotes improved coping strategies that protect against the declining feelings of low self-esteem, despite the physical and emotional changes associated with aging (Touhy and Jett, 2018). High levels of self-esteem and sexual quality of life are associated with successful aging in postmenopausal women (White and Taliaferro, 2016). Nursing interventions aimed at enhancing self-concept and self-esteem in older adults are essential, particularly during illness, injury, or disability. Encouraging physical exercise can enhance the global well-being needed for successful aging and health-related quality of life (Hsu and Lu, 2018). Changing negative attitudes toward the elderly on the part of health care providers is essential to assure positive patient outcomes (Haesler et al., 2016).

Implications for Practice

- Clarify what the life changes mean and the effect on self-esteem. Discuss perceptions of health problems, declining socioeconomic status, spousal loss or bereavement, and loss of social support following retirement (Haesler et al., 2016).
- Conduct supportive conversations to understand challenges to the patient's perceptions of body image adjustments as part of aging and

changes associated with illness, injury, or disability (Hsu and Lu, 2018).

- Assess for preoccupation with physical complaints. Thoroughly assess patient's complaints and, if no physical explanation exists, encourage him or her to verbalize needs (e.g., fear, insecurity, loneliness) in a nonphysical way.
- Identify positive and negative coping mechanisms. Support effective strategies (Halter, 2018).
- Provide resources to help patient learn new positive coping mechanisms, including self-care practices of nutrition, sleep, and exercise (Leão et al., 2017).
- Encourage the use of storytelling and review of old photographs.
- Modify nursing interventions with patients experiencing dementia to support self-concept; recognize that self-concept in early dementia is largely intact (Touhy and Jett, 2018).
- Communicate that the older adult is worthwhile by actively listening to and accepting the person's feelings, being respectful, and praising healthy behaviors.
- Allow additional time to complete tasks. Reinforce the older adult's efforts at independence.

Family Effect on Self-Concept Development

The family plays a key role in creating and maintaining the self-concepts of its members. Children develop a basic sense of who they are from their family caregivers. A child also gains accepted norms for thinking, feeling, and behaving from family members (Hockenberry et al., 2019). Sometimes well-meaning parents cultivate negative self-concepts in children. Some literature (e.g., Crocetti et al., 2016) suggests that parents are the most important influences on a child's development, yet variations in parenting approach depend on the culture. Specifically a child's positive self-esteem and school achievement are fostered by parents who respond in a firm, consistent, and warm manner. High parental support and parental monitoring are related to greater self-esteem and lower risk behaviors. Parents who are harsh, inconsistent, or have low self-esteem themselves often behave in ways that foster negative self-concepts in their children. Positive communication and social support foster self-esteem and well-being in adolescence. To reverse a patient's negative self-concept, first assess the family's style of relating (see Chapter 10). Family and cultural

factors sometimes influence negative health practices such as excessive drinking (Box 33.4). Change in self-concept demands an evidence-based practice approach supported by the entire health care team.

Box 33.4 Evidence-Based Practice Self-Concept and the Impact on Adolescent Drinking Behaviors and Drug Use

PICOT Question: How does self-concept influence drinking behaviors and drug use in at-risk adolescents?

Evidence Summary

Adolescents experience changes in their physical appearance, social interactions, confidence, and independence. All of these influence self-concept. A low self-concept may precede or perhaps increase the risk for adolescent drinking (Bartsch et al., 2017). Because many teens engage in behaviors that increase the potential for morbidity and mortality, helping youth develop a healthy self-concept may prevent health risk behaviors, including teen drinking and drug use (Kann et al., 2018). In 2017, the CDC reported that 29.8% of high school students endorsed current alcohol use, and 19.8% reported current marijuana use. In addition, 14.0% of students had taken prescription pain medicine without a health care provider's prescription or differently than how the prescriber told them to use it. Nationwide, 8.8% of high school students had smoked cigarettes and 13.2% had used an electronic vapor product on at least 1 day during the 30 days before the survey (Kann et al., 2018). Identifying risk and protective factors is important when creating drinking, cigarette and electronic vapor products, and drug prevention programs, as well as harm reduction programs (Eleuteri et al 2017). Enhancing opportunities to learn skills to increase self-compassion, self-awareness, resiliency, and self-worth, as well as to improve relationships with peers and families, may reduce the risk behaviors in adolescents (Bartsch et al, 2017).

Application to Nursing Practice

- Drinking prevention efforts should include stress management and improvement in self-esteem (Bartsch et al., 2017).
- A priority nursing action is the assessment of child and adolescent coping strategies. Appropriate techniques include effective

communication, conflict resolution, and stress management (Leão et al., 2017).

- Families, peers, teachers, and health care providers should instill students' cultural pride, which promotes self-concept and the use of protective factors against risk behaviors such as drinking and drug use (Benninger and Savahl, 2017).
- Family, social, and behavioral factors are important issues to address during preadolescence and adolescence (Benninger and Savahl, 2017; Halter, 2018).
- Identifying risk factors for early drug and alcohol use, including genetic predisposition, family environment, and cultural identity, needs to be a priority for health care providers.

Nurse's Effect on Patient's Self-Concept

Your acceptance of a patient with an altered self-concept can promote positive change. Often this simply involves sitting with a patient and forming a therapeutic relationship. When a patient's physical appearance has changed, it is likely that both the patient and the family look to nurses and observe their verbal and nonverbal responses and reactions to the changed appearance. You need to remain aware of your own feelings, ideas, values, expectations, and judgments. Self-awareness is critical in understanding and accepting others. Nurses derive their self-concepts and professional identity from their public image; work environment; education; and their professional, social, and cultural values. Positive self-esteem and interprofessional collaboration appear to protect nurses from burnout and emotional exhaustion, which in turn allows nurses to deliver quality patient care (Manomenidis et al., 2017). You need to assess and clarify the following self-concept issues about yourself before caring for patients:

- Thoughts and feelings about lifestyle, health, and illness
- Awareness of how your nonverbal communication affects patients and families
- Personal values and expectations and how these affect patients
- Ability to convey a nonjudgmental attitude toward patients and families
- Preconceived attitudes toward cultural differences in self-concept and self-esteem

Some patients with a change in body appearance or function are extremely sensitive to the verbal and nonverbal responses of the health care team. A positive, matter-of-fact approach to care provides a model for the patient and family to follow. For example, when you observe a positive change in a patient's behavior, note it and allow the patient to establish its meaning. Nurses have a significant effect on patients by conveying genuine interest and acceptance. Including self-concept issues in the planning and delivery of care can influence patient outcomes positively. Building a trusting nurse-patient relationship that incorporates both the patient and family in the decision-making process enhances self-concept and self-esteem. You can individualize your approach by highlighting a patient's unique needs and incorporating alternative health care practices or methods of spiritual expression into the plan of care. It is important that health care providers understand the degree to which self-esteem and sexuality affect patient outcomes.

Your nursing care significantly affects a patient's body image. For example, the body image of a woman following a mastectomy is positively influenced by showing acceptance of the mastectomy scar. On the other hand, a nurse who has a shocked or disgusted facial expression contributes to the woman developing a negative body image. Patients closely watch the reactions of others to their wounds and scars, and it is very important to be aware of your responses toward the patient. Statements such as "This wound is healing nicely" or "This tissue looks healthy" are affirmations for the body image of the patient. Nonverbal behaviors convey the level of caring that exists for a patient and affect self-esteem. Anticipate personal reactions, acknowledge them, and focus on the patient instead of the unpleasant task or situation. Nurses who put themselves in the patient's situation incorporate measures to ease embarrassment, frustration, anger, and denial.

Preventive measures against self-concept stressors, early identification of existing stressors, and appropriate treatment minimize the intensity of self-concept stressors and the potential effects for a patient's self-esteem. Learn to design specific self-concept interventions to fit a patient's profile of risk factors. It is essential to assess a patient's perception of a problem and work collaboratively to resolve self-concept issues. Interventions designed to promote active living and healthy eating may be beneficial for preventing childhood obesity, improving self-esteem, preventing chronic diseases, and improving health outcomes in adulthood.

Critical Thinking

Successful critical thinking requires a synthesis of knowledge, experience, information gathered from patients and families, critical thinking attitudes, and intellectual and professional standards. Clinical judgments require you to anticipate information, analyze the data, and make decisions regarding your patient's care. During assessment consider all elements that build toward making an appropriate nursing diagnosis.

In the case of self-concept, it is essential to integrate knowledge from nursing and other disciplines, including self-concept theory, communication principles, and a consideration of cultural and developmental factors. Previous experience in caring for patients with self-concept alterations helps to individualize care. Self-concept profoundly influences a person's response to illness. A critical thinking approach to care is essential.

REFLECT NOW

Describe a situation you encountered recently in which your own self-concept or self-esteem negatively influenced the care you provided.

◆ Nursing Process

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care.

◆ Assessment

During the assessment process thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care. In assessing self-concept and self-esteem, first focus on each component of self-concept (identity, body image, and role performance). Then determine the patient's perceptions of these factors to reveal his or her level of self-esteem. Assessment also includes identifying the patient's self-concept stressors (Fig. 33.3), the number and intensity of stressors, observing the range of behaviors suggesting an altered self-concept (Box 33.5), and identifying coping resources and patterns. Gathering comprehensive assessment data requires the critical synthesis of information from multiple sources (Fig. 33.4). In addition to direct questioning (Box 33.6), gather much of the data regarding self-concept through observation of the patient's nonverbal behavior and by paying attention to the content of the patient's conversations. Take note of the manner in which patients talk about the people in their lives because this provides clues to both stressful and supportive relationships and key roles the patient assumes. Use knowledge of developmental stages to determine which areas are likely to be important to the patient, and inquire about these aspects of the person's life. For example, ask a 70-year-old patient about his life and what has been important to him. The individual's conversation likely provides data relating to role performance, identity, self-esteem, stressors, and coping patterns.

Box 33.5 Behaviors Suggestive of Altered Self-Concept

- Avoidance of eye contact

- Slumped posture

- Unkempt appearance

- Overly apologetic

- Hesitant speech

- Overly critical or angry

- Frequent or inappropriate crying

- Negative self-evaluation

- Excessively dependent

- Hesitant to express views or opinions

- Lack of interest in what is happening

- Passive attitude

- Difficulty in making decisions

- Self-harm behaviors

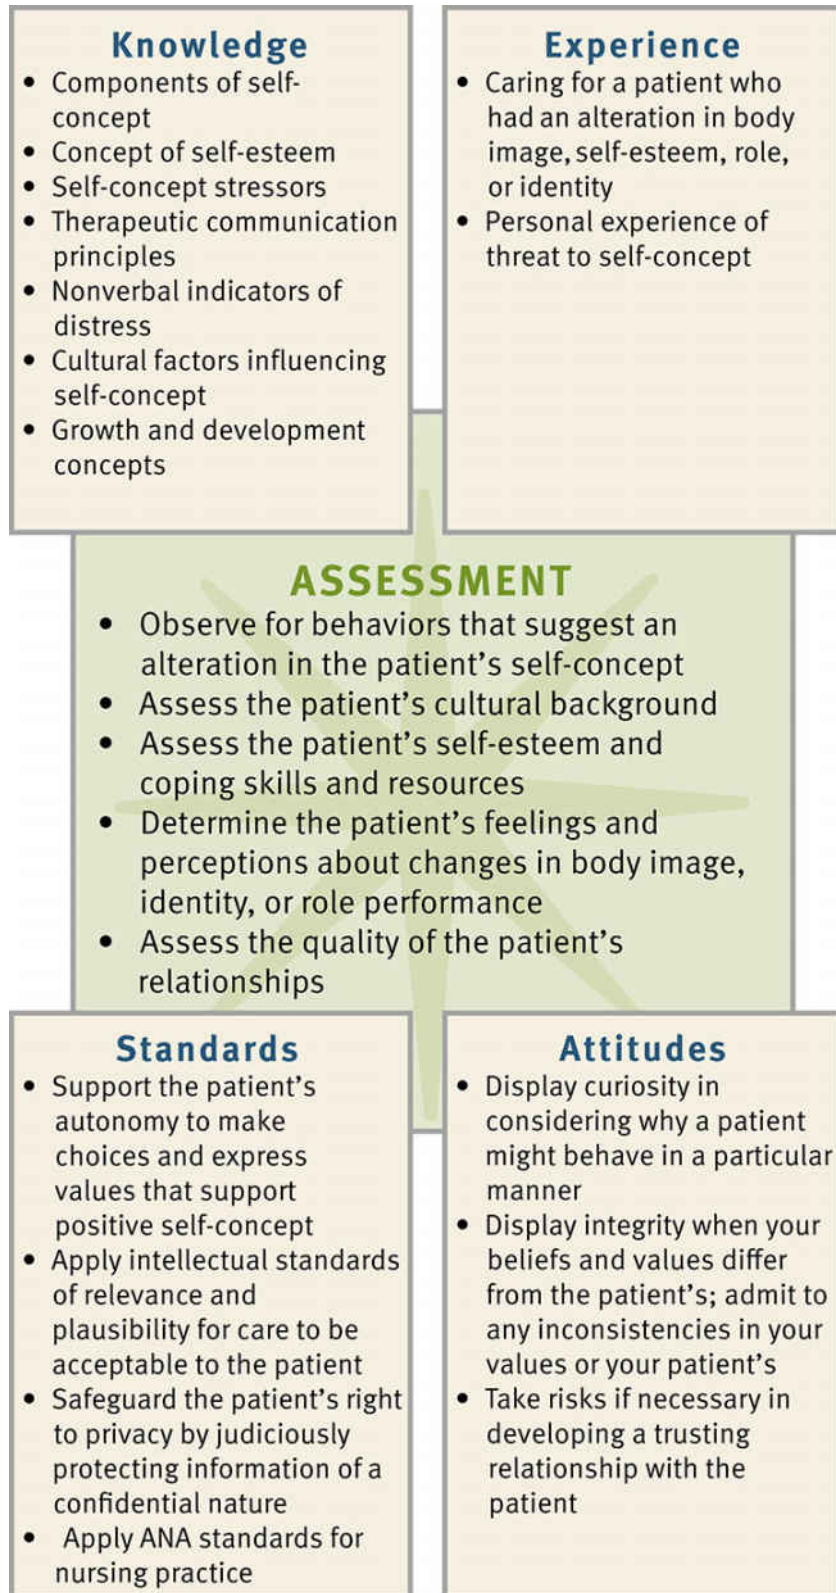

FIG. 33.4 Critical thinking model for self-concept assessment.

Box 33.6 Nursing Assessment Questions

Nature of the Problem

- How would you describe yourself?
- Which aspects of your appearance do you like?
- Tell me about the things you do that make you feel good about yourself.
- Tell me about your primary roles. How effective are you at carrying out each of these roles?

Onset and Duration

- When did you start to think or feel differently about yourself?
- How long have you struggled with _____ (specify identity, body image, role performance, or self-esteem)?
- Can you remember a time when you felt good about yourself?

Effect on Patient

- Tell me how your (e.g., loss of a breast, loss of hand function) affects your ability to take care of yourself.
- What impact does your self-esteem have on relationships?
- How does your self-esteem affect other areas of your life, such as decision making, socializing with friends?
- Have you considered hurting yourself (specify self-mutilation, suicidal gestures)?

Through the Patient's Eyes

An important factor in assessing self-concept is the person's viewpoint of his or her health condition and its influence on self-concept. Give patients the opportunity to tell their stories of how they perceive their illness or condition affecting their identity, their image of themselves, and their ability to lead a normal lifestyle. Assess their expectations of health care by asking them how interventions will make a difference. This is also an

opportunity to discuss the patient's goals. For example, a nurse teaching relaxation exercises to a patient who is experiencing anxiety related to an upcoming diagnostic study asks the patient about his expectations of the relaxation exercise that they have been practicing together. The patient's response gives the nurse valuable information about his beliefs and attitudes regarding the efficacy of the interventions and the potential need to modify the nursing approach.

Building Competency in Patient-Centered Care

You are caring for a patient who is recovering from a stroke. As you prepare to assess his self-esteem and self-concept, which questions might you ask him and his family to identify the factors that currently are influencing his self-esteem and self-concept?

Coping Behaviors

Assessment of a patient's coping behaviors includes a review of his or her internal and external resources. Knowledge of how a patient has dealt with stressors in the past provides insight into his or her style of coping. Patients do not address all issues in the same way, but they often use a familiar coping pattern for newly encountered stressors. Identify previous coping strategies to determine whether these patterns have contributed to healthy functioning or created more problems. For example, the use of drugs or alcohol during times of stress often creates additional stressors (see [Chapter 37](#)).

Significant Others

Exploring resources and strengths such as availability of significant others or prior use of community resources is important in formulating a realistic and effective plan of care. Valuable information comes from conversations with family and significant others. Significant others sometimes have insights into the person's way of dealing with stressors. They also have knowledge about what is important to the person's self-concept. The way in which a significant other talks about the patient and the significant other's nonverbal behaviors provide information about which kind of support is available for the patient.

REFLECT NOW

Reflect on how you could have improved your self-concept assessment of a patient who was either under 18 or over 50.

• Nursing Diagnosis

Carefully consider the assessment data to identify a patient's actual or potential problem areas. Rely on knowledge and experience, apply appropriate professional standards, and look for clusters of assessment findings that indicate a nursing diagnosis. The following list provides examples of self-concept-related nursing diagnoses:

- *Disturbed Body Image*
- *Disturbed Personal Identity*
- *Impaired Role Performance*
- *Situational Low Self-Esteem*

Making nursing diagnoses about self-concept is complex. Often isolated data are assessment findings for more than one nursing diagnosis (Box 33.7). For example, a patient expresses feelings of uncertainty and inadequacy. These assessment data may be found in both *Anxiety* and *Situational Low Self-Esteem*. Realizing that the patient is demonstrating assessment findings of more than one nursing diagnosis guides you to gather specific data to validate and differentiate the underlying problem. To further assess the possibility of *Anxiety* as a nursing diagnosis, consider whether the person has any of the following assessment findings: Is the person experiencing increased muscle tension, shakiness, a sense of being "rattled," or restlessness? These symptoms suggest *Anxiety* as the more appropriate diagnosis. On the other hand, if he or she expresses a predominantly negative self-appraisal, including inability to handle situations or events and difficulty in making decisions, these findings suggest that *Situational Low Self-Esteem* is more appropriate. To further aid in differentiating between the two provisional diagnoses, information regarding recent events in the person's life and how he or she has viewed

himself or herself in the past provide insight into the most appropriate nursing diagnosis. As you gather additional data, usually the priority nursing diagnosis becomes evident.

Box 33.7 Nursing Diagnostic Process Situational Low Self-Esteem

Assessment Activities	Assessment Findings
Ask patient to explain thoughts and feelings about self.	Patient is tearful and reports negative thoughts about self. She reports not wanting to have any visitors.
Observe patient’s behavior and ask family whether she is experiencing emotional or behavioral changes.	Spouse describes withdrawal and avoidance of intimacy. He describes wife as unable to make decisions.
Determine whether patient has had issues with self-esteem in the past and her plans to improve her self-esteem.	Patient denies experiencing self-esteem issues during adulthood. She is receptive to counseling to discuss ways to return to high self-esteem.

Validate the nursing diagnosis by sharing observations with the patient and allowing him or her to verify perceptions. This approach often results in the patient providing additional data, which further clarifies the situation. For example, “I noticed that you jumped when I touched your arm. Are you feeling uneasy today?” allows the patient to verify whether he or she is in fact anxious and to describe his or her concerns.

• Planning

During planning synthesize knowledge, experience, critical thinking attitudes, and standards (Fig. 33.5). Critical thinking ensures that a patient’s plan of care integrates information known about the individual and key critical thinking elements (see the [Nursing Care Plan](#)). Professional nursing scope and standards of practice (e.g., [ANA, 2015](#)) establish ethical and evidence-based practice guidelines for selecting effective nursing interventions.

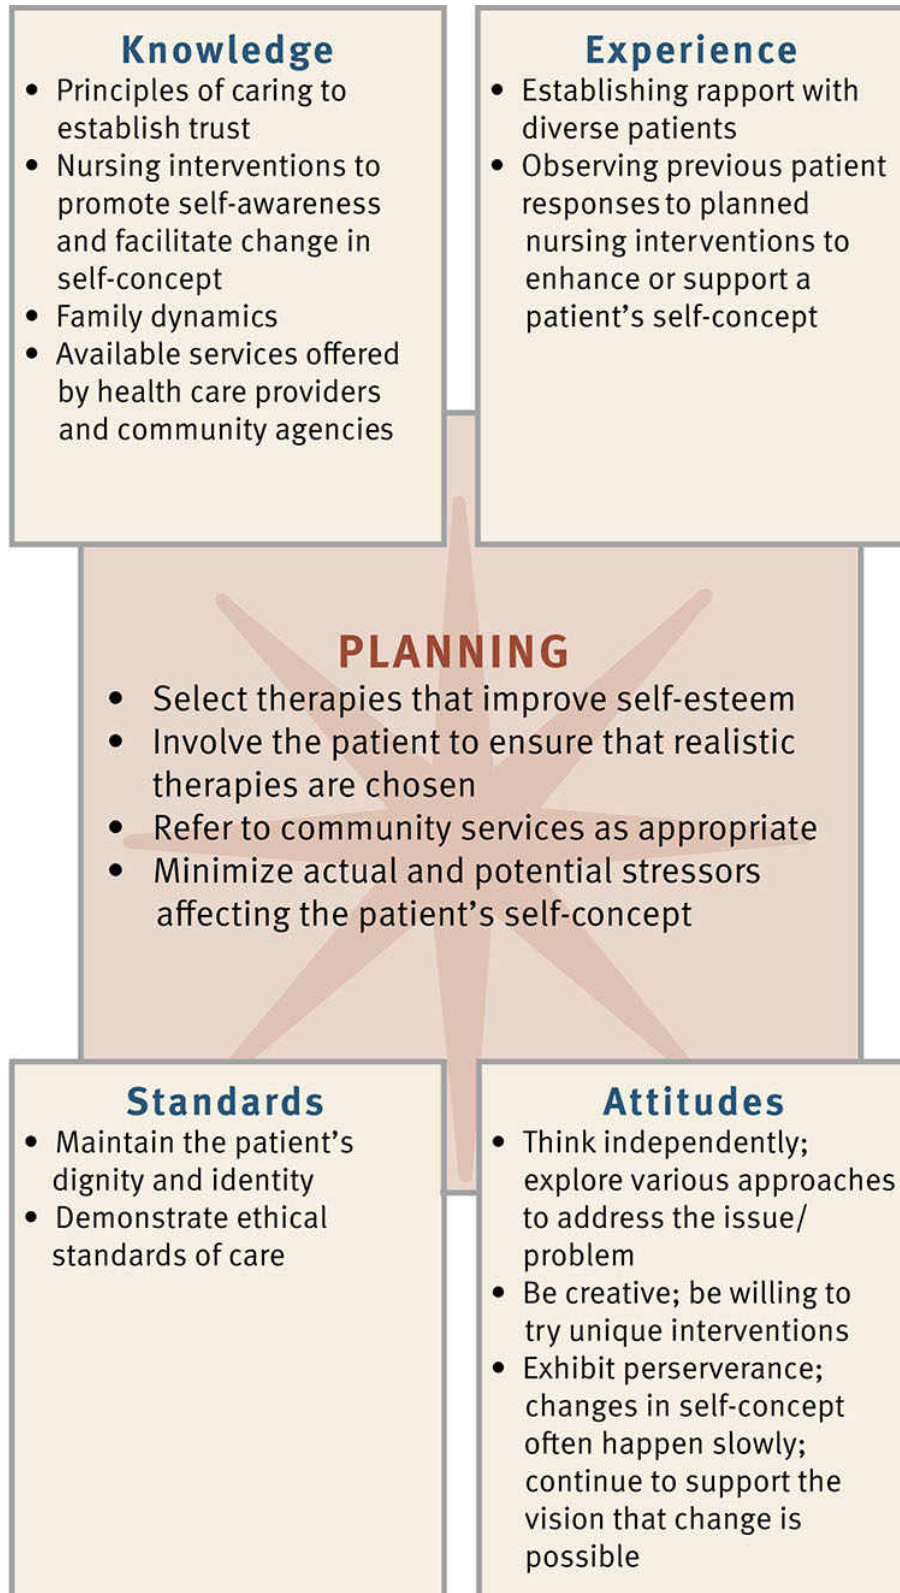

FIG. 33.5 Critical thinking model for self-concept planning.

Another method to help plan care is a concept map. An example of an illustrative concept map (Fig. 33.6) shows the relationship of a primary health problem (postoperative bilateral radical mastectomy) and four nursing diagnoses and several interventions. The concept map shows how the nursing diagnoses are interrelated. It also helps to show the interrelationships among nursing interventions. A single nursing intervention can be effective for more than one diagnosis.

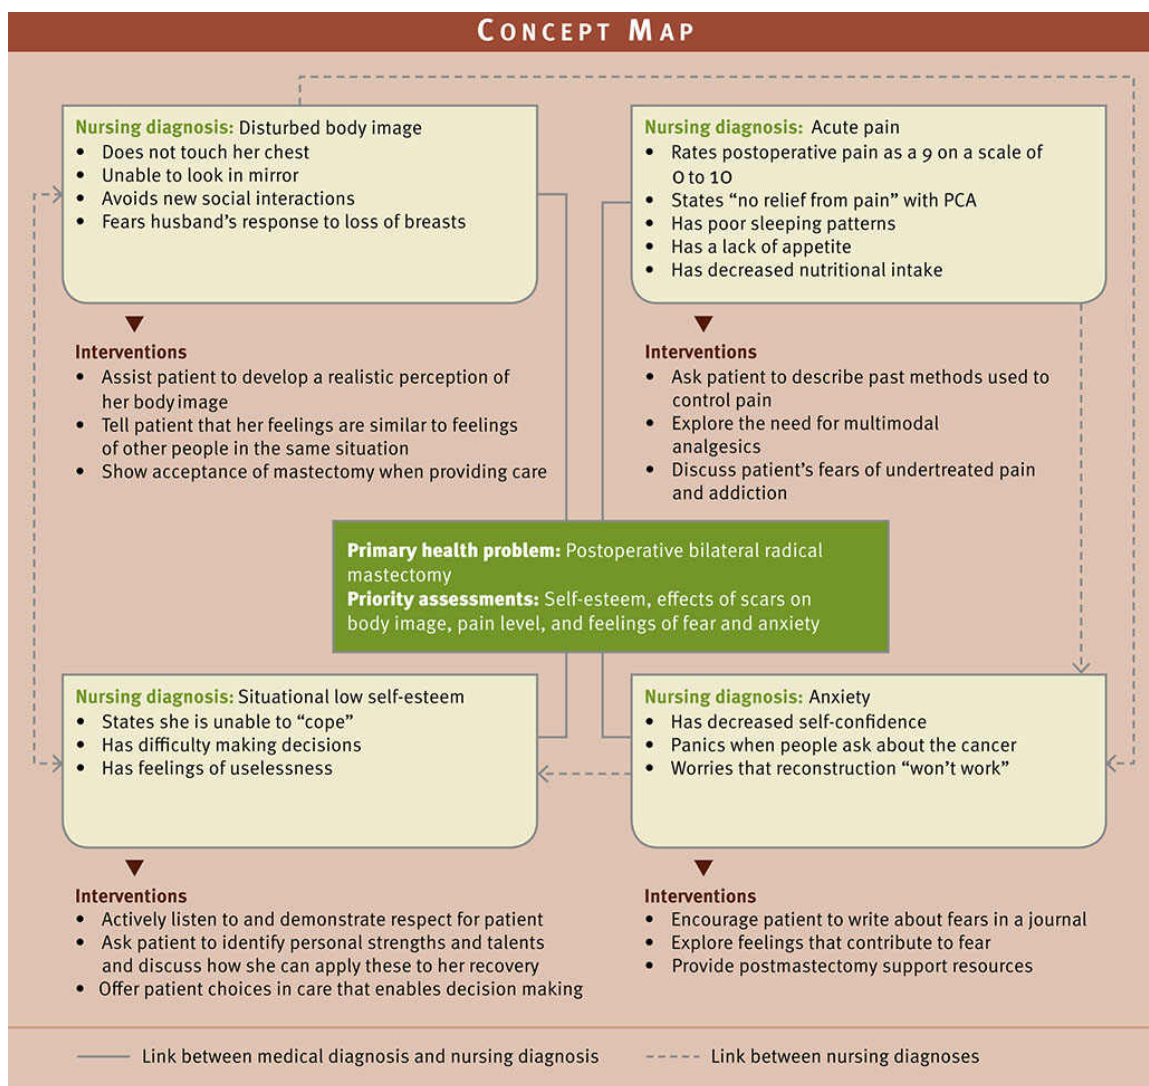

FIG. 33.6 Concept map for Mrs. Johnson. *PCA*, Patient-controlled analgesia.

Goals and Outcomes

Develop an individualized plan of care for each nursing diagnosis. Work collaboratively with the patient to set realistic expectations for care. Make sure that goals are individualized and realistic with measurable outcomes. In establishing goals consult with the patient about whether they are achievable. Consultation with significant others, mental health clinicians, and community resources results in a more comprehensive and workable plan. When you set goals, consider the data necessary to demonstrate that the patient's problem would change if the nursing diagnosis were managed. The outcome criteria should reflect these changes. For example, a patient is diagnosed with *Situational Low Self-Esteem related to a recent job layoff*. Establish a goal: "Patient's self-esteem will improve in 1 week." Examples of expected outcomes directed toward that goal include the following:

- The patient discusses a minimum of three areas of her life in which she is functioning well.
- The patient is able to voice the recognition that losing her job is not reflective of her worth as a person.
- The patient reports the ability to discuss her feelings in a support group.

Setting Priorities

A care plan presents the goals, expected outcomes, and interventions for a patient with an alteration in self-concept. Interventions help a patient adapt to the stressors that led to the self-concept disturbance and support and reinforce the development of coping methods. Often a patient perceives a situation as overwhelming and feels hopeless about returning to the level of previous functioning. He or she often needs time to adapt to physical changes but can work toward progressive improvement in self-concept and self-esteem.

Establishing priorities includes using therapeutic communication to address self-concept issues, which ensures that the patient's ability to address physical needs is maximized. Look for strengths in both the individual and the family, and provide resources and education to turn limitations into strengths. Patient teaching creates understanding of the normalcy of certain situations (e.g., nature of a chronic disease; change in relationships; effect of a loss). Often, once patients understand their situations, their sense of hopelessness and helplessness is lessened.

REFLECT NOW

Reflect about some self-concept priorities for an adolescent with facial trauma following a motor vehicle accident.

Nursing Care Plan

Disturbed Body Image

Assessment

Mrs. Johnson is recovering from a left radical mastectomy. She is in her room requesting that the curtains remain drawn at the window and lights off. She doesn't initiate any interaction with hospital staff when they enter her room. She received pain medication about 30 minutes ago, and the nurse sits with Mrs. Johnson to discuss how the impact of the mastectomy is affecting her body image and self-esteem.

Assessment Activities	Assessment Findings ^a
Assess identity and body image concerns (e.g., sexual role, femininity). Ask how the loss of her breast has affected her sense of self.	Mrs. Johnson looks away, shakes her head , and states, " I feel like less of a woman . My husband says I'm still attractive, but I don't believe him. I really don't want to talk with him."
Observe Mrs. Johnson's mood and affect and her nonverbal communication and interactions with others.	Mrs. Johnson demonstrates intermittent eye contact, frequent crying when alone , pulling hospital gown tightly across chest, and superficial conversations with family members.
Assess Mrs. Johnson's involvement in self-care activities.	Mrs. Johnson is unable to decide when to bathe, comb her hair, or apply typical makeup. She avoids looking in a mirror.
Ask Mrs. Johnson if she would like opportunities to participate in treatment activities.	Mrs. Johnson avoids looking at or touching her chest and does not ask questions about her condition. "I don't know if I want to do anything right now."

^a Assessment findings are shown in bold type.

Nursing Diagnosis:

Disturbed body image related to negative view of self after mastectomy

Planning

Goals	Expected Outcomes (NOC) ^b
	Self-Esteem
Mrs. Johnson will demonstrate self-care practices within 2 days and will verbalize improved self-esteem within 4 days.	Mrs. Johnson meets basic grooming and hygiene needs within 2 days. Mrs. Johnson verbalizes improved feelings of self-acceptance and self-worth within 4 days.
	Body Image
	Mrs. Johnson demonstrates positive adjustments to changes in body appearance within 1 week.

^b Outcome classification labels from Moorhead S, et al: *Nursing Outcomes Classification (NOC): measurement of health outcomes*, ed 6, St Louis, 2018, Elsevier.

Interventions (Nic) ^c	Rationale
Self-Esteem Enhancement	
Use communication techniques to facilitate an environment that will increase self-esteem.	A therapeutic nurse-patient relationship promotes positive patient outcome, including the patient assuming responsibility for her own care (Halter, 2018).
Engage patient in discussion about her changed physical appearance and how she can select attractive clothing.	Self-esteem and body image are strong predictors of depression. The nurse must assess thoughts and feelings, including depression and risk for suicide, to ensure the patient's safety and make appropriate referrals (Smith, 2018).
Encourage increased responsibility for self, and help patient assume self-care practices.	Promoting self-care practices, including improved sleep, exercise, and nutrition, enhances self-esteem and overall health (Leão et al., 2017).
Body Image Enhancement	
Provide patient-centered care to support self-care practices and acceptance of alterations in physical appearance.	A threat to body image and overall self-concept often influences self-care practices and acceptance of changes in physical appearance (Halter, 2018).

^c Intervention classification labels from Butcher HK, et al: *Nursing Interventions Classification (NIC)*, ed 7, St Louis, 2018, Elsevier.

Evaluation

Evaluation Activity	Patient Response/Finding	Outcome Status
Ask Mrs. Johnson how effective she feels in her ability to identify and express feelings verbally and nonverbally.	Mrs. Johnson reports, "I've been able to talk with my husband, even about my concerns that he won't find me attractive anymore."	Mrs. Johnson demonstrates a positive adjustment to changes in body appearance within 1 week.
Monitor changes in Mrs. Johnson's statements about herself.	Mrs. Johnson is making fewer negative comments and evaluating body image more realistically but remains dissatisfied with appearance.	Mrs. Johnson demonstrates a positive adjustment to changes in body appearance within 1 week.
Observe Mrs. Johnson's participation in self-care related to mastectomy.	Mrs. Johnson is more assertive in completing basic hygiene; uses a mirror to examine mastectomy scar.	Mrs. Johnson meets basic grooming and hygiene needs within 2 days and verbalizes improved feelings of self-acceptance and self-worth within 4 days.

Teamwork and Collaboration

A patient's perceptions of significant others are important to incorporate into the plan of care. Individuals who have experienced deficits in self-concept before the current episode of treatment have often established a system of support that includes mental health clinicians, clergy, and other community resources. Before including family members, consider the patient's desires for their involvement and cultural norms regarding who most frequently makes decisions in the family. Patients who are experiencing threats to or alterations in self-concept often benefit from collaboration with mental health and community resources to promote increased awareness. Additional resources include physical therapy, occupational therapy, behavioral health, social services, and pastoral care. Knowledge of available resources allows appropriate referrals. Improving your own self-esteem and professional identity through effective interprofessional teamwork can promote resilience and prevent burnout, which in turn can promote better patient outcomes ([Manomenidis et al., 2017](#)).

Implementation

As with all the steps of the nursing process, a therapeutic nurse-patient relationship is central to the implementation phase. Collaboratively you develop the goals and outcome criteria and then consider nursing interventions for promoting a healthy self-concept and helping a patient

move toward his or her goals. To identify effective nursing interventions, consider each nursing diagnosis and individualize interventions that address the diagnosis. Collaborating with members of the health care team maximizes the comprehensiveness of the approach to self-concept issues. Regardless of the health care setting, it is important to work with patients and their families or significant others to promote a healthy self-concept. For example, select nursing interventions that help patients regain or restore the elements that contribute to a strong and secure sense of self. The approaches chosen vary according to the level of care required.

Health Promotion

Work with patients to help them develop healthy lifestyle behaviors that contribute to a positive self-concept. Measures that support adaptation to stress such as proper nutrition, regular exercise within the patient's capabilities, adequate sleep and rest, and stress-reducing practices contribute to a healthy self-concept. Nurses are in a unique position to identify lifestyle practices that put a person's self-concept at risk or to suggest altered self-concepts. For example, a young teacher visits a clinic due to being unable to sleep and experiencing anxiety. In gathering the nursing history, lifestyle practices such as too little rest, a large number of life changes occurring simultaneously, and excessive use of alcohol emerge. These data, when taken together, suggest actual or potential self-concept disturbances. Determine how the patient views the various lifestyle elements to facilitate his or her insight into behaviors, and make referrals or provide needed health teaching.

Acute Care

In the acute care setting some patients experience potential threats to their self-concept because of the nature of the treatment and/or diagnostic procedures. Threats to a person's self-concept often result in anxiety and/or fear. You need to address a patient's numerous stressors, including fear of unknown diagnoses (diagnostic tests), the need to modify lifestyle, and anticipated changes in functioning. In the acute care setting there is often more than one stressor, thus increasing the overall stress level for the patient and family.

Nurses in the acute care setting encounter patients who face the need to adapt to an altered body image as a result of surgery or other physical change. With shortened lengths of stay, addressing these needs is difficult to do while in an acute care setting; thus appropriate follow-up and

referrals, including home care, are essential. Remain sensitive to the patient's level of acceptance of any changes. Forcing confrontation with a change before the patient is ready likely delays his or her acceptance. Signs that a person is receptive to accepting a change include asking questions related to how to manage a particular aspect of what has happened or looking at the changed body area. As the patient expresses readiness to integrate the body change into his or her self-concept, let him or her know about support groups that are available, and offer to make the initial contact.

Restorative and Continuing Care

Often in a home care environment a nurse has the opportunity to work with a patient to reach the goal of attaining a more positive self-concept. Interventions are based on the premise that the patient first develops insight and self-awareness concerning problems and stressors and then acts to solve the problems and cope with the stressors. One way to achieve this is by reframing the patient's thoughts and feelings in a more positive way. Incorporate this approach into patient teaching for alterations in self-concept, including situational low self-esteem, that sometimes are present in the home care setting ([Box 33.8](#)).

Box 33.8 Patient Teaching Alterations in Self-Esteem

Objective

- Patient will verbalize ways to improve situational low self-esteem.

Teaching Strategies

- Provide information needed to allow patient to better care for self.
- Have patient identify strengths and weaknesses and reinforce strengths and successes.
- Reaffirm that patient is responsible for behavior.
- Discuss situations in which patient's stress may intensify.
- Explore patient's coping responses to problems.

- Incorporate psychiatric co-morbidities (e.g., depression, anxiety, somatoform disorders) and alterations to self-esteem and body image when planning patient education sessions.
- Collaboratively identify alternative solutions and encourage alternatives not previously tried (e.g., communication skills, decision-making skills, healthy coping strategies).

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning.

- Describe the new communication skills you have tried since we last met.
- Tell me about the decisions about your care that you have made this week.
- Which coping strategies are you using now?

Increase a patient's self-awareness by allowing him or her to openly explore thoughts and feelings. A priority nursing intervention is the expert use of therapeutic communication skills to clarify the expectations of a patient and family. Open exploration makes the situation less threatening for a patient and encourages behaviors that expand self-awareness. Use a nonjudgmental approach when accepting a patient's thoughts and feelings, help the patient clarify interactions with others, and be empathic.

Help the patient define problems clearly and apply those coping mechanisms most suitable for the problem. Work closely with him or her to analyze adaptive and maladaptive responses, contrast alternatives, devise a plan, and discuss outcomes. Collaborate with the patient to identify alternative solutions and develop realistic goals to facilitate real change and encourage further goal-setting behaviors. Design opportunities that result in success, reinforce the patient's skills and strengths, and help him or her find needed assistance. Encourage the patient to commit to decisions and actions to achieve goals by teaching him or her to move away from ineffective coping mechanisms and develop successful coping strategies. Supporting attempts that are helpful is essential because with each success a patient is motivated to make another attempt.

• Evaluation

Through the Patient's Eyes

Use critical thinking to evaluate a patient's perceived success in meeting each goal and the established expected outcomes (Fig. 33.7). Frequent evaluation of patient progress is necessary. Determine if the patient perceives satisfaction with relationships with health care providers and the interventions they have provided. A patient's satisfaction with care depends on perceiving supportive relationships with caregivers.

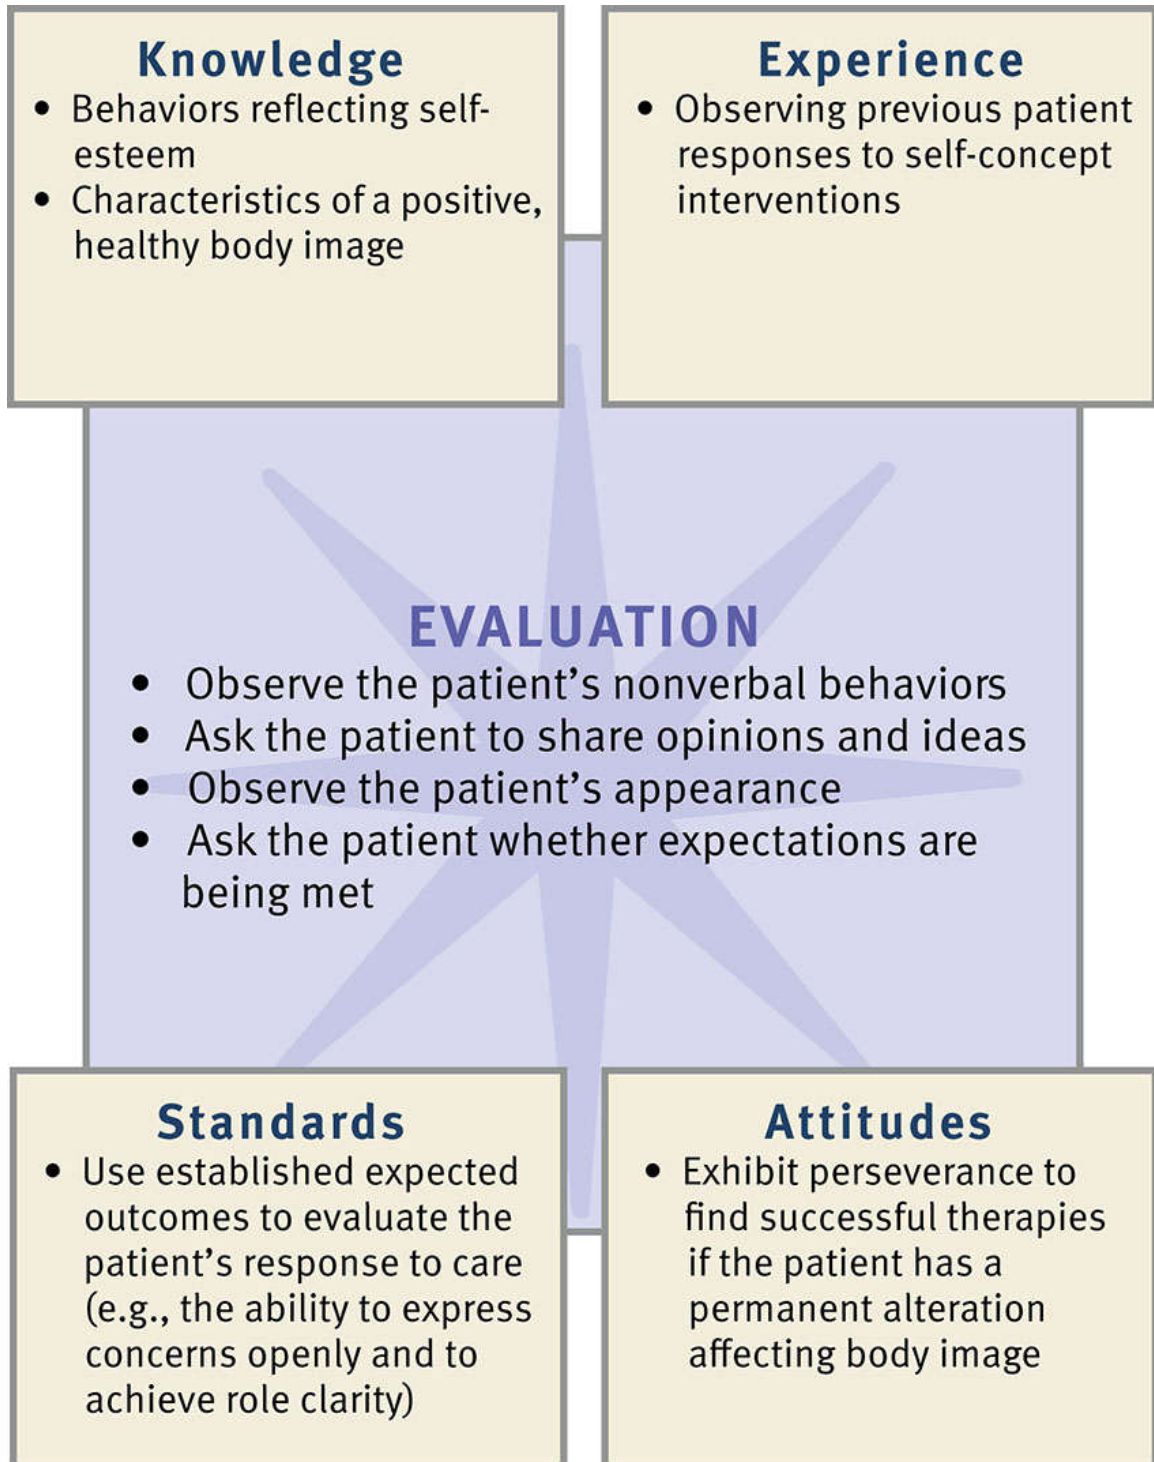

FIG. 33.7 Critical thinking model for self-concept evaluation.

Patient Outcomes

Expected outcomes for a patient with a self-concept disturbance include displaying behaviors indicating a positive self-concept, verbalizing statements of self-acceptance, and validating acceptance of change in appearance or function. Key indicators of a patient's self-concept are nonverbal behaviors. For example, a patient who has difficulty in making eye contact demonstrates a more positive self-concept by making more frequent eye contact during conversation. Social interaction, adequate self-care, acceptance of the use of prosthetic devices, and statements indicating understanding of teaching all indicate progress. Investing in satisfying activities, exerting choices in daily life, understanding their own needs during transitions, and adapting to life circumstances are evidence of self-esteem and self-efficacy in older adults (Touhy and Jett, 2016). A positive attitude toward rehabilitation and increased movement toward independence facilitate a return to preexisting roles at work or at home. Patterns of interacting also reflect changes in self-concept. For example, a patient who has been hesitant to express personal views more readily offers opinions and ideas as self-esteem increases.

The goals of care sometimes become unrealistic or inappropriate as a patient's condition changes. Revise the plan if needed, reflecting on successful experiences with other patients. Patient adaptation to major changes can take a year or longer, but the fact that this period is long does not suggest problems with adaptation. Look for signs that the patient has reduced some stressors and that some behaviors have become more adaptive. If initial outcomes regarding self-concept are not met, individualize care using the following questions:

- Tell me what you will do if you are not able to return to work (may substitute "school" or "home") as planned.
- Whom will you contact if you are not feeling any better about yourself in 2 weeks?
- What are you doing to actively improve how you view yourself and your perception of how others view you?
- How will you know that your sense of worth is improving?

Changes in self-concept take time. Although change is often slow, care of a patient with a self-concept disturbance is rewarding.

Key Points

- Components of self-concept including identity, body image, and role performance are affected by developmental milestones and life events.
- Self-concept and self-esteem stressors include developmental and relationship changes, illness (particularly chronic illness involving changes in what were normal activities), surgery, accidents, and the responses of other individuals to changes resulting from these events.
- Identity, body image, and role performance change with developmental milestones and the response to those events.
- The nurse influences the self-concept of patients, and the nurse's self-concept is influenced by the practice environment and is positively affected by effective teamwork.
- Planning and implementing nursing interventions for self-concept disturbance involve expanding the patient's self-awareness, encouraging self-exploration, aiding in self-evaluation, helping formulate goals in regard to adaptation, and helping patients achieve these goals.
- Be aware of how cultural variations impact a patient's self-concept and self-esteem and incorporate culturally sensitive interventions.

Reflective Learning

- Reflect on a statement a patient, friend, or family member made about identity, body image, role performance, or self-esteem. How did you respond? How could you have improved your response?
- Describe a situation you encountered recently in which your own self-concept or self-esteem positively influenced the care you provided.

- Describe how you would individualize a self-concept assessment for a patient recovering from a below-the-knee amputation.

Review Questions

1. A 50-year-old woman is recovering from a bilateral mastectomy. She refuses to eat, discourages visitors, and pays little attention to her appearance. One morning the nurse enters the room to see the patient with her hair combed and makeup applied. Which of the following is the best response from the nurse?
 1. "What's the special occasion?"
 2. "You must be feeling better today."
 3. "This is the first time I've seen you look this good."
 4. "I see that you've combed your hair and put on makeup."
2. A 30-year-old patient diagnosed with major depressive disorder has a nursing diagnosis of *Situational Low Self-Esteem related to negative view of self*. Which of the following are appropriate interventions by the nurse? (Select all that apply.)
 1. Encourage reconnecting with high school friends.
 2. Role-play to increase assertiveness skills.
 3. Focus on identifying strengths and accomplishments.
 4. Provide time for journaling to explore underlying thoughts and feelings.
 5. Explore new job opportunities.
3. A patient who is depressed is crying and verbalizes feelings of low self-esteem and self-worth, such as "I'm such a failure ... I can't do anything right." What is the nurse's best response?
 1. Remain with the patient until he or she validates feeling more stable.

2. Tell the patient that is not true and that every person has a purpose in life.
 3. Review recent behaviors or accomplishments that demonstrate skill ability.
 4. Reassure the patient that you know how he or she is feeling and that things will get better.
4. A 20-year-old patient diagnosed with an eating disorder has a nursing diagnosis of *Situational Low Self-Esteem*. Which of the following nursing interventions are appropriate to address self-esteem? (Select all that apply.)
1. Offer independent decision-making opportunities.
 2. Review previously successful coping strategies.
 3. Provide a quiet environment with minimal stimuli.
 4. Support a dependent role throughout treatment.
 5. Increase calorie intake to promote weight stabilization.
5. The nurse can increase a patient's self-awareness and self-concept through which of the following actions? (Select all that apply.)
1. Helping the patient define personal problems clearly
 2. Allowing the patient to openly explore thoughts and feelings
 3. Reframing the patient's thoughts and feelings in a more positive way
 4. Having family members assume more responsibility during times of stress
 5. Recommending self-help reading materials
6. Which of the following assessment findings suggest an altered self-concept? (Select all that apply.)
1. Uneven gait
 2. Slumped posture and poor personal hygiene
 3. Avoidance of eye contact when answering a question

4. Requests for visits from the chaplain
 5. Frequent use of the call light
7. The home health nurse is visiting a 90-year-old man who lives with his 89-year-old wife. He is legally blind and is 3 weeks' post right hip replacement. He ambulates with difficulty with a walker. He comments that he is saddened now that his wife has to do more for him and he is doing less for her. Which of the following is the priority nursing diagnosis?
1. Impaired Self Toileting
 2. Lack of Knowledge Regarding Resources for the Visually Impaired
 3. Disturbed Body Image
 4. Risk for Situational Low Self-Esteem
8. A nurse is working with an older adult who recently moved to an assisted-living center because of declining physical capabilities associated with the normal aging process. Which nursing interventions are directed at promoting self-esteem in this patient?
1. Commending the patient's efforts at completing self-care tasks
 2. Assuming that the patient's physical complaints are attention-seeking measures
 3. Minimizing time discussing memories and past achievements spent with the patient
 4. Limiting decision-making opportunities for the patient to reduce stress
9. A nurse is caring for a 40-year-old male diagnosed with Crohn's disease several years ago, resulting in numerous hospitalizations each year for the past 3 years. Which of the following behaviors interfere with the developmental tasks of middle adulthood? (Select all that apply.)

1. Sends birthday cards to friends and family
 2. Refuses visitors while hospitalized
 3. Self-absorbed in physical and psychological issues
 4. Performs self-care activities
 5. Communicates feelings of inadequacy
10. When assessing a patient's adjustment to the role changes brought about by a medical condition such as a stroke, the nurse asks about which of the following? (Select all that apply.)
1. What are your thoughts about returning to work?
 2. What questions do you have about your medications?
 3. How has your health affected your relationship with your partner?
 4. What level of physical activity are you able to perform?
 5. What concerns do you have about another stroke?

Answers: 1.4; 2.3, 4; 3.1; 4.1, 2; 5.1, 2, 3; 6. 2, 3; 7.4; 8.1; 9.2, 3, 5; 10. 1, 3.

Sexuality

OBJECTIVES

- Identify personal attitudes, beliefs, and biases related to sexuality.
- Discuss a nurse's role in maintaining or enhancing a patient's sexual health.
- Describe key concepts of sexual development across the life span.
- Identify causes of sexual dysfunction.
- Assess a patient's sexuality and sexual health.
- Formulate appropriate nursing diagnoses for patients with alterations in sexuality.
- Identify patient risk factors in the area of sexual health.
- Identify and describe nursing interventions to promote sexual health.
- Evaluate patient outcomes related to sexual health needs.
- Use critical thinking skills when helping patients meet their sexual needs.

Sexually transmitted infections (STIs), p. 708

Transgender, p. 707

Sexuality is a broad term that refers to all aspects of being sexual, including how you identify yourself sexually and with whom you choose to be intimate. It is a part of who you are as a person and is important for overall health. Sexuality includes a person's thoughts and feelings about the body, a sense of femaleness and maleness, romantic and erotic attachments toward others, and attitudes toward sexual functioning. Our sexual health is based on our ability to form healthy relationships with others. Sex is considered a basic physiological need, and sexual intimacy throughout the life span is equally important for sexual health. Healthy sexuality enables people to develop and maintain their fullest potential.

Sexuality is important for overall health. Even though discussion of sexual topics has increased over the years, individuals of all ages lack knowledge regarding sexuality. Although patients may be hesitant to bring up their concerns, they often share their feelings when a nurse addresses sexuality in a relaxed, matter-of-fact manner. To feel comfortable addressing sexuality, nurses need therapeutic communication skills (see [Chapter 24](#)) and must be knowledgeable about all aspects of sexuality, including values and issues surrounding sexuality. Religious teachings, cultural influences on gender roles, beliefs about sexual orientation, and social and environmental climates influence the values systems for both patients and health care providers.

Expression of an individual's sexuality is influenced by interactions among biological, social, psychological, spiritual, religious, economic, political, historical, and cultural factors (World Health Organization [WHO], 2018a). In addition, values, attitudes, and beliefs as well as behaviors and relationships with others influence sexuality.

Sexuality differs from *sexual health*. According to WHO (2018a; 2018b), **sexual health** is a state of physical, emotional, mental, and social well-being in relation to sexuality and is not merely the absence of disease or dysfunction. Sexual health requires a positive and respectful approach to sexuality and sexual relationships, as well as the possibility of having pleasurable and safe sexual experiences that are free of coercion, discrimination, and violence. People who are sexually healthy have a positive and respectful approach to sexuality and sexual relationships.

Scientific Knowledge Base

A broad knowledge base allows you to have a holistic view of patients, thus promoting quality patient care that best meets the sexuality and sexual health needs of each patient and family.

A sound scientific knowledge base regarding sexuality provides you with the necessary information to help your patients achieve sexual health. A basic understanding of sexual development, sexual identity and sexual orientation, contraception, and sexually transmitted infections (STIs) is necessary.

Sexual Development

Sexuality changes as a person grows and develops. Each stage of development brings changes in sexual functioning and the role of sexuality in relationships. Sexuality is a complex process that involves many factors. It begins at birth and continues throughout life. [Erikson's psychosocial theory of development \(1963\)](#) helps you understand key tasks that individuals face at various stages of development. Early researchers focused on sexuality from adolescence to middle age, but we now understand that sexuality is already in progress at birth and continues throughout life, including into old age ([LeVay et al., 2019](#)).

Infancy and Early Childhood

The first several years of life are crucial in the development of sexuality and gender identity. Commonly, a child identifies with the parent or caregiver of the same sex and develops a complementary relationship with the parent or caregiver of the opposite sex. Children become aware of differences between the sexes, begin to perceive that they identify as male or female, and interpret the behaviors of others as socially consistent with the binary categories of female or male ([LeVay et al., 2019](#)).

School-Age Years

During the school years parents, educators, and peer groups serve as role models and teach children how to relate to other people. Preadolescent children often segregate by sex, which minimizes heterosexual activities and facilitates same-sex sexual behaviors. This early sexual behavior is not indicative of sexual orientation ([LeVay et al., 2019](#)). School-age children generally have questions regarding the physical and emotional aspects of

sex. They need accurate information from home and school about changes in their bodies and emotions during this period and what to expect as they move into puberty. Knowledge about normal emotional and physical changes associated with sexual maturation decreases anxiety as these changes begin to happen.

Puberty/Adolescence

The emotional changes during puberty and adolescence are as dramatic as the physical ones. Pre-adolescence is often marked by increased sexual interest (LeVay et al., 2019). Adolescents function within a powerful peer group, with the almost constant anxiety of “Am I normal?” and “Will I be accepted?” (Fig. 34.1). They face many decisions and need accurate information on topics such as body changes, sexual activity, emotional responses within sexual relationships, STIs, contraception, and pregnancy. The status of sexual health education varies throughout the United States and is insufficient in many areas. In most states, fewer than half of high schools teach all 19 sexual health topics recommended by the Centers for Disease Control and Prevention (CDC). In addition, sex education is not starting early enough; in no state did more than half of middle schools teach all 19 sexual health topics recommended by the CDC. Finally, sex education has been declining over time. The percentage of US schools in which students are required to receive instruction on HIV prevention also significantly decreased (CDC, 2017b).

FIG. 34.1 Adolescents function within a powerful network of peers as they explore their sexual identity.
©bikeriderlondon.

Adolescence is often a time when individuals explore their sexual identity and primary sexual orientation (LeVay et al., 2019). Adolescents often face significant stress related to sexual identity. They benefit from education about sexuality and sexual health issues, including sexually transmitted infections such as human immunodeficiency virus (HIV) (Strong and Folse, 2015).

In the United States almost 40% of high school students report that they have had sexual intercourse at least one time, and 10% of high school students had had four or more sexual partners (Kann et al., 2018). Social media also impacts adolescent sexuality since it may be the first opportunity to explore their sexuality freely. Social media provides multiple types of sexual experiences, which could include cyberbullying, sexting, and posting of revenge porn (Eleuteri et al., 2017). Adolescents who engage in risky sexual behaviors can experience negative health outcomes such as STIs and unintended pregnancy (LeVay et al., 2019). Some of the highest STI rates are among youth aged 20 to 24, especially youth of color. The presence of another STI greatly increases the likelihood that a person exposed to HIV will become infected (CDC, 2018d).

In addition, the pattern of risk-taking behavior tends to be established and continue throughout life. Parents need to understand the importance of providing factual information, sharing their values, and promoting sound decision-making skills. Adolescents and parents often disagree about whether they talked about sexual issues, which reinforces the need

for clear communication ([Grossman et al., 2017](#)). Parents and guardians need to know that, even with the best guidance and information, adolescents make their own decisions and need to be held accountable for them. Support from peers, family, school counselors, clergy, nurses, and other health professionals is important during this time.

Young Adulthood

Although young adults have matured physically, they continue to explore and mature emotionally in relationships. Intimacy and sexuality are issues for all young adults whether they are in a sexual relationship, choose to abstain from sex, remain single by choice, or are not in a committed relationship. Sexual activity is often defined as a basic need, and healthy sexual desire is channeled into forms of intimacy throughout a lifetime. At times, young adults require support and education or therapy to achieve satisfying sexual relationships.

Middle Adulthood

Changes in physical appearance in middle adulthood sometimes lead to concerns about sexual attractiveness. In addition, actual physical changes related to aging affect sexual functioning. Decreasing levels of estrogen in perimenopausal woman lead to diminished vaginal lubrication and decreased vaginal elasticity. Both of these changes often lead to dyspareunia, or the occurrence of pain during intercourse. Decreasing levels of estrogen may also result in a decreased desire for sexual activity. As men age they are likely to experience changes such as an increase in the postejaculatory refractory period and delayed ejaculation. Anticipatory guidance regarding these normal changes, using vaginal lubrication, and creating time for caressing and tenderness ease concerns regarding sexual functioning. Some aging adults also need to adjust to the impact of chronic illness, medications, aches, pains, and other health concerns about sexuality. Older adults who report being highly satisfied with their sex lives report moderate to high sexual self-esteem ([Santos-Iglesias et al., 2016](#)).

Later in the adult years some individuals have to adjust to the social and emotional changes associated with children moving away from home. This results in either a time of renewed intimacy between partners or a time when formerly intimate partners realize that they no longer care for one another or have common interests. In either case, when children leave home, intimate relationships usually change.

Older Adulthood

Sexuality in older adults is an important aspect of health that often is overlooked by health care providers. Studies show a positive correlation between sexual activity and physical health in older adults (Touhy and Jett, 2018). Research indicates that many older adults are more sexuality active than previously thought and engage in high-risk sexual encounters, resulting in a steady increase of human immunodeficiency virus (HIV) and STI rates (Box 34.1).

Box 34.1 FOCUS ON OLDER ADULTS **Sexuality in Older Adults**

- Sexuality and continued interest in sex throughout middle and late life are usually associated with good physical health.
- Physiological changes with aging that influence sexual response are multifactorial and related to various factors, including circulation and hormones.
- Issues with the aging sexual response are often related to illnesses and side effects from medications.
- Older adults are often reluctant to discuss sexual problems with health care providers.
- Older adults who live in extended-care facilities often lose their privacy and experience a decline in physical and cognitive abilities that affects their sexual expression. People who live in assisted-living facilities have more privacy and are often able to live as couples.
- As the population ages and remains healthy, increasing numbers of older lesbian, gay, bisexual, and transgendered (LGBTQ+) people remain sexually active.
- Increased availability of treatments for male and female sexual dysfunction contributes to continued sexual activity throughout the life span.
- Older sexually active adults are at risk for contracting sexually transmitted infections. Because the risk of pregnancy is not an issue, older adults often do not recognize the need for protected sex when becoming active with new and/or multiple partners.

Touhy TA, Jett K: *Ebersole & Hess' gerontological nursing and healthy aging*, ed 5, St Louis, 2018, Elsevier.

Factors that determine sexual activity in older adults include present health status, medications, past and present life satisfaction, and the status of marital or intimate relationships. For example, many older women are widowed or divorced and lack available sexual partners, which accounts for their decline in sexual activity. Nurses working with older adults need to assess the sexuality of their patients, sexual interest and functioning, and plan accordingly (Touhy and Jett, 2016). It is essential to maintain a nonjudgmental attitude and convey that sexual activity is normal in later years. It is important to have adequate knowledge about sexuality across the life span and to be aware of your own attitudes and beliefs while promoting sexual health in elderly patients (Atallah, 2016). Improving health care providers' sexual health knowledge and changing negative attitudes toward the sexuality of the older adult is essential to assure positive patient outcomes (Haesler et al., 2016).

To be effective in promoting sexual health, you need to understand the normal sexual changes that occur as people age. The excitement phase prolongs in both men and women, and it usually takes longer for them to reach orgasm. The refractory time following orgasm is also longer. Both genders experience a reduced availability of sex hormones. Men often have erections that are less firm and shorter acting. Women usually do not have difficulty maintaining sexual function unless they have a medical condition that impairs their sexual activity. Typically the infrequency of sex in older women is related to the age, health, and sexual function of their partner. Women continue to experience changes related to menopause, and those with problems related to urinary incontinence often experience embarrassment during intercourse. Couples who have physically disabling conditions often need information about which positions are more comfortable when having sexual intercourse (LeVay et al., 2019).

Sexual Identity and Sexual Orientation

Sexual identity is how a person thinks about himself or herself sexually; it includes gender identity, gender role, and sexual orientation. **Gender identity** is a person's private view of maleness and femaleness, and gender role is the feminine and masculine behavior exhibited. Assessing one's **sexual orientation**, defined as a person's sexual identity in relation

to the gender to which they are attracted, and gender identity requires you to be accepting of responses that fall within the LGBTQ+ (lesbian, gay, bisexual, transgender, queer, questioning, asexual, and others) continuum (Strong and Folse, 2015).

As a person grows and develops, so does his or her sexuality. Knowledge of sexual development and changes throughout the life span is essential for you as a nurse. An adult has achieved physical maturation but is continuing to explore and define emotional maturation in relationships. Even into adulthood people continue to struggle with questions about who they are, how they want to present themselves, and what type of partners they find most attractive. As a nurse, it helps to have a clear sense of your own sexual identity because it influences your ability to form open relationships, which is needed to support patients' sexual health. You will provide care to individuals whose sexual orientation and sexual identity are heterosexual (attracted to different-sex partners), **lesbian** or **gay** (same-sex partners; women-women and men-men, respectively), **bisexual** (both male and female partners), or **transgender** (people whose gender identity or expression is different from their sex at birth), queer (an umbrella term representing all individuals who fall out of the gender and sexuality binary "norms"), questioning (exploring one's sexual orientation or identity), asexual or aromantic (does not experience sexual or romantic attraction), fluid (fluctuating mix of options), pansexual (sexual attraction to members of all gender identities/expressions), and cisgender (gender identity, gender expression, and biological sex all align), as well as uniquely defined by your patient (VandenBos, 2015). You will also care for patients who are involved in intimate relationships with several partners and for patients whose sexual relationships occur outside of marriage or a committed relationship. You may not learn a great deal about a patient's sexual preferences, even if you ask direct questions. As a caregiver, you must learn to accept a person's sexual orientation and sexual identity and help the individual understand the implications that his or her health condition has on maintaining healthy sexual relationships and on achieving positive health outcomes.

Sexuality Stressors

As a nurse, you work with patients who are making decisions or dealing with issues related to sexuality on a regular basis. For example, people of all ages face reproductive health issues, including contraception, infertility, sexual dysfunction, and sexual satisfaction. Understanding some of the

decisions and issues that patients face increases your effectiveness in helping them reach their maximum level of sexual health.

Lesbian, gay, bisexual, or transgender, queer, and other (LGBTQ+) individuals have unique stressors related to their sexual identity and sexual orientation, which is the emotional, romantic, or sexual attraction to others. Peer, family, and social support is often lacking. As nurses, we must increase efforts to ensure a culturally competent and knowledgeable nursing workforce while eliminating health disparities and improving patient outcomes in vulnerable populations, including the LGBTQ+ community. Nurses are in a unique position to support a patient and provide education and resources based on his or her individual needs. Patients who are LGBTQ+ experience barriers to health care that include fear of discrimination, insensitivity, and lack of knowledge about LGBTQ+-specific health needs. This places individuals in this population at high risk for health issues such as sexually transmitted infections, depression, and victimization ([Strong and Folse, 2015](#)). Research has also shown that young gay and bisexual men who have sex with older partners are at a greater risk for HIV infection because an older partner is more likely to have had more sexual partners or other risks and is more likely to be infected with HIV ([CDC, 2017a](#)).

Health care providers should specifically state it is important to disclose sexual preferences and behaviors since many patients do not make the connection between sexuality and physical health ([Fuzzell et al., 2016](#)). Alterations in sexual health occur from a variety of situations such as illness, infertility, trauma, and abuse. **Sexual dysfunction** involves problems with desire, arousal, or orgasm. Erectile dysfunction is a common problem among older men. It is generally related to chronic diseases such as diabetes, kidney disease, alcohol dependence, depression, neurological disorders, vascular insufficiency, and diseases of the prostate ([Touhy and Jett, 2016](#)). In addition, side effects of medications or medical conditions also contribute to sexual dysfunction. Examples of common medications that can cause sexual dysfunction include statins, antihypertensives, antidepressants, antipsychotics, and benzodiazepines. Older adult women can also experience sexual dysfunction. For example, in a study of older women who experienced a stroke, sexuality was affected by negatively impacting self-concept and by limiting the ways in which sexuality could be expressed ([Lever and Pryor, 2017](#)). The causes of sexual dysfunction are both physiological and psychological. Sometimes the cause of a dysfunction cannot be identified or is a result of a combination of several factors.

Because sexual dysfunction sometimes results from the use of medications, it is important to include a discussion of sexual side effects in patient teaching. Your patient is more likely to adhere to a treatment plan if you discuss side effects of medications that alter sexual function with both partners and the patient is able to make an informed decision. Our current state of health greatly influences sexual response (from desire to arousal to orgasm). The availability of sexual performance-enhancing medication such as sildenafil and tadalafil has changed the lives of many couples. These medications treat erectile dysfunction but are contraindicated in men with coronary artery disease or those taking common cardiac drugs.

Changing physical appearance and concerns about physical attractiveness affect sexual functioning. Many older adults remain sexually active. Some older adults face health concerns and societal attitudes that make it difficult for them to continue sexual activity. Although declining physical abilities sometimes make sex as they knew it painful or impossible, with intervention older adults are able to experiment with and learn alternative ways of sexual expression.

Hormonally stimulated changes brought on by developmental maturation are also stressors that affect sexuality across the life span. Menarche, the onset of menstrual cycle in girls, is occurring at an earlier age in the United States, and some adolescent girls are unaware that it is normal to grow pubic, underarm, and body hair and deposit more fat on their hips and breasts, all of which also affect body image.

As boys approach puberty, physical changes include nocturnal emissions and ejaculation, increasing sexual desire, and increased hygiene needs. Patient teaching needs to include instruction on breast and testicular self-examinations and prevention of **sexually transmitted infections** (STIs), which are spread through oral, anal, or vaginal sexual contact. Mutually monogamous relationships, delayed sexual debut, and the consistent use of latex condoms reduce the risk of STIs as well as unplanned pregnancies (Kerpelman et al., 2016). Risky sexual behavior is reduced in adolescents with solid self-esteem; you can support an adolescent's sexual and psychological health by providing health information and reinforcing deliberate sexual decision making (Kerpelman et al., 2016).

Older women experiencing menopause, including the cessation of menstrual periods, experience changes in vaginal lubrication and sexual interest. Most menopausal women recognize the importance of maintaining an active sex life, but many report a reduced sex drive,

decreased sexual interest, and mood changes that may require intervention by a health care provider (Touhy and Jett, 2018). High levels of self-esteem and sexual quality of life are associated with successful aging in postmenopausal women (White and Taliaferro, 2016).

Sexual abuse, assault, and rape are also stressors that affect self-concept and sexuality. Be alert to clues that suggest abuse (Table 34.1). In addition, observe the interaction between the patient and partner for additional clues. Controlling behaviors such as speaking for the person or refusing to leave him or her alone with a caregiver are suggestive of emotional and perhaps physical or sexual abuse. If you suspect abuse, interview the patient privately. A patient will probably not admit to problems of abuse with the abuser present. Some of the following questions are useful: “Are you in a relationship in which someone is hurting you?” or “Have you ever been forced to have sex when you didn’t want to?” When you recognize or report abuse, mobilize treatment immediately for the victim and the family. The most important factor to consider is the safety of the suspected victim.

TABLE 34.1

Signs and Symptoms That Indicate Possible Current Sexual Abuse or a History of Sexual Abuse

Types of Findings	Symptoms Often Found in Children	Symptoms Often Found in Adults
Injuries and/or physical signs	<ul style="list-style-type: none"> Bruises, bleeding, soreness, infection, or irritation of external genitalia, anus, mouth, or throat Sexually transmitted infections Recurrent urinary tract infections Unintended pregnancy Chronic pain Difficulty walking or sitting Unusual odor in genital area Penile discharge Torn, stained, or bloody underclothing 	<ul style="list-style-type: none"> Welts, bruising, swelling, scars, burns, or lacerations on arms, legs, breasts, or abdomen Wounds that do not match the patient’s “story” Multiple bruises in various stages of healing Vaginal or rectal bleeding Fractures of face, nose, ribs, or arms Trauma to labia, vagina, cervix, or anus Vomiting or abdominal tenderness
Behavior, nonverbal and/or vague somatic complaints	<ul style="list-style-type: none"> Physical aggression Sexual acting out Excessive masturbation Expressions of low self-esteem Poor school performance Poor peer relationships Sleep disturbances Social withdrawal and excessive daydreaming Running away from home Substance abuse or suicide attempts 	<ul style="list-style-type: none"> Facial grimacing Absence of facial response or flat affect Anxiety Depression Panic attacks Difficulty sleeping Slow, unsteady gait

Data from Hockenberry MJ, Wilson D: *Wong’s nursing care of infants and children*, ed 11, St Louis, 2019, Elsevier; Touhy TA, Jett K: *Ebersole & Hess’ gerontological nursing and healthy aging*, ed 5, St Louis, 2018, Elsevier.

REFLECT NOW

Reflect on a statement a patient made recently about sexuality and how you could have improved your response.

Nursing Knowledge Base

Use critical thinking skills and basic nursing knowledge when addressing patients' sexual health needs. Draw from the following areas of nursing knowledge: sociocultural dimensions of sexuality, decisional issues, and alterations in sexual health.

Factors Influencing Sexuality

Sociocultural Dimensions of Sexuality

People assign different meanings to sexuality based on their culture, gender, education, socioeconomic status, and religion. Society plays a powerful role in shaping sexual values and attitudes and in supporting specific expression of sexuality in its members.

Each cultural and social group has its own set of rules and norms that guide sexual behavior, sexual health, and the willingness to discuss this private part of life. For example, cultural norms influence how people find partners, whom they choose as partners, how they relate to one another, how often they have sex, and what they do when they have sex. Personal beliefs enable certain practices and prohibit others ([Box 34.2](#)).

Box 34.2 Cultural Aspects of Care **Cultural Factors and Human Immunodeficiency Virus**

All sexually active individuals are at risk for HIV; however, some races and cultures have higher infection rates. Black/African American gay and bisexual men account for the largest number of HIV diagnoses, followed by Hispanic/Latino gay and bisexual men, and then white gay and bisexual men. Over time, diagnoses in white gay and bisexual men have decreased, while diagnoses in Latino and black gay and bisexual men have risen (HIV.gov, 2018). African Americans continue to experience the greatest burden of HIV compared with other races and ethnicities. In 2016, African Americans represented 12% of the US population but accounted for 44% of HIV diagnoses. Similarly, Hispanics/Latinos are also disproportionately affected by HIV as they represented about 18% of the US population but accounted for 25% of HIV diagnoses (CDC, 2018a; HIV.gov, 2018).

The most recent data from the Youth Risk Behavior Surveillance System (YRBS), which monitors health risk behaviors that contribute to the leading causes of death and disability among youth, reveal low rates of HIV testing, higher use of substances paired with sexual activity, low rates of condom use, and multiple sexual partners; such behaviors lead to an increased risk of becoming HIV positive. Specifically, only 10% of high school students have been tested for HIV; among male students who had sexual contact with other males, only 21% have ever been tested for HIV. Thirty-two percent of male students who had sexual contact with other males drank alcohol or used drugs before their most recent sexual intercourse, compared with 21% of all students who are currently sexually active. Nationally, 43% of all sexually active high school students and 49% of male students who had sexual contact with other males did not use a condom the last time they had sexual intercourse. One-third (33%) of male students who had sexual contact with other males reported sexual intercourse with 4 or more persons during their lives, compared with 12% of all students who had ever had sexual contact (CDC, 2017a).

Older adults also are a high risk population. People aged 50 and older accounted for 17% of the 39,782 new HIV diagnoses in 2016 in the United States. Among people aged 50 and older, blacks/African Americans accounted for 42% of all new HIV diagnoses. Whites accounted for 37%, Hispanics/Latinos accounted for 18%, and other races/ethnicities accounted for 4%. Among people aged 50 and older, half of new HIV diagnoses were among gay and bisexual men, 15% were among heterosexual men, 24% were among heterosexual women, and 12% were among people who inject drugs. One-third of people aged 50 and older already had late-stage infection (AIDS) when they received an HIV diagnosis, which has implications for inadvertent transmission (CDC, 2018b).

Health care providers need to consider cultural values and their influence on sexual practices when working with the diverse populations. It is important for nurses to develop and implement HIV prevention programs in the communities most affected by HIV. The CDC has committed to funding from 2017 to 2022 for community-based organizations to provide HIV testing to young gay and bisexual men and transgender youth of color, with the goals of identifying previously undiagnosed HIV infections and linking those who have HIV to care and prevention services. CDC grants have also been targeted to deliver effective prevention and evidence-based interventions for antiretroviral therapy adherence for older Americans (Kann et al., 2018).

Implications for Patient-Centered Care

- Establish a therapeutic relationship with a patient/family before discussing sexual health (Halter, 2018).
- Provide both males and females written and verbal information in English and other languages regarding contraception, sexually transmitted infections (STIs), and HIV testing and management options (CDC, 2018a).
- Target adolescents by expanding education on STIs, HIV, and contraception in middle- and high-school curricula (CDC, 2017b).
- Increase HIV testing at community clinics and offer combined laboratory work for STIs and HIV to promote acceptance (CDC, 2018c).
- Promote cultural-specific and bilingual multimedia and community education about HIV risk-reduction strategies (CDC, 2018a).

Impact of Pregnancy and Menstruation on Sexuality

Sexual interest and activity of women and their partners vary during pregnancy and menstruation. Some cultures encourage sexual intercourse or male-female contact during menstruation and pregnancy, but others strictly forbid it. For example, in the Hindu culture a woman avoids worship, cooking, and other members of the family during menstruation. Research has found no physiological contraindication to intercourse during menstruation or during most pregnancies. Female sexual interest tends to fluctuate during pregnancy, with increased interest during the second trimester and often decreased interest during the first and third trimesters. There is often a decrease in libido during the first trimester because of nausea, fatigue, and breast tenderness. During the second trimester blood flow to the pelvic area increases to supply the placenta, resulting in increased sexual enjoyment and libido. During the third trimester the increased abdominal size often makes finding a comfortable position difficult (LeVay et al., 2019).

Discussing Sexual Issues

Sexuality is a significant part of each person's being, yet sexual assessment and interventions are not always included in health care. The area of sexuality is often emotionally charged for nurses and patients. Sometimes

nurses avoid discussing sexual issues with patients because they lack information or have different values than their patients. Nurses who have difficulty discussing topics related to sexuality need to explore their discomfort and develop a plan to address it. If you are uncomfortable with topics related to sexuality, the patient is unlikely to share sexual concerns with you. You need to be aware of your personal beliefs before discussing sexuality with your patients.

Decisional Issues

Individuals make many decisions about their sexuality. Some nurses help patients make decisions about contraception and abortion.

Promoting or Preserving Sexual Health

Contraception

Decisions patients make regarding **contraception**, or the prevention of pregnancy, have far-reaching effects on their lives. Pregnancy, whether planned or unplanned, significantly affects the life of the mother and father and often their support network. Effects are physical, interpersonal, social, financial, and societal. The choice to use contraception is multifaceted and not completely understood. Factors that affect the effectiveness of contraception include the type of method used, the couple's understanding of the method, the consistency of use, and adherence to the requirements of the chosen method. Choice of contraception method varies in relation to the age, ethnicity, marital status, income, education, sexual orientation, and previous pregnancies of the woman. Mobile apps are available to help patients and health professionals monitor reproductive health (e.g., to remind you when to take oral contraceptives, to replace your transdermal patch or vaginal ring, or when your most fertile time is occurring).

Numerous contraceptive options are available to sexually active couples today. They provide varying levels of protection against unwanted pregnancies. Some methods do not require a prescription, whereas others require a prescription or some other type of intervention from a health care provider. Methods that are effective for contraception do not always reduce the risk of STIs. For example, the pill and intrauterine contraceptive device (IUD) are effective as birth control but not for protection from STIs. A latex condom should be used during each act of intercourse to reduce the risk of STIs. Effectiveness varies with each contraceptive method and

the consistency of use. Unplanned pregnancies occur because contraceptives are not used, are used inconsistently, or are used improperly. As a nurse, you serve an important role in discussing options with patients. Although reasons for recent declines in teen pregnancy are not totally clear, evidence suggests these declines are due to more teens abstaining from sexual activity and more teens who are sexually active using birth control than in previous years.

Still, the US teen pregnancy rate is substantially higher than in other Western industrialized nations, and racial/ethnic differences persist (Kann et al., 2018).

Nonprescription Contraceptive Methods

Nonprescription methods for contraception include abstinence, barrier methods, and timing of intercourse with regard to a woman's ovulation cycle. Although abstinence from sexual intercourse is 100% effective in preventing pregnancy, it is often difficult for both men and women to use consistently. Any act of unprotected intercourse potentially results in pregnancy and exposure to STIs.

Barrier methods include over-the-counter spermicidal products and condoms. Spermicidal products (e.g., creams, jellies, foams, and sponges) are put into the vagina before intercourse to create a spermicidal barrier between the uterus and ejaculated sperm. A latex condom is a thin rubber sheath that fits over the penis to prevent entrance of sperm into the vagina. A diaphragm is a barrier method to prevent pregnancy, which must be used with a spermicide with each sexual encounter. Vaginal spermicides and condoms are most effective when instructions are followed carefully; their combined use is more effective in preventing pregnancy than the use of either one alone.

Nonprescription methods of contraception based on the physiological changes of the menstrual cycle include the rhythm, basal body temperature, cervical mucus, and fertility-awareness methods. Couples who use these methods need to understand the reproductive cycle of the woman's body and the subtle signs and signals that her body gives during the cycle. To prevent pregnancy, couples should abstain from sexual intercourse during designated fertile periods.

Contraceptive Methods That Require a Health Care Provider's Intervention

Contraceptive methods that require the intervention of a health care provider include hormonal contraception, IUDs, the diaphragm, the cervical cap, and sterilization. Hormonal contraception is available in several forms: oral contraceptive pills, vaginal contraceptive rings, hormonal injections, subdermal implant, transdermal skin patches, and IUDs. Hormonal contraception alters the hormonal environment to prevent ovulation, thicken cervical mucus, and thin the lining of the uterus.

An IUD is a plastic device inserted by a health care provider into the uterus through the cervical opening. IUDs contain either copper or progesterone, and some contain a progestin hormone called levonorgestrel that is often used in birth control pills. The primary mechanism by which both types of IUDs prevent pregnancy is to stop the sperm from fertilizing an egg. The release of progesterone may also increase cervical mucus thickness and alter the lining of the uterus.

The diaphragm is a round, rubber dome that has a flexible spring around the edge. It is used with a contraceptive cream or jelly and is inserted in the vagina so that it provides a contraceptive barrier over the cervical opening. The woman needs to be refitted after a significant change in weight (10-lb gain or loss) or pregnancy. The cervical cap functions like the diaphragm; however, it covers only the cervix. It may be left in place longer, and some perceive it as more comfortable than the diaphragm.

Sterilization is the most effective contraception method other than abstinence. Female sterilization, or tubal ligation, involves cutting, tying, or otherwise ligating the fallopian tubes. In male sterilization, or vasectomy, the vas deferens, which carries the sperm away from the testicles, is cut and tied. Both a tubal ligation and a vasectomy usually are considered permanent surgical procedures, although reversal is possible and unintended pregnancies have been reported.

Abortion

Nineteen percent of all established pregnancies in the United States end in abortion; it is estimated that 1 in 3 American women will have an abortion by the age of 45. Young single women, low-income women, and minorities are disproportionately represented (LeVay et al., 2019). The most recently reported abortion rates reflect a decline, with women in their twenties accounting for the majority of abortions (Kann et al., 2018). The safety and availability of abortions in the United States improved after the 1973 Supreme Court decision *Roe v Wade*, which established the right of every

woman to have an abortion. Abortions are safer and less costly when performed in the early weeks of pregnancy.

Abortion is a hotly debated issue. Women and their partners who face an unwanted pregnancy may consider it as an option. If caring for a patient contemplating abortion, provide an environment in which the patient is able to discuss the issue openly, allowing exploration of various options with an unwanted pregnancy. Discuss religious, social, and personal issues in a nonjudgmental manner with patients. Reasons for choosing an abortion vary and include terminating an unwanted pregnancy or aborting a fetus known to have birth defects. When a woman chooses abortion as a way of dealing with an unwanted pregnancy, the woman and often her partner experience a sense of loss, grief, and/or guilt.

Be aware of personal values related to abortion. As a nurse you are entitled to your personal views. You should not be forced to participate in counseling or procedures contrary to your beliefs and values. It is essential to choose specialties or places of employment where personal values are not compromised and the care of a patient in need of health care is not jeopardized.

Prevention of Sexually Transmitted Infections

Responsible sexual behavior includes knowing one's sexual partner and the partner's sexual history, being able to openly discuss drug-use history with the partner, not allowing drugs or alcohol to influence decision making and sexual practices, and using STI and contraceptive protective devices.

The incidence of STIs continues to increase. Approximately 20 million people in the United States are diagnosed with an STI each year, with the highest incidence occurring in men who have sex with men, bisexual men, and youths between the ages of 15 and 24 ([CDC, 2018e](#)). The prevalence of STIs is a major health concern for several reasons. In addition, race, poverty, access to health care, and sexual practices contribute to disparities in the STI rates. Commonly diagnosed STIs include syphilis, gonorrhea, chlamydia, trichomoniasis, and infection with the human papillomavirus (HPV) and herpes simplex virus (HSV) type II (genital warts and genital herpes, respectively).

As the name implies, STIs are transmitted from infected individuals to partners during intimate sexual contact. The site of transmission is usually genital, but sometimes it is oral-genital or anal-genital. People most likely to be infected share one key characteristic: unprotected sex with multiple partners. Gonorrhea, chlamydia, syphilis, and pelvic inflammatory disease

(PID) are caused by bacteria and are usually curable with antibiotics. Patients need to take antibiotics for the full course of treatment. However, an emerging concern is that some of these bacterial infections (e.g., gonorrhea and syphilis) are now developing antibiotic-resistant strains. Infections such as HSV types I and II, HPV, and HIV are caused by viruses and cannot be cured.

A major problem in dealing with STIs is finding and treating the people who have them. Some people do not know that they are infected because symptoms are sometimes absent or go unnoticed. Common symptoms of an STI include discharge from the vagina, penis, anus, or throat; pain during sex or when urinating; and unexplained rash or lesions. Because sexual behavior often includes the whole body rather than just the genitalia, many parts of the body are potential sites for an STI. The perineum, anus, and rectum frequently are involved in sexual activity. Furthermore, any contact with another person's body fluids around the head or an open lesion on the skin, anus, or genitalia can transmit an STI (LeVay et al., 2019).

Sometimes people do not seek treatment because they are embarrassed to discuss sexual symptoms or concerns. Often they are hesitant to talk about their sexual behavior if they believe that it is not "normal." Any sexual behavior that embarrasses a patient often hinders the detection of an STI. Develop communication skills and a nonjudgmental attitude to provide effective care for those diagnosed with one. Detect valuable clues about an STI by establishing trust, talking with patients in a matter-of-fact manner, and asking questions in a caring manner. Assess attitudes toward sexuality and adjust the intervention to make it acceptable to the patient's sexual value system.

Human Immunodeficiency Virus Infection

HIV infection is a bloodborne pathogen and is present in most body fluids. It is sometimes spread through sexual contact. Transmission occurs when there is an exchange of body fluid. Primary routes of transmission include contaminated intravenous (IV) needles, anal intercourse, vaginal intercourse, oral-genital sex, and transfusion of blood and blood products.

The natural history of HIV progresses in three stages. The primary infection stage lasts for about a month after contracting the virus. During this time the person often experiences flulike symptoms. Then he or she enters the clinical latency phase; at this time there are no symptoms of infection. HIV antibodies appear in the blood about 6 weeks to 3 months after infection. If left untreated, people who are infected with HIV live

about 10 years. The last stage, acquired immunodeficiency syndrome (AIDS), happens when a person begins to show symptoms of the disease. AIDS is a serious, debilitating, and eventually fatal disease. Antiretroviral therapy (ART) or highly active antiretroviral therapy (HAART) and having an experienced HIV clinician greatly increase the survival time of people who live with HIV/AIDS (CDC, 2018c).

Human Papillomavirus Infection

Human papillomavirus (HPV) is the most common sexually transmitted infection in the United States. An estimated 50% to 75% of sexually active men and women acquire HPV at some point in their lives, with 14 million new infections occurring annually. Most HPV infections are asymptomatic and self-limiting; most infected people eventually clear the virus from their bodies and become noninfectious to others in a couple of years (LeVay et al., 2019). However, certain types can cause cervical cancer in women and anogenital cancers and genital warts in both men and women. HPV is spread through direct contact with warts, semen, and other body fluids from others who have the disease. The textured warts often have a cauliflower appearance and are most common on the penis and scrotum in men and the vagina and cervix in women. While there is screening available for cervical cancer for women, there is no screening for the other cancers caused by HPV infection, such as cancers of the mouth/throat, anus/rectum, penis, vagina, or vulva (CDC, 2016).

The HPV vaccination provides safe, effective, and lasting protection against the HPV infections that most commonly cause cancer (CDC, 2016). The Gardasil 9 vaccine is recommended for males and females in early adolescence (ages 11 or 12 years old) to decrease the risk for cancers associated with HPV, including genital warts and cancers of the cervix, vagina, vulva, penis, anus, and throat (CDC, 2016). The greatest benefit occurs when individuals receive the vaccines before sexual activity or exposure to the virus. Two doses of the 9-valent HPV vaccine are recommended for preteens, and 3 doses are advised for older adolescents and young adults. Misinformation remains prevalent and impacts rates of vaccination (Box 34.3).

Box 34.3 Evidence-Based Practice Barriers Associated With Consenting to the Human Papillomavirus

Vaccine

PICOT Question: Does providing education about the human papillomavirus (HPV) vaccine to parents, preteens, and adolescents influence the decision to receive the HPV vaccine?

Evidence Summary

HPV is the most common sexually transmitted infection (STI) in the United States and is associated with development of anogenital cancers and genital warts in males and females (CDC, 2016). The Gardasil-9 vaccine targets 9 types of HPV, including the specific HPVs linked to cancer and warts. It is recommended for all youths ages 11 to 26 years, but vaccination rates in the United States are low. Parental acceptance of the vaccine influences vaccination status, and parents have voiced concern that the vaccine is unsafe or that it will encourage risky sexual behavior despite evidence indicating otherwise (LeVay et al., 2019). Less research has been conducted on male vaccination adherence, but barriers such as lack of knowledge concerning health risks, confusion about the need for vaccination of boys as well as girls, and provider recommendation to parents have all been shown to impact vaccination rates in males. A longitudinal study demonstrated that when administered to adolescents, the Gardasil HPV4 vaccine demonstrated ongoing clinically effective protection and sustained antibody titers over 10 years. Moreover, no new serious adverse effects occurred. Acquisition of new sexual partners among patients 16 years and older averaged 1 per year, which does not support the concern about sexual promiscuity following the vaccine (Ferris et al., 2017). Health care professionals need to consider these findings to encourage vaccine understanding and acceptance among parents and youths.

Application to Nursing Practice

- Vaccine recommendation by health care professionals can increase vaccine acceptance by the public and reduce the incidence of HPV-related cancers.
- Clinicians should recommend HPV vaccination in the same way and on the same day that they recommend other routinely recommended vaccines for preteen patients at age 11 or 12 years (CDC, 2016).
- Nurses need to discuss the benefits of the vaccine with parents and youths ages 11 to 26 years and offer catch-up vaccines as needed.

- Reduce parental concerns by sharing research that indicates that vaccine administration does not increase sexual activity or risk behaviors.
- Continue to teach safe sex practices.

Chlamydia

The bacterium *Chlamydia trachomatis* causes chlamydia. It is the most commonly reported infectious disease in the United States, affecting about 3 million Americans each year (CDC, 2018e). Chlamydia is spread by contact with fluids from the infected site. The infection can be transmitted during the birthing process and cause conjunctivitis and pneumonia in newborns. It frequently infects the cervix and, if left untreated, can cause PID, ectopic pregnancy, and infertility from damage to the female reproductive organs. Most people do not realize that they are infected with chlamydia because it causes few symptoms (CDC, 2018d). Thus, the CDC recommends annual screening for all sexually active women up to age 25. High-risk populations are people who have multiple sex partners or are infected with other STIs and men who have sex with men.

Alterations in Sexual Health

Infertility

Infertility is the inability to conceive after 1 year of unprotected intercourse. A couple who wants to conceive but is unable to has special needs. Some experience a sense of failure and think that their bodies are defective. Sometimes the desire to become pregnant grows until it permeates most waking moments. Some individuals become preoccupied with creating just the right circumstances for conception. With advances in reproductive technology, infertile couples face many choices that involve religious and ethical values and financial limitations.

Choices for the infertile couple include pursuit of adoption, medical assistance with fertilization, or adapting to the probability of remaining childless. Organizations such as RESOLVE: The National Organization of Infertility, a national support group for couples with infertility, or international adoption groups provide couples with support and offer referral sources.

Sexual Abuse

Sexual abuse is a widespread health problem. Abuse crosses all gender, socioeconomic, age, and ethnic groups. Most often it is at the hands of an intimate partner or family member. Sexual abuse has far-ranging effects on physical and psychological functioning. Sometimes it begins, continues, or even intensifies during pregnancy. Cues that raise a question of possible sexual abuse include extreme jealousy and refusal to leave a woman's presence. The overall appearance is sometimes that of a very concerned and caring husband or boyfriend, when the underlying reason for this behavior is very different.

Nurses are in an ideal position to assess occurrences of sexual violence, help patients confront these stressors, and educate individuals regarding community services. Nurses are mandated reporters and must report suspected child and elder abuse to the proper authorities. When you suspect or recognize abuse, mobilize support for the victim and the family. When abuse is suspected, remember to *not* ask the patient about any abusive behaviors in the presence of the suspected abuser. Provide privacy and obtain information in a protective environment. When there is abuse, all family members usually require therapy to promote healthy interactions and relationships.

Patients who have been raped often need to work through the crisis before feeling comfortable with intimate expressions of affection. The partner needs to know how to help and support the patient. Children who have been molested sexually need to understand that they are not at fault for the incident. The parents need to understand that their response is critical to how the child reacts and adapts.

Personal and Emotional Conflicts

Ideally sex is a natural, spontaneous act that passes easily through a number of recognizable physiological stages and ends in one or more orgasms. In reality this sequence of events is more the exception than the rule. You will care for patients who have problems with one or more of the stages of sexual activity, including the feeling of wanting sex, the physiological processes and emotions of having sex, and the feelings experienced after sex. For example, some women and men who are taking antidepressants report that their ability to reach orgasm is affected negatively.

Sexual Dysfunction

Sexual dysfunction, the absence of complete sexual functioning, is common. The incidence of sexual dysfunction in the general population is estimated to be as high as 40% in men and 60% to 80% in women (Touhy and Jett, 2018). It is more prevalent in men and women with poor emotional and physical health (Box 34.4). Sometimes the exact cause cannot be determined.

Box 34.4 Illnesses and Medications That Affect the Sexual Health of Men and Women

Illnesses	Medications
<ul style="list-style-type: none"> • Diabetes mellitus • Cancer (e.g., prostate, breast, colon, ovarian, testicular, rectal) • Neuropathy • Spina bifida • Spinal cord injury • Heart disease (e.g., unstable angina, uncontrolled hypertension) • Chronic obstructive pulmonary disease • Human immunodeficiency virus infection • Substance abuse • Depression • Anxiety 	<ul style="list-style-type: none"> • Antibiotics and antivirals • Antihyperlipidemics • Antihypertensives • Antiglycemics • Antiarthritics • Antiparkinsons • Analgesics • Antidepressives • Anxiolytics • Antipsychotics • Diuretics

Data from Touhy TA, Jett K: *Ebersole and Hess' toward healthy aging: human needs and nursing response*, ed 9, St Louis, 2016, Elsevier.

The incidence of erectile dysfunction (ED) increases with age but can occur in men under 40 (LeVay et al., 2019). Risk factors are similar to those for heart disease (e.g., diabetes mellitus, hyperlipidemia, hypertension, hypothyroidism, chronic renal failure, smoking, obesity, alcohol abuse, and lack of exercise). The etiology of ED is often multifactorial. Neurogenic problems, medications, or endocrine or psychogenic factors can cause it. An age-related decrease in testosterone often results in decreased tone of the erectile tissues.

One of the most common problems affecting women of all ages is hypoactive sexual desire. Biological, organic, or psychosocial factors can contribute to the incidence of HSDD. Chronic medical conditions such as breast or gynecological cancers and hormonal fluctuations, pain, or depression and anxiety can contribute to a decreased interest in sexual intimacy (LeVay et al., 2019).

Critical Thinking

Successful critical thinking requires synthesis of knowledge, experience, information gathered from patients, critical thinking attitudes, and intellectual and professional standards. Nurses use clinical judgment to anticipate information needs, analyze assessment data, and make appropriate decisions regarding patient care. [Fig. 34.2](#) shows how to use elements of critical thinking and patient assessment data to develop appropriate nursing diagnoses.

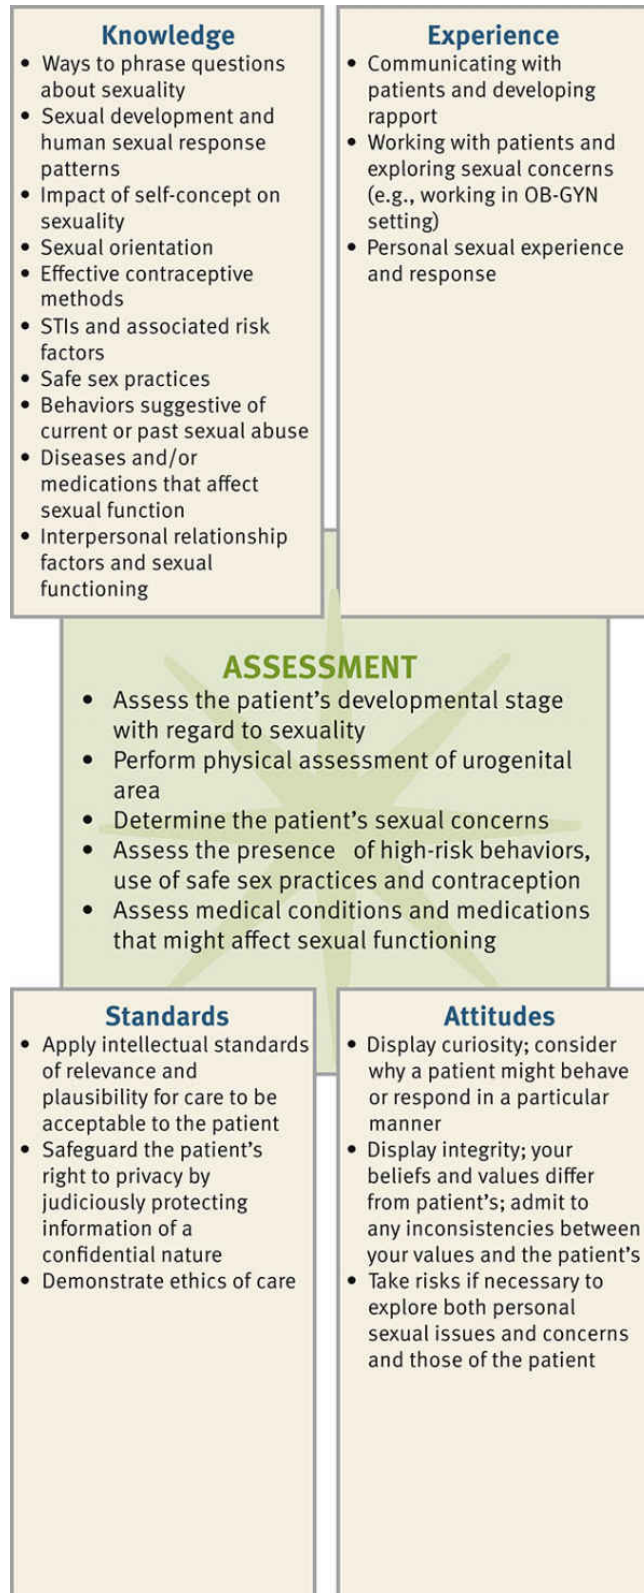

FIG. 34.2 Critical thinking model for sexuality assessment. *OB-GYN*, Obstetric-gynecological; *STI*, sexually transmitted infection.

In the case of sexuality, integrate knowledge from nursing and other disciplines. Have a thorough understanding of safe sex practices and the risks and behaviors associated with sexual problems to anticipate how to assess a patient and interpret findings. Use previous experiences to provide care for patients with sexual issues in a more reflective and helpful way. Patients have different customs and values from those of your own. Professional standards require respect for each patient as an individual. Critical thinking attitudes such as integrity require you to recognize when personal opinions and values conflict with those of the patient and to consider how to proceed in a way that is mutually beneficial.

REFLECT NOW

Consider a patient you have cared for who would have benefited from a discussion of sexual health concerns. What factors enhanced or interfered with your ability to discuss those concerns?

◆ Nursing Process

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach to help you develop and implement an individualized plan of care. Assess all relevant factors, including physical, psychological, social, and cultural, to determine a patient's sexual well-being. The nursing role in addressing sexual concerns ranges from ongoing assessment to providing information, counseling, and referral. Keep in mind that nurses are not expected to have answers to all identified sexual issues and concerns.

The Nurse's Influence on the Patient's Sexuality

A positive and matter-of-fact approach to care provides a model for the patient and family to follow. It is important that health care providers understand the degree to which self-esteem and sexuality affect patient outcomes.

How you respond to patients who have experienced changes in body appearance sets the stage for how they come to see themselves. The patient with a change in body functioning or appearance is often extremely sensitive to your verbal and nonverbal responses. Building a trusting nurse-patient relationship and appropriately including a patient in decision making will support most patients' healthy sexuality. Sometimes individualized approaches, including supporting the use of alternative healing techniques or methods of spiritual expression, help a patient adapt to changes in sexual health.

When you consider the sexuality of patients, think about your own knowledge regarding sexual development, sexual orientation, sexual response, STIs, contraception, and alterations in sexual health. Also consider your knowledge base about communication (see [Chapter 24](#)). Your own sexuality, sexual experiences, and communication style are valuable when trying to understand your patient's experiences. Do not convey negative feelings to patients.

Attempts at self-exploration teach us about our bodies and the potential for providing pleasure. Your attitude about masturbation may have stemmed from personal experience or from values or beliefs communicated by other people. Games such as "doctor" and "nurse" may have provided early sex play and exploration. In addition, your own sexual experiences add to understanding the complexities of a first sexual

encounter or the challenges of sexual interactions when you or an intimate partner are ill. In addition to personal experiences related to sexuality, use what you have learned through working with other patients as you assess and develop trust with current patients.

Assessment

During the assessment process thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care.

Through the Patient's Eyes

As in any patient assessment, it is important to understand a patient's expectations regarding care. Questions such as "What would you like to have happen in regard to your sexual health problems?" and "What initial steps might you take?" help a patient identify desired outcomes. It is important to set aside personal views and consider a patient's needs and preferences for care.

Factors Affecting Sexuality

In gathering a sexual history consider physical, functional, relationship, lifestyle, developmental, and self-esteem factors that influence sexual functioning. Sexual desire varies among individuals; some people want and enjoy sex every day, whereas others want sex only once a month, and still others have no sexual desire and are quite comfortable with that fact. Sexual desire becomes an issue if the person wants to satisfy it more often, if he or she believes that it is necessary to measure up to some cultural norm, or if there is a discrepancy between the sexual desires of the partners in a relationship.

Ask patients to describe factors that typically influence their sexual desire. Knowing a patient's medical history and probing for information is helpful. For example, minor illness, medications, and fatigue often decrease sexual desire. Lifestyle factors such as the use or abuse of alcohol, lack of sleep, lack of time, or the demands of caring for a new baby are other influencing factors. For example, working parents sometimes feel so overburdened that they perceive sexual advances from a partner as an additional demand on them. Confirm factors that potentially affect sexual desire and determine with the patient the extent to which sexual function is impaired.

Self-concept issues (see [Chapter 33](#)), including identity, body image, role performance, and self-esteem, affect a patient's sexuality. Consider how these factors relate to a patient's condition. For example, poor body image associated with chronic disease magnifies feelings of rejection. This often results in diminished or absent sexual desire.

Issues in a relationship often affect sexual desire. After the initial glow of a new relationship has faded, some couples find that they have major differences in their values or lifestyles. Ask couples to describe how close they feel to each other and how often they interact on an intimate level. Assess communication patterns between sexual partners to determine sexual satisfaction within a relationship.

Sexual Health History

Most patients want to know how medications, treatments, and surgical procedures influence their sexual relationship even though they often do not ask questions. With experience nurses recognize that most patients welcome the opportunity to talk about their sexuality, especially when they are experiencing difficulties. The classic PLISSIT model ([Annon, 1976](#)) provides an approach that nurses can use to assess sexuality in patients ([Box 34.5](#)).

Box 34.5 PLISSIT Assessment of Sexuality

Permission to discuss sexuality issues

Limited Information related to sexual health problems being experienced

Specific Suggestions—only when the nurse is clear about the problem

Intensive Therapy—referral to professional with advanced training if necessary

Modified from Annon JS: The PLISSIT model: a proposed conceptual scheme for the behavioral treatment of sexual problems, *J Sex Educ Ther* 2(2):1, 1976.

Incorporate assessment questions related to sexuality in the nursing history ([Box 34.6](#)). Using an opening statement puts a patient at ease when introducing these questions (e.g., "Sex is an important part of life, and a

person's health status often affects sexuality. Many people have questions and concerns about their sexual health. What questions or concerns do you have now?"). Use knowledge of developmental stages to determine which areas are likely to be important for your patient. For example, when gathering a sexual history from an older adult, it is important to keep in mind that some have difficulty in discussing intimate details with health care providers.

Box 34.6 Nursing Assessment Questions

- Are you sexually active?
- With whom do you have sex: men, women, or both?
- How many sexual partners do you have (or have you ever had)?
- How do you feel about the sexual aspects of your life?
- Have you noticed any changes in the way you feel about yourself?
- How has your illness, medication, or surgery affected your sex life?
- It is not unusual for people with your condition to be experiencing some sexual changes. Have you noticed any changes, or do you have any concerns?
- Are you in a relationship in which someone is hurting you?
- Has anyone ever forced you to have sex against your will?
- Tell me what you know about safe sex practices, use of contraceptives, or prevention of sexually transmitted infections.
- Tell me the safe sex practices that you follow.

Nurses who conduct sexual assessments of children and adolescents face special challenges. Use language that is accurate and that the child or adolescent understands. Also promote normal development, avoid minimizing problems, and screen for sexual concerns while making the child or adolescent feel at ease. The sexual counseling of minors raises ethical and legal issues regarding a patient's rights to health care and education on the one hand and a parent's or guardian's right to supervise information on the other. Children and adolescents frequently respond when they know that having questions related to sexuality is normal. Being open, positive, and interested when introducing sexual questions is helpful.

In light of the prevalence of intimate partner violence, questions relating to abusive relationships are important. Address these questions in private. Recognizing both subjective and objective signs and symptoms of abuse in children and adults helps to identify this too-common problem (see [Table 34.1](#)).

Some individuals are too embarrassed or do not know how to ask sexual questions directly. Look for clues that a person has questions. For example, a patient expresses concern about how his or her partner will respond now or makes a sexual comment or joke. Observing for and listening to concerns about sexuality take practice. With experience you develop skill in clarifying and paraphrasing to help individuals express sexual concerns. By including sexuality in the nursing history, you acknowledge that it is an important component of health and create an opportunity for a person to discuss sexual concerns.

Sexual Dysfunction

Many illnesses, injuries, medications, and aging changes have a negative effect on sexual health, which results in either temporary or permanent sexual dysfunction. Apply knowledge about conditions and medications that frequently cause sexual dysfunction while assessing a patient's risks (see [Box 34.4](#)). Being aware of the possible effects of physical problems, altered self-concept, medications, and the factors addressed thus far on sexual functioning helps you conduct a thorough assessment. Some patients bring up the topic of sexual dysfunction. Other times issues become evident as the patient answers other nursing history questions.

Physical Assessment

The physical examination is important in evaluating the cause of sexual concerns or problems and usually provides the best opportunity to teach an individual about sexuality. In examining a woman's breasts and the external and internal genitalia, a nurse has the opportunity to assess the woman's reaction, answer questions, and provide information about the examination of anatomical and physiological structures. For example, a nurse teaches a woman how to perform breast self-examination during physical assessment. During physical assessment of the genitalia, he or she teaches men how to perform testicular self-examination (see [Chapter 30](#)). Knowledge of normal scrotal anatomical structures helps men detect signs of testicular cancer. Instruct both men and women on signs and symptoms

of STIs during the examination when patients' histories suggest risks for them.

REFLECT NOW

Reflect on a statement one of your patients made about sexuality and how you could have improved your response.

• Nursing Diagnosis

After completing an assessment, you apply critical thinking to the diagnostic process and select diagnoses applicable to the patient's needs. Assessment findings related to sexuality often include history of surgery of reproductive organs, changes in appearance or body image, a history of or current physical or sexual abuse, chronic illness, or developmental milestones such as puberty or menopause. To make a nursing diagnosis related to sexual dysfunction, consider anatomical, physiological, sociocultural, ethical, and situational issues thoroughly. Possible nursing diagnoses related to sexual functioning are listed here:

- *Problematic Sexual Behavior*
- *Difficulty Coping*
- *Lack of Knowledge of Contraception*
- *Impaired Sexual Functioning*
- *Risk for Impaired Reproductive Function*

Clarify assessment findings and ensure that the patient perceives a problem or difficulty with sexuality (Box 34.7). Determining the etiological or contributing factors helps you plan effectively and select the appropriate nursing interventions. For example, nursing interventions appropriate for the nursing diagnosis of *Impaired Sexual Functioning* will differ for different etiological factors. *Impaired Sexual Functioning related to misinformation about the risk of sexually transmitted infections* requires

counseling and education on how to maintain safe sexual practices. In contrast, patients who experience *Impaired Sexual Functioning related to physical abuse* need counseling and referral to community resources (e.g., crisis services and physical abuse support group).

Box 34.7 Nursing Diagnostic Process **Impaired Sexual Functioning**

Assessment Activities	Assessment Findings
Review medical and medication history	History of hypertension History of uncomplicated myocardial infarction (MI) Takes propranolol
Have patient describe sexual problems	Less interested in having intercourse with wife since taking propranolol Rarely has sexual intercourse with wife Sometimes has trouble having an erection
Patient's fears and concerns	Fearful will have chest pain or another MI while having intercourse

Planning

Goals and Outcomes

Synthesize information from multiple resources to develop an individualized plan of care (Fig. 34.3). Critical thinking ensures that a patient's plan of care integrates all that a nurse knows about an individual's sexuality. Professional standards are especially important to consider when developing a plan of care. Maintain a patient's dignity and identity at all times. For example, to convey respect for the patient's gender identity preferences, ask the patient about preferred pronouns, and use the patient's preferred pronouns in all interactions.

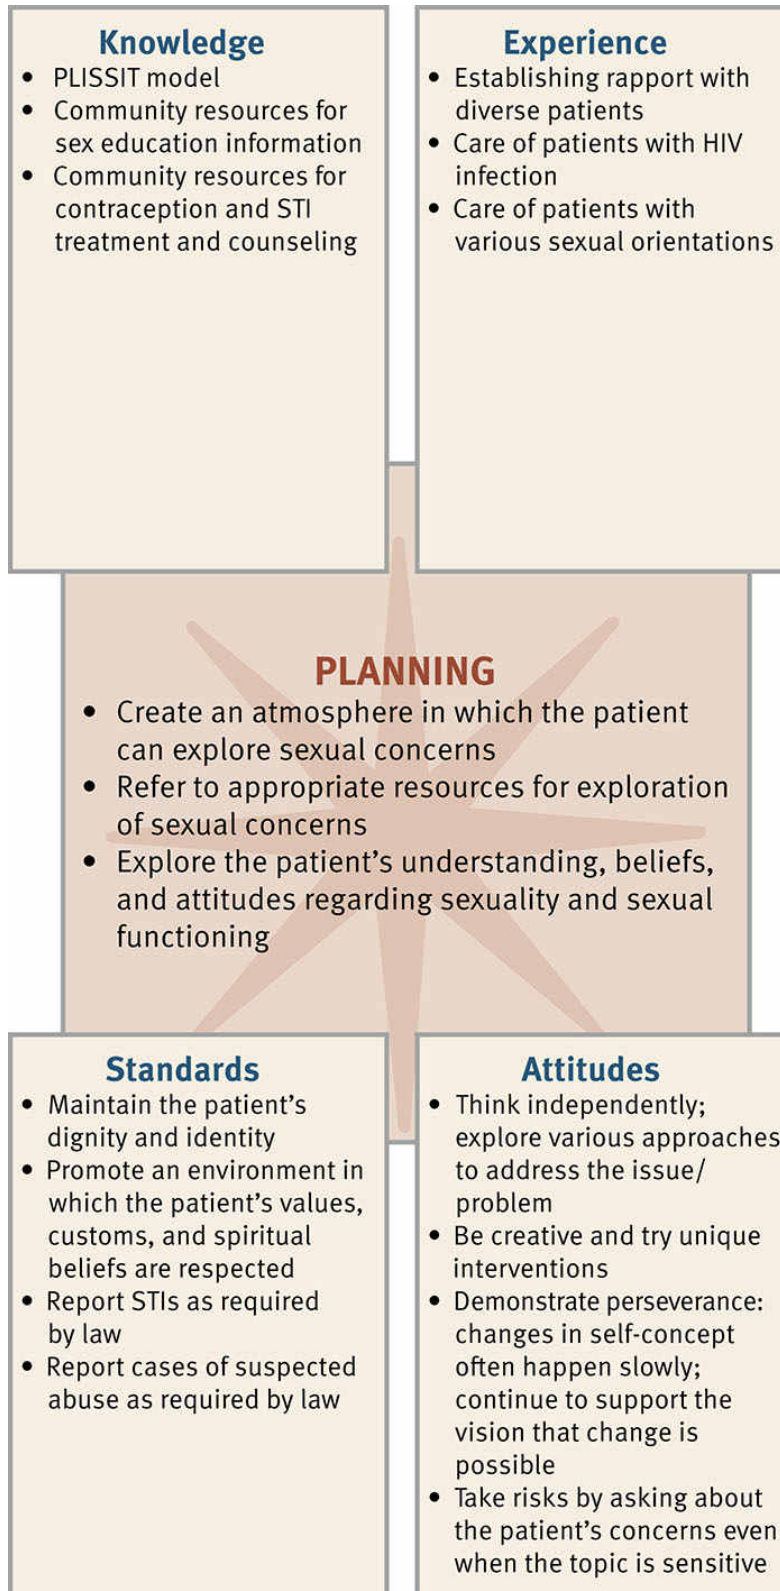

FIG. 34.3 Critical thinking model for sexuality planning. *HIV*, Human immunodeficiency virus; *STI*, sexually transmitted infection.

Develop an individualized plan of care for each nursing diagnosis (see the **Nursing Care Plan**). Set realistic goals and measurable outcomes with the patient. For example, a patient who has dyspareunia has a nursing diagnosis of *Impaired Sexual Functioning related to decreased sexual desire*. You and your patient develop a goal to report decreased anxiety and greater satisfaction with sexual activity within 1 month. Expected outcomes include that the patient does the following:

- Discusses stressors that contribute to sexual dysfunction with partner within 2 weeks
- Identifies alternative, satisfying, and acceptable sexual practices for self and partner within 4 weeks

A concept map is another method that is useful in organizing patient care (Fig. 34.4). The concept map shows the relationship of a medical diagnosis (decreased libido and depression) to the four nursing diagnoses identified from the patient assessment data. It also shows the links and relationship to the nursing diagnosis and interventions appropriate for each diagnosis. For example, *Difficulty Coping* affects and contributes to *Withdrawn Behavior*, and as long as the patient has difficulty coping, the withdrawn behavior continues or perhaps worsens.

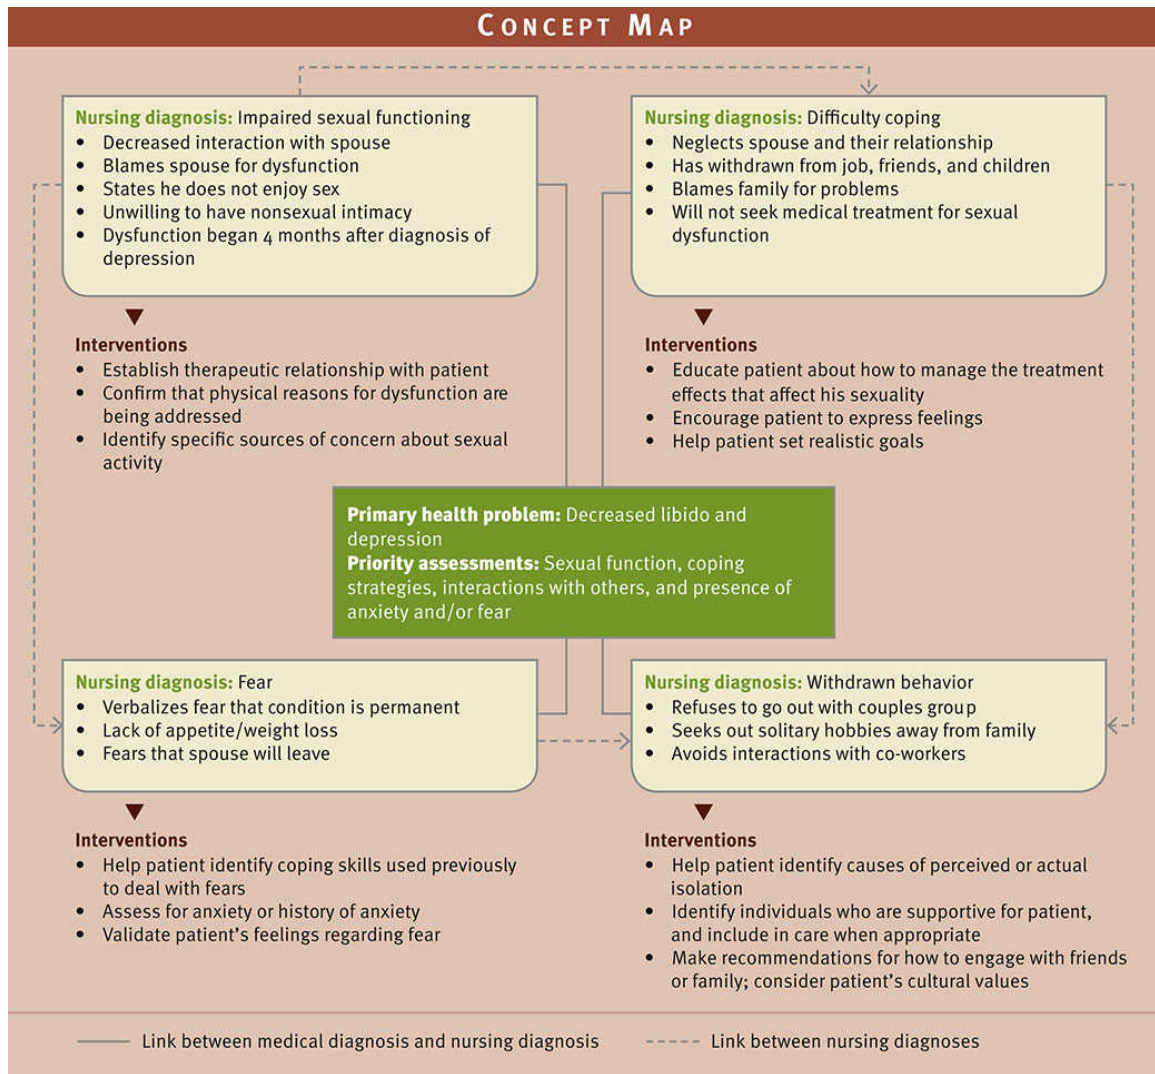

FIG. 34.4 Concept map for Mr. Clements.

Setting Priorities

The care plan shows the goals, expected outcomes, and interventions for a patient experiencing impaired sexual functioning. Nursing interventions for patients with sexual concerns focus on supporting a patient's need for intimacy and sexual activity. Patients often feel overwhelmed and hopeless about returning to the level of previous sexual functioning and usually need time to adapt to physical and psychosocial changes that affect their sexuality and sexual health.

The priority in addressing needs related to sexuality includes establishing a therapeutic relationship so that the patient feels comfortable in discussing issues related to sexuality. Look for strengths in both the patient and the family while providing education and access to resources

to turn limitations into strengths. Patient teaching communicates the normalcy of feelings following certain situations (e.g., the diagnosis of a chronic illness or the loss of a body part). In collaboration with the patient, you determine a patient's needs and plan accordingly.

A patient's current problems and needs help you determine the priorities related to his or her sexual health. Priorities for sexual health often include resuming sexual activities. For example, if a patient is recovering from a mastectomy and is having problems resuming an intimate relationship with her spouse because of problems related to body image, you help her adapt to and cope with the changes in her body image associated with the mastectomy. Once the patient's issues related to body image are resolved, she is able to restore intimacy with her spouse and address her sexual health needs.

Building Competency in Teamwork and Collaboration

Mr. Clements asks what lifestyle changes he will need to make after discharge from the hospital. You know that patients with cardiovascular problems often require an interprofessional approach to achieve optimal recovery, and you arrange for consultation with different health professionals. You inform Mr. Clements that he will work with a team of experts, including cardiologists, physical therapists, dietitians, and counselors. Assure him that you will share your assessment data and plan of care with the team and will recommend nurses who can remain involved in his outpatient care. Discuss how each of these professionals will contribute to Mr. Clements' care during and after hospitalization.

Teamwork and Collaboration

You often collaborate with other health care providers and make referrals to community resources when planning care for a patient's sexuality (Box 34.8). Nurses generally raise awareness of sexual issues, clarify concerns, and/or provide information. Nurses who have specialized education in sexual functioning and counseling provide more intensive sex therapy. It is necessary to understand the limits of your knowledge base and to include other health care providers, such as sex therapists, clinical psychologists, and social workers as appropriate, to meet patients' needs for sexual health. For example, conflicts in marriage usually require

intensive treatment with a mental health professional or certified sex therapist. For the woman who is currently in an abusive relationship, the nurse collaborates with special women's shelters that provide counseling and serve as a safe place for her while further plans are made.

Box 34.8 Examples of Community Resources Relating to Sexuality

- Community and free clinics offering contraceptive information and resources
- Health department (often for both family planning and sexually transmitted infections)
- Groups that provide education/services for those with particular conditions include the following:
 - American Diabetes Association
 - American Heart Association
 - Muscular Dystrophy Association
 - Muscular Sclerosis Society
- Sexual abuse support groups and hot lines
- Women's shelters (for those who are at risk of continued physical and/or sexual abuse)
- Resolve: The National Infertility Association (<http://www.resolve.org>)
- North America Menopause Society (<http://www.menopause.org>)

Implementation

Promote sexual health as a component of overall health and wellness by identifying patients at increased risk, providing appropriate information, helping individuals gain insight into their problems, and exploring methods to deal with them effectively.

Health Promotion

Helping patients maintain or gain sexual health involves consideration of factors that influence sexual satisfaction. Educate patients about sexual health, including measures for contraception, safe sex practices, and prevention of STIs. Regular breast self-examinations, mammograms, and

Papanicolaou (Pap) smears are important sexual health measures for women; testicular self-examinations are important for men. Offer the 9-valent HPV vaccine to males and females who are between 11 and 26 years of age (CDC, 2016). The vaccine is safe for girls as young as 9 years old and is recommended for females ages 11 to 26 if they have not already completed the three required injections. Booster doses currently are not recommended. The vaccine is most effective if administered before sexual activity or exposure.

Exploring an individual’s values, discussing levels of satisfaction, and providing sex education require therapeutic communication skills. Structure the environment and timing to provide privacy, comfort, and uninterrupted time. For example, when discussing methods of contraception with a woman, provide education in a private area with the patient fully dressed rather than in the examination room when the patient is only partially clothed.

Nursing Care Plan

Impaired Sexual Functioning

Assessment

Mr. Clements is 65 years old and had a myocardial infarction (MI) 3 days ago. He has hypertension, which is being treated with propranolol. Mr. Clements is married and lives with his wife. You know that patients who have had MIs and are taking antihypertensive medications are at risk for experiencing sexual problems. Mrs. Clements expresses a desire to continue having a sexual relationship with her husband.

Assessment Activities	Assessment Findings ^a
Ask Mr. Clements whether his interest in sex has changed since he started to take propranolol.	He responds that he has been less interested in having sexual intercourse with his wife since he started to take propranolol.
Ask Mr. Clements whether he has had difficulties with an erection.	He states that since he started to take propranolol, he sometimes has trouble having an erection.
Ask Mr. Clements what concerns or fears he has about resuming his sexual relationship with his wife now that he has had an MI.	He states that he is afraid that after discharge he will have chest pain or another heart attack if he has sexual intercourse with his wife.

^a Assessment Findings are shown in bold type.

Nursing diagnosis:

Impaired sexual functioning related to altered body function (side effects of propranolol) and lack of knowledge

Planning

Goal	Expected Outcomes (NOC) ^b
Sexual Functioning	
Patient will express satisfaction with sexual relationship with wife within 1 month.	Patient expresses renewed sexual interest within 2 weeks. Patient sustains arousal through orgasm within 3 weeks.

^b Outcome classification labels from Moorhead S, et al: *Nursing Outcomes Classification (NOC): measurement of health outcomes*, ed 6, St Louis, 2018, Elsevier.

Interventions (NIC) ^c	Rationale
Sexual Counseling	
Establish trust and respect with Mr. Clements. Offer privacy during conversations.	Establishing trust and offering privacy express sense of caring, increasing likelihood of patient's ability to express concerns (Halter, 2018).
Discuss possible effects of MI and propranolol on sexual functioning and resumption of sexual activity.	Discussion enhances understanding about reasons for sexual difficulties and provides safe guidelines for resumption of sexual intercourse following MI.
Include Mrs. Clements in discussions about sexual issues as frequently as possible and when appropriate.	Including partner in the plan of care can enhance personal and intimate relationships and improve health outcomes.
Anxiety Reduction	
Encourage Mr. Clements to express fears about resuming sexual activity, and assure him that others who have had MIs experience similar fears.	Sexual dysfunction sometimes occurs after an MI because of anxiety and/or from side effects of medications. Knowing that feelings and fears are normal helps decrease anxiety and encourages return of sexual activity.

^c Intervention classification labels from Butcher HK, et al: *Nursing Interventions Classification (NIC)*, ed 7, St Louis, 2018, Elsevier.

Evaluation

Evaluation Activity	Patient Response/Finding	Outcome Status
Ask Mr. Clements whether he and his wife are satisfied with their sexual relationship during return office visit.	Mr. Clements reports that his interest in sex is back to normal and that he is able to have an erection.	Mr. Clements reports sexual interest and function; he and his wife are satisfied with their relationship.

Topics of education vary and often are related to a patient's developmental level. For example, a nurse talks to school-age children regarding the appearance of breast buds or pubic hair. When discussing sexual health with patients of childbearing age, always consider a patient's cultural and religious beliefs regarding contraception. The discussion includes the desire for children, usual sexual practices, and acceptable

methods of contraception. Review all methods of contraception to allow patients to make informed decisions.

Major developmental events (e.g., puberty, menopause) prompt education about sexuality. Situational crises such as a life change with pregnancy, illness, divorce, extreme financial stress, placement of a spouse in a nursing home, or loss and grief affect sexuality. Some effects last for days, months, or years and are often minimized when the individual is prepared for possible changes in sexual functioning.

Demonstrate recognition, acceptance, and respect for an older adult's sexuality by displaying a willingness to openly discuss sex and sexuality-related concerns. Strategies that enhance sexual functioning include the following (LeVay et al., 2019).

- Avoid alcohol (in excess) and tobacco.
- Eat well-balanced meals.
- Plan sexual activity for times when the couple feels rested.
- Take pain medication if needed before sexual intercourse.
- Use pillows and alternate positioning to enhance comfort.
- Encourage touch, kissing, hugging, and other tactile stimulation.
- Communicate concerns and fears with partner and health care provider.

Individuals who have more than one sex partner or whose partner has other sexual experiences need to learn about safe sex practices. Provide information about STI symptoms and transmission, use of condoms, and risky sexual activities (e.g., trauma from penile-anal sex). To prevent HIV infection, teach patients to avoid having multiple sex partners and to use condoms correctly to reduce the risk of HIV/AIDS (Box 34.9). Role-playing is useful in helping a person learn to say no or in negotiating with a partner to use a condom. When discussing safe sex, consider patients' physical and emotional health.

Box 34.9 PATIENT TEACHING **Using a Condom**

Correctly

Objective

- Patient will verbalize correct use of a condom.

Teaching Strategies

- Develop a trusting relationship with patient.
- Explain to patient to always use a latex or rubber condom when having vaginal, oral, or anal sex and to store condoms in a cool, dry place away from sunlight.
- Encourage patient to read the label on the condom package to check the expiration date and ensure that the condom protects against sexually transmitted infections.
- Instruct patient to never reuse a condom or use a damaged condom.
- Explain how to apply the condom correctly (e.g., put it on as soon as the penis is hard and before vaginal, anal, or oral contact; gently squeeze any air out from the tip of the condom, leaving space for semen; unroll the condom to the base of the penis).
- Teach patient to pull out right after ejaculating and hold onto the condom when pulling out.
- Instruct patient to use only water-based lubricants (e.g., K-Y jelly) to prevent the condom from breaking; do not use petroleum jelly, massage oils, body lotions, or cooking oil.

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- Ask patient to describe where condoms are stored.
- Ask patient questions that verify understanding of instruction (e.g., What would you do if you noticed that a condom you just opened had an open slit in it?).

Encourage patients to have regular health and screening examinations to maintain sexual health. Often asymptomatic STIs are diagnosed during a physical examination with appropriate laboratory work. Annual health examinations provide an opportunity to discuss contraception and safe sex practices. However, some people do not seek annual health examinations routinely. For example, some women frequently do not have breast examinations, mammograms, and cervical cancer screening because of religious and cultural beliefs about modesty. Develop a therapeutic

relationship with patients and provide culturally sensitive education that is written at an appropriate reading level (see [Chapter 25](#)). Barriers to reproductive health services include cultural beliefs, access to health care, and low health literacy.

Acute Care

Illness and surgery create situational stressors that often affect a person's sexuality. During periods of illness individuals experience major physical changes, the effects of drugs or treatments, the emotional stress of a prognosis, concern about future functioning, and separation from significant others. Never assume that sexual functioning is not a concern merely because of an individual's age or the severity of prognosis. After identifying concerns, address them in the context of his or her value system.

When a patient identifies sexual concerns, initiate discussion and education appropriately. Refer to appropriate outpatient resources if needed. Help patients anticipate how their illness or disease will change over time and the adjustments that will be necessary to achieve sexual fulfillment.

Restorative and Continuing Care

You need to establish relationships with couples to encourage honest and open discussions about sexual health during restorative or continuing care. Address needs by taking a sexual health history and implementing a basic model such as PLISSIT to provide options for patients (see [Box 34.5](#)). Assessment and management of sexual concerns are important when promoting sexual intimacy and providing closeness and closure between partners at the end of life.

In the home environment it is important to provide information on how an illness limits sexual activity and give ideas for adapting or facilitating sexual activity. Interventions range from giving permission for a partner to lie in bed and hold a patient to coordinating nursing care and medications to provide opportunity for privacy and intimacy. Often nurses help individuals create an environment that is comfortable for sexual activity in the home. This sometimes involves making recommendations for ways to arrange the bedroom to accommodate physical limitations. For example, some individuals who are in a wheelchair prefer being able to move the chair close to the side of the bed at an angle that allows for more ease in touching and caressing. Suggestions regarding how to accommodate

barriers such as Foley catheters or drainage tubes contribute to sexual activity.

In the long-term care setting facilities need to make proper arrangements for privacy during residents' sexual experiences (LeVay et al., 2019). The ideal situation is to set up a pleasant room that is used for a variety of activities that the resident is able to reserve for private visits with a spouse or partner. If this is not possible, arrange for the roommate of a patient to be somewhere else to allow a couple time alone. Never leave patients alone in a situation in which injury is possible.

• Evaluation

Through the Patient's Eyes

Evaluate patients' perceptions of nursing interventions to determine whether their expectations have been met. Critical thinking ensures that you apply what is known about sexuality and a patient's unique situation.

Have follow-up discussions with the patient or partner to determine whether they were satisfied with your approaches. Sexuality is felt more than observed, and sexual expression requires an intimacy that is not amenable to observation.

Patient Outcomes

Evaluate whether your patient achieved outcomes established in the plan of care (Fig. 34.5). Ask patients questions about risk factors, sexual concerns, and their level of satisfaction. Observe behavioral cues such as eye contact, posture, and extraneous hand movements that indicate comfort or suggest continued anxiety or concern as topics are addressed. Anticipate the need to modify expectations with an individual and partner when evaluating outcomes. Sometimes you need to establish more appropriate time frames in which to achieve target goals. Ask patients to define what is acceptable and satisfying while considering the partner's level of sexual satisfaction. When outcomes are not met, begin to ask questions to determine appropriate changes in interventions. Examples of questions include the following:

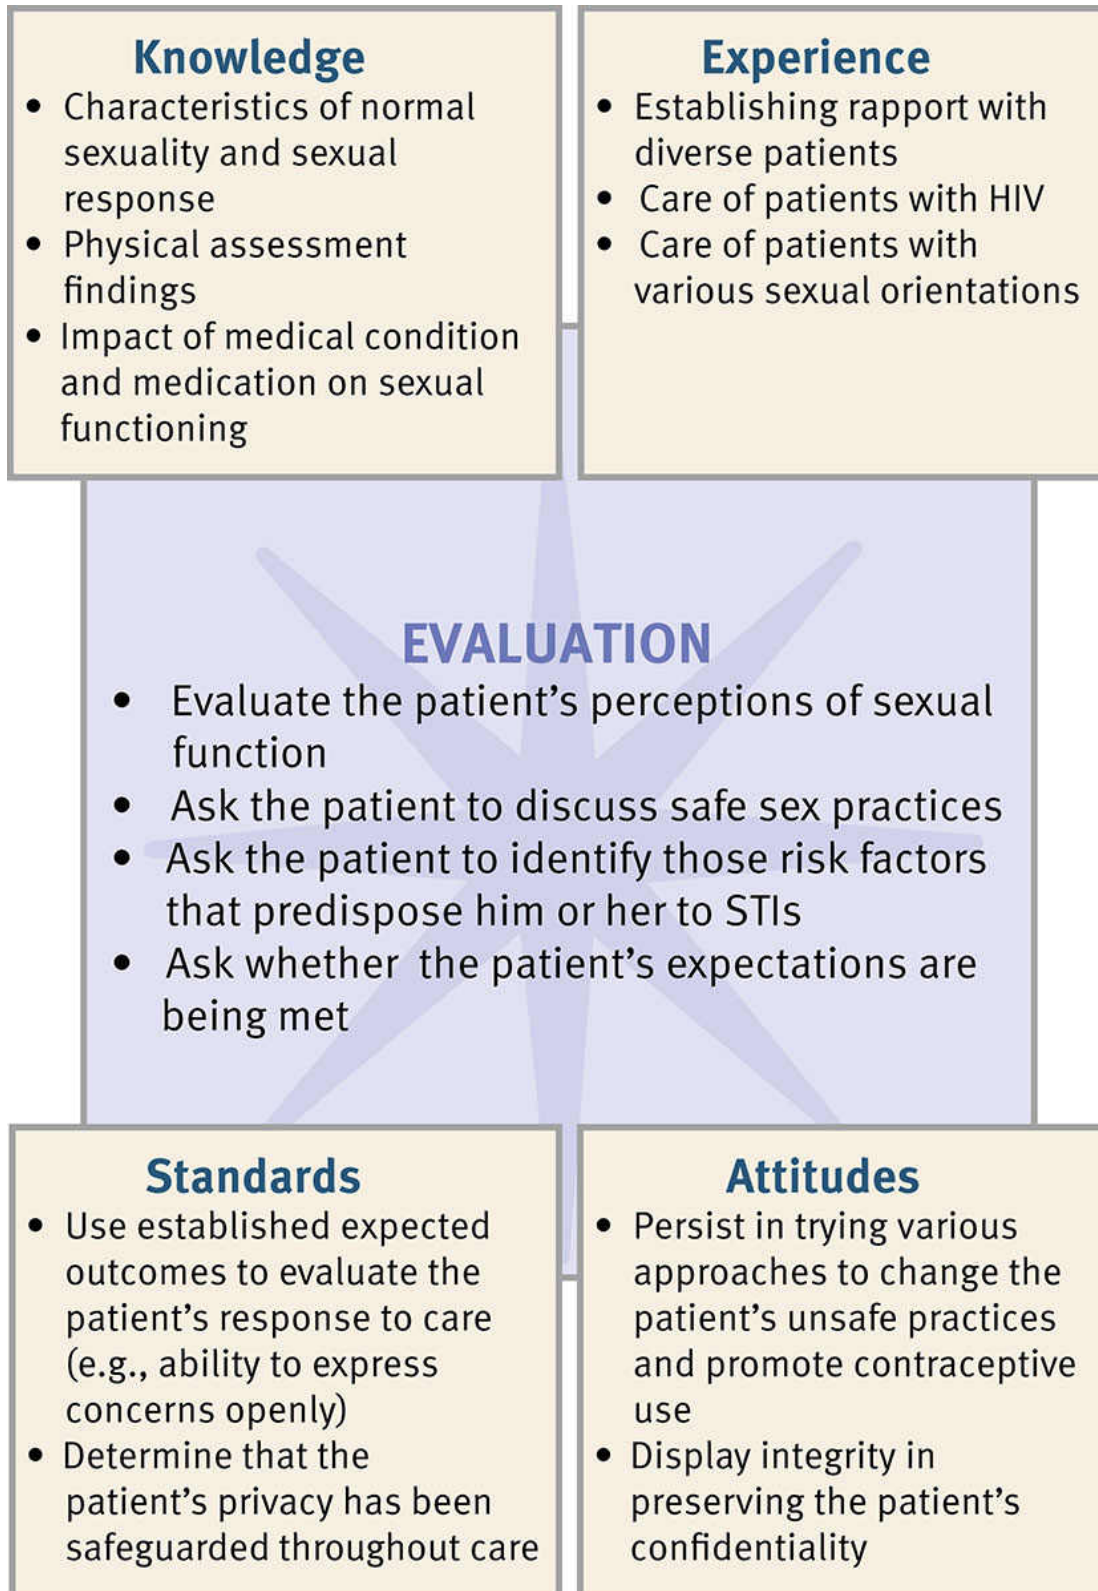

FIG. 34.5 Critical thinking model for sexuality evaluation. *HIV*, Human immunodeficiency virus; *STI*, sexually transmitted infection.

- What other questions do you have about your sexual health?
- Did you experience less pain during sexual intercourse after taking your pain medication?
- Which positions did you find most comfortable when you had sexual intercourse? Which positions were most awkward?
- What barriers are preventing you from discussing your feelings and fears with your partner?

Key Points

- Nurses must be knowledgeable about all aspects of sexuality, including how their own values and issues surrounding sexuality impact patient-centered care.
- The nurse is educationally and experientially positioned to take the lead among health care providers to promote sexual health.
- Sexual health involves physical and psychosocial aspects and contributes to an individual's sense of self-worth and positive interpersonal relationships.
- The nurse must thoroughly assess potential causes of sexual dysfunction to promote effective treatment.
- Sexuality is related to all dimensions of health. Therefore, address sexual concerns or problems as a routine part of nursing care.
- Nursing diagnoses related to alterations in sexuality demonstrate the interface between physical and psychological issues.
- Patient risk factors include inadequate sex education and risky behaviors, including low rates of testing, substance use, low condom use, and multiple partners.
- Development and life changes, ethical decisional issues, fertility, personal and emotional conflicts, illness, and hospitalization all affect a patient's sexuality.

- Improved communication with one's partner and establishment or return to a mutually satisfying sex life are important outcomes following alterations in sexual health.
- Expert communication and attention to a patient's nonverbal communication will result in compassionate care surrounding sexuality and sexual health.

Reflective Learning

- State examples of nonjudgmental questions you can ask your patient to determine his or her gender identity.
- How would you establish a therapeutic relationship to put a patient at ease discussing the intimate aspects of his or her life?
- Describe how you would provide patient education to a couple experiencing problems with their sexual functioning. Provide at least three strategies that they could use to enhance their sexual functioning.

Review Questions

1. A 16-year-old female tells the school nurse that she doesn't need the human papillomavirus (HPV) vaccine since her partner always uses condoms. The best response by the nurse to this statement is:
 1. "Latex condoms are the most effective way to eliminate the risk of HPV transmission."
 2. "Your parents may not want you to receive the HPV vaccine since it has been shown to increase sexual risk taking and sexual activity."
 3. "The HPV 9-valent vaccine is recommended for males and females even if they use condoms because it targets the specific viruses that cause cancer and genital warts."

4. "You are past the recommended age to receive the vaccine."
2. An adolescent who is pregnant for the first time is at her initial prenatal visit. The women's health nurse practitioner (WHNP) informs the patient that she will be screening her for sexually transmitted infections (STIs). The patient replies, "I know I don't have an STI because I don't have any symptoms." Which responses by the WHNP would be appropriate? (Select all that apply.)
 1. "Untreated STIs can cause serious complications in pregnancy, so we routinely screen pregnant women."
 2. "Bacterial STIs don't usually cause symptoms, or you could have an asymptomatic viral STI."
 3. "Chlamydia screening is recommended for all sexually active women up to age 25 even if asymptomatic."
 4. "People between the ages of 15 and 24 are often asymptomatic and have the highest incidence of STIs."
 5. "There is no need to screen for infection since you aren't having any problems or symptoms."
3. A nurse who recently graduated from nursing school is providing discharge instructions to a patient who suffered a myocardial infarction (MI). The nurse knows that sexual issues are common after an MI but feels uncomfortable bringing up this topic. What is the best way for the nurse to handle this situation? (Select all that apply.)
 1. Instruct the patient to discuss any sexual concerns with his or her partner after discharge.
 2. Avoid discussing the topic unless the patient brings it up.
 3. Ask a more experienced nurse to cover this with the patient and learn from the example.
 4. Plan to attend conferences or training soon on how to discuss such issues.

5. Encourage the patient to discuss any personal concerns with the cardiologist.
4. The nurse is gathering a history from a 72-year-old male patient being admitted to a nursing home. The patient requests a private room. The nurse understands that:
 1. The patient cannot be sexually active since he is moving into a nursing home.
 2. The patient may be requesting a private room to facilitate an intimate relationship with his partner.
 3. There is no need to take a sexual history since most older adults are uncomfortable discussing intimate details of their lives.
 4. Older adults in nursing homes usually do not participate in sexual activity.
5. The nurse is providing education on sexually transmitted infections (STIs) to a group of older adults. The nurse knows that further teaching is needed when the participants make which statements? (Select all that apply.)
 1. "I don't need to use condoms since there is no risk for pregnancy."
 2. "I should be screened for an STI each time I'm with a new partner."
 3. "I know I'm not infected because I don't have discharge or sores."
 4. "I was tested for STIs last year, so I know I'm not infected."
 5. "The infection rate in older adults is low because most are not sexually active."
6. The nurse is providing community education about how the sexual response changes with age. Which statement made by one of the adults indicates the need for further information?

1. "Health problems such as diabetes, chronic obstructive pulmonary disease, and hypertension have little effect on sexual functioning and desire."
 2. "It usually takes longer for both sexes to reach an orgasm."
 3. "Most of the normal changes in function are related to alteration in circulation and hormone levels."
 4. "Many medications can interfere with sexual function."
7. The nurse is gathering a sexual health history on a patient being admitted to the hospital for surgery. Which question demonstrates a nonjudgmental attitude?
1. Can you tell me your sexual orientation?
 2. How do you and your wife feel about intimacy?
 3. Do you have sex with men, women, or both?
 4. Do you have sexual intercourse at your age?
8. The nurse reviews the health history of a 48-year-old man and notes that he was started on medications for elevated blood pressure and depression at his last annual physical. He tells the nurse that over the past 6 months he is having difficulty sustaining an erection. The nurse understands that: (Select all that apply.)
1. Nurses are not expected to discuss sexual issues with male patients and the physician should address this.
 2. Sexual function can be affected by some medications.
 3. Sexually transmitted infections (STIs) can cause complications such as erectile dysfunction and screening should be done.
 4. Some men with health issues experience erectile dysfunction.
 5. Medications used to treat hypertension and depression seldom interfere with sexual function.
9. The school nurse is counseling an adolescent male who is returning to school after attempting suicide. He denies

substance abuse and has no history of treatment for depression. He says he has no friends or family who understand him. Critical thinking encourages the nurse to consider all possibilities, including which of the following? (Select all that apply.)

1. Adolescents often explore their sexual identity and expose themselves to complications such as sexually transmitted infections (STIs) or unplanned pregnancy.
 2. Peer approval and acceptance are not important in this age-group.
 3. Lesbian, gay, bisexual, and transgender (LGBTQ+) youth often experience stress from identification with a sexual minority group.
 4. Knowledge about normal changes associated with puberty and sexuality can decrease stress and anxiety.
 5. Adolescence is a time of emotional stability and self-acceptance.
10. A 53-year-old female being treated for breast cancer tells the nurse that she has no interest in sex since her surgery 2 months ago. The nurse is aware that: (Select all that apply.)
1. Sexual issues are expected in a woman this age.
 2. Women experience sexual dysfunction more frequently than men.
 3. Hypoactive sexual desire disorder (HSDD) occurs in women over 65 years of age.
 4. Medical conditions such as cancer often contribute to HSDD.
 5. Disturbances in self-concept affect sexual functioning.

Spiritual Health

OBJECTIVES

- Discuss the influence of spirituality on patients' health practices.
- Describe the relationship among faith, hope, and spiritual well-being.
- Compare and contrast the concepts of religion and spirituality.
- Assess a patient's spirituality and spiritual health.
- Explain the importance of establishing caring relationships with patients to provide spiritual care.
- Discuss nursing interventions designed to promote a patient's spiritual health.
- Identify approaches for establishing presence with patients.
- Evaluate patient outcomes related to spiritual health.

Inner strength and peace, p. 724

Meaning and purpose in life, p. 724

The word *spirituality* comes from the Latin word *spiritus*, which refers to breath or wind. The spirit gives life to a person. It signifies whatever is at the center of all aspects of a person's life. Florence Nightingale believed that spirituality was a force that provided energy needed to promote a healthy hospital environment and that caring for a person's spiritual needs was just as essential as caring for his or her physical needs (O'Brien, 2014). Today **spirituality** is often defined as an awareness of one's inner self and a sense of connection to a higher being, nature, or some purpose greater than oneself (Carson, 2017). It includes personal beliefs that help a person maintain hope and get through difficult situations (March and Caple, 2016). A person's health depends on a balance of physical, psychological, sociological, cultural, developmental, and spiritual factors. Spirituality helps individuals achieve the balance needed to maintain health and well-being and to cope with changes in their health status.

Too often nurses and other health care providers fail to recognize the spiritual dimension of their patients because spirituality is not scientific enough, it has many definitions, and it is difficult to measure. In addition, there are nurses and health care providers who are uncertain about a supreme God or being and uncomfortable with discussing spirituality, while others claim that they do not have time to address patients' spiritual needs (Chen et al., 2017a; Connerton and Moe, 2018). The concepts of spirituality and religion are often interchanged, but spirituality is a much broader and more unifying concept than religion (Dahlkemper, 2016; Carson, 2017). While religion is an organized, institution-related practice that is commonly associated with particular beliefs, spirituality focuses on an individual's connection to a higher being, nature, or some purpose greater than oneself (Caplan, 2017).

The human spirit is powerful, and spirituality has different meanings for different people. Some people do not believe in the existence of God (**atheist**), or they believe that there is no known ultimate reality (**agnostic**). Nonetheless spirituality is important regardless of a person's religious beliefs. Atheists search for meaning in life through their work and their relationships with others. Agnostics discover meaning in what they do or how they live, the "here and now," because they find no ultimate meaning for the way things are. They believe that people bring meaning to what they do.

A nurse's personal spiritual health is important to his or her own values and beliefs and can influence attitudes toward spiritual care, professional

commitment, and caring ([Chiang et al., 2016](#)). You need to be aware of your own spirituality to provide appropriate and relevant spiritual care to others. As a nurse, you need to care for the whole person and accept a patient's beliefs and experiences ([Connerton and Moe, 2018](#)). Being able to determine the importance that spirituality holds for patients depends on your ability to develop caring relationships (see [Chapter 7](#)).

Scientific Knowledge Base

The relationship between spirituality and healing is not completely understood. However, an individual's intrinsic spirit seems to be an important factor in healing. Healing often takes place because of believing. For example, research shows that spirituality positively affects and enhances physical and psychological health, quality of life, health promotion behaviors, and disease prevention activities (Heo et al., 2018; Trevino and McConnell, 2015).

Spirituality has a positive impact on the ability to cope with anxiety, stress, and depression in family caregivers (Vitorino et al., 2018), mothers with infants in the neonatal intensive care unit (Alemdar et al., 2018), nursing students (Fabbris et al., 2017), patients living with cancer (Hefner et al., 2017), and patients experiencing infertility (Romeiro et al., 2017). Integrative body-mind techniques that include relaxation, guided imagery, mindfulness training, and music reduce perceptions of pain and anxiety (Fan et al., 2014). A person's inner beliefs and convictions are powerful resources for healing. When you support the spirituality of patients and their families, you help them achieve desirable health outcomes.

REFLECT NOW

What have you observed as patient outcomes when spiritual care was provided to patients?

Nursing Knowledge Base

Nursing research shows the association between spirituality and health. For example, spiritual well-being has a potential protective effect against psychosocial distress at the end of life (Bernard et al., 2017). Research also shows that when patients who have cancer participate in religious and spiritual activities, they remain actively engaged socially and continue to have satisfying relationships (Sherman et al., 2015). More research is needed, but the interest in studying the relationship between spirituality and health is greatly contributing to nursing science.

Current Concepts in Spiritual Health

A variety of concepts describing spiritual health are a part of professional nursing practice. To provide meaningful and supportive spiritual care, it is important to understand the concepts of spirituality, spiritual well-being, faith, religion, and hope. Each concept offers direction in understanding the views that individuals have of life and its value.

Spirituality

Spirituality is a complex concept that is unique to each individual; it depends on a person's culture, development, life experiences, beliefs, and ideas about life (Connerton and Moe, 2018). It is an inherent human characteristic that exists in all people, regardless of their religious beliefs. It gives individuals the *energy* needed to discover themselves, cope with difficult situations, and maintain health. Energy generated by spirituality helps patients feel well and guides choices (e.g., type and extent of health care) made throughout life. Spirituality enables a person to love, have faith and hope, seek meaning in life, and nurture relationships with others. Because it is subjective, multidimensional, and personal, researchers and scholars cannot agree on a universal definition of spirituality (Connerton and Moe, 2018). However, five distinct but overlapping constructs define it (Fig. 35.1).

Spirituality

FIG. 35.1 The concept of spirituality has five distinct but overlapping constructs.

- **Self-transcendence**—a sense of authentically connecting to one’s inner self. This contrasts with **transcendence**, the belief that a force outside of and greater than the person exists beyond the material world ([Hatamipour et al., 2015](#)). Self-transcendence is a positive force. It allows people to have new experiences and develop new perspectives that are beyond ordinary physical boundaries.

Examples of transcendent moments include the feeling of awe when holding a new baby or looking at a beautiful sunset.

- **Connectedness**—being *intrapersonally* connected within oneself; *interpersonally* connected with others and the environment; and *transpersonally* connected with God or an unseen higher power. Through connectedness patients move beyond the stressors of everyday life and find comfort, faith, hope, and empowerment (Hakanson and Ohlen, 2016).
- **Faith**—allows people to have firm beliefs despite lack of physical evidence. Faith enables people to believe in and establish transpersonal connections. Although many people associate faith with religious beliefs, it also exists without them (Christman and Mueller, 2017). For example, one might have faith that all people are good, without being a practitioner of a religion.
- **Hope**—has several meanings that vary on the basis of how it is being experienced; it usually refers to an energizing source that has an orientation to future goals and outcomes (Griggs and Walker, 2016).
- **Inner strength and peace**—spirituality gives people the ability to find a dynamic and creative sense of *inner strength* to use when making difficult decisions. This source of energy helps people stay open to change and life challenges, provides confidence in decision making, and promotes connections with others and a positive outlook on life (Boman et al., 2017). *Inner peace* fosters calm, positive, and peaceful feelings despite life experiences of chaos, fear, and uncertainty. These feelings help people feel comforted even in times of great distress (Hatamipour et al., 2015).
- **Meaning and purpose in life**—spirituality also helps people find *meaning and purpose* in both positive and negative life events (Dobratz, 2016; Hatamipour et al., 2015).

Spirituality is an integrating theme. A person's concept of spirituality begins in childhood and continues to grow throughout adulthood. It represents the totality of one's being, serving as the overriding perspective that unifies the various aspects of an individual. It spreads through all dimensions of a person's life, whether or not the person acknowledges or develops it.

Spiritual Well-Being

The concept of **spiritual well-being** has multiple dimensions. The common dimensions of spiritual well-being include meaning and purpose, a sense of peace or fulfillment, and connectedness with others and God or a higher power ([Bai et al., 2016](#)). Those who experience spiritual well-being feel connected to others and are able to find meaning or purpose in their lives. Those who are spiritually healthy experience joy, are able to forgive themselves and others, accept hardship and mortality, and report an enhanced quality of life ([Haugan et al., 2014](#); [Cottrell, 2016](#)).

Faith

In addition to being a component of spirituality, the concept of faith has other definitions. It is a cultural or institutional religion such as Judaism, Buddhism, Islam, or Christianity. It is also a relationship with a divinity, higher power, or spirit that incorporates a reasoning faith (belief) and a trusting faith (action). Reasoning faith provides confidence in something for which there is no proof. It is an acceptance of what reasoning cannot explain. Sometimes faith involves a belief in a higher power, spirit guide, God, or Allah. It is also the way a person chooses to live. It gives purpose and meaning to an individual's life, allowing for action.

Religion

Religion is associated with the "state of doing," or a specific system of practices associated with a particular denomination, sect, or form of worship. It is a system of organized beliefs and worship that a person practices to outwardly express spirituality. Many people practice a faith or belief in the doctrines and expressions of a specific religion or sect, such as the Lutheran church or Judaism. People from different religions view spirituality differently. For example, a Buddhist believes in Four Noble Truths:

1. Life is suffering.
2. Suffering is caused by karma and disturbing emotions.
3. Suffering can be eliminated by eliminating karma and disturbing emotions.
4. To eliminate karma, disturbing emotions, and suffering, one follows an eightfold path (i.e., right understanding, intention, speech, action, livelihood, effort, mindfulness, and concentration) ([Rinpoche, 2017](#)).

A Buddhist turns inward, valuing self-control, whereas a Christian looks to the love of God to provide enlightenment and direction in life.

When providing spiritual care, it is important to understand the differences between religion and spirituality. Many people tend to use the terms interchangeably. Although closely associated, they are not synonymous. Religious practices encompass spirituality, but spirituality does not need to include religious practice. Religious care helps patients maintain their faithfulness to their belief systems and worship practices. Spiritual care helps people identify meaning and purpose in life, look beyond the present, and maintain personal relationships and a relationship with a higher being or life force.

Hope

A spiritual person's faith brings hope. When a person has the attitude of something to live for and look forward to, hope is present. It is a multidimensional concept that provides comfort while people endure life-threatening situations, hardships, and other personal challenges. Hope is closely associated with faith; it is energizing and motivates people to achieve goals, such as adopting healthy behaviors. People express hope in all aspects of their lives to help them deal with life stressors. It is a valuable personal resource whenever someone is facing a loss (see [Chapter 36](#)) or a difficult challenge ([Griggs and Walker, 2016](#)).

Spiritual Health

People gain spiritual health by finding a balance between their values, goals, and beliefs and their relationships within themselves and others. Throughout life a person often grows more spiritual, becoming increasingly aware of the meaning, purpose, and values of life. In times of stress, illness, loss, or recovery, a person uses previous ways of responding or adjusting to a situation. Often these coping styles lie within a person's spiritual beliefs.

Spiritual beliefs change as patients grow and develop ([Table 35.1](#)). Spirituality begins as children learn about themselves and their relationships with others, including a higher power. Nurses who understand a child's spiritual beliefs are able to care for and comfort the child ([Johnston Taylor et al., 2015](#)). As children mature into adulthood, they experience spiritual growth by entering into lifelong relationships with people who share similar values and beliefs.

TABLE 35.1**Relationship Between Developmental Stage and Spirituality**

Erickson's Developmental Stage	Spiritual Beliefs
Trust vs. Mistrust Birth to 18 months	Spiritual well-being provided by parents Trust provides basis for hope Love, affection, security, and a stimulating environment promote spirituality
Autonomy vs. Shame and Doubt 20-36 months	Fascination with magic and mystery Often believes that illness is related to bad behavior Begins to learn the difference between right and wrong Imitates parents' spiritual or religious actions; recites prayers and sings simple religious songs, but does not understand their meanings Interprets meanings literally
Initiative vs. Guilt 3-6 years	Feels guilty when not acting responsibly Influenced by spiritual and religious stories, examples, moods, and actions Models moral behaviors of parents Begins to ask about God or supreme beings
Industry vs. Inferiority 6-12 years	Wants to learn about spirituality Has a clear picture of God or supreme being, morality, and the difference between right and wrong Sorts fantasy from fact Demands proof of reality and believes literal meanings of spiritual stories
Identity vs. Identity Confusion Adolescence	Reflects on inconsistencies in stories Begins to question spiritual practices, forms own opinions, and occasionally discards parents' beliefs Abstract reasoning leads to exploration of moral issues Spirituality comes from connectedness with family, nature, and God or a supreme being
Intimacy vs. Isolation and Loneliness Young adulthood	Establishes self-identity and world view Forms independent beliefs, attitudes, and lifestyles Uses principles to solve problems when individual's and society's rules conflict
Generativity vs. Stagnation Middle-age adulthood	Develops appreciation of past spiritual experiences Embraces people from different faiths and religions Reviews value system during crisis Values others
Ego identity vs. Despair and Disgust Older adulthood	Values love and interactions with others Focuses on overcoming oppression and violence Beliefs vary based on many factors such as gender, past experiences, religion, economic status, and ethnic background

Data from Edelman CL, Mandle CL: *Health promotion throughout the life span*, ed 8, St Louis, 2014, Elsevier; and Hockenberry MJ, et al: *Wong's nursing care of infants and children*, ed 11, St Louis, 2019, Elsevier.

Beliefs among people vary on the basis of cultural factors such as gender, past experience, religion, ethnicity, and economic status. Healthy spirituality in older adults gives peace and acceptance of the self and is often the result of a lifelong connection with a higher power. Illness and loss sometimes threaten and challenge the spiritual developmental process. Older adults often express their spirituality by turning to important relationships and giving of themselves to others (Touhy and Jett, 2018).

Factors Influencing Spirituality

When illness, loss, grief, or a major life change occurs, people either use spiritual resources to help them cope and search for meaning, or spiritual needs and concerns develop. **Spiritual distress** is “a disruption in the life principle that pervades a person’s entire being and transcends the person’s biologic and psychosocial nature” (Andrews and Boyle, 2016, p. 399). It causes people to question their identity and feel doubt, loss of faith, and a sense of being alone or abandoned. Individuals often question their spiritual values or the meaning of life, raising questions about their way of life, purpose for living, and source of meaning (Connerton and Moe, 2018). Spiritual distress also occurs when there is conflict between a person’s beliefs and prescribed health regimens or the inability to practice usual rituals.

Acute Illness

Sudden, unexpected illness often creates spiritual distress. For example, both a 50-year-old patient who has a heart attack and a 20-year-old patient who is in a motor vehicle accident face crises that threaten spiritual health. The sudden illness or injury creates an unanticipated scramble to integrate and cope with new realities (e.g., disability). People often look for ways to remain faithful to their beliefs and value systems. Some pray, attend religious services more often, or spend time reflecting on the positive aspects of their lives. Often conflicts develop around a person’s beliefs and the meaning of life. Anger is common; sometimes patients express it against God or a higher power, their families, themselves, and their nurses or other health care providers. The strength of patients’ spirituality influences their ability to cope with and recover from sudden illness or injury. Having a better understanding of your patients’ illnesses and conditions helps you spiritually support them (Sweat, 2015). Nurses play a key role in helping patients resolve feelings of spiritual distress. Nurses

create a healing environment and maximize recovery by enhancing patients' spiritual well-being (Estores and Frye, 2015)

Chronic Illness

Many chronic illnesses threaten a person's independence, causing fear, anxiety, and spiritual distress. Dependence on others for routine self-care needs often creates feelings of powerlessness. Powerlessness and the loss of a sense of purpose in life impair the ability to cope with alterations in functioning. Spirituality is an important dimension of how patients adapt to and live with chronic illness. Successfully adapting to these changes strengthens a person spiritually, but it sometimes takes a long-term plan to help a patient with a chronic illness achieve spiritual well-being. As a nurse, you are in a unique position to help patients reevaluate their lives and achieve spiritual health (Box 35.1). Successful adaptation provides spiritual growth. Patients who have a sense of spiritual well-being feel connected with a higher power, are able to find meaning and purpose in life, and are better able to cope with and accept their chronic illness (Carron, 2016). Exploring the meaning of pain and suffering with patients allows you to provide spiritual support during their illnesses (Sweat, 2015).

Box 35.1 Evidence-Based Practice **Spiritual**

Interventions and Patient Outcomes

PICOT Question: Does the use of spiritual care interventions among adults improve patient outcomes?

Evidence Summary

Nursing care for patients needs to focus on mind, body, and spirit. It is important to include spiritual interventions in a patient's plan of care that will help to relieve spiritual distress and enhance spiritual well-being (Ricci-Allegra, 2018). Providing spiritual care to patients helps the patient cope with illness and therapies (Trevino and McConnell, 2015).

Researchers have found that the use of spiritual interventions helps to decrease anxiety and reduce depression in patients with cancer and heart failure (Pantuso, 2015; Heo et al., 2018). Both verbal communication and nonverbal communication, such as presence, are useful when providing spiritual care to patients (Minton et al., 2018). The use of a spiritual care board allowing patients to express their feelings helped patients cope with

their illnesses and feel at peace (Berning et al., 2016). Before providing spiritual care to patients, it is important for nurses to assess for patients' cues to respect patient beliefs and autonomy (Ebrahimi et al., 2017).

Application to Nursing Practice

- Use active listening and therapeutic communication to develop rapport with your patients (Bone et al., 2018).
- Offer to pray or read scripture with patients (Minton et al., 2018).
- Turn on a patient's favorite religious music station or television channel (Abuatiq, 2015).
- Conduct a spiritual assessment or history from each of your patients (Pantuso, 2015).
- Be nonjudgmental in your assessment and care of patients, showing respect for each patient's spiritual beliefs (Ebrahimi et al., 2017).
- Offer to contact pastoral care or the chaplain for patients (Bone et al., 2018).

Terminal Illness

Dying is a holistic process encompassing a patient's physical, social, psychological, and spiritual health (Finocchiaro, 2016). Terminal illness causes fears of physical pain, loss of independence, isolation, the unknown, and dying. It creates an uncertainty about what death means, making patients susceptible to spiritual distress. However, some patients have a spiritual sense of peace that enables them to face death without fear. Spirituality helps these patients find peace in themselves and their death. Individuals experiencing a terminal illness find themselves reviewing life and questioning its meaning. Those who struggle ask common questions, such as "Why is this happening to me?" or "What have I done?" Terminal illness affects family and friends as well. It causes members of the family to ask important questions about its meaning and how it will affect their relationship with the patient (see [Chapter 36](#)). When caring for dying patients, help them gain a greater sense of control over their illness, whether they are in a health care setting (e.g., the hospital) or at home.

Near-Death Experience

Some nurses care for patients who have had a near-death experience (NDE). An NDE is a psychological phenomenon of people who either have

been close to clinical death or have recovered after being declared dead. It is not associated with a mental disorder. Instead experts agree that NDE describes a powerfully close brush with physical, emotional, and spiritual death. For example, people who have an NDE after cardiopulmonary arrest often tell the same story of feeling themselves rising above their bodies and watching caregivers initiate lifesaving measures. Commonly, patients who have had an NDE describe it as feeling totally at peace, having an out-of-body experience, being pulled into a dark tunnel, seeing bright lights, and meeting people who preceded them in death ([Martial et al., 2017](#)). Instead of moving toward the light, they learn that it is not time for them to die, and they return to life ([Johnson, 2015](#); [Rawlings and Devery, 2015](#)).

Patients who have an NDE may be reluctant to discuss it, thinking family or caregivers will not understand. A nurse's acceptance and response to the patient's report of the NDE impacts how much the patient shares about the experience ([Rawlings and Devery, 2015](#)). NDEs are often transformational and can be either positive or negative experiences ([Johnson, 2015](#)). However, individuals experiencing an NDE who discuss it openly with family or caregivers find acceptance and meaning from this powerful experience ([Rawlings and Devery, 2015](#)). They are often no longer afraid of death, and they have a decreased desire to achieve material wealth. They also report increased sensitivity to different chemicals such as alcohol and medications. After patients have survived an NDE, promote spiritual well-being by remaining open, giving patients a chance to explore what happened, and supporting them as they share the experience with significant others ([Rawlings and Devery, 2015](#)).

Critical Thinking

Successful critical thinking requires a synthesis of knowledge, experience, information gathered from patients, critical thinking attitudes, and intellectual and professional standards. Clinical judgments require you to anticipate information, analyze the data, and make decisions regarding your patient's care. During assessment, consider all elements that build toward making an appropriate nursing diagnosis ([Fig. 35.2](#)).

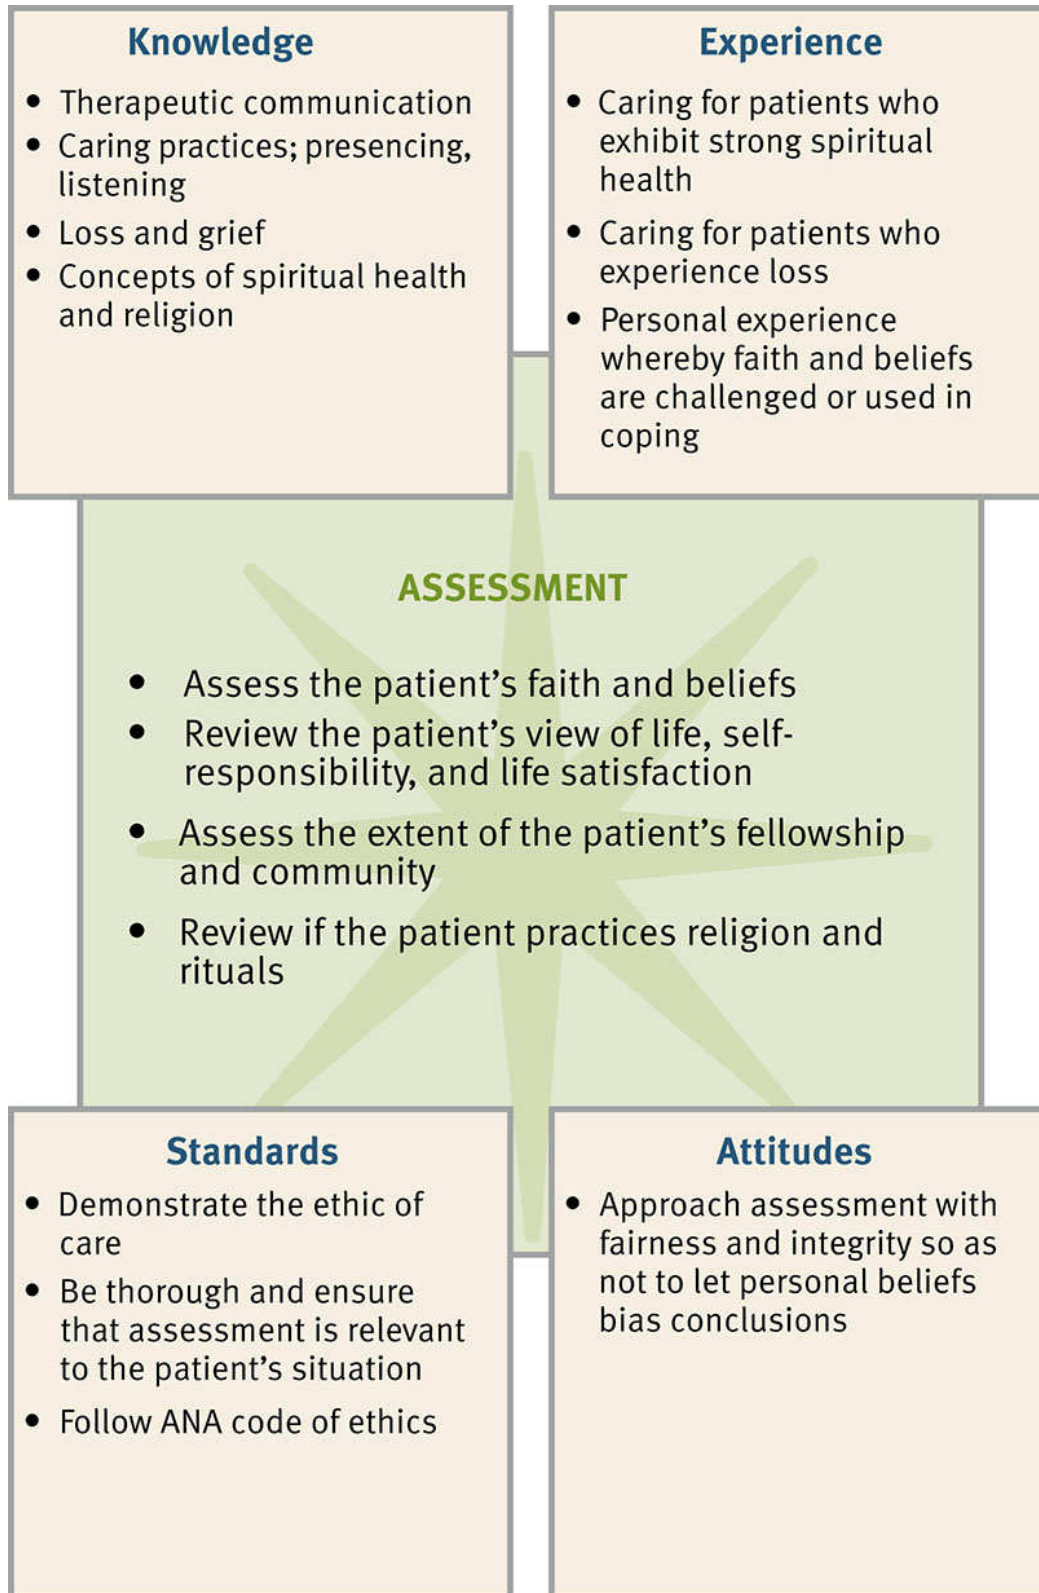

FIG. 35.2 Critical thinking model for spiritual health assessment. ANA, American Nurses Association.

The helping role is important in nursing practice. Patients look to nurses for help that is different from the help they seek from other health care professionals. Expert nurses acquire the ability to anticipate personal issues affecting patients and their spiritual well-being. Critical thinking and the application of knowledge and skills help nurses enhance patients' spiritual well-being and health. Nurses who are comfortable with their own spirituality often are more likely to care for their patients' spiritual needs. Beliefs of a health care provider affect the discussion of treatment options with patients and ultimately their health care choices (Delgado, 2015). There are nurses who feel strongly about providing spiritual care as part of their holistic practice. Nurses who foster their own personal, emotional, and spiritual health become resources for their patients and use their own spirituality as a tool when caring for themselves and their patients.

After becoming comfortable with your own spirituality (e.g., knowing your belief system, following practices that strengthen your meaning and purpose in life), use your nursing knowledge to anticipate your patients' personal issues and the resulting effect on spiritual well-being. Your knowledge about the concept of spirituality, your understanding of ethics (see Chapter 22), and your knowledge of a patient's faith and belief systems help to provide appropriate spiritual care. Knowledge of a patient's values, beliefs, preferences, and needs provides insight into a person's spiritual practices. Application of therapeutic communication principles (see Chapter 24) and caring principles (see Chapter 7) helps you establish therapeutic trust with patients. An individual's spiritual beliefs are very personal. When you integrate patient preferences, values, and beliefs into spiritual care, you provide patient-centered care with sensitivity and respect for the diversity of human experience (QSEN Institute, 2018).

Personal experience in caring for patients in spiritual distress is valuable when helping them identify coping options. You need to determine whether your spirituality is beneficial in assisting patients. Nurses who sense a personal faith and hope regarding life may be better able to help their patients. A nurse learns from his or her personal faith system and previous professional experiences how to provide spiritual care comfortably (Delgado, 2015).

Because each person has a unique spirituality, know your own beliefs so that you can care for each patient without bias (Delgado, 2015). Use critical thinking when assessing each patient's reaction to illness, injury, and loss and determining whether spiritual intervention is necessary. Humility is

essential, especially when caring for patients from diverse cultural backgrounds. Recognize personal limitations in knowledge about patients' spiritual beliefs and religious practices. Effective nurses show genuine concern as they assess their patients' beliefs and determine how spirituality influences their patients' health. You demonstrate integrity by refraining from voicing your opinions about religion or spirituality when your beliefs conflict with those of your patients.

The application of intellectual standards helps you make accurate clinical decisions and helps patients find meaningful and logical ways to acquire spiritual wellness. Critical thinking ensures that you obtain significant and relevant information when assessing and making decisions about patients' spiritual needs. Avoid making assumptions about their religion and beliefs. Significance and relevance are standards of critical thinking that allow you to explore the issues that are most meaningful to patients and most likely to affect spiritual well-being.

In setting standards for quality health care, [The Joint Commission \(TJC\) \(2017\)](#) requires health care organizations to acknowledge patients' rights to spiritual care and to provide for patients' spiritual needs through pastoral care or others who are certified, ordained, or lay individuals. The standards also require that you assess patients' beliefs and spiritual practices. The [HealthCare Chaplaincy Network \(2016\)](#) has developed evidence-based structural and process indicators and outcome metrics for quality spiritual care.

The [American Nurses Association Code of Ethics for Nurses \(2015\)](#) requires nurses to practice nursing with compassion and respect for the inherent dignity, worth, and uniqueness of every person. It is essential to promote an environment that respects patients' values, customs, and spiritual beliefs. Routinely implementing standard nursing interventions such as prayer or meditation is coercive and unethical. Therefore, determine which interventions are compatible with your patient's beliefs and values before selecting them based on patient input. An ethic of caring (see [Chapter 7](#)) provides a framework for decision making and places the nurse as the patient's advocate.

REFLECT NOW

Consider your own spiritual beliefs and spiritual health. How do your own spiritual beliefs and spiritual health impact the care you provide your patients?

◆ Nursing Process

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to use to develop and implement an individualized plan of care. Understanding a patient's spirituality and then appropriately identifying the level of support and resources needed require a broad perspective and an open mind. As a nurse you are ethically responsible for meeting the spiritual needs of your patients. People experience the world and find meaning in life differently. Application of the nursing process from the perspective of a patient's spiritual needs is not simple. It goes beyond assessing his or her religious practices. Caring for your patients' spiritual needs requires you to be compassionate and remove any personal biases or misconceptions. Be willing to share and discover their meaning and purpose in life, illness, and health. Identify common values and respect unique commitments and values with your patients by having quiet conversations, listening effectively, and communicating using presence and touch when appropriate (Delgado, 2015).

◆ Assessment

During the assessment process thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care. Because completing a spiritual assessment takes time, conduct an ongoing assessment over the course of a patient's stay in the health care setting if possible. Convey caring in your manner and communication style. Caring is conveyed by knowing your patient's cultural values and beliefs; respecting privacy, diversity and individual needs; and interacting and listening to the patient and his or her family (Darnell and Hickson, 2015). Be open to successfully promoting an honest discussion about each patient's spiritual beliefs. Your spiritual assessment will reveal the patient's beliefs about life, health, and a Supreme Being or power.

Through the Patient's Eyes

It is essential to take the time to assess a patient's viewpoints and establish a trusting relationship. Talking about spirituality with a patient helps build a trusting relationship that often leads to conversations about spirituality and health outcomes (Carson, 2017). As you and your patients reach a point of learning together, spiritual caring occurs. Be sure to

discuss what is meaningful and relevant to your patients. Encourage them to discuss their personal beliefs and faith traditions. Explore the meaning that their illnesses have in their lives, based on their faith beliefs. Discover the patients' expectations by asking questions such as "How can we best partner with you to meet your spiritual needs while you are here?" "What is important to you spiritually?" "Are there particular religious or prayer practices that are important for you to continue while you are in the hospital?" "Are there special practices that help you manage your illness or pain?" or "Is there anyone we can call who is a source of strength, support, or comfort for you?" Conducting an assessment is therapeutic for you and your patients because it conveys a level of caring and support from the nurse to the patient ([ANA, APA, and ISPN, 2014](#)).

Assessment Tools

Listening to a patient's story is an essential method for obtaining a spiritual assessment. However, you can assess your patients' spiritual health in several different ways, using open-ended questions to prompt them to tell their story or asking them direct questions ([Box 35.2](#)). Focus your assessment on aspects of spirituality most likely to be influenced by life experiences, events, and questions in the case of illness and hospitalization. Asking direct questions requires you to feel comfortable in asking others about their spirituality. Some health care agencies and researchers have created assessment tools to clarify patients' values and to assess their level of spirituality. For example, the spiritual well-being (SWB) scale has 20 questions that assess a patient's relationship with God and his or her sense of life purpose and life satisfaction ([Life Advance, 2009](#)). The FICA assessment tool ([Borneman et al., 2010](#); [Puchalski and Romer, 2000](#)) evaluates spirituality and is closely correlated to quality of life. FICA stands for the following criteria:

Box 35.2 Nursing Assessment Questions

Spirituality and Spiritual Health

- Which experiences in the past have been most difficult for you?
- What gives you hope during those difficult times?
- Which aspects of your spirituality have been most helpful to you?

- Which aspects of your spirituality would you like to discuss?

Faith, Belief, Fellowship, and Community

- To what or whom do you look as a source of strength, hope, or faith in times of difficulty?
- How does your faith help you cope?
- What can I do to support your religious beliefs or faith commitment? Would you like me to pray with you or perhaps read from the Koran or Bible?
- What gives your life meaning?

Life and Self-Responsibility

- How do you feel about the changes this illness has caused?
- How do these changes affect what you now need to do?

Life Satisfaction

- How happy or satisfied are you with your life?
- Which accomplishments help you feel satisfied with your life?
- What is it that makes you feel dissatisfied?

Connectedness

- What feelings do you have after you pray or meditate?
- Who do you feel is the most important person in your life?

Vocation

- How has your illness affected the way you live your life spiritually at home or where you work?
- In what way has your illness affected your ability to express what is important in life to you?

- F—Faith or belief
- I—Importance and Influence
- C—Community
- A—Address (interventions to address)

Effective assessment tools such as the SWB scale and FICA help you remember important areas to assess. Patient responses to the assessment items on the tools indicate areas that you need to investigate further. For example, if, after using the FICA tool with a young man who is having difficulty accepting a new diagnosis of prostate cancer, you find out that he does not want you or his pastor to help him address this issue, you need to spend time understanding how the patient plans to manage this new illness. Remember, when using any spiritual assessment tool, do not impose your personal values on your patient. Be careful about making false assumptions about your patients' beliefs based on your personal values and beliefs. When you understand the overall approach to spiritual assessment, you are able to enter into thoughtful discussions with patients, gain a greater awareness of the personal resources they bring to a situation, and incorporate the resources into an effective plan of care.

Faith/Belief

When assessing a patient's faith, first determine his or her beliefs, especially those that influence hope. For example, ask how a patient believes a chemotherapy drug will affect a newly diagnosed form of cancer. Ask the patient whether he or she believes in the skill or competence of his or her physician. Determine which of your patient's beliefs guide him or her to find meaning in life events and to thus make decisions. Ask your patient whether he or she is able to live according to his or her beliefs. Finally, assess to what extent your patient interrelates with self, others, and/or a source of authority. Faith in an authority (such as a health care provider or senior family member) provides a sense of confidence that guides a person in exercising beliefs and experiencing growth. Assess a person's faith in an authority by asking "To whom do you look to for guidance in life?" The patient's response to an open-ended question such as this is likely to open the door for a meaningful discussion. Listen carefully and explore what is meaningful to the patient.

Determine whether a patient has a religious source of guidance that conflicts with medical treatment plans and affects the options that nurses and other health care providers are able to offer patients. For example, if a patient is a Jehovah's Witness, blood products are not an acceptable form

of treatment ([Jehovah's Witnesses, 2019](#)). Christian Scientists may refuse any medical intervention, believing that their faith heals them. It is also important to understand a patient's philosophy of life. Your assessment should reveal the basis of the patient's belief system regarding meaning and purpose in life and the patient's spiritual focus. Asking a patient "Describe for me what is most important in your life" or "Tell me what gives your life meaning or purpose" helps to assess the basis of his or her spiritual belief system. This information often reflects the impact that illness, loss, or disability has on a person's life. Considerable religious diversity exists in the United States. A patient's religious faith and practices, views about health, and the response to illness influence how nurses provide support.

Life and Self-Responsibility

Spiritual well-being includes life and self-responsibility. Individuals who accept change in life, make decisions about their lives, and are able to forgive others in times of difficulty have a higher level of spiritual well-being. During illness patients often are unable to accept limitations or do not know how to regain a functional and meaningful life. Their feelings and struggles often reflect spiritual distress. However, they often use their spiritual well-being as a resource for adapting to changes and dealing with limitations. Assess the extent to which a patient understands the limitations or threats posed by an illness (e.g., activity restriction, sexual intimacy with a partner, risk of medical complications) and the manner in which he or she chooses to adjust to them. Ask, "Tell me how you feel about the changes caused by your illness" and "How do these changes affect what you now need to do?"

Connectedness

People who are connected to themselves, others, nature, and God or another Supreme Being usually report higher levels of physical and emotional health ([Hakanson and Ohlen, 2016](#)). One way patients remain connected is by praying ([Fig. 35.3](#)). Prayer is personal communication with one's higher power that provides a sense of hope, strength, security, and well-being; it is a part of faith. Patients often use prayer when other treatments are ineffective, when they are experiencing fear or anxiety, or when they feel that they have no control over what is happening to them ([Christensen et al., 2018](#); [O'Brien, 2014](#)). Help patients become or remain connected by respecting each patient's unique sense of spirituality. Assess

a patient's connectedness by asking open-ended questions: "Whom do you believe is the most important person in your life?" "In what way do you stay connected spiritually?" "Is prayer something helpful to you?" or "What feeling do you have after you pray?"

FIG. 35.3 Praying keeps individuals connected to their God.

Life Satisfaction

Spiritual well-being is tied to a person's satisfaction with life and what he or she has accomplished, even in the case of children (Dobratz, 2016). When people are satisfied with life and how they are using their abilities, more energy is available to deal with new difficulties and resolve problems. You assess a patient's satisfaction with life by asking questions such as "How happy or satisfied are you with your life?" or "Tell me how satisfied you feel about what you have accomplished in life" or "Describe what makes you feel dissatisfied with your life."

Culture

Spirituality is a personal experience within a cultural context. It is important to know a patient's cultural background and assess his or her values about the health care problem and impending treatment (see [Chapter 9](#)). It is common in many cultures for individuals to believe that they have led a worthwhile and purposeful life. Remaining connected with their cultural heritage often helps patients define their place in the world and express their spirituality. Asking them about their faith and belief systems is a good beginning for understanding the relationship between culture and spirituality ([Box 35.3](#)).

Box 35.3 Cultural Aspects of Care Spirituality and Culture

Spirituality and spiritual health vary among cultures. Remember that a person's culture is defined by his or her age, gender, social position, political association, religion, or other variables such as ethnicity and educational background. One's culture influences religious practices as well as beliefs about health and illness. One way to assess a patient's spirituality through a cultural lens is to first understand his or her definition of health, wellness, and illness. For example, ask questions such as "What do you call your health problem?" "What do you think has caused it?" "What do you think your sickness does to you?" and "How do you find strength to cope with this problem?"

You want to assess how a patient's spirituality is affected by his or her culture. If your focus is on a patient's ethnicity, know the unique characteristics of that ethnic group's spiritual values. Ethnicity impacts culturally significant events such as birth, death, puberty, childbearing, child rearing, and illness and death (Giger, 2018). There are often rituals tied to spirituality and religion for events such as weddings, funerals, and holidays (Giger, 2018). Many cultures have treatments for illness and disease that are rooted in folk medicine, holistic care, or spiritual interventions

Implications for Patient-Centered Care

- Explore the spirituality of patients from different cultural backgrounds; assess the meaning of health and how patients achieve balance, stability, peace, or comfort in their lives.

- Offer a universal and holistic approach when assessing patients' needs (see Chapter 9); demonstrate cultural competence and use therapeutic communication techniques.
- During assessment respect patients' human rights, values, customs, and spiritual beliefs (see Chapter 9).
- Spiritual assessment should be interprofessional. If you feel uncomfortable with religion or spirituality, respectfully identify whether a patient wishes referral to an appropriate professional chaplain or clergy.
- Avoid use of language that alienates or discriminates among different cultures and belief systems.
- Use a professional interpreter if necessary.

Fellowship and Community

Fellowship is one kind of relationship that an individual has with other people, including immediate family, close friends, associates at work or school, fellow members of a place of worship, and neighbors. More specifically, this includes the extent of the community of shared faith between people and their support networks. Many times social support from faith-based groups helps patients cope with illness and participate in health promotion behaviors (Plunkett et al., 2015). To assess a patient's supportive community, ask questions such as "Who do you find to be the greatest source of support in times of difficulty?" or "When you've faced difficult times in the past, who has been your greatest resource?"

Explore the extent and nature of a person's support networks and their relationship with the patient. It is unwise to assume that a given network offers the kind of support that a patient desires. For example, calling a patient's pastor to request a visit is inappropriate if the patient has little fellowship with the pastor or the pastor's faith community. Does the patient have one significant fellowship or several? What level of support does the community give? Do they visit, say prayers, or support the patient's immediate family? Learn whether openness exists between a patient and the people with whom a fellowship has formed.

Ritual and Practice

Assessing the use of rituals and practices helps you understand a patient's spirituality. Rituals include participation in worship, prayer, sacraments (e.g., baptism, Holy Eucharist), fasting, singing, meditating, scripture

reading, and making offerings or sacrifices. Different religions have different rituals for life events. For example, Buddhists practice baptism later in life and find burial or cremation acceptable at death. Followers of Islam practice Salah, the second of the Five Pillars of Islam, requiring all Muslims who have reached puberty to worship five times daily, facing the holy city of Mecca. Orthodox and conservative Jews circumcise their newborn sons 8 days after birth. Determine whether illness or hospitalization has interrupted a patient's ability to follow usual rituals or practices. A ritual often provides the patient with structure and support during difficult times. If rituals are important to a patient, use them as part of nursing intervention.

Vocation

Individuals express their spirituality on a daily basis in life routines, work, play, and relationships. It is often a part of a person's identity and vocation. Determine whether illness, injury, or hospitalization alters the ability to express some aspect of spirituality as it relates to the person's work or daily activities. Expression of spirituality includes showing an appreciation for life in the variety of things people do, living in the moment and not worrying about tomorrow, appreciating nature, expressing love toward others, and being productive. When illness or loss prevents patients from expressing their spirituality, understand the psychological, social, and spiritual implications and provide appropriate guidance and support. Questions to ask include, "How has your illness affected the way you live your life spiritually at home or where you work?" or "How has your illness affected your ability to express what's important in life for you?"

Building Competency in Patient-Centered Care

You are caring for Amanda, a 32-year-old who experienced a miscarriage at 14 weeks' gestation. Amanda and her husband have been trying to get pregnant with their second child. They have a 4-year-old son at home. This is the second miscarriage that Amanda has experienced. When you walk into Amanda's room, she is staring out the window and does not turn her head. You can tell that she has been crying. She has a flat affect

and states, “I just don’t know why God did this to me again. How am I going to go on from here?”

Identify at least three questions you will ask Amanda to assess her spiritual well-being and plan effective, patient-centered care.

REFLECT NOW

Consider how your own spiritual and religious beliefs influence your assessment of your patients’ spiritual health. In what ways are you most effective; least effective?

• Nursing Diagnosis

A spiritual assessment allows a nurse to learn a great deal about a patient and the extent that spirituality plays in his or her life. Exploring a patient’s spirituality sometimes reveals responses to health problems that require nursing intervention or the existence of a strong set of resources that allow the patient to cope effectively. Analyze data to find risk factors or patterns of assessment findings, and select appropriate nursing diagnoses ([Box 35.4](#)). In identifying diagnoses, recognize the significance that spirituality has for all types of health problems. Ensure that each negative or problem-focused nursing diagnosis has an accurate related factor to guide the selection of individualized, purposeful, and goal-directed interventions ([Herdman and Katmisuru, 2018](#)). Examples of nursing diagnoses that apply to spiritual health include the following:

Box 35.4 Nursing Diagnostic Process **Decreased Spiritual Distress**

Assessment Activities	Assessment Findings
Ask patient to describe personal source of faith and hope.	Patient expresses inner strength and source of guidance.
Have patient describe level of satisfaction with life.	Life has purpose and meaning; patient finds satisfaction while providing community service as a volunteer.
Determine who provides greatest source of strength and support to patient during times of difficulty.	Patient pursues interactions with friends and family.

- *Risk for Spiritual Status*
- *Decreased Spiritual Distress*
- *Hopelessness*
- *Powerlessness*
- *Spiritual Distress*

Decreased Spiritual Distress is based on assessment findings that show a person's ability to experience and integrate meaning and purpose in life through connectedness with self and others. A patient with this nursing diagnosis has potential resources on which to draw when faced with illness or a threat to well-being.

The nursing diagnosis *Spiritual Distress* creates a different clinical picture. Assessment findings reveal patterns that reflect a person's actual or potential dispiritedness (e.g., expressing lack of hope, meaning, or purpose in life; expressing anger toward God; or verbalizing conflicts about personal beliefs). Patients likely to experience spiritual distress include those who have poor relationships, have experienced a recent loss, or are suffering some form of mental or physical illness.

Accurate selection of diagnoses requires critical thinking. Review and analyze all concrete data (e.g., religious rituals and sources of fellowship), your assessment of previous patient experiences, your own spirituality, and your appraisal of the patient's spiritual well-being. Commonly patients have multiple nursing diagnoses.

• Planning

During the planning step of the nursing process, develop a plan of care for each of the patient's nursing diagnoses. Critical thinking at this step is important because you reflect on previous experiences and apply knowledge and critical thinking attitudes and standards in selecting the

most appropriate nursing interventions (Fig. 35.4). Prior experience with other patients is valuable when selecting interventions to support spiritual well-being. Integrate assessment data with knowledge about resources and therapies available for spiritual care to develop an individualized plan of care (see the [Nursing Care Plan](#)). Match the patient's needs with evidence-based interventions that are supported and recommended in the clinical and research literature. Use a concept map (Fig. 35.5) to organize patient care and show how the patient's medical diagnosis, assessment data, and nursing diagnoses are interrelated.

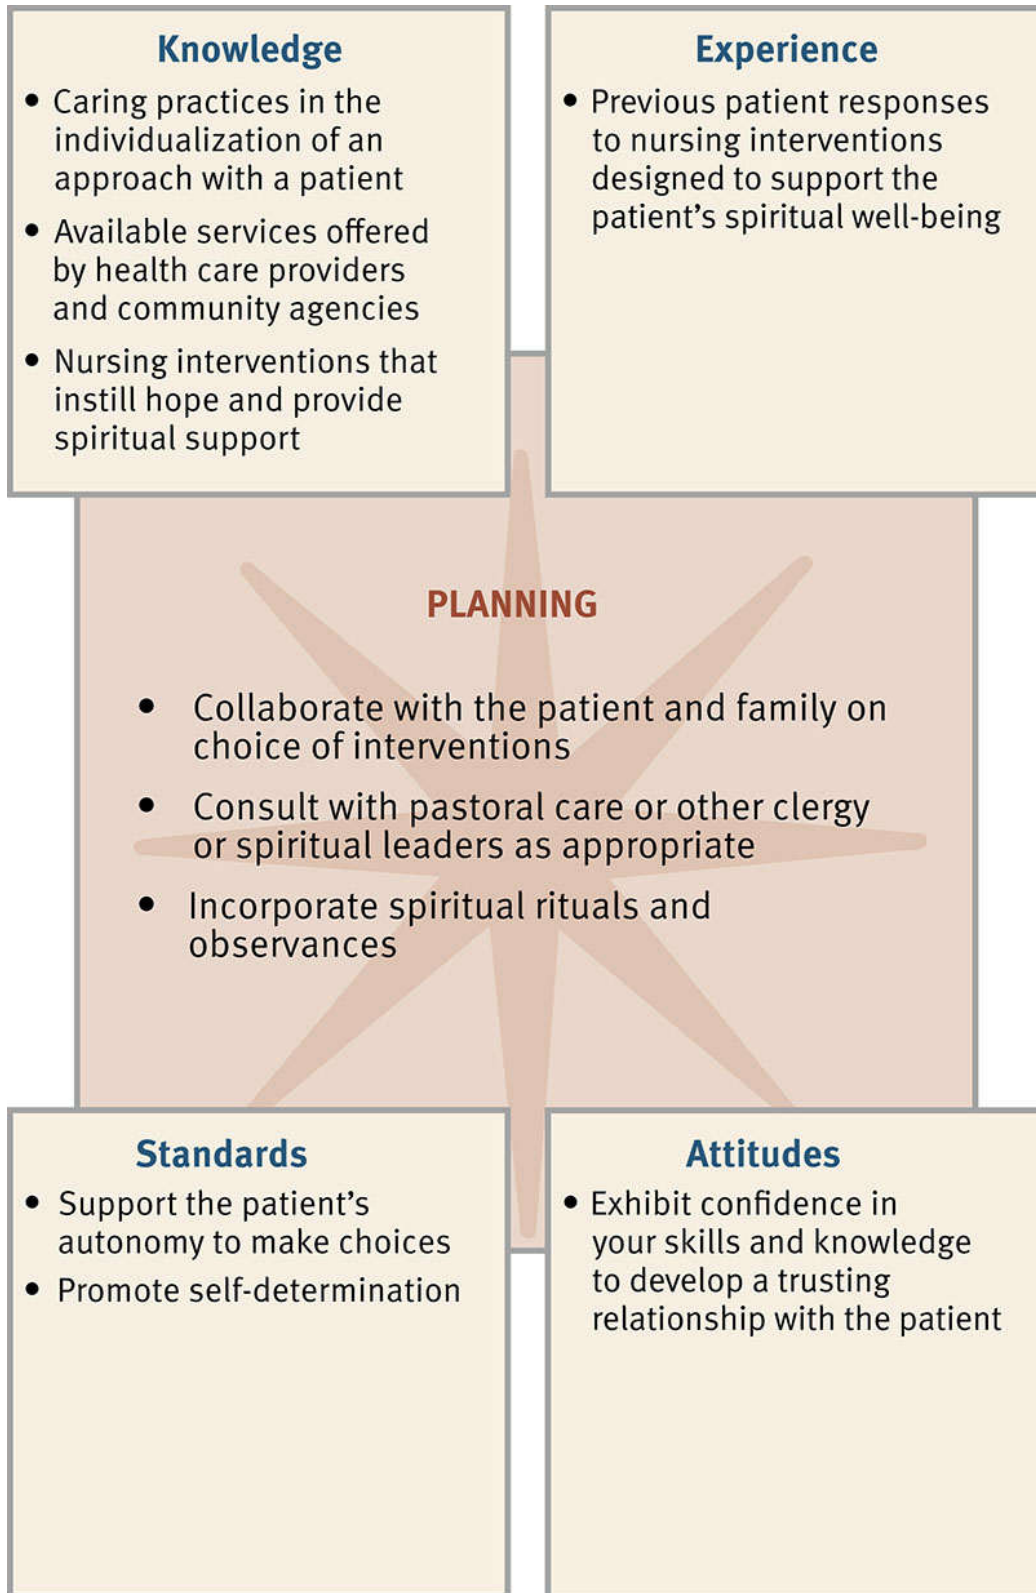

FIG. 35.4 Critical thinking model for spiritual health planning.

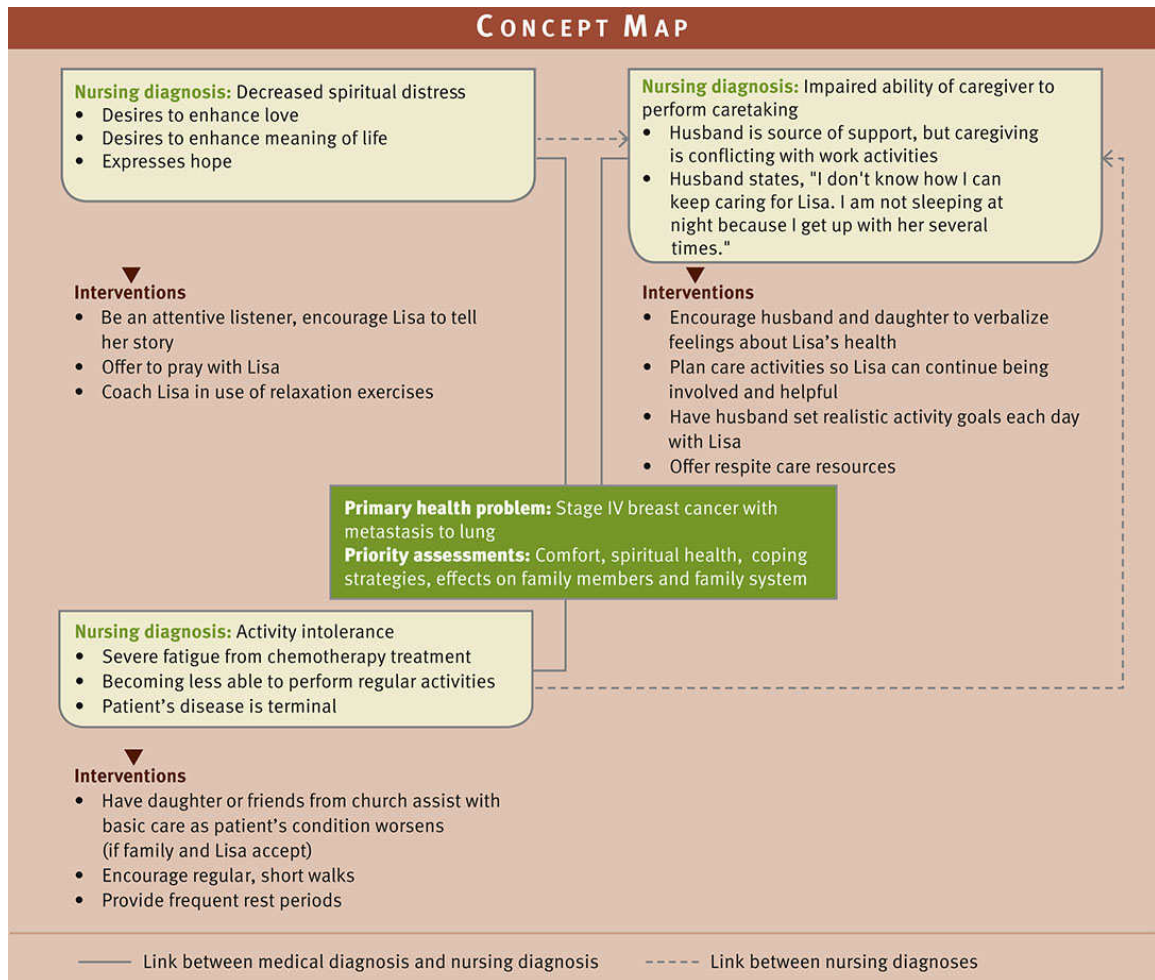

FIG. 35.5 Concept map for Lisa Owens.

Confidence, an important critical thinking attitude, builds trust, enabling you and a patient to enter into a healing relationship together. Attempting to meet or support patients' spiritual needs frequently requires the need of additional resources. Because spiritual care is so personal, standards of autonomy and self-determination are critical in supporting the patient's decisions about the plan of care.

Goals and Outcomes

A spiritual care plan includes realistic and individualized goals along with relevant outcomes. Goals for spiritual nursing care focus on helping patients integrate their own religious and spiritual beliefs with their health and illness states to give meaning to their lives (Andrews and Boyle, 2016). It is very important to collaborate closely with patients when setting goals for spiritual support and growth and choosing related interventions. Setting realistic goals requires you to know a patient well. When spiritual

care requires helping patients adjust to loss or stressful life situations, goals are long term. However, short-term outcomes such as renewing participation in religious practices help patients progressively reach a more spiritually healthy situation. In establishing a plan of care, an example of a goal and associated outcomes follows:

The patient will improve personal harmony and connections with members of his or her support system.

- The patient expresses an acceptance of illness.
- The patient reports the ability to rely on family members for support.
- The patient initiates social interactions with family and friends.

Setting Priorities

Spiritual care is very personalized. Your relationship with a patient allows you to understand the patient's priorities in the context of his or her spiritual life. When establishing a mutually agreed-on plan with the patient, he or she is able to identify what is most important. Spiritual priorities do not need to be sacrificed for physical care priorities. For example, when a patient is in acute distress, focus care to provide him or her a sense of control to minimize powerlessness. When a patient is terminally ill, spiritual care often is the most important nursing intervention in supporting patients and families in grief (see [Chapter 36](#)).

Teamwork and Collaboration

If a patient participates in an organized religion, with permission of the patient, involve members of the clergy or church, temple, mosque, or synagogue in the plan of care when appropriate. In a hospital setting the pastoral care department is a valuable resource. These spiritual care professionals offer insight about how and when to best support patients and their families. Spiritual care providers provide direct support in the form of actively addressing spiritual or religious needs of a patient and family, having discussions about family members' feelings and patient values, and reminiscing with families about a patient ([Veloza-Gomez et al., 2017](#)). Significant others such as spouses, siblings, parents, and friends need to be involved in the patient's care as appropriate. This means that you learn from an assessment which individuals or groups have formed a relationship with the patient and which ones the patient desires to involve. These individuals sometimes participate in all levels of the plan of care.

They often assist in giving physical care, providing emotional comfort, and sharing spiritual support.

• Implementation

After establishing a caring relationship with a patient and an individualized plan of care, you are able to implement a patient-centered care approach. Having a thorough understanding of a patient's spiritual needs enables you to deliver care in a sensitive, creative, and appropriate manner.

Health Promotion

Spiritual care needs to be a central theme in promoting an individual's overall well-being because of its importance in health promotion (Vlasblom et al., 2015). In settings where health promotion activities occur, patients often need information, counseling, and guidance to make the necessary choices to remain healthy.

Establishing Presence

Nurses contribute to a sense of well-being and provide hope for recovery when they spend time with their patients. Establishing presence by sitting with a patient to attentively listen to his or her feelings and situation, talking with the patient, accepting or supporting the patient's need to cry, and simply offering

Decreased Spiritual Distress

Assessment

Lisa Owens is a 61-year-old female who was diagnosed with stage IV breast cancer over 2 years ago. She has undergone numerous rounds of chemotherapy. Her husband, Richard, is 59 years old and a financial assistant at a local bank. The Owenses have two adult children, with one daughter who is unmarried and lives 2 miles away. The other child, a son, is married; his wife is pregnant, and they live out of town. Lisa has numerous side effects from her advancing disease and chemotherapy. She has ongoing hip pain from the cancer spread to the bone, reduced

sensation in her feet, chronic fatigue, and difficulty in sleeping. Her husband provides most of her support at home, but this sometimes interferes with his ability to do the work that he brings home. Lisa is coming to the outpatient chemotherapy infusion center to begin another course of chemotherapy. The nurse who has been seeing Lisa knows that she regularly attends church with her husband.

Assessment Activities	Assessment Findings ^a
Ask Lisa to describe what it is about her cancer that frightens her most.	Lisa explains, "I have found it makes me appreciate what I have with my family. That being said, I worry that I will not see my grandchild born, but I hope the chemotherapy will give me some time and it will make me feel a bit better. "
Have Lisa tell you whom she finds to be the greatest source of support since she has been taking chemotherapy.	Lisa has received support from her husband and daughter. She wants to be able to show them her love, saying, "I still want to be there for them."
Ask Lisa whether she feels satisfaction with her life.	Lisa responds, "We always want more, don't we? I have been blessed, but I think God gave me this illness so I can show others what life means. "

^a **Assessment Findings** are shown in bold type.

Nursing Diagnosis

Decreased Spiritual Distress

Planning

Goals	Expected Outcomes (NOC) ^b
	Spiritual Health
Lisa will express a personal sense of spiritual well-being.	Lisa engages in regular prayer and meditation.
	Lisa expresses her feelings through writing.

^b Outcome classification labels from Moorhead S, et al: *Nursing Outcomes Classification (NOC)*, ed 6, St Louis, 2018, Elsevier.

Interventions (NIC) ^c	Rationale
Spiritual Growth Facilitation	
Plan discussions with Lisa during treatment and listen, allowing her to sort out concerns she might have about her future. Include Lisa's husband if she desires.	Listening provides support or comfort in spiritual care (Veloza-Gomez et al., 2017). Building a therapeutic relationship is important to providing spiritual care (Minton et al., 2018).
Offer to pray with Lisa as she describes what she hopes for.	Individualized spiritual interventions in patients with cancer can improve spiritual well-being and decrease depression (Pantuso, 2015).
Introduce Lisa to journaling. Encourage her to begin by writing what is meaningful to her about her illness and family	The use of journaling helps individuals facing a crisis deal with the unknown and express their feelings; find meaning and spiritual connection; and physically, emotionally, and spiritually heal (Connerton and Moe, 2018; Neathery, 2018).
Spiritual Support	
Discuss with Lisa the likely times that her chemotherapy will affect her most and how she can schedule involvement in church activities around those times.	Chemotherapy can cause severe fatigue. Faith communities such as a church play an important role in fostering belief systems (Timmins, 2015).
Teach Lisa methods of relaxation, meditation, and guided imagery.	Relaxation methods help promote quality of life and enhance serenity and dignity. Relaxation responses have been associated with improved physiological (blood pressure, exercise capacity, and cardiac symptoms) and psychological (depression and anxiety) outcomes (Heo et al., 2018; Pantuso, 2015).

^c Intervention classification labels from Butcher HK, et al: *Nursing Interventions Classification (NIC)*, ed 7, St Louis, 2018, Elsevier.

Evaluation

Evaluation Activity	Patient Response/Finding	Outcome Status
Ask Lisa to describe in what way meditation exercises have helped her.	Lisa reported using meditation daily after being at clinic. She states, "I feel calm. It allows me to connect with God, and know I have my loving family to help me."	Lisa finds meditation to be a helpful way to enhance her spirituality and well-being.
Have Lisa review her discussions with family and/or church members.	Lisa reports, "We have been talking more. My family knows that I see each day as a blessing and that my hope is to see my son's baby. My church really keeps me connected."	Enhanced connectedness is positively affecting sense of spiritual well-being.

time are powerful spiritual care approaches (Carson, 2017). Presence is part of the art of nursing. Benner (1984) explains that presence involves "being with" a patient versus "doing for" a patient. It is being able to offer closeness with a patient physically, psychologically, and spiritually. It helps to prevent emotional and environmental isolation (see Chapter 7).

When health promotion is the focus of care, your presence gives patients the confidence needed to discuss ways to remain healthy. Show your caring presence by listening to patients' concerns; when appropriate, involve family members in discussions about patients' health. Show self-confidence when providing health instruction, and support patients as they make decisions about their health. The patient who seeks health care is often fearful of experiencing an illness that threatens loss of control and looks for someone to offer competent direction. Encouraging words of

support and a calm, decisive approach establish a presence that builds trust and well-being.

Supporting a Healing Relationship

Learn to look beyond isolated patient problems and recognize the broader picture of a patient's holistic needs. For example, do not just look at a patient's back pain as a problem to solve with quick remedies; rather look at how the pain influences his or her ability to function and achieve goals established in life. A **holistic** view enables you to establish a helping role and a healing relationship. Three factors are evident when a healing relationship develops between nurse and patient:

1. Realistically mobilizing hope for the nurse and patient
2. Finding an interpretation or understanding of the illness, pain, anxiety, or other stressful emotion that is acceptable to the patient
3. Helping the patient use social, emotional, and spiritual resources (Benner, 1984)

Mobilizing a patient's hope is central to a healing relationship. Hope motivates people to face challenges in life (Broadhurst and Harrington, 2015). Help patients find things for which to hope. For example, help a patient newly diagnosed with diabetes learn how to manage the disease in a way that will allow the patient to continue a productive and satisfying way of life. An adult daughter who has decided to become caregiver to her older adult parent hopes to be able to protect the parent from injury or worsening disability. You instruct the daughter on basic care skills so that her hope can be realistic. Hope is future oriented and helps a patient work toward goals (Yarcheski and Mahon, 2016). Hope helps patients work toward recovery. To help patients achieve hope, work together to find an explanation for their situation that is acceptable to them. Help a patient realistically exercise hope by supporting positive attitudes toward life or the desire to be informed and make decisions.

Remain aware of a patient's spiritual resources and needs. It is always important for patients to be able to express and exercise their beliefs and find spiritual comfort. When life stressors or chronic illness create confusion or uncertainty, recognize the potential effect on a patient's well-being. How do you use and strengthen spiritual resources? Begin by encouraging a patient to discuss the effect that an illness has had on personal beliefs and faith, thus giving the chance to clarify any

misconceptions or inaccuracies in information. Having a clear sense of what illness will be like helps an individual apply many resources toward recovery.

Acute Care

Within acute care settings patients experience multiple stressors that threaten their sense of control. Ongoing assessment of spiritual needs is essential because a patient's needs often change rapidly. Support and enhancement of a patient's spiritual well-being are challenges when the focus of health care seems to be on treatment and cure rather than care. Lack of time, lack of education or training, language barriers, confusion over one's own spirituality, lack of family involvement, and patient privacy are other barriers to spiritual care in acute care settings (Chen et al., 2017a; Vlasblom et al., 2015). To meet these challenges, display a soothing presence and supportive touch when providing care. The artful use of hands, encouraging words of support, promotion of connectedness, and a calm and decisive approach establish a nurse presence that builds trust.

Support Systems

Use of support systems is important for patients who are in any health care setting. They provide patients with the greatest sense of well-being during hospitalization and serve as a human link connecting the patient, the nurse, and the patient's lifestyle before an illness. Part of a patient's caregiving environment is the regular presence of supportive family and friends. Provide privacy during visits and plan care with the patient and the patient's support network to promote the interpersonal bonding that is needed for recovery. The support system is a source of faith and hope and an important resource in conducting meaningful religious rituals.

When patients look to family and friends for support, encourage them to visit the patient regularly. Help family members feel comfortable in the health care setting, and use their support and presence to promote the patient's healing. For example, including family members in prayer is a thoughtful gesture if it is appropriate to the patient's religion and if the patient and family members are comfortable with participating together. Having the family bring meaningful spiritual or religious symbols to the patient's bedside offers significant spiritual support.

Other important resources to patients are spiritual advisers and members of the clergy. Collaboration with these individuals fosters an

interprofessional approach to patient care (Bone et al., 2018). Professional spiritual care providers, such as chaplains, have expertise in understanding how an illness influences a person's beliefs and how these beliefs influence the patient's responses to illness, recovery, or preparation for death. When members of the clergy are requested by patients or families, keep clergy informed of any physical, psychosocial, or spiritual concerns affecting the patient. A spiritual care provider is especially helpful in discussing patient and family wishes about end-of-life care (Ruth-Sahd et al., 2018) (see Chapter 36). Respect patients' spiritual values and needs by allowing time for pastoral care members to provide spiritual care and facilitating the administration of sacraments, rites, and rituals.

Diet Therapies

The intake of food satisfies and promotes a sense of comfort. Food and nutrition are important aspects of patient care and often an important component of some religious observances (Table 35.2). Food and the rituals surrounding the preparation and serving of food are sometimes important to a person's spirituality. Consult with a dietitian to integrate patients' dietary preferences into daily care. In the event that a hospital or other health care agency cannot prepare food in the preferred way, ask the family to bring meals that fit into dietary restrictions posed by the patient's condition.

TABLE 35.2**Religious Dietary Regulations Affecting Health Care**

Religion	Dietary Practices
Hinduism	Some sects are vegetarians. The belief is not to kill <i>any</i> living creature.
Buddhism	Some are vegetarians and do not use alcohol. Many fast on Holy Days.
Islam	Consumption of pork and alcohol is prohibited. Followers fast during the month of Ramadan.
Judaism	Some observe the kosher dietary restrictions (e.g., avoid pork and shellfish, do not prepare and eat milk and meat at same time).
Christianity	Some Baptists, Evangelicals, and Pentecostals discourage use of alcohol and caffeine. Some Roman Catholics fast on Ash Wednesday and Good Friday. Some do not eat meat on Fridays during Lent.
Jehovah's Witnesses	Members avoid food prepared with or containing blood.
Mormonism	Members abstain from alcohol and caffeine.
Russian Orthodox Church	Followers observe fast days and a "no-meat" rule on Wednesdays and Fridays. During Lent all animal products, including dairy products and butter, are forbidden.
Native Americans	Individual tribal beliefs influence food practices.

Supporting Rituals

Nurses provide spiritual care by supporting patients' participation in spiritual rituals and activities. Plan care to allow time for religious readings, spiritual visitations, or attendance at religious services. Allow family members to plan a prayer session or an organized reading of scriptures or the Koran on a regular basis. Make arrangements with spiritual care professionals, at the request of the patient, for the patient and family to participate in religious practices (e.g., receiving sacraments). Clergy often visit people who are unable to attend religious services. Taped meditations, classical or religious music, and televised religious services provide other effective options. Always respect the icons, medals, prayer rugs, crosses, or other items that a patient brings to a health care setting, and ensure that they are not accidentally lost, damaged, or misplaced. Supporting spiritual rituals is especially important for older adults (Box 35.5).

Box 35.5 Focus on Older Adults Spirituality and Spiritual Health

- There is an association between an older adult's spirituality and his or her ability to adjust or cope with illness and other life stressors (Chen et al., 2017b).
- Older adults achieve spiritual resilience by frequently expressing gratitude (e.g., via prayer, meditation, or discussions with friends) and finding ways to maintain purpose in life (e.g., helping family, volunteering) (Manning, 2014).
- Religious activities, attitudes, and spiritual experiences are very common among older adults. Older adults who experience spiritual well-being have better emotional health, experience a sense of peace that helps them accept life transitions, and experience to some extent improved physical health (Dahlkemper, 2016).
- Enhance connectedness by helping older patients find meaning and purpose in life by listening actively to concerns and being present (Dahlkemper, 2016).
- Beliefs in the afterlife increase as adults age. Offer to coordinate visits from clergy, social workers, lawyers, and financial advisers so that patients feel as though they have completed all unfinished business. Leaving a legacy (e.g., oral history, art, photographs) to loved ones prepares an older adult to leave the world with a sense of meaning and maintains a way to continue connection for the one left behind (Touhy and Jett, 2018).
- Greater social support in older adults positively impacts spiritual well-being (Chen et al., 2017b).

Restorative and Continuing Care

For patients who are recovering from a long-term disability or who suffer from chronic or terminal disease, spiritual care becomes especially important. Many of the nursing interventions applicable in health promotion and acute care apply to this level of health care as well.

Prayer

The act of prayer gives an individual the opportunity to renew personal faith and belief in a higher being in a specific, focused way that is either

highly ritualized and formal or quite spontaneous and informal. For example, a patient may choose to say a prayer just before leaving for a surgical procedure. A patient who is a follower of Islam will want to say daily prayers (Salah) five times a day. Prayer is an effective coping resource for physical and psychological symptoms (deAndrade Alvarenga et al., 2017). Patients pray in private or participate in group prayer with family, friends, or clergy. Muslims must be clean before they pray, so offer hygiene measures according to Islam practices (Islamic Supreme Council of America, 2019). Some pray while listening to music. Be supportive of prayer by giving the patient privacy if desired, learning whether the patient wishes to have you participate, and suggesting prayer when you know that it is a coping resource for the patient. You can also be present with the patient through offering to spend several minutes of silence with the patient (Christensen et al., 2018). Delgado (2015) found that nurses tend to pray for patients rather than with patients; sharing the fact that prayer has been offered gives patients comfort and support. Alternatives include listening to calming music or reading a book, poetry, or inspirational texts selected by the patient.

Meditation

Meditation creates a relaxation response that reduces daily stress. Patients who meditate often state that they have an increased awareness of their spirituality and of the presence of God or a Supreme Being. Meditation improves symptoms and depression in patients and helps patients move from negative to positive thoughts (Heo et al., 2018). Meditation exercises give patients relief from pain, insomnia, anxiety, and depression and increase coping and the ability to relax (Starkweather, 2017). Meditation involves sitting quietly in a comfortable position with eyes closed and repeating a sound, phrase, or sacred word in rhythm with breathing while disregarding intrusive thoughts. Individuals who meditate regularly (twice a day for 10 or 20 minutes) may experience decreased metabolism and heart rate, easier breathing, and slower brain waves (Box 35.6). Chapter 32 addresses relaxation approaches.

Box 35.6 Patient Teaching Meditation Techniques

Objective

- The patient will verbalize feelings of relaxation and self-transcendence after meditation.

Teaching Strategies

- Give patient a brief description of information and a printed teaching guide that describes how to meditate.
- Prepare a space: Simple things such as lighting a candle, turning off a cell phone, or sitting in a special quiet room or place that has minimal interruptions can support meditation practice.
- Set an intention or ask a question: This sets a direction for meditation. Have the patient ask an open-ended question such as “What is my purpose?” or “Who/what am I?”
- Explain that peaceful music or the quiet whirring of a fan also blocks out distractions.
- Teach steps of meditation (i.e., sit in a comfortable position with the back straight; breathe slowly; and focus on a sound, prayer, or image).
- Encourage patient to meditate for 10 to 20 minutes twice a day.
- Answer questions and reinforce information as needed.

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- How did you feel after meditating?
- What did you learn about yourself while doing meditation?

Supporting Grief Work

Patients who experience terminal illness or who have suffered permanent loss of body function because of a disabling disease or injury require a nurse’s support in grieving and coping with their loss. Your ability to enter into a caring, therapeutic, and spiritual relationship with patients supports them during times of grief (see [Chapter 36](#)).

• Evaluation

Through the Patient's Eyes

The evaluation of a patient's spiritual care requires you to think critically in determining whether efforts at restoring or maintaining the patient's spiritual health were successful (Fig. 35.6). This requires including the patient by determining whether his or her expectations were met. Ask patients whether you and the health care team met their expectations or whether there was anything else you could have done to enhance their spiritual well-being or to enable them to practice important religious rituals. Additionally, asking a patient "Have you felt comfortable in saying what you feel is important to you spiritually?" will help determine whether you developed an effective healing relationship. In addition, evaluate any other concerns that arise in the course of the patient's spiritual care and support. Apply critical thinking attitudes and use therapeutic communication techniques to ensure sound nursing judgments.

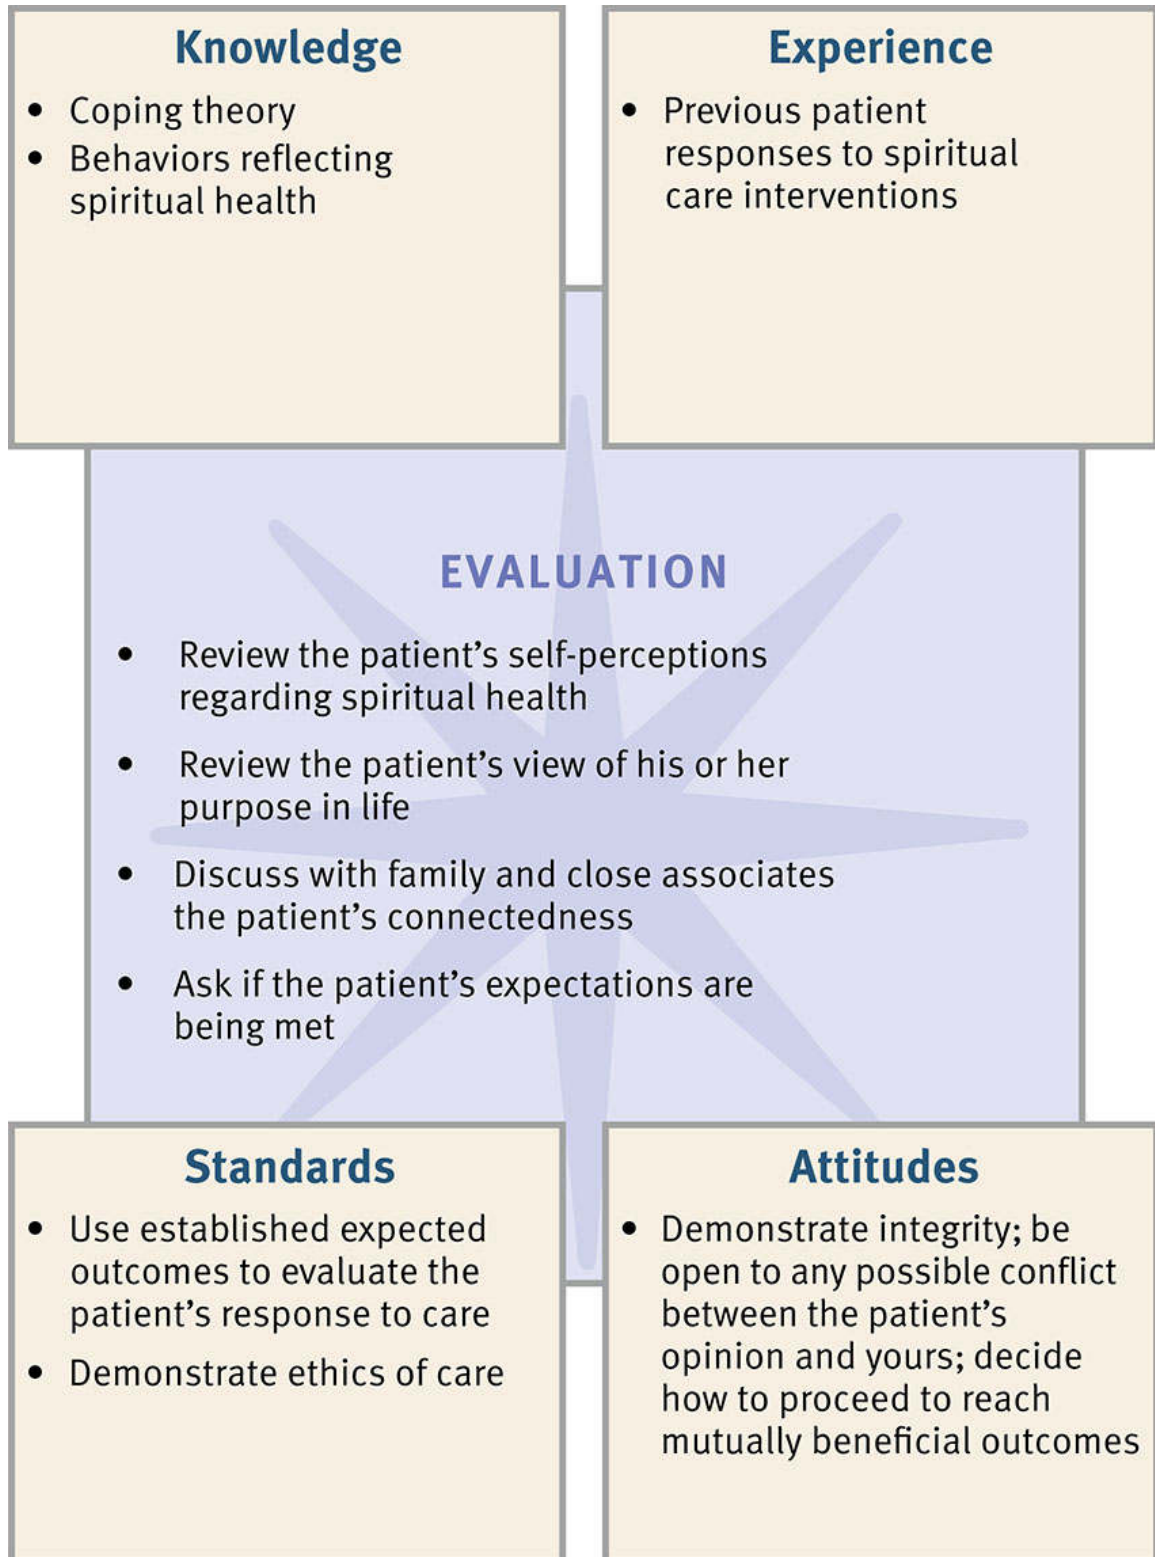

FIG. 35.6 Critical thinking model for spiritual health evaluation.

Patient Outcomes

Attaining spiritual health is a lifelong process. In evaluating outcomes established during the planning phase, compare a patient's level of spiritual health with the behaviors and perceptions noted in the nursing assessment. Evaluation data related to spiritual health are usually subjective. For example, if your assessment finds the patient losing hope, the follow-up evaluation involves asking him or her whether feelings of hope have been restored. Include family and friends, as appropriate, when gathering evaluative information. Successful outcomes reveal the patient developing an increased or restored sense of connectedness with family; maintaining, renewing, or reforming a sense of purpose in life; and for some a confidence and trust in a Supreme Being or power. When outcomes are not met, ask questions to determine appropriate continuing care. Examples of questions to ask include the following:

- Do you feel the need to forgive someone or to be forgiven by someone?
- Which spiritual activities such as prayer or meditation were helpful to you?
- Would you like for me to ask a friend, family member, or someone from pastoral care to talk with you?
- What can I do to help you feel more at peace?
- Sometimes people need to give themselves permission to feel hope when they experience difficult events. What can you do to allow yourself to feel hope again?

Key Points

- Research shows that spirituality positively affects and enhances physical and psychological health, quality of life, health promotion behaviors, and disease prevention activities.
- Faith and hope are closely linked to a person's spiritual well-being, providing an inner strength for dealing with illness and disability.
- Spirituality is a much broader and more unifying concept than religion, as it is an inherent human characteristic that gives

individuals the energy needed to discover themselves, cope with difficult situations, and maintain health.

- Religion differs from spirituality in that it is an organized, institution-related practice that is commonly associated with particular beliefs.
- Nursing assessment of a patient's spiritual needs includes a review of the patient's faith, connectedness, life and self-responsibility, life satisfaction, and fellowship and community.
- An assessment includes patients' cultural backgrounds, including their values about health care problems and impending treatments.
- Learning to practice caring and compassion helps you discover a patient's life values and meaning.
- The personal nature of spirituality requires open communication and the establishment of trust between you and a patient.
- Spiritual care providers provide direct support in the form of actively addressing spiritual or religious needs of a patient and family and having discussions about family members' feelings and patient values.
- Prayer is an evidence-based coping resource for physical and psychological symptoms.
- Common religious rituals include private worship, prayer, singing, use of a rosary, and scripture reading.
- Establishing presence involves attentive listening, talking with patients and answering questions, conveying a sense of trust, and simply offering your time.
- During evaluation successful outcomes reveal a patient developing an increased or restored sense of connectedness with family and maintaining, renewing, or reforming a sense of purpose in life.

Reflective Learning

- Using the FICA assessment tool, complete a personal assessment of your own spirituality.
- Select a patient that you will be assigned to care for during the next week. Assess for and describe the spiritual needs of that patient.
- Discuss the interventions you used to meet the spiritual needs of that patient.

Review Questions

1. The nurse is caring for a patient who has just had a near-death experience (NDE) following a cardiac arrest. Which intervention by the nurse best promotes the spiritual well-being of the patient after the NDE?
 1. Allowing the patient to discuss the experience
 2. Referring the patient to pastoral care
 3. Having the patient talk to another patient who had an NDE
 4. Offering to pray for the patient
2. The nurse is caring for a patient who is very depressed and decides to complete a spiritual assessment using the FICA tool. Using the FICA assessment tool, match the criteria on the left with the appropriate assessment question on the right.

1. F—Faith __	a. Tell me if you have a higher power or authority that helps you act on your beliefs
2. I—Importance of spirituality __	b. Describe which activities give you comfort spiritually
3. C—Community __	c. To whom do you go for support in times of difficulty?
4. A—Interventions to address spiritual needs __	d. Your illness has kept you from attending church. Is that a problem for you?

3. Which statement made by a patient who is recovering after recently experiencing third-degree burns shows connectedness?

1. "My pain medicine helps me feel better."
 2. "I know I will get better if I just keep trying."
 3. "I see God's grace and become relaxed when I watch the sun set at night."
 4. "I feel so much closer to God after I read my Bible and pray."
4. A nurse is caring for a patient who is Muslim and has diabetes. Which of the following items does the nurse need to remove from the meal tray when it is delivered to the patient?
1. Small container of vanilla ice cream
 2. A dozen red grapes
 3. Bacon and eggs
 4. Garden salad with ranch dressing
5. A 44-year-old male patient has just been told that his wife and child were killed in an auto accident while coming to visit him in the hospital. Which of the following statements are assessment findings that support a nursing diagnosis of *Spiritual Distress related to loss of family members*? (Select all that apply.)
1. "I need to call my sister for support."
 2. "I have nothing to live for now."
 3. "Why would my God do this to me?"
 4. "I need to pray for a miracle."
 5. "I want to be more involved in my church."
6. A patient has just learned she has been diagnosed with a malignant brain tumor. She is alone; her family will not be arriving from out of town for an hour. The nurse has been caring for her for only 2 hours but has a good relationship with her. What is the most appropriate intervention for support of her spiritual well-being at this time?
1. Make a referral to a professional spiritual care adviser.

2. Sit down and talk with the patient; have her discuss her feelings and listen attentively.
 3. Move the patient's Bible from her bedside cabinet drawer to the top of the over-bed table.
 4. Ask the patient whether she would like to learn more about the implications of having this type of tumor.
7. A nurse is preparing to teach an older adult who has chronic arthritis how to practice meditation. Which of the following strategies are appropriate? (Select all that apply.)
1. Encourage family members to participate in the exercise.
 2. Have patient identify a quiet room in the home that has minimal interruptions.
 3. Suggest the use of a quiet fan running in the room.
 4. Explain that it is best to meditate about 5 minutes 4 times a day.
 5. Show the patient how to sit comfortably with the limitation of his arthritis and focus on a prayer.
8. A nursing student is developing a plan of care for a 74-year-old-female patient who has spiritual distress over losing a spouse. As the nurse develops appropriate interventions, which characteristics of older adults should be considered? (Select all that apply.)
1. Older adults do not routinely use complementary medicine to cope with illness.
 2. Older adults dislike discussing the afterlife and what might have happened to people who have passed on.
 3. Older adults achieve spiritual resilience through frequent expressions of gratitude.
 4. Have the patient determine whether her husband left a legacy behind.

5. Offer the patient her choice of rituals or participation in exercise.

9. A nurse used spiritual rituals as an intervention in a patient's care. Which of the following questions is most appropriate to evaluate its efficacy?
 1. Do you feel the need to forgive your wife over your loss?
 2. What can I do to help you feel more at peace?
 3. Did either prayer or meditation prove helpful to you?
 4. Should we plan on having your family try to visit you more often in the hospital?

10. The nurse is caring for a 50-year-old woman visiting the outpatient medicine clinic. The patient has had type 1 diabetes since age 13. She has numerous complications from her disease, including reduced vision, heart disease, and severe numbness and tingling of the extremities. Knowing that spirituality helps patients cope with chronic illness, which of the following principles should the nurse apply in practice? (Select all that apply.)
 1. Pay attention to the patient's spiritual identity throughout the course of her illness.
 2. Select interventions that you know scientifically support spiritual well-being.
 3. Listen to the patient's story each visit to the clinic, and offer a compassionate presence.
 4. When the patient questions the reason for her long-time suffering, try to provide answers.
 5. Consult with a spiritual care adviser, and have the adviser recommend useful interventions.

Loss and Grief

OBJECTIVES

- Identify a nurse's role when caring for patients who are experiencing loss, grief, or death.
- Describe the types of loss experienced throughout life.
- Examine grief theories.
- Identify types of grief.
- Describe characteristics of a person experiencing grief.
- Discuss variables that influence a person's response to grief.
- Develop a nursing care plan for a patient and family experiencing loss and grief.
- Identify ways to collaborate with family members and the interprofessional team to provide palliative care.
- Describe interventions for symptom management in patients at the end of life.
- Discuss the criteria for hospice care.
- Describe care of the body after death.

KEY TERMS

Actual loss, p. 741

Ambiguous loss, p. 742

Anticipatory grief, p. 742

Autopsy, p. 755

Bereavement, p. 742

Complicated grief, p. 742

Disenfranchised grief, p. 742

Grief, p. 741

Hope, p. 744

Hospice, p. 751

Maturational loss, p. 741

Mourning, p. 741

Necessary loss, p. 741

Normal (uncomplicated) grief, p. 742

Organ and tissue donation, p. 755

Palliative care, p. 751

Postmortem care, p. 756

Perceived loss, p. 741

Situational loss, p. 741

Loss is an inevitable part of life. Accompanying each loss are feelings of grief and sadness. Whether a patient is facing infertility or an amputation, an unwanted diagnosis or impending death, you are in a position to offer both the patient and family support to cope with the loss and comfort when continued life is not possible. Nurses in all practice settings and specialties provide grief support for the majority of dying patients and their families. Like grief, death is as inescapable in practice as it is in life. There is a trend for an increase in palliative and hospice care for patients with serious chronic illness and for patients with terminal diagnoses. Palliative and hospice care can be offered within health care facilities as well as in patients' homes.

Although people agree that death is a part of life, many are hesitant to talk about it because of feelings of fear or uncertainty and not wanting to upset others. Talking openly about death is discouraged in American society (i.e., in our everyday lives, our language, and even our thinking) ([Matzo and Sherman, 2015](#)). An example is our avoidance of the word "died" and instead the use of words such as "passed away" or "gone." You need to learn how to become comfortable in discussing such sensitive topics and in providing patients with the opportunity to express their desires for care at the end of life. With the Self-Care Determination Act of 1990 (a law requiring that patients be made aware of their medical decision rights), nurses and other health care providers are starting these conversations earlier, but there is more work left to do. You have the

opportunity to advocate for patients and the high quality of care deserved at the end of life.

As a nurse you will learn to provide what patients and families need most at the time of a serious loss as well as at the end of life: compassion, attentiveness, and patient-centered care. As with other nursing situations, the more experience you have in caring for the grieving and the dying, the more confident, courageous, and compassionate you will become when caring for patients and families at this intimate and meaningful time. Your skills and knowledge base will develop quickly if you have the desire and willingness to learn, be present, and seek the help needed to learn how to give excellent care. Whether it is educating patients and families about advance directives, managing patients' symptoms, or simply holding a hand, nurses care for the grieving and dying and their families every day. It is the caring actions of nurses that help a patient and family during these times (see [Chapter 7](#)).

Scientific Knowledge Base

Loss

Life provides each person with multiple opportunities to grieve a loss or change. Sometimes the change is welcomed (marriage, birth of a child), and sometimes not (divorce, loss of a job, death). Changes related to loss can also be expected (child growing older and moving out of parent's home) or unexpected (sudden accident or death). Losses can be of tangible things, such as a body part or function, a pet, or a possession. Or losses can be intangible, such as the loss of self-esteem, a personal relationship, confidence, or a dream.

The experience of loss starts early in life and continues until death. Children develop independence from the adults who raise them, and as they begin and leave school, change friends, begin careers, and form new relationships, loss is a part of their maturation. From birth to death people form attachments and experience loss. Illness can also be a source of loss. It can change a person's functioning and therefore his or her job, family role, income level, and overall quality of life (Table 36.1). How one grieves depends on cultural norms, belief systems, support systems, and personal faith (AACN and CHNMC, 2014).

TABLE 36.1

Types of Loss

Definition	Implications of Loss
Loss of possessions or objects (e.g., theft, deterioration, misplacement, or destruction)	Extent of grieving depends on value of object, sentiment attached to it, or its usefulness.
Loss of known environment (e.g., leaving home, hospitalization, new job, moving out of a rehabilitation unit)	Loss occurs through maturational or situational events or by injury/illness. Loneliness or uncertainty in an unfamiliar setting threatens self-esteem, hopefulness, or belonging.
Loss of a significant other (e.g., divorce, loss of friend, trusted caregiver, or pet)	Close friends, family members, and pets fulfill psychological, safety, love, belonging, and self-esteem needs.
Loss of an aspect of self (e.g., body part, job, psychological or physiological function)	Illness, injury, or developmental changes result in loss of a valued aspect of self, altering personal identity and self-concept.
Loss of life (e.g., death of family member, friend, co-worker, or one's own death)	Those left behind after a death grieve for the loss of life of a loved one. Dying people also feel sadness or fear pain, loss of control, and dependency on others.

Life changes are normal, expected, and often positive. As people age, they learn that change always involves a **necessary loss**. They learn to expect that most necessary losses eventually are replaced by something different or better. However, some losses cause them to undergo permanent changes in their lives that threaten their sense of belonging and security. The death of a loved one, divorce, or loss of independence changes life forever and often significantly disrupts a person's physical, psychological, and spiritual health.

A **maturational loss** is a form of necessary loss and includes all normally expected life changes across the life span. A toddler experiences separation anxiety from a parent when starting preschool. A grade school child may not want to lose a favorite teacher and classroom. A college student may not want to leave the campus community. Maturational losses associated with normal life transitions help people develop coping skills to use when they experience unplanned, unwanted, or unexpected loss.

Other losses seem unnecessary and are not part of expected maturation experiences. Sudden, unpredictable external events bring about **situational loss**. For example, a person in an automobile accident sustains an injury with permanent physical changes that make it impossible to return to work or school, leading to loss of function, income, life goals, and self-esteem.

Losses may be actual or perceived. An **actual loss** occurs when a person can no longer feel, hear, see, or know a person or object. Examples include the loss of a body part, death of a family member, or loss of a job. Lost valued objects include those that wear out or are misplaced, stolen, or ruined. A **perceived loss** is uniquely defined by the person experiencing the loss and is less obvious to other people. For example, some people perceive rejection by a friend to be a loss, which creates a loss of confidence or changes an individual's status in the social group. How the individual interprets the meaning of the perceived loss affects the intensity of the grief response. Perceived losses are easy to overlook by others because they are experienced so internally and individually, but they are as painful as an actual loss and grieved in the same way.

Each person responds to loss differently. The type of loss and a person's previous experience with and perception of loss influence the depth and duration of the grief response. For some individuals the loss of an object (e.g., home or treasured gift) generates the same level of distress as the loss of a person, depending on the value the person places on the object. Chronic illnesses, disabilities, and hospitalization produce multiple losses.

When entering an institution for care, patients lose access to familiar people and environments, privacy, and control over body functions and daily routines. A chronic illness or disability adds financial hardships for most people and often brings about changes in lifestyle and dependence on others. Even brief illnesses or hospitalizations cause temporary changes in family role functioning, daily activities, and relationships.

Death is the ultimate loss. Although it is an expected part of life, death represents the unknown and can generate anxiety, fear, and uncertainty for many people. It creates a permanent separation of people and can cause fear, sadness, and regret for the dying person, family members, friends, and caregivers. A person's culture, spirituality, personal beliefs, and values; previous experiences with death; and degree of social support influence the way he or she approaches death.

Grief

Grief is a "normal but bewildering cluster of ordinary human emotions arising in response to a significant loss, intensified and complicated by the relationship to the person or the object lost" (Mitchell and Anderson, 1983) (see chapters 9 and 35). The grief experience is not a state but a process (Mughal and Siddiqui, 2019). Grief cannot be prevented. It is very personal. No two people grieve the same loss the same way, nor do they journey through grief in the same way. Grief work is very hard and requires enormous amounts of energy from the griever. It is rarely orderly and predictable. Most individuals recover adequately within a year after a loss; however, some individuals experience an extension of the standard grieving process, described as complicated grief or prolonged grief disorder (Mughal and Siddiqui, 2019). Because objects, memories, and anniversaries can cause a surge in feelings of loss, grief work is never fully completed. However, grief can diminish, and healing can occur when the pain of loss is less (AACN and CHNMC, 2014).

Coping with grief involves a period of **mourning**, the outward, social expressions of grief and the behavior associated with loss (AACN and CHNMC, 2014). Most mourning rituals are culturally influenced, learned behaviors. For example, the Jewish mourning ritual of *Shivah* is a time period when normal life activities come to a stop. Those mourning welcome friends into the home as a way of honoring the dead and receive support during the mourning period.

The term **bereavement** encompasses both grief and mourning and includes the emotional responses and outward behaviors of a person

experiencing loss. Allow people experiencing bereavement to talk about their loss. Reassure them that their feelings are normal and encourage them to postpone making major decisions ([AACN and CHNMC, 2014](#)). Recognizing that there are different types of grief can help nurses plan and implement appropriate care.

Normal Grief

Normal (uncomplicated) grief is a common and universal reaction characterized by complex emotional, cognitive, social, physical, behavioral, and spiritual responses to loss and death. Some normal feelings of grief are disbelief, yearning, anger, and depression. Although the manner of a person's death (expected, violent, sudden, unexpected) affect a survivor's ability to grieve normally, it does not always determine how an individual will actually grieve. Helpful coping mechanisms for people who are grieving include hardiness and resilience, a personal sense of control, and the ability to make sense of and identify positive possibilities after a loss.

Anticipatory Grief

Often a person experiences **anticipatory grief** before the actual loss or death occurs, especially in situations of prolonged or predicted loss, such as caring for patients diagnosed with dementia or amyotrophic lateral sclerosis (ALS). Family members often grieve the impending death of a loved one because of the impending loss of companionship, control, and sense of freedom and the mental and physical changes experienced by their loved one. Nurses need to recognize anticipatory grief when it occurs. It is common to misconstrue a patient's symptoms as depression, disrespect, or a dismissive attitude, which is a barrier to providing quality end-of-life care ([Moon, 2016](#)).

When grief extends over a long period, people absorb loss gradually and begin to prepare for its inevitability. They may experience intense responses to grief (e.g., shock, denial, and tearfulness) before the actual death occurs and often feel relief when it finally happens. Another way to think about anticipatory grief is that it gives people time to prepare or complete the tasks related to the impending death. Although preparing for death helps some individuals, it increases stress for others, creating an emotional roller coaster of highs and lows.

Disenfranchised Grief

People may experience **disenfranchised grief** when their relationship to the deceased person is not socially sanctioned, cannot be shared openly, or seems of lesser significance. The person's loss and grief do not meet the norms of grief acknowledged by his or her culture, thereby cutting the grieving person off from social support and the sympathy given to people with more socially acceptable losses. Examples include the death of a former spouse, a married lover, or an incarcerated person, or a terminated pregnancy ([AACN and CHNMC, 2014](#)).

Ambiguous Loss

Sometimes people experience losses that are marked by uncertainty. **Ambiguous loss**, a type of disenfranchised grief, can occur when the person who is lost is physically present but not psychologically available, as in cases of severe dementia or brain injury. Other times the person is gone (e.g., after a kidnapping, when someone is taken as a prisoner of war, when there is no body found after a disaster such as 9/11, or when someone goes missing), but the grieving person maintains an ongoing, intense psychological attachment, never sure of the reality of the situation. Ambiguous losses are particularly difficult to process because of the lack of finality and unknown outcomes ([Walter and McCoyd, 2015](#)). Recently, ambiguous loss for parents has become more prevalent as more children identify as transgendered ([Coolhart et al., 2018](#)). Nurses also will encounter more refugees and immigrants experiencing ambiguous loss of their homeland ([Perez and Arnold-Berkovits, 2018](#)).

Complicated Grief

Some people do not experience a normal grief process. In **complicated grief** a person has a prolonged or significantly difficult time moving forward after a loss. He or she experiences a chronic and disruptive yearning for the deceased; has trouble accepting the death and trusting others; and/or feels excessively bitter, emotionally numb, or anxious about the future. Complicated grief has prolonged symptoms of painful emotions and sorrow for more than 1 year ([Mughal and Siddiqui, 2019](#)). Complicated grief can also be understood as persistent grief that is so severe that it impacts normal functioning and quality of life ([Perng and Renz, 2018](#)). Patients show a preoccupation with the deceased and feel inner emptiness, have no interest in life, and sleep poorly ([Mughal and Siddiqui, 2019](#)). Complicated grief occurs more often when a person had a conflicted relationship with the deceased, prior or multiple losses or

stressors, mental health issues, or lack of social support. Loss associated with homicide, suicide, sudden accidents, or the death of a child has the potential to become complicated. Specific types of complicated grief include chronic, exaggerated, delayed, and masked grief.

Chronic Grief

A person with chronic grief experiences a normal grief response, except that it extends for a longer period of time. This can include years to decades of intense grieving.

Exaggerated Grief

A person with an exaggerated grief response often exhibits self-destructive or maladaptive behavior, obsessions, or psychiatric disorders. Suicide is a risk for these individuals.

Delayed Grief

In delayed grief a person's grief response is unusually delayed or postponed because the loss is so overwhelming that the person must avoid the full realization of the loss. A delayed grief response is frequently triggered by a second loss, sometimes seemingly not as significant as the first loss—for example, a college student whose parent has died, but the full realization of the loss comes after the family pet dies or the student fails a course.

Masked Grief

Sometimes a grieving person behaves in ways that interfere with normal functioning but is unaware that the disruptive behavior is a result of the loss and ineffective grief resolution ([AACN and CHNMC, 2014](#)). Physical symptoms exhibited by the masked grief could be headaches, heartburn, rashes, or tachycardia.

Theories of Grief and Mourning

Knowledge of grief theories and normal responses to loss and bereavement helps you to better understand these complex experiences and how to help a grieving person. Grief theorists describe the physical, psychological, and social reactions to loss. Remember that people who vary from expected norms of grief or theoretical descriptions are not abnormal. The variety of theories supports the complexity and

individuality of grief responses. Although most grief theories describe how people cope with death, they also help to understand responses to other significant losses (Table 36.2).

TABLE 36.2

Theories of Grief and Mourning

<p>Stages of Dying Kübler-Ross (1969)</p>	<p>Denial The person cannot accept the fact of the loss. It is a form of psychological protection from a loss that the person cannot yet bear.</p> <p>Anger The person expresses resistance or intense anger at God, other people, or the situation.</p> <p>Bargaining The person cushions and postpones awareness of the loss by trying to prevent it from happening.</p> <p>Depression The person realizes the full impact of the loss.</p> <p>Acceptance The person incorporates the loss into life.</p>
<p>Attachment Theory Bowlby (1980)</p>	<p>Numbing Protects the person from the full impact of the loss</p> <p>Yearning and Searching Emotional outbursts of tearful sobbing and acute distress; common physical symptoms in this stage: tightness in chest and throat, shortness of breath, a feeling of lethargy, insomnia, and loss of appetite</p> <p>Disorganization and Despair Endless examination of how and why the loss occurred or expressions of anger at anyone who seems responsible for the loss</p> <p>Reorganization Accepts the change, assumes unfamiliar roles, acquires new skills, builds new relationships, and begins to separate himself or herself from the lost relationship without feeling that he or she is lessening its importance</p>
<p>Grief Tasks Model Worden (2008)</p>	<p>Accepts the reality of the loss Experiences the pain of grief Adjusts to a world in which the deceased is missing Emotionally relocates the deceased and moves on with life</p>
<p>Rando’s “R” Process Model Rando (1993, 2014)</p>	<p>Recognize the loss React to the pain of separation Recollect and re-experience the relationship with the deceased Relinquish old attachments Readjust to life after loss Reinvest by putting emotional energy into new people</p>
<p>Dual Process Model Stroebe and Schut (1999)</p>	<p>Loss-Oriented activities: grief work, dwelling on the loss, breaking connections with the deceased person, and resisting activities to move past the grief Restoration-Oriented activities: attending to life changes, finding new roles or relationships, coping with finances, and participating in distractions, which provide balance to the loss-oriented state</p>

Criticism exists for the stages and task theories because they fail to capture the complexity and diversity of the experience (Hall, 2014). The

more recent grief theories take into consideration that human beings construct their own experiences and truths differently and make their own meanings when confronted with loss and death. Differences in social and historical context, family structure and meaning of relationships, and cognitive capacities shape an individual's truths and grief experiences. No one's grief follows a predetermined path, nor is it linear. Grief is cyclical, with movement forward and backward. Educating griever about the cyclical pattern of grief work prepares them for difficult days among the better days. Consider a widow several months after the death of her husband. She may have had several weeks of feeling less sad and depressed. If unprepared for the cyclical nature of grief, she may be taken off guard by her strong grief reaction to a phone call for her husband or a commercial advertising his favorite candy. Knowing that these feelings will come and go helps the griever to be prepared for them and allows for the necessary self-care.

REFLECT NOW

Reflect on a loss that you experienced. What type of loss was it? How did you experience the cyclical nature of grief related to your loss?

Nursing Knowledge Base

Nurses develop plans of care to help patients and family members who are undergoing loss, grief, or death experiences. Nurses implement plans of care in all settings on the basis of nursing research, practice evidence, nursing experience, and patient and family preferences. Extensive nursing education programs support the improvement of end-of-life care. The End-of-Life Nursing Education Consortium (ELNEC) provides nurses with basic and advanced curricula to care for patients and families experiencing loss, grief, death, and bereavement ([AACN and CHNMC, 2014](#)). The American Nurses Association (ANA) developed the Scope and Standards of Hospice and Palliative Nursing Practice in conjunction with the Hospice and Palliative Care Nurses Association ([ANA, 2014](#)). Professional nursing organizations such as the American Society of Pain Management Nurses and the American Association of Critical Care Nurses offer evidence-based practice guidelines for managing clinical and ethical issues at the end of life in many health care settings.

Factors Influencing Loss and Grief

Multiple factors influence the way a person perceives and responds to loss. They include developmental factors, personal relationships, the nature of the loss, coping strategies, socioeconomic status, and cultural and spiritual influences and beliefs. Nursing research has contributed to this knowledge base.

Human Development

Patient age and stage of development affect the grief response. For example, toddlers cannot understand loss or death but often feel anxiety over the loss of objects and separation from parents. Common expressions of grief include changes in eating and sleeping patterns, bowel and bladder disturbances, and increased fussiness ([AACN and CHNMC, 2014](#)). School-age children understand the concepts of permanence and irreversibility but do not always understand the causes of a loss. Some have intense periods of emotional expression and experience changes in eating, sleeping, and level of social engagement ([AACN and CHNMC, 2014](#)).

Young adults experience many necessary developmental losses related to their evolving future. Illness or death disrupts the young adult's future dreams and establishment of an autonomous sense of self. Midlife adults

also experience major life transitions such as caring for aging parents, dealing with changes in marital status, and adapting to new family roles (Walter and McCoyd, 2015). For older adults the aging process leads to necessary and developmental losses. Some older adults experience age discrimination, especially when they become dependent or are near death, but they show resilience after a loss as a result of their prior experiences and developed coping skills (Box 36.1).

Box 36.1 Focus on Older Adults Grief Considerations in Older Adults

- There is little evidence that grief experiences differ because of age alone. Responses to loss are more likely related to the nature of the specific loss experience and individual differences.
- Increased age increases the likelihood that older adults have faced multiple losses. Older adults residing in communal living situations experience many losses as friends die.
- Many older adults exhibit resilience. Others around them can learn from their courage and ability to respond to life challenges.
- Older adults are at risk for complicated grieving as a result of multiple losses, potential for cognitive impairment, or decreased physical resources. The risks include depression (Bruinsma et al., 2015), loneliness, and accompanying functional decline.
- Physical decline caused by chronic illness sometimes leads to grief over lost health, function, and roles.
- Older adults benefit from the same therapeutic techniques as people in other age-groups. Evidence indicates that positive reappraisal (cognitive restructuring) helps older adults adapt to significant losses (e.g., seeing a cardiac diagnosis as the opportunity to become healthy by eating nutritiously and exercising regularly). Relieving depression and maintaining physical function are therapeutic goals for grieving older adults.

Personal Relationships

When loss involves another person, the quality and meaning of the lost relationship influence the grief response. When a relationship between two

people was very rewarding and well connected, the survivor often finds it difficult to move forward after the death. Grief work is hampered by regret and a sense of unfinished business, especially when people are close but did not have a good relationship at the time of death. Social support and the ability to accept help from others are critical variables in recovery from loss and grief. Grievers experience less depression when they have highly satisfying personal relationships and friends to support them in their grief.

Nature of the Loss

Exploring the nature of a loss will help you understand the effect of the loss on a patient's behavior, health, and well-being. Was the loss avoidable? Is it permanent or temporary? Is it actual or imagined? Encouraging patients to share information about their loss will help you better develop appropriate interventions that meet the individualized needs of your patients.

Highly visible losses generally stimulate a helping response from others. For example, the loss of one's home from a tornado often brings community and governmental support. A more private loss such as a miscarriage brings less support from others. A sudden and unexpected death poses challenges different from those of a person in a debilitating chronic illness. When the death is sudden and unexpected, the survivors do not have time to say good-bye. In chronic illness survivors have memories of prolonged suffering, pain, and loss of function. Death by violence or suicide or multiple losses by their very nature complicate the grieving process in unique ways ([Walter and McCoyd, 2015](#)).

Coping Strategies

The losses that patients face from the time they were children often influence the coping skills they will use when faced with larger and more painful losses in adulthood. These coping strategies such as talking, journaling, and sharing their emotions with others may be healthy and effective. They may also be unhealthy and ineffective, such as increased use of alcohol, drugs, and violence. Nurses provide support by assessing patients' coping strategies, educating about new and healthy strategies, and encouraging the use of these strategies.

Socioeconomic Status

Socioeconomic status influences a person's grief process in direct and indirect ways. Because of role changes, a newly widowed mother finds

herself working several jobs to make ends meet and does not find time to initiate self-care or grieve the loss of her spouse. With limited resources, activities that support healthy grief work such as buying a tree to plant in honor of the deceased or travel to a support group may be unrealistic. Practical implications also exist when there are limited resources. A patient with limited finances is unable to replace a car demolished in an accident and pay for the associated medical expenses.

Culture

During times of loss and grief patients and families draw on the social and spiritual practices of their cultures to find comfort, expression, and meaning in the experience (Walter and McCoyd, 2015). To provide the best care possible, it is necessary for us to ask about cultural beliefs and practices. Patients and families will rarely offer this information without prompting. Expressions of grief in one culture do not always make sense to people from a different culture. Try to understand and appreciate each patient's cultural values related to loss, death, and grieving (see Chapter 9). For example, some cultures hold back their public displays of emotion. In other cultures, behaviors such as public wailing and physical demonstrations of grief, including survivor body mutilation, show respect for the dead. Remember, culture extends beyond the geographic location of a person. Consider the influence of sexual and gender orientation, socioeconomic status, and family makeup (blended versus nuclear) when assessing cultural influence on grief practices and death rituals.

Spiritual and Religious Beliefs

Like cultural influences, spirituality and/or religious practices and beliefs provide a framework to navigate, understand, and heal from loss, death, and grief (see Chapter 35). A person's faith often influences the response to an illness, treatment, advanced life-support options, autopsy, organ donation, and what happens to the body and spirit after death. Patients draw on their spiritual beliefs to provide comfort and seek understanding at times of loss. You must remain open to the varying views and beliefs that are in contrast to your own to best support and care for your patients and their families. To never offend a patient and to offer high-quality care, you must assess your patient's and family's beliefs and practices and encourage expression of them whenever possible. You should encourage patients and families to draw on their spiritual resources (e.g., faith in a higher power, communities of support, friends, a sense of hope and

meaning in life, and religious practices). Spirituality affects the patient's and family members' ability to cope with loss as well. Using a holistic approach when caring for a patient and family ensures that you are providing them with the best possible individualized care.

Hope, a multidimensional concept considered to be a component of spirituality, energizes and provides comfort to individuals and families experiencing personal challenges. Hope gives a person the ability to see life as enduring or having meaning or purpose. With hope a patient moves from feelings of weakness and vulnerability to living as fully as possible. Maintaining a sense of hope depends in part on a person having strong relationships and emotional connectedness to others. On the other hand, spiritual distress often arises from a patient's inability to feel hopeful or to foresee any favorable outcomes. Spirituality and hope play a vital role in a patient's adjustment to loss and death (see [Chapter 35](#)).

Critical Thinking

Successful critical thinking requires a synthesis of knowledge, experience, information gathered from patients, critical thinking attitudes, and intellectual and professional standards. Clinical judgment requires you to anticipate information, analyze the data, and make decisions regarding your patient's care. During assessment consider all elements that build toward making an appropriate nursing diagnose ([Fig. 36.1](#)).

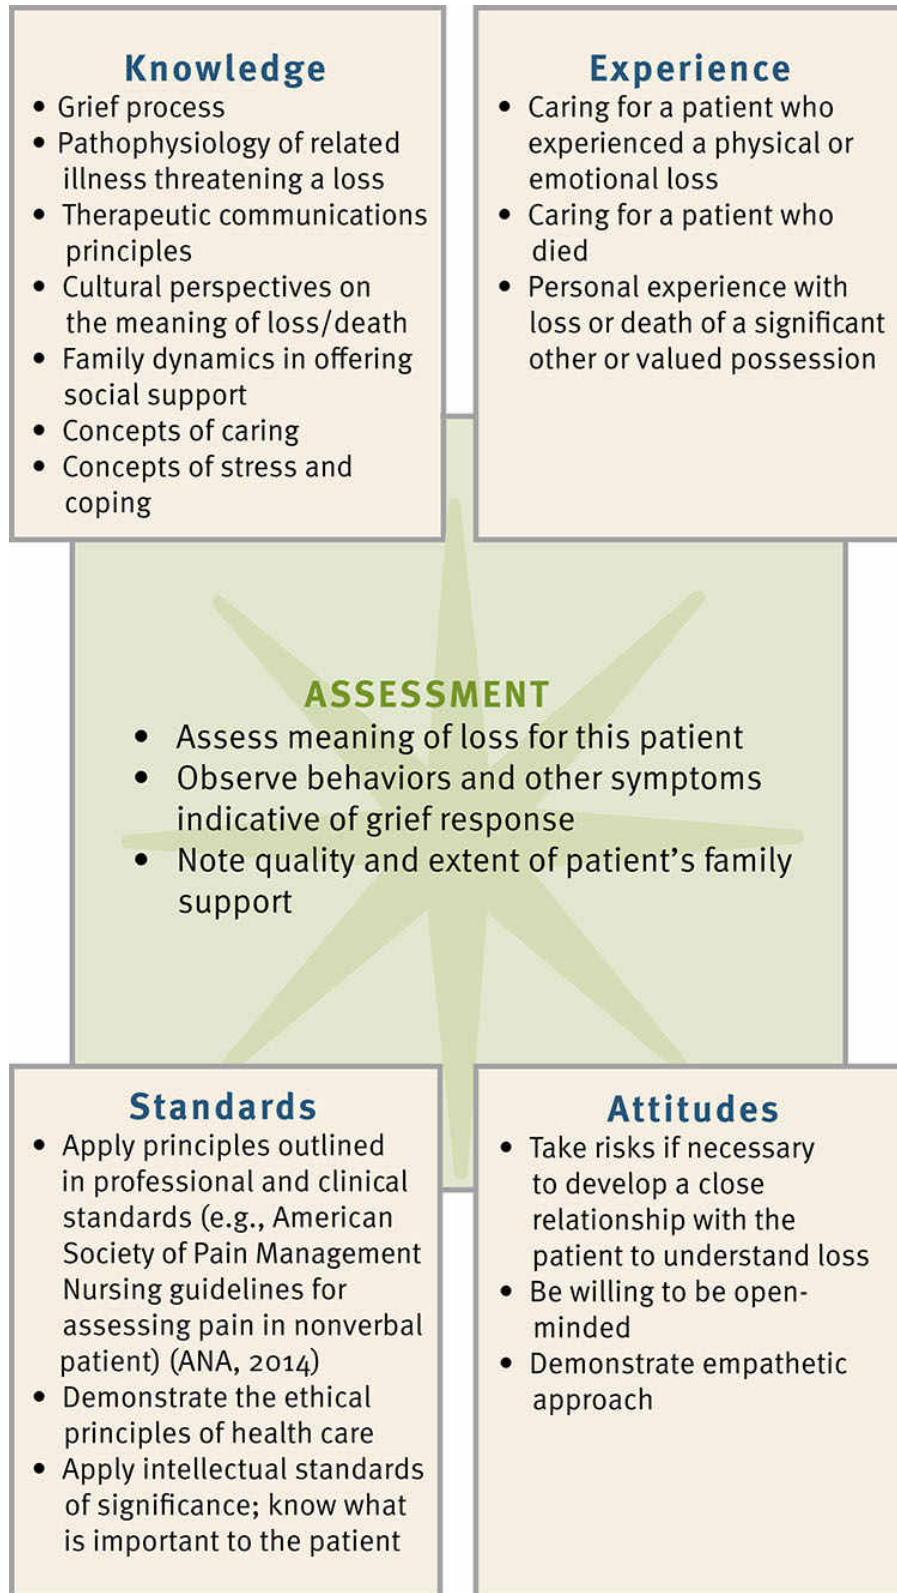

FIG. 36.1 Critical thinking model for loss, death, and grieving assessment.

To understand a patient's subjective experiences of loss, form assessment questions on the basis of your theoretical and professional knowledge of grief and loss, but then listen carefully to the patient's perceptions. A culturally competent nurse also uses culture-specific understanding of grief to explore the meaning of loss with a patient.

Being familiar with commonly experienced responses to loss enables you to better understand a patient's emotions and behaviors. Some patients ignore, lash out, plead with, or withdraw from other people as part of a normal response to loss. Instead of "taking things personally," a critically thinking nurse integrates theory, prior experience, appreciation of subjective experiences, and self-knowledge to respond to the patient's emotions with patience and understanding. In designing plans of care, use professional standards, including the Nursing Code of Ethics (see [Chapter 22](#)), the dying patient's bill of rights ([Box 36.2](#)), the ANA Scope and Standards of Hospice and Palliative Nursing Practice (2014), and the American Society of Pain Management Nursing's position statement for pain management at the end of life ([Reynolds et al., 2013](#)).

Box 36.2 The Dying Person's Bill of Rights

- I have the right to be treated as a living human until I die.
- I have the right to maintain a sense of hopefulness, however changing its focus may be.
- I have the right to be cared for by those who can maintain a sense of hopefulness, however changing this might be.
- I have the right to express my feelings and emotions about my approaching death in my own way.
- I have the right to participate in decisions concerning my care.
- I have the right to expect continuing medical and nursing attention even though "cure" goals must be changed to "comfort" goals.
- I have the right not to die alone.
- I have the right to be free from pain.
- I have the right to have my questions answered honestly.
- I have the right to retain my individuality and not be judged for my decisions that may be contrary to beliefs of others.

- I have the right to expect that the sanctity of the human body will be respected after death.
- I have the right to be cared for by caring, sensitive, knowledgeable people who will attempt to understand my needs and be able to gain some satisfaction in helping me face my death.

REFLECT NOW

Remember how you felt after a loss you experienced. What emotions did you feel and what coping strategies worked for you? How does your family/culture typically respond to death and loss?

◆ Nursing Process

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care.

◆ Assessment

During the assessment process thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care. A trusting, helping relationship with grieving patients and family members is essential to the assessment process. A caring nurse encourages a patient to tell his or her story. Look for opportunities to invite patients to share their experiences, being aware that attitudes about self-disclosure; sharing of emotions; or talking about illness, fears, and death are shaped by an individual's personality, coping style, and culture. This information is invaluable to understanding the unique and individual needs of each patient.

Through the Patient's Eyes

One of the best things that you can do for patients and families is to be present. By using the skills of active listening, silence, and therapeutic touch, you can establish a trusting relationship with your patients. This trusting relationship will help you explore with patients their unique responses to grief or their preferences for end-of-life care, which may include advance directives. Patient perceptions and expectations influence the prioritization of nursing diagnoses. To assess patient perceptions, ask, "What is the most important thing I can do for you right now?" You usually gather information from patients first, but with advanced illness and as death approaches, patients often rely on family members to communicate for them. Encourage family members to share their goals and perceptions with you. Most often they provide valuable information about patient preferences and clarify misunderstandings or identify overlooked information. Assess patients' and family members' understanding of treatment options to implement a mutually developed care plan. Assessment of grief responses extends throughout the course of an illness into the bereavement period following a death. During this time, you can work to normalize the grief response ([AACN and CHNMC, 2014](#)). Patients with advanced chronic illness and their families eventually face

end-of-life care decisions and should discuss the content of any advance directives together. Patients, family members, and the health care team discuss end-of-life care preferences early in the assessment phase of the nursing process. If you feel uncomfortable in assessing a patient's wishes for end-of-life care by yourself, ask a health care provider experienced in discussing these issues to help you. Communicate what you have learned about patient preferences during any registered nurse (RN) hand-off, at health care team conferences, in written care plans, and through ongoing consultation (see [Chapter 26](#)).

Speak to patients and family members using honest and open communication, remembering that cultural practices influence how much information the patient shares. Keep an open mind, listen carefully, and observe the patient's verbal and nonverbal responses. Facial expressions, voice tones, and avoided topics often disclose more than words. Anticipate common grief responses but allow patients to describe their experiences in their own words. Open-ended questions such as "What do you understand about your diagnosis?" or "You seem sad today. Can you tell me more?" may open the door to a patient-centered discussion. Many people find it difficult to talk about loss, fear, death, or grief. The use of pauses, gentle questioning, and silence honors the patient's privacy and readiness to talk. Talk to patients and family members in a private, quiet setting, considering the culture normal of the individual. For example, in some cultures, the health care provider will be expected to discuss the information with the husband or father of the female patient, not directly with her, so that the male can pass the filtered information to the female. In other cultures, the patient may want to have family members present so that everyone hears the same thing and has an opportunity to add to the conversation. However, some people want their concerns and questions addressed privately. As you gather assessment data, summarize and validate your impressions with the patient or family member. Information from the medical record and from other members of the health care team, including physicians, social workers, and spiritual care providers, contributes to your assessment data.

Because of the importance of symptom management and priority of comfort in end-of-life care, prioritize your initial assessment to encourage patients to identify any distressing symptoms. Completing a thorough assessment is difficult when patients are in pain, anxious, depressed, or short of breath.

Grief Variables

Conversations about the meaning of loss to a patient often lead to other important areas of assessment, including the patient's coping style, the nature of family relationships, social support systems, the nature of the loss, cultural and spiritual beliefs, life goals, family grief patterns, self-care, and sources of hope (Box 36.3). Use skills appropriate for assessing a patient's culture, family, self-concept, or spiritual beliefs (see Chapters 9, 10, 33, and 35) to gain a deeper understanding of his or her loss.

Box 36.3 Nursing Assessment Questions

Nature of Relationships

- How long have you known _____ (the deceased person)?
- What role did (name person) play in your life?
- Tell me about what your relationship with (name person) meant to you.

Social Support Systems

- In times of loss, who is "there for you"? Absent? Who provides support?
- What do others do for you that is most meaningful or helpful?
- Are family/friends available when needed? Which friends or relatives do you wish were here?

Nature of the Loss

- What does this loss mean to you?
- What other losses have you experienced?
- Was this loss expected or unexpected?

Cultural and Spiritual Beliefs

- What is your belief about death? Meaning of life?

- Which rituals/practices are important to you at the end of life?
- How do members of your culture or religious group respond to this type of loss?

Life Goals

- What are your life goals at this time?
- How have your goals changed because of this experience?
- Are you able to see what you will do in the future?

Family Grief Patterns

- How have you/your family dealt with loss in the past?
- What are your family's strengths?
- How have family relationships changed as a result of your loss?
- What role do you assume in your family during stressful situations?

Self-Care

- Tell me how you're feeling.
- What are you doing to take care of yourself now?
- What helps you when you feel this sad? What doesn't help?
- What can I do for you?

Hope

- What do you hope for right now?
- What helps you to remain hopeful? What causes you to lose hope?

Knowing the commonly experienced reactions to grief and loss and grief theories guides your critical thinking and assessment skills. A single behavior can occur in all types of grief. If a patient who is grieving describes loneliness and difficulty in falling asleep, consider all factors surrounding the loss in context. What was the loss? When did it occur? What was the meaning of the loss to the patient? For example, when your

patient exhibits signs of a normal grief reaction, but you learn that the loss occurred 2 years ago, the patient's response most likely indicates a complicated, chronic grief experience. Focus your assessment on how a patient is reacting to loss or grief and not on how *you* believe that patient should be reacting.

Grief Reactions

Use psychological and physical assessment skills to assess a patient's unique grief responses. Most grieving people show some common outward signs and symptoms (Box 36.4). Analyze assessment data and identify possible related causes for the signs and symptoms that you observe. For example, after a significant loss a person may have a sad affect, withdrawn behaviors, headaches, upset stomach, and decreased ability to concentrate. You associate these symptoms with several potential causes, including anxiety, gastrointestinal disturbances, medication side effects, or impaired memory. Careful analysis of the symptoms in context leads you to an accurate nursing diagnosis. Ask: How are the symptoms related to one another when they occur? When did they begin? Were they present before the loss? To what does the person attribute them?

Box 36.4 Symptoms of Normal Grief

Feelings <ul style="list-style-type: none">• Sorrow• Fear• Anger• Guilt or self-reproach• Anxiety• Loneliness• Fatigue• Helplessness/hopelessness• Yearning• Relief Cognitions (Thought Patterns) <ul style="list-style-type: none">• Disbelief• Confusion or memory problems• Problems in making decisions• Inability to concentrate• Feeling the presence of the deceased	Physical Sensations <ul style="list-style-type: none">• Headaches• Nausea and appetite disturbances• Tightness in the chest and throat• Insomnia• Oversensitivity to noise• Sense of depersonalization ("Nothing seems real")• Feeling short of breath, choking sensation• Muscle weakness• Lack of energy• Dry mouth Behaviors <ul style="list-style-type: none">• Crying and frequent sighing• Distancing from people• Absentmindedness• Dreams of the deceased• Keeping the deceased's room intact• Loss of interest in regular life events• Wearing objects that belonged to the deceased
--	--

Loss takes place in a social context; thus, family assessment is a vital part of your data gathering. If a father of a young family is dying, he will

not be able to fulfill certain roles, causing a change in family structure. When a person develops a disability, the patient and family members realign their roles and responsibilities to meet new demands. Family members also experience a variety of physical and psychological symptoms. Assess the family's response to loss and recognize that sometimes they are dealing with their grief at a different pace.

REFLECT NOW

Explore your feelings about entering the sacred space of another's family at the time of an emotionally charged loss. How do you think you would manage your own emotions?

• Nursing Diagnosis

Use critical thinking to cluster assessment data cues, identify assessment findings, draw conclusions regarding the patient's actual or potential needs or resources, and identify nursing diagnoses applicable to the patient's situation ([Box 36.5](#)). In addition to numerous diagnoses related to physical symptoms at the end of life, additional nursing diagnoses relevant for patients experiencing grief, loss, or death include:

Box 36.5 Nursing Diagnostic Process **Hopelessness** **Related to Deteriorating Physiological Condition**

Assessment Activities	Assessment Findings
Ask patient to discuss her understanding of her health situation.	Patient sighs and offers a negative view of her future; turns away from health care professionals.
Observe patient's nonverbal behavior.	Patient sighs, keeps eyes closed; decreased verbalization.
Observe patient's responses to care options.	Patient does not want scheduled test. "There is nothing they can do."
Assess activity level.	Patient states that she has no energy and reports pain; can't sleep, wants to stay in bed.
Observe patient's interactions with others.	Patient shows lack of interest, communicates minimally, and does not want to contact daughter yet.

- *Impaired Family Coping*
- *Death Anxiety*
- *Pain (Acute or Chronic)*
- *Dysfunctional Grief*
- *Anticipatory Grief*

You cannot make accurate nursing diagnoses based on just one or two assessment findings. Carefully review your patient's assessment data to consider whether more than one diagnosis applies. For example, a dying patient who cries often, has angry outbursts, and reports nightmares gives evidence of several possible nursing diagnoses: *Pain (Acute or Chronic)*, *Dysfunctional Grief*, or *Spiritual Distress*. Examine the available data, validate assumptions with the patient, and look for other validating behaviors and symptoms before making a diagnosis.

As part of the diagnostic process, identify the appropriate "related to" factor for each negative or actual nursing diagnosis. Clarification of the related factors ensures that you select appropriate interventions. For example, a nursing diagnosis of *Dysfunctional Grief related to the permanent loss of mobility* requires different interventions than a diagnosis of *Dysfunctional Grief related to infertility after an ectopic pregnancy*.

When identifying nursing diagnoses related to a patient's grief or loss, you sometimes identify other related diagnoses. Some patients experiencing grief or impending death have nursing diagnoses such as *Denial About Illness Severity* or *Impaired Mobility*. A patient entering the phase of active dying often has diagnoses related to physical changes, including *Urinary Incontinence*, *Bowel Incontinence*, *Acute Pain*, *Nausea*, *Altered Perception*, and *Impaired Breathing*.

• Planning

Nurses provide patient-centered holistic care to patients experiencing grief, death, or loss. [Fig. 36.2](#) illustrates the interrelatedness of critical thinking factors during the planning phase of the nursing process. The use of critical thinking ensures a well-designed care plan that supports a patient's self-esteem and autonomy by including him or her in the planning process. A care plan for a patient who is dying focuses on comfort; preserving dignity and quality of life; and providing family members with emotional, social, and spiritual support (see the [Nursing Care Plan](#)).

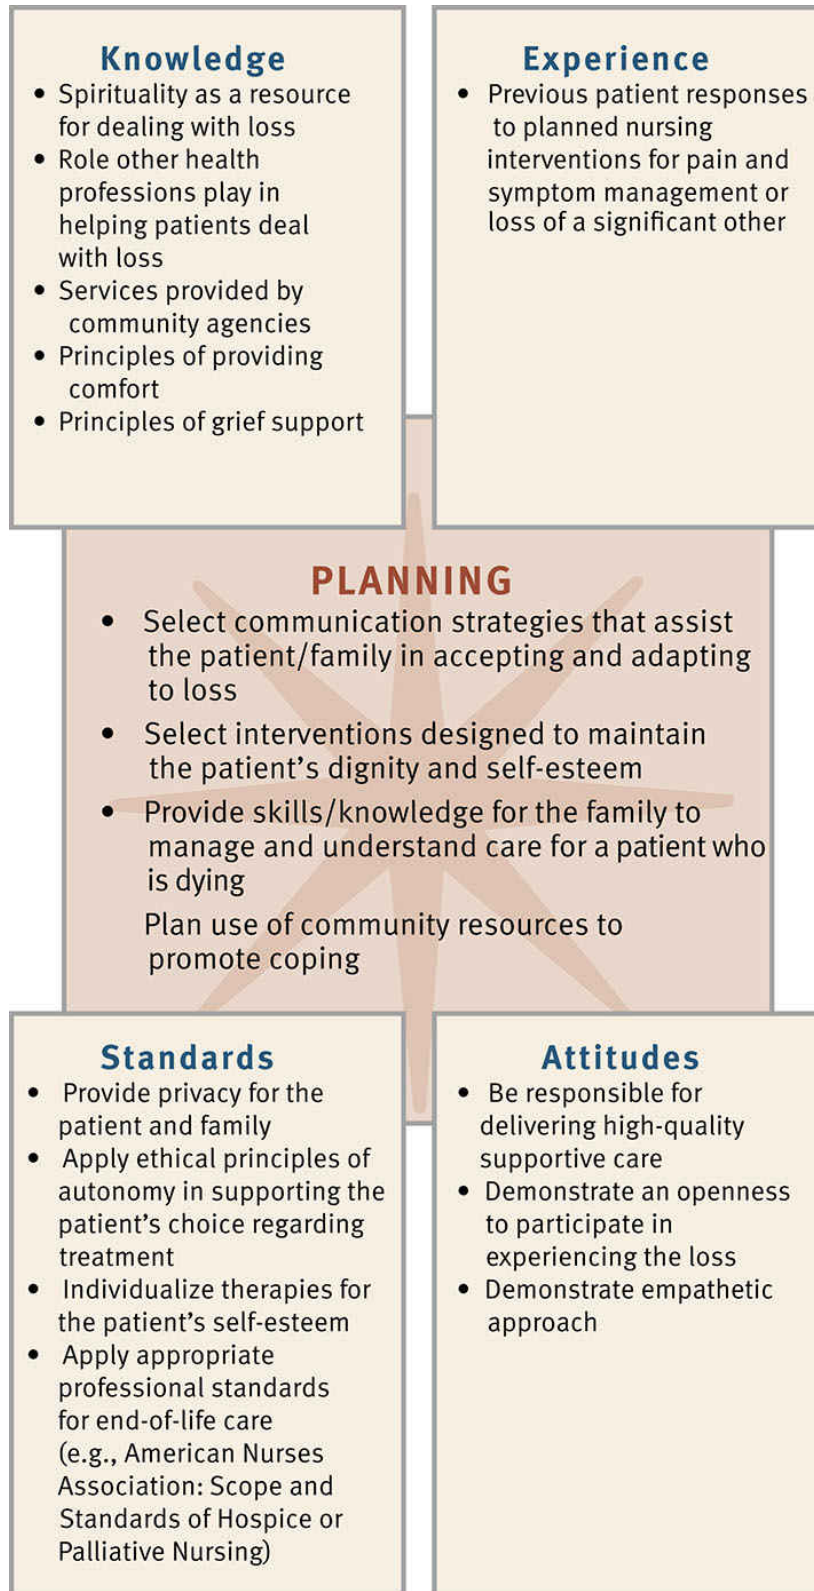

FIG. 36.2 Critical thinking model for loss, death, and grieving planning.

REFLECT NOW

Reflect on your feelings as you plan care for a patient who is terminally ill. How will you feel about engaging in conversations about care while talking about something that causes so many people distress?

Nursing Care Plan

Hopelessness

Assessment

Mrs. Allison, an 80-year-old woman, was brought to the hospital after a neighbor found her lying on the floor, unable to get up after a fall. She lives alone since her husband died 2 years ago. She was admitted to the hospital with low blood pressure, dehydration, severe back pain, and weakness. She reports fatigue, recent weight loss, and loss of appetite. Her diagnostic tests indicate that she has leukemia, for which she needs a bone marrow biopsy for confirmation. The nurse notes that Mrs. Allison appears withdrawn and tearful.

Assessment Activities	Assessment Findings ^a
Ask open-ended questions. "It looks as if you're having a difficult time. What do you understand about your situation right now?"	"The doctors say that I might have leukemia. " Shrugging her shoulders , she states, " There's nothing they can do. I don't want the bone marrow test. "
Observe Mrs. Allison's behaviors and nonverbal communication.	Mrs. Allison appears sad and keeps her eyes closed. She cries and sighs frequently.
Assess Mrs. Allison's pain and energy level.	Mrs. Allison's great toes are swollen and red and sore to the touch. Reports constant back pain. She has " no energy for anything. "
Observe Mrs. Allison's interactions and interest in others.	Mrs. Allison does not look at people and does not want to talk to her daughter yet.
Assess meaning of recent events with Mrs. Allison and invite her to talk about her situation.	Mrs. Allison states, " I'm done with life and ready to be with my late husband. "

^a **Assessment findings** are shown in **bold** type.

Nursing Diagnosis:

Hopelessness related to declining physical condition

Planning

Goals	Expected Outcomes (NOC) ^b
Hope	
Mrs. Allison will discuss two care priorities and preferences within 1 day.	Mrs. Allison identifies the concerns causing the greatest amount of suffering or distress.
	Mrs. Allison identifies ways she can live at home with the help of others.

^b Outcome classification labels from Moorhead S, et al: *Nursing Outcomes Classification (NOC): measurement of health outcomes*, ed 6, St Louis, 2018, Elsevier.

Interventions (NIC) ^c	Rationale
Hope Inspiration	
Develop an open and caring relationship through active listening and emotional support.	Individuals approaching the end of life often experience fragmented care delivery. Therapeutic communication supports patient- and family-centered care at the end of life and helps to ensure that patient needs are communicated among all health care professionals (Meghani et al., 2015).
Provide frequent conversations with patient and family regarding patient's symptom management and grief.	Frequent conversations with patient and family provide opportunities to discuss end-of-life care values, goals, and preferences (Meghani et al., 2015).
Pain Management	
Provide pharmacological and nonpharmacological relief for chronic back and foot pain.	Anxiety, pain, and suffering are reduced with effective pain management, and quality of life is improved (Paice, 2015).
Grief Work Facilitation	
Help Mrs. Allison identify her personal goals, desires, and priorities. Evaluate effectiveness and promote goal achievement as appropriate.	Allowing the patient to direct care decisions helps the patient and family select priority of care and increases patient and family understanding of current and proposed treatments (Coyle, 2015).
Help Mrs. Allison identify her desires for advance care planning, drawing on available resources in and outside the hospital.	Hope near the end of life can be achieved by having a sense of control over future care (Mattes and Sloane, 2015).
Discuss Mrs. Allison's spiritual beliefs, practices, needs, and resources.	Inclusion of spiritual assessment and spiritual care practices at the end of life increases patient's sense of connectedness and overall quality of life (Dose et al., 2014).

^c Intervention classification labels from Butcher HK, et al: *Nursing Interventions Classification (NIC)*, ed 7, St Louis, 2018, Elsevier.

Evaluation

Evaluation Activity	Patient Response/Finding	Outcome Status
Use open-ended question: "Can you tell me what is most distressing or worrisome right now?"	Mrs. Allison explains, "I'm not sure what will happen. I may not be able to take care of myself much longer."	Fear of the unknown is causing the greatest amount of distress.
Ask, "Who has offered to help you when you get home?"	Mrs. Allison states, "Well, my Bible study group will take turns taking me to appointments, and the choir members said they will be happy to bring meals to the house every Tuesday and Thursday."	Identified people who can help provide assistance at home.
Observe Mrs. Allison's planning activities and behavior with her daughter and friends.	Mrs. Allison and daughter discuss what they can do so that she can stay at home longer.	Mrs. Allison is making plans to live at home.

Goals and Outcomes

During planning establish realistic goals and expected outcomes on the basis of the nursing diagnoses. Consider a patient's own resources such as physical energy and activity tolerance, family support, and coping style. A nursing diagnosis of *Powerlessness related to experimental cancer therapy* with a goal of "Patient will be able to describe the expected course of disease" is realistic for a patient who frequently asks for clarification about the

treatment plan and participates in educational discussions. In contrast, an expected outcome of “Patient will identify a minimum of three effective coping skills” is appropriate for a patient with the same nursing diagnosis who is experiencing depression from feeling powerless about having experimental cancer treatment.

The goals of care for a patient experiencing loss are either short or long term, depending on the nature of the loss and the patient’s condition. Some nursing care goals for patients facing loss or death include accommodating grief, accepting the reality of a loss, or maintaining meaningful relationships. A possible goal for a young woman with advanced breast cancer is “Will maintain a sense of control,” with the following potential expected outcomes:

- Patient participates in all treatment decisions.
- Patient identifies a minimum of three ways to maintain a parental role in the care of her young child.
- Patient communicates a minimum of three treatment side effects or concerns to the health care team.

Setting Priorities

Encourage patients and family members to share their priorities for care at the end of life. Patients at the end of life or with advanced chronic illness are more likely to want their comfort, social, or spiritual needs met rather than pursuing medical cures. Then as a nurse prioritize a patient’s most urgent physical or psychological needs while also considering his or her expectations and priorities. If a patient’s goals include pain control and promoting self-esteem at the end of life, pain control takes priority when the patient experiences acute physical discomfort. Many terminal conditions can also influence a patient’s ability to breathe.

Pharmacological approaches are available to relieve dyspnea. When comfort needs have been met, you address other issues important to the patient and family. When it is realistic for the patient to remain independent, strategies that foster his or her sense of autonomy and ability to function independently take priority. A patient’s condition at the end of life often changes quickly; therefore maintain an ongoing assessment to revise the plan of care according to patient needs and preferences.

When a patient has multiple nursing diagnoses, it is not possible to address them all simultaneously. [Fig. 36.3](#) illustrates a concept map developed for Mrs. Allison, an elderly patient with a medical diagnosis of

advanced cancer (leukemia). In conjunction with her recent medical diagnosis, she experiences associated health problems identified in the nursing diagnoses *Chronic Pain*, *Impaired Low Nutritional Intake*, *Fatigue*, and *Hopelessness*. In such a situation determine which of the four diagnoses should take priority. The chronic pain experienced by the patient is often the first focus. Until her pain is under control, it will not be possible for her to feel more energized, eat well, or regain her sense of hopefulness.

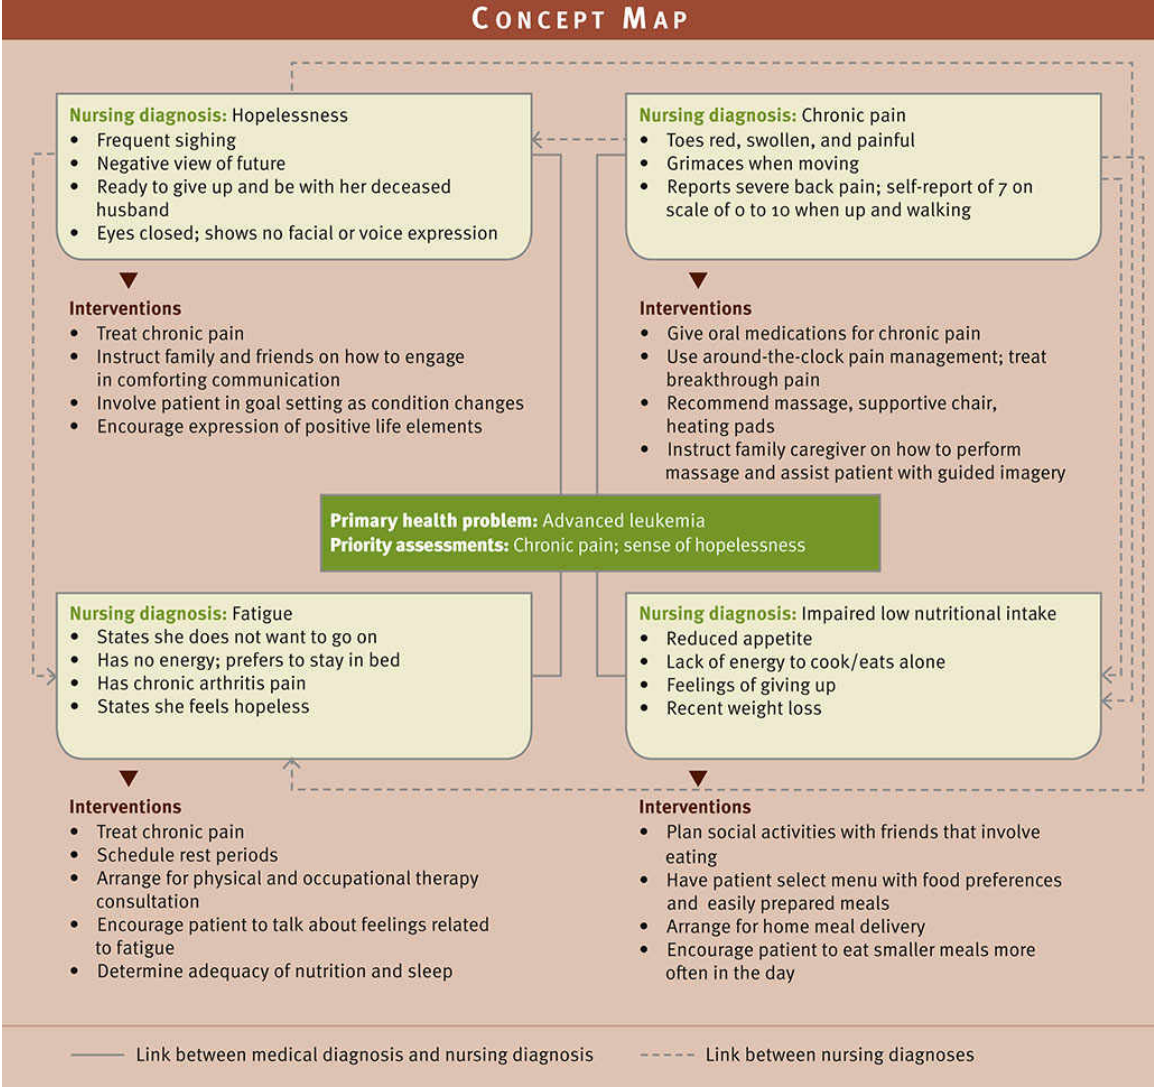

FIG. 36.3 Concept map for Mrs. Allison.

Teamwork and Collaboration

As described previously, grief, loss, and death affect people physically, emotionally, spiritually, and culturally. No one is able to address all of these dimensions alone. A team of nurses, physicians, social workers, spiritual care providers, nutritionists, pharmacists, psychologists, physical and occupational therapists, patients, and family members works together to provide palliative, grief, and end-of-life care. Massage or music/art therapists who provide alternative therapies are sometimes part of the team (see [Chapter 32](#)). As a patient's care needs change, team members take a more or less active role, depending on the patient's shifting priorities. Team members communicate with one another on a regular basis to ensure coordination and effectiveness of care.

Building Competency in Teamwork and Collaboration

You are caring for Mrs. Allison, an older patient who has recently been diagnosed with a terminal illness and is preparing for discharge home. She has lost strength as a result of decreased activity, depression, and back pain. Her greatest desire is to be able to attend weekly services at her church, but because of her weakness, pain, and fatigue, she is afraid that she will be unable to do so. She believes that her feelings of depression will improve if she can again participate in church activities. How can you, with the help of the interprofessional team, help Mrs. Allison respond to her spiritual needs and desire to be involved within her faith community?

Implementation

Health Promotion

Health promotion in complicated grief, serious chronic illness, or death focuses on facilitating successful coping and optimizing physical, emotional, and spiritual health. Many people continue to look for and find meaning even in difficult life circumstances. They often find personal growth and spiritual insights that they have not previously experienced and need family and nurse support as they strive to maintain a degree of normalcy, live with loss, make health care decisions, prepare for death when applicable, and adjust to disappointments, frustration, and anxieties along the way ([Box 36.6](#)).

Box 36.6 Patient Teaching Maintaining Self-Care

Objective

- The patient will participate in activities to manage symptoms.

Teaching Strategies

- Identify ways for patient to achieve personal goals.
- Instruct patient on ways to maintain usual daily routines that provide comfort and sense of normalcy.
- Demonstrate forms of complementary therapy that patient can use for symptom management.
- Discuss ways that patient can maintain a sense of control over end-of-life planning and maintain a realistic outlook (advance directives, funeral planning, and preferred location of death).
- Discuss patient's needs for the presence of particular support people or for solitude.
- Identify methods to facilitate safety and ease in managing activities of daily living as patient's abilities change (assistive devices, in-home caregivers).

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- Tell me what symptom-management methods you use and how effective each method is.
- Show me how you perform guided imagery in symptom management.
- Tell me about the changes that you made in your house that improve your safety.

Assist With End-of-Life Decision Making

Patients and family members often face complex treatment decisions at the end of life. Patients and families must decide which treatments to continue and which to forgo; to enroll in hospice or stay in the hospital; or to transfer to a nursing home, in-patient unit, or home. Even after the decision to enroll in hospice, questions arise about symptom management, artificial nutrition and hydration (e.g., feeding tube or parenteral nutrition), and the desired location for death. You can support and educate patients and families as they identify, contemplate, and ultimately decide how to best journey to the end of life.

Difficult ethical decisions at the end of life complicate a survivor's grief, create family divisions, or increase family uncertainty at the time of death (see [Chapter 22](#)). When ethical decisions are handled well, survivors achieve a sense of control and experience a meaningful conclusion to their loved one's death. Suggest to patients that they clearly communicate their wishes for end-of-life care so that family members are able to act as faithful surrogates when the patient can no longer speak for himself or herself. Some patients and family members rely on the nurse and other members of the health care team to initiate discussions regarding end-of-life care. Nurses often provide options that family members do not know are available and are advocates for patients and family members making decisions at the end of life in the form of an advance directive. When patients sign consent for a DNR (do not resuscitate) order, they have improved autonomy as well as increased quality of end-of-life care (Liang et al., 2016).

Palliative Care

Patients and families can benefit greatly from the specialized approach of palliative care. This holistic method to prevent and reduce symptoms promotes quality of life and whole-person well-being through care of the mind, body, and spirit.

Palliative care focuses on the prevention, relief, reduction, or soothing of symptoms of disease or disorders throughout the entire course of an illness. It is not simply care of the dying. The primary goal of palliative care is to help patients and families achieve the best possible quality of life ([Mariano, 2015](#)). Patients should receive palliative care as soon as possible when chronic or terminal disease starts creating difficult-to-manage symptoms. Palliative care is appropriate for patients of any age, with any diagnosis, at any time, and in any setting.

A large misconception concerning palliative care is that it is used only when curative treatments are no longer pursued. However, it is

appropriate both for patients still receiving aggressive treatment with hope of achieving a cure and for patients who have forgone any life-extending treatment (Coyle, 2015). It is important that you help patients and their families understand the distinction because often misunderstanding the purpose of palliative care causes patients to refuse it.

The [World Health Organization \(2018\)](#) summarizes palliative care philosophy as follows:

- Provides relief from pain and other distressing symptoms.
- Affirms life and regards dying as a normal process.
- Intends neither to hasten nor postpone death.
- Integrates the psychological and spiritual aspects of patient care.
- Offers a support system to help patients live as actively as possible until death.
- Offers a support system to help the family cope during the patient's illness and in their own bereavement.
- Uses a team approach to address the needs of patients and their families, including bereavement counseling, if indicated.
- Will enhance the quality of life and may also influence the course of illness.
- Is applicable early in the course of illness in conjunction with other therapies that are intended to prolong life, such as chemotherapy or radiation therapy, and includes those investigations needed to better understand and manage distressing clinical complications.

Because the focus of palliative care is comfort and improved quality of life, it is a valuable approach to caring for patients with a complex illness. A variety of therapies are used to provide patients with a holistic approach to symptom management and ultimately improved quality of life. Complementary therapies using an integrative approach have been shown to have a positive effect on feelings of depression and anxiety (see [Chapter 32](#)). For example, fatigue, a common symptom reported by patients receiving palliative care, responds to acupuncture and exercise. Massage has been shown to reduce the symptoms of pain, anxiety, nausea, shortness of breath, and stress and to increase relaxation and peacefulness.

When the goals of care change and cure for illnesses becomes less likely, the focus shifts to more palliative care strategies and ideally transition to hospice care, a more specialized form of palliative care for the dying.

Hospice Care

Hospice care is a philosophy and model for the care of redundant patients and their families at the end of life ([Hospice Foundation of America, 2018](#)). It gives priority to managing a patient's pain and other symptoms; comfort; quality of life; and attention to physical, psychological, social, and spiritual needs and resources. Patients accepted into a hospice program usually have less than 6 months to live. Hospice services are available in home, hospital, extended-care, and nursing home settings.

The cornerstone of hospice care is a trusting relationship between the hospice team and the patient and family. Knowing expectations, desired location of care, and family dynamics helps the hospice team provide individualized care at the end of life. Unlike traditional care, patients are active participants in all aspects of hospice care, and caregivers prioritize care according to patient wishes. Patient care goals are mutually set, and all participants fully understand the patient's care preferences and try to honor them. Hospice services provide bereavement visits made by the staff after the death of the patient to help the family move through the grieving process. Hospice programs are built on the following core beliefs and services:

- Patient and family are the unit of care
- Coordinated home care with access to inpatient and nursing home beds when needed
- Symptom management
- Physician-directed services
- Provision of an interprofessional care team
- Medical and nursing services available at all times
- Bereavement follow-up after patient's death
- Use of trained volunteers for visitation and respite support

To be eligible for home hospice services, a patient must have a family caregiver to provide care when the patient is no longer able to function alone. Home care aides offer help with hygienic needs, and a nurse is available to coordinate and manage symptom relief. Nurses providing hospice care use therapeutic communication, offer psychosocial care and expert symptom management, promote patient dignity and self-esteem, maintain a comfortable and peaceful environment, provide spiritual comfort and hope, protect against abandonment or isolation, offer family support, help with ethical decision making, and facilitate mourning.

Hospice team members offer 24-hour accessibility and coordinate care between the home and inpatient setting. A patient receiving home hospice care may enter an inpatient hospice unit for stabilization of symptoms or caregiver respite. As a patient's death comes closer, the hospice team provides intensive support to the patient and family ([Hospice Foundation of America, 2018](#)).

With the death of a patient, family members benefit from the many resources of the health care team. When the patient chooses to die at home, family members provide direct care, which is often emotionally stressful and physically exhausting. In the home setting family caregivers benefit from respite care. During respite care a patient temporarily receives care from others so that family members are able to get away to rest and relax. Hospice program benefits include some days of respite care. Inform family members of home care, hospice, and community service options so that they can access the best resources for their situation.

Therapeutic Communication Approaches

The heart of nursing care is the establishment of a caring and trusting relationship with your patient. This patient-focused approach allows you to respond to patients rather than react and encourages the sharing of important information. Open-ended questions invite patients to elaborate on their thoughts and encourage them to tell their stories. Patients usually give short answers (yes or no) when you use closed-ended questions, which limit what we can learn about their situation. Use active listening, learn to be comfortable with silence, and use prompts (e.g., "go on," "tell me more") to encourage continued conversation. Empathizing, therapeutic touch, and offering self are also effective ways to therapeutically communicate with patients. Specifically, empathizing allows patients to see that their feelings are normal and that as the nurse you understand. Sometimes questioning a patient feels uncomfortable; thus stating an observation, such as "You look worried" or "You didn't eat much lunch" invites patients to respond without feeling pressure to answer (see [Chapter 24](#)).

Feelings of sadness, numbing, or anger make talking about these situations especially difficult. For example, a patient may experience anger during grief and lash out at caregivers. Some patients even become demanding and accusing. Remain supportive by letting patients and family members know that feelings such as anger are normal by saying, "I see that you're upset right now, and that's understandable. I'm here to talk with you if you want." Encourage patients to share the emotions and

concerns of greatest importance to them and then acknowledge their feelings and concerns in a nonjudgmental manner. If a patient chooses not to share feelings or concerns, express a willingness to be available at any time. Some patients do not discuss emotions for personal or cultural reasons, and others hesitate to express their emotions for fear that people will abandon or judge them. If you are reassuring and respectful of a patient's privacy, a therapeutic relationship is likely to develop. Sometimes patients need to begin to resolve their grief privately before they discuss their loss with others, especially strangers.

Do not avoid talking about a topic. When you sense that a patient wants to talk about something, make time to do so as soon as possible. This may be very challenging if you are in a busy acute care setting; however, it is a necessary part of quality nursing care and should be made a priority. Above all, remember that a patient's emotions are not something you can "fix." Instead view emotional expressions as an essential part of the patient's adjustment to significant life changes and development of effective coping skills. Help family members access other professional resources. Social workers, psychologists, chaplains, and case managers can offer additional information and support to families and patients in grief.

Provide Psychosocial Care

Patients at the end of life experience a range of psychological symptoms, including anxiety, depression, powerlessness, uncertainty, and isolation. They can experience anguish from the unknown surroundings, treatment options, health status, and the dying process. Worry or fear is common in many patients and often heightens their perception of discomfort and suffering. You can alleviate some of it by providing information to them about their condition, the course of their disease, and the benefits and burdens of treatment options. Most hospitals have health care professionals who can provide counseling.

Manage Symptoms

Managing the multiple symptoms commonly experienced when patients are chronically ill or dying remains a primary goal of palliative care nursing ([Table 36.3](#)). Uncontrolled symptoms cause distress, discomfort, and suffering to patients and families, which often complicates the dying experience. Despite the availability of effective treatment options for pain, many patients experience avoidable pain at the end of life because of misconceptions by nurses or family members (see [Chapter 44](#)). Maintain

an ongoing assessment of a patient's pain and evaluate his or her response to interventions. Reassure the family repeatedly of the need for pain control even if the patient does not appear in pain. Discuss pain control with the family frequently, and dispel any myths regarding dependence on opioids. You are responsible to advocate for change if the patient does not obtain relief from the prescribed regimen. It is imperative that you assess patients' nonverbal cues because they often are unable to communicate their intentions. During the dying process patients' renal and liver function decline, decreasing metabolism and rate of drug clearance, which might require modification to the dosage of medication. Also, be aware that advancing disease pathology, anxiety, or delirium sometimes requires the use of higher doses or different drug therapies.

TABLE 36.3**Promoting Comfort in the Terminally Ill Patient**

Symptoms	Characteristics or Causes	Nursing Implications
Pain	Pain has multiple causes, depending on patient diagnosis.	Collaborate with team members to identify and implement appropriate pharmacological and nonpharmacological interventions to reduce pain and promote comfort (see Chapter 44).
Skin discomfort	Any source of skin irritation increases discomfort.	Keep skin clean, dry, and moisturized. Monitor for incontinence.
Mucous membrane discomfort	Mouth breathing or dehydration leads to dry mucous membranes; tongue and lips become dry or chapped.	Provide oral care at least every 2 to 4 hours. Apply a light film of lip balm for dryness. Apply topical analgesics to oral lesions prn.
Corneal irritation	Blinking reflexes diminish near death, causing drying of cornea.	Optical lubricants or artificial tears reduce corneal drying.
Fatigue	Metabolic demands, stress, disease states, decreased oral intake, and heart function cause weakness and fatigue.	Provide periods of rest and educate patient about energy conservation.
Anxiety	Physical, social, or spiritual distress causes anxiety; causes may be situational or event specific.	Provide opportunity for patient to express feelings through active listening. Provide calm, supportive environment. Consult members of the health care team to determine whether pharmacological interventions are appropriate.
Nausea	Nausea is caused by medications, pain, or decreased intestinal blood flow with impending death.	Determine the cause of nausea and work to reduce nausea triggers such as strong smells. Administer antiemetics or promotility agents. Encourage patients to lie on their right side. Provide oral care at least every 2 to 4 hours.
Constipation	Opioids, other medications, and immobility slow peristalsis. Lack of bulk in diet or reduced fluid is a cause.	Increase fiber in diet if appropriate. Administer stool softeners or laxatives as needed. If possible, encourage increased liquid intake and regular periods of ambulation.
Diarrhea	Disease processes, treatment or medications, and gastrointestinal (GI) infections are causes.	Consult with members of the health care team to determine the cause and make appropriate changes. Provide skin care and easy accessibility to the toilet or bedside commode.
Urinary incontinence	Progressive disease and decreased level of consciousness are causes.	Provide good skin care and frequent assessment for incontinent urine. Place Foley catheter as appropriate.
Altered nutrition	Medications, depression, decreased activity, and decreased blood flow to GI tract are causes. Nausea produces anorexia.	Encourage patient to eat small, frequent meals of preferred foods. Patients should never be forced to eat.
Dehydration	Patient is less willing or able to maintain oral fluid intake; has fever.	Reduce discomfort from dehydration; give mouth care at least every 2 to 4 hours; offer ice chips or moist cloth to lips. Keep lips and tongue moist.

Symptoms	Characteristics or Causes	Nursing Implications
Ineffective breathing patterns (e.g., dyspnea, shortness of breath)	Anxiety; fever; pain; increased oxygen demand; disease processes; and anemia, which reduces oxygen-carrying capacity, are causes.	Treat or control underlying cause. Use nonpharmacological interventions such as elevating the head of the bed to promote lung expansion. Provide oxygen as needed. Keeping the air cool provides ease and comfort for the terminal patient. Using morphine or benzodiazepines to treat tachypnea is sometimes appropriate.
Noisy breathing ("death rattle")	Noisy breathing is the sound of secretions moving in the airway during inspiratory and expiratory phases caused by thick secretions, decreased muscle tone, swallow, and cough.	Elevate head to facilitate postural drainage. Turn patient at least every 2 hours. Provide oral care and maintain hydration as tolerated.

Remain alert to the potential side effects of opioid administration: constipation, nausea, sedation, respiratory depression, or myoclonus. Family members often worry about potential addiction to opioid medications. Not only is the incidence of true addiction very low, but a patient's need for pain relief at the end of life takes priority. Education is necessary to help families understand the need for appropriate use of opioid medications.

Promote Dignity and Self-Esteem

A patient's sense of dignity depends on a positive self-regard and the ability to find meaning in life and feel valued by others. A sense of dignity is reinforced by respectful treatment from caregivers. Nurses promote a patient's self-esteem and dignity by respecting him or her as a whole person (i.e., as a person with feelings, accomplishments, and passions independent of the illness experience). Respecting and valuing the things that a patient cares about validates the person and at the same time strengthens communication among the patient, family members, and the nurse. Sharing time with patients as they share their life stories helps you know them and facilitates the development of individualized interventions.

Attending to the patient's physical appearance also promotes dignity and self-esteem. Cleanliness, absence of body odors, and clean clothing give patients a sense of worth. When caring for a patient's bodily functions, show patience and respect, especially after the patient becomes dependent on others. Remember that patients are directing care at the end of life. Allow them to make decisions such as how and when to administer personal hygiene, diet preferences, and timing of nursing interventions. Keep the patient and family members informed about daily activities,

tests, or therapies; their purposes; and anticipated effects. Provide privacy during nursing care procedures and be sensitive to when the patient and family need time alone together.

Maintain a Comfortable and Peaceful Environment

A comfortable, clean, pleasant environment helps patients relax, promotes good sleep patterns, and minimizes symptom severity. Keep a patient comfortable through frequent repositioning, making sure that bed linens are dry, and controlling extraneous environmental noise and offensive odors. Pictures, cherished objects, and cards or letters from family members and friends create a familiar and comforting environment for the patient dying in an institutional setting. When possible, allow patients to wear their own pajamas or lounging clothes to promote a sense of comfort and familiarity. Consider nonpharmacological interventions such as massage therapy to increase patient comfort (Paice, 2015). Family members are often able to provide these interventions, increasing their sense that they are making a positive contribution. Use patient-preferred music in the background, provide guided-imagery exercises, and dim the lights to provide a soothing environment for the patient and family. Patient-preferred forms of complementary therapies offer noninvasive methods to increase comfort and well-being at the end of life (Mariano, 2015) (see Chapter 32).

Promote Spiritual Comfort and Hope

Patients are comforted when they have assurance that some aspect of their lives will transcend death; therefore, helping patients make connections to their spiritual practice or cultural community can be a useful intervention. Draw on the resources of spiritual care providers in an institutional setting or collaborate with the patient's own spiritual or religious leaders and communities. Making an audiotape or videotape for the family, writing letters, or keeping a journal assures patients that something of their essence will survive past their death.

The spiritual concept of hope takes on special significance near the end of life. Nursing strategies that promote hope are often quite simple: be present and provide whole-person care. Patients perceive the love of family and friends, faith, goal setting, positive relationships with professional caregivers, humor, and uplifting memories as hope promoting. Circumstances that hinder the preservation of hope include abandonment or isolation, uncontrolled symptoms, or being devalued as a

person. Patients and their families hope for different things over the course of their experience with illness and death. Balancing each perspective is imperative to quality patient care at the end of life. Some hope to live for an anniversary, sit outdoors for a meal, see an important person one last time, gain pain relief, or have a peaceful death. Listen for shifts in patients' hopes and find ways to help them meet their desired goals.

Protect Against Abandonment and Isolation

Many patients with terminal illness fear dying alone. Patients with chronic disease often become socially isolated by choice. However, most patients feel more hopeful when others are near to help them. Nurses in institutional settings need to answer call lights promptly and check on patients often to reassure them that someone is close at hand. If family members always plan to stay with the patient or if you have assessed high privacy needs for the patient and family, a private room is best.

Some family members who have a difficult time accepting a patient's impending death cope by making fewer visits. When family members do visit, inform them of the patient's status and share meaningful insights or encounters that you have had with the patient. Find simple and appropriate care activities for the family to perform, such as offering food, cooling the patient's face, combing hair, or filling out a menu. Nighttime can be particularly lonely for the patient. Suggest that a family member stay through the night if possible. Make exceptions to visiting policies, allowing family members to remain with patients who are dying at any time. Family members appreciate having open access or closeness to their loved one through their experiences at the end of life. Record contact information for them, so you can reach them at any time.

Support the Grieving Family

In palliative and hospice care patients and family members constitute the unit of care. When a patient becomes debilitated or approaches the end of life, family members also suffer. They describe caregiving at the end of life as unpredictable, frightening, and anguishing. Yet many family members find meaning in providing practical and simple care to their loved one. In these extremely intimate and emotionally challenging times, offer holistic, family-centered support, compassion, and education that incorporates the uniqueness of each patient. Often family members face challenging and complex situations long before their loved one is actively dying. Family members caring for people with serious life-limiting illness need attention

and support early and consistently throughout the experience of illness and death.

Educate family members in all settings about the symptoms that the patient is likely to experience and the implications for care (see [Table 36.3](#) and [Box 36.7](#)). For example, patients in the last days of life often develop anorexia or feel nauseated by food. Illness, excessive respiratory secretions, decreased activity, treatments, and fatigue decrease a patient's caloric needs and appetite. Family members, distressed with the decline, often believe that they need to encourage the patient to eat. Because the goal of palliative care is comfort, do not force the patient to do anything that is causing discomfort. Eating in the last days of life often causes the patient pain and discomfort. In addition, as the body is shutting down, the nutrients in food are not able to be absorbed. Therefore, forcing patients to eat does not benefit the patient. Help families shift their focus to other helping activities during this time.

Box 36.7 Evidence-Based Practice Managing Opioid-Induced Constipation

PICOT Question: In patients who are terminally ill, what is the effect of pharmacological interventions to reduce opioid-induced constipation compared with nonpharmacological interventions?

Evidence Summary

A majority of patients at the end of life use opioids to control pain and discomfort. A common side effect of opioids is opioid-induced constipation (OIC). This adds to unpleasant and uncomfortable symptoms experienced by the patient. Nurses commonly use nonpharmacological measures such as ambulation and increasing fiber and fluids to help patients with constipation, but these traditional interventions may be inappropriate for patients at the end of life. Besides using laxatives, stimulants, or stool softeners, several new drugs are available. Naloxegol is an oral peripherally acting selective μ -opioid antagonist that has been shown to be safe and effective for the treatment of OIC (Nee et al., 2018). Methylnaltrexone, a derivative of naltrexone, is a subcutaneous drug also with highly positive outcomes (Star and Boland, 2018).

Application to Nursing Practice

- Although there are positive improvements in the treatment of opioid-induced constipation, prevention is key.
- Use the lowest dose possible of the least constipating opioid to control pain—for example, fentanyl instead of oxycodone.
- Try traditional nonpharmacological interventions, if appropriate, and laxatives before trying naloxegol or methylnaltrexone (Star and Boland, 2018).

Family members who have limited experience with death do not know what to expect. They may need personal time with you to share their concerns, ask about treatment options, validate perceived changes in the patient's status, or explore the possible meaning of patient behaviors. Whenever possible, communicate news of a patient's declining condition or impending death when family members are together, so they can support one another. Provide information privately and stay with the family as long as needed or desired. Reduce family member anxiety, stress, or fear by describing what to expect as death approaches. Become familiar with common manifestations of impending death ([Box 36.8](#)), remembering that patients usually experience some but not all of these changes. Do not try to predict the time of death; instead use your assessments to help family members anticipate what is happening. Be compassionate and sensitive in how you share information. "Mottling is an expected sign as a body begins shutting down" instead of "when a person gets closer to death, we see mottling" ([Fig. 36.4](#)). Share your observations and through your role modeling encourage a sense of patience, compassion, and comfort throughout the dying process.

Box 36.8 Physical Changes Hours or Days Before Death

- Increased periods of sleeping/unresponsiveness
- Circulatory changes with coolness and color changes in extremities, nose, fingers (cyanosis, pallor, mottling) (see [Fig. 36.4](#))
- Bowel or bladder incontinence
- Decreased urine output; dark-colored urine
- Restlessness, confusion, or disorientation

- Decreased intake of food or fluids; inability to swallow
- Congestion/increased pulmonary secretions; noisy respirations (death rattle)
- Altered breathing (apnea, labored or irregular breathing, Cheyne-Stokes pattern)
- Decreased muscle tone, relaxed jaw muscles, sagging mouth
- Weakness and fatigue

FIG. 36.4 Skin mottling.

From Adams J, et al: *Emergency medicine: clinical essentials*, ed 2, Philadelphia, 2014, Elsevier.

During the dying process check frequently on families, offering support, information, and, if appropriate, encouragement to continue touching and talking with their loved ones. In the time immediately following death determine the family's needs. Some families will want to touch or hold the deceased; others will not. Make the deceased accessible by lowering side rails, leaving hands exposed, and setting a chair close to the bedside. Depending on agency policies, allow the family the necessary time to be with their loved one.

After death help the family make decisions such as notification of a funeral home, transportation of family members, and collection of the patient's belongings. Nurses are a primary source of family support. Remember that, because of differing responses to grief, some family members prefer to be alone at the time of and after the death, whereas others want to be surrounded by a support community. When uncertain about what a family member prefers for support, pose simple questions and offer suggestions for assistance.

Facilitate Mourning

Nurses who work with grieving family members often provide bereavement care after the patient's death. Helpful strategies for assisting grieving persons include the following:

- Help the survivor accept that the loss is real. Discuss how the loss or illness occurred or was discovered, when, under what circumstances, who told him or her about it, and other factual topics to reinforce the reality of the event and put it in perspective.
- Support efforts to adjust to the loss. Use a problem-solving approach. Have survivors make a list of their concerns or needs, help them prioritize, and lead them step-by-step through a discussion of how to proceed. Encourage survivors to ask for help.
- Encourage establishment of new relationships. Reassure people that new relationships do not mean that they are replacing the person who has died. Encourage involvement in nonthreatening group social activities (e.g., volunteer activities or church events).
- Allow time to grieve. "Anniversary reactions" (e.g., renewed grief around the time of the loss in subsequent years) are common, along with renewed grief at holidays. A return to sadness or the pain of grief is often worrisome. Openly acknowledge the loss, provide reassurance that the reaction is normal, and encourage the survivor to reminisce.
- Interpret "normal" behavior. Being distractible, having difficulty sleeping or eating, and thinking that they have heard the deceased's voice are common behaviors for survivors following loss. These symptoms do not mean that an individual has an emotional problem or is becoming ill. Reinforce that these behaviors are normal and will resolve over time.
- Provide continuing support. Following a loss, survivors need the support of a nurse with whom they have bonded for a time,

especially in cases of in-home care or hospice nursing. Your goal is to fulfill an important role in the deceased's life and death, helping survivors through some very intimate and memorable times.

Attachment for a period of time after the death is appropriate and healing for both the survivor and you. However, it is imperative that professional boundaries always be maintained.

- Be alert for signs of ineffective, potentially harmful coping mechanisms such as alcohol and substance abuse or excessive use of over-the-counter analgesics or sleep aids.

Care After Death

Federal and state laws require institutions to develop policies and procedures for certain events that occur after death: requesting organ or tissue donation, performing an autopsy, certifying and documenting the occurrence of a death, and providing safe and appropriate postmortem care. In accordance with federal law, a specially trained professional (e.g., transplant coordinator or social worker) makes requests for **organ and tissue donation** at the time of every death. The person requesting organ or tissue donation provides information about who can give consent legally, which organs or tissues can be donated, associated costs, and how donation affects burial or cremation.

In extremely stressful circumstances created by the loss of a loved one, grieving survivors usually cannot remember all they were told. Nurses provide support and reinforce or clarify explanations. In addition, understanding the physiology of organ donation is often difficult for family members. Even though a patient who is brain dead is legally declared dead, he or she remains on life support to provide the vital organs with blood and oxygen before transplant. The appearance of a live-looking body confuses the family, and they need help to understand that the life support is only preserving the vital organs. Nonvital tissues such as corneas, skin, long bones, and middle ear bones are taken at the time of death without artificially maintaining vital functions. If the deceased has not left behind instructions concerning organ and tissue donation, the family gives or denies consent at the time of death. Review your state organ-retrieval laws and institutional policy and procedure regarding the formal consent process. Be aware that the laws governing whom to approach for organ donation may not be acceptable in other cultures.

Family members give consent for an **autopsy** (i.e., the surgical dissection of a body after death) to determine the exact cause and circumstances of death or to discover the pathway of a disease (see [Chapter 23](#)). In most

cases a coroner or medical examiner determines the need to perform an autopsy. Law sometimes requires that an autopsy be performed when death is the result of foul play; homicide; suicide; or accidental causes such as motor vehicle crashes, falls, the ingestion of drugs, or deaths within 24 hours of hospital admission. Follow state and agency requirements regarding removal of lines (e.g., IVs, indwelling urinary catheter) in patients when an autopsy is ordered.

Usually the physician or other designated health care provider asks for autopsy permission while the nurse answers questions and supports the family's choices. Inform family members that an autopsy does not deform the body and that all organs are replaced in the body. Family members are often comforted to know that others may be helped by either the gift of organ and tissue donation or autopsy. Respect and honor family wishes and final decisions.

Documentation of a death provides a legal record of the event. Follow agency policies and procedures carefully to provide an accurate and reliable medical record of all assessments and activities surrounding a death. Physicians or coroners sign some medical forms, such as a request for autopsy, but the nurse gathers and records much of the remaining information surrounding a death. Nurses also usually witness or delegate the signing of forms (e.g., release of body or personal belongings forms). Nursing documentation becomes relevant in risk management or legal investigations into a death, underscoring the importance of accurate, legal reporting. Documentation also validates success in meeting patient goals or provides justification for changes in treatment or expected outcomes. [Box 36.9](#) lists important documentation elements for end-of-life care.

Box 36.9 Documentation of End-of-Life Care

- Time and date of death and all actions taken to respond to the impending death
- Verification of death according to health care agency policy
- Name of health care provider certifying the death
- People notified of the death (e.g., health care providers, family members, organ request team, morgue, funeral home, spiritual care providers) and person who declared the time of death
- Name of person making request for organ or tissue donation

- Special preparations of the body (e.g., desired or required spiritual, religious and cultural rituals)
- Medical tubes, devices, or lines left in or on the body
- Personal articles left on and secured to the body
- Personal items given to the family with description, date, time, to whom given
- Location of body identification tags
- Time of body transfer and destination
- Any other relevant information or family requests that help clarify special circumstances

Family members deserve and expect a clear description of what happened to their loved one, especially in cases of sudden, unusual, or unexpected circumstances. Give *only* factual information in a nonjudgmental, objective manner, and avoid sharing your opinions. State law and agency policy govern the sharing of the written medical record information, which usually involves a written request. Follow legal guidelines for documentation and sharing of medical records (see [Chapter 23](#)).

When a patient dies in an institutional or home care setting, nurses provide or delegate **postmortem care**, the care of a body after death. Above all, a deceased person's body deserves the same respect and dignity as that of a living person and needs to be prepared in a manner consistent with the patient's cultural and religious beliefs. Death produces physical changes in the body quite quickly; thus, you need to perform postmortem care as soon as possible to prevent discoloration, tissue damage, or deformities. Many hospitals have a policy for how many hours the body can stay on the unit before being sent to the morgue. This is important as this is the time that family members have to mourn directly after death.

Maintaining the integrity of cultural and religious rituals and mourning practices at the time of death gives survivors a sense of fulfilled obligations and promotes acceptance of the patient's death ([Box 36.10](#)). The ability of families to mourn in a manner consistent with cultural values helps survivors experience some predictability and control in an otherwise uncertain and confusing time. Some cultures consider "family" as more than a nuclear biological unit. Health care providers need to understand the makeup of a family network and know which individuals to involve in end-of-life decisions and care.

Box 36.10 Cultural Aspects of Care **Care of the Body**

After Death

Loved ones use cultural-specific rituals and mourning practices to achieve a sense of acceptance and inner peace and participate in socially accepted expressions of grief. One's culture greatly influences which behaviors and rituals are expected at the time of death. Institutional guidelines and end-of-life care procedures for patients from all cultures provide standards based on showing compassion, maintaining privacy and dignity, and respecting patients' and family members' cultural beliefs and practices. Expert end-of-life care allows time for patients and their families to make private and public preparations and to complete unfinished communication. Understanding the uniqueness of cultural expectations at the end of life helps you to know which questions to ask. The following cultural or religious practices are not necessarily exclusive to the culture named but are offered to give you an idea of some culture-specific concerns that you may encounter in end-of-life care.

Implications for Patient-Centered Care

Honoring the patient's and the family's cultural and spiritual customs is very important when caring for the dying and the dead. Here are some important things to know (or ask) concerning special ways to care for the body during and after death.

- Will there be large extended-family groups, including the church family, coming to be present at the time of death?
- Will the family be having organs donated or an autopsy completed?
- Do the patient and family believe in an afterlife?
- Should a religious leader be called to the deathbed for a prayer or blessing?
- Does the deceased require special bathing or clothes after death?
- Will family or male members of the religious order need to stay with the deceased while waiting for transport/burial?
- Can only members of the same gender tend to the deceased's body?
- Does the body need to lie with the head facing a certain direction?

You will coordinate patient and family care during and after a death. Become familiar with applicable policies and procedures for postmortem

care because they vary across settings or institutions. See the procedural guideline ([Box 36.11](#)) for standard activities for care of the body after death.

Box 36.11 Procedural Guidelines **Care of the Body After Death**

Delegation and Collaboration

The skill of care of the body after death can be delegated to assistive personnel (AP). Nurses often find it meaningful to help care for a patient after death and assist the AP whenever possible. Instruct the AP to:

- Contact the nurse for all questions and procedures related to organ/tissue donation and autopsy requests.
- Alert nurse to family members' questions related to manner of death or after-death activities.

Equipment

Bath towels, washcloths, washbasin, scissors, clean disposable gloves, gown (if high risk of exposure to body fluids), shroud kit with name tags, bed linen, documentation forms.

Steps

1. Confirm that the health care provider certified the death and documented the time of death and actions taken.
2. Determine whether the health care provider requested an autopsy. An autopsy is required for deaths that occur under certain circumstances.
3. Validate the status of request for organ or tissue donation. Given the complex and sensitive nature of such requests, only specially trained personnel make the requests. Maintain sensitivity to personal, spiritual, religious, and cultural beliefs in this process.
4. Identify the patient using two identifiers (e.g., name and birthday or name and medical record number according to agency policy).
5. Perform hand hygiene and apply disposable gloves. Apply gown if risk of exposure to body fluids is high.

6. Provide sensitive and dignified nursing care to the patient and family.
 - a. Elevate the head of the bed as soon as possible after death to prevent discoloration of the face.
 - b. Collect ordered specimens.
 - c. Ask whether the family wishes to participate in preparation of the body. Offer to make arrangements for supportive company for the family (patient/family religious leader, spiritual care personnel, or bereavement specialist) during body preparation.
 - d. Ask about family requests for body preparation, such as wearing special clothing or religious artifacts. Be aware that personal, religious, or cultural practices determine whether to shave male facial hair. Get permission before shaving a beard.
 - e. Remove all equipment, tubes, and indwelling lines. Note that autopsy or organ donation often poses exceptions to removal; thus, consult agency policy in these situations.
 - f. Cleanse the body thoroughly, maintaining safety standards for body fluids and contamination when indicated. Remove gloves and gown (if needed) and perform hand hygiene.
 - g. Comb patient's hair or apply personal hairpieces.
 - h. Cover body with a clean sheet, place head on a pillow, and leave arms outside covers if possible. Close eyes by gently holding them shut; leave dentures in the mouth to maintain facial shape; cover any signs of body trauma.
 - i. Prepare and clean the environment, deodorize room if needed, and lower the lights.
 - j. Offer family members the option to view the body. Ask whether they want you or other support people to accompany them. Honor and respect individual choices.
 - k. Encourage grievers to say goodbye in their own way: words, touch, singing, spiritual or religious rituals, or prayers.
 - l. Provide privacy and a quiet, peaceful atmosphere. Assess family members' need or desire for your presence at this time. If you leave, tell them how to reach you.
 - k. Determine which personal belongings stay with the body (e.g., wedding ring or religious symbol), and give other

personal items to family members. Document time, date, description of the items taken, and who received them. Save any items that are left behind accidentally and contact family for further instructions.

- l. Apply identifying name tags and shroud according to agency policy before transporting the body. Perform hand hygiene.
- m. Complete documentation in the narrative notes section (see Box 36.9).
- n. Maintain privacy and dignity when transporting the body to another location; cover the body or stretcher with a clean sheet.

• Evaluation

Through the Patient's Eyes

The success of the evaluation process depends partially on the bond that you have formed with the patient and family. Through a trusting relationship, patients are more likely to share personal expectations or their wishes, especially if encouraged through appropriate questioning. The following questions evaluate if patient perceptions have been met:

- What is the most important thing I can do for you at this time?
- Are your needs being addressed in a timely manner?
- Are you getting the care for which you hoped?
- Would you like me to help you in a different way?
- Do you have a specific request that I have not met?

Refer back to the goals and expected outcomes established during the planning phase to determine if the patient and family perceive that goals were met. A patient's responses and perceptions of the effectiveness of nursing interventions help determine whether the existing plan of care is effective or different strategies are necessary. Even when a patient is not seeking care specifically related to a loss, be alert for signs and symptoms of grief. They provide the criteria for evaluating whether a patient is coping with a loss and how he or she is moving through the grief process. Critical thinking ensures that the evaluation process accurately reflects the patient's situation and desired outcomes (Fig. 36.5).

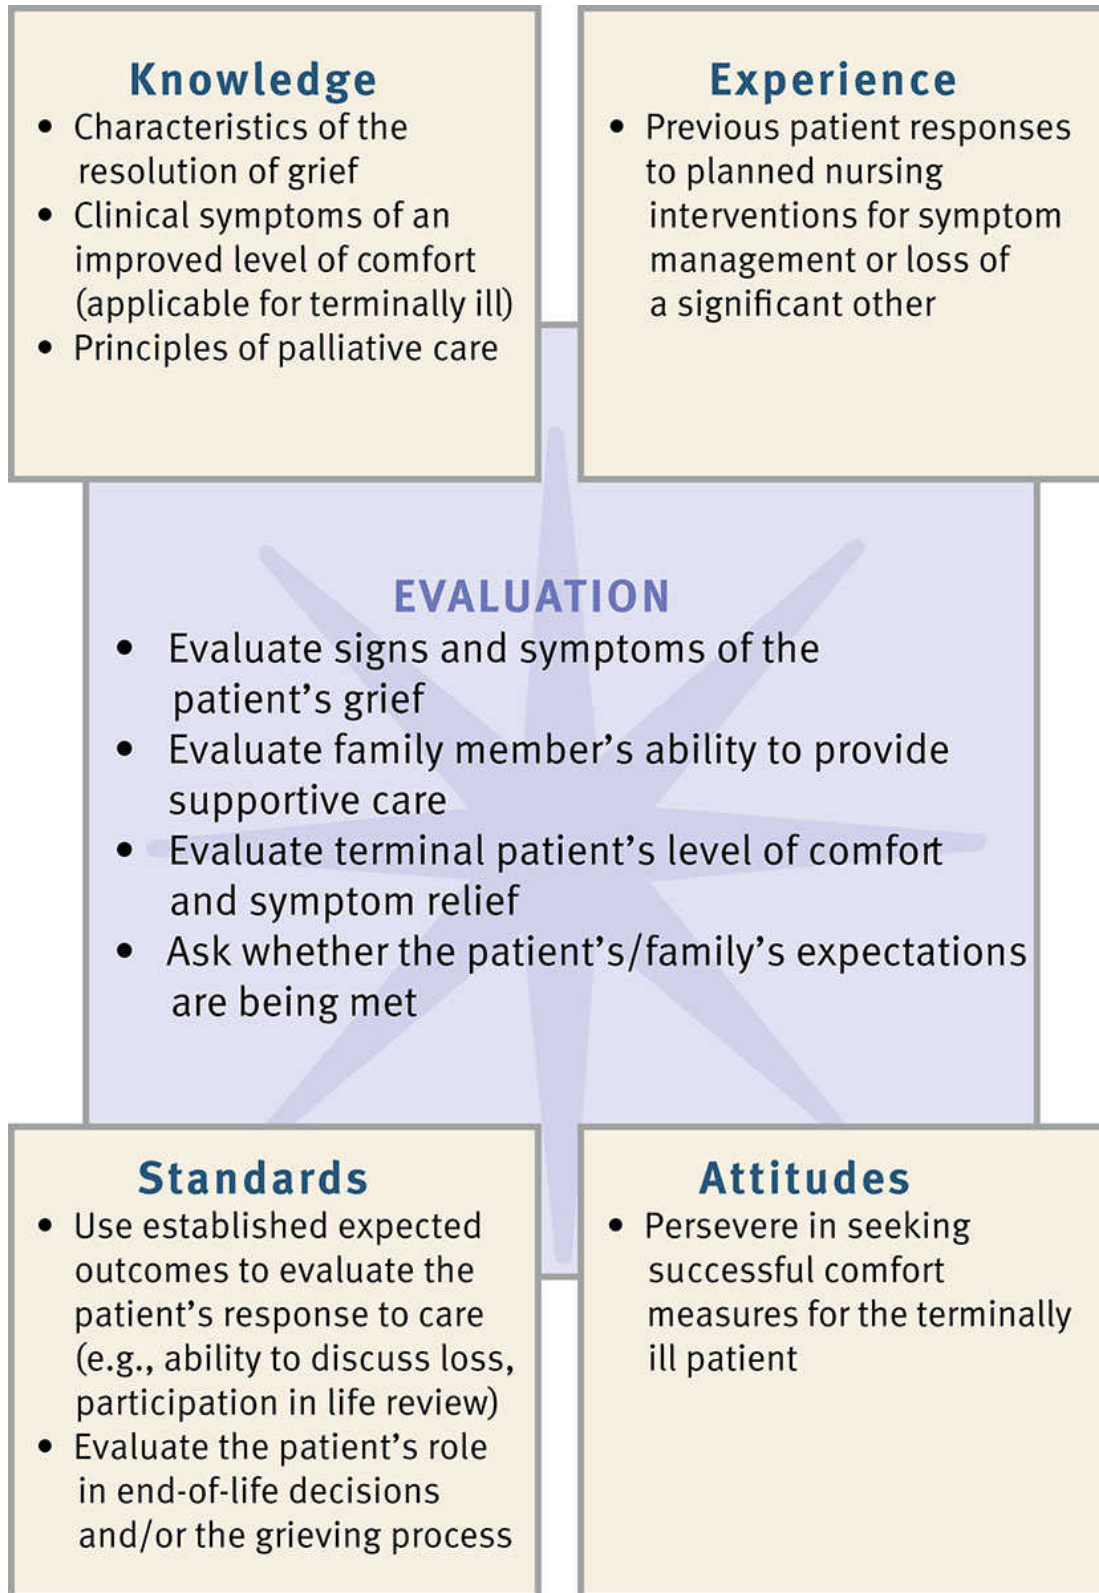

FIG. 36.5 Critical thinking model for loss, death, and grief evaluation.

Patient Outcomes

Review the goals and expected outcomes of the plan of care to determine if nursing interventions were successful or if modifications are needed. For example, if the goal is to have the patient communicate a sense of hope to family members, evaluate verbal and nonverbal communication and behaviors for cues related to expressions of hope. If the goal is to achieve a level of comfort, evaluate if the severity of pain has declined and if the patient is able to participate in more self-care activities. Continue to evaluate the patient's progress, the effectiveness of the interventions, and patient and family interactions.

In-home care settings it is critically important to include family members in the evaluation process. The short- and long-term outcomes that signal a family's recovery from a loss guide your evaluation. Short-term outcomes indicating effectiveness of grief interventions include talking about the loss without feeling overwhelmed, improved energy level, normalized sleep and dietary patterns, reorganization of life patterns, improved ability to make decisions, and finding it easier to be around other people. Long-term achievements include the return of a sense of humor and normal life patterns, renewed or new personal relationships, and decrease of inner pain.

Key Points

- When caring for patients who are experiencing loss, facilitate the grief process by helping them feel the loss, express it, and move through their grief.
- Loss comes in many forms, based on the values and priorities learned within a person's sphere of influence (i.e., family, friends, religion, society, and culture) as well as a natural part of maturation.
- Survivors move back and forth through a series of stages or tasks many times, possibly extending over a long period of time.
- Depending on the characteristic and context of the loss, as well as of the griever, there are several types of grief that can be

experienced.

- People who are grieving use their own unique history, context, and resources to make meaning out of their loss experiences. Listen as patients share the experience in their own way.
- A person's development, coping strategies, socioeconomic status, personal relationships, nature of loss, and cultural and spiritual beliefs influence the way he or she perceives and responds to grief.
- Assess the wishes of a patient and family for end-of-life care, including the preferred place for death, desired level of intervention, and expectations for pain and symptom management.
- Establish a caring presence and use effective communication strategies to encourage patients to share to the degree they are comfortable. Collaborate with other members of the health care team to provide holistic care for management of symptoms and to provide a variety of support measures to the patient and family.
- Quality end-of-life care focuses on improving quality of life through management of unpleasant symptoms such as pain, anxiety, and nausea.
- Hospice is a philosophy of family-centered, whole-person care for individuals with a life-limiting illness likely to result in death within 6 months.
- After determining that an autopsy will be performed, the body of the deceased is cared for and treated with the same level of care and compassion, respect, and dignity as when the person was alive.

Reflective Learning

- Knowing that you disagree with a patient's choice to not seek further treatment, how do you continue to compassionately support the patient while keeping your personal thoughts and beliefs from influencing your care?
- Think about how, from a cultural or spiritual perspective, you will begin and maintain a conversation about advance directives with your patient and the patient's family.
- Often, we think of death as a form of failure, that somehow health care professionals didn't get it right. However, how can quality end-of-life care embody what it means to truly provide the best for our patients?

Review Questions

1. To best assist a patient in the grieving process, which factors are most important for the nurse to assess? (Select all that apply.)
 1. Previous experiences with grief and loss
 2. Religious affiliation and denomination
 3. Ethnic background and cultural practices
 4. Current financial status
 5. Current medications
2. Which interventions does a nurse implement to help a patient at the end of life maintain autonomy while in a hospital? (Select all that apply.)
 1. Use therapeutic techniques when communicating with the patient.
 2. Allow the patient to determine timing and scheduling of interventions.
 3. Allow patients to have visitors at any time.
 4. Provide the patient with a private room close to the nurses' station.

5. Encourage the patient to eat whenever he or she is hungry.
3. The nurse recognizes that which factors influence a person's approach to death? (Select all that apply.)
 1. Culture
 2. Spirituality
 3. Personal beliefs
 4. Previous experiences with death
 5. Gender
 6. Level of education
4. A nurse has the responsibility of managing a patient's postmortem care. What is the proper order for postmortem care when there is no autopsy ordered?
 1. Bathe the body of the deceased.
 2. Collect any needed specimens.
 3. Remove all tubes and indwelling lines.
 4. Position the body for family viewing.
 5. Speak to the family members about their possible participation.
 6. Ensure that the request for organ/tissue donation and/or autopsy was completed.
 7. Notify support person (e.g., spiritual care provider, bereavement specialist) for the family.
 8. Accurately tag the body, including the identity of the deceased and safety issues regarding infection control.
 9. Elevate the head of the bed.
5. Which comments to a patient by a new nurse regarding palliative care needs are correct? (Select all that apply.)
 1. "Even though you're continuing treatment, palliative care is something we might want to talk about."

2. "Palliative care is appropriate for people with any diagnosis."
 3. "Only people who are dying can receive palliative care."
 4. "Children are able to receive palliative care."
 5. Palliative care is only for people with uncontrolled pain.
6. A patient is receiving palliative care for symptom management related to anxiety and pain. A family member asks whether the patient is dying and now in "hospice." What does the nurse tell the family member about palliative care? (Select all that apply.)
1. Palliative care and hospice are the same thing.
 2. Palliative care is for any patient, any time, any disease, in any setting.
 3. Palliative care strategies are primarily designed to treat the patient's illness.
 4. Palliative care relieves the symptoms of illness and treatment.
 5. Palliative care selects home health care services.
7. When planning care for a dying patient, which interventions promote the patient's dignity? (Select all that apply.)
1. Providing respect
 2. Viewing the patient as a whole
 3. Providing symptom management
 4. Showing interest
 5. Being present
 6. Inserting a straight catheter when the patient has difficulty voiding
8. What are the physical circulatory changes that occur as death approaches?
1. Skin irritation
 2. Mottling
 3. Increased urine output

4. Weakness

9. When providing postmortem care, which actions are necessary for the nurse to complete?

1. Locating the patient's clothing
2. Calling the funeral home
3. Providing culturally and religiously sensitive care in body preparation
4. Providing postmortem care to protect the family of the deceased from having to view the body

10. Which actions by the nurse help grieving families? (Select all that apply.)

1. Encourage involvement in nonthreatening group social activities.
2. Follow up with the family in their home.
3. Remind them that feelings of sadness or pain can return around anniversaries.
4. Encourage survivors to ask for help.
5. Look for overuse of alcohol, sleeping aids, or street drugs.

Stress and Coping

OBJECTIVES

- Explain the three stages of the general adaptation syndrome.
- Describe characteristics of post-traumatic stress disorder.
- Discuss the integration of stress theory with nursing theories.
- Identify the effects that compassion fatigue can have in the health care workplace.
- Explain stress-management techniques that help individuals cope with stress.
- Discuss the process of crisis intervention.
- Develop a care plan for patients who are experiencing stress.
- Discuss how stress in the workplace affects nurses.

Stressors, p. 761
Trauma, p. 761

Stress can impact the physical and mental well-being of patients as well as their entire families and communities. Nurses need to become familiar with stress and consider its effects when delivering patient care. Equally important, health care professionals also experience stressful events in the course of clinical practice and their own lives. Nurses need to consider their own stress by recognizing burnout, compassion fatigue, and second victim syndrome. It is important for nurses to understand stress-management techniques to aid their own personal coping and to design stress-management interventions for patients and families.

Stress is described as an actual or alleged hazard to the balance of homeostasis. It is often described as a physical, chemical, or emotional factor that produces tension in the body or the mind (Banasik and Copstead, 2019). Such factors are referred to as stressors. **Stressors** are any physical, psychological, or social stimuli that are capable of producing stress and endangering homeostasis (Banasik and Copstead, 2019). Stressors differ in their scope, strength, and duration. A stressor of less intensity can still have a substantial influence if it continues over time. An important element in the perception of a stressor is appraisal. **Appraisal** is how a person interprets the impact of the stressor. It is also a personal evaluation of the meaning of the event to what is happening and a consideration of the resources on hand to help manage the stressor. Stress emerges when an individual considers the event as a threat and the ability

to respond to the demands placed on the individual by the event to be overwhelming. Thus, stress can lead to personal growth and development or overwhelm a person and lead to illness or worsening of existing acute or chronic illnesses ([Liu et al., 2017](#)).

People experience stress as a consequence of daily life events and experiences—such as loss of a loved one, change in job responsibilities, or illness—which stimulates their ability to think clearly and stay alert to the environment. How people react to stress depends on how they view and evaluate the impact of the stressor, its effect on their situation and support at the time of the stress, and their usual coping mechanisms. When stress overwhelms existing coping mechanisms, patients lose emotional balance, and a crisis results. If symptoms of stress persist beyond the duration of the stressor, a person experiences a **trauma** ([Sacks et al., 2017](#)).

Scientific Knowledge Base

Hans Selye, a Vienna-born endocrinologist, was the first scientist to single out the physical side effects of stress. While conducting experiments related to hormone production, Selye noticed that his subjects showed a similar set of side effects regardless of the type of life-threatening stimulus that researchers presented. Selye termed this collection of responses the **general adaptation syndrome (GAS)**, a three-stage set of physiological processes that prepare, or adapt, the body for danger so that an individual is more likely to survive when faced with a threat (Waude, 2016).

Selye (1993) identified the three stages to the stress response as (1) initial alarm, (2) resistance as a person attempts to compensate for changes induced by the alarm stage, and (3) a state of exhaustion if the person cannot adapt successfully during the stage of resistance or if stress remains unrelieved. When stress reaches chronic and harmful levels, negative consequences follow. Selye's initial theory has evolved as scientists have learned more about the physiological responses to stress.

General Adaptation Syndrome

The general adaptation syndrome (GAS), the three-stage reaction to stress, describes how the body responds physiologically to stressors (Fig. 37.1). The GAS is triggered either directly by a physical event or indirectly by a psychological event. It involves several body systems, especially the neuroendocrine mechanism, which responds immediately to stress (see Fig. 37.1). When the body encounters a physical demand such as an injury, the pituitary gland initiates the GAS. A fundamental concept underlying this reaction is that the body will attempt to return to a state of balance, a process referred to as **allostasis** (Banasik and Copstead, 2019).

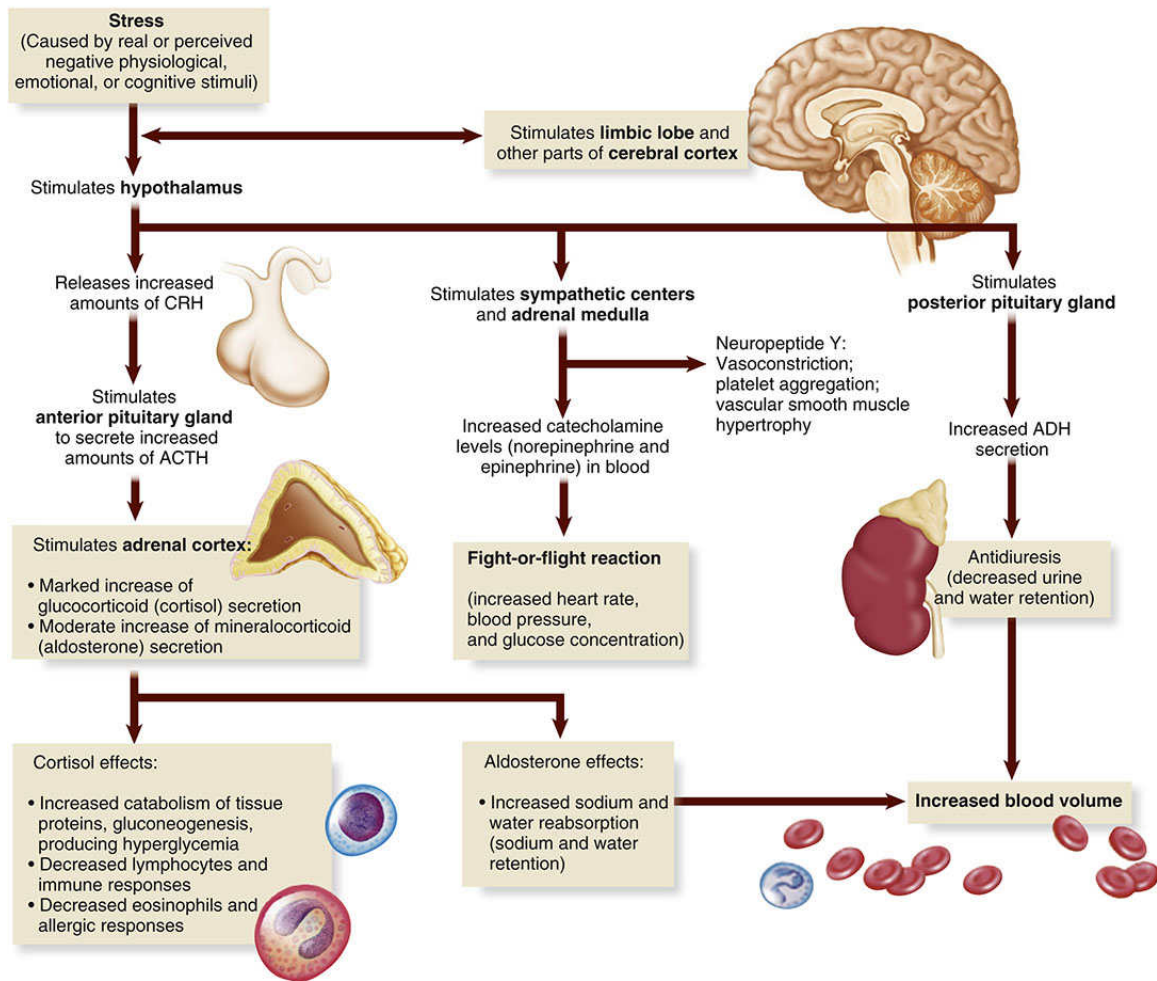

FIG. 37.1 Short-term and long-term stress response. Some effects are immediate, such as the sympathetic fight-or-flight reaction, and some effects are longer-term, such as the hormonal effects. *ACTH*, Adrenocorticotropic hormone; *ADH*, antidiuretic hormone; *CRH*, corticotropin-releasing hormone. From Patton KT: *Anatomy & physiology*, ed 10, St Louis, 2019, Elsevier.

During the **alarm stage** the central nervous system is aroused, and body defenses are mobilized; this is the **fight-or-flight response**. During this stage rising hormone levels result in increased blood volume, blood glucose levels, epinephrine and norepinephrine, heart rate, blood flow to muscles, oxygen intake, and mental alertness. In addition, the pupils of the eyes dilate to produce a greater visual field. If the stressor poses an extreme threat to life or remains for a long time, the person progresses to the second stage, resistance.

The **resistance stage** also contributes to the fight-or-flight response, and the body stabilizes and responds in an attempt to compensate for the changes induced by the alarm stage (Huetter et al., 2017). Hormone levels, heart rate, blood pressure, and cardiac output should return to normal,

and the body tries to repair any damage that occurred. However, these compensation attempts consume energy and other bodily resources.

In the **exhaustion stage** continuous stress causes progressive breakdown of compensatory mechanisms. This occurs when the body is no longer able to resist the effects of the stressor and has depleted the energy necessary to maintain adaptation. The physiological response has intensified, but the person's ability to adapt to the stressor diminishes (Huether et al., 2017). Even in the face of chronic demands, an ongoing state of chronic activation can occur. This chronic arousal with the presence of powerful hormones causes excessive wear and tear on bodily organs and is called **allostatic load**. A persistent allostatic load can cause long-term physiological problems such as chronic hypertension, depression, sleep deprivation, chronic fatigue syndrome, and autoimmune disorders (Huether et al., 2017).

Immune Response

The physiological interactions between the neuroendocrine stress response and the immune system are complex. The stress response directly influences the immune system (Huether et al., 2017). Stress causes prolonged changes in the immune system, which can result in impaired immune function. As stress increases, the person is more susceptible to changes in health such as increased risk for infection, high blood pressure, diabetes, and cancers (Casey and Tiaki, 2017).

Reaction to Psychological Stress

Each person responds differently to physiological threats. They produce different reactions in different people and indirectly activate the GAS. The intensity and duration of the psychological threat and the number of other stressors that occur at the same time affect the person's response. In addition, whether the person anticipated the stressor influences its effect. It is often more difficult to cope with an unexpected stressor. Personal characteristics that influence the response to a stressor include the level of personal control, presence of a social support system, and feelings of competence.

Stress can be viewed as a transaction between a person and the environment. A person appraises or mentally rates an event in terms of its meaning and then experiences stress only if the event or circumstance is considered significant. Evaluating an event in terms of personal meaning is **primary appraisal**. Appraisal of an event or circumstance is an ongoing

perceptual process. Stress results when a person identifies an event or circumstance as a harm, loss, threat, or challenge. **Secondary appraisal**, the process by which a person considers possible available coping strategies or resources, occurs at the same time. Stress occurs if the demands placed on the person by the event exceed the ability to cope. Balancing factors contribute to restoring equilibrium. According to crisis theory, because feedback cues lead to reappraisals of the original perception, coping behaviors constantly change as individuals perceive new information. When coping behaviors are ineffective and repeated over and over, a state of stress can result. Stress emerges either when a person views an event as posing a significant risk of harm or when the person is not able to cope with the event's demands.

Coping is a person's cognitive and behavioral efforts to manage a stressor (Can et al., 2017). It is important to physical and psychological health because stress is associated with a range of psychological and health outcomes (Can et al., 2017). The effectiveness of coping strategies is influenced by a variety of factors, such as a person's age, cultural background, individual circumstances, and past use of coping strategies. Thus no single coping strategy works for everyone or for every stressor.

In stressful situations most people use a combination of problem- and emotion-focused coping strategies. In other words, when under stress a person obtains information, takes action to change the situation (problem-focused), and regulates emotions tied to the stress (emotion-focused). In some cases, people avoid thinking about the situation or change the way they think about it without changing the actual situation itself.

The type of stress, people's goals, their beliefs about themselves and the world, and personal resources determine how people cope with stress (Enns et al., 2018). Resources include problem-solving skills, financial status, social skills, support from family and friends, physical attractiveness, health and energy, and personal stress-management techniques such as optimism and mindfulness (Desiree et al., 2015).

Coping mechanisms include psychological adaptive behaviors. Such behaviors are often task oriented, involving the use of direct problem-solving techniques to cope with threats. **Ego-defense mechanisms** regulate emotional distress and thus give a person protection from anxiety and stress. They help a person cope with stress indirectly and offer psychological protection from a stressful event. Everyone uses them unconsciously to protect against feelings of worthlessness and anxiety. Occasionally a defense mechanism becomes distorted and no longer helps the person adapt to a stressor. However, people generally find them very

helpful in coping and use them spontaneously (Box 37.1). Frequently short-term stressors activate ego-defense mechanisms. These usually do not result in psychiatric disorders.

Box 37.1 Examples of Ego-Defense Mechanisms

- Compensation: Making up for a deficiency in one aspect of self-image by strongly emphasizing a feature considered an asset (e.g., a person who is a poor communicator relies on organizational skills)
- Conversion: Unconsciously repressing an anxiety-producing emotional conflict and transforming it into nonorganic symptoms (e.g., difficulty in sleeping, loss of appetite)
- Denial: Avoiding emotional conflicts by refusing to consciously acknowledge anything that causes intolerable emotional pain (e.g., a person refuses to discuss or acknowledge a personal loss)
- Displacement: Transferring emotions, ideas, or wishes from a stressful situation to a less anxiety-producing substitute (e.g., a person transfers anger over an interpersonal conflict to a malfunctioning computer)
- Identification: Patterning behavior after that of another person and assuming that person's qualities, characteristics, and actions
- Dissociation: Experiencing a subjective sense of numbing and a reduced awareness of one's surroundings
- Regression: Coping with a stressor through actions and behaviors associated with an earlier developmental period

Types of Stress

Stress is often caused by work, family, daily hassles, trauma, and crisis. Stress may be acute or chronic. One person looks at a stimulus and sees it as a challenge, leading to mastery and growth. Another sees the same stimulus as a threat, leading to stagnation and loss. The individual with family responsibilities and a full-time job outside the home can experience chronic stress. It occurs in stable conditions and from stressful roles. Living with a long-term illness produces chronic stress. Conversely, time-limited events that threaten a person for a relatively brief period provoke acute stress. Recurrent daily hassles such as commuting to work,

maintaining a house, dealing with difficult people, and managing money further complicate chronic or acute stress.

Post-traumatic stress disorder (PTSD) begins when a person experiences or witnesses a traumatic event and responds with intense fear or helplessness. PTSD is common among military personnel and veterans and police, particularly soldiers who have been involved in combat or police involved in violent acts. Soldiers often witness or participate in disturbing events, producing dramatic symptoms. Some other examples of traumatic events that lead to PTSD include motor vehicle crashes, natural disasters, or violent personal assault. Anxiety associated with PTSD is sometimes manifested by nightmares and emotional detachment. Some people with PTSD experience **flashbacks**, or recurrent and intrusive recollections of the event. Depression and PTSD commonly occur together (Halter, 2018).

Secondary traumatic stress is the trauma a person experiences from witnessing other people's suffering. It is a component of compassion fatigue and is common in health care workers and first responders. Secondary traumatic stress results in intrusive symptoms such as nightmares and anxiety. People with this condition begin to avoid interactions and have difficulties in sleeping and relating to friends or family.

A **crisis** implies that a person is facing a turning point in life. This means that previous ways of coping are ineffective, and the person must change. There are three types of crises: (1) maturational or **developmental crises**, (2) **situational crises**, and (3) disasters or **adventitious crises** (Halter, 2018). A new developmental stage such as marriage or the birth of a child requires new coping styles. Developmental crises occur as a person moves through the stages of life. External sources such as a job change, a motor vehicle crash, or severe illness provoke situational crises. A major natural disaster, man-made disaster, or crime of violence creates an adventitious crisis.

Patient-centered care offers a context for crisis intervention (Steenkamp, 2015). The view of the person experiencing a crisis is the frame of reference for it. The vital questions for a person in crisis are "What does this mean to you?" and "How is it going to affect your life?" What causes extreme stress for one person is not always stressful to another. The perception of the event, situational supports, and coping mechanisms all influence return of equilibrium. A person either grows or regresses as a result of a crisis, depending on how he or she manages the situation (Halter, 2018).

REFLECT NOW

How would a nurse determine that a patient is moving from the alarm stage to the resistance stage of the general adaptation syndrome?

Nursing Knowledge Base

Nurses have proposed theories related to stress and coping. In addition, because nurses commonly assume roles to support patients in stress, research has expanded the knowledge base for the nature of stress and management alternatives.

Nursing Theory and the Role of Stress

Many nursing theories explain and describe stress. For example, explanation of the concepts of stress and reaction to stress are components of the Betty Neuman Systems Model. The Neuman Systems Model uses a systems approach to help you understand the responses of patients, families, and communities to stressors. A systems approach explains that a stressor at one place in a system affects other parts of the system; a system is a person, family, or community. Events are multidimensional and not caused or affected by only one thing. Every person develops a set of responses to stress that constitute the “normal line of defense” (Smith and Parker, 2016; [Neuman and Fawcett, 2011](#)). This line of defense maintains health and wellness. Physiological, psychological, sociocultural, developmental, or spiritual influences buffer stress. The Neuman Systems Model of nursing views a patient, family, or community as constantly changing in response to the environment and stressors.

Callista Roy’s Adaptation Model describes how an individual can effectively respond to stressors in the environment. According to Roy’s theory, a person has the ability to modify external stimuli to allow adaptation to occur. A nurse assists an individual with modifying and regulating peripheral stimuli to promote a supportive healing environment ([Cherry and Jacob, 2019](#)).

On the other hand, Pender’s Health Promotion Model focuses on promoting health and managing stress ([Murdaugh et al., 2015](#)). In this model people are capable of assessing their own abilities and assets and want to live in ways that enable them to be as healthy as possible. Interventions such as increasing physical activity, improving diet and nutrition, and using stress-management strategies help the individual become and remain healthy.

Factors Influencing Stress and Coping

Potential stressors and coping mechanisms vary across the life span (e.g., adolescence, adulthood, and old age bring different stressors). The appraisal of stressors, the amount and type of social support, and coping strategies all depend on previous life experiences and affect how a person reacts to that stressor. Situational and social stressors place people who are vulnerable at higher risk for prolonged stress.

Situational Factors

Situational stressors in the workplace that affect nurses and other health care professionals include high-acuity patient load, job environment, constant distractions, responsibility, conflicting priorities, and intensity of care (e.g., trauma, emergency, or critical care areas) (Mealer et al., 2014; Ueno et al., 2017). In addition, changing shifts increases fatigue and work-related stress.

Some nurses often ease coping with shift work by knowing their own circadian rhythms. People who function best in the morning have the greatest difficulty with night work and changing shifts. As people age, they tend to become more morning oriented. Morning people need to be counseled about the potentially negative effects of night work for them. In general, people doing shift work need to maintain as consistent a sleep and mealtime schedule as possible (Lin et al., 2014; Solomon et al., 2016).

Adjusting to chronic illness is another type of situational stress. The physical limitations posed by a disease state and the uncertainty associated with treatment and illness trigger stress in patients and family caregivers of all ages. Sometimes illness changes how people manage their stress. For example, Antony et al. (2018) found that caregivers of patients with cancer who were receiving palliative care used both negative and positive coping strategies to deal with the stress of caregiving. Having difficulty in paying for treatment and limited access to health care providers also create stress. Although being a family caregiver for someone with a chronic illness such as Alzheimer's disease is stressful, the actions of competent health care providers often help minimize the stress for family caregivers.

Maturational Factors

Stressors vary with life stage. According to Erikson's developmental theory, individuals experience predictable stages of development as particular tasks are accomplished and mastered for each stage. Children who are in the stage of initiative versus guilt identify stressors related to

physical appearance, families, friends, and school. During this stage, teaching impulse control and cooperative behaviors is imperative. Preadolescents experience stress related to self-esteem issues, changing family structure as a result of divorce or death of a parent, or hospitalizations. Erikson asserts that during this stage, they can develop a sense of inferiority without proper support for learning new skills. As adolescents search for identity with peer groups and separate from their families, they also experience stress. In addition, they face stressful questions about sex, jobs, school, career choices, and using mind-altering substances. During this stage of development, stress can occur because of preoccupation with appearance and body image. Adolescents should strive to develop and accept personal identity.

Stress for adults centers around major changes in life circumstances. These include the many milestones of beginning a family and a career, losing parents, seeing children leave home, and accepting physical aging. Social development is important during this stage. In old age stressors include the loss of autonomy and mastery resulting from general frailty or health problems that limit stamina, strength, and cognition ([Box 37.2](#)). Nurses and other health care providers need to differentiate signs of stress and crisis in older adults from dementia and acute confusion.

Box 37.2 Focus on Older Adults **Understanding Differences in Stress and Coping Among Older Adults**

- Ordinary hassles of day-to-day living create a source of stress; older adults have more hassles with home maintenance and health than do younger people.
- Older adults often use more passive, intrapersonal, emotion-focused forms of coping such as distancing, humor, accepting responsibility, and reappraising the stressor in a positive way.
- Life experiences and perspectives of older adults make most problems seem insignificant, especially when older adults have acquired appropriate stress-management techniques (Jackson et al., 2018).
- Older adults' coping improves based on earlier experience with coping with traumatic situations (Jackson et al., 2018).

- Impaired coping affects overall health in older adults more than in younger adults (Rayens and Reed, 2014).
- Because of the high incidence of depression in older adults, you need to assess for suicidal thoughts and intent.
- When marital or partnership dyads are present, the perceived stress of one member has a greater effect on the other member than occurs with middle or young adults (Rayens and Reed, 2014).

Sociocultural Factors

Environmental and social stressors often lead to developmental problems. Potential stressors that affect any age-group but that are especially stressful for young people include prolonged poverty and physical disability. Children become vulnerable when they lose parents and caregivers through divorce, imprisonment, or death or when parents have mental illness or substance-abuse disorders. Living under conditions of continuing violence, disintegrated neighborhoods, or homelessness affects people of any age, especially young people (Murdaugh, et al., 2015).

A person's culture also influences stress and coping. Cultural variations produce stress, particularly if a person's values differ from the dominant culture in aspects of gender roles, family relationships, and religious beliefs (Giger, 2017, Shavitt et al., 2016). Other aspects of cultural variations begin with language difference, geographical location, family relationships, time orientation, access to health care programs, and disparities in health care (Box 37.3) (see Chapter 9).

Box 37.3 Cultural Aspects of Care

Variations in Stress Appraisal and Coping Strategies

A patient's culture defines what is stressful to the person and ways of coping with stress (Giger, 2017). Cultural context shapes the types of situations that produce stress. Culture affects how a person leaves the parental home, experiences health crises or chronic illness, cares for the family, or becomes disabled or dependent. Furthermore, how a person appraises stress also depends on his or her culture. What is perceived as a major stressor in one culture is sometimes viewed as a minor problem in another. For example, cultures may address developmental transitions and turning points in life differently.

Coping strategies are also influenced by one's cultural background. Cultures vary in their emotion- and problem-focused coping strategies. Some stress that emotions should be controlled, whereas others believe in expressing emotion. Cultures provide different resources for coping with stress (Giger, 2017). These include the legal system for conflict resolution, advice givers or support groups, and rituals.

Implications for Patient-Centered Care

- Realize that stressors and coping styles vary with different cultures.
- Reflect on your own perceptions of stress and coping in a cultural context.
- Assess the influence of culture on a patient's appraisal of stress.
- Identify the presence of individualized cultural practices related to stress management.
- Determine resources in a patient's culture that facilitate coping.

Compassion Fatigue

Compassion fatigue is a term used to describe a state of burnout and secondary traumatic stress. Secondary traumatic stress is the stress that health care providers experience when witnessing and caring for others who are suffering. Examples include an oncology nurse who cares for patients undergoing surgery and chemotherapy over the long term for their cancer or a spouse who witnesses his wife deteriorating over the years from Alzheimer's disease. Burnout occurs when perceived demands outweigh perceived resources (Brown et al., 2018). It is a state of physical and mental fatigue and exhaustion that often affects health care providers because of the nature of their work environment. Perceived inadequate staffing, long work shifts, demands of patient acuity, and dysfunctional relationships (patients and other care providers) serve as triggers for ongoing stress. Over time, giving of oneself in often intense caring environments can result in emotional exhaustion, leaving a nurse feeling irritable, restless, and unable to focus and engage with patients. This condition may be viewed as a failure to cope because it often occurs in situations in which the nurse is unable to practice self-care, social support is lacking, and organizational pressures are influencing staffing levels.

Compassion fatigue is a condition that can overwhelm health care providers and cause physical, mental, and emotional health issues (Hunsaker et al., 2015). The feelings of hopelessness and anxiety from

compassion fatigue usually result in feelings of inadequacy and lower self-esteem. These factors can lead to the health care provider lashing out in an attempt to cope with these feelings and stress. This often manifests itself as *lateral violence*, which refers to a deliberate and harmful behavior demonstrated in the workplace by one employee to another. This includes health care providers engaging in bullying and potentially assaultive behaviors toward co-workers ([Embree and White, 2010](#); [Christie and Jones, 2013](#)).

Early recognition of the risk for compassion fatigue is essential. A supportive work environment helps guide a nursing unit in designing communication techniques to identify, prevent, and adapt to potential compassion fatigue situations ([Hunsaker et al., 2015](#)). For example, a nurse-led program on an oncology unit that included education, exercise and social support was found to be effective in decreasing the nurses' compassion fatigue ([Yilmaz et al., 2018](#)).

Second Victim Syndrome

Second victim syndrome affects health care providers when a medical error that results in significant harm to a patient and the patient's family occurs ([Hartley, 2018](#)). Often overlooked, nurses who have been involved in such a medical error can sustain complex psychological harm that can lead to detrimental outcomes such as suicide. These fatal errors can haunt nurses throughout their lives, leading to symptoms that are similar to post-traumatic stress disorder. One potential outcome is that nurses "move on" and work on gaining additional knowledge and skills to prevent errors in the future. But in many cases, nurses are reluctant to return to work because of fear of isolation from the organization, loss of confidence, remorse, depression, humiliation, and guilt ([Hartley, 2018](#)).

Being aware of the potential for second victim syndrome allows health care agencies to provide support the moment such an event occurs. Health care agencies need to provide support for as long as deemed necessary. Although the care and support of patients and families is a priority, the second victim has a right to be treated with respect and dignity and to be supported by peers and the organization. Proposed rights for second victims include respect, just treatment, understanding and compassion, supportive care, transparency, and the opportunity to contribute ([Grissinger, 2014](#)).

Critical Thinking

Successful critical thinking requires a synthesis of knowledge, experience, information gathered from patients, critical thinking attitudes, and intellectual and professional standards. Clinical judgments require you to anticipate information, analyze the data, and make decisions regarding your patient's care. During assessment consider all elements that build toward making an appropriate nursing diagnosis.

Integrate knowledge from nursing and other disciplines, previous experiences, and information gathered from patients to understand stress and its effect on a patient and family. Know the neurophysiological changes that occur in a patient experiencing the alarm reaction, resistance stage, and exhaustion stage of the GAS. In addition, know communication principles that contribute to assessing a patient's behaviors. Give utmost attention to determining the patient's perception of the situation and his or her ability to cope with the stress. If a patient's usual coping skills have not helped or his or her support systems have failed, use crisis intervention counseling.

Experience teaches you to understand the patient's unique perspective and recognize that no two people are exactly alike. Experience with patients also helps you to recognize responses to stress. In addition, personal experiences with stress and coping increase your ability to empathize with a patient temporarily immobilized by stress.

Be confident in the belief that you and your patients can effectively manage stress. Patients who feel overwhelmed and perceive events as beyond their capacity to cope rely on you as an expert. Patients respect your advice and counsel and gain confidence from your belief in their ability to move past the stressful event or illness. Patients overwhelmed by life events are often unable, at least initially, to act on their own behalf and require either direct intervention or guidance. Integrity is an essential attitude that allows you to respect a patient's perception of the stressor. Encourage the patient to explain his or her unique viewpoint and situation.

The practice standards for psychiatric mental health nursing ([ANA, 2014](#)) guide assessment of a patient's stress, coping mechanisms, and support system before intervening. Use linguistic and culturally effective communication skills to clearly and precisely understand a patient's perception of stress. Focus on factors relevant to his or her well-being. In addition, the patient expects you to exhibit confidence and integrity when

he or she feels vulnerable. Be especially aware of the ethical responsibility in caring for someone who has diminished autonomy as a result of stress.

REFLECT NOW

What questions would you ask a patient to determine whether his or her stress is related to situational, maturational, or sociocultural factors?

◆ Nursing Process

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care.

◆ Assessment

During the assessment process, thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care.

Through the Patient's Eyes

Assessment of a patient's stress level and coping resources requires that you first establish a trusting nurse-patient relationship because you are asking a patient to share personal and sensitive information. Learn from the patient both by asking questions and by observing nonverbal behavior and the patient's environment. Synthesize the information and adopt a critical thinking attitude while observing and analyzing patient behavior (Fig. 37.2). Often a patient has difficulty in expressing exactly what is most bothersome about a situation until there is an opportunity to discuss it with someone who has time to listen.

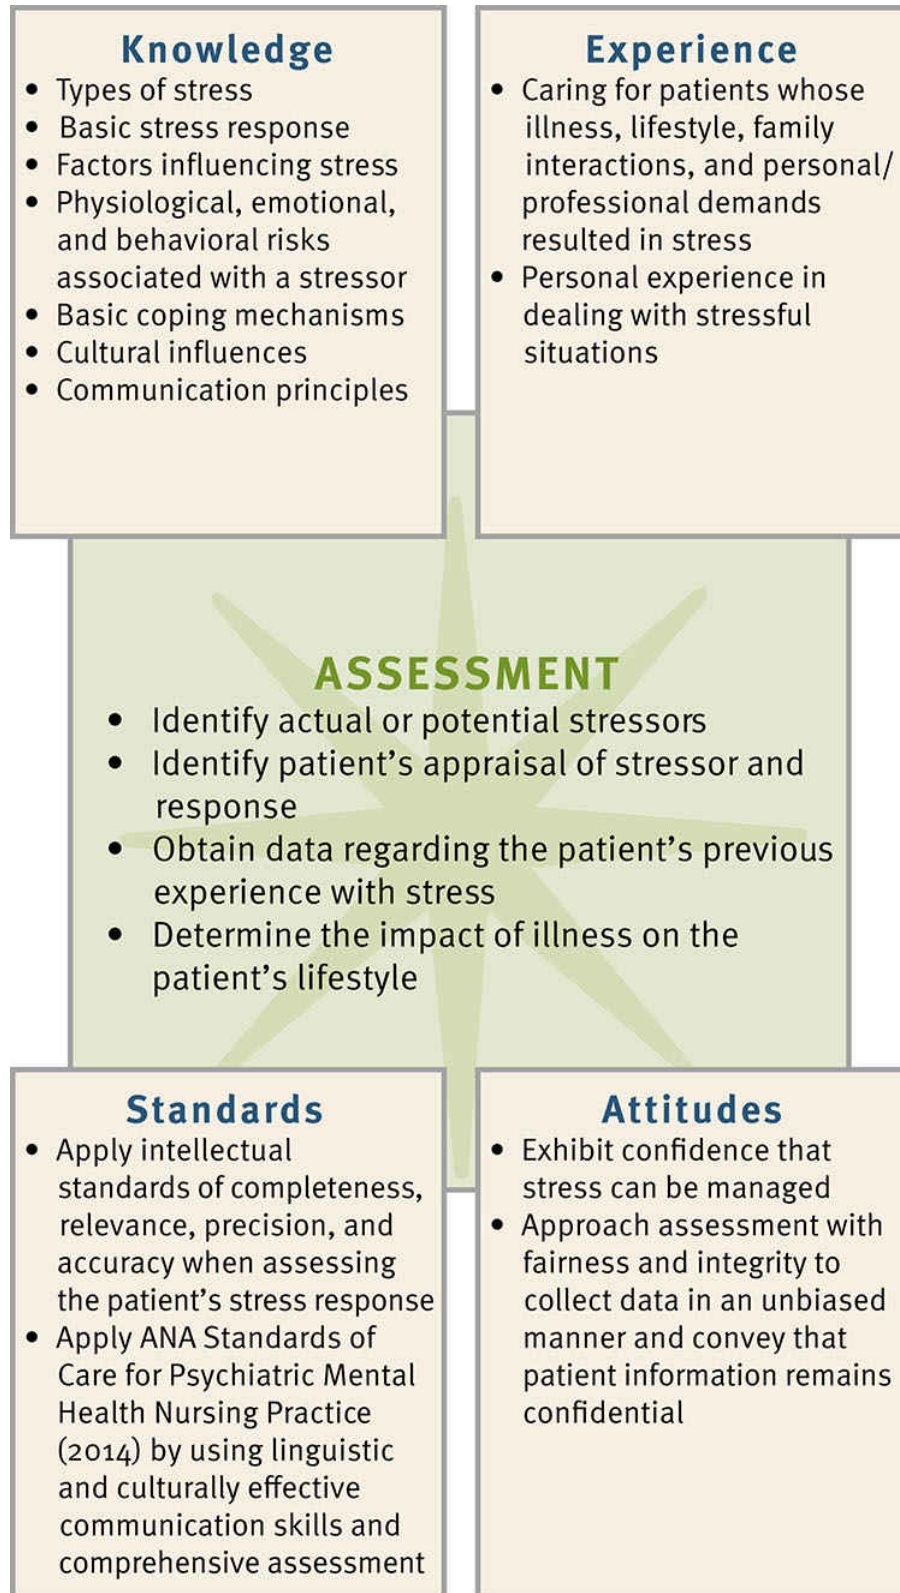

FIG. 37.2 Critical thinking model for stress and coping assessment. ANA, American Nurses Association.

Begin your assessment with an open-ended question, such as “What is happening in your life that caused you to come today?” or “What happened in your life that is *different*?” This requires the patient to focus. Next assess the patient’s perception of the event, available situational supports, and what he or she usually does when there is an unsolvable problem. Determine whether a person is suicidal or homicidal by asking directly, “Are you thinking of hurting yourself or someone else?” If so, determine in a caring and concerned manner whether the person has a plan and the lethality of the plan (i.e., ingestion of pills versus self-inflicted gunshot wound).

Take time to understand a patient’s meaning of the precipitating event and the ways in which stress is affecting his or her life. Allow time for the patient to express priorities for coping with stress. For example, in the case of a woman who has just been told that a breast mass was identified on a routine mammogram, it is important to know what the patient wants and needs most from the nurse. Although some women in this situation identify their need for information about biopsy or mastectomy as their personal priority, others need guidance and support in discussing how to share the news with family members.

Stress also occurs in a family or a community. Stress in a family sometimes arises from a critically ill family member, the sudden loss of a job, a move, or becoming homeless. Community stressors include a natural disaster such as a major flood or the sudden, unexpected death of a beloved teacher or teenager. To develop appropriate and safe nursing care when caring for families or communities, ensure that you understand the meaning stress has for that group.

Subjective Findings

Create a nonthreatening environment when assessing a patient’s level of stress and coping resources. Sit at the same height as the patient, arranging the interview environment with the chairs at a 90-degree angle or side by side so that you can maintain or avoid eye contact comfortably (Halter, 2018). Begin to develop a trusting relationship with your patient while you gather information about the patient’s health status from his or her perspective. Use the interview to determine the patient’s view of the stress, coping resources, any possible maladaptive coping, and adherence to prescribed medical recommendations such as medication or diet (Box 37.4). If the patient is using denial as a coping mechanism, assess if he or she is overlooking necessary information. As in all interactions with the

patient, respect the confidentiality and sensitivity of the information shared.

Box 37.4 Nursing Assessment Questions

Patient Safety

- Are you having difficulty with sleeping? Falling asleep? Staying awake?
- Is there any change in your eating patterns?
- Have you had any accidents at home, in the car, at school, or on the job?
- Do you have any thoughts of harming yourself or others?

Perception of Stressor

- What do you believe is stressing you right now?
- What impact does this stressor have on your lifestyle?
- How does this stressor impact you now? How will it impact you in the future?

Available Coping Resources

- Which strategies have you used in the past to deal with stress?
- Are you able to talk with friends or family?
- What is relaxing for you?

Maladaptive Coping Used

- Have you started using alcohol or tobacco to deal with your stress?
- Do you use any over-the-counter or herbal medications to manage your stress?
- Do you use any street drugs to cope?

Adherence to Healthy Practices

- How long ago did you see your health care provider?
- What is your exercise routine?
- Which type of meals do you eat? Are your meals regular?
- Are you taking your prescribed medications as ordered?

Objective Findings

Obtain objective findings related to stress and coping through observation of the appearance and nonverbal behavior of a patient. Observe grooming and hygiene, gait, characteristics of the handshake, actions while sitting, quality of speech, eye contact, and the attitude of the patient during the interview. Before the interview begins or at the end of the interview, depending on the anxiety level of the patient, obtain basic vital signs to assess for physiological signs of stress such as elevated blood pressure, heart rate, or respiratory rate. Make certain to incorporate cultural components of interpreting the patient's nonverbal communication behaviors.

REFLECT NOW

What is the nurse's priority if a patient expresses thoughts of self-harm?

Nursing Diagnosis

A review of assessment data leads you to cluster data that indicate a potential or actual stressor and the patient's response. Clustering data, along with the application of your knowledge and experiences with patients in stress, leads to individualized nursing diagnoses ([Box 37.5](#)).

Box 37.5 Nursing Diagnostic Process **Difficulty Coping**

Assessment Activities	Assessment Findings
Ask patient about change in sleeping patterns.	Sleep disturbance Difficulty falling asleep at night
Ask patient to complete a sleep diary for 2 weeks.	Excessive sleeping Frequent awakenings at night
Observe patient's behavior and response to questions during assessment.	Fatigue Inability to concentrate Inaccurate response to questions Inappropriate laugh or crying
Observe patient's appearance.	Poor grooming Lack of eye contact
Ask patient about changes in eating patterns.	Weight gain or loss Lack of interest in food

Nursing diagnoses for people experiencing stress generally focus on coping. Specifically, major assessment findings of *Difficulty Coping* include verbalization of an inability to cope and an inability to ask for help. To gather assessment data, ask the patient what is of most concern at the time of the interview. It is important to allow patients sufficient time to answer. Observe for nonverbal signs of anxiety, fear, anger, irritability, and tension, which may indicate ineffective coping. Other assessment findings include the presence of life stress, an inability to meet role expectations and basic needs, alteration in societal participation, self-destructive behavior, change in usual communication patterns, high rate of accidents, excessive food intake, drinking, smoking, and sleep disturbances. Stress or the inability to cope often results in multiple nursing diagnoses. Examples of these diagnoses include but are not limited to the following:

- *Anxiety*
- *Despair*
- *Difficulty Coping*
- *Risk for Post Trauma Response*
- *Stress Overload*

• Planning

Goals and Outcomes

Desirable goals for people experiencing stress frequently include effective coping, family coping, and family caregiver emotional health. Examples of outcomes might include the following: patient engages in a support group, family members are able to discuss loss together, or caregiver participates in respite care. A nurse selects interventions for reducing stress and improving coping, such as coping enhancement and crisis intervention. The nurse considers nursing diagnoses and the goals identified mutually with the patient when individualizing interventions and selecting resources available to a patient (Fig. 37.3).

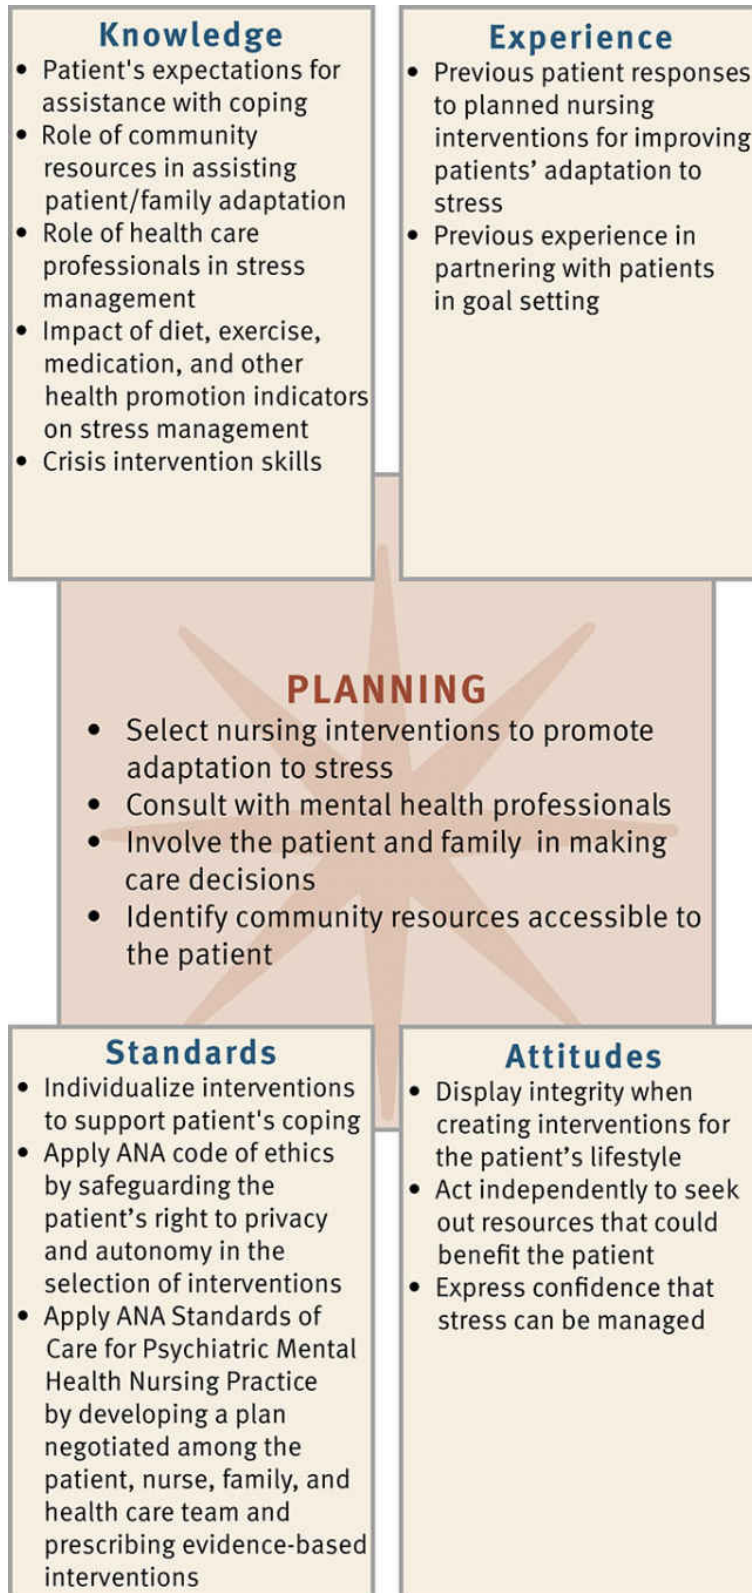

FIG. 37.3 Critical thinking model for stress and coping planning. ANA, American Nurses Association.

Nursing interventions are designed within the framework of primary, secondary, and tertiary prevention. At the primary level of prevention, you direct nursing activities to identify individuals and populations who may be at risk for stress. Nursing interventions at the secondary level include actions directed at symptoms, such as protecting the patient from self-harm. Tertiary-level interventions help the patient readapt and can include relaxation training and time-management training. The nurse and the patient assess the level and source of the existing stress and determine the appropriate intervention to reduce it (Murdaugh et al., 2015) (see the [Nursing Care Plan](#)).

REFLECT NOW

You are planning care for a patient with two school-age children who is also caring for a sick parent in her home. The patient's three siblings who live within a 25-mile radius refuse to help. A diagnosis of *Stress Overload* is included in the plan of care. Identify an appropriate goal and outcome.

A tool for planning care is a concept map (Fig. 37.4). Concept maps identify multiple nursing diagnoses for a patient from the assessment database and show how they are related. In this example the nursing diagnoses are linked to the patient's medical diagnosis of depression. In addition, the concept map shows the relationship among the nursing diagnoses *Impaired Low Nutritional Intake: Deficient Food Intake*, *Difficulty Coping*, *Anxiety*, and *Powerlessness*. Use of a concept map requires critical thinking skills to organize patient data and helps to plan for patient-centered care.

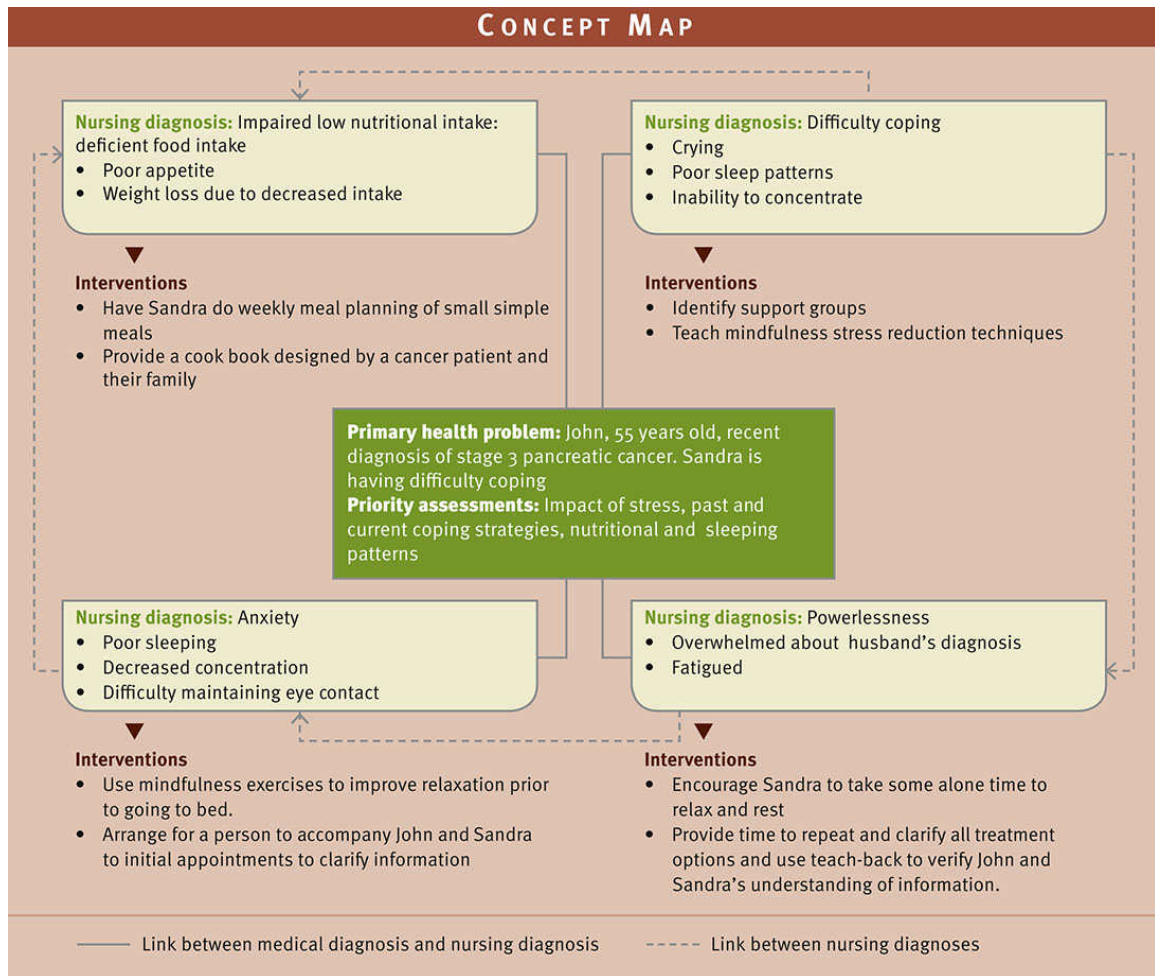

FIG. 37.4 Concept map for Sandra.

Nursing Care Plan

Difficulty Coping

Assessment

Sandra and John have been married 3 years and are both 55 years of age. They both work and are planning their retirement at age 66. Last month, John was diagnosed with stage 3 pancreatic cancer. Presently, John and Sandra are at the Cancer Center to decide on treatment. When you greet the couple, you notice that they both look tired; Sandra is disheveled, and John is clean-shaven and well groomed. John states that he is worried about Sandra as she appears “just worn out,” and he expresses fear that she will not be able to help him through this medical crisis.

Assessment Activities	Assessment Findings ^a
Ask Sandra how she feels about John's diagnosis.	Sandra states, "I don't know how I feel. I know I feel very alone."
Ask Sandra what she remembers about John's treatment options.	She states, "I really can't remember anything but stage 3 pancreatic cancer. I know this is a bad cancer.
Ask John and Sandra about friends and relatives they have for support.	Both are only children and have no other family ; they moved 1 year ago for new jobs. They both work for the same company but state that they have few close friends .
Ask Sandra to identify people she can turn to for help.	Sandra sobs and says that she doesn't have any friends she can rely on . They are active in their church. On further discussion Sandra mentions a close friend from her hometown.
Ask Sandra about sleep and nutrition patterns.	She can't get to sleep easily and awakens 3 to 4 times per night . She states, "My appetite is poor ; I'm just not hungry. I think I've lost weight ."
Assess Sandra's mood and affect by asking how she is feeling.	She states, " I am so tired and overwhelmed ."

^a Assessment findings are shown in bold type.

Nursing Diagnosis

Difficulty Coping related to insufficient social support

Planning

Goals	Expected Outcomes (NOC) ^b
	Social Support
Sandra achieves social support from her community in 1 month.	Sandra identifies at least one person in her community who can help support her in this crisis. Sandra participates in a local support group weekly.

^b Outcome classification labels from Moorhead S, et al: *Nursing Outcomes Classification (NOC)*, ed 6, St Louis, 2018, Elsevier.

Interventions (NIC) ^c	Rationale
Support System Enhancement	
Identify community-based cancer support systems for patients and family for Sandra and John.	Support systems for both patient and family are an effective intervention to cope with the stress of a cancer diagnosis and related therapies and decision making (Meiner and Yeager, 2019).
Help Sandra identify a person who is willing to accompany her to some of John's appointments.	Having another person hear some of the treatment options and treatment procedures provides opportunities to clarify the discussion. During high-stress times the patient and family may not hear the material provided by health care providers completely (Doron et al., 2014).
Explore community resources for a short-term educational group for both Sandra and John for self-care tools to reduce stress.	Educational groups help caregivers develop self-care tools to reduce stress, change negative self-talk, communicate more effectively, and make difficult decisions (Oken et al., 2018).

^c Intervention classification labels from Butcher HK, et al: *Nursing Interventions Classification (NIC)*, ed 7, St Louis, 2018, Elsevier.

Evaluation

Evaluation Activity	Patient Response/Finding	Outcome Status
Ask Sandra for the name of a person she can call for help during a crisis.	Sandra identified two people in her church community. One is a cancer survivor; the second is the spouse of a patient currently receiving cancer treatment.	Sandra meets with each person in her church at least weekly for coffee or lunch, and she has invited them and their spouses to her home for dinner.
Ask Sandra whether she attended a support group.	Sandra reports she has attended two sessions.	Sandra accepts support from community.

Just as the nursing assessment of a patient's stress and coping depends on his or her perception of the problem and coping resources, the interventions focus on a partnership with the patient and support system, usually the family. In the case of a family or community stressor and impaired family or community coping, the view of the situation and resources is broader.

Setting Priorities

Consider the patient's perspective and responses to assessment questions when setting priorities for care (see the Nursing Care Plan). The patient's

and family member's physical condition and perception of stressors determine which nursing diagnosis has the greatest priority. As in all areas of nursing, patient safety is the priority.

If suicide or homicide is not an issue, identify if there are potential threats to the safety of vulnerable people who are under the care of the patient. Provide for their temporary care or supervision if necessary. Other potential threats to safety include nutritional deficits; insomnia; self-care deficits; and poor judgment and impulsiveness that may lead to unsafe decisions about sex, drugs, money, or damage to personal relationships that the person might later regret. Determine the degree of work, school, home, and family disruption in the person's life. After you have ensured safety, problem solve with patient in selecting priorities.

Teamwork and Collaboration

Sometimes nursing practice alone does not meet all the patient's and family's needs. To effectively plan individualized care, collaborate with occupational therapists, dietitians, pastoral care professionals, and health care professionals from other clinical specialties, depending on the patient's situation.

Consulting with advanced practice mental health nurses, psychiatrists, psychologists, or psychiatric social workers when a patient is experiencing stress from medical conditions or psychiatric disorders is necessary. An interprofessional approach addresses the holistic needs of the patient. Recognize the need for collaboration and consultation; inform the patient about potential resources; and arrange for interventions such as consultations, group sessions, or therapy as needed. A hospital social worker can share ideas for available resources both within the hospital and in the community. A home care nurse knows community services, support groups, and appropriate contacts.

In addition to maximizing use of available resources for the patient, collaborative care also benefits the nurse. While working with patients experiencing stress, you gain a broad understanding of the multitude of health care disciplines. Work becomes more satisfying. Contacts with other members of the interprofessional team and the community provide a feeling of contributing to the teamwork of providing holistic care.

Implementation

Health Promotion

Three primary modes of intervention for stress are to decrease stress-producing situations, increase resistance to stress, and learn skills that reduce physiological response to stress (Murdaugh et al., 2015). Educate patients and families about the importance of health promotion (Box 37.6).

Box 37.6 Patient Teaching Stress Management

Objective

- Patient will report less anxiety, depression, and pain related to chronic health problems.

Teaching Strategies

- Familiarize patient with mind-body therapies that are likely to benefit patient. Refer to a group or specialized practitioner when necessary (Holman et al., 2018; Oken et al., 2018):
 - Meditation
 - Progressive muscle relaxation
 - Guided imagery
 - Hypnosis
 - Yoga
 - Tai Chi
- Teach patient how to incorporate 15-30 minutes of exercise into daily activities (Kravitz, 2019).
- Instruct patient to identify and use relaxation techniques; for example:
 - Listen to music that you enjoy.
 - Keep a journal of your thoughts and feelings.
 - Replace unnecessary time-consuming activities with activities that are pleasurable or interesting.

Evaluation

Use the principles of teach back to evaluate patient/family caregiver learning:

- Tell me how the stress-reduction techniques that we practiced help you to cope.
- Tell me how the mindfulness activities are impacting your anxiety and ability to sleep.
- Show me how you do the progressive muscle relaxation exercises.

Regular Exercise and Rest

A regular exercise program improves muscle tone and posture, controls weight, reduces tension, and promotes relaxation (see [Chapter 38](#)). In addition, exercise reduces the risk of cardiovascular disease and improves cardiopulmonary functioning. Patients who have a history of a chronic illness, who are at risk for developing an illness, or are older than 35 years of age should begin a physical exercise program only after discussing the plan with a health care provider ([Fig. 37.5](#)).

FIG. 37.5 Regular exercise helps to cope with stress.
Courtesy Rudolph A. Furtado.

Regular rest and sleep are also effective in reducing stress and stress-related fatigue. When stressful situations are present, encourage patients and their family members to establish bedtime and sleep routines and try to stick to the schedule (see [Chapter 43](#)). Patients and family members who are well rested are able to manage stress, problem solve, and maintain a sense of control over the situation ([Kravitz, 2019](#)).

Building Competency in Evidence-Based Practice

As a nurse educator in a diabetes management clinic, you recognize the value of exercise for patients with diabetes. However, you know many of your patients have difficulty committing to exercising regularly. You've located current research that supports types of interventions that are effective in promoting physical activity among adults who are chronically ill. Some of these interventions include (1) targeting physical activity exclusively, (2) using behavioral (as opposed to cognitive) strategies, and (3) encouraging self-regulation and monitoring (Park and Iacocca, 2014; Phillips, et al., 2016).

1. Describe the relationship between an individual's beliefs and that person's intentions for engaging in physical activity.
2. Identify possible barriers that prevent patients from initiating or maintaining an exercise plan. How can you help individuals overcome these barriers?

Support Systems

A support system of family, friends, and colleagues who listen, offer advice, and provide emotional support benefits a patient experiencing stress ([Sunne and Huntington, 2017](#)). Many support groups are available to individuals (e.g., those sponsored by the American Heart Association, the American Cancer Society, hospitals, churches, and mental health organizations). Recent research shows that cancer survivors who effectively manage their stress make changes in their physical, psychosocial, and preventive health behaviors ([Bily, 2017](#)).

Time Management

Time-management techniques include developing lists of prioritized tasks. For example, help patients list tasks that require immediate attention, those that are important, those that can be delayed, and those that are routine and can be accomplished when time becomes available. In many cases setting priorities helps individuals identify tasks that are unnecessary or that can be delegated to someone else.

Guided Imagery and Visualization

Guided imagery is based on the belief that a person significantly reduces stress with imagination. It is a relaxed state in which a person actively uses imagination in a way that allows visualization of a soothing, peaceful setting. Typically, the image created or suggested uses many sensory words to engage the mind and offer distraction and relaxation.

Progressive Muscle Relaxation Therapies

In the presence of anxiety-provoking thoughts and events, a common physiological symptom is muscle tension. Progressive muscular relaxation diminishes physiological tension through a systematic approach to releasing tension in major muscle groups. Typically, an individual achieves a relaxed state through deep breathing. Once the patient is breathing deeply, direct him or her to alternately tighten and relax muscles in specific groupings ([Pangotra et al., 2018](#); [Tsitsi et al., 2017](#)).

Assertiveness Training

Assertiveness includes skills for helping individuals communicate effectively regarding their needs and desires. The ability to resolve conflict with others through assertiveness training reduces their stress. Becoming certified in assertiveness training gives you the chance to teach assertiveness in group settings.

Journal Writing

Journal writing is beneficial for enhancing both psychological and physical health ([Pavlacic, 2019](#)). For many people keeping a private, personal journal provides a therapeutic outlet for stress. Suggest that patients keep journals, especially during difficult situations. In a private journal, patients can express a full range of emotion and vent their honest feelings without hurting anyone else's feelings and without concern for how they appear to others.

Mindfulness-Based Stress Reduction

Mindfulness is a moment-to-moment present awareness with an attitude on nonjudgment, acceptance, and openness. This technique entails focusing on attentiveness on regular activities and truly enjoying pleasant experiences (Parsons et al., 2017). Mindfulness-based stress reduction (MBSR) meditative practices are effective in reducing psychological and physical symptoms or perceptions. They are effective in stress management and symptom control with certain chronic conditions (Box 37.7). Through mindfulness exercises people learn to self-regulate awareness and attention to feeling and implement effective changes. Patients use cognitive exercises and subjective experiences to process images or feelings (Desiree et al., 2015). Patients evaluate these feelings as pleasant or unpleasant and learn strategies to enhance the pleasant experiences and replace the unpleasant experiences. Through MBSR patients can control their stress response to illnesses and treatments, employees can manage job-related stress, and students can learn to manage stress anxiety.

Box 37.7 Evidence-Based Practice Impact of

Meditation Therapies on Illness-Related Stressors

PICOT Question: Does the use of a mindfulness-based stress reduction (MBSR) program for adult patients affect their level of anxiety and depression and psychological well-being?

Evidence Summary

Prolonged and recurrent stress is associated with multiple psychological and health outcomes. A person's ability to cope with these stressors impacts physical and psychological health and may result in high rates of morbidity (Greeson et al., 2018; Oken et al., 2018). While conventional medical treatments for common stress-related symptoms may relieve symptoms, they fail to address the underlying causes of stress (Greeson et al., 2018). A participatory medicine approach that incorporates behavioral, self-care practices (e.g., yoga, meditation) with conventional care is often beneficial. For example, patients who practiced yoga were effective in decreasing their anxiety and use of pain medication during a procedure (Kartin et al., 2017). Coping skills training in patients with diabetes decreased symptoms of depression and improved quality of life and metabolic control (Edraki et al., 2018).

Cognitive therapies, such as mindful meditation, have also been shown to improve subjective, patient-reported outcomes, including symptoms of stress, anxiety, depression, pain, fatigue, and quality of life (Oken et al., 2018; Greeson et al., 2018). Mindfulness is marked by a sense of focused attention allowing an individual to consciously act versus automatically react to stress (Greeson et al., 2018).

Cognitive therapies such as meditation and MBSR help patients deal with illness-related stressors. Patients who use these therapies often are better at managing the symptoms and psychological distress associated with their chronic conditions (Grensman et al., 2018). Individualize these therapies to the patient's needs, the ability to learn the therapy, and the concurrent treatment.

Application to Nursing Practice

- Assess a patient's perception of stress and specific coping strategies to help you identify the stressors and the patient's response to them (Lewis et al., 2017; Grensman et al., 2018; Edraki et al., 2018).
- Identify priority coping strategies to improve the patient's quality of life and reduce symptoms (Grensman et al., 2018; Edraki et al., 2018).
- Consider a patient's limitations when discussing specific coping strategies to optimize the patient's experience and increase the chance of success (Greeson et al., 2018; Oken et al., 2018).
- When instructing patients about the use of these techniques, reinforce that these stress-management techniques are to be used in addition to, not instead of, the patient's current treatment.

Stress Management in the Workplace

Stressors such as rapid changes in health care technology, diversity in the workforce, organizational restructuring, and changing work systems place stress on employees. **Burnout** occurs as a result of chronic stress. In nursing, burnout results when nurses perceive the demands of their work exceed perceived resources. It is manifested as emotional exhaustion, poor decision making, loss of a sense of personal identity, and feelings of failure.

It is important that nurses participate in self-care practices. For example, in oncology settings many nurses experience compassion fatigue. Effective strategies for compassion fatigue and how to help nurses deal with this phenomenon are available (see [Chapter 1](#)). Health care facilities use

mindfulness exercises, resilience training, staff relationship-building activities, and clinical debriefing to manage job-related stress and reduce burnout and nursing staff turnover (Brown et al., 2018). Recognizing the impact of shift work and changes in schedules enables some managers and nurses to use self-scheduling techniques. This reduces job-related stress and improves sleep quality, collaboration, and teamwork (Lin et al., 2014).

Recognizing the areas over which you have control and can change and those for which you do not have responsibility is a vital insight. Making a clear separation between work and home life is also crucial. Strengthening friendships outside the workplace, participating in creative activities for personal “recharging” of emotional energy, and spending off-duty hours in interesting activities all help reduce compassion fatigue.

REFLECT NOW

Create a personal plan to manage stress in the workplace.

Acute Care

Crisis Intervention

Crisis occurs when stress overwhelms a person’s usual coping mechanisms and demands mobilization of all available resources. A crisis creates a turning point in a person’s life because it changes the direction of his or her life in some way. The precipitating event usually occurs approximately 1 to 2 weeks before the individual seeks help, but sometimes it has occurred within the past 24 hours. Generally, a person resolves the crisis in some way within approximately 6 weeks. Crisis intervention aims to return the person to a precrisis level of functioning and promote growth (Fig. 37.6).

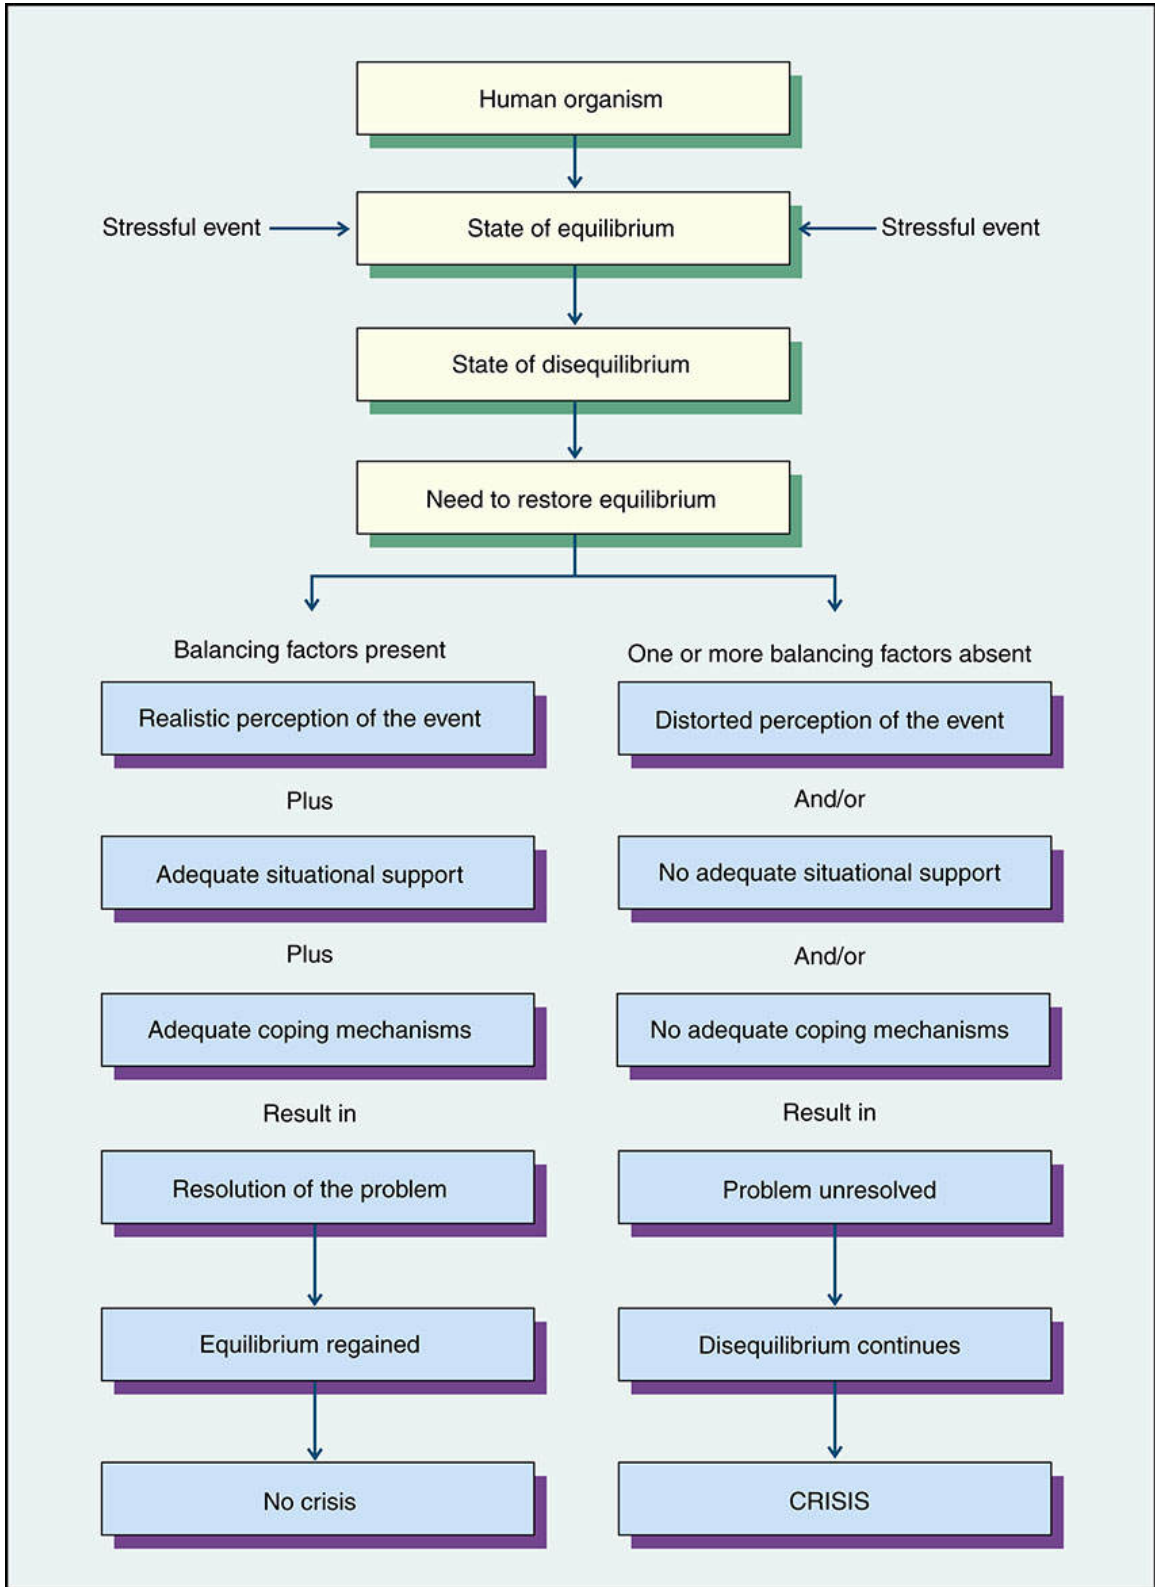

FIG. 37.6 Crisis intervention model.
 Redrawn from Aguilera DC: *Crisis intervention: theory and methodology*, ed 8, St Louis, 1998, Mosby.

Because an individual's or family's usual coping strategies are ineffective in managing the stress of the precipitating event during crisis, the use of new coping mechanisms is necessary. This experience forces the use of unfamiliar strategies and results in either a heightened awareness of previously unrecognized strengths and resources or deterioration in functioning. Thus, a crisis is often referred to as a situation of both danger and opportunity. Some individuals or families emerge from a crisis state functioning more effectively, whereas others find themselves weakened, and still others are completely dysfunctional.

Crisis intervention is a specific type of brief psychotherapy and has two specific goals. First is patient safety. Use external controls to protect the patient and others if the person is suicidal or homicidal. Second is anxiety reduction using techniques that put a patient's inner resources into effect. It is more directive than traditional psychotherapy or counseling, and any member of the health care team who has been trained in its techniques can use it. The basic approach is problem solving, and it focuses only on the problem presented by the crisis (Halter, 2018).

Help a patient make the mental connection between the stressful event and his or her reaction to it. This is crucial because he or she is sometimes unable to see the whole situation clearly. Help the person explore his or her feelings and emotions such as anger, grief, or guilt to help him or her reduce feelings of tension. In addition, you help the patient explore coping mechanisms, perhaps identifying new methods of coping. Finally, you help the person increase social contacts if he or she has been isolated and overly self-focused.

Restorative and Continuing Care

A person under stress recovers when the stress is removed or coping strategies are successful; however, a person who has experienced a crisis has changed, and the effects often last for years or for the rest of the person's life. The final stage of adapting to a crisis is acknowledgment of its long-term implications. If a person has coped with a crisis and its consequences successfully, he or she becomes more mature and healthier. When a person recovers from a stressful situation, the time is right for introducing stress-management skills to reduce the number and intensity of stressful situations in the future.

• Evaluation

Through the Patient's Eyes

A patient recovering from acute stress often spontaneously reports feeling better when the stressor is gone. The recovery from chronic stress occurs more gradually as the patient emerges from the strain. Your evaluation must include the patient's perceptions. Ask the patient about sleep patterns, appetite, and ability to concentrate. Ask how the patient feels about coping strategies that are being used, and determine their effectiveness. Ask patients to compare current feelings and behaviors with feelings and behaviors before the patient started experiencing stress (e.g., 6 months ago).

An essential part of the evaluation process is collaborating with patients to determine whether their own expectations from nursing have been met. Any revision in the plan of care includes steps to address patient expectations.

Patient Outcomes

Evaluation involves reassessing any new or recurring stress-related symptoms and whether the expected outcomes in the plan of care were achieved (Fig. 37.7). Remember that coping with stress takes time. Maintain ongoing communication with patients regarding their coping. Patients under severe stress or trauma often experience feelings of powerlessness, vulnerability, and loss of control. Address these feelings by actively involving patients and families in the processes of re-examining problems, prioritizing, goal setting, and revising interventions. Involving patients in these processes gives them an opportunity to direct their energy in a positive way and moves them toward taking greater responsibility for health maintenance and promotion.

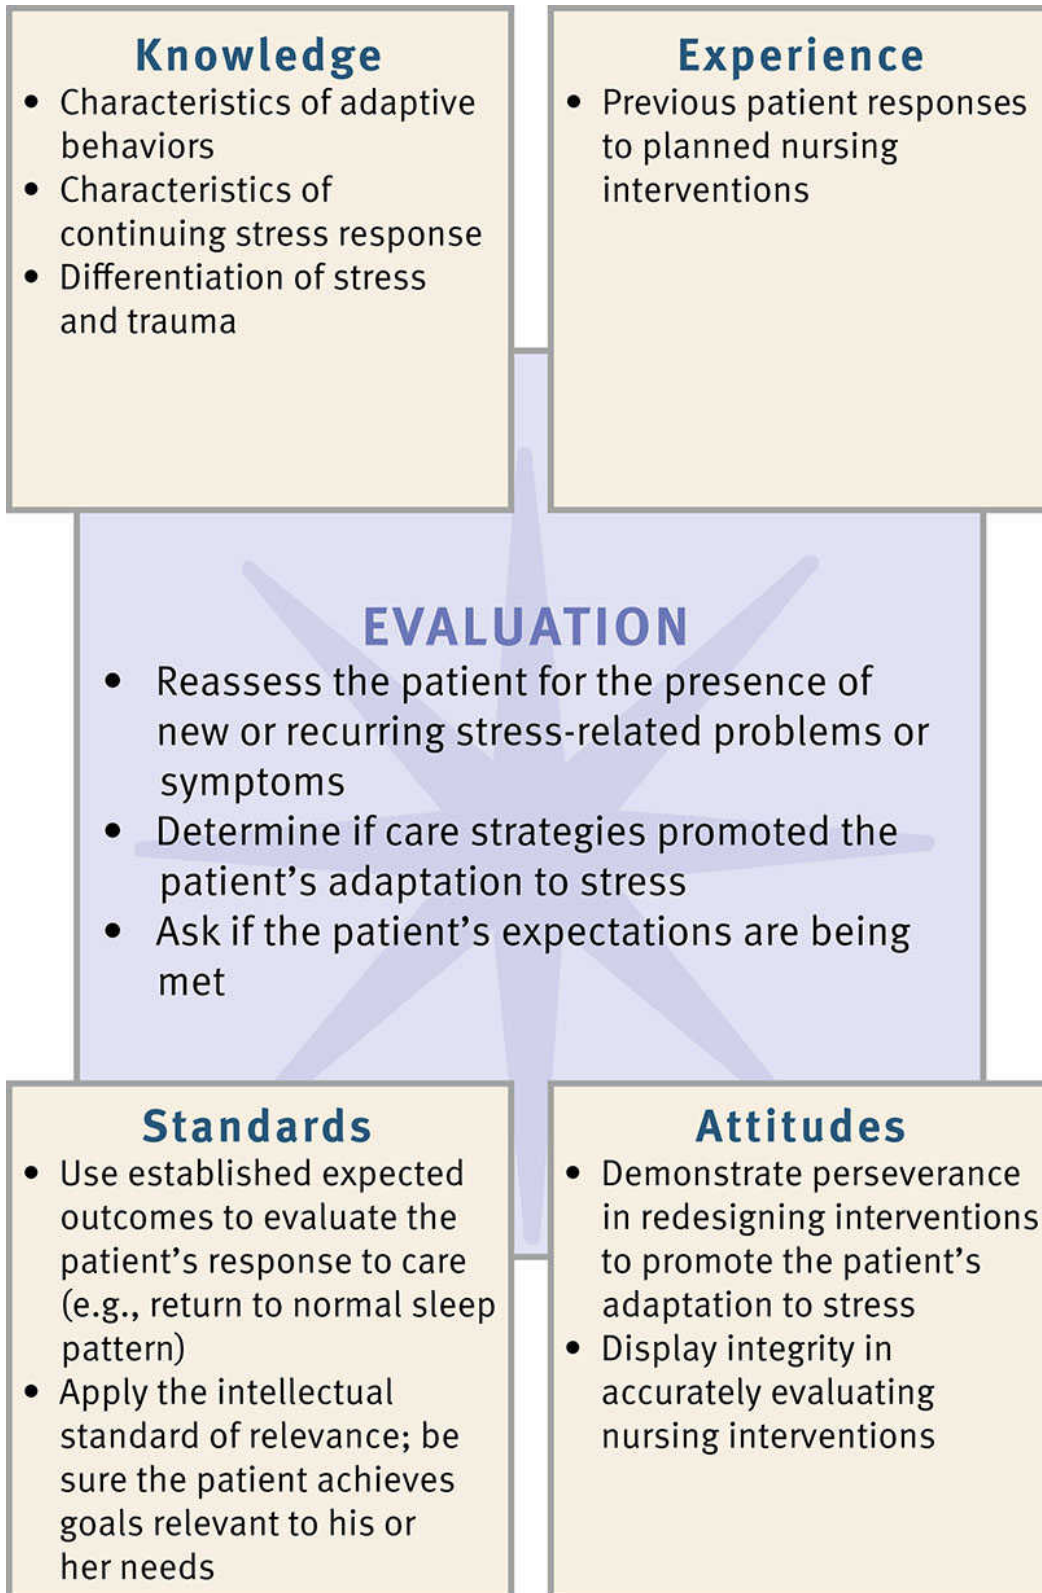

FIG. 37.7 Critical thinking model for stress and coping evaluation.

Engaging the patient as a partner in health care creates open communication. In such an environment the patient feels comfortable to give important feedback about interventions that are successful and helps you better understand why some interventions fail to meet the expected outcomes and established goals. If a patient reports continued acute stress, assess for safety by asking about whether there have been any recent stressors at home, in the car, or at work. Ask about coping strategies to determine whether the patient is using unsafe, maladaptive strategies. If the patient reports continued chronic stress, ask about his or her perception of the stressor and the coping behaviors used. Discuss the stressor with the patient to determine whether it needs to be redefined. If contact with a patient ends before you have achieved the resolution of goals, it is important to refer him or her to appropriate resources so that progress is not delayed or interrupted.

Key Points

- The general adaptation syndrome (GAS), an immediate physiological response to stress, involves specific autonomic nervous system and endocrine system responses during the alarm, resistance, and exhaustion stages.
- Post-traumatic stress disorder begins when a person experiences, witnesses, or is confronted with a traumatic event and responds with intense fear or helplessness. Anxiety associated with PTSD is sometimes manifested by nightmares and emotional detachment.
- Many nursing theories, such as the Neuman Systems Model or Callista Roy's Adaptation Model, explain and describe stress and help you understand how an individual, family, or community effectively responds to stressors in the environment.
- Compassion fatigue is a state of burnout and secondary traumatic stress that can overwhelm health care providers and result in feelings of hopelessness, inadequacy, and anxiety.

- A regular exercise program improves muscle tone and posture, controls weight, reduces tension, and promotes relaxation.
- An individual whose stress is so severe that he or she is unable to cope using any of the means that have worked before is experiencing a crisis.
- Crisis intervention aims to return the person to a precrisis level of functioning and promote growth.
- Assessment of a patient's stress level and coping resources requires that you first establish a trusting nurse-patient relationship because you are asking a patient to share personal and sensitive information.
- Three primary modes of intervention for stress are to decrease stress-producing situations, increase resistance to stress, and learn skills that reduce physiological responses to stress.
- In nursing, burnout results when nurses perceive that the demands of their work exceed perceived resources. It is manifested as emotional exhaustion, poor decision making, loss of a sense of personal identity, and feelings of failure.

Reflective Learning

- Consider the stressors you are experiencing in your own life while you are in your nursing education program. What stress-reducing and coping strategies are you using to manage the stress you are experiencing. What strategy do you find most effective?
- Think about a patient you cared for recently on the clinical unit. How did stress impact the patient's health? Discuss the response of the patient to this stress.
- You are developing a program to help nurses on the clinical unit cope with compassion fatigue. Discuss key points that you will

include in the program. What strategies will you teach the nurses to use to combat compassion fatigue?

Review Questions

1. The nurse is interviewing a patient in the community clinic and gathers the following information about her: she is intermittently homeless, a single parent with two children who have developmental delays. She has had asthma since she was a teenager. She does not laugh or smile, does not volunteer any information, and at times appears close to tears. She has no support system and does not work. She is experiencing an allostatic load. As a result, which of the following would be present during complete patient assessment? (Select all that apply.)
 1. Post-traumatic stress disorder
 2. Rising hormone levels
 3. Chronic illness
 4. Insomnia
 5. Depression
2. A patient who is having difficulty managing his diabetes mellitus responds to the news that his hemoglobin A1c, a measure of blood sugar control over the past 90 days, has increased by saying, "The hemoglobin A1c is wrong. My blood sugar levels have been excellent for the last 6 months." Which defense mechanism is the patient using?
 1. Denial
 2. Conversion
 3. Dissociation
 4. Displacement

3. When assessing a young woman who was a victim of a home invasion 3 months earlier, the nurse learns that the woman has vivid images of the event whenever she hears loud yelling or a sudden noise. The nurse recognizes this as _____.
4. While assessing an older woman who is recently widowed, the nurse suspects that this woman is experiencing a developmental crisis. Which questions provide information about the impact of this crisis? (Select all that apply.)
 1. With whom do you talk on a routine basis?
 2. What do you do when you feel lonely?
 3. Tell me what your husband was like.
 4. I know this must be hard for you. Let me tell you what might help.
 5. Have you experienced any changes in lifestyle habits, such as sleeping, eating, smoking, or drinking?
5. The nurse plans care for a 16-year-old male, taking into consideration that stressors experienced most commonly by adolescents include which of the following? (Select all that apply.)
 1. Loss of autonomy caused by health problems
 2. Physical appearance and body image
 3. Accepting one's personal identity
 4. Separation from family
 5. Taking tests in school
6. A 10-year-old girl was playing on a slide at a playground during a summer camp. She fell and broke her arm. The camp notified the parents and took the child to the emergency department according to the camp protocol for injuries. The parents arrive at the emergency department and are stressed and frantic. The 10-year-old is happy in the treatment room, eating a Popsicle

and picking out the color of her cast. List in order of priority what the nurse should say to the parents.

1. "Can I contact someone to help you?"
 2. "Your daughter is happy in the treatment room, eating a Popsicle and picking out the color of her cast."
 3. "I'll have the doctor come out and talk to you as soon as possible."
 4. "I want to be sure you are ok. Let's talk about what your concerns are about your daughter before we go see her."
7. When assessing an older adult who is showing symptoms of anxiety, insomnia, anorexia, and mild confusion, what is the first assessment the nurse conducts?
1. The amount of family support
 2. A 3-day diet recall
 3. A thorough physical assessment
 4. Threats to safety in her home
8. A 34-year-old single father who is anxious, tearful, and tired from caring for his three young children tells the nurse that he feels depressed and doesn't see how he can go on much longer. Which statement would be the nurse's best response?
1. "Are you thinking of suicide?"
 2. "You've been doing a good job raising your children. You can do it!"
 3. "Is there someone who can help you during the evenings and weekends?"
 4. "Tell me what you mean when you say you can't go on any longer."
9. The nurse is evaluating how well a patient newly diagnosed with multiple sclerosis and psychomotor impairment is coping.

Which statements indicate that the patient is beginning to cope with the diagnosis? (Select all that apply.)

1. "I'm going to learn to drive a car, so I can be more independent."
 2. "My sister says she feels better when she goes shopping, so I'll go shopping."
 3. "I'm going to let the occupational therapist assess my home to improve efficiency."
 4. "I've always felt better when I go for a long walk. I'll do that when I get home."
 5. "I'm going to attend a support group to learn more about multiple sclerosis."
10. A crisis intervention nurse is working with a mother whose child with Down syndrome has been hospitalized with pneumonia and who has lost her child's disability payment while the child is hospitalized. The mother worries that her daughter will fall behind in her classes during hospitalization. Which strategies are effective in helping this mother cope with these stressors? (Select all that apply.)
1. Referral to social service process reestablishing the child's disability payment
 2. Sending the child home in 72 hours and having the child return to school
 3. Coordinating hospital-based and home-based schooling with the child's teacher
 4. Teaching the mother signs and symptoms of a respiratory tract infection
 5. Telling the mother that the stress will decrease in 6 weeks when everything is back to normal

UNIT 7

Physiological Basis for Nursing Practice

OUTLINE

38. Activity and Exercise

39. Immobility

40. Hygiene

41. Oxygenation

42. Fluid, Electrolyte, and Acid-Base Balance

43. Sleep

44. Pain Management

45. Nutrition

46. Urinary Elimination

47. Bowel Elimination

48. Skin Integrity and Wound Care

49. Sensory Alterations

50. Perioperative Nursing Care

Activity and Exercise

OBJECTIVES

- Understand the role of the musculoskeletal and nervous systems in the regulation of activity and exercise.
- Understand the importance of exercise and activity for maintaining and promoting health.
- Apply nursing care interventions for preventing deconditioning in hospitalized inpatients.
- Describe the rationale for the use of safe patient handling techniques when transferring and assisting patients with ambulation.
- Understand factors to consider when planning an exercise program for patients across the life span.
- Describe how to assess patients for level of activity tolerance.
- Identify interventions designed to improve an individual's activity tolerance.
- Discuss the importance of minimal or no-lift policies for patients and health care providers.
- Describe nurses' responsibility in assisting patients to ambulate safely.
- Evaluate the achievement of patient outcomes following use of safe transfer techniques.

Stretch reflex, p. 781

Synovial joints, p. 778

Unossified, p. 780

Regular physical activity and exercise contribute to individuals' physical and emotional well-being. According to the [American Heart Association \(2018\)](#), physical activity:

- Elevates our mood and attitude.
- Keeps us physically fit.
- Helps one to quit smoking and stay tobacco-free.
- Boosts your energy level so you can get more done.
- Helps in the management of stress.
- Promotes a better quality of sleep.
- Improves your self-image and self-confidence.

Promoting activity and exercise is a principle that you, as a nurse, should apply in the care of patients in all health care settings. When promoting activity it is important to do so in a safe and efficient manner, especially for patients who are functionally impaired and in need of your assistance. Walking, turning, lifting, and carrying all are common actions used in delivering nursing care. These activities also pose risks. Health care workers frequently incur injuries, such as back injuries and overexertion, when moving or lifting patients incorrectly. You will apply safe patient handling standards and principles to reduce the risk of injury to patients and yourself when assisting patients with activities.

Frequently patients experience functional decline (the loss of the ability to perform self-care or **activities of daily living**). Such decline may result not only directly from illness or adverse treatment effects but also from **deconditioning** associated with imposed inactivity. The negative effects of deconditioning can be seen after short periods of time. Deconditioning involves physiological changes following a period of inactivity (e.g., bed rest or sedentary lifestyle). It is a particular risk for hospitalized patients who spend most of their time in bed, even when they are able to walk. As a result, nurses play an important role in increasing the overall activity of inpatients routinely to minimize the risk of deconditioning.

A program of regular physical activity and exercise has the potential to enhance all aspects of a patient's health. This chapter provides you with knowledge of exercise and activity as they relate to health promotion, the acute phase of illness, and the restorative and continuing care of patients.

Scientific Knowledge Base

Regular physical activity and exercise contribute to both physical and emotional well-being. Knowing the physiology and regulation of body mechanics, exercise, and activity helps you to provide individualized patient care.

Nature of Movement

Movement is a complex process that requires coordination between the musculoskeletal and nervous systems. As a nurse you will consider how a patient's physical and psychological conditions affect body movement. **Body mechanics** is a term that describes the coordinated efforts of the musculoskeletal and nervous systems. Knowing how patients initiate movement and understanding your own movements requires a basic understanding of the physics surrounding body mechanics. The body mechanics applied in the lifting techniques historically used in nursing practice often cause debilitating injuries to nurses and other health care staff ([Kanaskie and Snyder, 2018](#); [Noble and Sweeney, 2018](#)). Today nurses use evidence-based information about body alignment, balance, gravity, and friction when implementing nursing interventions such as transferring patients, assisting with ambulation, determining the risk of patient falls, and selecting the safest way to move or transfer patients ([AORN, 2018](#)).

Alignment and Balance

The terms **body alignment** and "posture" are similar and refer to the positioning of the joints, tendons, ligaments, and muscles while standing, sitting, and lying. Body alignment means that an individual's center of gravity is stable. Correct body alignment reduces strain on musculoskeletal structures, aids in maintaining adequate muscle tone, promotes comfort, and contributes to balance and conservation of energy. Without balance control the center of gravity is displaced.

Individuals require balance for maintaining a static position (e.g., sitting) and moving (e.g., transferring or walking). Disease, injury, pain, physical development (e.g., age), and life changes (e.g., pregnancy) compromise the ability to remain balanced. Medications that cause dizziness and prolonged immobility affect balance. Impaired balance is a major threat to mobility and physical safety and contributes to a fear of

falling and self-imposed activity restrictions ([Dickinson et al., 2018](#); [Musich et al., 2018](#)).

Gravity and Friction

Weight is the force exerted on a body by gravity. The force of weight is always directed downward, which is why an unbalanced object falls. Unsteady patients fall if their center of gravity becomes unbalanced because of the gravitational pull on their weight. To lift safely the lifter has to overcome the weight of the object and know its center of gravity. In symmetrical inanimate objects the center of gravity is at the exact center of the object. However, people are not geometrically perfect; their centers of gravity are usually at 55% to 57% of standing height and are in the midline, which is why using only the principles of body mechanics in lifting patients often leads to injury of a nurse or other health care professional.

Friction is a force that occurs in a direction to oppose movement. The greater the surface area of the object that is moved, the greater is the friction. A larger object produces greater resistance to movement. In addition, the force exerted against the skin while the skin remains stationary and the bony structures move is called shear. Unfortunately, a common example is when the head of a hospital bed is elevated beyond 60 degrees and gravity pulls a patient so that the bony skeleton moves toward the foot of the bed while the skin remains against the sheets. The blood vessels in the underlying tissue are stretched and damaged, resulting in impeded blood flow to the deep tissues. Ultimately pressure injuries often develop within the undermined tissue; the surface tissue appears less affected (see [Chapter 48](#)). To decrease surface area and reduce friction when patients are unable to assist with moving up in bed, nurses use an ergonomic assistive device such as a full-body sling. The sling mechanically lifts a patient off the surface of a bed, thereby preventing friction, tearing, or shearing of the patient's delicate skin; it also protects nurses and other health care staff from injury ([Noble and Sweeny, 2018](#)) (see [Chapter 39](#)).

Regulation of Movement

Coordinated body movement involves the integrated functioning of the musculoskeletal and nervous systems. Because these systems work together dynamically, they are often considered as a single functional unit.

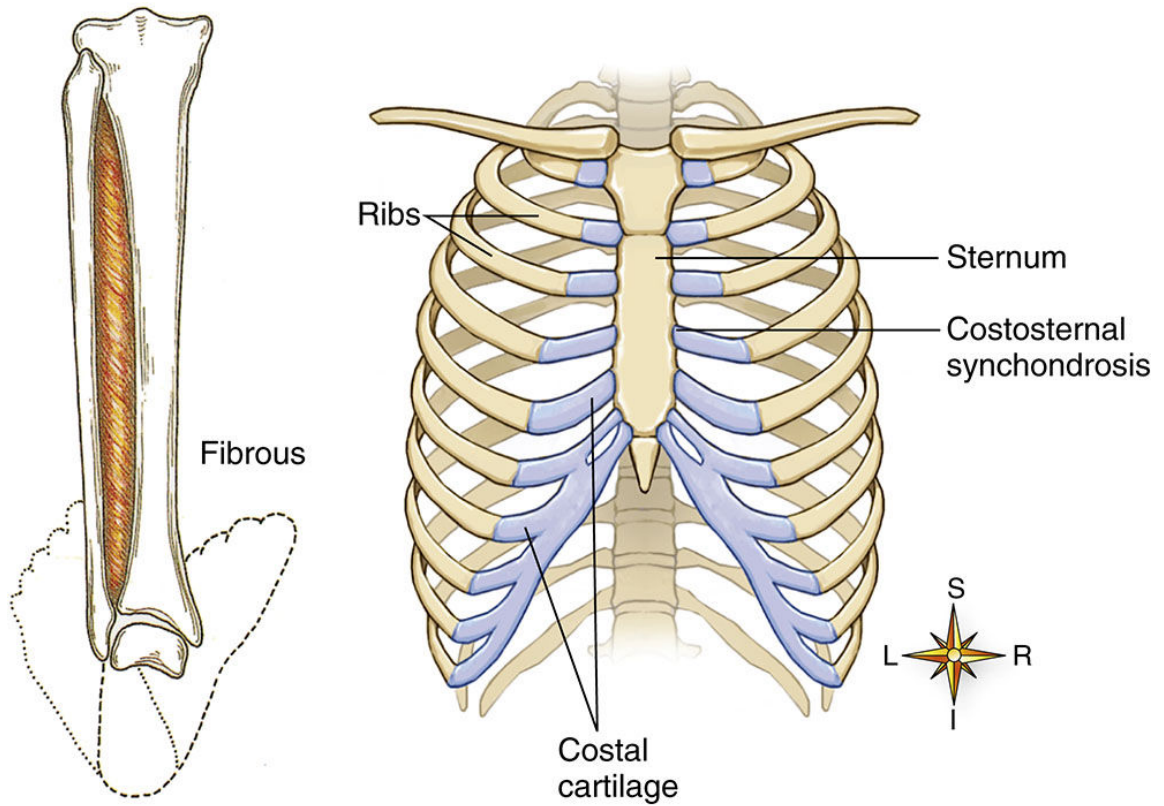

Skeletal System

The skeletal system provides attachments for muscles and ligaments and the leverage necessary for mobility. Thus the skeleton is the supporting framework of the body and is made up of four types of bones: long, short, flat, and irregular. Bones are important for mobilization because they are firm, rigid, and elastic. The aging process, as well as some nutritional and disease processes, has the potential to change the components of bone, which impacts mobility.

Firmness results from inorganic salts such as calcium and phosphate that are in the bone matrix. It is related to the rigidity of the bone, which is necessary to keep long bones straight, and enables bones to withstand weight-bearing. Elasticity and skeletal flexibility change with age. A newborn has a large amount of cartilage and is highly flexible but is unable to support weight. A toddler's bones are more pliable than those of an older person and are better able to withstand traumatic injury. Older adults, especially women, are more susceptible to bone loss (resorption) and osteoporosis, which increases the risk of fractures.

Joints

The region where two or more bones attach is referred to as a joint. Each joint is classified according to its structure and degree of mobility. There are three classifications of joints: cartilaginous, fibrous, and synovial (McCance and Huether, 2017). **Fibrous joints** fit closely together and are fixed, permitting little if any movement, such as the syndesmosis between the tibia and fibula (Fig. 38.1A). **Cartilaginous joints** have little movement but are elastic and use cartilage to unite separate bony surfaces, such as the synchondrosis that attaches the ribs to the costal cartilage. When bone growth is complete, the joints ossify (see Fig. 38.1B). **Synovial joints**, or true joints, such as the hinge type at the elbow, are freely movable and the most mobile, numerous, and anatomically complex body joints (see Fig. 38.2AB).

Ligaments, Tendons, and Cartilage

Ligaments, tendons, and cartilage support the skeletal system. Ligaments are white, shiny, flexible bands of dense fibrous tissue that bind joints and connect bones and cartilage. A ligament is one type of collagenous fiber that intertwines in irregular, swirling arrangements to form thick connective tissue (Patton, 2019). Ligaments are predominantly elastic fibers and are thus somewhat elastic in nature (Fig. 38.3). Some ligaments serve a protective function. For example, ligaments between the vertebral bodies and the ligamentum flavum prevent damage to the spinal cord during movement of the back.

FIG. 38.3 Tendons and ligaments of the shoulder.
 B From Patton KT, Thibodeau GA: *Anatomy & physiology*, ed 10, St Louis, 2019, Elsevier.

Tendons are white, glistening fibrous bands of tissue that occur in various lengths and thicknesses. Tendons connect muscle to bone and are strong, flexible, and inelastic. The Achilles tendon is the thickest and strongest tendon in the body. It begins near the midposterior of the leg and attaches the gastrocnemius and soleus muscles in the calf to the calcaneal bone in the back of the foot (Fig. 38.4). Cartilage is nonvascular (without blood vessels) supporting connective tissue located chiefly in the joints and thorax, trachea, larynx, nose, and ear. It has the flexibility of a firm, plastic material. Because of its gristlelike nature, cartilage sustains weight and serves as a shock absorber between articulating bones. Permanent cartilage is **unossified** (not hardened), except in advanced age and diseases such as osteoarthritis, which impairs mobility.

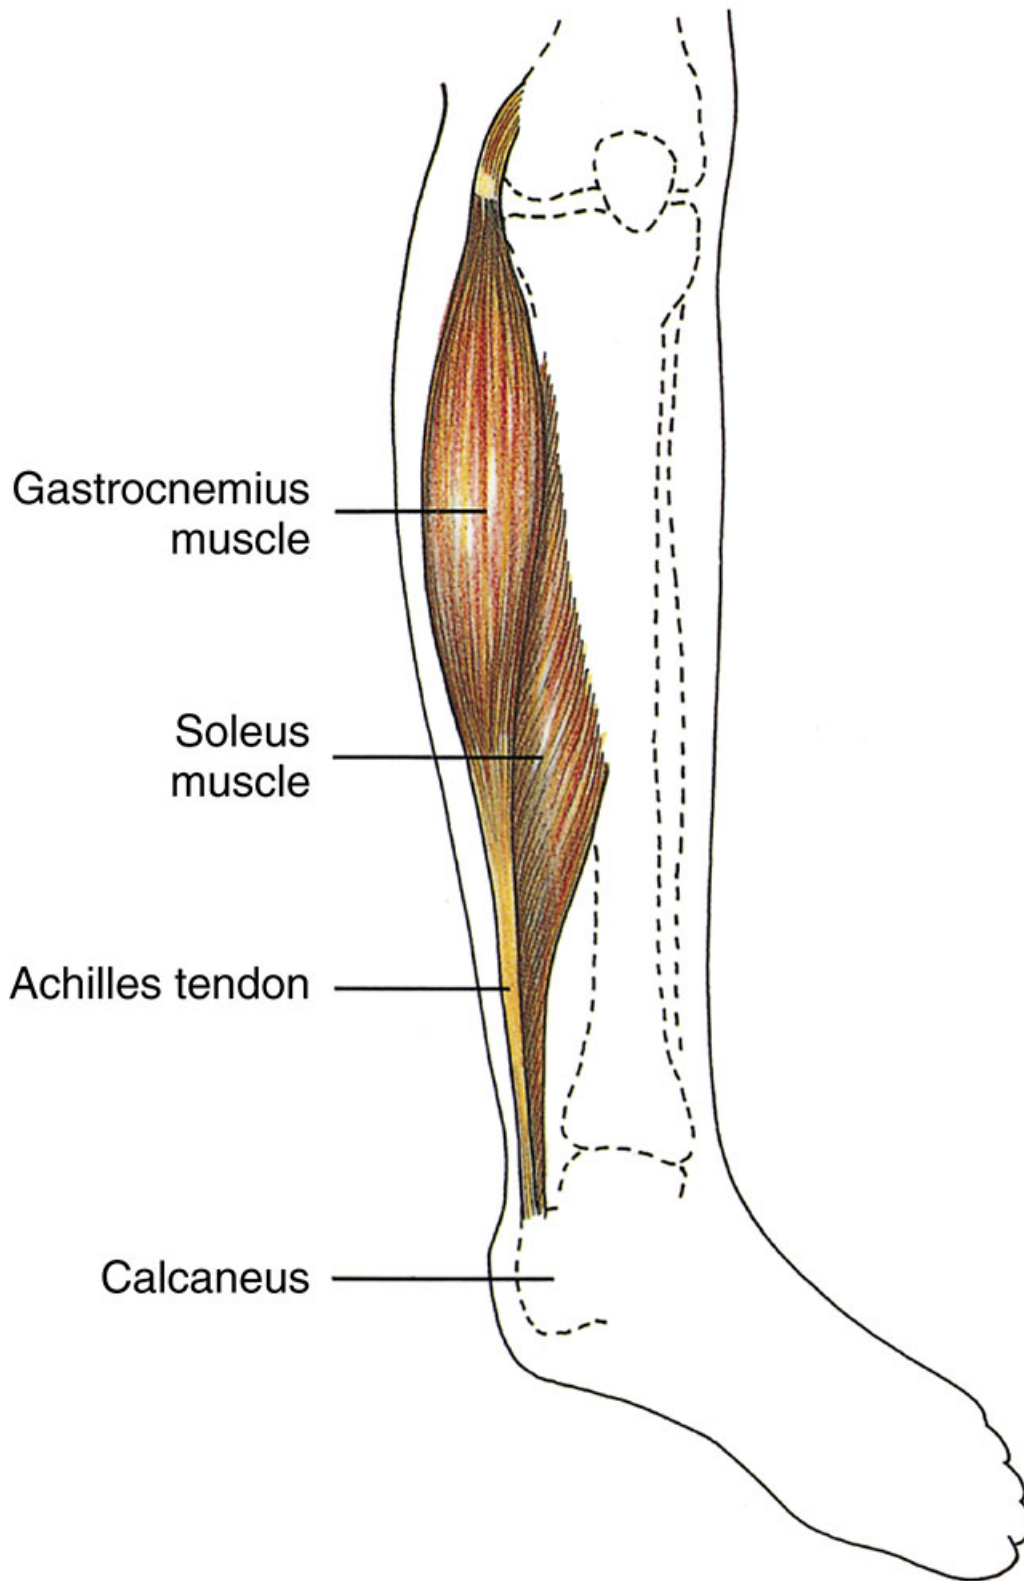

FIG. 38.4 Tendons and muscles of lower leg.

Strength and flexibility do not result entirely from joints, ligaments, tendons, and cartilage. Adequate skeletal muscle is also necessary.

Skeletal Muscle

Skeletal muscle cells have the ability to be stimulated, or excited, and thus can respond to regulatory mechanisms such as nerve signals (Patton, 2019). Skeletal muscles are composed of bundles of skeletal muscle fibers that generally extend the entire length of the muscle. Muscle fibers contract when stimulated by an electrochemical impulse that travels from the nerve to the muscle across the neuromuscular junction. The electrochemical impulse causes the filaments (predominantly protein molecules of myosin and actin) within the fiber to slide past one another, with the filaments changing length. Continued and efficient use of adenosine triphosphate (ATP), the energy source for muscular contraction, requires glucose and oxygen. Both nutrients reach the muscle fibers through vascular capillaries (Patton, 2019).

Skeletal muscles contract with varying degrees of strength based on the specific task (Patton, 2019). For example, during prolonged inactivity, muscles usually shrink, a condition called disuse atrophy (see Chapter 39) (Patton, 2019). Active use of muscles during exercise can increase muscle size and lead to hypertrophy. Contraction of skeletal muscles allows people to walk, talk, breathe, or participate in any physical activity. There are more than 600 skeletal muscles in the body. In addition to facilitating movement, these muscles determine the form and contour of our bodies. Most of our muscles span at least one joint and attach to both articulating bones. When contraction occurs, one bone is fixed while the other moves. The origin is the point of attachment that remains still; the insertion is the point that moves when the muscle contracts (Patton, 2019).

The amount of load placed on a muscle influences the strength of a skeletal muscle. Generally, the heavier the load, the stronger the contraction. Imagine lifting your hands with palms up in front of you and placing this textbook in your hand. You will feel your arm muscles contract more strongly as the book is placed in your hand because of the **stretch reflex** (Patton, 2019). Your arms and hands will try to maintain constancy of muscle length. The body has a negative feedback response when it detects the increased stretch caused by the load of the textbook. The information is relayed back to the central nervous system, which increases its stimulation of the muscle to counteract the stretch (Patton, 2019). The reflex maintains relatively constant muscle length, but when the load becomes too heavy and threatens injury to the muscle, the body

ignores the reflex and causes you to relax and drop the textbook (Patton, 2019).

There are two types of muscle contractions, isotonic and isometric. An isotonic or dynamic contraction is mobilizing, causing the body to move (Patton, 2019). In contrast, an isometric contraction is stabilizing, causing the body to hold a stable position (Patton, 2019). **Isotonic contractions** have two varieties, concentric and eccentric. In **concentric tension** increased muscle contraction causes muscle shortening, resulting in movement, such as when a patient uses an overhead trapeze to pull up in bed. **Eccentric tension** causes lengthening of a muscle to control the speed and direction of movement. For example, when using an overhead trapeze, a patient slowly lowers himself to the bed. The lowering is controlled when the antagonistic muscles lengthen. Concentric and eccentric muscle actions are necessary for active movement. **Isometric contraction** (static contraction) causes an increase in muscle tension or muscle work but no shortening or active movement of the muscle (e.g., instructing a patient to tighten and relax a muscle group, as in quadriceps set exercises or pelvic floor exercises). Voluntary movement is a combination of isotonic and isometric contractions.

Although isometric contractions do not result in muscle shortening, energy expenditure increases. This type of muscle work is comparable to having a car in neutral with the driver continually depressing the accelerator and racing the engine. The driver is not going anywhere but expends a large amount of energy. It is important to understand the energy expenditure (increased respiratory rate and increased work on the heart) associated with isometric exercises because the exercises are sometimes contraindicated in certain patients' illnesses (e.g., myocardial infarction [MI] or chronic obstructive pulmonary disease [COPD]).

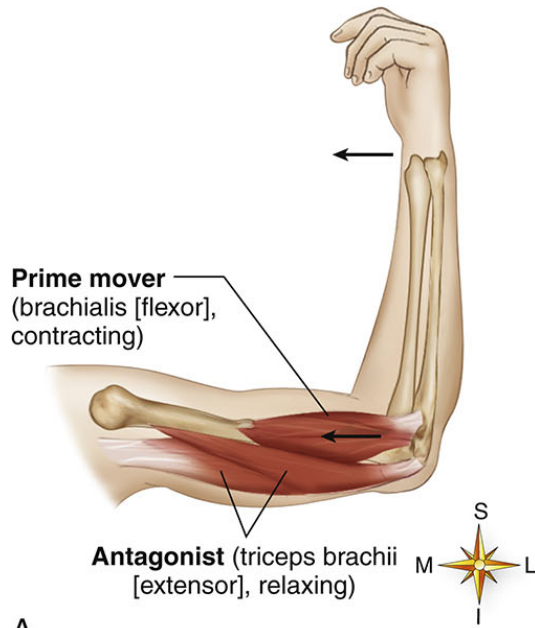

Muscles Concerned With Movement

Skeletal muscles usually act in groups, resulting in movement produced by the coordinated action of several muscles (Patton, 2019). Because some muscles contract while others relax, there is a functional classification of muscles (Table 38.1). These types of muscle actions are important to understand when you use your own muscles to move patients and when you assist patients in independent movement or exercises (Fig. 38.5). Movement is complex. Most muscles function as all the classifications (Patton, 2019). A prime mover during flexion may be an antagonist during extension or a synergist or fixator in rotation.

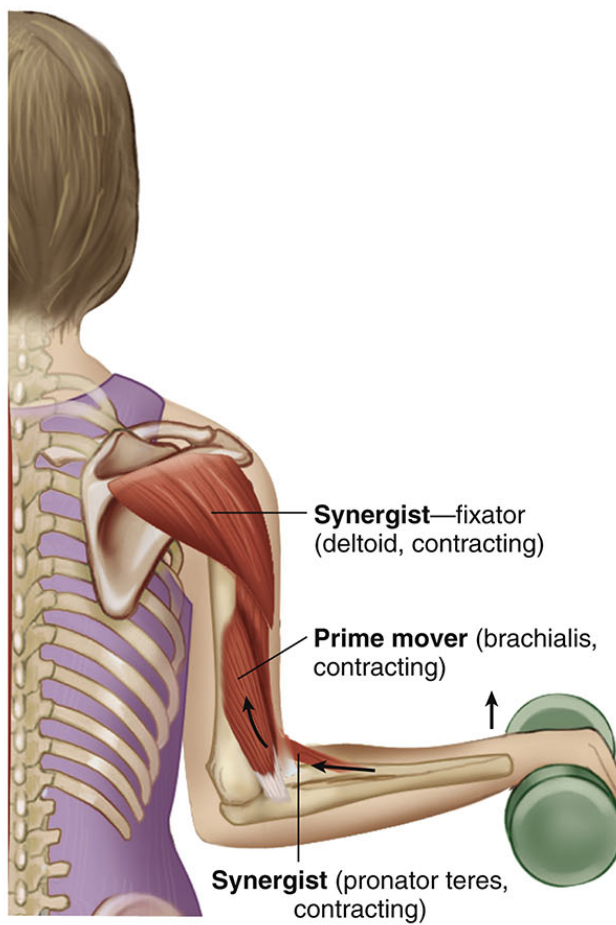

TABLE 38.1**Functional Classification of Muscle Action**

Term	Movement	Example
Prime mover	Muscle that directly performs a specific movement.	Brachialis is a prime mover when flexing the elbow.
Antagonist	Muscle that directly when contracting opposes prime mover or agonist. Relaxes while prime mover contracts. Provides precision and control during contraction of prime mover.	The triceps brachii is an extensor that relaxes when brachialis contracts.
Synergists	Muscle that contracts at same time as prime mover. Facilitates prime mover actions to produce more effective movement.	The deltoid contracts when brachialis contracts
Fixators	Muscles that stabilize joints; act as type of synergist. Serve to maintain posture and balance.	The deltoid maintains balance of arm when brachialis contracts.

Adapted from Patton KT: *Anatomy & physiology*, ed 10, St Louis, 2019, Elsevier.

A

B

FIG. 38.5 Muscle actions. **A**, The flexor muscle (brachialis) is the prime mover in flexing the elbow. The extensor muscle (triceps brachii) is the antagonist, relaxing to permit elbow flexion. The pronator teres muscle acts

as a synergist by also flexing the elbow. **B**, The brachialis is the prime mover of flexion of the elbow. The pronator teres muscle acts as a synergist by also flexing the elbow. To prevent the biceps from also moving the shoulder strains against the weight; the posterior portion of the deltoid muscle tenses to stabilize the shoulder, thus acting as a fixator muscle.

From Patton KT, Thibodeau GA: *Anatomy & physiology*, ed 10, St Louis, 2019, Elsevier.

When muscles shorten to contract, the type and extent of movement are determined by the load or resistance moved, the attachment of the tendons of the muscle to bone, and the type of joint involved (Patton, 2019). The muscles coordinate movement through a system of levers. The lever system makes the work of moving a weight or load easier. It occurs when specific bones such as the humerus, ulna, and radius and the associated joints such as the elbow act as a lever. Thus the force applied to one end of the bone to lift a weight at another point tends to rotate the bone in the direction opposite that of the applied force. Muscles that attach to bones of leverage provide the necessary strength to move an object.

Muscles Concerned With Posture

Gravity continually pulls on parts of the body; the only way the body is held in position is for muscles to pull on bones in the opposite direction. Muscles accomplish this counterforce by maintaining a low level of sustained contraction. Poor posture places more work on muscles to counteract the force of gravity. This leads to fatigue and eventually interferes with bodily functions and causes deformities.

Posture and movement depend on the skeleton and the shape and development of skeletal muscles. They also contribute to musculoskeletal function and often reflect personality, discomfort, and mood. For example, a person with a dramatic personality gestures with the hands, a person who is tired or depressed may slouch, and a person with abdominal pain may curl into a fetal-like position.

Coordination and regulation of different muscle groups depend on muscle tone and activity of antagonistic, synergistic, and antigravity muscles. **Muscle tone**, or tonus, is the normal state of balanced muscle tension. The body achieves tension by alternating contraction and relaxation without active movement of neighboring fibers of a specific muscle group. Muscle tone helps maintain functional positions such as sitting or standing without excess muscle fatigue and is maintained through continual use of muscles. Activities of daily living (ADLs) require muscle action and help maintain muscle tone. When a patient is immobile

or on prolonged bed rest, activity level, activity tolerance, and muscle tone decrease (see [Chapter 39](#)).

Nervous System

The nervous system regulates movement and posture. The precentral gyrus, or motor strip, is the major voluntary motor area and is in the cerebral cortex. A majority of motor fibers descend from the motor strip and cross at the level of the medulla. Transmission of impulses from the nervous system to the musculoskeletal system is an electrochemical event and requires a neurotransmitter. Basically neurotransmitters are chemicals (e.g., acetylcholine) that transfer the electrical impulse from the nerve across the myoneural junction to stimulate the muscle, causing movement. Movement is impaired by disorders that alter neurotransmitter production, transfer of impulses from the nerve to the muscle, or activation of muscle activity. For example, Parkinson's disease alters neurotransmitter production, myasthenia gravis disrupts transfer from the neurotransmitter to the muscle, and multiple sclerosis impairs muscle activity ([McCance and Huether, 2017](#)).

Proprioception

Proprioception is a muscle sense that makes us aware of the position of the body and its parts, including body movement, orientation in space, and muscle stretch ([Patton, 2019](#)). For example, if you close your eyes and bend your elbow, you will know where your hand and lower arm are even if you cannot see them. Stretch receptors associated with muscles, joint capsules, and tendons are classified as proprioceptors ([Patton, 2019](#)). Proprioceptors are located within muscle spindles. Rapidly conducting and slower-conducting nerve fibers encircle an area of the muscle spindle found within skeletal muscles. When a muscle stretches, the afferent impulses from sensory neurons pass to the spinal cord and are relayed to the brain, providing a means to monitor changes in muscle length ([Patton, 2019](#)). The nervous system regulates posture, which requires coordination of proprioception and balance. As a person carries out ADLs, proprioceptors monitor muscle activity and body position. For example, the proprioceptors on the soles of the feet contribute to correct posture while standing or walking. In standing, pressure is continuous on the bottom of the feet. The proprioceptors monitor the pressure, communicating this information through the nervous system to the antigravity muscles. The standing person remains upright until deciding

to change position. As a person walks, the proprioceptors on the bottom of the feet monitor pressure changes. Thus, when the bottom of the moving foot comes in contact with the walking surface, the individual automatically moves the stationary foot forward.

Balance and Alignment

Body balance occurs when a person is properly aligned with a relatively low **center of gravity** balanced over a wide, stable base of support. In the case of standing, a vertical line falls from the center of gravity through the base of support ([Fig. 38.6](#)). Adequate balance is necessary to stand, walk, turn, lift, or perform ADLs. Proper posture enhances body balance. The term “posture” means maintaining optimal body position or alignment that favors function. It requires the least muscular work to maintain, and places the least strain on muscles, ligaments, and bones ([McCance and Huether, 2017](#)). Nurses maintain patient alignment when positioning patients and when turning or moving them (see [Chapter 39](#)).

FIG. 38.6 Correct body alignment when standing.

The nervous system controls balance specifically through the inner ear, the cerebellum, and through vision. The inner ear contains specialized mechanoreceptors or hair cells that are stimulated through sound waves, creating nerve impulses perceived in the brain as either sound or balance (Patton, 2019). These sense organs that are involved in balance are located within the vestibule and semicircular canals of the ear. Together the sense organs function in dynamic equilibrium, a function needed to maintain

balance when the head or body rotates or suddenly moves (e.g., when turning in circles or bending over) (Patton, 2019). Normal vision aids balance because visual input from the eyes offers feedback as to whether you or the environment around you is moving.

Normal muscle action involves groups of muscles functioning together as a unit. The cerebellum coordinates patterns of muscle movement with the motor control areas of the cerebrum (Patton, 2019). The cerebellum coordinates action of the prime movers, antagonists, synergists and fixator muscles to make normal movement smooth, steady, and precise as to the force, rate, and extent of movement (Patton, 2019). These coordinated patterns of movement, such as the sequence of leg movements needed for walking, are learned and stored in the cerebellum (Patton, 2019). Nurses rely on balance to maintain proper body alignment and posture when providing patient care. This reduces strain on musculoskeletal structures and maintains adequate muscle tone. To achieve balance and alignment follow these steps:

- Widen your base of support by separating the feet to a comfortable distance.
- Bring the center of gravity closer to your base of support to increase balance.
- Bend your knees and flex the hips until squatting, and maintain proper back alignment to keep the trunk erect.

Nurses apply these techniques in a variety of care activities. For example, you raise the height of a hospital bed when performing a procedure such as changing a dressing to prevent bending too far at the waist and shifting the base of support.

Activity and Exercise

Physical activity (PA) is any movement produced by skeletal muscles that results in energy expenditure (e.g., occupational, sports, conditioning, and household activities). Physical exercise is a subset of PA that is planned, structured, and repetitive and has a final or an intermediate objective, such as the improvement or maintenance of physical fitness (Pinto et al., 2018). Sometimes exercise is also a therapeutic measure, as in the case of rehabilitation following surgery. A patient's individualized exercise program depends on the patient's activity tolerance or the type and amount of exercise or activity that the patient is able to perform.

Physiological, emotional, and developmental factors influence a patient's activity tolerance (see below).

An active lifestyle is important for maintaining and promoting health and psychological well-being (Covan, 2015; Edelman and Kudzma, 2018). The best program of physical activity is a combination of exercises (isotonic, isometric, and resistive) that produce different physiological and psychological benefits. Isotonic exercises (e.g., walking, swimming, jogging, and bicycling) cause muscle contraction and change in muscle length (isotonic contraction). Isotonic exercises enhance circulatory and respiratory functioning; increase muscle mass, tone, and strength; and promote osteoblastic activity that combats osteoporosis. Isometric exercises (e.g., quadriceps set exercises and contraction of the gluteal muscles) involve tightening or tensing muscles without moving body parts (isometric contraction). This form of exercise is ideal for patients who do not tolerate increased activity, such as a patient who is immobilized in bed (see Chapter 39). The benefits are increased muscle mass, tone, and strength, thus decreasing the potential for muscle wasting; increased circulation to the involved body part; and increased osteoblastic activity.

Resistive isometric exercises are those in which an individual contracts the muscle while pushing against a stationary object or resisting the movement of an object (Kim et al., 2017). A gradual increase in the amount of resistance and the length of time that the muscle contraction is held increases muscle strength and endurance. Examples of resistive isometric exercises are push-ups and hip lifting, in which a patient in a sitting position pushes with the hands against a surface such as a chair seat and raises the hips. Resistive isometric exercises promote muscle strength and provide sufficient stress against bone to promote osteoblastic activity.

Principles for Transfer and Positioning

Transfer and positioning techniques help patients to be more active. For example, transferring a patient from bed to chair enables the patient to be more participative in self-care activities. Using the principles of balance and alignment aids in safe patient transfer and positioning during routine care activities (see Chapter 39). Along with safe patient handling techniques, good balance and alignment decrease work effort and place less strain on musculoskeletal structures (Box 38.1). As a nurse you will teach colleagues and patients' families how to transfer or position patients properly. Teaching a patient's family how to transfer the patient from bed to chair increases and reinforces the family's knowledge about proper

transfer and position techniques once the patient returns home. Knowledge of the principles of balance and alignment is crucial. You also incorporate knowledge of physiological and pathological influences on body alignment and mobility.

Box 38.1 Principles of Safe Patient Transfer and Positioning

- Use mechanical lifts and lift teams when patients are unable to assist.
- When a patient is able to assist, remember these principles:
 - The wider the base of support, the greater the stability of the nurse.
 - The lower the center of gravity, the greater the stability of the nurse.
 - The equilibrium of an object is maintained as long as the line of gravity passes through its base of support.
 - Facing the direction of movement prevents abnormal twisting of the spine.
 - Dividing balanced activity between arms and legs reduces the risk of back injury.
 - Leverage, rolling, turning, or pivoting requires less work than lifting.
 - When friction is reduced between the object to be moved and the surface on which it is moved, less force is required to move it.

Pathological Influences on Body Alignment, Mobility, and Activity

Many pathological conditions affect body alignment and mobility. These conditions include congenital defects; disorders of bones, joints, and muscles; central nervous system damage; and musculoskeletal trauma (Table 38.2) (see Chapter 39). In addition, obesity, a chronic public health problem, negatively affects the musculoskeletal system, leading to disability problems. As a nurse, you consider these factors when your goal is to increase patient activity. Patients will have limitations, requiring you to adapt your approaches to care. For example, it is important to

understand which type of voluntary and involuntary movement is present after damage to the central nervous system. Does the patient have the ability to move an extremity? Void independently? This information affects the types of interventions you select to maximize your patient’s activity level while keeping him or her safe.

TABLE 38.2

Pathological Conditions Affecting Body Alignment and Mobility

Condition	Pathological Influence	Examples
<i>Congenital defects</i>	Abnormalities affect the efficiency of the musculoskeletal system in regard to alignment, balance, and appearance.	Osteogenesis imperfecta —inherited disorder. Causes bones to be porous, short, bowed, and deformed. As a result, children experience curvature of the spine and shortness of stature. Scoliosis —a structural curvature of the spine associated with vertebral rotation. Muscles, ligaments, and other soft tissues become shortened, affecting balance and mobility.
<i>Bone, joint, and muscle disorders</i>	Affect integrity of structures.	Osteoporosis —reduction of bone density or mass. The bone remains biochemically normal but has difficulty maintaining integrity and support, leading to fractures.
<i>Inflammatory joint diseases</i>	Cause inflammation or destruction of the synovial membrane and articular cartilage and cause systemic signs of inflammation.	Arthritis —changes in articular cartilage combined with overgrowth of bone at the articular ends. Degenerative changes commonly affect weight-bearing joints. Articular disruption —trauma to the articular capsules and ranges from mild, such as a tear resulting in a sprain, to severe, such as a separation leading to dislocation.
<i>Central nervous system disorder</i>	Damages part of the central nervous system that regulates voluntary movement and causes impaired body alignment and immobility.	Traumatic head injury —damage in the motor strip of the cerebrum. The amount of voluntary motor impairment is directly related to the amount of destruction of the motor strip. Spinal cord injury —damage to spinal cord results in loss of function (permanent or temporary) below the level of the injury. A patient’s loss of function will depend on level of spinal cord affected.
<i>Musculoskeletal trauma</i>	Results in bruises, contusions, sprains, and/or fractures.	Bone fracture —simple or complex disruption of bone tissue continuity; often creates need for temporary immobility of affected body part.

Obesity

Obesity deserves special consideration because it is a major international public health problem affecting children and adults. Researchers in the

United States have found the obesity prevalence to be 16.9% in the age-group of 2 to 19 years and 8.4% in the age-group of 2 to 5 years (Skinner and Skelton, 2014), with an upward trend of prevalence in children with the severest forms of obesity (Pinto et al., 2016). Risk factors for childhood obesity are numerous; however, poor dietary habits, playing video games with an excess of screen time, and lack of exercise are significant factors. According to the Centers for Disease Control and Prevention (CDC), the prevalence of obesity among adults was 39.8% and affected about 93.3 million of US adults in 2015 to 2016 (CDC, 2018). Adults are more at risk for obesity due to a lack of healthy diet habits and limited physical activity and exercise.

Obesity impairs an individual's musculoskeletal health. Association has been found between obesity and numerous medical conditions, including osteoarthritis, low back pain, osteoporosis, gait disturbances (placing more stress on lower extremity joints), and soft tissue problems (e.g., pain in the neck, shoulder, elbow, and wrist/hand) (Anandacoomarasamy et al., 2008). Patients who are obese require adaptations in the approaches used to assist with walking, transfer, and positioning. Obesity directly impacts a patient's quality of life, especially in the ability to perform ADLs effectively.

REFLECT NOW

Consider being assigned to a patient who has a history of arthritis affecting the hips. The patient requires assistance with activities of daily living. Reflect on how musculoskeletal system function might be affected and how it will affect ways for planning patient activity.

Nursing Knowledge Base

Application of nursing knowledge about activity and exercise allows you to think critically about the holistic needs of patients and then make sound decisions about the relevant interventions to provide. Nursing knowledge as it pertains to activity and exercise helps you assess, identify, and intervene when patients have decreased activity tolerance or physical limitation that affects their mobility and/or ability to exercise.

Safe Patient Handling and Mobility

Nurses are exposed to overexertion and physical injury from the hazards related to moving and transferring patients. This is true in all patient care settings. Manually lifting and transferring patients has contributed in the past to a high incidence of work-related musculoskeletal problems and back injuries in nurses and other health care staff. Most care activities related to patient handling involve one or more of the following: lifting with extended arms, lifting when near the floor, lifting when sitting or kneeling, lifting with the trunk twisted or the load off to the side of the body, lifting with one hand or in a restricted space, or lifting during a shift lasting longer than eight hours ([Waters, 2007](#)). The growing trend toward injuries in the health care setting led to important nursing research. Research led by Dr. Audrey Nelson and Andrea Baptiste provided standardized methods for determining how to handle, move, and mobilize patients and supported the use of patient handling techniques based on individual patient characteristics and conditions ([Nelson and Baptiste, 2006](#); [Martin et al., 2014](#)).

Evidence-based research has shown that safe patient handling and mobility interventions significantly reduce overexertion injuries by replacing manual patient handling with safer methods guided by ergonomic principles ([NIOSH, 2016](#); [Matz, 2019](#)). Ergonomics is the design of work tasks to best suit the capabilities of workers. In the case of safe patient handling and mobility (SPHM), it involves improved assessment, the use of mechanical equipment, and safety procedures to lift and move patients. Many states have laws

mandating SPHM in health care agencies. Comprehensive SPHM programs include the following ([US Department of Veterans Affairs, 2016](#)):

- Standardized assessment tools for identifying a patient's mobility level, such as the Banner Mobility Assessment Tool (BMAT) ([Boynton et al., 2014b](#))
- An ergonomics assessment of patient rooms and health care environments
- Clinical/patient assessment algorithms to select the right equipment and number of staff for each patient handling and mobility task
 - Right equipment includes assistive devices in the form of ceiling lifts made available in patient rooms. Lifts help care providers transfer patients from beds to stretchers or wheelchairs and can be used to assist patients during walking.
 - Portable lifting devices that can be moved from room to room. The lifting equipment uses slings or vests to hold patients securely and reduce the risk of slipping, falling, or being dropped when walking.
- Unit peer leaders who function as safe patient handling experts and staff trainers
- Use of safety huddles to share information among staff members that will keep staff and patients safe
- A minimal-lift policy

The use of SPHM techniques is a standard for best practices in the moving, handling, and transfer of patients. In addition to reducing injuries to health care providers, the use of SPHM techniques improves patient outcomes. OSHA reports that SPHM programs result in patients having fewer falls, skin tears, and pressure injuries ([OSHA, 2017](#)).

Factors Influencing Activity and Exercise

Factors influencing activity and exercise include developmental changes, behavioral aspects, environmental issues, family and social support, and cultural and ethnic origin. Consider these areas of knowledge and apply this information in a plan of care whether a patient is seeking health promotion, acute care, or restorative and continuing care.

Developmental Changes

Throughout the life span the appearance and functioning of the body undergo change. Knowledge of growth and development (see [Chapters 12 to 14](#)[Chapter 12](#)[Chapter 13](#)[Chapter 14](#)) prepares you to anticipate the types of activities that patients of all ages are capable of performing. For example, the developmental process results in children acquiring independence in daily living by improving their gross motor capacity, as well as manual, intellectual, and communicative functioning ([Kim et al., 2017](#)).

A newborn infant's spine is flexed and lacks the anteroposterior curves of an adult. As growth and stability increase, the thoracic spine straightens, and the lumbar spinal curve appears, which allows sitting and standing. As an infant grows, musculoskeletal development permits support of weight for standing and walking, allowing the child to explore its environment. A toddler's posture is awkward because of the slight swayback and protruding abdomen. Toward the end of toddlerhood, posture appears less awkward, curves in the cervical and lumbar vertebrae are accentuated, and foot eversion disappears. From the third year through the beginning of adolescence, the musculoskeletal system continues to grow and develop. Greater coordination enables a child to perform tasks such as washing hands and brushing teeth, which require fine motor skills. Adolescent growth is often sporadic and uneven. As a result, the adolescent appears awkward and uncoordinated. Adolescent girls usually grow and develop earlier than boys. Hips widen, and fat deposits in the upper arms, thighs, and buttocks. The adolescent boy's changes in shape are usually a result of long-bone growth and increased muscle mass.

A middle-age adult should normally have full musculoskeletal function. An adult with correct posture and body alignment feels

good, looks good, and generally appears self-confident. A healthy adult also has the necessary musculoskeletal development and coordination to carry out ADLs and physical exercise. However, for people 45 to 64 years of age, the percentage of adults with two or more common chronic conditions increases. Most people with multiple chronic conditions (MCCs) are of working age (Box 38.2). Nurses must consider the burden of MCCs on nonelderly adults, who represent more than 60% of all adults with MCCs (Adams, 2017). Chronic disease significantly affects how to individualize activity and exercise therapy programs.

Box 38.2 Common Chronic Health Conditions Among Young Adults

- Heart disease
- Stroke
- Asthma
- Arthritis
- Chronic obstructive pulmonary disease
- Cognitive impairment
- Diabetes
- Depression
- Chronic kidney disease
- Cancer other than skin
- Hypertension

Data from Adams ML: *Differences between younger and older US adults with multiple chronic conditions*, Centers for Disease Control and Prevention: Preventing Chronic Disease, Volume 14, September 7, 2017. https://www.cdc.gov/pcd/Issues/2017/16_0613.htm. Accessed April 18, 2019.

A progressive loss of total bone mass occurs with older adults. Some of the possible causes of this loss include physical inactivity, hormonal changes, and increased osteoclastic activity (i.e., activity by cells responsible for bone tissue absorption). The effect of bone loss is weaker bones, causing vertebrae to be softer and long shaft bones to be less resistant to bending, making an individual prone to fractures and muscle injuries. Older adults may walk more slowly and incorrectly and appear less coordinated. Many are afraid of falling ([Lavidan et al., 2018](#); [Tomita et al., 2018](#)) They often take smaller steps and keep their feet closer together, which decreases the base of support and thus alters body balance. Physical exercise can improve endurance, coordination, and muscle stability and reduce the risk for falls and injuries (see [Chapter 14](#)).

Behavioral Aspects

It is important to consider your patients' knowledge of exercise and activity, their values and beliefs about exercise and health, barriers to a program of exercise and physical activity, and current exercise behaviors or habits. One barrier to exercise is whether a patient has multiple chronic diseases. Symptoms of one chronic condition (e.g., difficulty in breathing related to asthma) may interfere with another condition (diabetes), preventing the patient from engaging in needed regular exercise. Patients are more open to developing an exercise program if they are at the stage of readiness to change their behavior ([Tsang et al., 2015](#)). Patients' decisions to change behavior and include a daily exercise routine in their lives often occur gradually with repeated information individualized to their needs and lifestyle.

Cultural Background

Exercise and physical fitness are beneficial to all people. However, there are cultural differences regarding the extent to which people exercise ([Box 38.3](#)). A study has shown that leisure physical activity comprises only about 10% of total nonwork physical activity among adults ([Saffer et al., 2013](#)). Individuals with a lower level of education and minority racial/ethnic groups tend to have higher

levels of physical activity at work but lower levels of nonwork physical activity. The difference may limit the positive effects of physical activity on an individual's health because nonwork physical activity has a stronger positive association with health relative to work physical activity (Saffer et al., 2013). When developing a physical fitness program for culturally diverse populations, consider their education regarding the value of exercise and learn about what motivates individuals to exercise and which activities are appropriate and enjoyable.

Box 38.3 Cultural Aspects of Care Physical

Inactivity Among Ethnic Groups

The Centers for Disease Control and Prevention (Watson et al., 2016) reports that inactivity prevalence among adults 50 years of age and older was significantly higher among women than men, among Hispanics and non-Hispanic blacks than among non-Hispanic whites, and among adults who reported ever having one or more of seven selected chronic diseases than among those not reporting one. Inactivity prevalence significantly increased with decreasing levels of education and increasing body mass index. Physical activity is identified as having an important role in the prevention and treatment of diseases such as type 2 diabetes (Watson et al., 2016; Scarton et al., 2017).

Implications for Patient-Centered Care

- Physical inactivity is a modifiable risk factor for the development of type 2 diabetes. Prevention and treatment programs need to focus heavily on exercise and be tailored to the activity tolerance of the individual patient.
- Support promotion of physical activity through formal programs in schools, churches, and governmental agencies within black and Native American communities.
- Incorporate motivational factors into exercise programs such as providing a healthy snack or meal for participants and

furnishing each patient with a log to monitor weight loss and blood glucose levels.

Environmental Issues

Work Site

A common barrier for many individuals to being physically active is the lack of time needed to engage in a daily exercise program. Some work sites help their employees overcome the obstacle of time constraints by offering physical activity opportunities at the work site, reminders, and rewards for those committed to physical fitness. For example, a simple walking path that provides employees with the opportunity to walk at work may address barriers such as not having time to walk, concerns about their own neighborhood safety, or lack of social support (CDC, 2017). Such activity programs improve worker productivity and morale. Reminders within a work site such as signs that encourage employees to use the stairs instead of elevators are useful. Rewards such as free parking or discounted parking fees are also effective for employees who park in distant lots and walk.

Schools

Children today are less active, resulting in an increase in childhood obesity. Schools are excellent facilitators of physical fitness and exercise. Strategies for physical activity incorporated early into a child's daily routine often provide a foundation for lifetime commitment to exercise and physical fitness.

Community

Creating or modifying environments to make it easier for people to walk, run, or bike is a strategy that not only increases individuals' physical activity, but also makes communities better places to live. Communities designed to support physical activity are often called active communities (CDC, 2019a). Community support of physical fitness is instrumental in promoting the health of its members (e.g.,

providing walking trails and track facilities in parks, maps to guide access, and physical fitness classes). Success in implementing physical fitness programs depends on collaboration among public health agencies, parks and recreational associations, state and local governmental agencies, health care agencies, and the members of the community.

Family and Social Support

Social support is one motivational tool to encourage and promote exercise and physical fitness. In a systematic review that studied the association between social support and physical activity among older adults, it was found that people with greater social support for physical activity are more likely to do leisure time physical activity, especially when support comes from family members (Smith et al., 2017). This study noted that the physical activity levels of women are more likely than men to be influenced by general social support. A qualitative study identified factors to enable middle-aged women to engage in physical activity included daily structure that incorporated physical activity, anticipated positive feelings associated with physical activity (intrinsic motivator), and accountability to others (psychosocial motivator) (McArthur et al., 2014). An example of social support influencing exercise is having a friend or significant other engage a patient to participate in a “buddy system” (i.e., they walk together each day at a specified time) or weekly exercise classes. This companionship provides for socialization, increases the enjoyment, and develops a commitment to physical fitness. Parents support their children in engaging in physical activity by providing encouragement, praise, and transportation to sporting events or exercise facilities. Other parents support physical activity by including their children in family outings such as bicycling or a basketball game in the neighborhood schoolyard.

Critical Thinking

Successful critical thinking requires a synthesis of knowledge, experience, information gathered from patients, critical thinking attitudes, and intellectual and professional standards. Clinical judgments require you to anticipate information, analyze the data, and make decisions regarding patient care.

To understand activity tolerance, physical fitness, and the effects on patients, you integrate knowledge from nursing and other disciplines, previous experiences, and information gathered from patients. As you plan patient care, consider the relationship among a variety of concepts to provide the best outcome for your patients. For example, you lay the foundation for planning and decision making by understanding the relationship between the musculoskeletal system and health alterations that may create problems with activity and exercise and transferring and moving patients. Professional standards provide valuable guidelines for exercise and physical fitness. One example is the *Physical Activity Guidelines for Americans* issued by the [Department of Health and Human Services \(2019\)](#); the department's guidelines provide evidence-based recommendations for adults and youth (ages 3 through 17) to safely get the physical activity they need to stay healthy. Another standard is the American Diabetes Association's position statement on physical activity and exercise for individuals with diabetes ([Colberg et al., 2016](#)).

Your experiences and critical thinking attitude affect the problem-solving approach with patients and are evaluated with each new patient. Remember that some patients have the capacity for recovery in spite of the loss of some physical function. Restoration of function begins early in the care of patients whose ability to perform self-care is disrupted. Encouragement, support, commitment, and perseverance are important critical thinking attitudes to apply for these patients. Problems with activity and mobility are often prolonged; creativity is necessary when designing interventions for improving patients' activity tolerance and mobility skills.

REFLECT NOW

Think about a patient you cared for; what support systems did he or she have? How did the patient use his or her support system in regard to promoting daily physical activity? How can you incorporate the use of a support system in a patient's exercise program?

◆ Nursing Process

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care.

◆ Assessment

An assessment for determining a patient's activity and exercise needs must be comprehensive, considering the patient's physical condition, activity history, socioeconomic resources, and readiness to exercise. You critically analyze assessment findings and also determine a patient's personal goals regarding activity to ensure that you make patient-centered clinical decisions required for safe and effective nursing care. During assessment consider normal physiological changes in growth and development and any deviations to expect based on the patient's health condition. Provide opportunities for patients to observe their posture and obtain important information about other factors that contribute to poor alignment, such as inactivity, fatigue, malnutrition, and psychological problems. During assessment ([Fig. 38.7](#)) also consider all of the critical thinking elements that help you make appropriate nursing diagnoses.

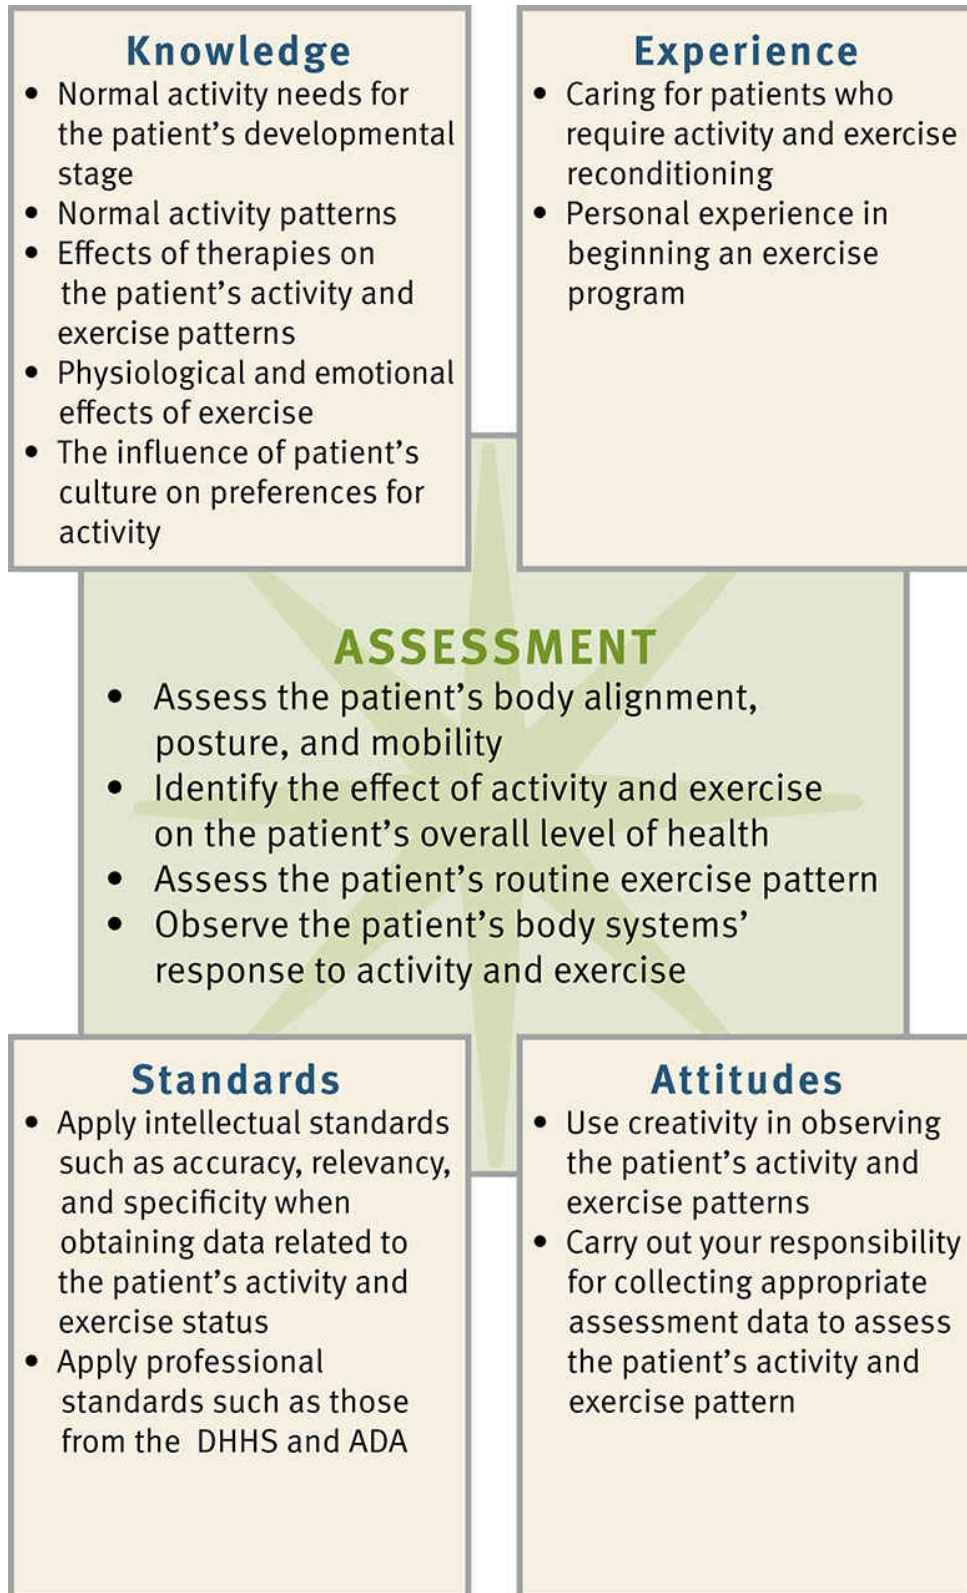

FIG. 38.7 Critical thinking model for activity and exercise assessment. *ADA*, American Diabetes Association; *DHHS*, Department of Health and Human Services.

Through the Patient's Eyes

Your ability to provide patient-centered care requires your patient to be willing and ready to participate in any activity or exercise program you plan. This requires you to assess the patient's expectations, values, and beliefs about how activity and exercise affect his or her health. You will assess the patient's daily activity and exercise routine (Box 38.4), compare with how any illness or injury has changed the routine, and consider the recommendations for exercise made by the patient's health care provider. Discuss with the patient how he or she perceives engaging in activity and exercise at home or in the health care setting. It is also important to assess a patient's perceptions of what is acceptable activity in relationship to any symptoms experienced during exercise. One of the factors affecting physical activity is freedom from pain. When patients experience pain or fatigue following exercise, they often lack commitment to desired interventions. When patients are content with their present physical activity and fitness, they do not perceive a need for improvement.

Box 38.4 Nursing Assessment Questions

Readiness to Exercise

- To what extent do you enjoy exercising? What is your belief in the ability to exercise?

Nature of the Problem

- Tell me about any problems you are having with staying active and exercising regularly.
- How much do you normally exercise each day? Each week?
- Describe the type of exercise you prefer.
- How long do you exercise at any given time?

Signs and Symptoms

- Tell me about any discomfort you have when you exercise (or after exercising).
- Describe for me the pain or shortness of breath that you feel.
- Do you ever feel chest discomfort or pain during exercise or activity?

Onset and Duration

- Tell me when and how your exercise habits have changed since your illness/injury.
- Which activities cause you to become short of breath/have pain?
- How long does it take to resume normal breathing after exercise or an activity?

Severity

- How far do you walk before the pain in your legs begins?
- On a scale of 0 to 10 (10 being the worst discomfort), rate your leg/back pain.
- Do you describe your shortness of breath as minimal, moderate, or severe after activities and/or exercise?

Barriers to Exercise and Activity

- Tell me what prevents you from exercising regularly each day.
- Do you have any health problems (such as asthma, arthritis) that affect your ability to carry out daily activities such as grocery shopping, washing clothes, or daily walking? Do you have any physical limitations that prevent you from exercising on a daily basis?
- Do you have access to a community walking path and exercise equipment?

Patient Values

- Tell me what you believe about how exercise affects your health.

- How confident are you in being able to perform the exercises your doctor has recommended?

Effect on Patient

- How has the lack of an exercise routine affected your weight?
- Do you feel more tired since you have not been able to exercise routinely?

Readiness to Exercise

Perceived self-efficacy is a judgment of capability and applies to a person's willingness to engage in an activity such as exercise. The outcomes people anticipate, such as from an exercise program, depend on their judgments of how well they will be able to perform in given situations (Bandura, 2006). The Transtheoretical Model (TTM), which incorporates the concept of self-efficacy, can be applied for tailoring interventions to patients' readiness to change and can enhance patient progress and help patients use therapeutic resources more effectively (LaMorte, 2018). However, individualizing an intervention depends on your accurate assessment of a patient's stage of change (SOC).

The TTM is a model of intentional change that focuses on the decision making of an individual regarding changing behavior (e.g., starting to exercise, changing a diet, taking medications correctly). The model operates on the assumption that people do not change behaviors quickly and decisively; instead behavioral change occurs continuously through a cyclical process (LaMorte, 2018). An individual will move back and forth through six stages of change:

- Precontemplation—Individuals do not intend to change their behavior in the next 6 months; they are unaware of the problem behavior or are demoralized by unsuccessful previous attempts to change behavior.
- Contemplation—Individuals are aware they need to change their behavior. They intend to take action within the next 6 months but lack commitment to actually start changing.
- Preparation—Individuals have decided to take action in the immediate future, usually measured as the next month. They often

- have a concrete plan of action, such as buying an exercise bike, joining a club, or asking family members to walk with them.
- Action — Individuals have made specific overt changes in their lifestyles within the past 6 months.
 - Maintenance— People have shown the desired behavior for over 6 months and are working to prevent relapse.

Your assessment of the stage that best describes your patient's readiness to exercise will determine how you plan patient care. Begin by asking the patient to what extent he or she enjoys exercising and his or her belief in the ability to exercise. This is a factor positively associated with adult physical activity ([Healthy People 2020, 2019](#)). What is the patient's current activity level? If a patient tells you that he or she does not exercise and does not intend to start in the next 6 months, he is in the precontemplation stage. If the patient has been thinking about exercising or has tried to exercise but does so inconsistently, he or she is likely in the contemplation phase. A patient who describes a plan to exercise after discharge from a hospital or rehabilitation center is in the preparation stage. If the patient reports actively being engaged in exercise weekly and for the past several months, the patient is in the action stage. If your patient has been exercising but is facing new obstacles that affect his or her ability to remain active, he or she is in the maintenance stage. Use your assessment findings related to the patient's readiness for change to select the nursing interventions most likely to complement the stage of change and move the patient toward activity engagement.

Socioeconomic Factors

Assess the patient's socioeconomic resources for being able to engage in an activity or exercise plan. Socioeconomic factors will impact a patient's readiness or ability to exercise. For example, does the patient have access to exercise facilities or public parks and walking areas? What time during a typical day does the patient perceive he or she is able to engage in exercise? How many hours in a day does the patient work? Is there social support available to the patient? Studies have shown a correlation between an individual's educational level, income, and ability to pay for fees/equipment with their level of involvement in physical activity ([O'Donoghue et al., 2018](#))

Physical Health

Assess a patient's physical condition to determine readiness to exercise. This includes status of body alignment, muscle strength and coordination, and integrity of joints and other structures using physical examination techniques (see [Chapter 30](#)). Also review in the medical record for any chronic diseases or conditions that affect a patient's ability to be mobile and active.

Body Alignment

Help a patient feel at ease when assessing body alignment. Your aim is to not have the patient assume an unnatural or rigid position. You will assess a patient's alignment during standing, sitting, and then lying down as a patient is able. The assessment of body alignment has the following objectives:

- Determining normal physiological changes in body alignment resulting from growth and development for each patient
- Identifying deviations in body alignment caused by incorrect posture
- Providing opportunities for patients to observe their posture
- Identifying learning needs of patients for maintaining correct body alignment
- Identifying trauma, muscle damage, or nerve dysfunction
- Obtaining information concerning other factors that contribute to incorrect alignment, such as fatigue, malnutrition, and psychological problems

[Chapter 39](#) describes in detail how to assess patients' alignment while standing, sitting, and lying supine.

Mobility

The adequacy of a patient's mobility affects his or her coordination and balance while walking, the ability to carry out ADLs, and the ability to participate in an exercise program. The assessment of mobility has five components: sitting, standing, range of motion, gait, and exercise.

Sitting

You may incorporate this assessment into your earlier assessment of sitting alignment. Note whether a patient can sit on the side of the bed or in a chair upright. A patient's ability to do so affects his or her ability to

perform self-care activities. When assessing the ability of patients to sit, allow them to use a side rail (when present). Skill 38.2 describes the Banner Mobility Assessment Tool (BMAT), a validated tool that includes a component for assessment of a patient's mobility while sitting (Boynton et al., 2014b).

Standing

Do not rely on a patient's self-report that he or she is able to stand independently without support or assistance. This commonly occurs when nurses rush to admit or transfer patients, allowing patients to offer simply "yes" or "no" responses to an admission form question. When you assess a patient's ability to stand, it is appropriate to have the patient use an assistive device for support (if one is typically used). The BMAT (Boynton et al., 2014b) includes a measure for assessing a patient while standing. A patient should be able to raise the buttocks off the bed and hold for a count of five (Boynton et al., 2014a,b). The ability to achieve this maneuver indicates good mobility and balance, which are needed to safely stand (see Skill 38.2).

Range of Motion

Observing range of motion (ROM) is one of the first assessment techniques used to determine the degree of limitation or injury to a joint. Assess ROM to clarify the extent of joint stiffness, swelling, pain, limited movement, and unequal movement. Chapter 30 covers a thorough ROM assessment. Limited ROM indicates inflammation such as arthritis, fluid in the joint, altered nerve supply, or contractures. Increased mobility (beyond normal) of a joint indicates connective tissue disorders, ligament tears, and possible joint fractures.

Gait

The term *gait* describes a particular manner or style of walking. It is a coordinated action that requires the integration of sensory function, muscle strength, proprioception, balance, and a properly functioning CNS (vestibular system and cerebellum). A gait cycle begins with the heel strike of one leg and continues to the heel strike of the other leg. Assessing a patient's gait allows you to draw conclusions about balance, posture, and the ability to walk without assistance, all of which affect the risk for falling. Here are a few ways to assess a patient's gait:

1. Observe the patient entering the room, and note speed, stride, and balance.
2. Ask the patient to walk across the room, turn, and come back.
3. Ask the patient to walk heel-to-toe in a straight line. This may be difficult for older patients even in the absence of disease, so stay at the patient's side during the walk.

Exercise

During assessment, determine a patient's preferred form of exercise, level of intensity, and frequency of exercise. [Box 38.4](#) provides examples of questions to ask related to a patient's exercise and activity routines and tolerance. Determine whether a patient participates in sufficient physical activity by comparing your findings with the [CDC \(2019b\)](#) recommendations: Adults need at least 2 hours and 30 minutes (150 minutes) of [moderate-intensity aerobic activity](#) (i.e., brisk walking) every week and [muscle-strengthening activities](#) on 2 or more days a week that work all major muscle groups (legs, hips, back, abdomen, chest, shoulders, and arms). The activity can be spread across a week. Your assessment of the patient's activity provides baseline information for both exercise and activity tolerance. In addition, baseline information is beneficial when establishing a patient's exercise and rehabilitation plan following an illness or injury. When a person exercises, physiological changes occur in body systems ([Box 38.5](#)).

Box 38.5 Effects of Exercise

<p>Cardiovascular System</p> <ul style="list-style-type: none"> • Increased cardiac output • Improved myocardial contraction, thereby strengthening cardiac muscle • Decreased resting heart rate • Improved venous return <p>Pulmonary System</p> <ul style="list-style-type: none"> • Increased respiratory rate and depth followed by a quicker return to resting state • Improved alveolar ventilation • Decreased work of breathing • Improved diaphragmatic excursion <p>Metabolic System</p> <ul style="list-style-type: none"> • Increased basal metabolic rate • Increased use of glucose and fatty acids • Increased triglyceride breakdown • Increased gastric motility • Increased production of body heat 	<p>Musculoskeletal System</p> <ul style="list-style-type: none"> • Improved muscle tone • Increased joint mobility • Improved muscle tolerance to physical exercise • Possible increase in muscle mass • Reduced bone loss <p>Activity Tolerance</p> <ul style="list-style-type: none"> • Improved tolerance • Decreased fatigue <p>Psychosocial Factors</p> <ul style="list-style-type: none"> • Improved tolerance to stress • Reports of "feeling better" • Reports of decrease in illness (e.g., colds, influenza)
--	---

Data from McCance KL, Huether SE: *Pathophysiology: the biologic basis for disease in adults and children*, ed 8, St Louis, 2017, Mosby.

During exercise you improve muscle tone, strength, and size and cardiopulmonary conditioning. As a result you are able to exercise longer with each strengthening of the muscles. Exercise also enhances joint mobility because the exercise itself requires movement of body parts.

Activity Tolerance

Activity tolerance is the type and amount of exercise or work that a person is able to perform without undue exertion or injury ([Box 38.6](#)). Observe patients after ambulation, self-bathing, or sitting in a chair for several hours and assess their verbal report of fatigue and weakness. Do they show difficulty breathing or report being short of breath after exercise? Assess heart rate and blood pressure response to activity by comparing with baseline rates at rest. Both heart rate and blood pressure should increase. When you care for a patient who is relatively healthy and able to exercise regularly, assess what he or she sets as a target heart rate during exercise. Use this finding to determine whether the patient has set an adequate target rate for exercise training ([AHA, 2015](#)).

Box 38.6 Factors Influencing Activity Tolerance

Physiological Factors <ul style="list-style-type: none">• Skeletal abnormalities• Muscular impairments• Endocrine or metabolic illnesses (e.g., diabetes mellitus, thyroid disease)• Hypoxemia• Decreased cardiac function• Decreased endurance• Impaired physical stability• Pain• Sleep pattern disturbance• Prior exercise patterns• Infectious processes and fever	Emotional Factors <ul style="list-style-type: none">• Anxiety• Depression• Chemical addictions• Motivation Developmental Factors <ul style="list-style-type: none">• Age• Sex Pregnancy <ul style="list-style-type: none">• Physical growth and development of muscle and skeletal support
---	---

Modified from Lewis SL, et al: *Medical-surgical nursing assessment and management of clinical problems*, ed 10, St Louis, 2017, Mosby.

REFLECT NOW

Think about a patient you have cared for who is usually physically active but has been acutely ill. What questions could you ask to assess the patient's current level of physical activity tolerance? What physical assessments would you also measure?

Nursing Diagnosis

A comprehensive patient assessment provides clusters of assessment findings to support a nursing diagnosis. Accuracy is essential when selecting a nursing diagnosis. For example, you consider nursing diagnoses of *Activity Intolerance* or *Fatigue* in a patient who reports being tired and weak. Further review of assessment data (e.g., abnormal heart rate and verbal report of weakness) leads to a definitive diagnosis (*Activity Intolerance*).

When patients have problems with activity and exercise, nursing diagnoses often focus on the ability to move. In the case of negative or problem-focused nursing diagnoses the related factors direct nursing interventions. This requires the correct selection of the related factors. For example, *Activity Intolerance related to excess weight gain* requires very different interventions than if the related factor is prolonged bed rest. [Box 38.7](#) provides an example of how the diagnostic process leads to accurate diagnosis selection. The following are examples of nursing diagnoses related to activity and exercise:

Box 38.7 Nursing Diagnostic Process Impaired Mobility

Assessment Activities	Assessment Findings
Observe patient's gait.	Shuffled gait Uncoordinated gait Patient report of slower walking speed
Observe patient performing tasks such as feeding, dressing, or recreational activities.	Uncoordinated movements Limited fine-motor coordination
Measure range of joint motion.	Reduced joint motion in lower and/or upper extremities Stiffness in joints
Measure patient's strength.	Has difficulty rising to sitting position or exiting bed

- *Activity Intolerance*
- *Risk for Injury*
- *Impaired Mobility in Bed*
- *Impaired Mobility*
- *Acute or Chronic Pain*

• Planning

During planning synthesize information from multiple resources and involve the patient in decision making (Fig. 38.8). Critical thinking ensures that the patient's plan of care integrates all patient information and is patient centered. Professional standards are especially important to develop a plan that is evidence based. These standards often establish scientifically proven guidelines for selecting effective nursing interventions.

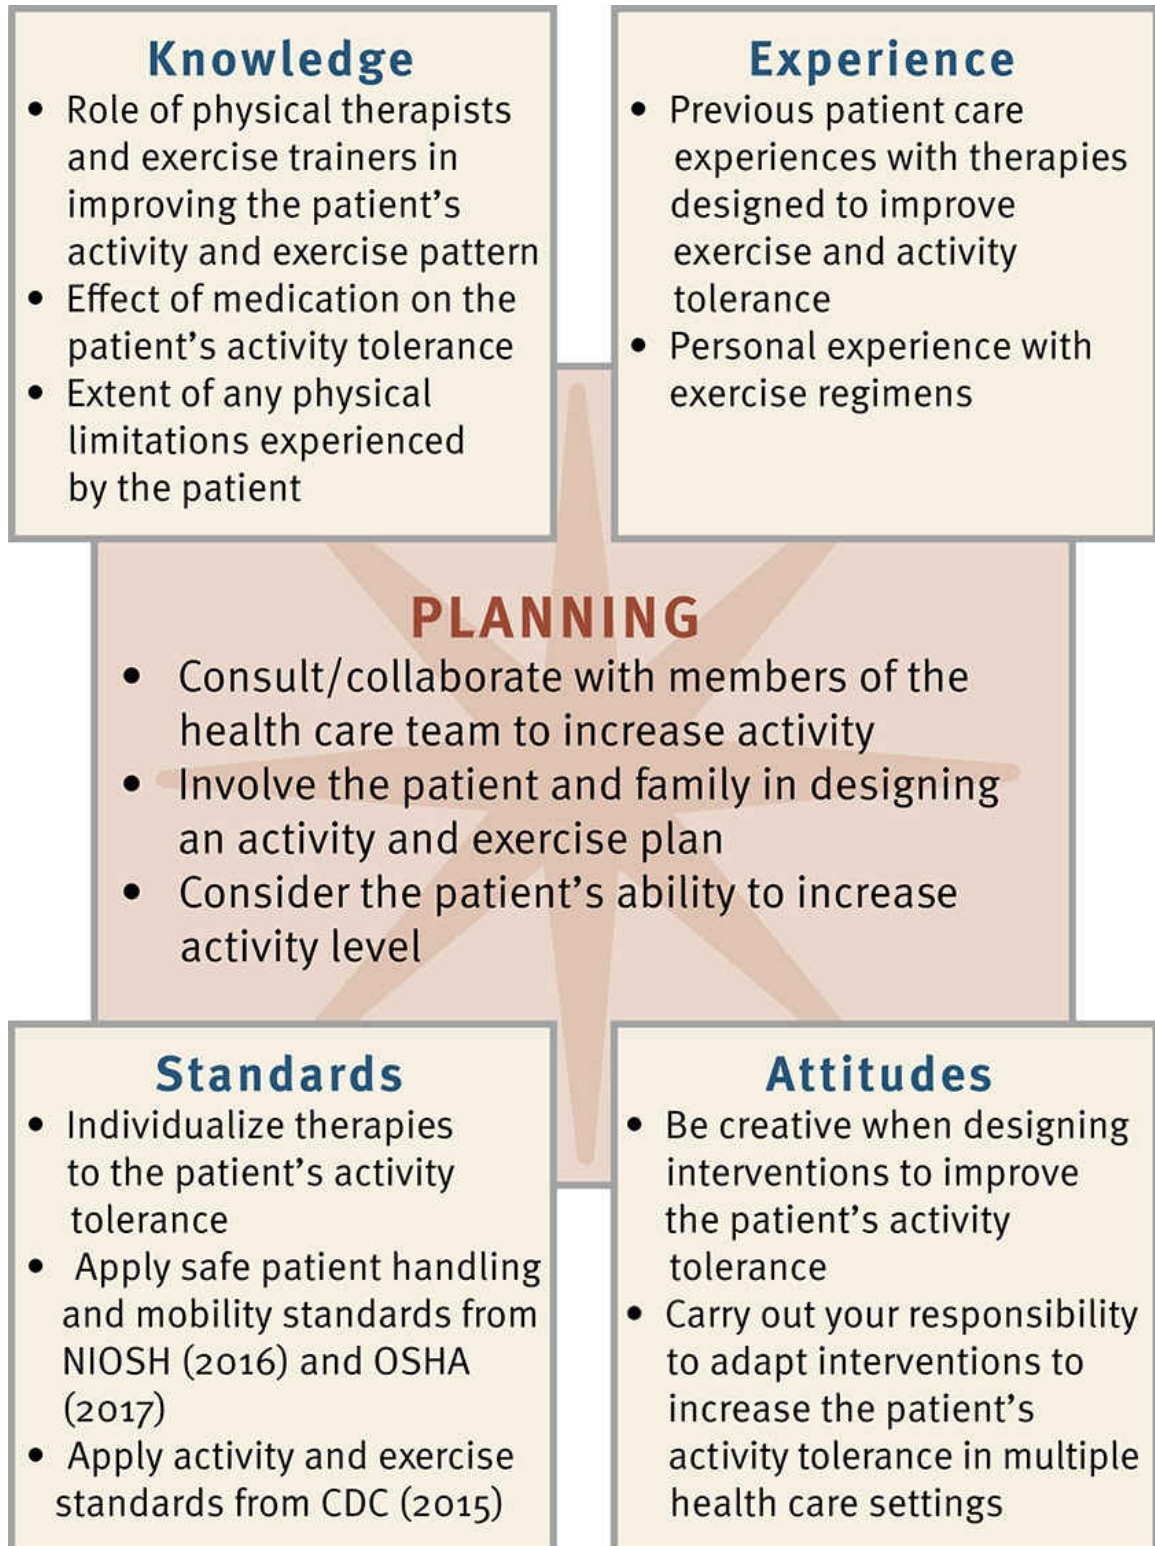

FIG. 38.8 Critical thinking model for activity and exercise planning. *CDC*, Centers for Disease Control and Prevention; *NIOSH*, National Institute for Occupational Safety and Health; *OSHA*, Occupational Safety and Health Administration.

A concept map is a tool to assist in the planning of care. It shows the relationship between multiple nursing diagnoses and planned interventions. Fig. 38.9 shows the relationship between a patient’s medical diagnosis of heart failure and the identified nursing diagnoses and related nursing interventions.

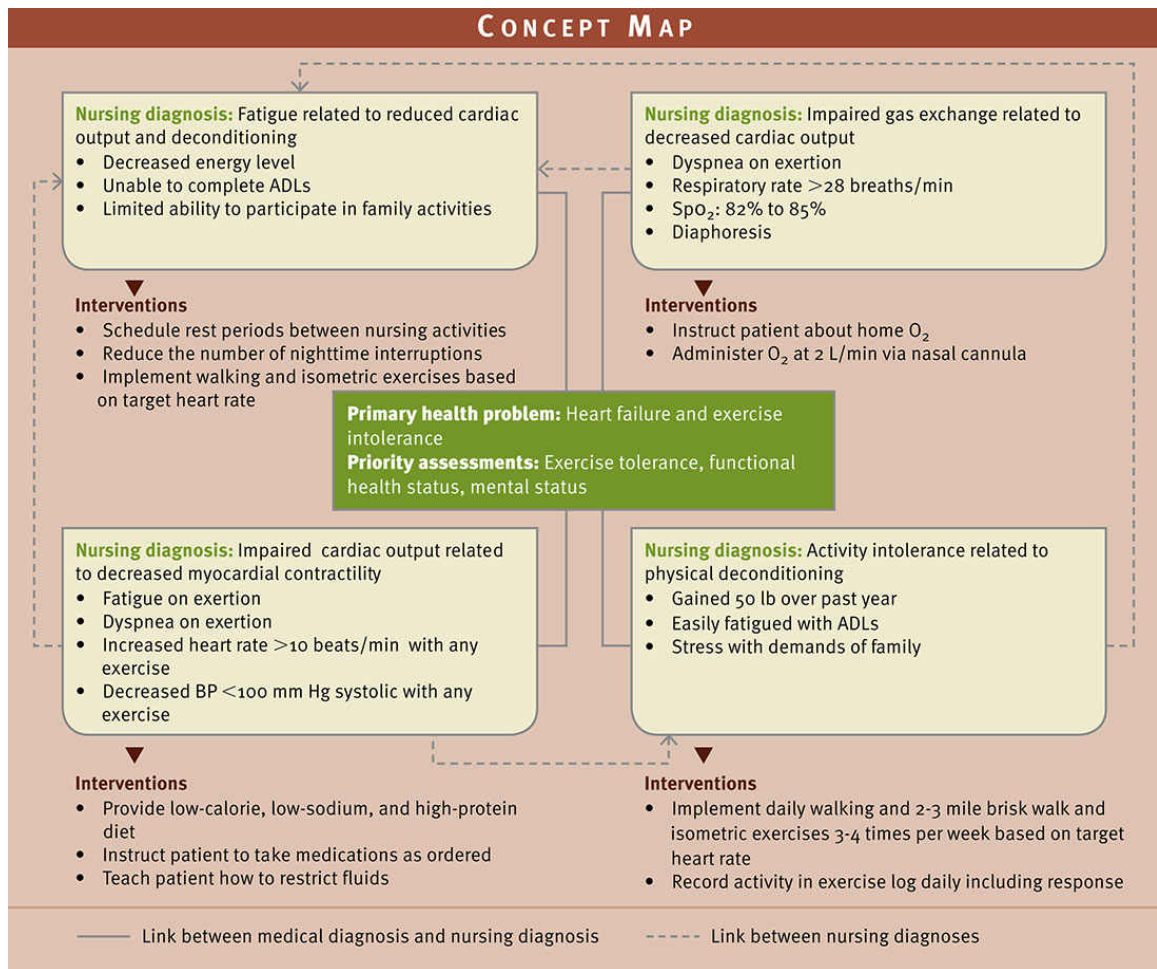

FIG. 38.9 Concept map for Mrs. Smith. *ADLs*, Activities of daily living; *BP*, blood pressure.

Goals and Outcomes

After identifying appropriate nursing diagnoses, you and the patient set goals and expected outcomes to direct interventions. If a goal involves the improvement in a patient’s level of activity, integrating the patient’s goal is critical to ensure adherence. The plan also includes consideration of any risks for injury to the patient and preexisting health concerns. It is

important to have knowledge of the patient's home environment when planning therapies to maintain or improve activity, body alignment, and mobility. Include the patient's family and/or caregiver in the care plan unless the patient prefers no family involvement. Family caregivers play critical roles in the home environment, motivating and coaching patients to stay active. Developing a structured plan for regular exercise has been shown to be beneficial in improving adherence. (McArthur et al., 2014). The general goal related to exercise and activity is to improve or maintain the patient's motor function and independence. The following are examples of outcomes for patients with deficits in activity and exercise:

- Participates in prescribed physical activity while maintaining appropriate heart rate, blood pressure, and breathing rate
- Verbalizes an understanding of the need to gradually increase activity on the basis of tolerance and symptoms
- Explains reason physical condition requires balancing rest and activity

Setting Priorities

Care planning is patient centered, taking into consideration the patient's most immediate needs and preferences. For example, is a patient comfortable enough to participate in exercise, or does the acute occurrence of symptoms require you to delay an exercise session? You determine the immediacy urgency of any problem by its effect on the patient's mental and physical health. Because of the many skills associated with the care of patients who have the diagnoses of *Activity Intolerance* and/or *Impaired Mobility*, such as turning, transferring, and positioning, it is easy to overlook the complications associated with these health alterations. Therefore be vigilant in monitoring the patient and supervising assistive personnel in carrying out activities to prevent complications and potential injury.

Teamwork and Collaboration

Planning involves understanding the resources needed to maintain a patient's function and independence. For example, it is important to collaborate with health care providers and physical and occupational therapists. Health care providers will prescribe physical and occupational therapy as needed and note any limits or guidelines for activity levels. Physical therapists are best equipped to identify the specific exercises that

patients should perform. Occupational therapists assist patients with adaptive devices and techniques to perform ADLs while improving mobility. Sometimes long-term rehabilitation is also necessary. Discharge planning begins when a patient enters the health care system and involves identifying his or her expectations regarding physical activity, readiness to exercise, and what is planned by the health care team. In addition, always individualize a plan of care directed at meeting the actual or potential needs of the patient (see the [Nursing Care Plan](#)).

• Implementation

Health Promotion

A sedentary lifestyle contributes to the development of many health-related problems. The US Department of Health and Human Services (USDHHS) has developed guidelines recognizing that physical activity is key to improving the health of the nation. The report called *Physical Activity Guidelines for Americans* is based on the latest scientific evidence and is an essential resource for health professionals who make recommendations for how individuals can improve their health through regular physical activity ([USDHHS, 2019](#)). There are guidelines for all age-groups, including children, adolescents, adults, older adults, and pregnant women ([Box 38.8](#)).

Box 38.8 Physical Activity Guidelines for Americans

Adults

- Move more and sit less throughout the day. Some physical activity is better than none. Adults who sit less and do any amount of moderate-to-vigorous physical activity gain some health benefits.
- For substantial health benefits, adults should do at least 150 minutes (2 hours and 30 minutes) to 300 minutes (5 hours) a week of moderate-intensity, or 75 minutes (1 hour and 15 minutes) to 150 minutes (2 hours and 30 minutes) a week of vigorous-intensity aerobic physical activity, or an equivalent combination of moderate- and vigorous-intensity aerobic activity. Preferably, aerobic activity should be spread throughout the week.

- Additional health benefits are gained by engaging in physical activity beyond the equivalent of 300 minutes (5 hours) of moderate-intensity physical activity a week.
- Adults should also do muscle-strengthening activities of moderate or greater intensity and that involve all major muscle groups on 2 or more days a week, as these activities provide additional health benefits.

Older Adults

Key guidelines for adults also apply. In addition, the following key guidelines apply to older adults:

- As part of weekly physical activity, older adults should do multicomponent physical activity that includes balance training as well as aerobic and muscle-strengthening activities.
- Older adults should determine their level of effort for physical activity relative to their level of fitness (e.g., knowing target heart rate).
- Older adults with chronic conditions should understand whether and how their conditions affect their ability to do regular physical activity safely.
- When older adults cannot do 150 minutes of moderate-intensity aerobic activity a week because of chronic conditions, they should be as physically active as their abilities and conditions allow.

From US Department of Health and Human Services: *Physical activity guidelines for Americans*, ed 2, 2018. https://health.gov/paguidelines/second-edition/pdf/Physical_Activity_Guidelines_2nd_edition.pdf. Accessed May 2, 2019.

A nurse practicing in a primary care or community setting has a responsibility for partnering with patients to find ways to help them improve their physical activity. For example, community health nurses may work with local governments to find ways to improve access to recreational areas (e.g. parks, walking paths) in a town or city. Participating in health fairs or community walks is a way for nurses to be visible to the community and share information about physical activity with residents.

In primary care a patient-centered approach ensures that individuals set goals for activity that allow them to achieve the benefits they value (USDHHS, 2019). This patient-centered approach helps ensure that an exercise program is relevant and suited to patient preferences and resources (Box 38.9). In setting activity goals, people can consider doing a variety of activities that are both indoor and outdoor. For example, a brisk walk in the neighborhood with friends for 45 minutes on 3 days a week and walking to lunch twice a week may be appropriate for someone who wants to increase both physical activity and socializing (USDHHS, 2019). Patients who love gardening might plan regular yard work as part of their aerobic activity. Take a holistic approach to develop and implement a plan that enhances the patient's overall physical fitness.

Box 38.9 Procedural Guidelines **Helping Patients to Exercise**

Delegation and Collaboration

- The skill of promoting early activity and exercise in the outpatient setting regarding activity and exercise education cannot be delegated.

Equipment

Weights, resistance bands (optional based on physical therapy recommendations)

Steps

1. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy.
2. Measure patient's baseline heart rate or have patient/family caregiver do measurement. *Provides baseline for activity tolerance.*
3. Identify patient's activity/exercise history:
 - Which type of regular daily exercise do you perform at home?
 - Do you exercise or play a sport at least 3 times a week?
 - On a scale of 0 to 5 with 0 being no daily exercise and 5 strenuous regular daily exercise, how would you rate

yourself?

- How long have you been exercising regularly?
4. Ask patient to what extent he or she enjoys exercising and what his or her beliefs are about the ability to exercise. Does the patient prefer indoor or outdoor activities?
 5. Determine whether patient has social support from peers, family, or spouse.
 6. Determine whether patient has access to a fitness center or other area to exercise. Is the neighborhood considered safe?
 7. Consider these factors in your assessment: patient's age, income level, time available to exercise, rural resident, overweight, being disabled. *Factors negatively associated with adult participation in activity* (Healthy People 2020, 2019)
 8. Have patient rate level of quality of life based on current activity level.
 9. Initiate an outpatient exercise program that contains any of the following components:
 - Warm-up (5-10 minutes) — *directs needed blood flow to muscles and prepares body for exercise, helping to prevent injury*
 - Strengthening exercises
 - Endurance exercises
 - Balance exercises
 - Flexibility exercises — *lessen tightness of muscles and improve joint ROM*
 - Cool-down exercises (5-10 minutes) — *help body recover from exercises*

Consult with physical therapy to help develop complete exercise program that fits needs of your patient. A good resource is:
<http://health.gov/paguidelines/guidelines>.

10. Recommend strength training for adults to improve strength and bone density in collaboration with physical therapy.
11. Recommend aerobic exercise (see Box 38.8). The US Department of Health and Human Services (2019) recommends aerobic exercises to include moderate and vigorous activities (e.g., climbing stairs; playing sports; or walking, jogging, swimming, or biking). Activities such as dancing, yoga, and yard work are beneficial to older adults who prefer what they perceive as less rigorous forms of exercise.

12. Recommend balance exercises for older adults to decrease risk of falls. Have patient be sure to have something sturdy nearby on which to hold (wall or chair) if he or she becomes unsteady. Perform exercises: standing on one foot, walking heel to toe, balance walking, back leg raises, side leg raises. Have patient do strength exercises (back leg raises, side leg raises) 2 or more days per week, but not on any 2 days in a row (NIH, n.d.).
13. Recommend that the patient perform a cool-down (5 to 10 minutes) after exercising: quadriceps stretch; hamstring/calf stretch; chest and arm stretch; neck, upper back, and shoulder stretch.
14. Measure heart rate during and after exercise. Compare with baseline. Stop physical activity when:
 - Heart rate (HR) is above targeted heart rate OR
 - HR is more than a 20% decrease from resting value OR
 - HR is less than 40 beats/min
15. **Use Teach-Back:** “We’ve talked about doing a warm-up and cool-down as part of your exercise plan. Tell me why each is important.” Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly.
16. Document in outpatient record the exercises recommended. Document patient response if you witness patient exercising.

Before starting an exercise program, be sure the patient’s health care provider has cleared him or her for regular activity. Then teach patients how to calculate their maximum heart rate:

- First subtract the patient’s current age in years from 220.
- Then have the patient calculate his or her target heart rate by taking 60% to 90% of the maximum.

The patient’s health care provider should recommend a maximum, or when working with patients, start on the low end and steadily increase the target as exercise tolerance improves.

No matter which exercise prescription is implemented for the patient, warm-up and cool-down periods need to be included in the program (Edelman and Kudzma, 2018). The warm-up period usually lasts about 5 to 10 minutes and frequently includes stretching, calisthenics, and/or the aerobic activity performed at a lower intensity. It prepares the body and decreases the potential for injury. The cool-down period follows the

exercise routine and usually lasts about 5 to 10 minutes. It allows the body to readjust gradually to baseline

Nursing Care Plan

Activity Intolerance

Assessment

Mrs. Smith is a 52-year-old housewife. She is overweight and recently was diagnosed with adult-onset diabetes. During a visit to her primary care provider, she tells the nurse practitioner that she always feels tired. Mrs. Smith also has a history of mild heart failure, treated with medication. She expresses feelings of stress caused by excessive demands on her time at work. The nurse practitioner wants to assist her in developing an exercise plan she is likely to adhere to.

Assessment Activities	Assessment Findings ^a
Ask Mrs. Smith her views about participating in regular activity and exercise.	She responds, "I gained 30 lb over the past year. I become easily fatigued , and sometimes when I get home, I don't have the energy to finish my household chores. I used to like to exercise, but now I don't even want to leave the house anymore. I know I have to get healthier, and it's time to do something about it."
Ask Mrs. Smith about her routine exercise habits.	She responds, "I once exercised about 4 days a week, walking in the park just down from my house. About 10 years ago I enjoyed swimming with friends at the Y. But with the recent demands of work, having to do overtime a lot, I have not walked for 2 months. Have not swum in years. I have not felt like walking like I used to. I feel pulled in every direction; that increases my stress , and then I want to eat, eat, and eat!"
Perform baseline assessment.	Age: 52 years Weight: 225 lb (102 kg) Blood pressure: 152/90 mm Hg (at rest) Pulse: 88 beats/min (at rest) Breathing rate: 28 breaths/min (at rest) Blood pressure: 164/96 mm Hg (after climbing 10 steps) Pulse: 120 beats/min (after climbing 10 steps) Breathing rate: 36 breaths/min (after climbing 10 steps) with self-reported shortness of breath

^a Assessment findings are shown in bold type.

Nursing Diagnosis:

Activity intolerance related to inactivity and reduced cardiovascular fitness

Planning

Goals	Expected Outcomes (NOC) ^b
	Activity Tolerance
Mrs. Smith will achieve a planned moderate-activity exercise program weekly.	Mrs. Smith performs an exercise plan that includes 150 minutes weekly of walking and swimming combined.
Mrs. Smith will achieve a 30-lb weight loss in 6 months.	Mrs. Smith will follow a DASH diet eating plan of 2000 calories a day.
Mrs. Smith's activity tolerance will improve above baseline within 2 months.	Mrs. Smith will achieve target heart rate of 60% of maximum heart rate (168 beats per min) after 20 min walking – 100 beats/min. Mrs. Smith will self-report a reduced sense of shortness of breath following walking at 1 month.

^b Outcome classification labels from Moorhead S, et al., editors: *Nursing Outcomes Classification (NOC)*, ed 6, St Louis, 2018, Elsevier.

Interventions (Nic) ^c	Rationale
Exercise Promotion	
Base Mrs. Smith's instruction about beginning an exercise program on her contemplation phase of readiness. Discuss the physiological benefits of how regular exercise can improve her quality of life.	Regular exercise and physical activity are associated with a significantly lower CVD risk. Long-term studies have shown that increased physical activity is associated with a reduction in all-cause mortality and may modestly increase life expectancy (Nystoriak et al., 2018).
Develop a progressive exercise plan: Start with warm-up exercises for 3-5 minutes before walking, and perform cool-down exercises for 3-5 minutes after walking. Begin walking 20 minutes in neighborhood 2 times a week over the next 2 weeks; then 20 minutes 3-4 times a week in the third and fourth weeks, increasing to 30 minutes, 4 times each week. Have Mrs. Smith plan a weekly swimming session at the neighborhood Y.	There is a relationship between greater amounts of physical activity and attenuated weight gain in adults, with some evidence to support that this relationship is most pronounced when physical activity exposure is above 150 minutes per week (Office of Disease Prevention and Health Promotion, 2018).

Table Continued

Interventions (Nic) ^c	Rationale
Design a DASH eating plan that incorporates the patient's daily meal pattern with food preferences in the following groups: • Fresh vegetables, fruits, and whole grains • Fat-free or low-fat dairy products, fish, poultry, beans, nuts, and vegetable oils • Limiting foods that are high in saturated fat • Limiting sugar-sweetened beverages and sweets	DASH is a flexible and balanced eating plan recommended by the National Heart, Lung, and Blood Institute (n.d.a.) It helps create a heart-healthy eating style for life, combining it with other lifestyle changes, such as physical activity, to gain control of blood pressure and LDL-cholesterol levels.
Schedule routine visits/phone calls with Mrs. Smith for follow-up and review of exercise and dietary log, progress, and barriers.	Patients are more likely to increase physical activity and adhere to an exercise program if they are counseled by a health care professional (Edelman and Kudzma, 2018).

^c Intervention classification labels from Butcher HK, et al., editors: *Interventions Classification (NIC)*, ed 7, St Louis, 2018, Elsevier.

Evaluation

Evaluation Activity	Patient Response/Finding	Outcome Status
Review patient's exercise log.	Patient walked 20 minutes twice the first and second weeks, 20 minutes three times the next week. Went swimming once.	Participation in exercise plan is increasing; achieved 40 to 60 minutes weekly exercise.
Review dietary log and record weight, blood pressure, and pulse.	Weight after 3 weeks, 210 lb; resting heart rate remains between 85 to 90 beats/min; 110 beats/min after walking; blood pressure, 146/86 mm Hg.	15-lb weight loss achieved. Improved exercise tolerance: Resting heart rate is within normal range. Achieved targeted heart rate after walking Blood pressure is lower but not at expected range. Monitor blood pressure as patient continues to lose weight.
Ask Mrs. Smith if she feels short of breath during walking or swimming.	"That first week or so of walking I felt some shortness of breath. I feel it less so now."	Activity tolerance improved with exercise.

functioning and provides an opportunity to combine movement such as stretching with relaxation-enhancing mind-body awareness. When caring for older adults, special considerations are needed to adapt an exercise plan that ensures patient safety (Box 38.10).

Box 38.10 Focus on Older AdultsSpecial

Considerations for Older Adults in Initiating and Maintaining an Exercise Program

- Encourage older adults to avoid prolonged sitting and get up and stretch. Frequent stretching decreases the risk of developing joint contractures.
- Be sure that the older patient maintains proper body alignment when sitting to minimize joint and muscle stress.
- Teach patients how to use stronger joints or larger muscle groups. Efficient distribution of the workload decreases joint stress and pain.
- Provide resources for planned exercise programs. Weight-bearing exercise, such as tai chi, walking, hiking, jogging, climbing stairs, playing tennis, and dancing, and resistance exercises, such as lifting weights, strengthen bones (NIH, 2018).
- Recommend resistance- and agility-training programs. These forms of exercise reduce fear of falling and increase sense of well-being in older adults (Kwun et al., 2012).
- Have older adults avoid high-impact programs that can lead to bone fractures (NIH, 2018).
- Teach older adults that it is never too late to begin an exercise program (Edelman and Kudzma, 2018). Consult a health care provider before beginning an exercise program, particularly in the presence of heart or lung disease and other chronic illnesses.
- Use assessment data and consult with physical therapy to determine when you need to adjust exercise programs for those in advanced age.
- Encourage older adults who are unable to participate in a formal exercise program to improve joint mobility and enhance circulation by simply stretching and exaggerating movements during the performance of routine activities of daily living.

Building Competency in Quality Improvement

To assess individualized improvement in a patient's tolerance to activity, you need to use quality measures to understand a patient's performance. Determine the optimal cardiopulmonary response(s) to exercise for a patient who is 45 years old and whose health care provider set a desired 80% of maximum heart rate as a target.

Many patients find it difficult to incorporate an exercise program into their daily lives because of time constraints or lack of resources (e.g., no open parks or walking paths). For these patients it is beneficial to reinforce that they can use ADLs (e.g., gardening, climbing stairs when doing laundry) to accumulate the recommended 30 minutes or more per day of moderate-intensity physical activity. Other patients benefit from a prescribed exercise and physical fitness program carefully designed to meet their own goals and expectations. A patient-centered exercise program will include a combination of aerobic exercises, stretching and flexibility exercises, and resistance training suited to a patient's home or community environment. Cross-training is recommended for the patient who prefers to exercise every day. For example, the patient runs one day and does yoga the next day.

Stretching and flexibility exercises include active ROM and stretching of all muscle groups and joints. This form of exercise is ideal for warm-up and cool-down periods. Benefits include increased flexibility, improved circulation and posture, and an opportunity for relaxation.

Resistance training increases muscle strength and endurance and is associated with improved performance of ADLs and avoidance of injuries and disability. Formal resistance training includes weight training; but patients can obtain the same benefits by performing ADLs such as pushing a vacuum cleaner, raking leaves, or shoveling snow. Some patients use weight training to bulk up their muscles for the purpose of developing tone and strength and to stimulate and maintain healthy bone.

Acute Care

Because patients in acute care are at risk for deconditioning, the encouragement of early ambulation and performing exercises that involve stretching and active ROM is important. The level of exercise allowed will depend on the patient's physical condition. Physical therapists will collaborate on an exercise plan, including progressive walking, walking with assist devices, and isometric exercises. If needed, provide patients ordered analgesics for pain 30 minutes before exercise. Do not administer an analgesic that makes the patient feel dizzy.

Early Mobility

Recently concerted efforts have been made in hospitals to increase inpatients' activity and mobility levels as soon as possible to prevent deconditioning and other complications of immobilization (see Skill 38.1). The [American Association of Critical Care Nurses \(AACN\) \(2013\)](#) has developed an early progressive mobility protocol for critical care patients (see agency policy) and similar protocols are being developed for orthopedic ([King, 2012](#)), neurosurgery ([Walia et al., 2018](#)), and general surgery patients. Use of the protocols has improved patient outcomes ([Box 38.11](#)). When patients are transferred out to general nursing units, early mobility protocols should continue. This is often a challenge because staff nurses on general units often have difficulty routinely ambulating patients because of overall patient care demands, access to equipment, or unfamiliarity with transfer skills. Some hospitals have designated special mobility teams or mobility assistants to engage patients in early ambulation and activity. Typical early mobility protocols include specific assessment parameters for each level of mobility, with patients progressing from passive and active assistive ROM exercises to sitting on side of bed, transferring and sitting in a chair, and progressive ambulation ([AACN, 2013](#)).

Box 38.11 Evidence-Based Practice Benefits of Early Mobility Protocols

PICOT Question: Do acutely ill hospitalized patients have improved clinical outcomes after participating in early mobility protocols compared with standard postoperative recovery routines?

Evidence Summary

Early mobilization is a complex intervention that requires careful patient assessment and management, as well as interprofessional team cooperation ([Hodgson et al., 2018](#)). However, the reported benefits of early mobilization include reduced ICU-acquired weakness, improved functional recovery within the hospital, improved walking distance at hospital discharge, and reduced length of hospital stay ([Hashem et al., 2016](#); [Tipping et al., 2017](#)). Outcomes vary depending on patient factors such as physiological instability (hemodynamic, respiratory, neurological), sedation, delirium/agitation, psychological state, and pain ([Hodgson et al., 2018](#)). Care team factors can also create barriers to early

mobility intervention, including poor work culture, lack of communication, lack of leadership, disengaged team members, and inexperienced staff (Hodgson et al., 2018). Research has shown that unit culture, rather than patient-related factors, may be the main barrier to early mobilization in ICUs (Hodgson et al., 2015).

Application to Nursing Practice

- Having a dedicated mobility team with strong unit leadership facilitates protocol implementation (Hodgson et al., 2018).
- Interprofessional team planning with team meetings and daily goal setting is essential.
- Be knowledgeable of a patient's current condition and the clinical parameters set for early mobility to begin or proceed, and carefully assess patient response to activity.
- The presence of invasive intravenous lines, endotracheal intubation, and feeding tubes do not contraindicate early mobility (Hashem et al., 2016).

Isometric Exercises

Isometric exercises are prescribed for patients who do not tolerate increased activity ([Chapter 39](#)). A physical therapist will typically collaborate with the patient's health care provider in selecting isometric exercises most beneficial for a patient. As a nurse, your role is to support patients in knowing how the exercises are to be performed correctly so that you can observe for any problems or difficulties. For example, an exercise program that includes isometric exercises of the biceps and triceps will prepare a patient for crutch walking. Instruct the patient to stop the activity if pain, fatigue, or discomfort is experienced. Review the patient's chart and collaborate with physical therapy and the health care provider if any clinical changes develop (e.g., increased blood pressure, heart irregularity) that might contraindicate isometric exercise.

During isometrics, a patient tightens or contracts a muscle group for 10 seconds and then completely relaxes for several seconds ([Resnick et al., 2012](#)). Repetitions are increased gradually for each muscle group until the isometric exercise is repeated 8 to 10 times. Instruct patients to perform the exercises slowly and to increase repetitions as their physical condition improves. A patient needs to do isometric exercise for quadriceps and

gluteal muscle groups, which are used for walking, 4 times a day until the patient is ambulatory.

Range of Motion Exercise

The easiest intervention to maintain or improve joint mobility for patients and one that can be coordinated with other activities is the use of ROM exercises (see [Chapter 39](#)). There are three types of range of motion exercise: active, active assisted, and passive. In active range of motion (AROM) exercises patients move specific joints independently based on their muscular weakness and the type of activity that needs strengthening. The exercise moves the joint and soft tissues through the available physiological ranges of motion. AROM exercises are used when a patient is able to voluntarily contract, control, and coordinate a movement when such a movement is not contraindicated ([Dutton, 2014](#)). As a nurse you should know the contraindications to AROM, including a healing fracture site, a healing surgical site, severe and acute soft tissue trauma, and cardiopulmonary dysfunction ([Dutton, 2014](#)). [Chapter 39](#) discusses active assisted and passive ROM exercises.

Walking

Walking increases joint mobility and can be measured by length of time or distance walked, such as down a hospital hallway or actual number of feet walked. Measure distances walked in estimated feet or yards instead of charting “ambulated to nurses’ station and back.” Some hospital or rehab units will have markers along floorboards designating distances. Illness or trauma usually reduces activity tolerance, resulting in the need for help with walking or the use of assistive devices such as crutches, canes, or walkers. Patients who increase their walking distance before discharge improve their ability to independently perform basic ADLs, increase activity tolerance, and have a faster recovery after surgery ([AAN, 2015](#); [Walia et al., 2018](#)).

Helping a Patient Walk

Helping a patient walk requires preparation. Assess the patient’s strength, coordination, baseline vital signs, and balance to determine the type of assistance needed. Also assess his or her orientation and determine whether there are any signs of distress. Postpone walking if you determine that the patient cannot walk safely. Evaluate the environment for safety before ambulation (e.g., removal of obstacles, a clean and dry floor, and

the identification of rest points in case the patient's activity tolerance becomes less than expected or if the patient becomes dizzy). Also have the patient wear supportive, nonskid shoes.

Help the patient to a position of sitting at the side of the bed and dangling the legs over the side of the bed for 1 to 2 minutes before standing. Some patients experience orthostatic hypotension (i.e., a drop in systolic pressure by at least 20 mm Hg or a drop in diastolic pressure by at least 10 mm Hg within 3 minutes of rising to an upright position (Shibao et al., 2013; Fedorowski and Melander, 2013). Those at higher risk are patients who are immobilized, patients who are on prolonged bed rest, older adults, and patients with chronic illnesses such as diabetes mellitus and cardiovascular disease. Signs and symptoms of orthostatic hypotension include dizziness, light-headedness, nausea, tachycardia, pallor, and even fainting. Orthostatic hypotension usually stabilizes quickly, but if the patient develops dizziness lasting 60 seconds, return the patient to bed (Myszanski, 2014). Dangling a patient's legs before standing is an intermediate step that allows assessment of the patient before changing positions to maintain safety and prevent injury to the patient. In some instances you need to take the patient's blood pressure while he or she is sitting on the side of the bed.

Several methods are used to help a patient ambulate. For those who can bear weight easily provide support at the waist with a gait belt so that the patient's center of gravity remains midline. The belt helps you to stabilize patients if they lose their balance. A gait belt is *not* to be used in *lifting* or *carrying a patient by the waist*. A gait belt encircles a patient's waist below the belly button, snugly, being sure two fingers fit between the belt and patient's body. Don't place a gait belt over incisions, stitches, tubes, or intravenous lines, and never use one on a pregnant patient. When using a gait belt, hold the gait belt behind the patient, with your palms facing up, but avoid trying to lift or catch patients by mistake, causing you a back injury. If the person is unable to walk under his or her own power or has too high a risk of falls, something more protective than a gait belt should be utilized (i.e., motorized sit-to-stand lift, ceiling lift with ambulation sling, or a nonpowered stand-raise aide with ambulation capacity).

If the patient has a fainting (syncope) episode or begins to fall, your natural instinct will be to support or catch the patient. Trying to stop or minimize a fall can cause you injury. However, an approach used by physical therapists involves assuming a wide base of support with one foot in front of the other, thus supporting the patient's body weight (Fig. 38.10A). While holding the gait belt, try to extend one leg, let the patient

slide against the leg, and gently lower him or her to the floor, protecting the head (Fig. 38.10BC). Use caution to prevent your own injury, especially if the patient is overweight. When the patient attempts to ambulate again, proceed more slowly, monitoring for reports of dizziness; take the patient's blood pressure before, during, and after ambulation. The key to preventing staff injuries is to focus on reducing the number of preventable patient falls and falls with injury through accurate patient assessments and the use of proper equipment.

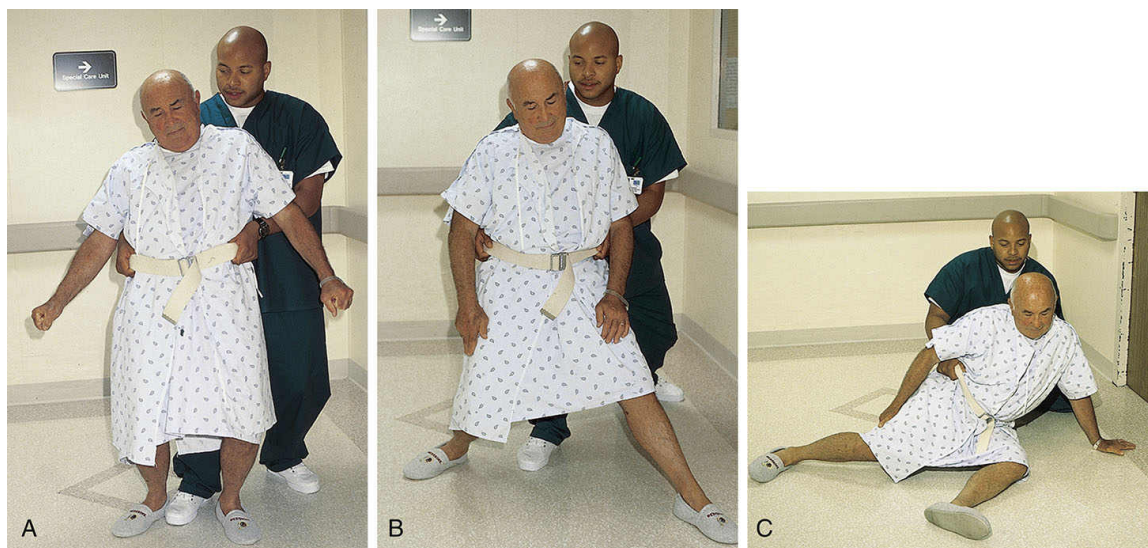

FIG. 38.10 **A**, Stand with feet apart to provide a broad base of support. **B**, Extend one leg and let patient slide against it to the floor. **C**, Bend knees to lower body as patient slides to the floor.

Restorative and Continuing Care

Restorative and continuing care involves implementing activity and exercise strategies to help the patient with ADLs after acute care is no longer needed. Restorative and continuing care also includes activities and exercises that restore and promote optimal functioning in patients with specific chronic illnesses such as coronary heart disease (CHD), hypertension, COPD, and diabetes mellitus.

Assistive Devices for Walking

In collaboration with other health care professionals such as physical therapists, promote activity and exercise by teaching the proper use of canes, walkers, or crutches, depending on the assistive device most

appropriate for the patient's condition. Assist devices are recommended for patients unable to bear full weight on one or more joints of the lower extremities. Other indications for use are instability, poor balance, or pain in weight-bearing. An assist device can reduce the risk of fall, decrease pain with mobility, and improve balance (Touhy and Jett, 2018). However, the devices can also be a risk factor for falling if used incorrectly. You will collaborate with a physical therapist in selecting the proper device for a patient (Table 38.3).

TABLE 38.3**Types of Assist Devices**

Type of Device	Features	Measurement
<p>Canes: lightweight, easily movable devices approximately waist high, made of wood or metal. Two types: single straight-legged and quad (see Fig. 38.12).</p>	<p>Straight canes provide support and balance for patients who have mild balance or strength impairments. Quad canes are often used for patients who have unilateral weakness from a neurological event/disease (i.e., stroke) and require more support than a straight cane. Patient keeps the cane on the stronger side of the body (Fairchild et al., 2018). Nurse stands on the patient's weak side for support (Fairchild et al., 2018).</p>	<p>Have patient stand upright with arms relaxed down with normal bend at the elbow (15 to 30 degrees). The handle of the cane should be close to the patient's wrist crease. Cane handle should fit comfortably in palm of hand.</p>
<p>Crutches: wooden or metal staff. Two types of crutches: the double adjustable Lofstrand or forearm crutch and the axillary wooden or metal crutch.</p>	<p>Use of crutches is usually temporary (e.g., after ligament damage to the knee). Some patients, such as those with paralysis of the lower extremities, need crutches permanently.</p>	<p>Measurements include the patient's height, the angle of elbow flexion, and the distance between the crutch pad and the axilla. Measure standing: Position crutches with crutch tips at 15 cm (6 inches) laterally to side and 15 cm in front of patient's feet (tripod position). Crutch pads should be 3.75–5 cm (1½–2 inches or 2–3 finger widths) under axilla with the elbows slightly flexed (American College of Foot and Ankle Surgeons, 2020; Fairchild et al., 2018). Height of handgrips must be adjusted so that patient's elbow is slightly flexed or grip sits at approximate height of wrist crease. Both height of crutch and handgrip dimensions are adjustable on a well-made crutch.</p>
<p>Walkers: extremely light, movable devices, approximately waist high and made of metal tubing (see Fig. 38.11). They have four widely placed, sturdy legs. They can also have 2–4 wheels.</p>	<p>Has a wide base of support, providing stability and security when walking.</p>	<p>Have patient step inside walker. When patient relaxes arms at side of body and stands up straight, top of walker should line up with crease on inside of wrist). Elbows should flex about 15 to 30 degrees when standing inside walker, with hands on handgrips (American Academy of Orthopaedist Surgeons, 2015; Fairchild et al., 2018).</p>

Walkers

A walker is a lightweight, movable device that stands about waist high and consists of a metal frame with handgrips, four widely placed sturdy legs, and one open side (Fig. 38.11). A walker can be used by a patient who has lower extremity weakness or has problems with balance. Walkers with wheels are useful for patients who have difficulty lifting and advancing the walker as they walk because of limited balance or endurance.

However, the disadvantage is that the walker can roll forward when weight is applied. A patient uses a walker correctly by holding the handgrips on the upper bars, taking a step, moving the walker forward, and taking another step. A walker requires a patient to lift the device up and forward. The patient should not lean over the walker or walk behind it; otherwise he or she might lose balance and fall. Walkers should not be used on stairs. Teach patients how to use walkers safely and avoid the risk of falling.

FIG. 38.11 Patient using a walker.

Canes

Canes provide less support than a walker and are less stable. The most common cane is the straight-legged, the length of which should be equal

to the distance between the greater trochanter and the floor (Fairchild et al., 2018). Have the patient keep the cane on the stronger side of the body. For maximum support when walking, the patient places the cane forward 15 to 25 cm (6 to 10 inches), keeping body weight on both legs. He or she moves the weaker leg forward to the cane, so body weight is divided between the cane and the stronger leg. The patient then advances the stronger leg past the cane so the weaker leg and the body weight are supported by the cane and weaker leg. During walking the patient continually repeats these three steps. The patient needs to learn that two points of support such as both feet or one foot and the cane are on the floor at all times.

The quad cane provides the most support and is used when there is partial or complete leg paralysis or some hemiplegia (Fig. 38.12). You teach the patient the same three steps that are used with the straight-legged cane.

FIG. 38.12 Bottom of quad cane.

Crutches

Crutches are often needed to increase mobility. The use of crutches is often temporary (e.g., after ligament damage to the knee). However, some patients need them permanently. A crutch is a wooden or metal staff. The

forearm crutch has a handgrip and a metal band that fits around the patient's forearm. The metal band and the handgrip are adjusted to fit the patient's height. The more common axillary crutch has a padded curved surface at the top, which fits under the axilla. A handgrip in the form of a crossbar is held at the level of the palms to support the body. It is important to measure crutches for the appropriate length and to teach patients how to use their crutches safely to achieve a stable gait, ascend and descend stairs, and rise from a sitting position. Always begin crutch instruction with guidelines for safe use ([Box 38.12](#)).

Box 38.12 Patient Teaching Crutch Safety

Objective

- Patient will describe and demonstrate safe crutch walking.

Teaching Strategies

- Teach patient not to lean on crutches to support body weight.
- Teach patient with axillary crutches about the dangers of pressure on the axillae, which occurs when patient leans on the crutches to support body weight.
- Explain why patient needs to use only crutches that were measured for him or her.
- Show patient how to routinely inspect crutch tips. Securely attach rubber tips to crutches. Replace worn tips. Rubber crutch tips increase surface friction and help prevent slipping.
- Explain that crutch tips need to remain dry. Water decreases surface friction and increases risk of slipping. Show patient how to dry crutch tips if they become wet; patient may use paper or cloth towels.
- Show patient how to inspect structure of crutches. Cracks in a wooden crutch decrease its ability to support weight. Bends in aluminum crutches alter body alignment.
- Provide patient with list of medical supply companies in the community for obtaining repairs, new rubber tips, handgrips, and crutch pads.

- Instruct patient to have spare crutches and tips readily available.

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- Describe four principles of crutch safety that you will use.
- Show me the proper way to use your crutches to walk.
- Describe for me steps you will take to keep your crutches in proper working order.

Measuring for Crutches

Measurement for an axillary crutch includes the patient's height, the angle of elbow flexion, and the distance between the crutch pad and the axilla (see [Table 38.3](#)). When crutches are fitted, ensure that the length of the crutch is two to three finger widths from the axilla and position the tips approximately 2 inches lateral and 4 to 6 inches anterior to the front of the patient's shoes.

Position the handgrips so that the axillae are not supporting the patient's body weight. Pressure on the axillae increases risk to underlying nerves, which sometimes results in partial paralysis of the arm. Determine correct position of the handgrips with the patient upright, supporting weight by the handgrips with the elbows slightly flexed. Elbow flexion (approximately 15 to 30 degrees) may be verified with a goniometer ([Fig. 38.13](#)). When you determine the height and placement of the handgrips, verify that the distance between the crutch pad and the patient's axilla is 1½ to 2 inches (two to three finger widths) ([Fig. 38.14](#)).

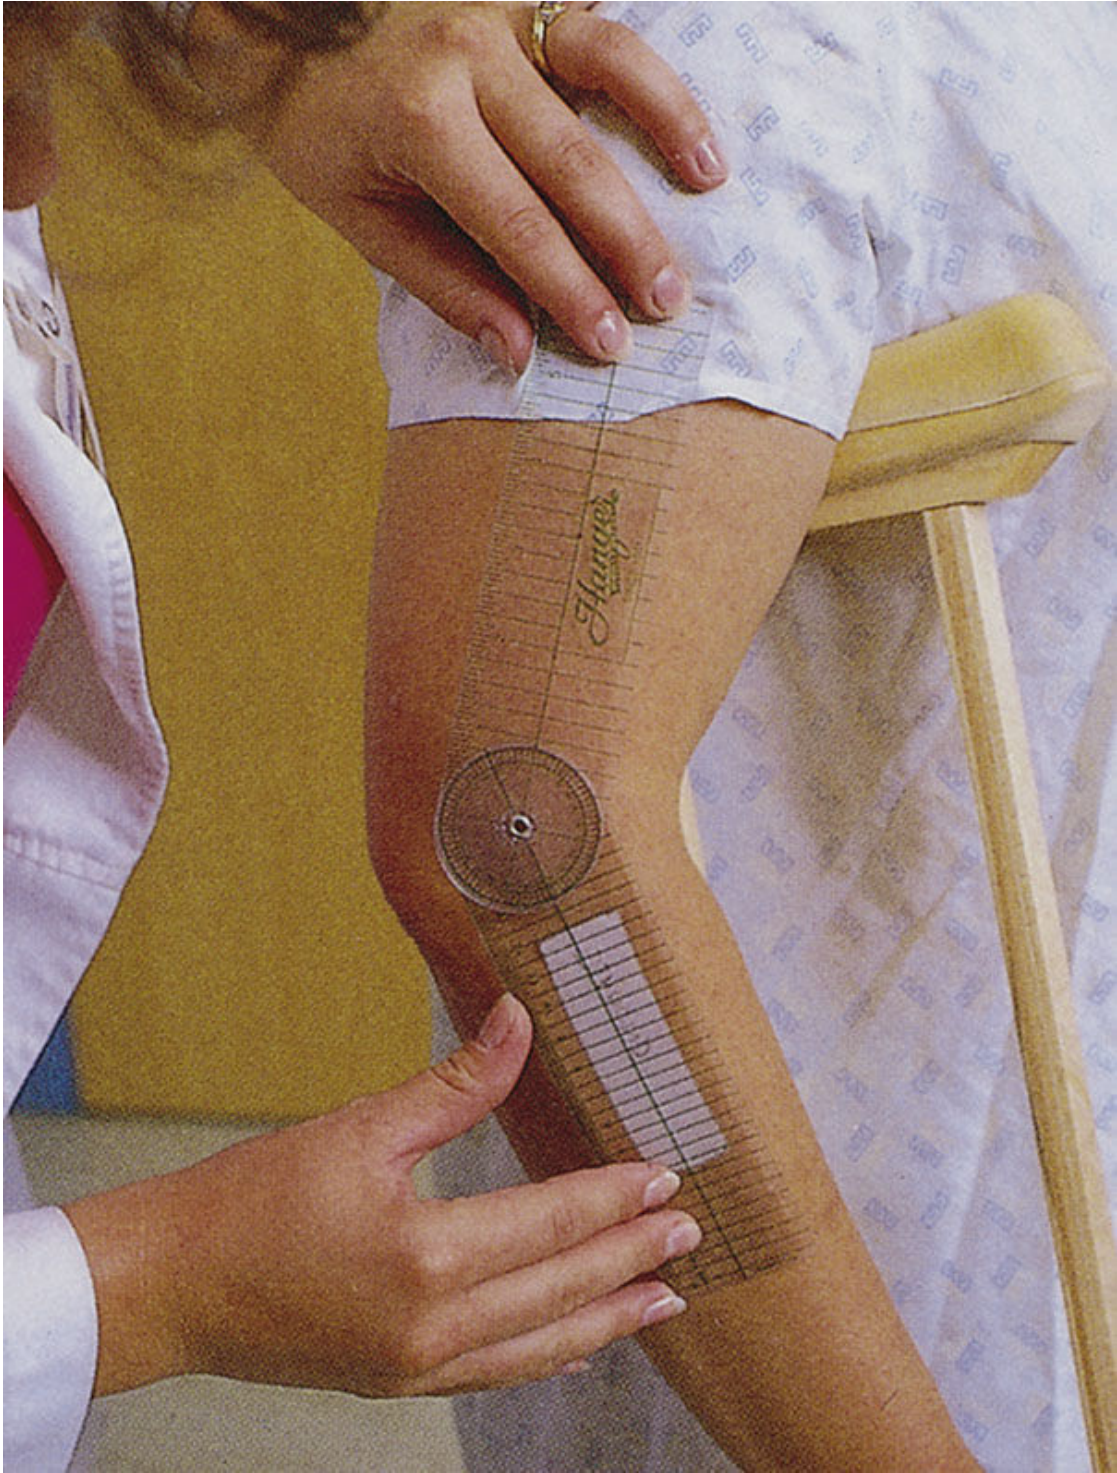

FIG. 38.13 Using the goniometer to verify correct degree of elbow flexion for crutch use.

FIG. 38.14 Verifying correct distance between crutch pads and axilla.

Crutch Gait

Patients assume a **crutch gait** by alternately bearing weight on one or both legs and on the crutches. A physical therapist in collaboration with the health care provider will determine the appropriate gait by assessing the patient's physical and functional abilities and the disease or injury that resulted in the need for crutches. This section summarizes the basic crutch stance and the four standard gaits: four-point alternating gait, three-point alternating gait, two-point gait, and swing-through gait.

The basic crutch stance is the tripod position, formed when the crutches are placed 15 cm (6 inches) in front of and 15 cm (6 inches) to the side of each foot (Fig. 38.15). This position improves the patient's balance by

providing a wider base of support. The body alignment of the patient in the tripod position includes an erect head and neck, straight vertebrae, and extended hips and knees. The axillae should not bear any weight. The patient assumes the tripod position before crutch walking.

FIG. 38.15 Tripod position, basic crutch stance.

Four-point alternating, or four-point, gait gives stability to the patient but requires weight-bearing on both legs. Each leg is moved alternately with each opposing crutch so that three points of support are on the floor at all times ([Fig. 38.16A](#)).

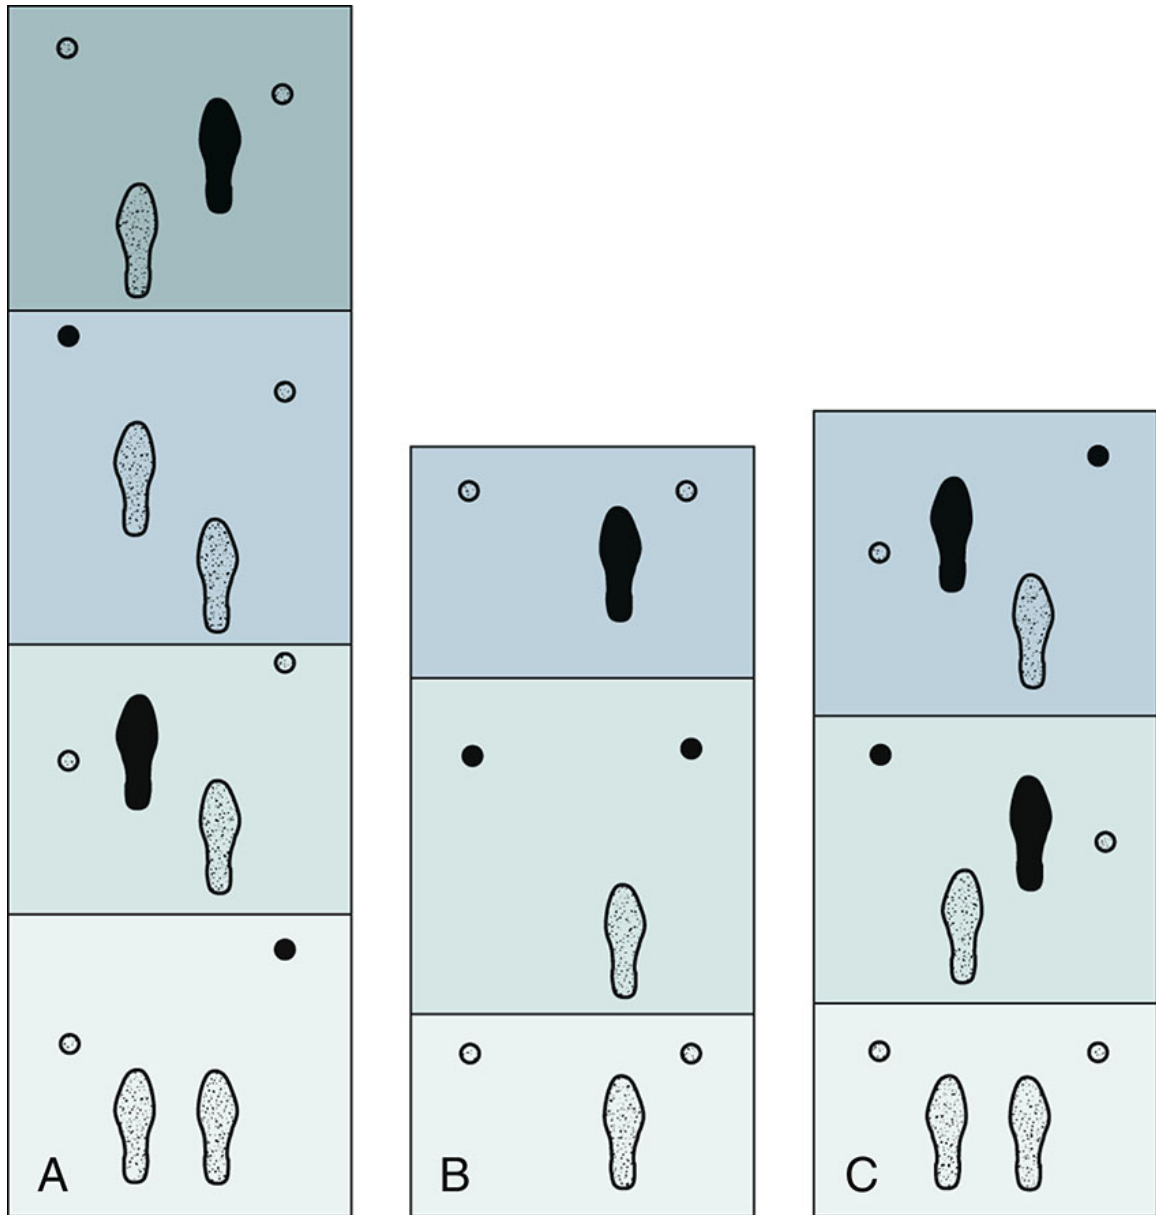

FIG. 38.16 **A**, Four-point alternating gait. Solid feet and crutch tips show the order of foot and crutch tip movement in each of the four phases. (Read from bottom to top.) **B**, Three-point gait with weight borne on unaffected leg. Solid foot and crutch tips show weight-bearing in each phase. (Read from bottom to top.) **C**, Two-point gait with weight borne partially on each foot and each crutch advancing with opposing leg. Solid areas indicate leg and crutch tips bearing weight.

Read from bottom to top.

Three-point alternating, or three-point, gait requires the patient to bear all of the weight on one foot. In a three-point gait the patient bears weight on both crutches and then on the uninvolved leg, repeating the sequence (see [Fig. 38.16B](#)). The affected leg does not touch the ground during the

early phase of the three-point gait. Gradually the patient progresses to touchdown and full weight-bearing on the affected leg.

The two-point gait requires at least partial weight-bearing on each foot (see [Fig. 38.16C](#)). The patient moves a crutch at the same time as the opposing leg, so the crutch movements are similar to arm motion during normal walking.

Individuals with paraplegia who wear weight-supporting braces on their legs frequently use the swing-through gait. With weight placed on the supported legs, the patient places the crutches one stride in front and then swings to or through them while they support his or her weight.

Using Crutches To Ascend and Descend Stairs

Climbing stairs with the use of a railing is the safest way for a patient with crutches to ascend stairs. Be aware that there is a risk for falling using this technique. Your responsibility is to monitor a patient's balance carefully. Be sure there are no obstacles on the stairs, such as stacks of magazines or other items. Have the patient hold the handrail for support with one hand (strong leg next to railing). You carry the crutch positioned next to the handrail as the patient places the other crutch under the axilla of affected side. Have the patient transfer his or her body weight to the crutch while holding the handrail with one hand ([Fig. 38.17A](#)). Stay behind the patient, holding on to the gait belt. Then have the patient support his or her weight evenly between the handrail and crutch. Next, the patient places some weight on crutch and then steps up the first step with weight-bearing foot (stronger leg) ([Fig. 38.17B](#)). Have patient get his or her balance leaning forward with weight on good leg. Then ask the patient to straighten the good knee, push down on crutches and lift his or her body weight, bringing the affected leg and then the crutch up the stair ([Fig. 38.17C](#)). Always make sure the crutch tip is completely on the stair ([Washington University Physicians, 2017](#)). Repeat sequence for each step, and instruct patient to climb one stair at a time.

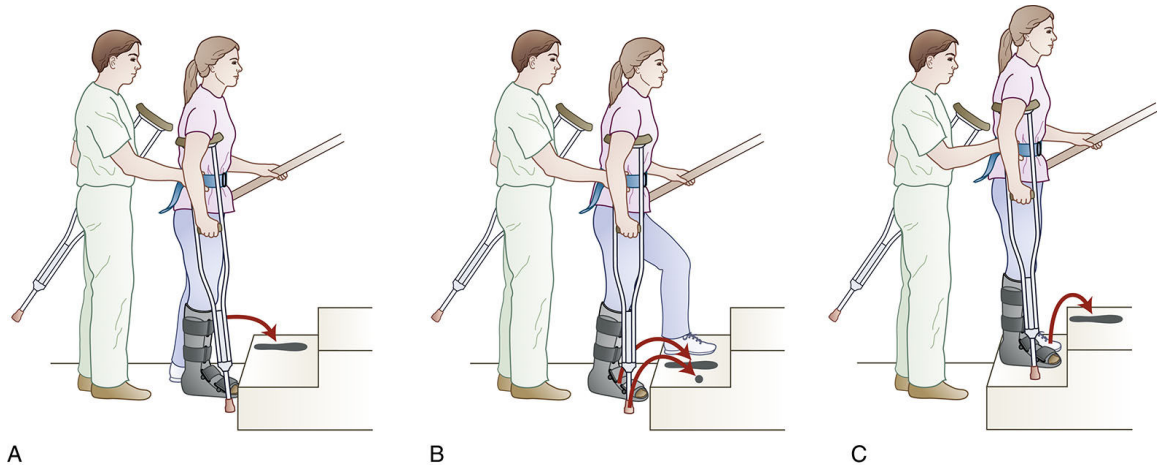

FIG. 38.17 Ascending stairs with crutches.

When a patient descends stairs, he or she remains at risk for falling. Assist the patient using extreme caution. Have the patient stand close to the edge of the top step (Fig. 38.18A). Have the patient hold the handrail with one hand (affected leg next to railing). You carry the crutch positioned next to the handrail as the patient places the other crutch under the axilla of the strong side. Stand above the patient while holding the gait belt. For support, have the patient lower the crutch down to the step below and then move his or her affected leg down (Fig. 38.18B) (Washington University Physicians, 2017). The patient then brings the strong leg down the step and supports his or her weight evenly between handrail, good leg, and crutch (Fig. 38.18C). Be sure that patient has good balance. Always make sure the crutch tip is completely on the stair. Caution patient not to hop.

FIG. 38.18 Descending stairs with crutches.

Remember, when going up stairs, lead with the stronger leg. When going down stairs, lead with the affected leg. Because in most cases patients need to use crutches for some time, they need to be taught to use them on stairs before discharge. Instruction applies to all patients who are dependent on crutches, not just those who have stairs in their homes.

Sitting in a Chair with Crutches

The procedure for sitting in a chair involves phases and requires the patient to transfer weight (Fig. 38.19). First the patient positions himself or herself at the center front of the chair with the posterior aspect of the legs touching the chair. Then the patient holds both crutches in the hand opposite the affected leg. If both legs are affected, as with a person with paraplegia who wears weight-supporting braces, the patient holds the crutches in the hand on his or her stronger side. With both crutches in one hand, the patient supports body weight on the unaffected leg and the crutches. While still holding the crutches, the patient grasps the arm of the chair with the remaining hand and lowers his or her body into it. To stand the procedure is reversed, and the patient, when fully erect, assumes the tripod position before beginning to walk.

FIG. 38.19 Sitting in a chair. **A**, Both crutches are held in one hand. Patient transfers weight to crutches and unaffected leg. **B**, Patient grasps arm of chair with free hand and begins to lower herself into chair. **C**, Patient completely lowers herself into chair.

Restoration of Activity and Chronic Illness

Nurses design care plans individualized for increasing activity and exercise in patients with specific disease conditions and chronic illnesses such as coronary artery disease (CAD), hypertension, chronic obstructive pulmonary disease (COPD), and diabetes mellitus.

Coronary Artery Disease

Regular moderate-intensity aerobic exercise has been shown to reduce the risk of sudden cardiac death and acute MI (Bruning and Sturek, 2015). Increasing physical activity is an important modifiable behavior that can reduce the relative risk of CAD events (such as angina and myocardial infarction) because of its systemic benefits (Fig. 38.20). Regular moderate exercise enhances coronary artery blood flow and reduces incidents of angina by enhancing oxygen delivery to the heart muscle (myocardium) (Bruning and Sturek, 2015). Adherence and access to the necessary resources are often barriers to implementing healthy lifestyle changes in CAD patients (Bruning and Sturek, 2015). As a nurse you will play a role in discussing with patients how regular exercise specifically improves heart function and reduces development of other complications. Collaborate with home health and community nurses to help patients find resources to participate in cardiac rehab programs.

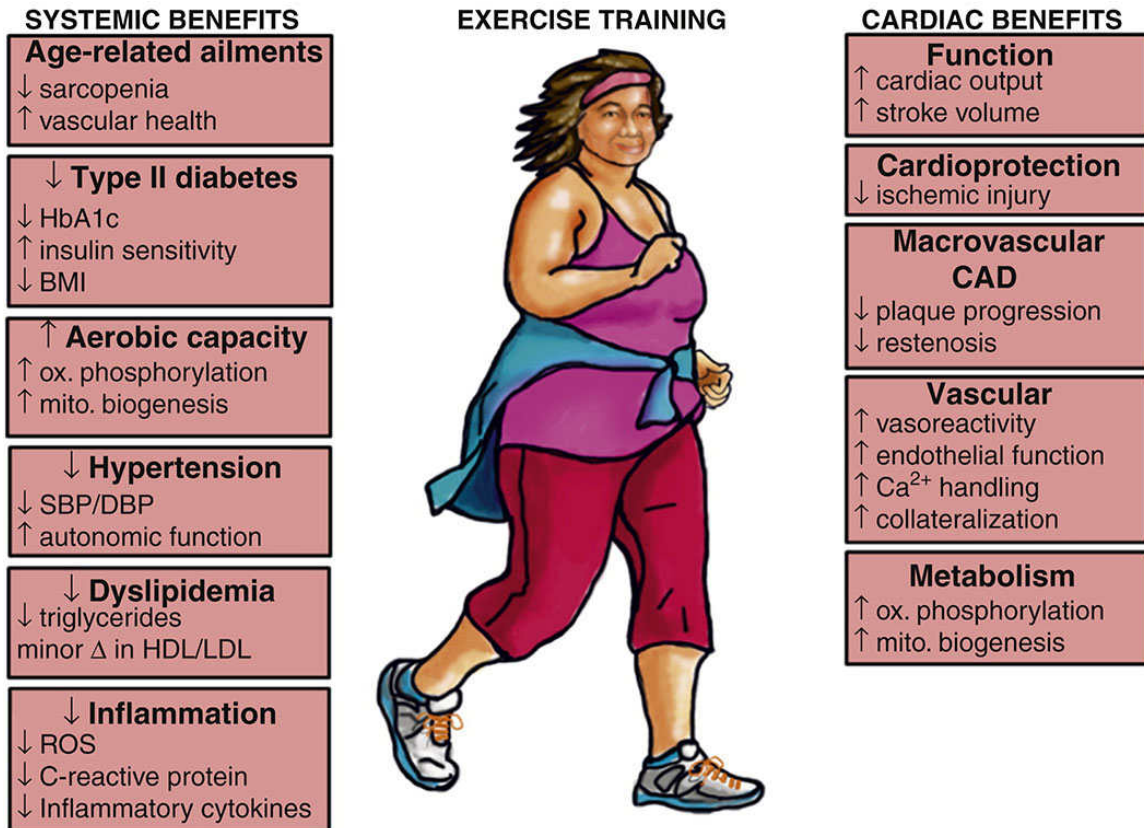

FIG. 38.20 Systemic benefits of regular moderate-intensity exercise.
 From: *Prog Cardiovasc Dis*. Author manuscript; available in PMC 2016 Mar
 1. Published in final edited form as: *Prog Cardiovasc Dis*. 2015 Mar-Apr;
 57(5): 443–453.

Hypertension

In addition to standard antihypertensive medications, the benefits of physical activity on hypertension and cardiovascular disease have been well demonstrated ([Hegde and Solomon, 2015](#)). A number of studies have consistently shown beneficial effects of exercise on hypertension, resulting in reductions in both systolic and diastolic blood pressure with as much as 5 to 7 mm Hg reductions in those with hypertension ([Hegde and Solomon, 2015](#)). Encourage patients to participate in low- to moderate-intensity aerobic exercise as it is the most effective in lowering blood pressure. In addition, a tai chi exercise program has demonstrated a significant reduction in systolic and diastolic blood pressures ([Lo et al., 2012](#); [Edelman and Kudzma, 2018](#)). Have patients with hypertension measure their BP daily at home and help them learn how reactions to stress can raise BP. Relaxation exercises are useful in reducing stress reactions.

Chronic Obstructive Pulmonary Disease

Pulmonary rehabilitation helps patients reach an optimal level of functioning. Exercise training has been shown to significantly improve health-related quality of life, exercise capacity, respiratory muscle strength, and exertional dyspnea in subjects with COPD and normal exercise capacity. Some patients are fearful of participating in exercise because of the potential of worsening dyspnea (difficulty breathing). This aversion to physical activity sets up a progressive deconditioning in which minimal physical exertion results in dyspnea. Pulmonary rehabilitation can help patients gain strength, reduce symptoms of anxiety or depression, and make it easier to manage routine activities, work, and social activities. Patients may have pulmonary rehabilitation in the hospital or a clinic, or they may learn physical therapy or breathing exercises to do at home (National Heart, Lung and Blood Institute, n.d.b.). Pulmonary rehabilitation provides a safe environment for monitoring patients' progress.

Diabetes Mellitus

Along with diet, glucose monitoring, and medication, physical activity and regular exercise are important components in the care of patients with diabetes mellitus. Moderate to high volumes of aerobic activity have been found to be associated with substantially lower cardiovascular and overall mortality risks in both type 1 and type 2 diabetes (Sluik et al., 2012). In type 1 diabetes, aerobic training increases cardiorespiratory fitness, decreases insulin resistance, and improves lipid levels and endothelial function (Chimen et al., 2012). In individuals with type 2 diabetes, regular training reduces HbA1c, triglycerides, blood pressure, and insulin resistance (Colberg et al., 2016). The recommendations for physical activity and exercise in diabetes from the position statement of the American Diabetes Association (Colberg et al., 2016) can be found at the following website: <http://care.diabetesjournals.org/content/39/11/2065>. It contains recommendations for reducing sedentary time and the type of physical activity and exercise recommended specifically for patients with type 1 and type 2 diabetes. Such recommendations should be part of your teaching plan for all patients with diabetes.

• Evaluation

Through the Patient's Eyes

For activity and exercise you measure the effectiveness of nursing interventions by evaluating whether the patient's expectations and goals of care have been reached. The patient is the only one who knows the effectiveness and benefits of activity and exercise. Ask the patient questions such as "How well did you tolerate walking, and is that what you expected?" and "You have been walking regularly for a month now; how has it made you feel?" Continuous evaluation helps to determine whether new or revised therapies are needed and whether new nursing diagnoses have developed.

Patient Outcomes

To evaluate the effectiveness of nursing interventions to enhance activity and exercise, make comparisons with baseline measures that include pulse, blood pressure, oxygen saturation (when available), strength, fatigue, and psychological well-being (Fig. 38.21). Compare actual outcomes with expected outcomes to determine the patient's health status and progression. Also consider standards for physical activity performance (e.g., ability to reach target heart rate). The following is an example of questions you might ask when your patients do not meet their expected outcomes:

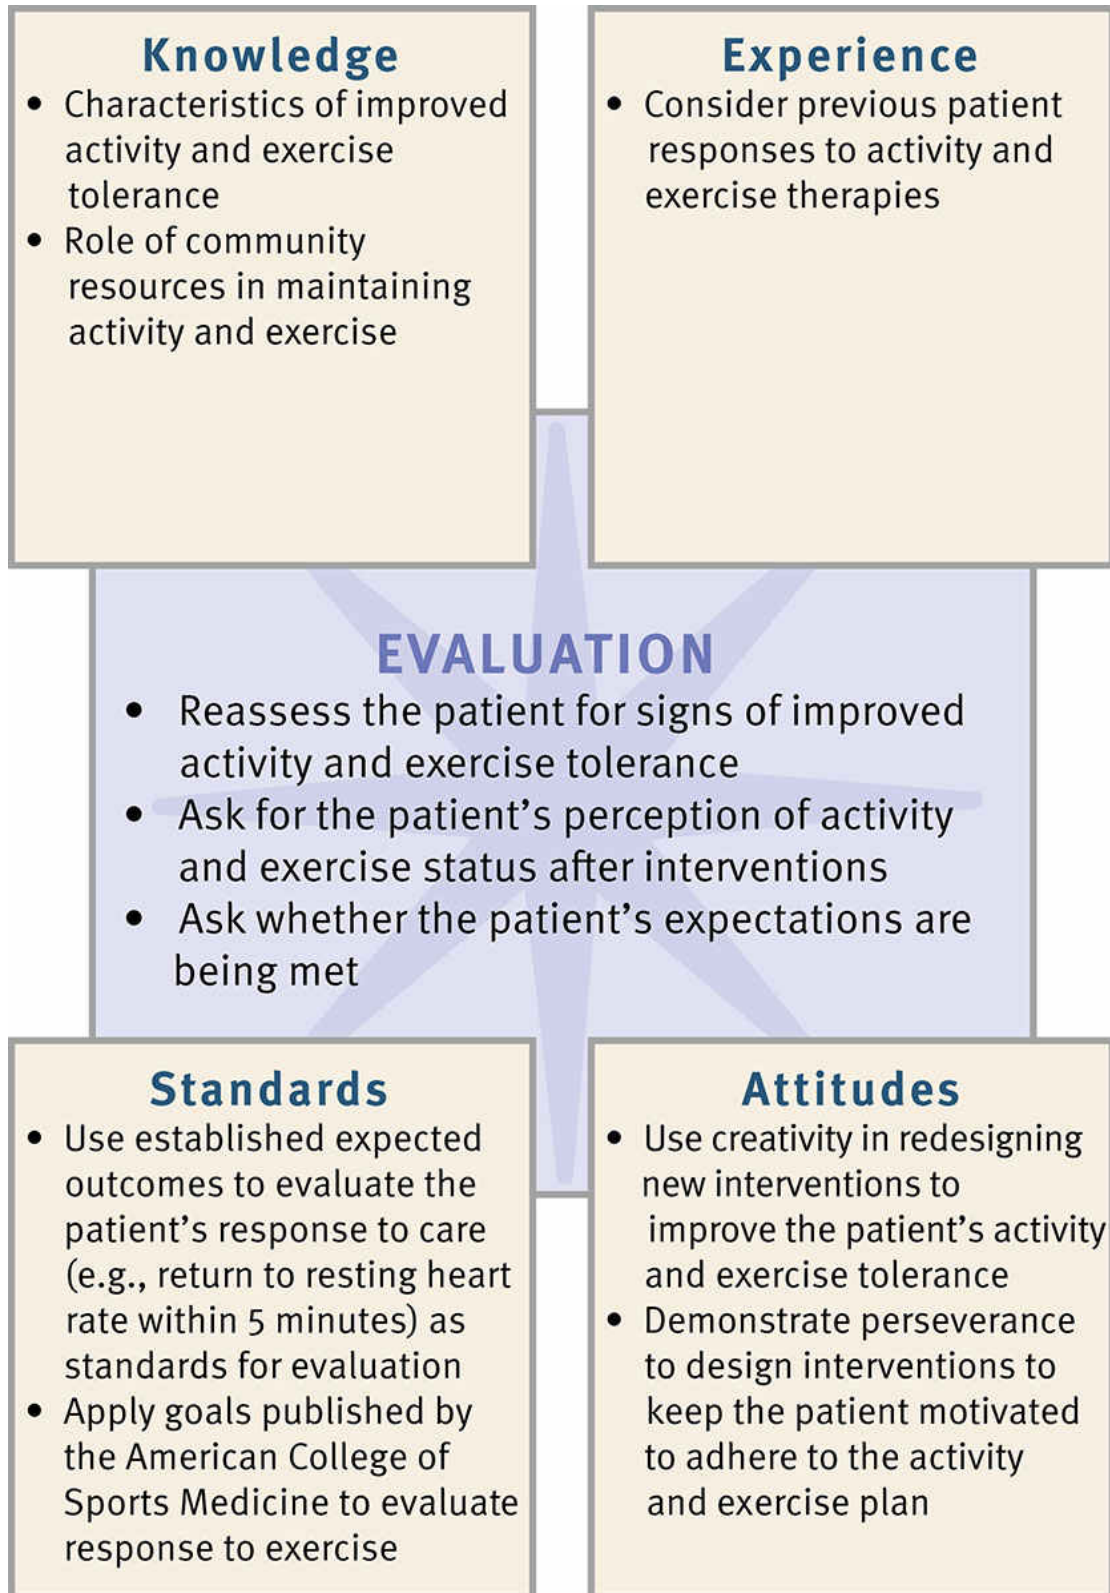

FIG. 38.21 Critical thinking model for activity and exercise evaluation.

- The last time we met you planned to walk outside for 20 minutes 3 days a week. However, you report that you are able to walk only twice a week right now. Tell me what you think is preventing you from meeting your goal.
- Your weight is the same this month as it was last month. We were hoping that increasing your activity would lead to a decrease in your weight. Help me understand the factors you believe are preventing you from losing weight right now.
- You state that you experience leg pain after walking short distances. Describe your pain. Which pain-relieving measures have you tried?

Safety Guidelines for Nursing Skills

Ensuring patient safety is an essential role of the professional nurse. To ensure patient safety, communicate clearly with the members of the health care team, assess and incorporate the patient's priorities of care and preferences, and use the best evidence when making decisions about your patient's care. When performing the skills in this chapter, remember the following points to ensure safe patient handling and individualized patient-centered care.

- Know a patient's level of mobility and strength to determine assistance that is required during ambulation and transferring.
- Assess a patient's physical risks for activity intolerance before beginning early mobility.
- Mentally review the transfer steps before beginning the procedure; this ensures both your safety and that of the patient.
- When assisting orthopedic patients with ambulation, stand on their unaffected side. For patients with neurological deficits stand on the affected side. For all other patients, stand on their affected side.
- Determine the transfer equipment indicated and the number of personnel needed to safely transfer a patient and prevent harm to health care providers (Table 38.4).

TABLE 38.4**Preventing Lift Injuries in Health Care Workers**

Action	Rationale
When planning to move a patient, arrange for adequate help. If your institution has a lift team, use it as a resource (Lin et al., 2012; OSHA, 2017).	A lift team is properly educated in techniques to prevent musculoskeletal injuries.
Use patient-handling equipment and devices such as height-adjustable beds, ceiling-mounted lifts, friction-reducing slide sheets, and air-assisted devices (OSHA, 2017).	These devices reduce the caregiver's muscular strain during patient handling.
Encourage patient to help as much as possible.	This promotes patient's independence and strength while minimizing workload.
Take position close to patient (or object being lifted).	Keeps object in same plane as lifter and close to caregiver's center of gravity. Reduces horizontal reach and stress on caregiver's back.
Tighten abdominal muscles and keep back, neck, pelvis, and feet aligned. Avoid twisting.	Reduces risk of injury to lumbar vertebrae and muscle groups. Twisting increases risk of injury (Lin et al., 2012).
Bend at knees; keep feet wide apart.	A broad base of support increases stability. Maintains center of gravity.
Use arms and legs (not back).	Leg muscles are stronger, larger muscles capable of greater work without injury.
Slide patient toward your body using pull sheet or slide board. When transferring patient onto a stretcher or bed, a slide board is more appropriate.	Sliding requires less effort than lifting. Pull sheet minimizes shearing forces, which can damage patient's skin.
Person with heaviest load coordinates efforts of team involved by counting to three.	Simultaneous lifting minimizes load for any one lifter.
Perform manual lifting as last resort and only if it does not involve lifting most or all of patient's weight.	Lifting is a high-risk activity that causes significant biochemical and postural stressors.

- Raise the side rail on the side of the bed opposite of where you are standing to prevent the patient from falling out of bed on that side.
- Arrange equipment (e.g., intravenous lines, feeding tube, indwelling catheter) so that it does not interfere with the transfer process.
- Evaluate the patient for correct body alignment and pressure risks after a transfer.
- Make sure that all personnel understand how the equipment functions before it is used.

Skill 38.1. Assisting with Ambulation (Without Assist Devices)

Delegation and Collaboration

The skill of assisting patients with ambulation can be delegated to assistive personnel (AP). The nurse directs the AP to:

- Apply safe patient handling principles when assisting patient out of bed or chair.
- Review steps to ensure patient is not having orthostatic hypotension when rising from a lying position in bed to sitting. Check patient's blood pressure before ambulation.
- Immediately return a patient to the bed or chair if he or she is nauseated, dizzy, pale, or diaphoretic, or if systolic BP has dropped at least 20 mm Hg within 3 minutes of sitting upright (Shibao et al., 2013). Report these signs and symptoms to the nurse immediately.
- Apply safe, nonskid shoes/socks and ensure that the environment is free of clutter and that there is no moisture on the floor before ambulating patient.

Equipment

- Nonskid footwear
- Transfer (gait) belt
- Stethoscope, sphygmomanometer, pulse oximeter (as needed)

Steps	Rationale
Assessment	
1. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2020).
2. Review medical record for patient's most recent activity experience, including distance ambulated, use of assist device, activity tolerance, balance and gait. Note history of orthostatic hypotension and any medications, chronic illnesses, gait alterations, or a history of falling.	Allows you to anticipate precautions to take in ambulating patient. History may reveal factors that will influence patient's ability to ambulate and be at risk for falling.
3. Review most recently recorded weight for patient and any report of patient's ability to stand and bear weight.	Determines whether assistance will be required from another health care provider.
CLINICAL DECISION: Use mechanical lift or transfer aid with minimum of two or three caregivers if a patient has partial weight-bearing with upper body strength or caregiver must lift more than 15.9 kg (35 lb)(TVAREF, 2016)	
4. Review health care provider's order for activity; note any mobility, range-of-motion, or weight-bearing restrictions.	Order required for patient to become progressively mobile.
5. Perform hand hygiene. Assess patient's baseline resting heart rate, blood pressure, oxygen saturation (when available), and respirations.	Provides a baseline to compare with assessment data monitored during and after walking to evaluate patient tolerance to exercise.
a. If patient's strength and endurance have been affected by illness or deconditioning, assess range of motion (ROM) and muscle strength (see Chapter 30) of lower extremities while patient in bed. Assess the patient's mobility, including ability to sit up on side of bed or in chair and ability to stand by using the Banner Mobility Assessment Tool (BMAT) (see Skill 38.2) (Boynton et al., 2014b).	Confirms patient's ability to assist with standing and walking. The BMAT is an assessment tool to guide a patient through 4 functional tasks in order to identify the level of mobility the patient can achieve (Boynton et al., 2014b).
6. Assess patient's or family caregiver's knowledge, experience, and health literacy level.	Ensures patient has the capacity to obtain, communicate, process, and understand basic health information (CDC, 2019).
7. Ask whether patient feels excessively tired or is currently experiencing any pain. Determine source and severity of pain (using a 0-to-10 pain-rating scale). Offer an analgesic 30 minutes before ambulation to improve patient's tolerance to exercise.	Pain may delay ambulation.
8. Assess patient's response to commands. Is he or she able to understand instructions and cooperate during ambulation? Is patient willing to ambulate?	Determines how safe it will be to engage patient to ambulate and precautions needed while walking.
9. Assess patient for any hearing or visual deficits (see Chapter 30).	May affect ability to understand instructions.
10. Refer to patient's mobility status and safe-handling algorithm (available in most agencies). Do not start procedure until all required caregivers are available.	Determines whether a lift device or mechanical transfer device is needed and the number of people needed to assist patient to stand.
Planning	
1. Determine the best time to ambulate, considering other scheduled activities such as bathing or other medical procedures.	Allows you to lessen likelihood patient will be fatigued at time of ambulation.
2. Provide privacy. Organize and set up any equipment/lift devices.	Ensures more efficiency, safe use of equipment, and safe ambulation.
3. Remove SCD from patient's legs if present (see Chapter 39). Note whether patient wears a mobile compression device; ambulation can occur safely with stockings in place.	Prevents patient from becoming tangled in cords.
4. Explain to patient in simple language how you are going to prepare for ambulation (e.g., gait belt application, distance planned to walk). Discuss benefits of walking and risks that you are adapting for to reduce chance of falling.	Allows patient to cooperate and lessens anxiety.
CLINICAL DECISION: If patient is on an early progressive mobility protocol, know distance walked during previous ambulation and attempt to increase distance at this time.	
Implementation	
1. If hands became soiled during assessment, perform hand hygiene.	Reduces transfer of microorganisms.
2. Assist patient from supine position to sitting position on edge of bed with bed positioned so that top of mattress is even with your elbows.	Reduces strain on your back.
a. With patient in supine position in bed, raise head of bed 30-45 degrees and place bed in low position, level with your hips. Raise upper side rail on side where patient will exit bed. Apply nonskid shoes or socks. If patient is fully mobile, allow to sit up on side of bed independently, using side rail to raise up.	Reduces strain on back during pivot to side of bed. Nonskid soles decrease risk for slipping during transfer. Always have patient wear nonskid shoes when ambulating; bare feet increase risk for falls.
b. If patient needs assistance to sit on side of bed, turn patient onto his or her side facing you while standing at the side of bed where patient will sit.	Positioning reduces strain on your back.

Table Continued

Steps	Rationale
CLINICAL DECISION: Follow this technique to assist patient to side of bed only if patient has upper body strength and can assist in moving. If patient is uncooperative or has no upper body strength to assist, use a mechanical lift or ceiling lift to move onto side of bed (see Skill 38.2).	
c. Stand opposite patient's hips. Turn diagonally to face patient and far corner of foot of bed.	Maintains straight alignment with patient.
d. Place your feet apart in wide base of support with foot closer to head of bed in front of other foot.	Maintains your balance.
e. Place your arm nearer to head of bed under patient's lower shoulder, supporting his or her head and neck. Place your other arm over and around patient's thighs (see illustration).	Position provides leverage for patient to rise to sitting position.
f. Move patient's lower legs and feet over side of bed as patient uses side rail to push and raise the upper body. Pivot weight onto your rear leg as you allow patient's upper legs to swing downward (see illustration). Do not lift legs. At same time, continue to shift weight to your rear leg and guide patient in elevating his/her trunk into upright position	Patient's effort in raising upper body lessens strain on your back. Avoid lifting to prevent accidental injury. Use a mechanical or ceiling lift if it becomes necessary to lift patient.
3. Allow patient to sit on the side of the bed with feet on floor for 2 to 3 minutes. Have patient alternately flex and extend feet, and move lower legs up and down without touching floor. Ask whether patient feels dizzy; if so, check blood pressure. Have patient relax and take a few deep breaths until dizziness subsides and balance is gained. If dizziness lasts more than 60 seconds or if systolic BP has dropped at least 20 mm Hg within 3 minutes of sitting upright, return patient to bed (Shibao et al., 2013; Frith et al., 2014; Mills et al., 2014). Recheck blood pressure.	Allows patient's circulation to equilibrate to reduce chance of orthostatic hypotension. Patient cannot be safely ambulated if dizziness develops.
4. Apply gait belt. Be sure that it completely encircles a patient's waist below the belly button (see illustration). Belt should fit snugly, being sure two fingers fit between the belt and patient's body. Avoid placing belt over any intravenous lines, incisions, or drainage tubes.	Gait belt allows you to maintain stability of patient as he/she stands and reduces risk for falling (Degelau et al., 2014; OSHA, 2014).

Step 2e Nurse places arm over patient's thighs, other arm under patient's shoulder as patient raises up.

Step 2f Nurse shifts weight to rear leg and guides patient to raise up to sitting position.

Steps	Rationale
	

Step 4 Application of gait/transfer belt.

Table Continued

Steps	Rationale
5. If patient is alert and can bear weight and balance while standing, allow him/her to stand independently. Assist by holding gait belt to offer balance assistance.	Patient capable of bearing weight needs assistance to reduce fall risk.
6. If patient cannot bear weight or cannot balance to stand independently and walk, use an ambulation lift or ceiling lift with gait harness (see Skill 38.2). Patient can walk with support of this mechanical device.	Provides needed stability as patient stands and continues to support patient while walking.
7. Confirm with patient the distance to ambulate.	Motivates patient to reach goal.
CLINICAL DECISION: At any time during ambulation if patient becomes unstable or reports feeling dizzy, seat him or her in chair or return to bed immediately. May need use of mechanical lift (see Skill 38.2). This prevents patient falls.	
8. <i>Option:</i> If patient has an IV line, place the IV pole on the same side as the site of infusion and instruct patient where to hold and push the pole while ambulating. It is best if another caregiver can push IV pole.	Prevents accidental pulling on IV catheter. Assist from second caregiver allows patient to focus on walking and may lessen risk of tripping
9. If a Foley catheter is present, carry the bag below the level of the bladder to prevent tension on the tubing.	Prevents reflux of urine from the bag back into bladder.
10. For orthopedic patients stand on patient's unaffected side. For patients with neurological deficits (e.g., stroke) stand on the affected side. For all other patients requiring assistance to maintain balance while weight-bearing, stand on involved side.	Positions provide balance and facilitate lowering patient to the floor if he or she is unable to continue because of weakness or dizziness. Helps support the affected limb of neurological patient (i.e., prevents knee buckling).
11. Grasp belt firmly with palm facing up (see illustration A). Take a few steps, guiding patient with one hand grasping the gait belt and the other hand placed under the elbow of the patient's flexed arm (see illustration B).	Belt used to maintain patient balance.
12. When ambulating in a hallway, position patient between yourself and the wall. Encourage patient to use handrails if available (see illustration B, Step 11).	The wall provides stable support for patients who start to fall away from you.
13. Observe how patient walks (posture, gait, balance), and determine distance patient can safely continue walking. Measure pulse and respirations as needed.	Monitors patient's tolerance to walking.
14. Return patient to bed or chair (Independent transfer or use of mechanical lift), and assist patient to assume a comfortable position. Be sure the nurse call system is accessible within patient's reach.	Gives patient sense of well-being. Ensures patient can call for assistance if needed.

Step 11 A, Nurse grasps gait belt firmly with palm up. B, Nurse guides patient by placing hand on patient's arm.

Table Continued

Steps	Rationale
15. Raise side rails (as appropriate), and lower bed to lowest position. Perform hand hygiene.	Ensures patient safety. Reduces transmission of microorganisms.
Evaluation	
1. Monitor vital signs. Compare HR during ambulation with target HR (if applicable). Ask whether patient feels dizzy or tired. Ask him or her to rate pain on pain scale.	Evaluates patient's response to postural changes and activity.
2. Note patient's behavioral response to walking.	Reveals level of motivation and self-care potential.
3. Use Teach-Back: "I want to be sure I explained the importance of increasing your walking distance each day and of continuing to walk once you go home. Tell me why it is important for you to be able to walk farther each day." Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly.	Determines patient's/family caregiver's level of understanding of instructional topic.
Unexpected Outcomes and Related Interventions	
<p>1. Patient starts to fall while walking.</p> <ul style="list-style-type: none"> Grasp patient's gait belt with both hands around his or her waist with palms up. Stand with feet apart for a broad base of support (see Fig. 38.10A). Extend one leg slightly forward, pull patient against you, and let him or her slide down your leg as you ease him or her to the floor (see Fig. 38.10B). <i>Caution:</i> If patient is obese, do not risk personal injury. If you extend leg too far, hyperextension could occur. Bend your knees and lower your body as patient slides to floor (see Fig. 38.10C). Stay with patient until help arrives. 	
<p>2. Patient does not tolerate walking due to fatigue, pain, dizziness, or other symptoms.</p> <ul style="list-style-type: none"> Return to bed or chair immediately. Measure vital signs. Notify health care provider or nurse in charge. 	
Recording and Reporting	
<ul style="list-style-type: none"> Record procedure and pertinent observations: baseline and postambulatory vital signs, distance walked, patient's tolerance, onset of weakness, fatigue, pain, poor balance or gait. Report to health care provider or nurse in charge change in vital signs or patient fall. Document evaluation of patient learning. 	

SKILL 38.2

Using Safe and Effective Transfer Techniques

Delegation and Collaboration

The skill of effective transfer techniques can be delegated to trained assistive personnel (AP). The nurse is responsible to initially assess patient's readiness and ability to transfer. The nurse directs the AP by:

- Assisting and supervising when moving patients who are transferred for the first time after prolonged bed rest, extensive surgery, critical illness, or spinal cord trauma.
- Explaining the patient's mobility restrictions, changes in blood pressure to look for, or sensory alterations that may affect safe transfer (e.g., medicated or confused).

- Explaining what to observe and report back to the nurse, such as dizziness or the patient's ability/inability to assist.

Equipment

- Gait belt, sling, or lapboard (as needed)
- Nonskid shoes, bath blankets, and pillows
- Chair with arms or wheelchair (position chair at 45- to 60-degree angle to bed, lock brakes, remove footrests, and lock bed brakes)
- Stretcher (position next to bed, lock brakes on stretcher, lock brakes on bed)
- Mechanical/hydraulic lift (use frame, canvas strips or chains, and hammock or canvas strips)
- Stand-assist lift device
- *Option:* Clean gloves (if risk of contacting soiled linen)

Step	Rationale
Assessment	
1. Identify patient using two identifiers (e.g., name and birthday or name and medical record number) according to agency policy. Explain procedure.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2020).
2. Refer to medical record for most recent recorded weight and height for patient.	Data determine whether mechanical transfer devices or friction-reducing device is needed for transfer.
3. Review history for previous fall and whether patient has a fear of falling.	Previous fall history is a significant fall risk. Having a fear of falling can alter one's gait and security in walking.
4. Assess medical record for previous mode of transferring to bed or chair (if applicable).	Ensures some consistency in how to assist with transfer.
Table Continued	

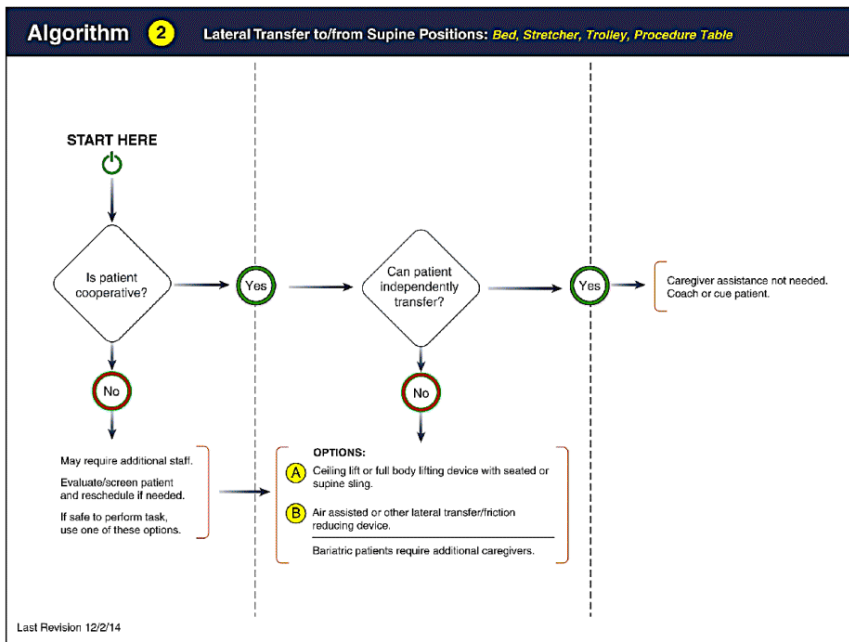

Step	Rationale
5. Perform hand hygiene. Assess patient for presence of neuromuscular deficits, motor weakness or incoordination, proprioception (awareness of posture), history of cognitive and visual dysfunction, altered balance (see Chapter 30).	Reduces transmission of microorganisms. Certain conditions increase risk of tripping, falling, or suffering potential injury during fall. Proprioception determines stability of patient's balance for transfer and risk for falls.
6. Assess the patient's mobility, including ability to sit up on side of bed or chair, and ability to stand. <i>Option:</i> Administer the Banner Mobility Assessment Tool (BMAT) (Boynton et al., 2014a,b): a. Sit and Shake: From a semireclined position, ask patient to sit upright and rotate to a seated position at the side of the bed; patient may use the bed rail. Note patient's ability to maintain bedside position. Ask patient to reach out and grab your hand and shake, making sure patient reaches across his/her midline. b. Stretch and Point: With patient in seated position at the side of the bed, have patient place both feet on the floor (or stool) with knees no higher than hips. Ask patient to extend one leg and straighten the knee, then bend the ankle and point the toes. Repeat with the other leg. c. Stand: Ask patient to elevate off the bed or chair (seated to standing) using an assistive device (walker, cane, bed rail). Patient should be able to raise buttocks off bed and hold for a count of five. May repeat once. d. Walk (march in place and advance step): Ask patient to march in place at bedside, then ask patient to step forward and back with each foot. Patient should display stability while performing tasks. Assess for stability and safety awareness.	The BMAT is a tool that assesses four functional tasks to identify the level of mobility a patient can achieve (Boynton et al., 2014a,b). The assessment aids in determining a patient's level of mobility (e.g., Mobility Level 1) and recommends equipment and tools needed to safely lift, transfer, and mobilize the patient. Findings serve as a communication tool across the continuum of care. If patient fails to Sit and Shake: use total lift with sling and/or positioning sheet and/or straps, and/or use lateral transfer devices such as rollboard, friction-reducing (slide sheets/tube), or air-assisted device. If patient fails Stretch and Point: use total lift for patient unable to weight-bear on at least one leg; use sit-to-stand lift for patient who can weight-bear on at least one leg. If patient fails to Stand: use nonpowered raising/stand aid (default to powered sit-to-stand lift if no stand aid available) or use total lift with ambulation accessories or use assistive device (cane, walker, crutches). If patient cannot Walk: use nonpowered raising/stand aid (default to powered sit-to-stand lift if no stand aid available) or use total lift with ambulation accessories or use assistive device (cane, walker, crutches).
CLINICAL DECISION: Do not rely on self-report from patient or family caregiver as to patient's ability to sit, stand, or ambulate. An objective assessment is needed to accurately determine a patient's capabilities.	
7. While assessing mobility, note any weakness, dizziness, or risk for orthostatic (postural) hypotension (e.g., previously on bed rest, first time arising from supine position after surgical procedure, history of dizziness when arising).	Determines risk of fainting or falling during transfer. Immobilized patients have decreased ability of autonomic nervous system to equalize blood supply, resulting in initial drop of 40 mm Hg systolic or more in blood pressure when rising from sitting position (Frith et al., 2014; Mills et al., 2014).
8. Assess activity tolerance, noting for fatigue during previous sitting and standing.	Determines ability of patient to help with transfer.
9. Assess sensory status, including central and peripheral vision, adequacy of hearing, and presence of peripheral sensation loss.	Visual field loss decreases patients' ability to see in direction of transfer and may impact their balance. Peripheral sensation loss decreases proprioception. Patients with visual and hearing losses need transfer techniques and communication methods adapted to their deficits.
CLINICAL DECISION: Patients with hemiplegia may "neglect" one side of the body (inattention to or unawareness of one side of body or environment), which distorts perception of the visual field. If patient experiences neglect of one side, instruct him or her to scan all visual fields when transferring.	
10. Assess level of comfort (e.g., joint discomfort, muscle spasm), and measure level of pain using scale of 0 to 10. Offer prescribed analgesic 30 minutes before transfer. (Note: Patient will require assistance when analgesic has been given.)	Pain reduces patient's motivation and ability to be mobile. Pain relief before transfer enhances patient's ability to participate (Schofield, 2014).

Step	Rationale
11. Assess patient's health literacy and cognitive status, including ability to follow verbal instructions, short-term memory, and recognition of physical	Determines patient's ability to follow directions and learn transfer techniques.

deficits and limitations to movement.	
CRITICAL DECISION: <i>Patients with dementia, head trauma, or degenerative neurological disorders may have perceptual cognitive defects that create safety risks. If the patient has difficulty comprehending, simplify instructions by providing one step at a time and maintain consistency.</i>	
12. Assess patient's level of motivation, such as eagerness versus unwillingness to be mobile, and perception of value of exercise.	Will affect patient's desire to engage in activity.
13. Assess need for special transfer equipment for home setting and previous mode of transfer (if applicable).	Providing appropriate aids greatly enhances transfer ability at home.
14. Assess patient's vital signs just before transfer.	Baseline measures will determine whether vital sign changes occur during activity, which will indicate activity intolerance. Patient with low blood pressure may not tolerate sudden position change and is at risk for orthostatic hypotension.

From VHA: *Safe patient handling and mobility algorithms*. 2014 revision. Reprinted with permission of VISN 8 Patient Safety Center of Inquiry, Tampa, FL.

<p>b. Allow patient to sit on the side of the bed for a few minutes. Have patient alternately flex and extend feet, and move lower legs up and down. Ask whether patient feels dizzy; if so, check blood pressure. Have patient relax and take a few deep breaths until dizziness subsides and balance is gained. If dizziness lasts more than 60 seconds, return patient to bed (Frith et al., 2014; Mills et al., 2014). Recheck blood pressure.</p>	<p>Allows patient's circulation to equilibrate to reduce chance of orthostatic hypotension.</p>
<p>CLINICAL DECISION: Remain in front of patient until he or she regains balance and continue to provide physical support to weak or cognitively impaired patient.</p>	
<p>c. Have a chair in position at 45-degree angle with one side against bed, facing foot of bed. Place bed in low position or to point where patient's feet are comfortably flat on the floor with the hip and knees at a 90-degree angle. Be sure bed brakes are locked.</p>	<p>Positions chair for easy access. Provides patient stability when transferring.</p>
<p>CLINICAL DECISION: If patient demonstrates weakness or paralysis of one side of the body, place chair on his or her strong side.</p>	
<p>Table Continued</p>	

Step	Rationale
d. If patient is cooperative and able to bear weight and balance while standing, allow independent transfer, using stand-and-pivot technique with one caregiver (OSHA, 2017).	Caregiver is providing extra support for balance only, <i>not</i> for lifting.
CLINICAL DECISION: <i>Patient may use assist device during transfer.</i>	
(1) Apply gait/transfer belt (see Skill 38.1).	Transfer belt allows you to maintain stability of patient during transfer and reduces risk for falling (Degelau et al., 2014).
(2) If not already in place, help patient apply stable, nonskid shoes/socks. If patient has a stronger leg, place it forward on floor, with weaker foot back.	Nonskid soles decrease risk for slipping during transfer. Always have patient wear nonskid shoes during transfer; bare feet increase risk for falls.
(3) Spread your feet apart. Flex hips and knees, aligning knees with patient's knees.	Ensures balance with wide base of support. Flexing knees and hips lowers your center of gravity to object that moves; aligning knees with those of patient stabilizes knees when patient stands.
(4) Grasp transfer belt along patient's sides (see illustration).	Transfer belt allows you to help patient move, keeping balance.
CLINICAL DECISION: <i>Patients should never be lifted with belt or by placing hands under their arms.</i>	
(5) On count of three, instruct patient to stand while straightening hips and legs and keeping knees slightly flexed (see illustration). Make sure that your body weight is moving in the same direction as patient's to ensure that you and patient are moving in same direction simultaneously. Unless contraindicated, patient may be instructed to use hands to push up if applicable.	Coordinated movement allows patient to stand easily as you help to maintain his or her balance.
(6) Maintain patient's balance as you pivot foot farthest from chair and then help patient ease into chair. Have patient hold arm rest for support (see illustration).	Pivoting allows adequate space for patient to move. Ability of patient to stand can be enhanced as you provide assistance with balance.
(7) Assist patient to assume proper alignment in sitting position. Provide support for any weakened upper extremity. You can use a sling or lap board to support an injured or weakened arm.	Prevents injury to patient from poor body alignment.
(i) Proper alignment for sitting position: head is erect, and vertebrae are in straight alignment. Body weight is evenly distributed on buttocks and thighs. Thighs are parallel and in horizontal plane. Both feet are supported flat on floor, and ankles are comfortably flexed. A 2.5- to 5-cm (1- to 2-inch) space is maintained between edge of seat and popliteal space on posterior surface of knee.	Prevents stress on intravertebral joints. Prevents increased pressure over bony prominences and reduces damage to underlying musculoskeletal system.

Step 2d(4) Nurse flexes hips and knees, aligns knees with patient's knee, and grasps transfer belt palms up.

Step

STEP 2d(5) Patient stands up at bedside before pivoting over to chair, bearing weight.

Step

Rationale

Step 2d(6) Patient uses armrests to ease into chair.

Table Continued

Step	Rationale
e. If patient is unable to cooperate (regardless of ability to bear weight) or does not have sufficient upper or lower body strength, use ceiling, hydraulic floor, or power-driven lift (see illustration) to transfer patient from bed to chair (OSHA, 2017). Use a minimum of two to three caregivers. Follow algorithm and manufacturer lift guidelines.	Use of ceiling-mounted lifts is a popular choice because of availability of lift in a patient's room. Power driven mobile lift is especially good for ambulating obese patients for early mobility. The use of mechanical lift devices is strongly recommended to transfer a patient to reduce risk for musculoskeletal injury (Degelau et al., 2014). The use of a safe mobility algorithm aids caregivers in selecting mechanical lifts and transfer devices appropriately for safer transfers (OSHA, 2014, 2017).
(1) Bring mechanical or power mobile lift to bedside or lower the ceiling lift and position properly.	Ensures safe elevation of patient off bed.
(2) Be sure chair is available next to bed for easy access. Allow adequate space to maneuver the lift.	Prepares environment for safe use of lift and subsequent transfer of patient into chair.
(3) Raise bed to high position with mattress flat. Lower side rail on side near chair.	Allows you to use proper body mechanics while positioning patient in hammock.
(4) Have second nurse positioned at opposite side of bed.	Maintains patient safety, preventing fall from bed.
(5) Roll patient on side away from you.	Positions patient for placement of lift sling.
(6) Place the sling or harness on bed so that it aligns correctly with patient's trunk and legs; place it against patient's back.	There are several types of lift slings: hammock sling, commode sling, mesh bath sling, and padded sling with or without head support. Place sling under patient's center of gravity and greatest part of body weight.
(7) Roll patient back toward you as second nurse pulls sling or harness through.	Ensures that sling is in proper position before lift.
(8) Return patient to supine position. Be sure that harness or sling straps are smooth over bed surface. A sling should extend from shoulders to knees (hammock) to support patient's body weight equally.	Completes positioning of patient on mechanical/hydraulic sling.
(9) Remove patient's glasses if appropriate.	Swivel bar is close to patient's head and could break eyeglasses.
(10) Roll the base of floor lift under patient's bed (on side with chair).	Positions lift efficiently and promotes smooth transfer.
(11) Attach lower horizontal bar of ceiling lift to sling level by following manufacturer directions. Lock valve if required.	Positions lift close to patient. Locking valve on hydraulic lift prevents injury to patient.
(12) Attach sling to lift device using sewn-in loop straps, chains, or adjustable straps. Attach hooks on chain to holes in sling. Short chains or straps hook to top holes of sling; longer chains hook to bottom of sling (see manufacturer directions).	Secures hydraulic lift to sling. Be sure any hooks that attach to metal chains face away from patient's skin. Follow manufacturer's instructions for applying sling or harness.
(13) Elevate head of bed to Fowler's position.	Positions patient in sitting position.
(14) Have patient fold arms over chest.	Prevents injury to patient's arms during transfer.

Step 24 Patient grasps handles as nurse turns on motorized power lift.

Step	Rationale
	Table Continued

Step	Rationale
(15) For ceiling lift turn on control device to raise the patient off the bed (see illustration). If the lift is a nonelectric lift, then pump the hydraulic handle using long, slow, even strokes until patient is raised off bed (see illustration).	Ensures safe support of patient during elevation.
(16) Use lift to raise patient off bed and use steering handle to pull lift from bed as you and another nurse maneuver patient to chair. Have second nurse alongside patient.	Lifts patient off the bed safely; nurse's position reduces any risk of patient falling from sling.
(17) For a hydraulic lift, roll base of lift around chair. Release check valve slowly or push the button down and lower patient into chair (see manufacturer directions) (see illustration).	Positions lift in front of chair into which patient is to be transferred. Safely guides patient into back of chair as seat descends.
(18) Close check valve of hydraulic lift, if needed, as soon as patient is down in chair and straps can be released. Newer lifts may not need this step (see manufacturer's directions).	If valve is left open, boom may continue to lower and injure patient.
(19) For a ceiling lift, steer sling over chair and use power button to lower patient into chair (see manufacturer's directions).	Provides for easy lowering of patient.
(20) Remove lifting device from hammock or sling. Then roll mechanical/hydraulic lift out of patient's path.	Prevents damage to skin and underlying tissues.
(21) Check patient's sitting alignment and correct if necessary.	Prevents injury from poor posture.
3. Perform lateral transfer from bed to stretcher. (Option: Apply clean gloves if bed linen soiled.): Assist patient into supine position in bed with head of bed lowered as much as patient can tolerate. Raise bed to working height so that top of mattress is even with your elbows. Refer to mobility assessment findings and safe patient handling algorithm to confirm appropriateness to transfer patient and whether other caregivers are needed.	The three-person lift (using drawsheet) for horizontal transfer from bed to stretcher is no longer recommended and is discouraged (Anderson et al., 2014; OSHA, 2014). Physical stress can be decreased significantly by using slide board or friction-reducing board positioned under drawsheet beneath patient. If available, air lateral transfer devices require less caregiver force to maneuver and are more comfortable for the patient.
CLINICAL DECISION: Lock brakes on bed and stretcher to prevent accidental patient fall.	
a. Can patient assist?	Patient's level of strength and weight determine level of help required for safe transfer. During any patient-transferring task, if any caregiver is required to lift more than 15.9 kg (35 lb) of patient's weight, patient is considered fully dependent, and an assist device is used (OSHA 2014, 2015).
(1) If patient can assist, caregiver is only needed to stand by for safety and coach patient in moving toward stretcher. Keep stretcher and bed locked as patient moves to stretcher.	Promotes patient safety.
(2) If patient is partially or not at all able to assist and is <91 kg (200 lb), use friction-reducing device or lateral transfer board.	Minimizes injury to skin as patient is laterally transferred.
(3) If patient is partially or not at all able to assist and is >91 kg (200 lb), use a ceiling lift with supine sling or a mechanical lateral transfer device with three caregivers.	Prevents need to pull patient if a lateral transfer board or device were to be used.
 <p data-bbox="354 1671 894 1688">Step 20(1): A, Ceiling lift. (Courtesy Wavely Clin Systems, a Prism Medical Co.) B, Patient lifted in hydraulic lift above bed.</p>	

Table Continued

Step	Rationale
b. Lateral transfer with friction-reducing device—slide board (see illustration) or air assisted device:	Maintains alignment of spinal column. Ensures that bed does not move inadvertently.
(1) Cross patient's arms on chest.	Prevents injury to arms during transfer.
(2) Lower side rails. To place slide board/air-assisted device under patient, position two nurses on side of bed toward which patient will be turned. Position third nurse on other side of bed.	Distributes weight equally between nurses.
(3) Fanfold drawsheet on both sides of patient.	Provides strong handles to grip drawsheet without slipping.
(4) On count of three logroll patient onto side toward the two nurses. Turn patient as one unit with smooth, continuous motion.	Maintains body in alignment, preventing stress on any part.
(5) Place slide board on bed, against patient's back and under drawsheet (see illustration A). <i>Option: Apply deflated air-assisted device (see illustration B).</i>	Prevents friction from contact of skin with board.
(6) Gently roll patient back onto slide board/air-assisted device and draw sheet (see illustration A). For an air-assisted device, secure safety straps around patient (see illustration B).	Positions patient for transfer. Safety straps prevent patient fall.
(7) Line up stretcher so that surface is ½ inch lower than bed. Recheck locked brakes on stretcher. Instruct patient not to move.	Eases transfer. Ensures that stretcher does not move inadvertently during transfer.
(8) Two nurses position themselves on side of stretcher while third nurse positions self on side of bed without stretcher. All three nurses place feet widely apart with one foot slightly in front of the other and grasp slide board or friction-reducing device.	Ensures safety and distribution of weight during transfer.
CLINICAL DECISION: A nurse may also be positioned at the head of patient's bed to protect and support his or her head and neck if patient is weak or unable to help.	
(9) Ensure that bed brakes are locked.	Promotes patient comfort and safety.
(10) Holding fan-folded drawsheet and one nurse counting to three, the two nurses pull drawsheet across slide board, positioning patient onto stretcher (see illustration A). The third nurse holds slide board in place. <i>Option: Inflate air-assisted device and slide patient across bed onto stretcher (see illustrations B and C).</i>	Slide board remains stationary, provides slippery surface to reduce friction, and allows patient to transfer easily to stretcher.
(11) Position patient in center of stretcher. Raise head of stretcher if not contraindicated. Raise stretcher side rails. Cover patient with blanket.	Provides for patient comfort.
4. After transferring patient to bed or chair, be sure patient is positioned comfortably. Place nurse call system in an accessible location within patient's reach.	Ensures patient safety.
5. Raise side rails (as appropriate) and lower bed to lowest position.	Ensures patient safety.
6. Place nurse call system in accessible location.	Promotes patient safety.
7. Remove and dispose of gloves (if used) and perform hand hygiene.	Reduces transmission of microorganisms.
Evaluation	
1. Monitor vital signs. Ask whether patient feels dizzy or tired. Ask him or her to rate pain on pain scale.	Evaluates patient's response to postural changes and activity.
2. Note patient's behavioral response to transfer.	Reveals level of motivation and self-care potential.

Step 2e(17) Use of hydraulic lift to lower patient into chair.

Step 3b Slide board.

Table Continued

Step	Rationale
<p>3. Use Teach-Back: "I want to be sure I explained the steps we are going to use to transfer you to the chair. Tell me the steps you can take to make the transfer safe." Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly.</p>	<p>Determines patient's/family caregiver's level of understanding of instructional topic.</p>

Unexpected Outcomes and Related Interventions

1. Patient is unable to comprehend or is unwilling to follow directions for transfer.
 - Reassess continuity and simplicity of your instruction.
 - If patient is tired or in pain, allow for rest period before transferring.
 - Consider medicating for pain before the next transfer, if indicated.
 - Consider using hydraulic lift.
2. Patient sustains injury on transfer.
 - Evaluate incident that led to injury (e.g., inadequate assessment, change in patient status, improper use of equipment, lack of assistive personnel).
 - Complete incident report according to agency policy.
3. Patient is unable to stand for time required to transfer to chair.
 - Consider use of hydraulic or power lift.

Step 3a(1) A. Two caregivers placing slide board under drawsheet and patient. B. Two caregivers placing air-assisted device under drawsheet and patient.

Step 3a(2) A. Patient rolls to opposite side, while other caregiver unrolls air-assisted device. B. Secure safety straps over patient on air-assisted device.

Table Continued

Step	Rationale
<p>Recording and Reporting</p> <ul style="list-style-type: none"> Record procedure, including pertinent observations: strength/weakness, ability to follow directions, weight-bearing ability or restrictions, balance, ability to pivot, use of assistive devices or lifts, number of personnel needed to assist, amount of assistance (muscle strength) required, and patient's tolerance to transfer. Document your evaluation of patient learning. Report transfer ability and assistance needed (including personnel and assist devices) to caregivers on next shift. Report progress or remission to rehabilitation staff (physical therapist, occupational therapist). <p>Home Care Considerations</p> <ul style="list-style-type: none"> Teach family how to use safe patient handling equipment if necessary. Teach patient and family about the importance of safety while helping patients with mobility. 	

Step 2b(1) A, Transfer of patient to stretcher using side board. B, Inflating air-assisted transfer device. C, Transfer of patient using air-assisted transfer device.

Key Points

- The musculoskeletal and nervous systems work in coordination to maintain balance, posture, and body alignment during lifting, bending, moving, and activities of daily living.
- An active lifestyle is important for maintaining and promoting health by enhancing the function of all body systems.
- Nurses intervene to increase inpatients' activity and mobility levels as soon as possible following illness or surgery to prevent deconditioning and other complications, including deep vein thrombosis.
- The use of proper transfer and lift devices and positioning techniques that use a patient's strength as well as proper ergonomics by a health care provider reduces patient injury and work-related injuries involving nurses
- Factors that will influence an exercise program include developmental stages, behavioral aspects, environmental issues, family and social supports, and cultural and ethnic influences.
- Assessment of a patient's verbal report of fatigue and weakness, ability to ambulate, and ability to perform activities of daily living, along with vital signs, determines activity tolerance.
- Helping patients plan for daily exercise, including moderate intensity aerobic activity, improves exercise tolerance.
- Ensuring the use of safe patient handling techniques to minimize manual lifting of patients reduces patient and health care provider injury and improves patient outcomes.
- Ensuring that a patient is safe during assisted ambulation requires you to use a gait belt, to stand on the correct side by the patient, and to monitor the patient's tolerance to walking.

- Comparisons with baseline measures that include pulse, blood pressure, oxygen saturation (when available), strength, fatigue, and psychological well-being determine a patient's response to transferring.

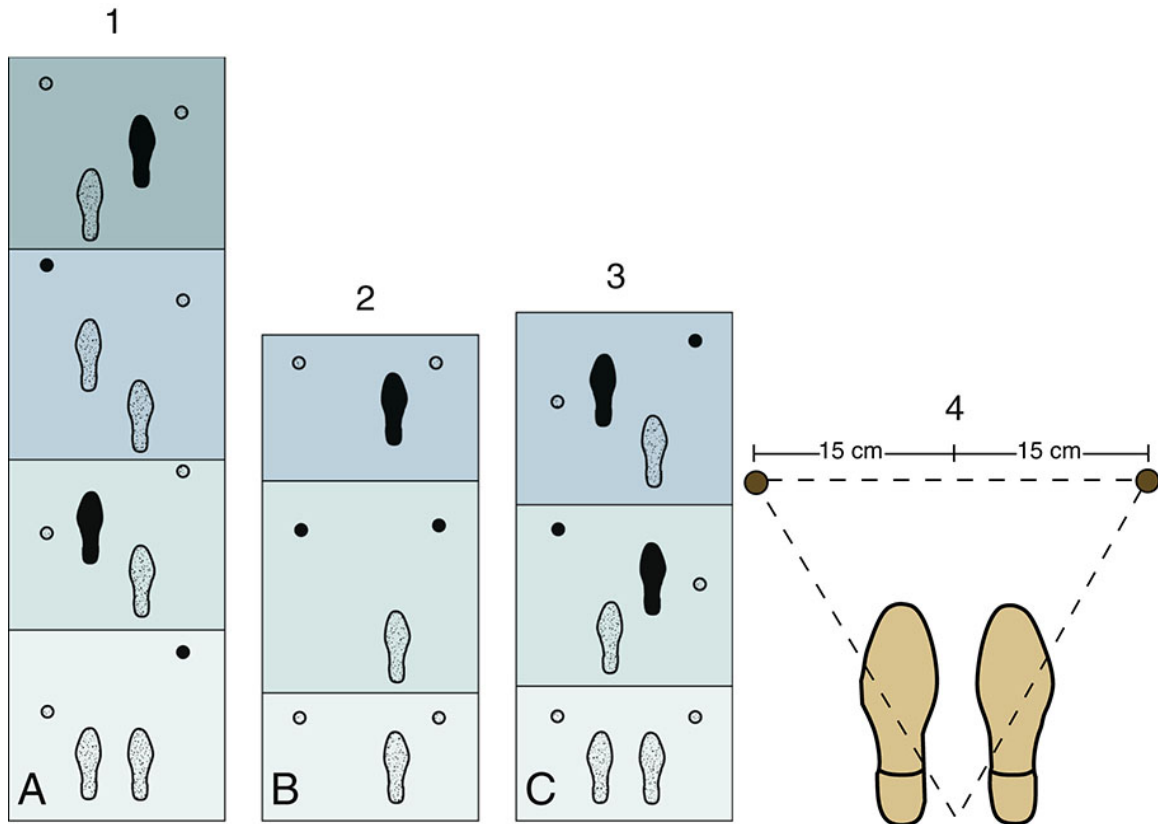

Reflective Learning

- Review your own exercise routines, and compare your activity with what is recommended by the *Physical Activity Guidelines for Americans*. What might you do differently?
- Reflect on a recent patient experience in which a patient needed to perform an activity but was unable to because of voiced complaints of pain. Describe what interventions you implemented.
- Recall any challenges you have recently had in transferring patients to a chair or stretcher, and describe the safe patient handling techniques you applied.

Review Questions

1. A nurse is instructing a patient who has decreased leg strength on the left side on how to use a cane. Which actions indicate proper cane use by the patient? (Select all that apply.)
 1. The patient keeps the cane on the left side of the body.
 2. The patient slightly leans to one side while walking.
 3. The patient keeps two points of support on the floor at all times.
 4. After the patient places the cane forward, he or she then moves the right leg forward to the cane.
 5. The patient places the cane forward 15 to 25 cm (6 to 10 inches) with each step.

2. A patient is experiencing some problems with joint stability in the right leg. The doctor has prescribed crutches for the patient to use while being allowed to bear weight only on the left leg. Which of the following gaits should the patient be taught to use?
 1. Four-point
 2. Three-point
 3. Two-point
 4. Swing-through
3. Which of the following motivates a patient to participate in an exercise program? (Select all that apply.)
 1. Providing a patient with a pamphlet on exercise
 2. Providing information to the patient when he or she is ready to change behavior
 3. Explaining the importance of exercise at the time of diagnosis of a chronic disease
 4. Having a structured daily plan that incorporates physical activity
 5. Having support from significant other to engage in exercise
4. Which of the following is the proper sequence for a four-point crutch gait?

5. The nurse is caring for an older adult in a long-term care setting. The nurse reviews the medical record to find that the patient has progressive loss of total bone mass. The patient's history and tendency to take smaller steps with feet kept closer together will most likely result in which of the following?
 1. Increase the patient's risk for falls and injuries
 2. Result in less stress on the patient's joints
 3. Decrease the amount of work required for patient movement
 4. Allow for mobility in spite of the aging effects on the patient's joints
6. Place in the correct order the steps needed (below) to transfer a patient with sufficient lower body strength to a chair.
 1. On count of three, instruct patient to stand while straightening hips and legs and keeping knees slightly flexed.

2. Assist patient to assume proper alignment in sitting position.
 3. Help patient apply stable, nonskid shoes/socks.
 4. Spread your feet apart. Flex hips and knees, aligning knees with patient's knees.
 5. Apply gait/transfer belt.
 6. Maintain patient's balance as you pivot foot farthest from chair and then help patient ease into chair.
 7. Grasp transfer belt along patient's sides.
7. Before transferring a patient from the bed to a stretcher, which assessment data does the nurse need to gather? (Select all that apply.)
1. Patient's weight
 2. Patient's activity tolerance
 3. Patient's level of mobility
 4. Recent laboratory values
 5. Nutritional intake
8. Which of the following indicates that additional assistance is needed to transfer a patient from the bed to the stretcher? (Select all that apply.)
1. The patient is 5 feet, 6 inches and weighs 120 lb.
 2. The patient speaks and understands English.
 3. The patient is returning to unit from recovery room after a procedure requiring conscious sedation.
 4. The patient has a history of being able to stand independently.
 5. The patient received analgesia for pain 30 minutes ago.
9. A 51-year-old adult comes to a medical clinic for an annual physical exam. The patient is found to be slightly overweight and reports being inactive, walking only 2 to 3 times a week with his wife after work. He has good muscle strength and

coordination of lower extremities. Which of the following recommendations from the *Physical Activity Guidelines for Americans* should the nurse suggest? Choose all that apply

1. Move more and sit less throughout the day.
 2. Participate in at least 90 minutes a week of moderate-intensity aerobic physical activity.
 3. Perform muscle-strengthening activities using light weights on 2 or more days a week.
 4. Walk at a vigorous pace with wife at least 150 minutes over five days a week.
 5. Focus on balance training.
10. Family members have asked for a meeting with the nursing staff of an assisted-living residential center to discuss the feasibility of their mother using a walker. The family is worried that her health is declining; they wonder whether she can use the walker safely. Which of the following instructions should the nurse give the family after assessing that it is safe for the woman to use a walker? (Select all that apply.)
1. A walker is useful for patients who have impaired balance.
 2. The patient uses a walker by pushing the device forward.
 3. Leaning over the walker improves the patient's balance.
 4. Walkers should not be used on stairs.
 5. If the patient has difficulty advancing the walker, a walker with wheels is an option.

Answers: 1.3, 5; 2. 2; 3.2, 4, 5; 4.1; 5.1; 6. 5, 3, 4, 7, 1, 6, 2; 7.1, 2, 3; 8.3, 5; 9. 1, 3, 4; 10. 1, 4, 5.

Immobility

OBJECTIVES

- Discuss physiological and pathological influences on mobility.
- Identify changes in physiological and psychosocial function associated with immobility.
- Assess for correct and impaired body alignment and mobility.
- Formulate appropriate nursing diagnoses for patients with impaired mobility.
- Develop individualized nursing care plans for patients with impaired mobility.
- Describe interventions for improving or maintaining patients' mobility.
- Discuss a nurse's role in the prevention of deep vein thrombosis in patients with reduced mobility.
- Evaluate patient outcomes for improving or maintaining mobility.

Optimized mobility correlates with positive patient outcomes. People are mobile for performing working and leisure tasks and for communicating emotions and nonverbal gestures. Mobility is also essential for self-defense, activities of daily living (ADLs), and recreational activities. Many functions of the body depend on mobility. Intact musculoskeletal and nervous systems are necessary for optimal physical mobility and functioning (see [Chapter 38](#)). When patients lose the ability to remain mobile and active, you apply scientific and nursing knowledge and skills to provide appropriate and competent care.

Scientific Knowledge Base

Nature of Movement

[Chapter 38](#) describes in detail the nature of movement—how muscles, bones, and the nervous system coordinate together to create movement. As a nurse you need to consider how each patient’s physical and psychological conditions affect body movement, including balance, body alignment, posture, and physical activity. Knowing how patients initiate movement and understanding your own movements require a basic understanding of the physics surrounding body mechanics. **Body mechanics** describes the coordinated efforts of the musculoskeletal and nervous systems. The body mechanics applied in the lifting and positioning techniques historically used in nursing practice often cause debilitating injuries to nurses and other health care staff ([Kanaskie and Snyder, 2018](#); [Noble and Sweeney, 2018](#)). Today nurses use evidence-based information about body alignment, balance, gravity, and friction when positioning patients, determining the risk of patient falls, and selecting the safest way to move or transfer patients ([AORN, 2018](#)) (see [Chapter 38](#)).

Implications of Impaired Mobility

Changes affecting the normal coordination of the musculoskeletal and nervous systems place patients at risk for numerous health-related problems. Understanding the physiology of these changes prepares you to better anticipate problems, implement prevention strategies, and also intervene proactively when problems do develop.

Balance and Alignment

Correct **body alignment** reduces strain on musculoskeletal structures, aids in maintaining adequate muscle tone, promotes comfort, and contributes to balance and conservation of energy. Without balance control the center of gravity is displaced. Individuals require balance for maintaining a static position (e.g., sitting) and moving (e.g., walking). Disease, injury, pain, physical development (e.g., age), and life changes (e.g., pregnancy) compromise the ability to remain balanced. Medications that cause dizziness and prolonged immobility affect balance. Impaired balance is a major threat to mobility and physical safety and contributes to a fear of falling and self-imposed activity restrictions ([Dickinson, et al., 2018](#); [Musich et al., 2018](#))

Gravity and Friction

Weight is the force exerted on a body by gravity. The force of weight is always directed downward, which is why an unbalanced object falls. Unsteady

patients fall if their center of gravity becomes unbalanced because of the gravitational pull on their weight. Patients who are at risk for being unsteady require the use of safe patient-handling techniques (see [Chapter 38](#)).

Patient lifting is now discouraged. To lift safely the lifter has to overcome the weight of the object and know its center of gravity. In symmetrical inanimate objects the center of gravity is at the exact center of the object. However, people are not geometrically perfect; their centers of gravity are usually at 55% to 57% of standing height and are in the midline, which is why choosing to use only the principles of body mechanics in lifting patients often leads to injury of a nurse or other health care professional (see [Chapter 38](#)).

Friction is a force that occurs in a direction to oppose movement. The greater the surface area of the object that is moved, the greater the friction. A larger object produces greater resistance to movement. In addition, the force exerted against the skin while the skin remains stationary and the bony structures move is called **shear**. Unfortunately a common example is when the head of a hospital bed is elevated beyond 60 degrees and gravity pulls a patient so that the bony skeleton moves toward the foot of the bed while the skin remains against the sheets. The blood vessels in the underlying tissue are stretched and damaged, resulting in impeded blood flow to the deep tissues. Ultimately pressure injuries often develop within the undermined tissue; the surface tissue appears less affected (see [Chapter 48](#)). To decrease surface area and reduce friction when patients are unable to assist with moving up in bed, use ergonomic assistive devices such as a full-body hydraulic lift. The lift moves a patient off the surface of a bed, thereby preventing friction, tearing, or shearing his or her delicate skin, and protects you and other health care staff from injury ([Noble and Sweeney, 2018](#)).

Skeletal System

The skeletal system provides attachments for muscles and ligaments and the leverage necessary for mobility. Bones are important for mobilization because they are firm, rigid, and elastic. The aging process, as well as some nutritional and disease processes, has the potential to change the components of bone, which impacts mobility.

Firmness in bones results from inorganic salts such as calcium and phosphate that are in the bone matrix. It is related to the rigidity of the bone, which is necessary to keep long bones straight, and enables bones to withstand weight-bearing. Elasticity and skeletal flexibility change with age. [Chapter 38](#) describes developmental changes in the musculoskeletal system.

The skeletal system protects vital organs (e.g., the skull around the brain and the ribs around the heart and lungs) and aids in calcium regulation. Bones store calcium and release it into the circulation as needed. Patients who have decreased calcium regulation and metabolism and who are immobile are at

risk for developing osteoporosis and **pathological fractures** (fractures caused by weakened bone tissue).

In addition, the internal structure of long bones contains bone marrow, participates in red blood cell (RBC) production, and acts as a reservoir for blood. Patients with altered bone marrow function or diminished RBC production tire easily because of reduced hemoglobin and oxygen-carrying ability. This fatigue decreases their mobility and increases the risk for falling.

Joints

The region where two or more bones attach is referred to as a joint. Each joint is classified according to its structure and degree of mobility (see [Chapter 38](#)).

Ligaments, Tendons, and Cartilage

Ligaments are white shiny, flexible bands of fibrous tissue that bind joints together, connect bones and cartilages, and aid joint flexibility and support. Tendons are white, glistening, fibrous bands of tissue that connect muscle to bone and are strong, flexible, and inelastic. Cartilage is nonvascular (without blood vessels) supporting connective tissue located chiefly in the joints and thorax, trachea, larynx, nose, and ear (see [Chapter 38](#)). The characteristics of the cartilage change with the aging process.

Skeletal Muscle

Movement of bones and joints involves active processes that are carefully integrated to achieve coordination. Skeletal muscles, because of their ability to contract and relax, are the working elements of movement. Anatomical structure and attachment to the skeleton enhance contractile elements of the skeletal muscle (see [Chapter 38](#)).

Nervous System

The nervous system regulates movement and posture. The precentral gyrus, or motor strip, is the major voluntary motor area and is in the cerebral cortex. A majority of motor fibers descend from the motor strip and cross at the level of the medulla. Movement is impaired by disorders that alter neurotransmitter production, transfer of impulses from the nerve to the muscle, or activation of muscle activity.

Pathological Influences on Mobility

Many pathological conditions affect mobility. Although a complete description of each is beyond the scope of this chapter, an overview of five pathological influences is presented.

Postural Abnormalities

Congenital or acquired postural abnormalities affect the efficiency of the musculoskeletal system and body alignment, balance, and appearance. Postural abnormalities can cause pain, impair alignment or mobility, or both. Knowledge about the characteristics, causes, and treatment of common postural abnormalities is necessary for safe lifting, transfer, and positioning (Table 39.1). Some postural abnormalities limit ROM. Nurses intervene to maintain maximum ROM in unaffected joints and often collaborate with physical therapists to design interventions to strengthen affected muscles and joints, improve the patient’s posture, and adequately use affected and unaffected muscle groups. Referral to and/or collaboration with a physical therapist enhances your interventions for a patient with postural abnormalities.

TABLE 39.1

Postural Abnormalities

Abnormality	Description	Cause	Possible Treatments ^a (McCance and Huether, 2017)
Torticollis	Inclining head to affected side, in which sternocleidomastoid muscle is contracted	Congenital or acquired condition	Surgery, heat, support, or immobilization, depending on cause and severity; gentle ROM
Lordosis	Exaggeration of anterior convex curve of lumbar spine	Congenital condition; temporary condition (e.g., pregnancy)	Spine-stretching exercises (based on cause)
Kyphosis	Increased convexity in curvature of thoracic spine	Congenital condition; rickets, osteoporosis; tuberculosis of spine	Spine-stretching exercises, sleeping without pillows, using bed board, bracing, surgical spinal fusion (based on cause and severity)
Scoliosis	Lateral S- or C-shaped spinal column with vertebral rotation, unequal heights of hips and shoulders	Sometimes a consequence of numerous congenital, connective tissue, and neuromuscular disorders	Approximately half of children with scoliosis require surgery Nonsurgical treatment is with braces and exercises
Congenital hip dysplasia	Hip instability with limited abduction of hips and occasionally adduction contractures (head of femur does not articulate with acetabulum because of abnormal shallowness of acetabulum)	Congenital condition (more common with breech deliveries)	Maintenance of continuous abduction of thigh so head of femur presses into center of acetabulum; abduction splints, casting, surgery
Knock-knee (genu valgum)	Legs curved inward so knees come together as person walks	Congenital condition; rickets	Knee braces; surgery if not corrected by growth
Bowlegs (genu varum)	One or both legs bent outward at knee, which is normal until 2 to 3 years of age	Congenital condition; rickets	Slowing rate of curving if not corrected by growth; with rickets, increase of vitamin D, calcium, and phosphorus intake to normal ranges
Clubfoot	95%: Medial deviation and plantar flexion of foot (equinovarus) 5%: Lateral deviation and dorsiflexion (calcaneovalgus)	Congenital condition	Casts, splints such as Denis Browne splint, and surgery (based on degree and rigidity of deformity)
Footdrop	Inability to dorsiflex and invert foot because of peroneal nerve damage	Congenital condition; trauma; improper position of immobilized patient	None (cannot be corrected); prevention through physical therapy; bracing with ankle-foot orthotic (AFO)

ROM, Range of motion.

^a Severity of condition and cause dictate treatment, which is individualized to the patient’s needs.

Muscle Abnormalities

Diseases lead to numerous alterations in musculoskeletal function. For example, the muscular dystrophies are a group of familial disorders that cause degeneration of skeletal muscle fibers. They are the most prevalent of the muscle diseases in childhood. Patients with muscular dystrophy experience progressive, symmetrical weakness and wasting of skeletal muscle groups, with increasing disability and deformity (McCance and Huether, 2017).

Damage to the Central Nervous System

Damage to any component of the central nervous system that regulates voluntary movement results in impaired body alignment, balance, and mobility. Trauma from a head injury, ischemia from a stroke (cerebrovascular accident [CVA]), or bacterial infection such as meningitis can damage the cerebellum or the motor strip in the cerebral cortex. Damage to the cerebellum causes problems with balance, and motor impairment is directly related to the amount of destruction of the motor strip. For example, a person with a right-sided cerebral hemorrhage with necrosis has destruction of the right motor strip that results in left-sided hemiplegia. Trauma to the spinal cord also impairs mobility. For example, a complete transection of the spinal cord results in a bilateral loss of voluntary motor control below the level of the trauma because motor fibers are cut. Neurodegenerative disorders also have a negative impact on mobility. For example, symptoms of Parkinson's disease may include rigidity, tremors, and postural instability (Shin et al., 2017).

Direct Trauma to the Musculoskeletal System

Direct trauma to the musculoskeletal system results in bruises, contusions, tears, sprains, and fractures. A fracture is a disruption of bone tissue continuity. Fractures most commonly result from direct external trauma, but they also occur as a consequence of some deformity of the bone (e.g., pathological fractures of osteoporosis, Paget's disease, metastatic cancer, or osteogenesis imperfecta). Young children are usually able to form new bone more easily than adults and, as a result, have few complications after a fracture. Treatment often includes positioning the fractured bone in proper alignment and immobilizing it to promote healing and restore function. Even this temporary immobilization results in some **muscle atrophy** loss of muscle tone, and joint stiffness.

Joint Disease

One of the most common pathological influences on mobility comes in the form of joint disease. As the US population ages, the prevalence of arthritis is expected to increase to 25% of the population by the year 2040 (Hootman et al., 2016). Osteoarthritis, loss of the articular cartilage, is the most common

noninflammatory arthritis, while rheumatoid arthritis is an example of a noninfectious inflammatory arthritis (McCance and Huether, 2017). In the acute care setting, nurses may care for patients with a variety of conditions who also have a history of joint disease. In addition, nurses care for medical or surgical admissions related to a specific joint disorder. An example of this is the patient admitted for a total joint replacement.

REFLECT NOW

As a registered nurse, you are responsible for completing a thorough admission assessment on each of your patients. Given the prevalence of comorbid issues that have the potential to impact mobility, what are five questions you would ask as you begin to explore mobility and immobility issues with your patient?

Nursing Knowledge Base

Fully understanding movement and mobility requires more than an overview of movement and the physiology and regulation of movement by the musculoskeletal and nervous systems. You need to know how to apply these scientific principles in the clinical setting to determine the safest way to move patients and to understand the effect of immobility on the physiological, psychosocial, and developmental aspects of patient care.

The Effects of Immobility

To determine how to move patients safely, you will assess their ability to move. **Mobility** refers to a person's ability to move about freely, and **immobility** refers to the inability to do so. Think of mobility as a continuum, with mobility on one end, immobility on the other, and varying degrees of partial immobility between the end points. Some patients move back and forth between mobility and immobility, but for others immobility is absolute and continues indefinitely. The terms *bed rest* and *impaired physical mobility* are used frequently when discussing patients on the mobility-immobility continuum.

Bed rest is an intervention that restricts patients to bed for therapeutic reasons and is sometimes prescribed for selected patients. The therapeutic reasons for bed rest include decreasing the oxygen needs of the body, reducing cardiac workload and pain, and allowing a debilitated patient to rest. Bed rest has many different interpretations among health care professionals. The duration of bed rest depends on the illness or injury and a patient's prior state of health.

The effects of muscular deconditioning associated with lack of physical activity are often apparent in a matter of days. The individual of average weight and height without a chronic illness on bed rest loses muscle strength from baseline levels at a rate of 3% a day (McCance and Huether, 2017). Vulnerable populations, such as older adults, are especially at risk for loss of function during acute illness and hospitalization (Wald et al., 2019). Immobility also is associated with cardiovascular, skeletal, and other organ changes. The term *disuse atrophy* describes the tendency of cells and tissue to reduce in size and function in response to prolonged inactivity resulting from bed rest, trauma, casting of a body part, or local nerve damage (McCance and Huether, 2017).

Periods of immobility due to disability or injury or prolonged bed rest during hospitalization cause major physiological, psychological, and social effects. These effects are gradual or immediate and vary from patient to patient. The greater the extent and the longer the duration of immobility, the more pronounced the consequences. The patient with complete mobility restrictions is continually at risk for the hazards of immobility. When possible, it is

imperative that patients, especially older adults, have limited bed rest and that their activity is more than bed to chair. Loss of walking independence increases hospital stays, need for rehabilitation services, or nursing home placement. In addition, the deconditioning related to reduced walking increases the risk for patient falls (AAN, 2015; Krupp et al., 2018, Kruschke and Butcher, 2017).

Systemic Effects

All body systems work more efficiently with some form of movement. When there is an alteration in mobility, each body system is at risk for impairment. The severity of the impairment depends on a patient's overall health, degree and length of immobility, and age. For example, older adults with chronic illnesses develop pronounced effects of immobility more quickly than do younger patients with the same immobility problem.

Metabolic Changes

Changes in mobility alter endocrine metabolism, calcium resorption, and functioning of the gastrointestinal (GI) system. The endocrine system, composed of hormone-secreting glands, maintains and regulates vital functions such as (1) response to stress and injury; (2) growth and development; (3) reproduction; (4) maintenance of the internal environment; and (5) energy production, use, and storage.

When injury or stress occurs, the endocrine system triggers a series of responses aimed at maintaining blood pressure and preserving life. It is important in maintaining homeostasis. Tissues and cells live in an internal environment that the endocrine system helps regulate through maintenance of sodium, potassium, water, and acid-base balance. It also regulates energy metabolism. Thyroid hormone increases the basal metabolic rate (BMR), and energy becomes available to cells through the integrated action of GI and pancreatic hormones (McCance and Huether, 2017).

Immobility disrupts normal metabolic processes, decreasing the metabolic rate; altering the metabolism of carbohydrates, fats, and proteins; causing fluid, electrolyte, and calcium imbalances; and causing GI disturbances such as decreased appetite and slowing of peristalsis. However, in the presence of an infectious process, immobilized patients often have an increased BMR as a result of fever or wound healing because these increase cellular oxygen requirements (McCance and Huether, 2017).

A deficiency in calories and protein is characteristic of patients with a decreased appetite secondary to immobility. The body is constantly synthesizing proteins and breaking them down into amino acids to form other proteins (see Chapter 45). When the patient is immobile, his or her body often excretes more nitrogen (the end product of amino acid breakdown) than it ingests in proteins, resulting in **negative nitrogen balance**. Weight loss,

decreased muscle mass, and weakness result from tissue catabolism (tissue breakdown) (McCance and Huether, 2017).

Another metabolic change associated with immobility is calcium resorption (loss) from bones. Immobility causes the release of calcium into the circulation. Normally the kidneys excrete the excess calcium. However, if they are unable to respond appropriately, hypercalcemia results. Pathological fractures may occur if calcium resorption continues as a patient remains on bed rest or continues to be immobile (McCance and Huether, 2017).

Impairments of GI functioning caused by decreased mobility vary. Difficulty in passing stools (constipation) is a common symptom. A condition known as pseudodiarrhea often results from a fecal impaction (accumulation of hardened feces). This finding is not normal diarrhea, but rather liquid stool passing around the area of fecal impaction (see Chapter 47). Left untreated, fecal impaction results in a mechanical bowel obstruction that partly or completely occludes the intestinal lumen, blocking normal propulsion of liquid and gas. The resulting fluid in the intestine produces distention and increases intraluminal pressure. Over time intestinal function becomes depressed, dehydration occurs, absorption ceases, and fluid and electrolyte disturbances worsen.

Respiratory Changes

Lack of movement and exercise places patients at risk for respiratory complications. Patients who are immobile are at high risk for developing pulmonary **atelectasis** (collapse of alveoli) and **hypostatic pneumonia** (inflammation of the lung from stasis or pooling of secretions). Both decreased oxygenation and prolonged recovery add to patients' discomfort (Lewis et al., 2017). In atelectasis secretions block a bronchiole or a bronchus, and the distal lung tissue (alveoli) collapses as the existing air is absorbed, producing hypoventilation. The site of the blockage affects the severity of atelectasis. Sometimes an entire lung lobe or a whole lung collapses. At some point in the development of these complications, there is a proportional decline in the patient's ability to cough productively. Ultimately the distribution of mucus in the bronchi increases, particularly when the patient is in the supine, prone, or lateral position. Mucus accumulates in the dependent regions of the airways (Fig. 39.1). Hypostatic pneumonia frequently results because mucus is an excellent place for bacteria to grow.

FIG. 39.1 Pooling of secretions in dependent regions of lungs in supine position.

Cardiovascular Changes

Immobilization also affects the cardiovascular system, frequently resulting in orthostatic hypotension, increased cardiac workload, and thrombus formation. **Orthostatic hypotension** is a drop in systolic pressure by at least 20 mm Hg or a drop in diastolic pressure by at least 10 mm Hg within 3 minutes of rising to an upright position (Shibao et al., 2013; Ball et al., 2019). Patients also experience symptoms of dizziness, light-headedness, nausea, tachycardia, pallor, or fainting when changing from the supine to standing position (Ball et al., 2019). In the immobilized patient decreased circulating fluid volume,

pooling of blood in the lower extremities, and decreased autonomic response occur. These are especially evident in the older adult.

As the workload of the heart increases, so does its oxygen consumption. Therefore the heart works harder and less efficiently during periods of prolonged rest. As immobilization increases, cardiac output falls, further decreasing cardiac efficiency and increasing workload.

Patients who are immobile are also at risk for thrombus formation. A **thrombus** is an accumulation of platelets, fibrin, clotting factors, and the cellular elements of the blood attached to the interior wall of a vein or artery, which sometimes occludes the lumen of the vessel ([Fig. 39.2](#)). Three factors contribute to venous thrombus formation: (1) damage to the vessel wall (e.g., injury during surgical procedures), (2) alterations of blood flow (e.g., slow blood flow in calf veins associated with bed rest), and (3) alterations in blood constituents (e.g., a change in clotting factors or increased platelet activity). These three factors are often referred to as *Virchow's triad* ([McCance and Huether, 2017](#)). As a nurse you will practice in numerous situations in which deep vein thrombosis (DVT) must be prevented, especially during perioperative care (see [Chapter 50](#)).

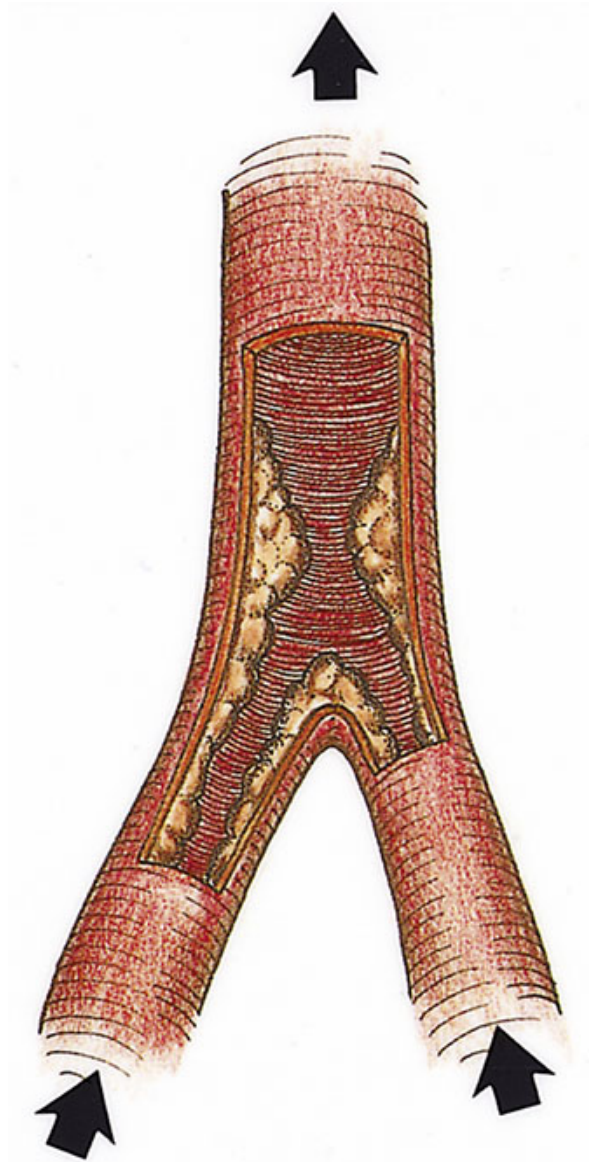

FIG. 39.2 Thrombus formation in a vessel.

Musculoskeletal Changes

Immobility causes permanent or temporary impairment of musculoskeletal structures. Because of protein breakdown, a patient loses lean body mass during immobility. The reduced muscle mass makes it difficult for patients to sustain activity without increased fatigue. If immobility continues and the patient does not exercise, there is further loss of muscle mass. Prolonged immobility often leads to disuse atrophy. Loss of endurance, decreased muscle mass and strength, and joint instability place patients at risk for falls (see [Chapter 27](#)).

Immobilization also causes two skeletal changes: impaired calcium metabolism and joint abnormalities. Because immobilization results in bone resorption, the bone tissue is less dense or atrophied, and **disuse osteoporosis** results. When disuse osteoporosis occurs, a patient is at risk for pathological fractures.

Osteoporosis is a major health concern in this country. By 2025, it is expected to be responsible for approximately 3 million fractures, with the lifetime risk of an osteoporosis fracture at 50% for women and 20% to 25% for men ([Gupta et al., 2018](#)). Although primary osteoporosis is different in origin from the osteoporosis that results from immobility, it is imperative that nurses recognize that immobilized patients are at high risk for accelerated bone loss if they have primary osteoporosis.

Immobility can lead to joint contractures. A **joint contracture** is an abnormal and possibly permanent condition characterized by fixation of a joint. It is important to note that flexor muscles for joints are stronger than extensor muscles and therefore contribute to the formation of contractures. Disuse, atrophy, and shortening of the muscle fibers cause joint contractures. When a contracture occurs, the joint cannot achieve full ROM. Contractures sometimes leave a joint or joints in a nonfunctional position, as seen in patients who are permanently curled in a fetal position. Early prevention of contractures is essential ([Box 39.1](#)) ([Meyers, 2017](#)).

Box 39.1 Evidence-Based Practice Patient Contractures and Treatments to Reduce Future Contractures for At-Risk Patients

PICOT Question: Can the use of early correct positioning, range-of-motion (ROM) exercises, and mechanical treatment modalities such as dynamic and static splints reduce joint contractures in the lower extremities in patients with at-risk conditions compared with patients who do not have any early intervention?

Evidence Summary

Joint contractures are common preventable disorders that can result in significant long-term morbidity and reduced patient independence. Contracture is the shortening of the connective tissue and is an abnormal and possibly permanent condition characterized by decreased range of joint motion and/or fixation of the joint. Contractures occur following prolonged joint positioning (immobility), neurological disorders, and surgical joint manipulation (Odgaard et al., 2018). Evidence shows that early prevention of contractures is essential (Winterton and Baldwin, 2018). These researchers found nonsurgical approaches such as antispasmodic medications, Botox

administration, serial casting, splinting, and physical and occupational therapies such as range-of-motion (ROM) exercises are helpful in preventing and minimizing this complication of impaired mobility.

Application to Nursing Practice

- In conjunction with an interprofessional health care team, develop an early intervention protocol using prescribed positioning, range-of-motion exercises, and/or splints to reduce the risk for contracture formation (Winterton and Baldwin, 2018).
- Health care agencies need to provide equipment (e.g., splints) and appropriate education for staff to reduce the risk of contractures.
- A collaborative plan of care, including a discharge plan, with a contracture prevention and muscle strengthening protocol must be developed on patient admission.
- Use positioning, ROM exercises, and ROM devices according to the individualized need of the patient and as ordered (Winterton and Baldwin, 2018).

One common and debilitating contracture is footdrop ([Fig. 39.3](#)). When **footdrop** occurs, the foot is permanently fixed in plantar flexion. Ambulation is difficult with the foot in this position because the patient cannot dorsiflex the foot. A patient with footdrop is unable to lift the toes off the ground and is at risk of stumbling. Patients who have had CVAs with resulting right- or left-sided paralysis (hemiplegia) are at risk for footdrop.

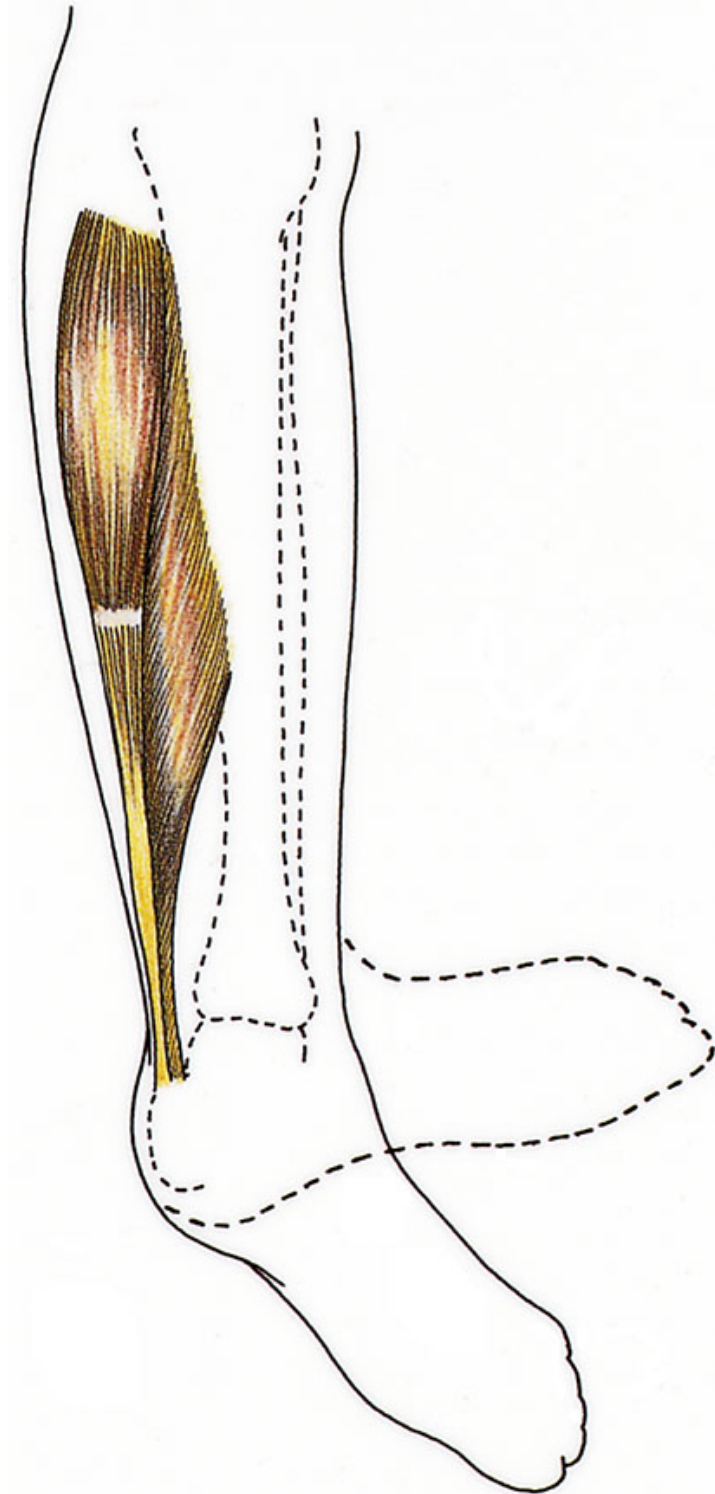

FIG. 39.3 Footdrop. Ankle is fixed in plantar flexion. Normally ankle is able to flex (*dotted line*), which eases walking.

Urinary Elimination Changes

Immobility alters a patient's urinary elimination. In the upright position urine flows out of the renal pelvis and into the ureters and bladder because of gravitational forces. When a patient is recumbent or flat, the kidneys and ureters move toward a more level plane. Urine formed by the kidney needs to enter the bladder unaided by gravity. Because the peristaltic contractions of the ureters are insufficient to overcome gravity, the renal pelvis fills before urine enters the ureters. This condition is called **urinary stasis** and increases the risk of urinary tract infection (UTI) and renal calculi (see [Chapter 46](#)). **Renal calculi** are calcium stones that lodge in the renal pelvis or pass through the ureters. Immobilized patients are at risk for calculi because they frequently have hypercalcemia ([McCance & Huether, 2017](#)).

As the period of immobility continues, fluid intake often diminishes. When combined with other problems such as fever, the risk for dehydration increases. As a result, urinary output declines on or about the fifth or sixth day after immobilization, and the urine becomes concentrated. Concentrated urine increases the risk for calculi formation and infection. Another cause of UTI in immobilized patients is the use of an indwelling urinary catheter (see [Chapter 46](#)).

Integumentary Changes

The changes in metabolism that accompany immobility add to the harmful effect of pressure on the skin in immobilized patients. This makes immobility a major risk factor for pressure injuries. Any break in the integrity of the skin is difficult to heal. Preventing a pressure injury is much less expensive than treating one; therefore preventive nursing interventions are imperative ([Barnes-Daly, et al, 2018](#); [Zubkoff et al., 2017](#)).

A **pressure injury** is an impairment of the skin as a result of prolonged ischemia (decreased blood supply) in tissues (see [Chapter 48](#)). It is characterized initially by inflammation and usually forms over a bony prominence. Ischemia develops when the pressure on the skin is greater than the pressure inside the small peripheral blood vessels supplying blood to the skin ([AHRQ, n.d.](#)).

Tissue metabolism depends on the supply of oxygen and nutrients to and the elimination of metabolic wastes from the blood. Pressure affects cellular metabolism by decreasing or totally eliminating tissue circulation. When a patient lies in bed or sits in a chair, the weight of the body is on bony prominences. The longer the pressure is applied, the longer is the period of ischemia and therefore the greater the risk of skin breakdown ([Stephens et al., 2018](#)). The prevalence of pressure injuries is highest in long-term care facilities, whereas hospital-acquired pressure injuries are the highest in adult intensive care units ([Ayello, 2017](#)).

Psychosocial Effects

Immobilization often leads to emotional and behavioral responses, sensory alterations, and changes in coping. Illnesses that result in limited or impaired mobility can cause social isolation and loneliness (Musich et al., 2018). Every patient responds to immobility differently.

Patients with restricted mobility may have some depression. Depression is an affective disorder characterized by exaggerated feelings of sadness, melancholy, dejection, worthlessness, emptiness, and hopelessness out of proportion to reality. It results from worrying about present and future levels of health, finances, and family needs. Because immobilization removes a patient from a daily routine, he or she has more time to worry about disability. Worrying quickly increases a patient's depression, causing withdrawal. Withdrawn patients often do not want to participate in their own care.

Developmental Changes

Immobility often leads to developmental changes in the very young and in older adults. The immobilized young or middle-age adult who has been healthy experiences few, if any, developmental changes. However, there are exceptions. For example, a mother with complications following birth has to go on bed rest and as a result cannot interact with her newborn as expected.

Infants, Toddlers, and Preschoolers

As a baby grows, musculoskeletal development permits support of weight for standing and walking. Posture is awkward because the head and upper trunk are carried forward. Because body weight is not distributed evenly along a line of gravity, posture is normally off balance, and falls occur often. When an infant, toddler, or preschooler becomes immobilized, it is usually because of trauma or the need to correct a congenital skeletal abnormality. Prolonged immobilization delays a child's gross motor skills, intellectual development, and musculoskeletal development.

Adolescents

The adolescent stage usually begins with a tremendous increase in growth (see [Chapter 12](#)). When the activity level is reduced because of trauma, illness, or surgery, the adolescent is often behind peers in gaining independence and accomplishing certain skills, such as obtaining a driver's license. Social isolation is a concern for this age-group when immobilization occurs.

Adults

An adult who has correct posture and body alignment feels good, looks good, and generally appears self-confident. The healthy adult also has the necessary musculoskeletal development and coordination to carry out ADLs (see [Chapter 13](#)). When periods of prolonged immobility occur, all physiological systems are at risk. In addition, the role of the adult often changes with regard to the family or social structure. Some adults lose their jobs, which affects their self-concept (see [Chapter 33](#)).

Older Adults

A progressive loss of total bone mass in older adults results from decreased physical activity, hormonal changes, and bone resorption. The effect of bone loss is weaker bones. Older adults often walk more slowly, take smaller steps, and appear less coordinated. Prescribed medications often alter their sense of balance or affect their blood pressure when they change position too quickly, increasing their risk for falls and injuries (see [Chapter 27](#)). The outcomes of a fall include not only possible injury but also hospitalization, loss of independence, psychological effects, and quite possibly death ([Hallford et al., 2017](#); [Musich et al., 2018](#); [Wald et al., 2019](#)).

Older adults often experience functional status changes secondary to hospitalization and altered mobility status ([Box 39.2](#)). Immobilization of older adults increases their physical dependence on others and accelerates functional losses ([Chase et al., 2018](#)). Immobilization of some older adults results from degenerative diseases, neurological trauma, or chronic illness. In some it occurs gradually and progressively; in others, especially those who have had a stroke, it is sudden. When providing nursing care for an older adult, encourage the patient to perform as many self-care activities as possible, thereby maintaining the highest level of mobility. Sometimes nurses inadvertently contribute to a patient's immobility by providing unnecessary help with activities such as bathing and transferring.

Box 39.2 Focus on Older Adults **Functional Decline in Hospitalized Immobile Older Adults**

For many older adults, admission to a hospital often results in functional decline despite the treatment for which they were admitted. Some older adults have problems related to mobility and quickly regress to a dependent state ([Chase et al., 2018](#)). Usual aging is associated with decreased muscle strength and aerobic capacity, which become exacerbated if a patient's nutritional state is poor.

- A nutritional assessment needs to be included in the plan of care for the older adult experiencing immobility.
- Anorexia and insufficient assistance with eating lead to malnutrition, which contributes to the known problems associated with immobility.
- Improved nutrition increases patient's ability to perform physical reconditioning exercises (Kruschke and Butcher, 2017).
- There is a direct relationship between the success of older adults' rehabilitation and their nutritional status (Barbour et al., 2017).

REFLECT NOW

Three patients are being admitted to an acute care hospital for surgery on their right hip. Patient #1 is a 9-month-old male, patient #2 is a 44-year-old male, and patient #3 is a 75-year-old female. Using foundational nursing knowledge, compare and contrast developmental needs, effects of immobility, and how their plans of care may differ.

◆ Nursing Process

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care. Patients with preexisting mobility impairments and those who are at risk for immobility will greatly benefit from a care plan that improves the patient's functional status, promotes self-care, maintains psychological well-being, and reduces the hazards of immobility.

◆ Assessment

During assessment, consider your patient's normal mobility status, the effects of any diseases or conditions on mobility, and the patient's risks for mobility alterations as a result of treatments ([Fig. 39.4](#)). Critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care.

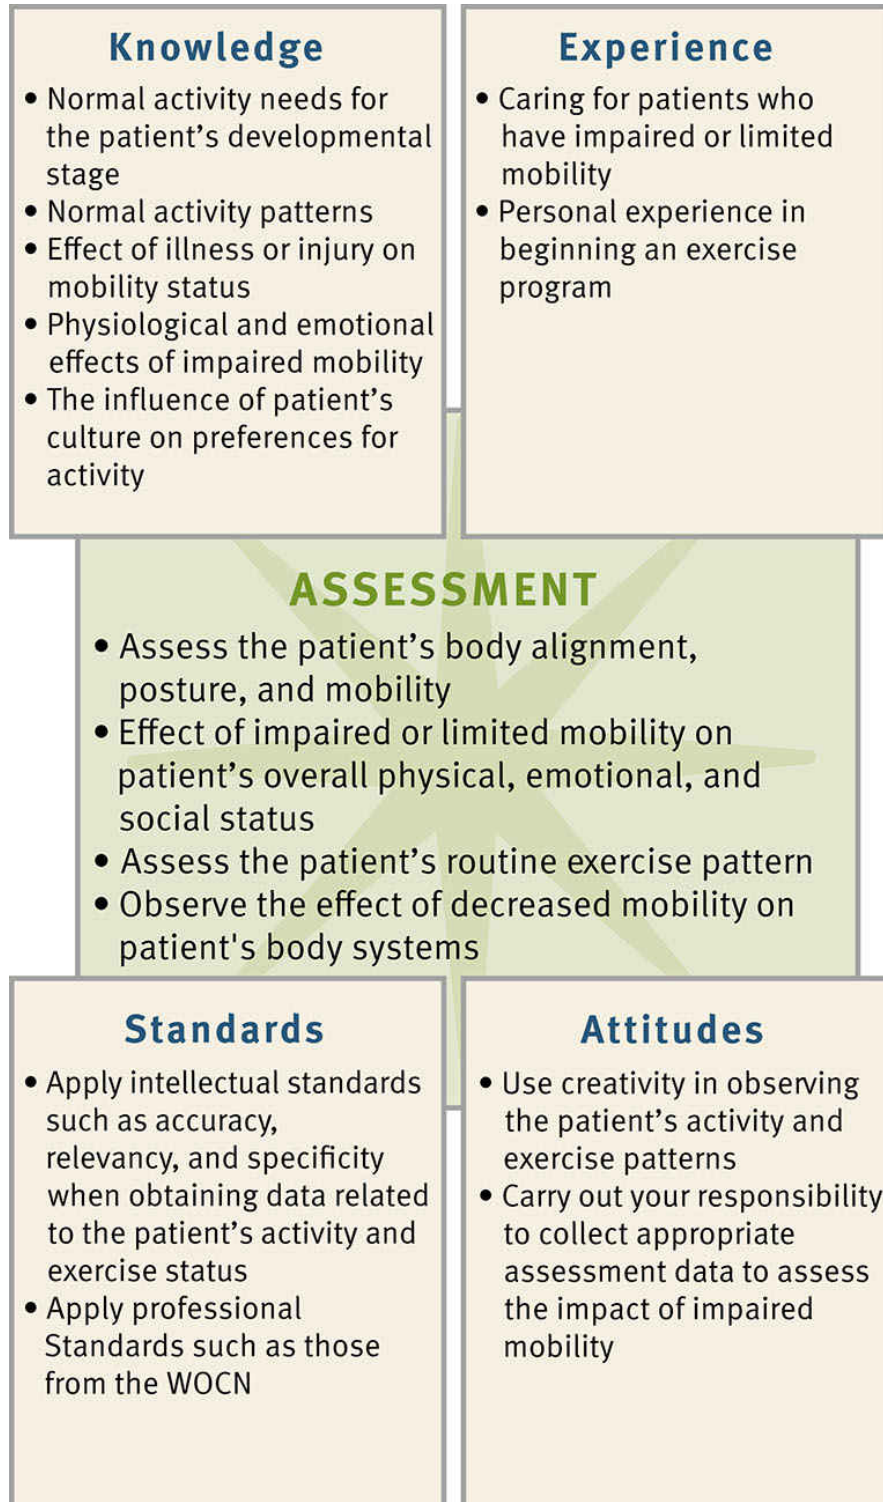

FIG. 39.4 Critical thinking model for assessing impaired mobility. WOCN, *Wound Ostomy and Continent Nurses Society*.

Through the Patient’s Eyes

Usually you will assess a patient's degree of mobility and immobility during the history interview and physical examination ([Box 39.3](#)). Keep in mind that the patient is a full partner in providing information and designing the plan of care. It is important to understand how any limitations in mobility are perceived by the patient, as well as his or her expectations of care. Does the patient understand whether a particular disease or condition will likely cause permanent disability? Has the patient had a disability for an extended period, and is he or she well adapted to the use of an assist device or even a wheelchair? Is the limitation in mobility sudden and unexpected, causing the patient to be fearful or full of questions? Always convey respect for the patient's preferences, values, and needs during assessment and when designing a plan of care ([Ackley and Ladwig, 2017](#)).

Box 39.3 Nursing Assessment Questions

Mobility

- Describe any changes you've noticed in your ability to walk and take care of yourself on a daily basis.
- Have you experienced any stiffness, swelling of a joint, muscle or joint pain, or difficulty with moving? If so, describe how this affects your movement and daily activities.
- Have you noticed any shortness of breath; if so, does it worsen when walking?

Immobility

- Describe your normal daily activity. Has this changed recently?
- How have your appetite and diet changed since you've had problems moving around?
- Describe what you eat in a normal day.
- Does your day seem very long?
- Describe for me a typical night's sleep.
- Have you noticed any places on your skin that are reddened or have any open sores?
- Describe any changes you've noticed in urinating and/or having bowel movements.

Mobility

When unsure of a patient's abilities, begin assessment of mobility with the patient in the most supported position, and move to higher levels according to his or her tolerance. Generally the assessment of movement starts while the patient is lying and proceeds to assessing sitting positions in bed, transfers to chair, and finally walking. This helps to promote the patient's safety.

When a patient is immobile, assessment focuses on the status of the musculoskeletal system and includes ROM, muscle strength, activity tolerance, and posture and alignment. **Range of motion (ROM)** is the maximum amount of movement available at a joint in one of the three planes of the body: sagittal, transverse, or frontal (Fig. 39.5). The sagittal plane is a line that passes through the body from front to back, dividing it into a left and right side. The frontal plane passes through the body from side to side and divides it into front and back. The transverse plane is a horizontal line that divides the body into upper and lower portions.

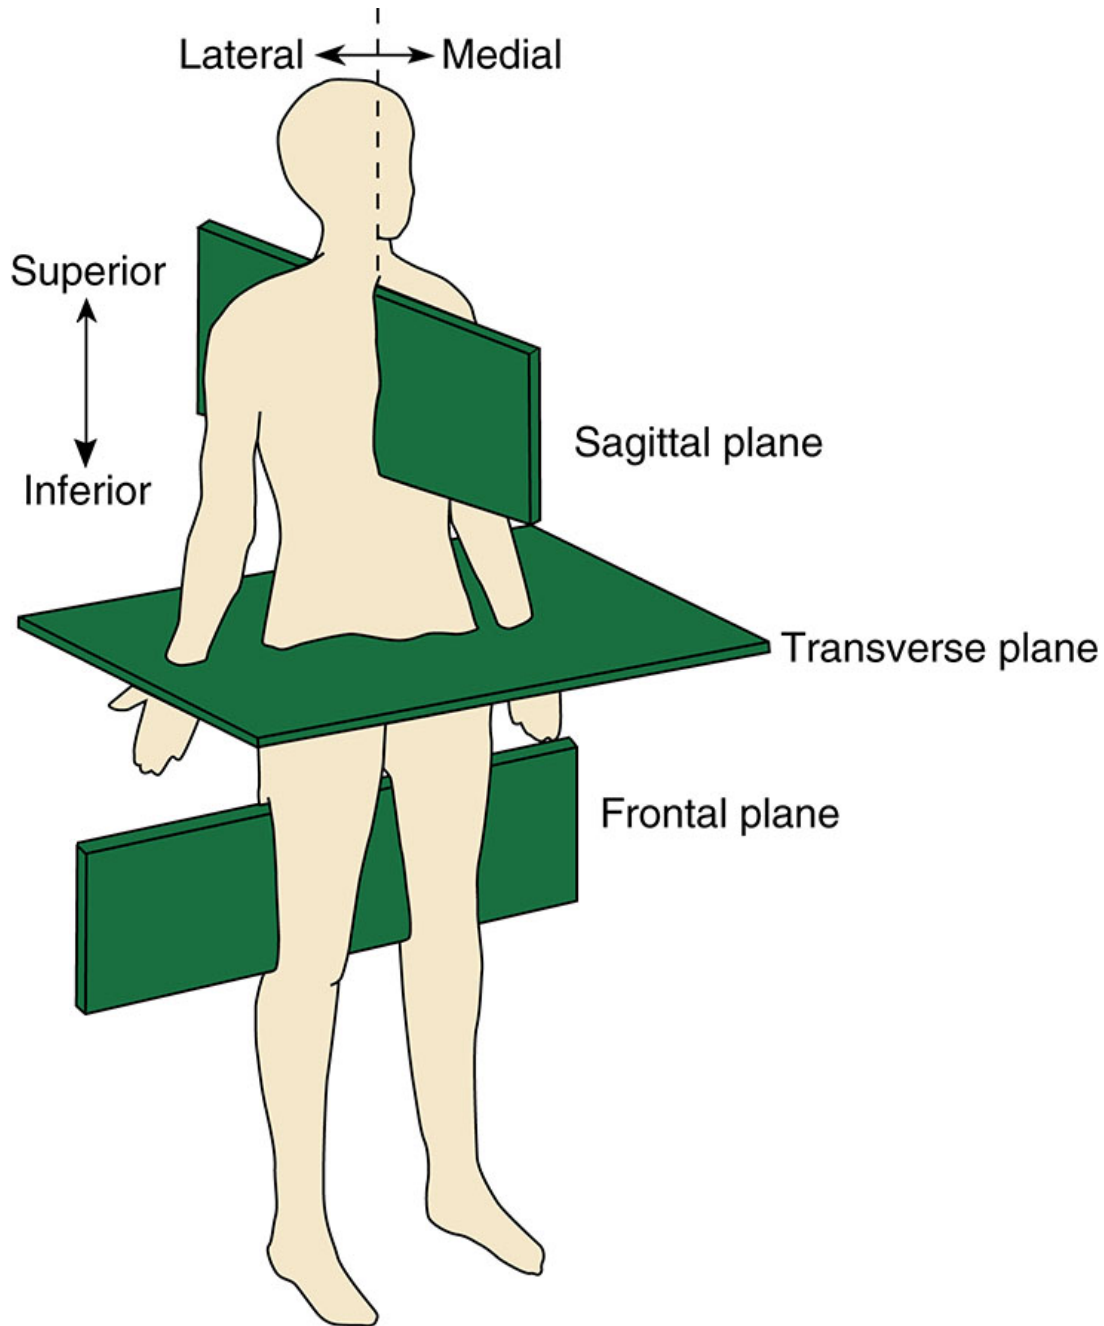

FIG. 39.5 Planes of body.

Ligaments, muscles, and the nature of the joint limit joint mobility in each of the planes. However, some joint movements are specific to each plane. In the sagittal plane, movements are flexion and extension (e.g., fingers and elbows), dorsiflexion and plantar flexion (feet), and extension (e.g., hip). In the frontal plane, movements are abduction and adduction (e.g., arms and legs) and eversion and inversion (feet). In the transverse plane, movements are pronation and supination (hands) and internal and external rotation (hips).

Assessment of range of motion (ROM) is an important baseline measurement that compares and evaluates whether loss in joint mobility is developing or has occurred. Refer to [Table 39.2](#) for normal joint ROM to compare with findings when you assess a patient's ROM. Be sure to assess all joints in the body. Ask questions about and physically examine a patient for stiffness, swelling, pain, or limited movement, and compare sides for unequal movement (see [Chapter 30](#)). If a patient has restricted ROM, your information will help you collaborate with physical therapists to select the type of ROM exercise a patient is able to perform, so you can reduce risk of complications ([Table 39.3](#)).

TABLE 39.2**Range-of-Motion Exercises**

Body Part	Type of Joint	Type of Movement	Range (Degrees)	Primary Muscles
Neck, cervical spine	Pivotal	<i>Flexion:</i> Bring chin to rest on chest.	45	Sternocleidomastoid
		<i>Extension:</i> Return head to erect position.	45	Trapezius
		<i>Hyperextension:</i> Bend head back as far as possible.	10	Trapezius
		<i>Lateral flexion:</i> Tilt head as far as possible toward each shoulder.	40-45	Sternocleidomastoid
		<i>Rotation:</i> Turn head as far as possible in circular movement.	180	Sternocleidomastoid, trapezius
Shoulder	Ball and socket	<i>Flexion:</i> Raise arm from side position forward to position above head.	45-180	Coracobrachialis, biceps brachii, deltoid, pectoralis major
		<i>Extension:</i> Return arm to position at side of body.	180	Latissimus dorsi, teres major, triceps brachii
		<i>Shoulder extension:</i> Move arm behind body, keeping elbow straight.	0-60	Latissimus dorsi, teres major, deltoid
		<i>Internal rotation:</i> With elbow flexed and shoulder abducted, rotate shoulder by moving arm until thumb is turned inward and toward back.	70-90	Pectoralis major, latissimus dorsi, teres major, subscapularis
		<i>External rotation:</i> With elbow flexed and shoulder abducted, move arm until thumb is upward and lateral to head.	90	Infraspinatus, teres major, deltoid
		<i>Circumduction:</i> Move arm in full circle. (Circumduction is combination of all movements of ball-and-socket joint.)	360	Deltoid, coracobrachialis, latissimus dorsi, teres major
Elbow	Hinge	<i>Flexion:</i> Bend elbow so lower arm moves toward its shoulder joint and hand is level with shoulder.	150	Biceps brachii, brachialis, brachioradialis
		<i>Extension:</i> Straighten elbow by lowering hand.	150	Triceps brachii
Forearm	Pivotal	<i>Supination:</i> Turn lower arm and hand so palm is up.	70-90	Supinator, biceps brachii
		<i>Pronation:</i> Turn lower arm so palm is down.	70-90	Pronator teres, pronator quadratus
Wrist	Condyloid	<i>Flexion:</i> Move palm toward inner aspect of forearm.	80-90	Flexor carpi ulnaris, flexor carpi radialis
		<i>Extension:</i> Move fingers and hand posterior to midline, bring dorsal surface of hand back as far as possible.	70-80	Extensor carpi radialis brevis, extensor carpi radialis longus, extensor carpi ulnaris
		<i>Radial deviation:</i> Bend wrist medially toward thumb.	Up to 30	Flexor carpi radialis brevis, extensor carpi radialis brevis, extensor carpi radialis longus.
		<i>Ulnar deviation:</i> Bend wrist laterally toward fifth finger.	30	Flexor carpi ulnaris, extensor carpi ulnaris
Fingers	Condyloid hinge	<i>Flexion:</i> Make fist.	90	Lumbricales, interosseus volaris, interosseus dorsalis
		<i>Extension:</i> Straighten fingers.	90	Extensor digiti quinti proprius, extensor digitorum communis, extensor indicis proprius
		<i>Hyperextension:</i> Bend fingers back as far as possible.	30-60	Extensor digitorum
		<i>Abduction:</i> Spread fingers apart.	30	Interosseus dorsalis
		<i>Adduction:</i> Bring fingers together.	30	Interosseus volaris
Thumb	Saddle	<i>Flexion:</i> Move thumb across palmar surface of hand.	90	Flexor pollicis brevis
		<i>Extension:</i> Move thumb straight away from hand.	90	Extensor pollicis longus, extensor pollicis brevis
		<i>Abduction:</i> Extend thumb laterally (usually done when placing fingers in abduction and adduction).	30	Abductor pollicis brevis
		<i>Adduction:</i> Move thumb back toward hand.	30	Adductor pollicis obliquus, adductor pollicis transversus
		<i>Opposition:</i> Touch thumb to each finger of same hand.		Opponens pollicis, opponens digiti minimi
Hip	Ball and socket	<i>Flexion:</i> Move leg forward and up.	110-120	Psoas major, iliacus, sartorius
		<i>Extension:</i> Move leg back beside other leg.	90-120	Gluteus maximus, semitendinosus, semimembranosus
		<i>Hyperextension:</i> Move leg behind body as far as possible.	30-50	Gluteus maximus, semitendinosus, semimembranosus
		<i>Abduction:</i> Move leg laterally away from body.	30-50	Gluteus medius, gluteus minimus
		<i>Adduction:</i> Move leg back toward medial position and beyond if possible.	20-30	Adductor longus, adductor brevis, adductor magnus
		<i>Internal rotation:</i> Turn foot and leg toward other leg.	45	Gluteus medius, gluteus minimus, tensor fasciae latae
		<i>External rotation:</i> Turn foot and leg away from other leg.	45	Obturatorius internus, obturatorius externus
		<i>Circumduction:</i> Move leg in circle.		Psoas major, gluteus maximus, gluteus medius, adductor magnus

Body Part	Type of Joint	Type of Movement	Range (Degrees)	Primary Muscles
Knee	Hinge	<i>Flexion:</i> Bring heel back toward back of thigh.	120-130	Biceps femoris, semitendinosus, semimembranosus, sartorius
		<i>Extension:</i> Return leg to floor.	120-130	Rectus femoris, vastus lateralis, vastus medialis, vastus intermedius
Ankle	Hinge	<i>Dorsal flexion:</i> Move foot so toes are pointed upward.	20-30	Tibialis anterior
		<i>Plantar flexion:</i> Move foot so toes are pointed downward.	45-50	Gastrocnemius, soleus

Foot	Gliding	<i>Inversion:</i> Turn sole of foot medially.	35 or less	Tibialis anterior, tibialis posterior
		<i>Eversion:</i> Turn sole of foot laterally.	10 or less	Peroneus longus, peroneus brevis
Toes	Condyloid	<i>Flexion:</i> Curl toes downward.	30-60	Flexor digitorum, lumbricalis pedis, flexor hallucis brevis
		<i>Extension:</i> Straighten toes.	30-60	Extensor digitorum longus, extensor digitorum brevis, extensor hallucis longus
		<i>Abduction:</i> Spread toes apart.	15 or less	Abductor hallucis, interosseus dorsalis
		<i>Adduction:</i> Bring toes together.	15 or less	Adductor hallucis, interosseus plantaris

TABLE 39.3

Range-of-Motion Alterations

Body Part	Alteration	Assessment Finding(s)
Neck	Flexion contracture—a patient’s neck is permanently flexed with the chin close to or actually touching the chest	Altered body alignment, changes in the visual field, and decreased level of independent functioning
Shoulder	The strongest muscle controlling the shoulder is the deltoid. It is in complete elongation in the normal position, but with alteration there is limited elongation	Difficulty moving the arms
Elbow	Fixed in full extension	Difficulty flexing and using arm for self-care activities
Forearm	Forearm becomes fixed in full supination	Use of hand is limited, unable to perform self-care activities
Wrist	Wrist becomes fixed, slightly flexed	Grasp is weaker
Fingers and thumb	Digits become more flexed; pain with movement	Unable to perform fine motor skills: picking up objects, ADLs, needlework, drawing
Hip	Contractures often fix the hip in positions of deformity. Excessive abduction makes the affected leg appear too short, whereas excessive adduction makes it appear too long	Limited ability to move about; walks with limp. Internal and external rotation contractures cause abnormal and unbalanced gait
Knee	Knees cannot remain stable under weight-bearing conditions unless there is adequate quadriceps power to maintain them in full extension	Knee is stiff. If fixed in full extension, a person needs to sit with leg out in front. If knee is stiffened in flexed position, person limps while walking
Ankle and foot	Joint becomes unstable. When the person relaxes as in sleep or coma, the foot relaxes and assumes a position of plantar flexion. As a result, it becomes fixed in plantar flexion (footdrop)	Abnormal gait. Impaired ability to walk independently
Toes	Excessive flexion of the toes results in clawing. Permanent clawing results in the foot being unable to rest flat on the floor	Abnormal gait

There are three types of range-of-motion exercises: active, active assisted, and passive (see [Chapter 38](#)). For example, you might need to provide support for a weak patient and assist while he or she performs most of the joint movement. Some patients are able to move some joints actively, whereas you will passively move others. Ligaments, muscles, and the nature of the joint limit patients’ mobility, and some joint movements are specific to their location in the body. Abduction and adduction of the arms and legs are an example of this specific type of movement. Abduction is the movement of an extremity

away from the midline of the body, and adduction is the movement of an extremity toward the midline of the body.

The major musculoskeletal changes expected during assessment of an immobilized patient include decreased muscle strength, loss of muscle tone and mass, and contractures. Patients with musculoskeletal injuries or chronic conditions require careful palpation of joints and extremities to minimize discomfort. Because immobilized patients are weakened, determine whether difficulty in moving joints is the result of fatigue or decreased ROM. Remember that a patient's total musculoskeletal system must be evaluated from the head and neck down to the toes. Any limitation not identified early can result in the patient developing a permanent complication that will impact mobility in the future.

Activity tolerance is the type and amount of exercise or work that a person is able to perform without undue exertion or injury. Many of the patients who have become immobilized may be very limited in their ability to walk or change position in bed. After activity, observe patients for difficulty breathing. Assess heart rate and blood pressure response to activity by comparing with baseline at rest. Both heart rate and blood pressure should increase. [Chapter 38](#) describes how to assess a patient's activity tolerance. Assessment of activity tolerance is necessary when planning activity such as walking, ROM exercises, or ADLs. Activity tolerance assessment includes data from physiological, emotional, and developmental domains.

Observing a patient's posture and alignment while sitting and lying in bed determines the type of assistance the patient requires for safe repositioning (i.e., notice which method the patient uses to push up in bed or whether the patient grabs onto objects to steady himself or herself). Aligning patients properly within their own restrictions helps to reduce discomfort and placement of stress on weakened or injured extremities.

As activity is incorporated into the plan of care, monitor patients' tolerance, and assess for dyspnea, shortness of breath, fatigue, chest pain, and/or a change in heart rate or blood pressure. The weak or acutely ill patient is unable to sustain even slight changes in activity because of the increased demand for energy. Seemingly simple tasks such as eating and moving in bed often result in extreme fatigue. When a patient experiences decreased activity tolerance, carefully assess how much time he or she needs to recover. Decreasing recovery time indicates improving activity tolerance.

Gait

Gait is the manner or style of walking, including rhythm, cadence, length of stride, and speed. Assessing gait allows for conclusions about balance, posture, and the ability to walk without assistance (see [Chapter 38](#)). While a patient walks, look for conformity, a regular, smooth rhythm and symmetry in the

length of leg swing; smooth swaying related to the gait phase; and a smooth, symmetrical arm swing (Ball et al., 2019). An abnormal gait is a common risk factor for patient falls.

Exercise Pattern

Exercise is physical activity for conditioning the body, improving health, and maintaining fitness. Nurses use it as therapy to correct a deformity or restore the overall body to a maximal state of health. When a person exercises, beneficial physiological changes occur in numerous body systems (see [Chapter 38](#)). Assess a patient's exercise history by asking what exercise he or she normally engages in and the normal amount of exercise performed daily and weekly. If a patient does not exercise regularly, you will want to focus on his or her activity tolerance. [Chapter 38](#) describes the approach for assessment of a patient's exercise patterns.

A weak or debilitated patient is unable to sustain even slight changes in activity because of the increased demand for energy. Seemingly simple tasks such as eating and moving in bed often result in extreme fatigue. When the patient experiences decreased activity tolerance, carefully assess how much time he or she needs to recover. Decreasing recovery time indicates improving activity tolerance.

People who are depressed, worried, or anxious are frequently unable to tolerate exercise. Depressed patients tend to withdraw rather than participate. Patients who worry or are frequently anxious expend a tremendous amount of mental energy and often report feeling fatigued. Because of this, they also experience physical and emotional exhaustion.

Body Alignment

The first step in assessing body alignment is to put patients at ease so that they do not assume unnatural or rigid positions. When assessing the body alignment of an immobilized or unconscious patient, remove pillows and positioning supports from the bed and place the patient in the supine position.

Standing

During assessment look for characteristics of correct body alignment for the standing patient:

1. The head is erect and midline.
2. When observed posteriorly, the shoulders and hips are straight and parallel.
3. When observed posteriorly, the vertebral column is straight.
4. When observed laterally, the head is erect, and the spinal curves are aligned in a reversed S pattern. The cervical vertebrae are anteriorly

convex, the thoracic vertebrae are posteriorly convex, and the lumbar vertebrae are anteriorly convex.

5. When observed laterally, the abdomen is comfortably tucked in, and the knees and ankles are slightly flexed. The person appears comfortable and does not seem conscious of the flexion of knees or ankles.
6. The arms hang comfortably at the sides.
7. The feet are slightly apart to achieve a base of support, and the toes are pointed forward.
8. When viewing the patient from behind, the center of gravity is in the midline, and the line of gravity is from the middle of the forehead to a midpoint between the feet. Laterally the line of gravity runs vertically from the middle of the skull to the posterior third of the foot ([Fig. 39.6](#)).

FIG. 39.6 Correct body alignment when standing.

Sitting

Assessment also includes characteristics of correct alignment of the sitting patient:

1. The head is erect, and the neck and vertebral column are in straight alignment.
2. The body weight is distributed evenly on the buttocks and thighs.
3. The thighs are parallel and in a horizontal plane.

- Both feet are supported on the floor ([Fig. 39.7](#)), and the ankles are flexed comfortably. With patients of short stature, use a footstool to ensure that ankles are flexed comfortably.

FIG. 39.7 Correct body alignment when sitting.

- A 2.5- to 5-cm (1- to 2-inch) space is maintained between the edge of the seat and the popliteal space on the posterior surface of the knee. This space ensures that there is no pressure on the popliteal artery or nerve to decrease circulation or impair nerve function.

6. The patient's forearms are supported on the armrest, in the lap, or on a table in front of the chair.

It is particularly important to assess alignment when sitting if the patient has muscle weakness, muscle paralysis, or nerve damage. Patients who have these problems have diminished sensation in the affected area and are unable to perceive pressure or decreased circulation. Proper alignment while sitting reduces the risk of musculoskeletal system damage in such a patient. The patient with severe respiratory disease who has orthopnea sometimes assumes a posture of leaning on the table in front of the chair in an attempt to breathe more easily.

Lying

People who are conscious have voluntary muscle control and normal perception of pressure. As a result, they usually assume a position of comfort when lying down. Because their ROM, sensation, and circulation are within normal limits, they change positions when they perceive muscle strain and decreased circulation.

Assess body alignment for a patient who is immobilized or bedridden with the patient in the lateral position (Fig. 39.8). Remove all positioning supports from the bed except for the pillow under the head and support the body with an adequate mattress. This position allows for full view of the spine and back and helps provide other baseline body alignment data such as whether the patient is able to remain positioned without aid. The vertebrae are aligned, and the position does not cause discomfort. Patients with impaired mobility (e.g., traction or arthritis), decreased sensation (e.g., hemiparesis following a CVA), impaired circulation (e.g., diabetes), and lack of voluntary muscle control (e.g., spinal cord injury) are at risk for damage when lying down.

FIG. 39.8 Correct body alignment when lying down.

Immobility

Assess the patient for the physiological hazards of immobility while performing a head-to-toe physical assessment (Table 39.4) (see Chapter 30). In addition, focus on the patient's psychosocial and developmental dimensions.

TABLE 39.4

Assessment of the Physiological Hazards of Immobility

System	Assessment Techniques	Abnormal Findings
Metabolic	Inspection	Slowed wound healing, abnormal laboratory data
	Inspection	Muscle atrophy
	Palpation	Generalized edema
Respiratory	Inspection	Asymmetrical chest wall movement, dyspnea, increased respiratory rate
	Auscultation	Crackles, wheezes
Cardiovascular	Auscultation	Orthostatic hypotension
	Auscultation, palpation	Increased heart rate, third heart sound, weak peripheral pulses, peripheral edema
Musculoskeletal	Inspection	Decreased range of motion, erythema, increased diameter in calf or thigh
	Palpation	Joint contracture, reduced muscle strength
	Inspection	Activity intolerance, muscle atrophy, joint contracture
Skin	Inspection, palpation	Break in skin integrity
Elimination	Inspection	Decreased urine output, cloudy or concentrated urine, decreased frequency of bowel movements
	Palpation	Distended bladder and abdomen
	Auscultation	Decreased bowel sounds

Metabolic System

When assessing metabolic functioning, measures of height and weight figure prominently. Also examine the turgor of the skin. Dehydration and edema increase the rate of skin breakdown in a patient who is immobilized. Review intake and output records for fluid balance. Does intake equal output? Intake and output measurements help to determine whether a fluid imbalance exists (see Chapter 42). Monitoring laboratory data such as levels of electrolytes, serum protein (albumin and total protein), and blood urea nitrogen (BUN) helps you to determine metabolic functioning.

Monitoring food intake and elimination patterns and assessing wound healing help to determine altered GI functioning and potential metabolic problems. If the patient has a wound, the rate of healing is affected by nutritional intake and nutrient absorption. Normal progression of healing indicates that metabolic needs of injured tissues are being met. Anorexia commonly occurs in patients who are immobilized. Assess the patient's food intake before the meal tray is removed to determine the amount eaten. Assess his or her dietary patterns and food preferences at the onset of immobilization to help prevent nutritional imbalances (see Chapter 45).

Respiratory System

Perform a respiratory assessment at least every 2 hours for patients with restricted activity. Inspect chest wall movements during the full inspiratory-expiratory cycle. If a patient has an atelectatic area, chest movement is often asymmetrical. Auscultate the entire lung region to identify diminished breath sounds, crackles, or wheezes. Focus auscultation on the dependent lung fields because pulmonary secretions tend to collect in these lower regions.

Assessment findings that indicate pneumonia include productive cough with greenish yellow sputum; fever; pain on breathing; and crackles, wheezes, and dyspnea.

Cardiovascular System

Cardiovascular nursing assessment of a patient who is immobilized includes monitoring blood pressure and heart rate and assessing the arteriovenous system. Because of the risk for orthostatic hypotension, measure blood pressure when a patient moves from lying to a sitting or standing position. Move a patient gradually during position changes, and monitor him or her closely for dizziness while assessing blood pressure in each position. These measurements document the patient's tolerance to postural changes and are vital to know when positioning or transferring patients from one position or location to another. The longer the period of immobility, the greater is the risk of orthostatic hypotension when the patient stands ([McCance and Huether, 2017](#)).

Assess heart rate, including the apical pulse. Lying down increases cardiac workload and results in an increased pulse rate. In older adults, the heart rate often does not tolerate the added workload, and a form of cardiac failure may develop. A third heart sound, heard at the apex of the heart, is an early indication of congestive heart failure.

Monitoring peripheral pulses (see [Chapter 30](#)) allows you to assess the ability of the heart to pump blood and the condition of the arterial system. Immediately document and report the absence of a peripheral pulse in the lower extremities, especially if the pulse was present previously. Check for capillary refill to determine tissue perfusion. Also note the color of extremities, as changes in venous and arterial function will alter skin color.

Edema sometimes develops in patients who have had tissue injury or whose heart is unable to handle the increased workload of bed rest. Because edema moves to dependent body regions, assessment of the patient experiencing immobility includes inspection of the sacrum, legs, and feet for edema. If the heart is unable to tolerate the increased workload, peripheral body regions such as the hands, feet, nose, and earlobes are colder than central body regions.

Venous thromboembolism (VTE) is a blood clot in a vein. It is related to two life-threatening conditions: deep vein thrombosis (DVT) (a clot in a deep vein,

usually the leg) and pulmonary **embolus** (a deep vein clot that breaks free from a vein wall, travels to the lungs, and blocks some or all of the blood supply) ([American Heart Association \[AHA\], 2017](#)). Venous thromboembolism is a hazard of immobility, as well as other medical conditions. Venous emboli that travel to the lungs are sometimes life threatening. More than 90% of all pulmonary emboli begin in the deep veins of the lower extremities ([McCance and Huether, 2017](#)).

Common risk factors for VTE include conditions that influence the **Virchow's triad**: *hypercoagulability* (e.g., clotting disorders, fever, dehydration); *venous wall abnormalities* (e.g., orthopedic surgery, varicose veins); and *blood flow stasis* (e.g., immobility, obesity, pregnancy). To assess the venous system for presence of a DVT determine whether the patient is experiencing leg pain by gently palpating under the thighs and along the calves. Note any tenderness or cramping, and look for redness. Gently palpate for presence of edema. Carefully compare findings in both legs; unilateral redness, tenderness, and edema indicate possible DVT. Also consider the patient's risk factors for a DVT ([Box 39.4](#)). The Wells score is an objective and widely used measure for determining a patient's risk for a DVT ([Table 39.5](#)) ([Wells, 1998](#); [Modi, 2016](#)). When you identify clinical indicators of a possible DVT, report to a health care provider immediately, and include the Wells score as appropriate. If a patient has antiembolic stockings or a sequential or mobile compression device (SCD/MCD), remove the stockings or device once every 8 hours or according to agency policy and reassess the calves and thighs.

Box 39.4 Risk Factors for Developing Deep Vein Thrombosis

- Surgery
- Trauma
- Long periods of not moving (bed rest, sitting, long car or airplane trips)
- Cancer and cancer therapy
- Past history of DVT
- Increasing age
- Pregnancy and the 4–6 weeks after giving birth
- Certain illnesses, including heart failure, inflammatory bowel disease, and some kidney disorders
- Hypertension
- Hyperlipidemia

- Nephrotic syndrome
- Autoimmune disease, including systemic lupus erythematosus
- Obesity
- Smoking
- Use of birth control pills
- Varicose veins
- Having a tube in a main vein (sometimes needed to give medications over a period of time)
- Having thrombophilia, one of several diseases in which the blood does not clot correctly

Table 39.5

Wells Score for the Prediction of Deep Vein Thrombosis

Parameter	Score
Active cancer (patient receiving treatment for cancer within previous 6 months or currently receiving palliative treatment)	1
Paralysis, paresis, or recent plaster immobilization of lower extremities	1
Recently bedridden for 3 days or more, or major surgery within previous 12 weeks requiring general or regional anesthesia	1
Localized tenderness along distribution of the deep vein system	1
Entire leg swollen	1
Calf swelling at least 3 cm more when compared with asymptomatic leg	1
Pitting edema localized to symptomatic leg	1
Collateral superficial veins	1
Previously documented DVT	1
Alternative diagnosis as likely as or greater than that of DVT	-2

Wells scoring system for DVT: -2 to 0: low probability; 1 to 2 points: moderate probability; 3 to 8 points: high probability.

From *World J Emerg Surg* 11:24, 2016. Published online 2016 Jun 8.
<https://doi.org/10.1186/s13017-016-0078-1>. Accessed January 18, 2020.

Measure bilateral calf circumference and record it daily as an alternative assessment for DVT. To do this, mark a point on each calf 10 cm down from the midpatella. Measure the circumference each day, using this mark for

placement of the tape measure. Unilateral increases in calf circumference are an early indication of thrombosis (Lewis et al., 2017). If the patient has a history of DVT, measurement of the thighs should also be conducted daily since the upper thigh is a common site for clot formation. Many hospitals now order Doppler ultrasounds to assess blood flow in arteries and veins to detect presence of clots. There is a high prevalence of asymptomatic DVTs, especially among elderly patients.

Musculoskeletal System

Major musculoskeletal abnormalities to identify during nursing assessment include decreased muscle tone and strength, loss of muscle mass, reduced ROM, and contractures. During assessment of ROM (described earlier) you can detect muscle tone by asking the patient to relax and then passively moving each limb at several joints to get a feeling for any resistance or rigidity that may be present. You assess for muscle strength by having the patient assume a stable position and then performing maneuvers to demonstrate strength of the major muscle groups (see [Chapter 30](#)).

Physical assessment cannot identify disease osteoporosis. However, patients on prolonged bed rest, postmenopausal women, patients taking steroids, and people with increased serum and urine calcium levels have a greater risk for bone demineralization. Consider the risk of disease osteoporosis when planning nursing interventions. Although some falls result in injury, others occur because of pathological fractures secondary to osteoporosis.

Integumentary System

Continually assess a patient's skin for breakdown and color changes such as pallor or redness. Consistently use a standardized assessment tool such as the Braden Scale. The screening tool identifies patients with a high risk for impaired skin integrity or early changes in the condition of patients' skin. Early identification allows for early intervention. Observe the skin often during routine care (e.g., when the patient is turned, during hygiene measures, and when providing for elimination needs). Frequent skin assessment, which can be as often as every hour and is based on patients' mobility, hydration, and physiological status, is essential to promptly identify changes in their skin and underlying tissues (see [Chapter 48](#)).

Elimination System

To determine the effects of immobility on elimination, assess the patient's total intake and output each shift and every 24 hours. Compare the amounts over time. Determine that the patient is receiving the correct amount and type of fluids orally or parenterally (see [Chapter 42](#)). Inadequate intake and output or

fluid and electrolyte imbalances increase the risk for renal system impairment, ranging from recurrent infections to kidney failure. Dehydration also increases the risk for constipation.

Immobility impairs GI peristalsis. Assessment of bowel elimination status includes the adequacy of a patient's dietary choices, bowel sounds, passing of flatus, and the frequency and consistency of bowel movements (see [Chapter 47](#)). Accurate assessment enables you to intervene before constipation and fecal impaction occur.

Psychosocial Assessment

Many alterations in developmental functioning are related to immobility. Often these problems are interrelated, and it is imperative that nursing care focus on all dimensions. Often the focus of immobility is on the easily visible physical problems such as skin impairment, but do not overlook its psychosocial and developmental aspects.

Abrupt changes in personality often have a physiological cause such as surgery, a medication reaction, a pulmonary embolus, or an acute infection. For example, the primary symptom of compromised older patients with a UTI or fever is confusion. Identifying confusion is an important component of a nurse's assessment. Acute confusion, or delirium, is a neuropsychiatric syndrome with alterations in arousal, attention, and cognition ([American Psychiatric Association \(APA\), 2013](#)). Delirium can be triggered by a wide variety of medical or surgical conditions ([Mulkey et al., 2018](#)). Delirium in older adults is not normal, especially after surgery or procedures (see [Chapter 50](#)). A thorough nursing assessment is the priority ([Chase et al., 2018](#)).

Common reactions to immobilization include boredom, anxiety, and feelings of isolation, depression, and anger. These patients often experience an intolerance to exercise. Depressed patients tend to withdraw rather than participate. Observe for changes in a patient's emotional status, and listen carefully to family if they report emotional changes. Examples of change that indicate psychosocial concerns are a cooperative patient who becomes less cooperative or an independent patient who asks for more help than is necessary. Investigate reasons for such alterations. Identifying how a patient usually copes with loss is vital (see [Chapters 36](#) and [37](#)). A change in mobility status, whether permanent or not, causes a grief reaction. Families are a key resource for information about behavioral changes.

Because psychosocial changes usually occur gradually, observe the patient's behavior on a daily basis. If behavioral changes occur, determine the cause(s) and evaluate the changes. Identifying the cause helps you to design appropriate nursing interventions.

Developmental Assessment

Include a developmental assessment of patients who are immobilized. When caring for a young child, determine whether he or she is able to meet developmental tasks and is progressing normally (see [Chapter 12](#)). The child's development sometimes regresses or slows because he or she is immobilized.

Immobilization of a family member changes family functioning. The family's response to this change often leads to problems, stress, and anxieties. When children see parents who are immobile, they sometimes have difficulty understanding what is occurring and coping. Assess the family's perceptions as to how roles have changed and how they are coping.

Immobility has a significant effect on the older adult's levels of health, independence, and functional status. Focus your assessment on the patient's ability to meet needs independently and to adapt to developmental changes such as declining physical functioning and altered family and peer relationships. A decline in developmental functioning needs prompt investigation to determine why the change occurred and interventions that can return the patient to an optimal level of functioning as soon as possible. Activities that reduce immobility and promote participation in ADLs are vital to preventing functional decline ([Hallford et al., 2017](#); [Musich et al., 2018](#)).

Building Competency in Quality Improvement

Ms. Cavallo's skilled care unit is implementing a quality improvement (QI) project focused on prevention of falls. The unit has been experiencing a notable increase in the number of falls over the past several months. A review of the literature notes that the consequences of falls are many, including the need for additional care, psychological effects, and even death. A good starting point is a detailed look at the patients who sustained falls. Did these individuals have risk factors or characteristics in common? Are any of these commonalities related to alterations in mobility? You recognize the need to develop a collaborative plan of care that includes all health care professionals that work on the unit, the patients, and their families. What are the best methods you can use to communicate your findings and strategies for fall prevention to all health care providers and family participating in Ms. Cavallo's care? How do you identify gaps between the unit and best practice? Which measures could you use to evaluate whether change has taken place?

REFLECT NOW

Mr. Brown, a 50-year-old man, is one day postop for left shoulder surgery to repair a rotator cuff injury sustained in a fall from a roof. He also has a fractured right tibia and mild concussion. As a nursing student, you know that assessment of mobility focuses on ROM, gait, exercise and activity tolerance, and body alignment. Given the multiple body parts injured in Mr. Brown's fall, reflect on what limitations and physical findings you might encounter. What questions can you ask to gain deeper understanding of what these injuries mean to Mr. Brown?

• Nursing Diagnosis

A patient who is experiencing an alteration in mobility often has one or more nursing diagnoses. The two diagnoses most directly related to mobility problems are *Impaired Mobility* and *Risk for Disuse Syndrome*. The diagnosis of *Impaired Mobility* applies to the patient who has some limitation but is not completely immobile. The diagnosis of *Risk for Disuse Syndrome* applies to the patient who is immobile and at risk for multisystem problems because of inactivity. Beyond these diagnoses, the list of potential diagnoses is extensive, because immobility affects multiple body systems. Possible nursing diagnoses include the following:

- *Impaired Airway Clearance*
- *Impaired Sleep*
- *Risk for Impaired Skin Integrity*
- *Risk for Constipation*
- *Social Isolation*

Assessment reveals clusters of data that indicate whether a patient is at risk or if a negative or problem-focused diagnosis exists. The clusters of data reveal at-risk factors or assessment findings that are observable assessment cues to support a diagnostic label. In the case of a negative or problem-focused diagnosis, the assessment data will reveal a related factor for the diagnosis. In addition to the accurate clustering of assessment data, an important part of formulating nursing diagnoses is identifying the relevant causative or related

factor (when a diagnosis is *negative or* problem focused) or risk factors (when a diagnosis is a risk diagnosis). You choose interventions that treat or modify the related factor *or risk* for the diagnosis to be resolved. Accurate identification of nursing diagnoses is important to planning patient-centered goals and subsequent nursing interventions that will best help the patient.

Impaired Mobility related to reluctance to initiate movement requires slightly different interventions than *Impaired Mobility* related to pain in the left shoulder. Thus it is critical that nursing assessment activities identify and cluster assessment findings that ultimately support the nursing diagnosis selected (Box 39.5). The diagnosis that is related to reluctance to initiate movement requires interventions aimed at keeping the patient as mobile as possible and encouraging him or her to perform self-care and ROM. The diagnosis related to pain requires you to assist the patient with pharmacological and nonpharmacological comfort measures (see Chapter 44) so that he or she is then willing and more able to move. In both situations you would explain how activity enhances healthy body functioning.

Box 39.5 Nursing Diagnostic Process: Impaired Mobility Related to Left Hip/Leg Pain ROM, Range of motion.

Assessment Activities	Assessment Findings
Measure ROM during extension and flexion of the hip.	Patient has limited ROM in left hip/leg.
Observe patient attempt to move her left leg.	Patient unable to lift her left leg off mattress.
Ask patient about perception of pain.	Patient complains of sharp pain (8 on scale of 0 to 10) in hip and leg when she tries to move them.
Ask patient about endurance and activity tolerance.	Patient reports no muscle strength in left leg. "I can't move it by myself."

Often the physiological dimension is the major focus of nursing care for patients with impaired mobility. Thus the psychosocial and developmental dimensions are neglected. Yet all dimensions are important to health. During immobilization some patients experience decreased social interaction and stimuli. These patients frequently use the nurse's call bell to request minor physical attention when their real need is greater socialization. Nursing diagnoses for health needs in developmental areas reflect changes from the

patient's normal activities. Immobility leads to a developmental crisis if the patient is unable to resolve problems and continue to mature.

Immobility also leads to multiple complications (e.g., renal calculi, DVT, pulmonary emboli, or pneumonia). If these conditions develop, collaborate with the health care provider or nurse practitioner for prescribed therapy to intervene. Be alert for and prevent these potential complications when possible.

• Planning

During planning, you synthesize information from scientific knowledge, your knowledge of the roles of resources, such as respiratory and physical therapy, and clinical standards, such as skin care guidelines from the Agency for Healthcare Research and Quality ([AHRQ, n.d.](#)) and the Wound Ostomy and Continence Nurses Society ([WOCN, 2016](#)), and from protocols for patients at risk for falls ([AACN, 2014](#)) ([Fig. 39.9](#)). You also apply critical thinking attitudes, such as creativity and perseverance, and consider past experiences with immobilized patients. Critical thinking ensures that the patient's plan of care integrates all that you know about the individual patient and key critical thinking elements. Professional standards are especially important to consider when you develop a plan of care. These standards often establish scientifically proven guidelines for selecting effective nursing interventions. Finally, as stated earlier, the patient is a full partner in designing the plan of care, and this input must be reflected when establishing the goals and outcomes.

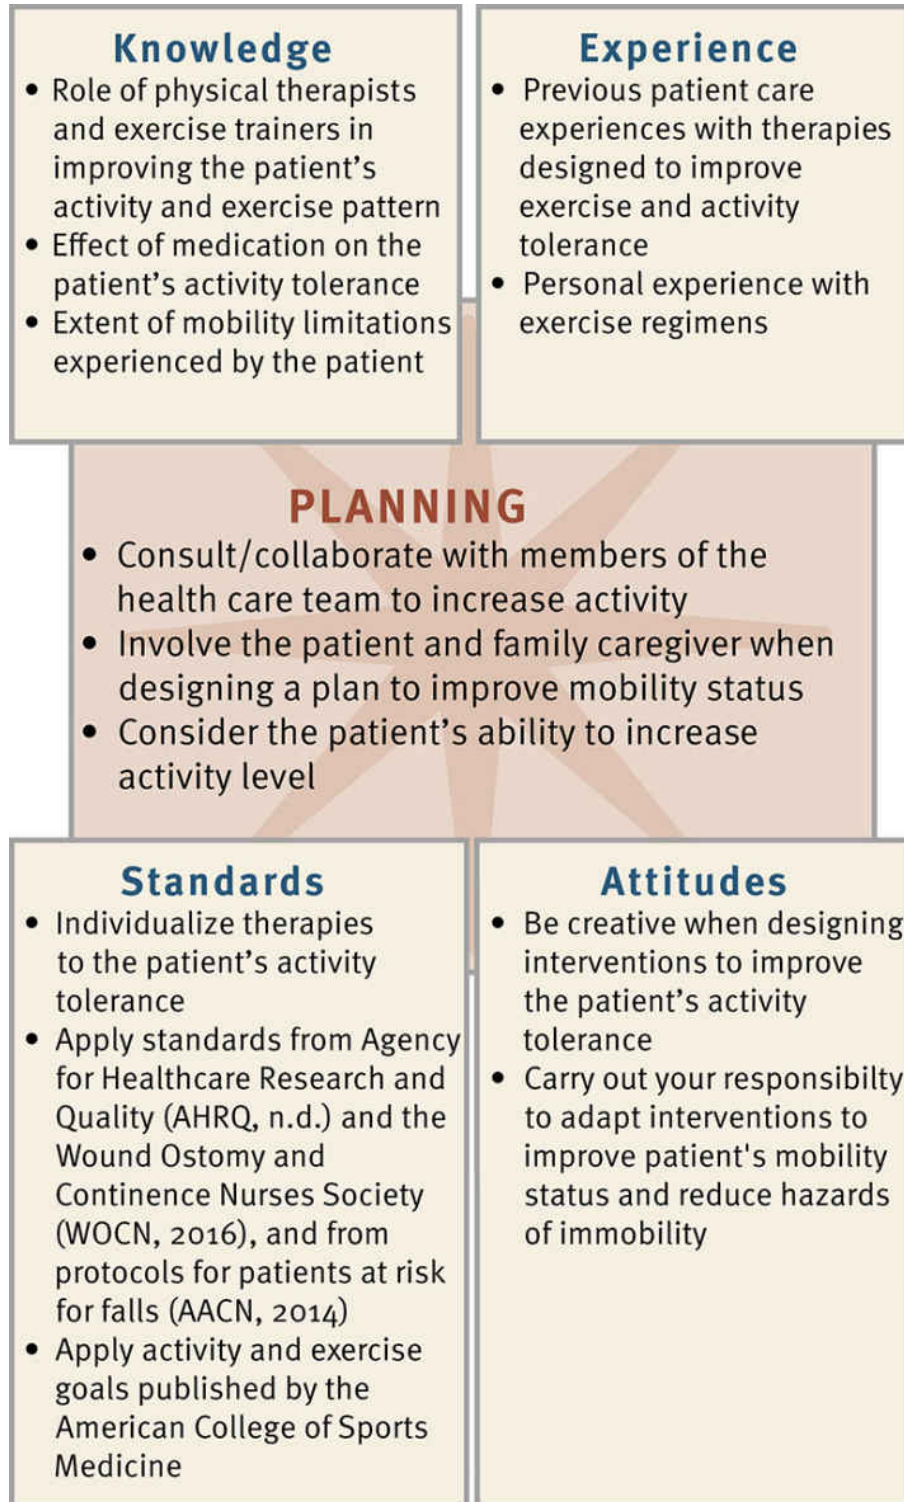

FIG. 39.9 Critical thinking model for planning for impaired mobility.

Impaired mobility affects all physiological symptoms and affects a patient's independence and psychosocial status. [Fig. 39.10](#) shows the relationship between impaired mobility and patient activity.

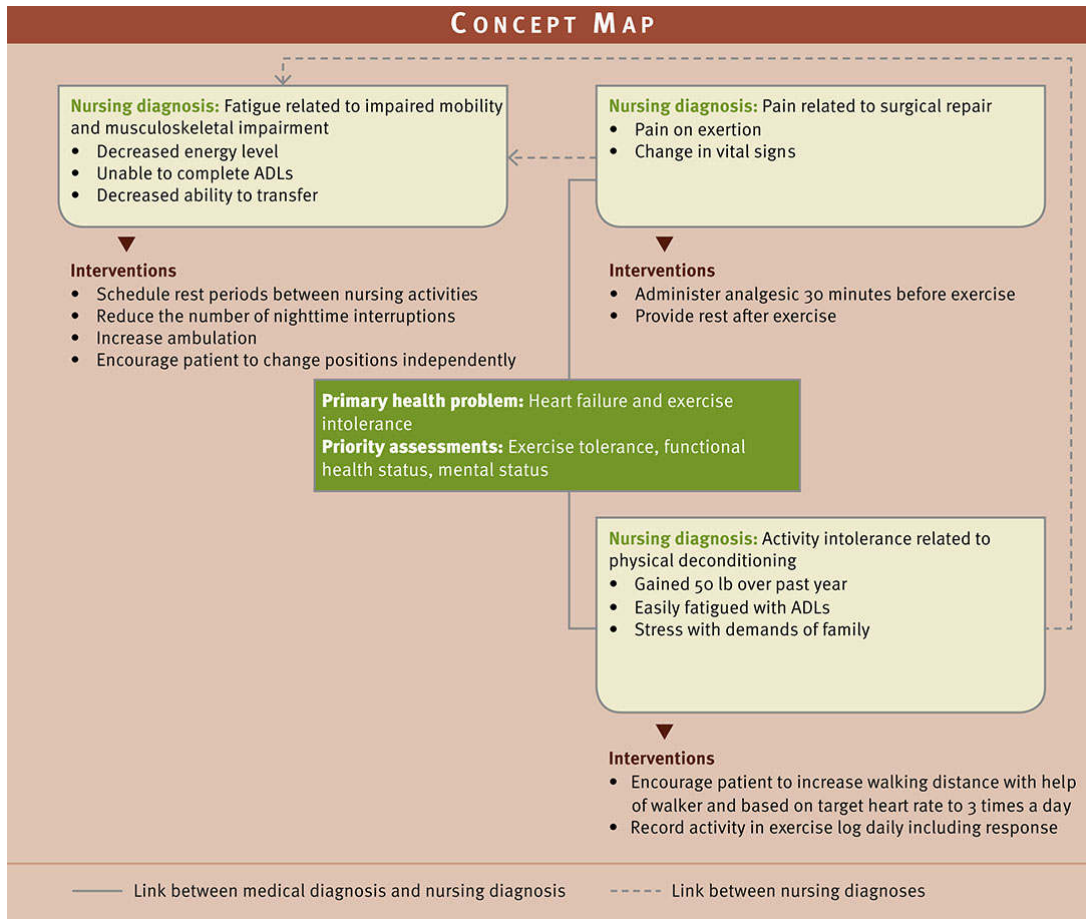

FIG 39.10 Concept map for Mrs. Cavallo.

Goals and Outcomes

Develop an individualized plan of care for each nursing diagnosis (see the [Nursing Care Plan](#)). Set realistic expectations for care, and include the patient and family when possible. Set goals that are individualized, realistic, and measurable. The goals focus on preventing problems or risks to impaired body alignment and mobility.

Nursing Care Plan

Impaired Mobility

Assessment

Ms. Carnella Cavallo, a 97-year-old patient, is admitted to a skilled care unit for rehabilitation 6 days after recovering from a surgically repaired fractured left hip. She has a history of smoking but stopped 40 years ago. She has no

cardiac problems and no hypertension. She describes having “aches” and “stiffness” when lying still in bed but denies pain. The three small incisions are clean, dry and intact.

Assessment Activities	Assessment Findings ^a
Ask Ms. Cavallo to rate her pain on a scale of 0 to 10.	She rates her pain as a 2 on a scale of 0 to 10 at rest, but it increases to an 8 with any movement of her left leg.
Assess Ms. Cavallo’s ability to transfer.	She is unable to transfer, even with help from chair to bed.
Ask Ms. Cavallo how her surgery has affected her mobility.	She responds that she wants to get out of bed, but when she moves her left leg, her nonverbal signs (grimacing and groaning) indicate that she is in severe pain. She says that it is a “ sharp, stabbing pain. ”

^a **Assessment findings** are shown in bold type.

Nursing diagnosis:

Impaired mobility related to musculoskeletal impairment from surgery and pain with movement

Planning

Goals	Expected Outcomes ^b
	Pain Control
Ms. Cavallo will have reduced pain during activity.	Ms. Cavallo’s pain is less than 6 during activity. Body positioning will be self-initiated
Ms. Cavallo will be able to transfer with assistive device by discharge.	Ms. Cavallo is able to move from her bed to her chair and back again using her walker and assist x1 within 3 days. Ms. Cavallo is able to transfer from her chair to her bedside commode using her walker within 3 days.
	Ambulation
Ms. Cavallo will walk 300 feet using her walker by discharge.	Ms. Cavallo walks to her door and around her room with her walker within 6 days. Ms. Cavallo walks 100 feet at a slow pace using her walker 3 times a day in 14 days at rehab and increases the distance that she walks by 100 feet every day after that.

^b Nursing outcomes classification from Moorhead S, et al., editors: *Nursing Outcomes Classification (NOC)*, ed 6, St Louis, 2018, Elsevier.

Interventions ^c	Rationale
Exercise Therapy: Ambulation	
Consult with physical therapist on selection of transfer technique.	Ensures safe transfer technique with less risk of patient injury.
Instruct Ms. Cavallo on safe transfer and ambulation techniques in an environment with few distractions. Provide written materials and the use of the teach-back method to reinforce verbal instructions.	Providing instruction in a quiet environment and using the teach-back method enhance learning (Bodenheimer, 2018; Centrella-Nigro and Alexander, 2017).
Establish realistic increments for transferring and increasing distance for ambulation.	Physiotherapy exercises, physical activity, and setting realistic goals for ambulation encourage activity in older adults (Kruschke, 2017; Musich et al., 2018).
Pain Management	
Administer pain medication on the basis of your assessment of Ms. Cavallo's needs and on an ATC schedule rather than prn. Consult with health care provider for order to adjust dose if patient exhibits signs of being in pain or complains of pain not relieved with current regimen.	Obtain order to adjust (increase or decrease dose) on the basis of a patient's report of pain severity or her ability to perform activities of daily living (ADLs) (Bonkowski et al., 2018).
Introduce nonpharmacological modalities such as ice or heat, positioning, mind-body directed therapies, and massage to support pain management.	The Joint Commission (TJC) revised its pain mandate to include required addition of evidence-based nonpharmacological therapies for pain as a scorable element of performance (TJC, 2018). Evidence-based nonpharmacological therapies are safe and effective components in postsurgical pain management and have potential to decrease the use of opioids and the related risk for misuse (Tiek et al., 2018).
Observe for signs of pain when patient is moving or attempting exercises from physical therapy (PT) and have prn dose of pain medication ordered if additional pain medication is needed for PT activities.	Have an "as needed" dose of pain medication for patient in case he/she requires a supplemental dose.

^c Intervention classification labels from Butcher HK, et al., editors: *Nursing Interventions Classification (NIC)*, ed 7, St Louis, 2018, Elsevier.

Evaluation

Evaluation Activity	Patient Response/Finding	Outcome Status
Ask Ms. Cavallo to rate her level of pain.	Ms. Cavallo reports pain at 5 during activity.	Ms. Cavallo has achieved improved pain control.
Observe Ms. Cavallo's ability to transfer from bed to chair.	Ms. Cavallo is able to transfer from bed to chair using her walker and stand-by assistance of nurse.	Ms. Cavallo has achieved goal of transferring with walker and assistance.
Assess Ms. Cavallo as she walks in the hall; measure how far she walks.	Ms. Cavallo is able to walk 200 feet in the hall with her walker by day 2 of rehab.	Activity level is improving. Continue interventions and continue to encourage ambulation.

Develop goals and expected outcomes to help patients achieve their highest level of mobility and reduce the hazards of immobility. For example, a patient who has left-sided paralysis following a stroke has two long-term goals. The first, directed toward improved mobility, is "Patient will use walker to ambulate safely in the home." A parallel goal directed toward the hazards of immobility is "Patient's skin will remain intact." Both of these goals are essential to restoring the patient's maximal mobility.

Because the patient has impaired sensation, both the patient and caregivers need to be aware of the patient's need to have the skin free of pressure.

Expected outcomes for the goal of the skin remaining intact include the following:

- Patient's skin color and temperature return to normal baseline within 20 minutes of position change.
- Patient changes position at least every 2 hours.

Setting Priorities

The effect that problems have on a patient's mental and physical health determines the immediacy of any problem. Set priorities when planning care to ensure that immediate needs are met first. This is particularly important when patients have multiple diagnoses. Plan therapies according to severity of risks to the patient, and individualize the plan according to the patient's developmental stage, level of health, and lifestyle.

It is especially important in priority setting to make sure that you do not overlook potential complications. Many times actual problems such as pressure injuries and disuse syndrome are addressed only after they develop. Therefore monitor the patient often, reinforcing prevention techniques to both the patient and other caregivers and supervising assistive personnel in carrying out activities aimed at preventing complications of impaired mobility.

Teamwork and Collaboration

Care of the patient experiencing alterations in mobility requires a team approach. Nurses often delegate select interventions that are appropriate for assistive personnel (AP) to perform. For example, in the case of postoperative patients who are at risk for respiratory problems from temporary immobility, AP can encourage the patient to do leg exercises, use the incentive spirometer, and cough and deep breathe (see [Chapter 50](#)). When patients have limited mobility as a result of paralysis, AP can turn and position patients and apply elastic stockings. They can also help the nurse measure leg circumferences and height and weight.

Collaborate with other health care team members such as physical or occupational therapists when it is essential to consider mobility needs. Understanding the need for and having open communications with other members of the interprofessional care team result in better patient outcomes and hopefully prevent the hazards of immobility. It is through these collaborative efforts and teamwork that patients benefit most. For example, physical therapists are a resource for planning ROM or strengthening exercises, and occupational therapists are a resource for planning new or altered ways to perform ADLs that patients need to learn. Wound care specialists and respiratory therapists are often involved in patient care, especially with

patients who are experiencing complications related to their immobility. Consult a registered dietitian when the patient is experiencing nutritional problems; refer him or her to a mental health advanced practice nurse, licensed social worker, or psychologist to assist with coping or other psychosocial issues.

Discharge planning begins when a patient enters the health care system. In anticipation of the patient's discharge from an institution, make appropriate referrals or consult a case manager or a discharge planner to ensure that the patient's needs are met at home. Consider the patient's home environment when planning therapies to maintain or improve body alignment and mobility. Referrals to home care or outpatient therapy are often needed if a patient continues to have mobility limitations when discharged.

Implementation

Health Promotion

Health promotion activities include a variety of interventions such as education, prevention, and early detection. Examples of health promotion activities that address mobility and immobility include prevention of work-related injury, fall prevention measures, exercise, and early detection of scoliosis.

Prevention of Work-Related Musculoskeletal Injuries

The rate of work-related injuries in health care settings has increased in recent years. According to the Department of Labor ([USDOL, 2017](#)), 59,710 occupational musculoskeletal injuries related to patient handling occurred in 2016. Most of these injuries occurred as a result of overexertion, which resulted in back injuries and other musculoskeletal problems. Back injuries are often the direct result of improper lifting and bending. The most common back injury is strain on the lumbar muscle group, which includes the muscles around the lumbar vertebrae. Injury to these areas affects the ability to bend forward, backward, and from side to side and limits the ability to rotate the hips and lower back. Research has demonstrated that ergonomic programs and safe patient-handling policies in health care facilities reduce costs, injuries to employees, and missed work days ([Klein et al., 2018](#); [Noble and Sweeney, 2018](#)).

Nurses and other health care staff are especially at risk for injury to lumbar muscles when lifting, transferring, or positioning immobilized patients. Therefore be aware of agency policies and protocols that protect staff and patients from injury. When lifting, assess the weight you will lift and determine the assistance you will need. Current safe patient-handling algorithms support that using mechanical or other ergonomic assistive devices is the safest way to reposition and lift patients who are unable to do these activities themselves.

Many agencies have developed special patient lift teams and have instituted a minimal lift policy (see [Chapter 38](#)).

Exercise

Although many diseases and physical problems cause or contribute to immobility, it is important to remember that exercise programs enhance feelings of well-being and improve endurance, strength, and health. Exercise reduces the risk of many health problems such as cardiovascular disease, diabetes, and osteoporosis from worsening. It is important to give patients options for how to stay active and how to change their behavior if exercise has not been their routine. [The Stanford Medicine \(2018\)](#) chronic disease self-management program encourages appropriate exercise for maintaining and improving strength, flexibility, and endurance. As a nurse you can encourage all patients to find a type of exercise that meets their lifestyle and particular health-related needs. For example, a patient with severe arthritis of the knees might benefit from aquatic therapy (exercise in a pool) rather than walking. Encourage hospitalized patients to perform stretching, ROM exercises, and light walking within the limits of their condition (see [Chapter 38](#)). Take cultural preferences into consideration when helping patients design exercise plans ([Box 39.6](#)).

Box 39.6 Cultural Aspects of Care **Cultural Influences on Mobility**

Cultural influences have an important role in exercise and physical activity. Specifically, culture influences an individual's preferences for activity and exercise. Certain cultures discourage involvement in organized recreational physical activities such as basketball, running, and aerobics. Ethnic dancing is an effective activity that is acceptable in many countries. Other cultures emphasize exercise in terms of activities of daily living, such as walking, gardening, and prayer or meditation.

A sedentary lifestyle places an individual at risk for being overweight (see [Chapter 38](#)). Children from many cultures who live in the United States are becoming more sedentary. Therefore a national health approach is needed for communities to provide social and physical environments that promote healthy choices. From the earliest age preventive health practices should be included in the educational process.

Implications for Patient-Centered Care

- Assess patterns of daily living and culturally prescribed activities before suggesting specific forms of exercise to patients.
- Help patients plan physical activities that are culturally acceptable.
- Exercise programs need to be flexible and accommodate family and community responsibilities of the culture.
- Encourage culturally specific and individually tailored interventions to facilitate commitment to exercise.
- Educate patients of all ages on the importance of exercise in preserving health, and correct any misconceptions.

Bone Health in Patients with Osteoporosis

Patients at risk for or diagnosed with osteoporosis have special health promotion needs. Encourage patients at risk to be screened for osteoporosis and assess their diets for calcium and vitamin D intake. Patients who have lactose intolerance need dietary teaching about alternative sources of calcium.

For patients diagnosed with osteoporosis, early evaluation, consultation with, and referral to health care providers, dietitians, and physical therapists are important interventions, especially when they become immobilized. The goal of the patient with osteoporosis is to maintain independence with ADLs. Assistive ambulatory devices, adaptive clothing, and safety bars help patients maintain independence. Patient teaching needs to focus on limiting the severity of the disease through diet and activity ([Box 39.7](#)).

Box 39.7 Patient Teaching Teaching Patients with Osteoporosis

Objective

- Patient will verbalize strategies to prevent or limit the severity of osteoporosis.

Teaching Strategies

- Instruct patient and/or family caregiver about common risk factors and how to modify lifestyle (e.g., smoking, caffeine, alcohol, hormone replacement as recommended by health care provider).
- Teach patient and/or caregiver the current recommended dietary allowances for calcium, and review culturally specific foods high in

calcium (e.g., milk fortified with vitamin D, leafy green vegetables, yogurt, and cheese).

- Instruct patient and/or caregiver in appropriate types of weight-bearing exercises as recommended by health care provider or physical therapist to prevent injury or fractures.
- Teach patient and/or caregiver about safety, fall prevention, and strategies to create a safe home environment (e.g., remove scatter rugs; ensure that hallways, steps, and rooms are well lit) (Bodenheimer, 2018).
- Instruct patient and/or caregiver in self-administration of prescribed medication used to treat osteoporosis.
- Promote positive self-image in patient by providing realistic yet optimistic and positive feedback about changes in appearance and mobility.

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- I want to make sure that you understand the teaching about osteoporosis. Tell me three lifestyle modifications you can make to prevent or limit the severity of osteoporosis.
- Describe for me at least four foods high in calcium and vitamins that you should include in your diet.
- Demonstrate for me weight-bearing exercises and tell me your plan for doing the exercises.
- Describe three safety strategies that you will implement while you are home to prevent falls.
- Explain the dosage schedule you will follow for your osteoporosis medications and the side effects that you should watch for.
- Describe how the osteoporosis is affecting your lifestyle and activities.

Acute Care

Patients in acute care settings who experience altered physical mobility usually are at risk for the hazards of immobility such as impaired respiratory status, orthostatic hypotension, and impaired skin integrity. Therefore design nursing interventions to reduce the impact of immobility on body systems and prepare the patient for the restorative phase of care.

Metabolic System

Because the body needs protein to repair injured tissue and rebuild depleted protein stores, give the immobilized patient a high-protein, high-calorie diet. A

high-calorie intake provides sufficient fuel to meet metabolic needs and replace subcutaneous tissue. Also ensure that the patient is taking vitamin B and C supplements when necessary. Supplementation with vitamin C is needed for skin integrity and wound healing; vitamin B complex assists in energy metabolism.

If the patient is unable to eat, nutrition must be provided parenterally or enterally. Total parenteral nutrition refers to delivery of nutritional supplements through a central or peripheral intravenous catheter. Enteral feedings include delivery through a nasogastric, gastrostomy, or jejunostomy tube of high-protein, high-calorie solutions with complete requirements of vitamins, minerals, and electrolytes (see [Chapter 45](#)).

Respiratory System

Patients who are immobilized and have reduced ventilation can benefit from a variety of nursing interventions that promote lung expansion and removal of pulmonary secretions. Patients need to frequently fully expand their lungs to maintain elastic recoil. In addition, secretions accumulate in the dependent areas of the lungs. Often patients with restricted mobility experience weakness, and as this progresses the cough reflex gradually becomes inefficient. All of these factors place patients at risk for developing pneumonia. The stasis of secretions in the lungs is life threatening for an immobilized patient.

Deep-breathing exercises, incentive spirometry, and controlled coughing are among the nursing interventions available to expand the lungs, dislodge and mobilize stagnant secretions, and clear the lungs (see [Chapters 41](#) and [50](#)). All of these interventions help reduce the risk of pneumonia. It is essential to implement pulmonary interventions early in all patients with limited mobility, even those who do not have pneumonia.

Encourage an immobile patient to deep-breathe and cough every 1 to 2 hours. Teach alert patients to deep breathe or yawn every hour or to use an incentive spirometer (when ordered). Controlled coughing, a common therapy for postoperative patients, involves taking in three deep breaths and then coughing with the third exhalation.

Chest physiotherapy (CPT) (percussion and postural drainage) is another method still used by respiratory therapists with the goal of keeping the airways clear (see [Chapter 41](#)). It helps the patient drain secretions from specific segments of the bronchi and lungs into the trachea so that he or she is able to cough and expel them. Respiratory assessment findings identify areas of the lungs requiring CPT. While this method is still widely used, high-level evidence for improved patient outcomes has not been seen in existing trials ([Strickland et al., 2013](#)).

Ensure that patients who are immobile have an adequate fluid intake. Unless there is a medical contraindication, an adult needs to drink at least 1100 to 1400

mL of noncaffeinated fluids daily. This helps keep mucociliary clearance normal. Expect pulmonary secretions to be removed easily with coughing and appear thin, watery, and clear. Without adequate hydration, pulmonary secretions become thick, tenacious, and difficult to remove. Offering fluids that patients prefer on a regularly timed schedule also helps with bowel and urine elimination and aids in maintaining circulation and skin integrity.

Cardiovascular System

The effects of bed rest or immobilization on the cardiovascular system include orthostatic hypotension, increased cardiac workload, and thrombus formation. Design nursing therapies to minimize or prevent these alterations.

Reducing Orthostatic Hypotension

When patients who are on bed rest or have been immobile move to a sitting or standing position, they often experience orthostatic hypotension. They have an increased pulse rate, a decreased pulse pressure, and a drop in blood pressure. If symptoms become severe enough, the patient can faint ([McCance and Huether, 2017](#)). To prevent injury, implement interventions that reduce or eliminate the effects of orthostatic hypotension. It occurs when a normotensive person develops symptoms and a drop in systolic pressure by at least 20 mm Hg or a drop in diastolic pressure by at least 10 mm Hg within 3 minutes of rising to an upright position ([Shibao et al., 2013](#)). Mobilize the patient as soon as the physical condition allows, even if this only involves dangling at the bedside or moving to a chair. This activity maintains muscle tone and increases venous return. Isometric exercises (i.e., activities that involve muscle tension without muscle shortening) have no beneficial effect on preventing orthostatic hypotension, but they improve activity tolerance. When getting an immobile patient up for the first time, assess the situation using a safe patient-handling algorithm ([US Department of Veterans Affairs, 2018](#)) or another appropriate mobility assessment/screening/scoring system. This is a precautionary step that protects you and the patient from injury and also allows the patient to do as much of the transfer as possible.

Reducing Cardiac Workload

A nursing intervention that reduces cardiac workload involves instructing patients to avoid using a Valsalva maneuver when moving up in bed, defecating, or lifting household objects. During a Valsalva maneuver a patient holds his or her breath and strains, which increases intrathoracic pressure and in turn decreases venous return and cardiac output. When the strain is released, venous return and cardiac output immediately increase, and systolic blood pressure and pulse pressure rise. These pressure changes produce a

reflex bradycardia and possible decrease in blood pressure that can result in sudden cardiac death in patients with heart disease. Teach patients to breathe out while defecating, lifting, or moving side-to-side or up in bed and to not hold their breath and strain.

Preventing Thrombus Formation

The Centers for Medicare and Medicaid Services identified 10 “Never Events” in 2008. A Never Event is a hospital-acquired event for which Medicare and other third-party payers will no longer pay hospitals at a higher rate for the increased costs of care. Deep vein thrombosis (DVT) is one of these Never Events. The most cost-effective way to address DVT is through an aggressive program of prophylaxis. Prevention of DVT is critical to reduce the risk of fatal and nonfatal pulmonary embolism. A prophylaxis program begins with identification of patients at risk and continues throughout their immobilization. This requires a collaborative role between nurses and health care providers. You will identify patient risk factors from the nursing assessment. There are nursing interventions you can employ to reduce the risk of thrombus formation in immobilized patients. Early ambulation; leg, foot, and ankle exercises; regularly provided fluids; frequent position changes; and patient teaching need to begin when a patient becomes immobile (see [Chapter 50](#)).

Prophylaxis also includes anticoagulation, mechanical prevention with graduated compression stockings, intermittent pneumatic compression devices, and foot pumps. Anticoagulation may include the use of aspirin, although this is somewhat controversial. Anticoagulants most often used include unfractionated heparin (UFH) (usually given as 5000 units two or three times daily), low-molecular-weight heparins (LMWHs) (e.g., enoxaparin or dalteparin), vitamin K antagonists (e.g., warfarin, but also acenocoumarol, phenindione, and dicoumarol), and fondaparinux (a selective factor Xa inhibitor) ([Cave et al., 2018](#)). Because bleeding is a potential side effect of anticoagulants, continually assess the patient for signs of bleeding, such as hematuria, bruising, coffee ground–like vomitus or GI aspirate, guaiac-positive stools, and bleeding gums.

Sequential compression devices (SCDs) and intermittent pneumatic compression (IPC) are used to prevent blood clots in the lower extremities. Research has shown that IPC significantly reduces the risk of DVT and significantly improves survival in a wide variety of patients who are immobile after stroke ([Zhang et al., 2018](#)). The SCD and IPC consist of sleeves or stockings made of fabric or plastic that are wrapped around the leg and secured with Velcro ([Box 39.8](#)). Once they are applied, connect the sleeves to a pump that alternately inflates and deflates the stocking around the leg. A typical cycle is inflation for 10 to 15 seconds and deflation for 45 to 60 seconds. Inflation pressures average 40 mm Hg. Use of SCD/IPC on the legs decreases

venous stasis by increasing venous return through the deep veins of the legs. For optimal results begin use of SCD/IPC as soon as possible (e.g., immediately after major surgery) and maintain it until the patient becomes fully ambulatory. Increasing numbers of IPC devices allow patients to ambulate with the device in place; this decreases the chances for the device to be removed or turned off during ambulation with a failure to reinitiate in a timely manner (Link, 2018). It is imperative that you take every opportunity to monitor and educate the patient on the importance of mechanical VTE prevention devices.

Box 39.8 Procedural Guidelines **Applying Sequential Compression Devices and Elastic Stockings**

Delegation and Collaboration

The skill of applying and maintaining graduated compression stockings and intermittent SCDs and MCDs may be delegated to assistive personnel (AP). The nurse initially determines the size of elastic stockings and assesses the patient's lower extremities for any signs and symptoms of a DVT or impaired circulation. The nurse directs the AP to:

- Remove SCD sleeves before allowing a patient to get out of bed.
- Report to the nurse if a patient's calf or thigh appears larger than the other or is red, tender, hot, or swollen or if the patient complains of calf pain.
- Report to the nurse if there is redness, itching, or irritation on the legs (signs of allergic reactions to elastic).
- Report to the nurse if the patient is routinely removing the compression device from the legs.

Equipment

Tape measure; powder or cornstarch (*optional*); graduated compression stockings or Velcro compression device sleeves; SCD/MCD insufflator with air hoses attached; compression device pump; hygiene supplies; *option*: cotton stockinette with MCD

Steps

1. Identify patient using at least two patient identifiers (e.g., name and birthday or name and medical record number) according to agency policy (TJC, 2020).

2. Review medical record for order for SCDs/MCDs or graduated compression stocking.
3. Review medical record to assess patient for risk factors for developing DVT (see Box 39.4). *An option is to use The Wells score, an objective and widely used measure for determining a patient's risk for a DVT (Wells, 1998; Modi, 2016) (see Table 39.5).*
4. Perform hand hygiene. Assess for contraindications for use of elastic stockings or compression devices:
 - a. Dermatitis or open skin lesions on area to be covered by stockings/sleeves
 - b. Recent skin graft to lower leg
 - c. Decreased arterial circulation in lower extremities as evidenced by cyanotic, cool extremities and/or gangrenous conditions affecting the lower limb(s)
 - d. If signs/symptoms of a DVT are present, *manipulation could cause a clot in vein within the leg to dislodge.*
5. Assess condition of patient's skin and circulation to the legs. Palpate pedal pulses; note any palpable veins, and inspect skin over lower extremities for edema, skin discoloration, warmth, presence of lesions.
6. Assess patient's or family caregiver's knowledge or experience regarding previous use of elastic compression stockings or compression devices. Assess patient's or family caregiver's health literacy.
7. Explain procedure and reason for applying elastic stockings/SCD/MCD to prevent DVT.
8. Close room curtains or door to provide privacy. Position patient in supine position.
9. Perform hand hygiene. Bathe patient's legs as needed. Dry thoroughly. Perform hand hygiene.
10. **Apply graduated compression stocking:**
 - a. Use tape measure to measure patient's leg to determine proper elastic stocking size (follow package directions).
 - b. *Option:* Apply a small amount of powder or cornstarch to legs provided that patient does not have sensitivity.
 - c. Turn elastic stocking inside out: place one hand into stocking, holding heel of stocking. Take other hand and pull stocking inside out until reaching the heel (see illustration).

STEP 10C Turn stocking inside out; hold heel and pull through.

- d. Place patient's toes into foot of elastic stocking up to the heel, making sure that stocking is smooth (see illustration A). Slide remaining portion of stocking over patient's foot, making sure that toes are covered. Make sure that foot fits into toe and heel position of stocking. Stocking will now be right side out (see illustration B).
- e. Slide stocking up over patient's calf until sock is completely extended. Be sure that stocking is smooth and that no ridges or wrinkles are present (see illustration).

STEP 10D **A**, Place toes into foot of stocking. **B**, Slide remaining part of stocking over foot.

STEP 10E Slide sock up leg until completely extended.

- f. Instruct patient not to roll stockings partially down, to avoid wrinkles, to avoid crossing legs, and to elevate legs while sitting.

11. Apply SCD sleeve(s):

- a. Remove SCD sleeves from plastic cover; unfold and flatten onto bed.
- b. Arrange SCD sleeve under patient's leg according to leg position indicated on inner lining of sleeve.
- c. Place patient's leg on SCD sleeve. Back of ankle should line up with ankle marking on inner lining of sleeve.
- d. Position back of knee with popliteal opening on inner sleeve (see illustration).
- e. Wrap SCD sleeve securely around patient's leg. Check fit of SCD sleeve by placing two fingers between patient's leg and sleeve (see illustration).
- f. Attach SCD sleeve connector to plug on mechanical unit. Arrows on connector line up with arrows on plug from mechanical unit (see illustration).

STEP 11D Position back of patient's knee with popliteal opening.

STEP 11E Check fit of SCD sleeve.

g. Turn mechanical unit on. Green light indicates that unit is functioning. Monitor functioning SCD through one full cycle of inflation and deflation.

12. Apply MCD sleeve (example: Calf Sleeve ActiveCare+SFT® Application):

- a. A cotton stockinette is provided along with the calf sleeves. Apply over patient's calves.
- b. Wrap the sleeve smoothly around the patient's calf and fasten it, beginning at the top, moving toward the bottom.
- c. Place 2 fingers between patient's calf and sleeve to be sure it is snug but not too tight (see illustration).

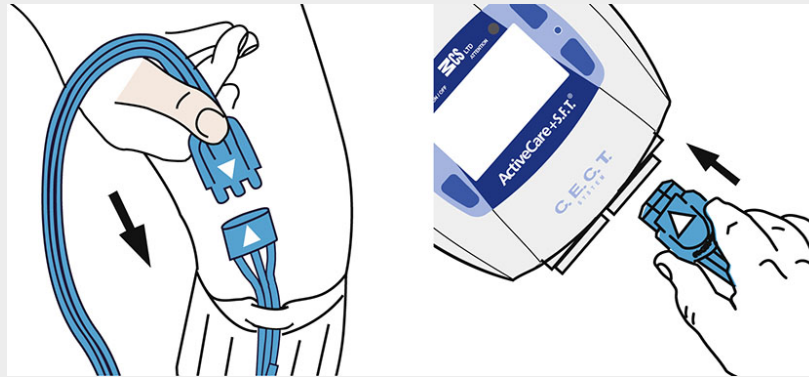

- d. The device has two identical extension tubes (see illustration). Use either end of the extension tube to connect to the sleeve or device pump.

STEP 11F Align arrows when connecting plug to mechanical unit.

STEP 12C Application of activecare+SFT® MCD to calves.
Courtesy zimmer biomet.

STEP 12D Powering on activecare+SFT® MCD.
Courtesy zimmer biomet.

- (1) Connect one end of the extension tube to the sleeve connector. The white arrows should be pointed toward each other.
 - (2) Connect the other end of the extension tube to the device pump. The white arrow should be facing upward.
- e. Press the power switch located at the back of the device to ON position (see illustration). After turning the device on, the Configuration Setup Screen is shown on the LCD screen and the sleeves should immediately start to inflate, from the bottom to the top.
 - f. Wait 60 seconds for the automatic operation of the device. The device automatically identifies which sleeves are connected, selects the suitable treatment mode, and will display information on the main LCD screen.
13. Position patient comfortably. Then place nurse call system in accessible location within patient's reach.

CLINICAL DECISION: *Caution patient not to exit bed and walk with SCDs in place. Have patient call for assistance. The patient may walk with MCD in place (see illustration).*

14. Raise side rails (as appropriate) and lower bed to lowest position. Perform hand hygiene.

STEP 12E Application of activecare+SFT® MCD connector hose to pump.
Courtesy zimmer biomet.

15. Remove compression stockings or SCD/MCD sleeves at least once per shift (e.g., long enough to inspect skin for irritation or breakdown and to determine patient's comfort level).
16. Evaluate skin integrity and circulation to patient's lower extremities as ordered (see agency policy).
17. **Use Teach-Back:** "We have reviewed the signs and symptoms you might have if a clot forms in your leg. Tell me what those symptoms are." Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly.
18. Record condition of lower extremities, application of stockings/SCDs/MCD, patient response to education.
19. Hand-off reporting: Report to health care provider or nurse in charge any signs that may indicate formation of DVT.

⚠ WARNING: Extension tubes may become tangled when walking with the **ActiveCare+SFT®** and **ActiveCare+DTx®** Systems. Adjust their length to avoid tripping injury or equipment damage.

Walking with activecare+SFT® MCD.
Courtesy zimmer biomet.

Elastic stockings (sometimes called *antiembolitic stockings*) also aid in maintaining external pressure on the muscles of the lower extremities and thus promote venous return (see [Box 39.8](#)). To obtain the correct size, measure the patient's calf, thigh, and leg length accurately. When considering applying graded compression stockings, first assess the patient's suitability for wearing them. Do not apply them if he or she has a local condition affecting the leg (e.g., any skin lesion, gangrenous condition, or recent vein ligation) because application compromises circulation. Apply them properly and remove them at least once per shift. Be sure to assess circulation at the toes to ensure that the stockings are not too tight. Another device for preventing DVT is the venous

plexus foot pump. It promotes circulation by mimicking the natural action of walking.

Proper positioning reduces a patient's risk of thrombus formation because compression of the leg veins is minimized. Therefore, when positioning patients, use caution to prevent pressure on the posterior knee and deep veins in the lower extremities. Teach patients to avoid the following: crossing the legs, sitting for prolonged periods of time, wearing clothing that constricts the legs or waist, and massaging the legs. Report suspected DVT immediately to the patient's health care provider. Elevate the leg but avoid pressure on the suspected thrombus area. Instruct the family, patient, and all health care personnel not to massage the area because of the danger of dislodging the thrombus.

ROM exercises and early mobility reduce the risk of contractures and aid in preventing thrombi. Activity causes contraction of the skeletal muscles, which in turn exerts pressure on the veins to promote venous return, thereby reducing venous stasis. Specific exercises that help prevent thrombophlebitis are ankle pumps, foot circles, and knee flexion. Ankle pumps, sometimes called *calf pumps*, include alternating plantar flexion and dorsiflexion. Foot circles require the patient to rotate the ankle. Encourage patients to make the letters of the alphabet with their feet every 1 to 2 hours. Knee flexion involves alternately extending and flexing the knee. These exercises are sometimes referred to as *antithrombotic exercises* and need to be done hourly while awake.

Maintaining Musculoskeletal Function

Exercises to prevent excessive muscle atrophy and joint contractures help maintain musculoskeletal function. Active ROM should be encouraged for any patient at risk for reduced musculoskeletal strength or functionality by improving joint mobility. When a patient has muscle weakness, fatigue, or pain, active assisted ROM exercises are more appropriate. A patient needs assistance with movement from an external force (e.g., manual support of an extremity, positioning to use the effects of gravity) because of weakness, pain, or changes in muscle tone (Dutton, 2014). Passive ROM exercises are indicated when a patient is not able or permitted to move a body part, as in the case of a paralyzed extremity or healing fracture (Dutton, 2014).

To ensure that patients routinely receive ROM exercises, schedule them at specific times, perhaps during another nursing activity such as the patient's bath. This enables you to systematically reassess mobility while improving the patient's ROM. In addition, bathing usually requires that extremities and joints are put through complete ROM.

Passive ROM exercises begin as soon as a patient's ability to move an extremity or joint is lost. Carry out movements slowly and smoothly, through a prescribed range, just to the point of resistance. ROM exercises should not

cause pain. **Never force a joint beyond the point of resistance.** Each joint movement needs to be repeated 5 times during a session, with sessions performed 2 to 3 times a day. When performing passive ROM exercises, stand at the side of the bed closest to the joint being exercised. Use a head-to-toe sequence and move from larger to smaller joints. If an extremity is to be moved or lifted, support the joint by holding distal and proximal areas adjacent to the joint (Fig. 39.11). Use a cupped hand to provide support under the joint (Fig. 39.12). See Table 39.2 for detailed ROM for each joint. Patients on bed rest need to have active ROM exercises incorporated into their daily schedules.

FIG. 39.11 Support joint by holding distal and proximal areas adjacent to joint.

FIG. 39.12 Use cupped hand under joint for support

Positioning Techniques

Patients with impaired nervous, skeletal, or muscular system functioning and increased weakness and fatigue often require help from nurses for positioning and maintenance of proper body alignment while in bed or sitting (see Skill 39.1). Several positioning devices are available for maintaining good body alignment for patients. Pillows are positioning aids and are sometimes readily available. Before using a pillow, determine whether it is the proper size. A thick pillow under a patient's head increases cervical flexion, which is not desirable. A thin pillow under bony prominences does not protect skin and tissue from damage caused by pressure. When additional pillows are unavailable or if they are an improper size, use folded sheets, blankets, or towels as positioning aids.

Apply positioning boots to prevent footdrop by maintaining the feet in dorsiflexion. Ankle-foot orthotic (AFO) devices also help maintain dorsiflexion. Patients who wear positioning boots or AFOs need to have these removed periodically (e.g., 2 hours on, 2 hours off).

A **trochanter roll** prevents external rotation of the hips when a patient is in a supine position. This is especially useful in patients who have lost the ability to move the lower extremities. To form a trochanter roll, fold a cotton bath blanket lengthwise to a width that extends from the greater trochanter of the femur to the lower border of the popliteal space (Fig. 39.13). Place the blanket under the buttocks and roll it counterclockwise until the thigh is in neutral

position or inward rotation. When the hip is aligned correctly, the patella faces directly upward. Use sandbags in place of or in addition to trochanter rolls. Sandbags are sand-filled plastic tubes or bags that are shaped to body contours.

FIG. 39.13 Trochanter roll.

Hand rolls maintain the thumb in slight adduction and in opposition to the fingers, which maintain a functional position. Assess the hand roll positioning to make sure that the hand is indeed in a functional position. Hand rolls are most often used with patients whose arms are paralyzed or who are unconscious. Do not use rolled washcloths as hand rolls because they do not keep the thumb well abducted, especially in patients who have a spastic paralysis. Hand-wrist splints are individually molded for a patient to maintain proper alignment of the thumb (slight adduction) and wrist (slight

dorsiflexion). Use splints only on the patient for whom they were made and follow the splint schedule (e.g., wear for 2 hours, remove for 2 hours).

The **trapeze bar** is a triangular device that hangs down from a securely fastened overhead bar that is attached to the bedframe. It allows a patient to pull with the upper extremities to raise the trunk off the bed, assist in transfer from bed to wheelchair, or perform upper-arm exercises ([Fig. 39.14](#)). It increases independence, maintains upper-body strength, and decreases the shearing action from sliding across or up and down in bed.

FIG. 39.14 Patient using trapeze bar.

Although each procedure for positioning has specific guidelines, there are universal steps to follow for patients who require positioning assistance. Following the guidelines reduces the risk of injury to the musculoskeletal system when a patient is sitting or lying. When joints are unsupported, their

alignment is impaired. Likewise, if joints are not positioned in a slightly flexed position, their mobility is decreased. During positioning also assess for pressure points. When actual or potential pressure areas exist, nursing interventions involve removal of the pressure, thus decreasing the risk for development of pressure injuries and further trauma to the musculoskeletal system. In these patients use the 30-degree lateral position.

Supported Fowler's Position

In the supported Fowler's position the head of the bed is elevated 45 to 60 degrees, and the patient's knees are slightly elevated without pressure to restrict circulation in the lower legs. The patient's illness and overall condition influence the angle of head and knee elevation and the length of time that the patient needs to remain in the supported Fowler's position. Supports need to permit flexion of the hips and knees and proper alignment of the normal curves in the cervical, thoracic, and lumbar vertebrae. The following are common trouble areas for a patient in the supported Fowler's position:

- Increased cervical flexion because the pillow at the head is too thick and the head thrusts forward
- Extension of the knees, allowing the patient to slide to the foot of the bed
- Pressure on the posterior aspect of the knees, decreasing circulation to the feet
- External rotation of the hips
- Arms hanging unsupported at the patient's sides
- Unsupported feet or pressure on the heels
- Unprotected pressure points at the sacrum and heels
- Increased shearing force on the back and heels when the head of the bed is raised greater than 60 degrees

Supine Position

Patients in the supine position rest on their backs. In the supine position the relationship of body parts is essentially the same as in good standing alignment, except that the body is in the horizontal plane. Use pillows, trochanter rolls, and hand rolls or arm splints to increase comfort and reduce injury to the skin or musculoskeletal system. The mattress needs to be firm enough to support the cervical, thoracic, and lumbar vertebrae. Shoulders are supported, and the elbows are slightly flexed to control shoulder rotation. A foot support prevents footdrop and maintains proper alignment. The following are some common trouble areas for patients in the supine position:

- Pillow at the head that is too thick, increasing cervical flexion

- Head flat on the mattress
- Shoulders unsupported and internally rotated
- Elbows extended
- Thumb not in opposition to the fingers
- Hips externally rotated
- Unsupported feet
- Unprotected pressure points at the occipital region of the head, vertebrae, coccyx, elbows, and heels

Prone Position

The patient in the prone position lies face or chest down. Often his or her head is turned to the side, but if a pillow is under the head, it needs to be thin enough to prevent cervical flexion or extension and maintain alignment of the lumbar spine. Placing a pillow under the lower leg permits dorsiflexion of the ankles and some knee flexion, which promote relaxation. If a pillow is unavailable, the ankles need to be in dorsiflexion over the end of the mattress. Although the prone position is seldom used in practice, consider this as an alternative, especially in patients who normally sleep in this position. The prone position also has some benefits in patients with acute respiratory distress syndrome and acute lung injury ([Barnes-Daly et al., 2018](#)). Specialty beds that safely position acutely ill patients in the prone position are available. Assess for and correct any of the following potential trouble points with patients in the prone position:

- Neck hyperextension
- Hyperextension of the lumbar spine
- Plantar flexion of the ankles
- Unprotected pressure points at the chin, elbows, female breasts, hips, knees, and toes

Side-Lying Position

In the side-lying (or lateral) position a patient rests on the side with the major portion of body weight on the dependent hip and shoulder. A 30-degree lateral position is recommended for patients at risk for pressure injuries (see [Chapter 48](#)). Trunk alignment needs to be the same as in standing. The patient needs to maintain the structural curves of the spine, the head needs to be supported in line with the midline of the trunk, and rotation of the spine needs to be avoided. The following trouble points are common in the side-lying position:

- Lateral flexion of the neck
- Spinal curves out of normal alignment

- Shoulder and hip joints internally rotated, adducted, or unsupported
- Lack of foot support
- Lack of protection for pressure points at the ear, shoulder, anterior iliac spine, trochanter, and ankles
- Excessive lateral flexion of the spine if the patient has large hips and a pillow is not placed superior to the hips at the waist

Sims' Position

Sims' position differs from the side-lying position in the distribution of the patient's weight. In Sims' position the patient places the weight on the anterior ileum, humerus, and clavicle. Trouble points common in Sims' position include the following:

- Lateral flexion of the neck
- Internal rotation, adduction, or lack of support to the shoulders and hips
- Lack of foot support
- Lack of protection for pressure points at the ileum, humerus, clavicle, knees, and ankles

Moving Patients

When moving a patient during repositioning, a safe transfer is the first priority. Patients require various levels of assistance to move up in bed, move to the side-lying position, or sit up at the side of the bed. For example, a young, healthy woman may need minimal support as she sits at the side of the bed for the first time after childbirth, whereas an older man may need help from two or more nurses to do the same task after surgery. Transfer devices are available to assist in patient positioning.

Always ask patients to help to their fullest extent possible during positioning. To determine what a patient is able to do alone and how many people are needed to help with positioning or transferring (see [Chapter 38](#)), assess him or her to determine whether the illness contradicts exertion (e.g., cardiovascular disease). Is the patient cooperative and capable of moving? Next determine whether the patient comprehends what is expected. For example, a patient recently medicated for postoperative pain is too lethargic to understand instructions; thus to ensure safety, two nurses are necessary to move him or her. Then determine the patient's comfort level. It is important to assess your personal strength and knowledge of the procedure. Finally determine whether the patient is too heavy or immobile for you to move alone ([Kanaskie and Snyder, 2018](#); [Olinsky and Norton, 2017](#)) (see [Chapter 38](#)).

Preventing Injury To the Integumentary System

The major risk to the skin from restricted mobility is the formation of pressure injuries. Early identification of high-risk patients helps prevent pressure injuries (see [Chapter 48](#)). Interventions aimed at prevention include turning and positioning and the use of therapeutic support surfaces and devices (e.g., low air loss mattresses, heel boots, flotation mattresses) to relieve pressure. Regular skin care (cleansing of soiled areas and use of moisturizers) aims to maintain the condition of the skin. Change the immobilized patient's position according to his or her activity level, perceptual ability, treatment protocols, and daily routines. For example, an obese patient or a very thin patient, both of whom have bowel incontinence, will require more frequent turning than standard practice.

Usually the time that a patient sits uninterrupted in a chair is limited to 1 hour. This interval is shortened in patients who are at very high risk for skin breakdown. Reposition patients frequently because uninterrupted pressure causes skin breakdown. Teach patients to shift their weight in a chair every 15 minutes. Chair-bound patients may benefit from a pressure-relief cushion such as an air, viscous fluid/foam, or gel/foam cushion that reduces pressure.

Elimination System

The nursing interventions for maintaining optimal urinary functioning are directed at keeping the patient well hydrated and preventing urinary stasis, calculi, and infections without causing bladder distention. Normal hydration (e.g., 800 to 2000 mL of noncaffeinated fluids daily) helps prevent renal calculi and UTIs. The well-hydrated patient needs to void large amounts of dilute urine that is approximately equal to fluid intake. Also record the frequency and consistency of bowel movements. Provide a diet rich in fluids, fruits, vegetables, and fiber to facilitate normal peristalsis. If a patient is unable to maintain regular bowel patterns, stool softeners, cathartics, or enemas are sometimes necessary. If the patient is incontinent, modify the care plan to include toileting aids and a hygiene schedule so that the increased urinary output does not cause skin breakdown.

Psychosocial Health

People who have a tendency toward depression or mood swings require nursing interventions that maintain normal development and provide physical and psychosocial stimuli. Anticipate changes in a patient's psychosocial status, and provide routine and informal socialization. Involve family or significant others when appropriate. Observe the patient's ability to cope with restricted mobility. In institutional health care settings try not to schedule nursing care activities between 10:00 PM and 7:00 AM to minimize sleep interruptions. When

care is required, combine activities. For example, administer medications, check an IV infusion, and assess vital signs when you enter the room to turn the patient or provide special skin care. If the nursing care plan is not improving coping patterns, consult a clinical nurse specialist, counselor, social worker, spiritual adviser, or other health care professional. Incorporate their recommendations into the care plan.

Nurses provide meaningful stimuli to maintain a patient's orientation. Plan nursing activities so that a patient is able to talk and interact with staff. If possible, place him or her in a room with others who are mobile and interactive. If a private room is required, ask staff members to visit throughout the shift to provide meaningful interaction. A daily newspaper helps the patient keep track of events and time. Bedside conversations at appropriate moments familiarize him or her with nursing activities, meals, and visiting hours. Books help occupy the patient when he or she is alone. The patient can participate in craft activities. Radio, television, iPods, MP3 players, and videotapes provide stimulation and help pass the time.

Involve patients in their care whenever possible. For example, encourage the patient to determine when the bed should be made and when scheduled ambulation is preferred. Some patients rest better during the night when fresh sheets are put on in the evening rather than in the morning. The patient needs to provide as much self-care as possible. Keep hygiene and grooming articles within easy reach. Encourage patients to wear their glasses or artificial teeth and shave or apply makeup. People use these activities to maintain their body image, thus improving their outlook.

Developmental Health

Ideally a patient who is immobilized for a lengthy period is able to maintain normal developmental processes. Nursing care should provide the mental and physical stimulation appropriate to a patient's age and developmental status. In the case of young children, incorporate play activities into the care plan. For example, completing puzzles helps a child to continue developing fine-motor skills, and reading helps him or her develop cognitively. Encourage parents to stay with a child who is hospitalized. Place a child who is immobilized with children of the same age who are not immobilized unless a contagious disease is present. Allow the child to participate in nursing interventions such as dressing changes, cast care, and care of traction. Learn to recognize significant changes from normal behavioral patterns, and consult with a pediatric clinical nurse specialist, counselor, or other health care professional.

Restricted mobility of older patients presents unique nursing problems. Older patients who are frail or have chronic illnesses are often at increased risk for the psychosocial hazards of immobility. Maintaining a calendar and clock with a large dial, conversing about current events and family members, and

encouraging visits from significant others reduce the risk of social isolation. Spending time in the room talking and listening to the patient also helps reduce the risk of social isolation.

Encourage older immobilized patients to perform as many ADLs as independently as possible. Patients need to continue to perform personal grooming if they did so before their mobility was restricted. This type of activity preserves the patient's dignity and gives him or her a sense of accomplishment.

Restorative and Continuing Care

The goal of restorative care for the patient who is immobile is to maximize functional mobility and independence and reduce residual functional deficits such as impaired gait and decreased endurance. The focus in restorative care is not only on ADLs that relate to physical self-care but also on **instrumental activities of daily living (IADLs)**. IADLs are activities that are necessary to be independent in society beyond eating, grooming, transferring, and toileting and include such skills as shopping, preparing meals, banking, and taking medications.

Nurses use many of the same interventions as described in the health promotion and acute care sections, but the emphasis is on working collaboratively with patients and their significant others and with other health care professionals to facilitate the patient's return to maximal functional ability in both ADLs and IADLs.

Intensive specialized therapy such as occupational or physical therapy is common. If the patient is in a rehabilitation institution, he or she probably goes to the therapy department 2 to 3 times a day. Your role is to work collaboratively with these professionals and reinforce exercises and teaching. For example, after a stroke, a patient is likely to receive gait training from a physical therapist; speech rehabilitation from a speech therapist; and help from an occupational therapist for household chores or ADLs, such as dressing, bathing, and toileting. The therapy is not always able to restore total functional health, but it often helps the patient adapt to the mobility limitations or complications. Equipment frequently used to help patients adapt to mobility limitations includes walkers, canes, wheelchairs, and assistive devices such as toilet seat extenders, reaching sticks, special silverware, and clothing with Velcro closures.

REFLECT NOW

Mrs. Kline is currently in a rehabilitation facility and uses a walker. Her discharge to home is planned in 2 days. Her husband has participated in her rehabilitation but feels he needs help in the home. Their insurance will provide home physical therapy three times a week for 3 weeks. The first visit will be a home assessment. Think about items in the home that might need modification following a home visit, such as tripping hazards (rugs, floor clutter), and items that need to be relocated to provide a clear walking path, such as an ottoman or coffee table. Think about kitchen items that may need to be relocated to avoid overreaching.

Walking and Exercise

A patient who is receiving restorative care continues to be involved in an exercise program, including progressive walking. Care may also include a continuation of ROM exercises. [Chapter 38](#) describes in detail how to assist a patient to ambulate.

Patients with **hemiplegia** (one-sided paralysis) or **hemiparesis** (one-sided weakness) will often need assistance with walking. When an assistive device is used, stand on the patient's affected side and support him or her with a gait belt. Providing support by holding a patient's arm is incorrect because you cannot easily support the patient's weight to lower him or her to the floor if he or she faints or falls. In addition, if the patient falls with the nurse holding an arm, a shoulder joint may be dislocated. [Chapter 38](#) describes how to assist a patient using crutches, walkers, and canes.

Psychotherapy

Recovery from a physical disability is difficult. Psycho-Physical Therapy is one holistic therapeutic approach that acknowledges the importance of addressing the body and spirit as well as the mind during therapeutic work ([Good Therapy, 2016](#)). Therapists combine physical movement work and psychotherapy techniques to help patients gain greater awareness of their abilities and how to proceed toward recovery. Rehabilitation psychologists support individuals as they cope with the mental and physical challenges their conditions present. They often teach their patients how to adapt and make lifestyle choices that promote good health ([APA, 2019](#)). A nurse involved in a

patient's rehab collaborates with the patient, family, and therapists to provide continuity in psychological support and patient education.

. Evaluation

Through the Patient's Eyes

Just as it is important to include the patient during the assessment and planning phase of the care plan, it is essential to have the patient's evaluation of the plan of care (Fig. 39.15). Were the patient's goals or expectations met? Ask the patient to describe his or her perception of recovery from immobilization. Does the patient feel mobility is improving? If not, what factors does the patient perceive are barriers? Determine with the patient and others involved with care whether the goals or outcomes established with and for the patient have indeed been met and whether it is necessary to revise the plan of care. A study involving stroke patients found that patients' intention of becoming independent positively affected their motor recovery, while family members' positive attitudes promoted patient's cognitive improvement (Fang, 2017). Involvement of patient and family is critical.

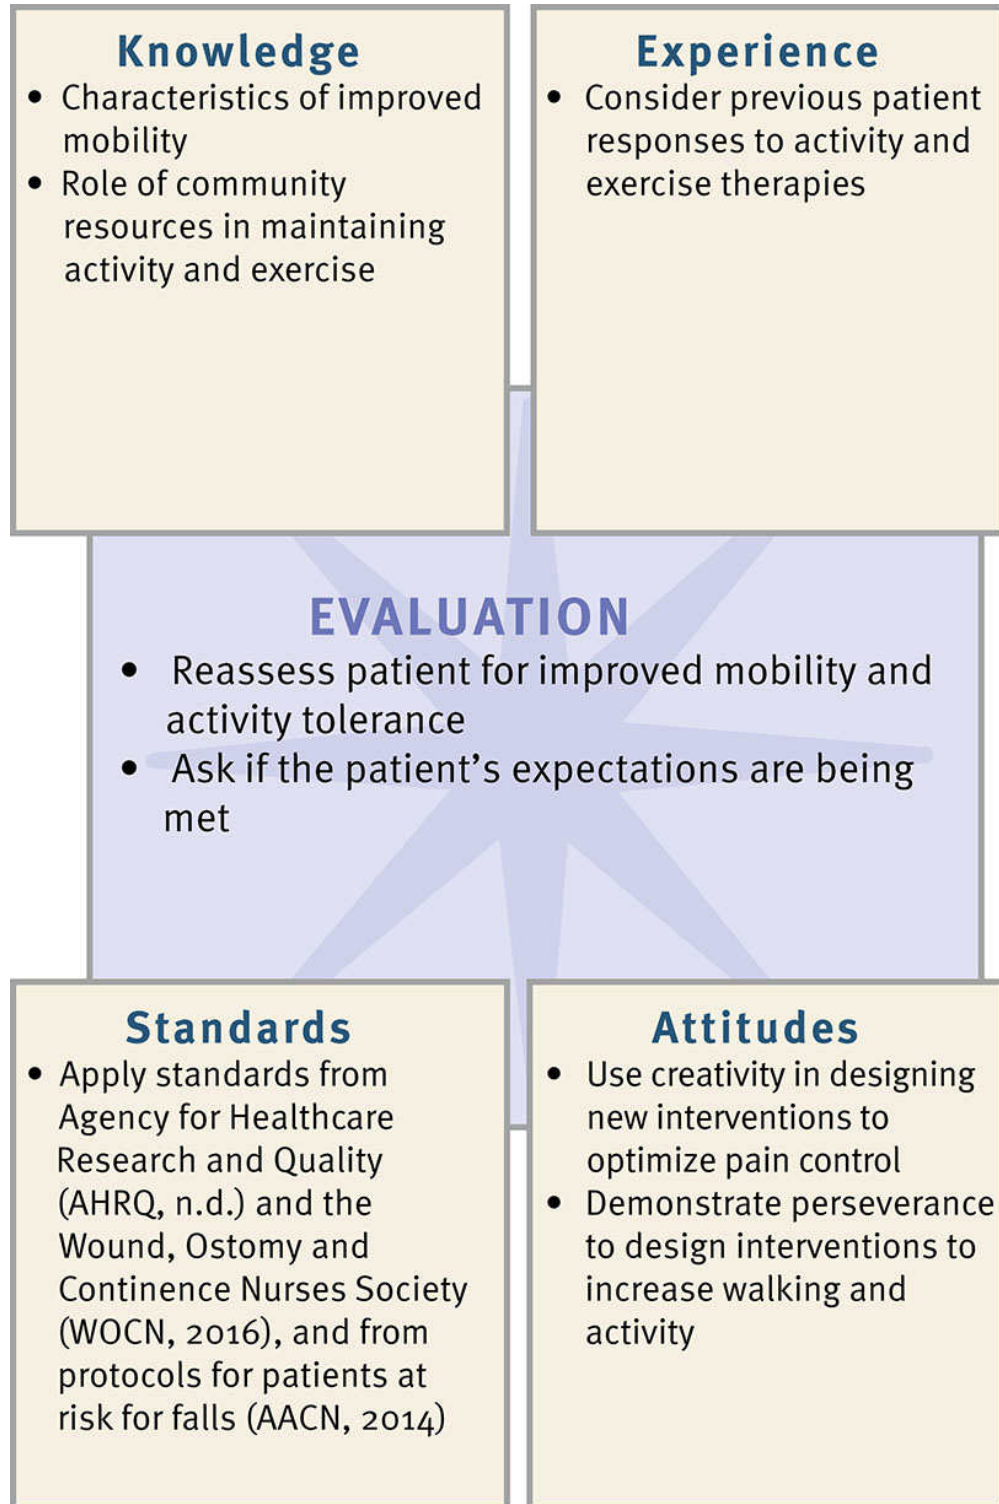

FIG. 39.15 Critical thinking model for evaluation of impaired mobility.

Patient Outcomes

From your perspective as the nurse, you are to evaluate expected outcomes and a patient's response to nursing care and compare the patient's actual outcomes with the outcomes selected during planning. For example, you evaluate a patient's ability to maintain or improve body alignment, joint mobility, walking, moving, or transferring. Evaluate the effectiveness of specific interventions designed to promote body alignment, improve mobility, and protect the patient from the hazards of immobility. Evaluate the patient's and family's understanding of all teaching provided as well. The continuous nature of evaluation allows you to determine whether new or revised therapies are required and whether new nursing diagnoses have developed.

When outcomes are not met, consider asking the following questions:

- Are there ways we can assist you to increase your activity?
- Which activities are you having trouble completing right now?
- How do you feel about not being able to dress yourself and make your own meals?
- Which exercises do you find most helpful?
- What goals for your activity would you like to set now?

Once these questions have been asked and you have addressed the limited mobility and its associated problems through the patient's eyes, you are prepared to adjust the plan of care to address the remaining clinical problems that your patient is experiencing related to immobility.

Safety Guidelines for Nursing Skills

Ensuring patient safety is an essential role of the professional nurse. To ensure patient safety, communicate clearly with the members of the health care team, assess and incorporate the patient's priorities of care and preferences, and use the best evidence when making decisions about your patient's care. When performing the skills in this chapter, remember the following points to ensure safe, individualized patient-centered care.

- Determine the amount and type of assistance required for safe positioning, including any transfer equipment and the number of personnel to safely transfer and prevent harm to patient and health care providers.
- During positioning raise the side rail on the side of the bed opposite of where you are standing to prevent the patient from falling out of bed on that side.

- Arrange equipment (e.g., intravenous lines, feeding tube, indwelling catheter) so that it does not interfere with the positioning process.
- Evaluate the patient for correct body alignment and pressure risks after repositioning.

Skill 39.1. Moving and Positioning Patients in Bed ◦

Delegation and Collaboration

The skills of moving and positioning patients in bed and maintaining correct body alignment can be delegated to assistive personnel (AP). The nurse instructs the AP by:

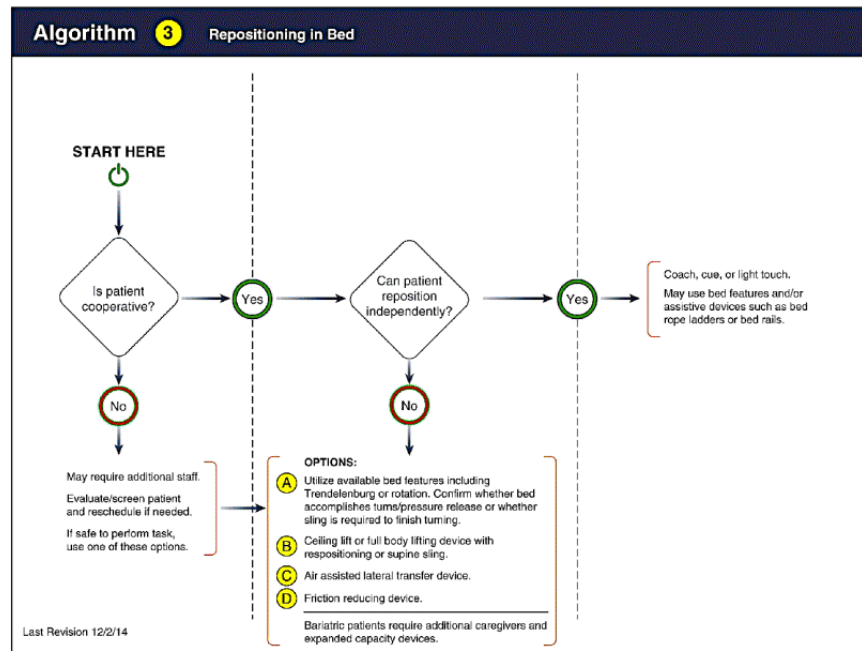

- Explaining any moving and positioning restrictions unique to patient (e.g., avoid prone position, patient has one-sided weakness).
- Designating specific times throughout the shift that AP must reposition patient.
- Providing information about patient's individual needs for body alignment (e.g., patient with spinal cord injury).

Equipment

- Pillows, drawsheet
- Appropriate safe patient-handling assistive devices (e.g., friction-reducing device, ceiling lift, or mechanical floor lift)
- Therapeutic boots/splints (*optional*)
- Trochanter rolls (*optional*)
- Hand rolls (*optional*)
- Clean gloves

Step	Rationale
Assessment	
1. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2020).
2. Refer to medical record for most recent recorded weight and height for patient.	Factors help to determine whether mechanical lift, mechanical transfer device, or friction-reducing device is needed for moving patient up in bed.
3. Check health care provider's orders for any restrictions in movement before positioning patient.	Some positions may be contraindicated in situations such as spinal cord injury; hip fracture; respiratory difficulties; neurological conditions; and presence of incisions, drains, or tubing.
4. Perform hand hygiene.	Reduces transmission of microorganisms.
5. Assess patient's or family caregiver's knowledge, experience, and health literacy	Ensures patient or family caregiver has the capacity to obtain, communicate, process, and understand basic health information (CDC, 2019).
6. Assess patient's range of motion (ROM) and current body alignment while patient is lying down.	Provides baseline data for later comparisons. Determines ways to improve position and alignment.
7. Assess for risk factors that contribute to complications of immobility:	Risk factors require patient to be repositioned more frequently.
a. Reduced sensation: Cerebrovascular accident (CVA), spinal cord injury, or neuropathy.	With reduced sensation, a patient has difficulty moving, has poor awareness of involved body part, and is unable to position body part and protect it from pressure.
b. Impaired mobility: Traction, arthritis, CVA, spinal cord injury, hip fracture, joint surgery, or other contributing disease processes.	Traction, bone fractures, surgery, or arthritic changes result in decreased ROM. Loss of function caused by CVA or spinal injury can lead to contractures.
c. Impaired circulation: Arterial insufficiency.	Decreased circulation predisposes patient to pressure injury.
d. Age: Very young, older adult.	Premature and young infants require frequent turning because their skin is fragile. Normal physiological changes of aging predispose to greater risks for developing complications of immobility.
8. Assess patient's level of consciousness and ability to cooperate in positioning.	Level of cooperation affects need for special aids or devices and additional caregivers. Patients with altered levels of consciousness may not understand instructions or be able to help during positioning.
Table Continued	

Step	Rationale
9. Assess patient for presence of pain; rate on scale of 0 to 10 (see Chapter 44).	Pain reduces patient's motivation and ability to be mobile. Pain relief before transfer enhances patient participation.
10. Assess condition of patient's skin, especially over bony prominences (see Chapter 48).	Provides baseline to determine effects of positioning. Routine positioning reduces occurrence of pressure injuries.
11. Assess patient's physical ability to help with moving and positioning. Can patient reposition independently?	Enables you to use patient's existing mobility, strength, and coordination during positioning. Determines need for additional help and assist devices to ensure patient and nurse safety.
12. Assess patient's vision and hearing (see Chapter 30)	Sensory deficits affect patient's ability to cooperate during repositioning.
13. Apply clean gloves (as needed) to assess for presence of drainage tubes, incisions, and equipment (e.g., traction). Empty drainage bags before positioning. Remove and dispose of gloves. Perform hand hygiene.	Alters positioning procedure and affects patient's ability to independently change positions.
14. Assess motivation of patient and ability of family caregivers to participate in moving and positioning if patient to be discharged home.	Indicates level of instruction needed before discharge.
Planning	
1. Consider all factors applicable to a repositioning algorithm (see illustration) or agency policy, and determine the caregiver resources and positioning equipment needed to perform positioning.	An important element of a safe patient-handling program is patient handling and mobility algorithms (Martin et al., 2014; OSHA, 2017).

STEP 1 Algorithm for repositioning patients in bed (<http://www.asphp.org/Wp-Content/Uploads/2016/06/New-And-Improved-Va-Algorithms-And-New-Sphm-App-Asptp-Rev-Mmm.ppt>).

Table Continued

Step	Rationale
2. If patient perceives level of pain to be enough to avoid movement, offer an analgesic (if ordered) 30 minutes before repositioning.	Will lessen discomfort when positioning extremities. Note: The frequency of an analgesic may not be available as frequently as a patient will require turning.
3. Remove all pillows and devices used in previous position.	Reduces interference during positioning procedure.
4. Explain positioning procedure to patient using plain language.	Helps decrease anxiety and increase cooperation.
5. Close door to room or bedside curtains	Provides for patient privacy.
Implementation	
1. Perform hand hygiene.	Reduces transmission of microorganisms.
2. Raise level of bed to comfortable working height, level with your elbows. Be sure brakes on bed are locked.	Raises level of work toward nurse's center of gravity and reduces risk for back injuries. Ensures patient safety.
3. Assist patient to move up in bed:	This is not a one-person task unless patient can help completely (OSHA, 2014). Pulling patients who have migrated in bed carries an extremely high risk of caregiver injury (Wiggermann, 2014).
a. Determine whether the patient can assist.	Determines degree of risk in repositioning patient and technique required to safely help patient.
(1) Patient can reposition independently:	Positioning techniques promote patient independence.
(a) Stand by for safety as needed. Stand at bedside to help with positioning of tubing and equipment as patient moves.	Prevents accidental tube dislodgment.
(b) Have patient place feet flat on mattress, grasp either side rails or overhead trapeze and, on a count of three, lift hips up and push legs so that body moves up in bed.	Patient uses muscles in coordinated way to smoothly move up in bed with hips lifted.
(2) Patient is unable to reposition independently (see algorithm):	
(a) Explain to patient how he or she can assist as caregivers use safe handling devices.	Patient cooperation improves efficiency of procedure.
(b) Use any available bed features such as Trendelenburg or rotation to move patient up in bed. Position patient supine with head of bed flat. A nurse stands on each side of bed.	Bed features will minimize amount of effort to reposition patient.
(c) If bed features are unavailable, use friction-reducing device or air-assisted lateral transfer device and three caregivers.	Reduces muscular strain during positioning. Devices avoid injury to patient's skin.
i. Position patient supine with head of bed flat. A nurse stands on each side of bed.	
ii. Remove pillow from under head and shoulders and place it at head of bed.	Provides easy access to move patient upward.
iii. Turn patient side to side to place friction-reducing device under drawsheet on bed, with device extending from shoulders to thighs/ankles. Option: Apply deflated air-assisted device.	Ensures device supports patient's full weight.
iv. Return patient to supine position.	
v. Have two caregivers firmly grasp drawsheet (one on each side of bed). Have third nurse hold on to end of friction-reducing device.	Slide board remains stationary, provides slippery surface to reduce friction, and allows patient to move up in bed easily.
vi. Holding fan-folded drawsheet and one nurse counting to three, the two nurses pull drawsheet across slide board, positioning patient up in bed. The third nurse holds slide board in place. Option: Inflate air-assisted device and slide patient up in bed	Positions patient smoothly without exerting shear against skin and without risk of injury to nurses.
(d) If patient weighs over 91 kg (200 lb), use appropriate number of caregivers and appropriate safe patient-handling devices (e.g., supine sling with ceiling lift or floor-based lift and two or more caregivers) to move and position patient.	Repositioning patients manually is associated with high risk of musculoskeletal injury (Wiggermann, 2014).
CLINICAL DECISION: Protect patient's heels from shearing force by having another caregiver lift heels while moving patient up in bed.	
4. Position patient in bed in one of the following positions. Ensure correct body alignment. Protect pressure areas.	Prevents injury to patient's musculoskeletal system and integument. Even positioning patient side to side requires use of safe patient-handling techniques.
a. Confirm whether patient can cooperate and move independently.	Determines degree of risk in repositioning patient and the technique required to safely help patient.
b. Begin with patient lying supine, and move up in bed following Steps 3a(1)–(2).	

Table Continued

Step	Rationale
c. Position patient in supported semi-Fowler's (see illustration) or Fowler's position:	
(1) With patient lying supine, elevate head of bed 45 to 60 degrees if not contraindicated.	Increases comfort, improves ventilation, and increases patient's opportunity to socialize or relax.
(2) Rest head against mattress or on small pillow.	Prevents flexion contractures of cervical vertebrae.
(3) Use pillows to support arms and hands if patient does not have voluntary control or use of hands and arms.	Prevents shoulder dislocation from effect of downward pull of unsupported arms, promotes circulation by preventing venous pooling, and prevents flexion contractures of arms and wrists.
(4) Position small pillow at lower back.	Supports lumbar vertebrae and decreases flexion of vertebrae.
(5) Place pillows lengthwise under each leg (midthigh to ankle) to support the knee in slight flexion (avoids hyperextension) and to allow the heels to float.	Prevents hyperextension of knee and occlusion of popliteal artery from pressure from body weight. Heels should not be in contact with bed. Floating heels prevent prolonged pressure of mattress on heels.
d. Position hemiplegic patient in supported semi-Fowler's or Fowler's position:	
(1) Elevate head of bed 30 to 60 degrees according to patient's condition. For example, those with increased risk for pressure injury remain at 30-degree angle (see Chapter 48).	Increases comfort, improves ventilation, and increases patient's opportunity to relax.
(2) Position patient in Fowler's position as anatomically straight as possible	Counteracts tendency to slump toward affected side. Improves ventilation and cardiac output; decreases intracranial pressure. Improves patient's ability to swallow and helps prevent aspiration of food, liquids, and gastric secretions.
(3) Position head on small pillow with chin slightly forward. If patient is totally unable to control head movement, avoid hyperextension of neck.	Prevents hyperextension of neck. Too many pillows under head may cause or worsen neck flexion contracture.
(4) Provide support for involved arm and hand by placing arm away from patient's side and supporting elbow with pillow.	Paralyzed muscles do not automatically resist pull of gravity as they do normally. As a result, shoulder subluxation, pain, and edema may occur.
(5) Place rolled blanket (trochanter roll) or pillows firmly alongside patient's legs to help prevent the patient from leaning toward the affected side.	Ensures proper alignment. Prevents external rotation of hips, which contributes to contractures.
(6) Support feet in dorsiflexion with therapeutic boots (see illustration) or splints.	Prevents plantar flexion contractures or footdrop by positioning patient's ankle in neutral dorsiflexion. Positions foot so that heel is aligned in opening of splint to prevent pressure. Other therapeutic boots or splints are manufactured with thick padding to cushion heel and prevent pressure injury.
e. Position patient in supported supine position:	
(1) Place patient supine with head of bed flat.	Necessary for properly aligning patient.
(2) Place small rolled towel under lumbar area of back.	Provides support for lumbar spine.
(3) Place pillow under upper shoulders, neck, and head.	Maintains correct alignment and prevents flexion contractures of cervical vertebrae.
(4) Place trochanter rolls or sandbags parallel to lateral surface of patient's thighs.	Reduces external rotation of hip.
(5) Place patient's feet in therapeutic boots or splints.	Maintains feet in dorsiflexion. Prevents plantar flexion contractures or footdrop.
(6) Place pillows under pronated forearms, keeping upper arms parallel to patient's body (see illustration).	Reduces internal rotation of shoulder and prevents extension of elbows. Maintains correct body alignment.
(7) Place hand rolls in patient's hands (see illustration). Consider physical therapy referral for use of hand splints.	Reduces extension of fingers and abduction of thumb. Maintains thumb slightly adducted and in opposition to fingers.
f. Position hemiplegic patient in supine position:	
(1) Place head of bed flat.	Necessary for positioning in supine position.
(2) Place folded towel or small pillow under shoulder of affected side.	Decreases possibility of pain, joint contracture, and subluxation. Maintains mobility in muscles around shoulder to permit normal movement patterns.

Step	Rationale
 <p>STEP 4C Supported Fowler's position.</p>	

STEP 4D(6) Foot boot with lower leg extension.

Table Continued

Step	Rationale
(3) Keep affected arm away from body with elbow extended and palm up. Position affected hand in one of recommended positions for flaccid or spastic hand. (Alternative is to place arm out to side, with elbow bent and hand toward head of bed.)	Maintains mobility in arm, joints, and shoulder to permit normal movement patterns. (Alternative position counteracts limitation of ability of arm to rotate outward at shoulder [external rotation]. External rotation must be present to raise arm overhead without pain.)
(4) Place folded towel under hip of involved side.	Diminishes effect of spasticity in entire leg by controlling hip position.
(5) Flex affected knee 30 degrees by supporting it on pillow or folded blanket.	Slight flexion breaks up abnormal extension pattern of leg. Extensor spasticity is most severe when patient is supine.
(6) Support feet with soft pillows placed against sole of feet at right angle to leg.	Maintains foot in dorsiflexion and prevents footdrop. Pillows prevent stimulation to ball of foot by hard surface, which has tendency to increase muscle tone in patient with extensor spasticity of lower extremity.
CLINICAL DECISION: Offer passive range of motion exercises frequently to retain or improve patient's existing ROM.	
g. Position patient in 30-degree lateral (side-lying) position (one nurse):	This position is recommended to prevent development of pressure injuries by reducing direct contact of trochanter with support surface (see Chapter 48).
(1) Lower head of bed completely or as low as patient can tolerate. Be sure mattress is at your waist level.	Provides position of comfort for patient and removes pressure from bony prominences on back.
(2) Lower side rail and position patient toward side of bed opposite direction toward which patient is to be turned. Place arms under shoulders and move upper trunk toward you first; then place arms under buttocks and upper legs and move lower trunk, supporting hips, toward you.	Provides room for patient to turn to side.
(3) Raise side rail and go to opposite side of bed.	
(4) Lower side rail and flex patient's knee that will not be next to mattress once positioned. Keep foot on mattress. Place one hand on patient's upper bent leg near hip and other hand on patient's shoulder.	Use of leverage makes turning to side easy.
(5) Roll patient onto side toward you.	Rolling decreases trauma to tissues. In addition, patient is positioned so that leverage on hip makes turning easy.
(6) Place pillow under patient's head and neck.	Maintains alignment. Reduces lateral neck flexion. Decreases strain on sternocleidomastoid muscle.
(7) Place your hands under patient's dependent shoulder and bring shoulder blade forward.	Prevents patient's weight from resting directly on shoulder joint.
(8) Position both arms in slightly flexed position. Support upper arm with pillow level with shoulder; other arm, by mattress.	Decreases internal rotation and adduction of shoulder. Supporting both arms in slightly flexed position protects joint. Ventilation improves because chest is able to expand more easily.
(9) Place your hands under patient's dependent hip and bring hip slightly forward so that angle from hip to mattress is approximately 30 degrees.	The 30-degree lateral position reduces pressure on trochanter; designed to prevent pressure injury.
(10) Place small tuck-back pillow behind patient's back. (Make by folding pillow lengthwise. Smooth area is slightly tucked under patient's back.)	Provides support to maintain patient on side.
 <p>STEP 42(3) Supported supine position with pillows in place.</p>	 <p>STEP 42(7) Place hand rolls in patient's hands.</p>

Table Continued

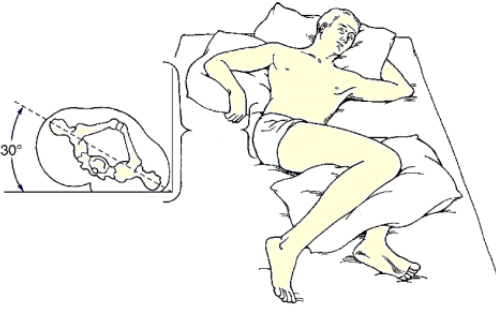

Step	Rationale
(11) Place pillow under semiflexed upper leg level at hip from groin to foot (see illustration).	Flexion prevents hyperextension of leg. Maintains leg in correct alignment. Prevents pressure on bony prominences.
<i>Option:</i> Place pillows or sandbags (if available) parallel against plantar surface of dependent foot. May also use ankle-foot orthotic on feet if available.	Maintains dorsiflexion of foot.
h. Position patient in Sims' (semi-prone) position:	
(1) Lower head of bed completely. Be sure mattress is at waist level.	Provides for proper body alignment while patient is lying down flat on abdomen.
(2) Place patient supine on side of bed opposite direction toward which he or she is to be turned. Place your arms under patient's shoulders and move the upper trunk toward you. Next, place arms under buttocks and upper legs to move trunk toward you, supporting the hips.	Prepares patient for position change.
(3) Move to other side of bed. Lower side rail and flex patient's knee that will not be next to mattress once positioned. Keep foot on mattress. Place one hand on patient's upper bent leg near hip and other hand on patient's shoulder. Turn patient toward you.	Uses leverage to move patient as a unit onto side.
(4) Position in lateral position with patient lying partially on abdomen. Raise side rail and move to other side of bed. Lower side rail and take your hands to lift patient's dependent shoulder out with arm placed at patient's side (see illustration).	Lifting dependent shoulder avoids pressure on joint.
(5) Place small pillow under patient's head.	Maintains proper alignment and prevents lateral neck flexion.
(6) Place pillow under flexed upper arm, supporting arm level with shoulder.	Prevents internal rotation of shoulder. Maintains alignment.
(7) Place pillow under flexed upper legs, supporting leg level with hip.	Prevents internal rotation of hip and adduction of leg. Flexion prevents hyperextension of leg. Reduces mattress pressure on knees and ankles.
(8) Place sandbag parallel against plantar surface of foot or place both feet in footboots.	Maintains foot in dorsiflexion. Prevents plantar flexion contractures or footdrop.
 <p data-bbox="362 1297 657 1312">STEP 4C(11) Thirty-degree lateral position with pillows in place.</p>	 <p data-bbox="1092 1050 1268 1075">STEP 4H(4) Prone position with pillows supporting lower legs.</p>

Table Continued

Step	Rationale
i. Logroll patient (three nurses):	
CLINICAL DECISION: A registered nurse supervises and helps the AP when there is a health care provider's order to logroll a patient. Patients with spinal cord injuries or who are recovering from neck, back, or spinal surgery need to keep the spinal column in straight alignment to prevent further injury.	
(1) Place small pillow between patient's knees.	Prevents tension on spinal column and adduction of hip.
(2) Cross patient's arms on chest.	Prevents injury to arms.
(3) Position two nurses on side toward which patient is to be turned and one nurse on side where pillows are to be placed behind patient's back(see illustration).	Distributes weight equally among nurses during turning.
(4) Fanfold drawsheet along backside of patient.	Provides strong handles for nurses to grip drawsheet without slipping.
(5) With one nurse grasping drawsheet at lower hips and thighs and the other nurse grasping drawsheet at patient's shoulders and lower back, roll patient as one unit in a smooth, continuous motion on count of three (see illustration).	Maintains proper alignment by moving all body parts at the same time, preventing tension or twisting of spinal column.
(6) Nurse on opposite side of bed places pillows along length of patient for support (see illustration).	Maintains patient in side-lying position.
(7) Gently lean patient, as a unit, back toward pillows for support (see illustration).	Ensures continued straight alignment of spinal column, preventing injury.
5. Be sure patient feels comfortable in new position. Place nurse call system in accessible location within patient's reach.	Gives patient sense of well-being. Ensures patient can call for help if needed.
6. Raise side rails (as appropriate), and lower bed to lowest position.	Ensures patient safety.
7. Perform hand hygiene.	Reduces transmission of microorganisms.
 <p data-bbox="362 1163 545 1178">STEP 4(1) Preparing patient for logroll.</p>	 <p data-bbox="1089 938 1273 968">STEP 4(6) Place pillows along patient's back for support.</p>
 <p data-bbox="362 1568 610 1583">STEP 4(5) Move patient as a unit, logrolling onto side.</p>	 <p data-bbox="1089 1365 1273 1394">STEP 4(7) Gently lean patient as a unit against pillows.</p>

Table Continued

Step	Rationale
EVALUATION	
1. Assess patient's respiratory status, body alignment, position, and level of comfort. Patient's body should be supported by adequate mattress, and vertebral column should be without observable curves.	Determines effectiveness of positioning and patient's tolerance. Additional supports (e.g., pillows, bath blankets) may be added or removed to promote comfort and correct body alignment.
2. Measure range of motion (ROM). Assess patient's ability to perform active range of motion and passive range of motion as needed to identify early joint contractures.	Determines whether joint contracture is developing.
3. Observe skin for areas of erythema, blistering, or breakdown. Pay special attention to bony prominences and areas and body regions that may be experiencing extended pressure.	Provides ongoing observation regarding patient's skin and musculoskeletal systems. Indicates complications of immobility or improper positioning of body part.
4. Use Teach-Back: "I want to be sure I explained the steps we are going to use to move and position you in bed. Please repeat the steps you can follow to help us move you up in bed." Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly.	Determines patient's/family caregiver's level of understanding of instructional topic.
Unexpected Outcomes and Related Interventions	
1. Joint contractures develop or worsen. <ul style="list-style-type: none"> • Increase frequency of ROM exercises to affected and immobilized areas (see Table 39.2). • Consider physical therapy consult for different positioning. 	
2. Skin shows areas of erythema and breakdown. <ul style="list-style-type: none"> • Increase frequency of turning and repositioning. • Place turning schedule above patient's bed. 	
3. Patient avoids moving. <ul style="list-style-type: none"> • Medicate with analgesia as ordered by health care provider to ensure patient's comfort before moving. • Allow pain medication to take effect before repositioning. 	
Recording and Reporting <ul style="list-style-type: none"> • Record on flow sheet or nurses' notes positioning change, time of change, and observations (e.g., condition of skin, joint movement, patient's ability to assist with positioning). • Document your evaluation of patient learning. • Report observations of patient's tolerance of position changes to nurse at change of shift. • Report skin or joint complications to health care provider. 	
Home Care Considerations <ul style="list-style-type: none"> • Assess the need for special transfer equipment to be used in the home setting. Assess home environment for hazards (e.g., throw rugs, electrical cords, slippery floors). If wheelchair is used, access must be possible through all doors, and space for transfer must be available in bathroom and bedroom. • Assess home to determine compatibility of environment with assistive devices (e.g., over-bed trapeze, mechanical lift, hospital bed). • Assess ability and motivation of patient and family caregivers to participate in moving and positioning patient in bed. • For patients who use wheelchairs at home, recommend these safety precautions: <ul style="list-style-type: none"> • Always check wheelchair locks, wheels, and footplates for proper functioning before use. • Never attempt to reach an object if you must move forward in the wheelchair seat or pick an object up from the floor by reaching between your knees. • Position wheelchair as close as possible to a desired object. Position the wheel casters so that they are extended away from the drive wheels to create the longest possible wheelbase. Reach back only as far as your arm will extend without changing your sitting position. • Always inspect any ramp, incline, decline, or pathway for hazards such as holes, obstacles, or slippery or uneven surfaces before proceeding. If you cannot see the entire ramp, ask someone to inspect it for you. 	

Key Points

- Injuries or disease processes that impact coordination and regulation of muscle groups pathologically influence mobility.
- Immobility increases the risk of skin breakdown and is directly related to the development of deep vein thromboses (DVT) and pulmonary emboli (PE).
- Immobility can negatively impact the ability to complete daily activities and can lead to boredom and social isolation.

- The risk of disabilities related to immobilization depends on the extent and duration of immobilization and the patient's overall level of health.
- Observing the appearance of extremities and measuring the range of motion of joints in various body positions assess for correct body alignment.
- The nursing process and critical thinking assist you in identifying nursing diagnoses so that you can individualize care for your patients who are experiencing or are at risk for the adverse effects of impaired body alignment and mobility.
- Patient movement algorithms serve as assessment tools for developing individualized approaches for safe patient handling and movement.
- Patients with impaired body alignment and mobility require the use of correct positioning techniques.
- Working collaboratively with health care providers, a nurse will identify patient risk factors for DVT and employ nursing interventions that reduce risk, such as early ambulation; leg, foot, and ankle exercises; regularly provided fluids; and frequent position changes.
- Careful and continuous evaluation of patient outcomes from both a nursing and patient perspective supports revision of the nursing care plan to continue optimization of mobility.

Reflective Learning

- Reflect on a recent clinical experience in which a patient needed to ambulate but was unable to because of voiced complaints of pain, and describe the interventions you implemented.
- Recall any challenges in patient repositioning experienced during a clinical day, and describe any safe patient-handling techniques you applied.

- Reflect on a patient experience you encountered today, and describe the risks the patient had because of reduced mobility.

Review Questions

1. A patient has been on bed rest for over 5 days. Which of these findings during the nurse's assessment may indicate a complication of immobility?
 1. Decreased peristalsis
 2. Decreased heart rate
 3. Increased blood pressure
 4. Increased urinary output
2. An older-adult patient has been bedridden for 2 weeks. Which of these complaints by the patient indicates to the nurse that he or she is developing a complication of immobility?
 1. Increase of appetite
 2. Gum soreness
 3. Difficulty in swallowing
 4. Left ankle joint stiffness
3. A patient is receiving 40 mg of enoxaparin subcutaneously every 12 hours while on prolonged bed rest to prevent thrombophlebitis. Because bleeding is a potential side effect of this medication, the nurse should continually assess the patient for what signs of bleeding? (Select all that apply.)
 1. Bruising
 2. Pale yellow urine
 3. Bleeding gums
 4. Coffee ground-like vomitus
 5. Light brown stool
4. Place the following steps in the correct order for positioning a patient in the 30-degree lateral side-lying position.
 1. Raise side rail and go to opposite side of bed.

2. Lower side rail and flex patient's knee that will not be next to mattress. Keep foot on mattress and place one hand on patient's upper bent leg near hip and other hand on shoulder.
 3. Lower head of bed flat if patient can tolerate it.
 4. Roll patient onto side toward you.
 5. Lower side rail and position patient on side of bed opposite the direction toward which patient is to be turned.
 6. Place hands under patient's dependent shoulder and bring shoulder blade forward.
 7. Place hands under patient's dependent hip and bring hip slightly forward so that angle from hip to mattress is approximately 30 degrees.
5. The effects of immobility on the cardiac system include which of the following? (Select all that apply.)
1. Thrombus formation
 2. Increased cardiac workload
 3. Weak peripheral pulses
 4. Irregular heartbeat
 5. Orthostatic hypotension
6. A 46-year-old patient is admitted to the emergency department following an automobile accident. The patient has a pelvic fracture and is ordered on bed rest and placed in an immobilization device to limit further injury until the fracture can safely be repaired. Which measures would be appropriate for this patient to prevent complications of bed rest? (Select all that apply.)
1. Administer intravenous analgesic as ordered.
 2. Have patient perform incentive spirometry.
 3. Support patient in active assistive ROM exercises of upper extremities.
 4. Provide patient a low-calorie diet.
 5. Apply sequential compression devices to legs.

7. A patient has an order for application of compression stockings. Place the following steps for application of the stockings in the correct order:
 1. Place patient's toes into foot of stocking up to the heel; keep smooth.
 2. Use tape measure to measure patient's leg for proper stocking size.
 3. Slide stocking up over patient's calf until sock is completely extended.
 4. Turn elastic stocking inside out, keeping hand inside holding heel. Take other hand and pull stocking inside out until reaching the heel.
 5. Slide remaining portion of stocking over patient's foot, covering toes. Be sure foot fits into toe and heel of stocking.

8. An older-adult patient is admitted following a hip fracture and surgical repair. Before ambulating the patient postoperatively on the evening of surgery, which of the following would be most important to assess? (Select all that apply.)
 1. Patient's usual dietary intake
 2. Time and date of the patient's last bowel movement
 3. Preadmission activity tolerance
 4. Baseline heart rate
 5. Patient's home living situation

9. A nurse is helping a patient perform active assisted range of motion in the right elbow. Which statement describes the correct technique?
 1. Support elbow by holding distal part of extremity.
 2. Grasp joint with fingers to provide support.
 3. Have patient move joint independently.
 4. Move the joint past the point of resistance.
 5. Perform the exercise a few times only, and gradually build up to more.

10. A middle-aged adult patient has limited mobility following a total knee arthroplasty. During assessment, the nurse notes that the patient is having difficulty breathing while lying supine. Which assessment data support a pulmonary issue related to immobility? (Select all that apply.)

1. Oxygen saturation of 89%
2. Irregular radial pulse
3. Diminished breath sounds bilateral bases on auscultation
4. BP: 132/84
5. Pain reported at 3 on scale of 0 to 10 following medication
6. Respiratory rate of 26

Hygiene

OBJECTIVES

- Describe factors that influence personal hygiene practices.
- Discuss how a nurse applies critical thinking when providing hygiene.
- Conduct a comprehensive assessment of a patient's total hygiene needs.
- Discuss conditions that place patients at risk for impaired skin integrity.
- Discuss factors that influence the condition of the nails and feet.
- Explain the importance of foot care for the patient with diabetes.
- Discuss conditions that place patients at risk for impaired oral mucous membranes.
- List common hair and scalp problems and their related interventions.
- Describe how hygiene care for the older adult differs from that for the younger patient.
- Discuss different approaches used in maintaining a patient's comfort and safety during hygiene care.
- Successfully perform hygiene procedures for the care of the skin, perineum, feet and nails, mouth, eyes, ears, and nose.
- Discuss how to adapt hygiene care for a patient who is cognitively impaired.

Personal hygiene influences patients' comfort, safety, and well-being. Hygiene includes cleaning and grooming activities that maintain personal body cleanliness and appearance. A variety of personal, social, financial, and cultural factors influence hygiene practices. Because hygiene care requires close contact with your patients, use communication skills (e.g., listening, reflecting, focusing) to promote caring therapeutic relationships (see [Chapter 24](#)). When providing hygiene, integrate other nursing activities, including patient assessment and interventions such as range-of-motion (ROM) exercises, application of dressings, or inspection and care of intravenous (IV) sites.

Healthy people are usually able to meet their own hygiene needs. However, physical or cognitive impairments and emotional challenges often cause individuals to need some degree of assistance with hygiene care. In agency and home care settings, assess each patient's ability to perform self-hygiene care according to individual needs and preferences. When making adaptations for hygiene techniques and approaches, always ensure privacy, convey respect, and foster a patient's independence, safety, and comfort.

Scientific Knowledge Base

Proper hygiene care requires an understanding of the anatomy and physiology of the skin, nails, oral cavity, eyes, ears, and nose. The skin and mucosal cells exchange oxygen, nutrients, and fluids with underlying blood vessels. The cells require adequate nutrition, hydration, and circulation to resist injury and disease. Good hygiene techniques promote the normal structure and function of these tissues.

Apply knowledge of pathophysiology to provide preventive hygiene care. Recognize disease states that create changes in the integument, oral cavity, and sensory organs. For example, diabetes mellitus often results in chronic vascular changes that impair healing of the skin and mucosa. In the early stages of acquired immunodeficiency syndrome (AIDS), fungal infections of the oral cavity are common. Paralysis of the trigeminal nerve (cranial nerve V) eliminates the blink reflex, causing risk of corneal drying. In the presence of conditions such as these, adapt hygiene practices to minimize injury. Use time spent providing hygiene care to assess for and identify abnormalities and initiate appropriate actions to prevent further injury to sensitive tissues.

The Skin

The skin serves several functions, including protection, secretion, excretion, body temperature regulation, and cutaneous sensation ([Table 40.1](#)). The layers of the skin include the epidermis, the dermis, and the subcutaneous tissue (also known as the *hypodermis*), which shares some of the protective functions of the skin.

TABLE 40.1**Function of the Skin and Implications for Care**

Function/Description	Implications for Care
Protection	
<p>Epidermis is a relatively impermeable layer that prevents entrance of microorganisms. Although microorganisms reside on skin surface and in hair follicles, relative dryness of surface of skin inhibits bacterial growth. Sebum removes bacteria from hair follicles. Acidic pH of skin further retards bacterial growth.</p>	<p>Weakening of the epidermis occurs by scraping or stripping its surface (e.g., use of dry razors, tape removal, improper turning or positioning techniques).</p> <p>Excessive dryness causes cracks and breaks in skin and mucosa that allow bacteria to enter. Emollients soften skin and prevent moisture loss, soaking skin improves moisture retention, and hydrating mucosa prevents dryness.</p> <p>Constant exposure of skin to moisture causes maceration or softening, interrupting dermal integrity and promoting ulcer formation and bacterial growth.</p> <p>Keep bed linen and clothing dry.</p> <p>Misuse of soap, detergents, cosmetics, deodorant, and depilatories causes chemical irritation. Alkaline soaps neutralize the protective acid condition of skin. Cleaning skin removes excess oil, sweat, dead skin cells, and dirt, which promote bacterial growth.</p> <p>Minimize friction to avoid loss of stratum corneum, which increases risk for pressure injuries.</p>
Sensation	
<p>Skin contains sensory organs for touch, pain, heat, cold, and pressure.</p>	<p>Smooth linen out to remove sources of mechanical irritation.</p> <p>Make sure that bath water is not excessively hot or cold.</p>
Temperature Regulation	
<p>Radiation, evaporation, conduction, and convection control body temperature.</p>	<p>Factors that interfere with heat loss alter temperature control.</p> <p>Wet bed linen or gowns increase heat loss.</p> <p>Excess blankets or bed coverings conserve heat and interfere with heat loss through radiation and conduction. Coverings promote heat conservation.</p>
Excretion and Secretion	
<p>Sweat promotes heat loss by evaporation. Sebum lubricates skin and hair.</p>	<p>Perspiration and oil sometimes harbor microorganisms.</p> <p>Bathing removes excess body secretions, but excessive bathing causes dry skin.</p>

The epidermis (outer layer) shields underlying tissues against water loss and injury, prevents entry of disease-producing microorganisms, and generates new cells to replace the dead cells that are continuously shed from the outer surface of the skin. Bacteria (normal flora) commonly reside on the outer epidermis. The resident normal flora do not cause disease but instead inhibit the multiplication of disease-causing microorganisms (see [Chapter 28](#)).

Bundles of collagen and elastic fibers form the thicker dermis that underlies and supports the epidermis. Nerve fibers, blood vessels, sweat glands, sebaceous glands, and hair follicles run through the dermal layers. Sebaceous glands secrete sebum, an oily, odorous fluid, into the hair follicles. Sebum softens and lubricates the skin and slows water loss from the skin when the humidity is low. More important, sebum has bactericidal action.

The subcutaneous tissue functions as a heat insulator, supports upper skin layers in withstanding stresses and pressure, and anchors the skin loosely to underlying structures such as muscle. The subcutaneous tissue layer contains blood vessels, nerves, lymph tissue, and loose connective tissue filled with fat cells. Very little subcutaneous tissue underlies the oral mucosa.

The skin often reflects a change in physical condition by alterations in color, thickness, texture, turgor, temperature, and hydration (see [Chapter 30](#)). As long as the skin remains intact and healthy, its physiological function remains optimal. Hygiene practices frequently influence skin status and can have beneficial and negative effects on the skin. For example, too-frequent bathing and use of hot water frequently lead to dry, flaky skin and loss of protective oils.

The Feet, Hands, and Nails

The feet, hands, and nails often require special attention to prevent infection, odor, and injury. The condition of a patient's hands and feet influences the ability to perform hygiene care. Without the ability to bear weight, ambulate, or manipulate the hands, a patient is at risk for losing self-care ability.

A wide range of dexterity exists in the hand because of the movement between the thumb and fingers. Any condition (e.g., arthritis, multiple sclerosis, traumatic hand injury) that interferes with hand movement (e.g., superficial or deep pain or joint inflammation) impairs a patient's self-care abilities. Foot pain often changes a patient's gait, causing strain on different joints and muscle groups. Discomfort while standing or walking limits self-care abilities.

The nails are epithelial tissues that grow from the root of the nail bed, located in the skin at the nail groove hidden by a fold of skin called the *cuticle*. A normal healthy nail appears transparent, smooth, and convex, with a pink nail bed and translucent white tip. Inadequate nutrition and disease cause changes in the shape, thickness, and curvature of the nail (see [Chapter 30](#)).

The Oral Cavity

The oral cavity consists of the lips surrounding the opening of the mouth, the cheeks running along the sidewalls of the cavity, the tongue and its muscles, and the hard and soft palate. The mucous membrane, continuous

with the skin, lines the oral cavity. The floor of the mouth and the undersurface of the tongue are richly supplied with blood vessels. Normal oral mucosa glistens and is pink, soft, moist, smooth, and without lesions. Ulcerations or trauma frequently results in significant bleeding. Several glands within and outside the oral cavity secrete saliva. Saliva cleanses the mouth, dissolves food chemicals to promote taste, moistens food to facilitate bolus formation, and contains enzymes. Medications, exposure to radiation, dehydration, and mouth breathing may impair salivary secretion in the mouth, which increases the patient's risk for **xerostomia**, or dry mouth.

A normal tooth consists of the crown, neck, and root. Healthy teeth appear in a variety of shades of white, smooth, shiny, and aligned. The condition of the oral cavity reflects overall health and indicates oral hygiene needs (see [Chapter 30](#)).

Difficulty in chewing develops when surrounding gum tissues become inflamed or infected or when teeth are lost or become loosened. Regular oral hygiene helps to prevent **gingivitis** (i.e., inflammation of the gums) and **dental caries** (i.e., tooth decay produced by interaction of food with bacteria).

The Hair

Hair growth, distribution, and pattern indicate a person's general health status. Special hair-care practices focus on care of the scalp, axilla, and pubic areas. Hormonal changes, nutrition, emotional and physical stress, aging, infection, and some illnesses affect hair characteristics. The hair shaft itself is lifeless, and physiological factors do not affect it directly. However, hormonal and nutrient deficiencies of the hair follicle cause changes in hair color or condition.

The Eyes, Ears, and Nose

When providing hygiene, the eyes, ears, and nose require careful attention because of sensitive anatomical structures. For example, the cornea of the eye contains many nerve endings sensitive to irritants such as soap.

The eyes secrete tears, which contain substances to cleanse and lubricate the eye and protect it from bacteria. Specialized glands in the auditory canal secrete cerumen, which traps foreign bodies and repels insects. Cerumen builds up and becomes impacted in some people. Patients with alterations in one or more of the senses often need help to meet their

hygiene needs. [Chapter 30](#) describes the structure and function of these organs.

REFLECT NOW

When you were in your anatomy and physiology classes, you learned about the skin and mucous membranes. Think about the impact of sun on the skin. What types of short- or long-term issues can occur on the skin with sun exposure?

Nursing Knowledge Base

A number of factors influence personal preferences for hygiene and the ability to maintain hygiene practices. Since no two individuals perform hygiene care in the same manner, you individualize patient care based on learning about his or her unique hygiene practices and preferences. Individualized hygiene care requires knowing the patient and using therapeutic communication skills to promote a trusting therapeutic relationship. Use the opportunities provided during hygiene care to assess a patient's health promotion practices, emotional status, and health care education needs and then offer educational interventions. Be aware that developmental changes influence the need and preferences for types of hygiene care.

Factors Influencing Hygiene

Social Practices

Social groups influence hygiene preferences and practices, including the type of hygiene products used and the nature and frequency of personal care practices. Parents and caregivers perform hygiene care for infants and young children. Family customs play a major role during childhood in determining hygiene practices, such as the frequency of bathing, the time of day bathing is performed, and even whether certain hygiene practices such as brushing the teeth or flossing are performed. As children enter adolescence, peer groups and media often influence hygiene practices, and health education is important. For example, health education impacts adolescent girls' choices related to menstrual hygiene (Kole et al., 2018). Young girls become more interested in their personal appearance and begin to wear makeup. During the adult years, involvement with friends and work groups shapes the expectations that people have about personal appearance. Some individuals' hygiene practices change because of changes in living conditions and available resources. This is common in older adults who have limited finances and in the homeless and people living in poverty.

Personal Preferences

Patients have individual preferences about how and when to perform hygiene and grooming care. Some patients prefer to shower, whereas others prefer to bathe. Patients select different hygiene and grooming products according to personal preferences. Knowing patients' personal preferences promotes individualized care. Culture plays a role in sensitivity to personal space and gender (see [Box 40.1](#) and [Chapter 9](#)). Help a patient develop new hygiene practices when indicated by an illness or condition. For example, you may need to teach a patient with diabetes proper foot hygiene or a bariatric patient adaptive bathing methods. Safe and effective patient-centered nursing care improves patient satisfaction and health and reduces costs ([Burman et al., 2013](#)).

Box 40.1 Cultural Aspects of CareHygiene

Practices

Patients deserve a culturally congruent plan for hygiene care. For many patients, culture influences hygiene practices, and hygiene care may become a potential source of conflict and stress in the caregiving environment (Marion et al., 2017). Patient-centered care mandates that care is aligned with patients' values, needs, practices, and expectations, providing equitable and ethical care, and that care be based on respect for an individual patient's cultural background (Henderson et al., 2018). A nurse must also consider other aspects of culture, such as a patient's educational and developmental levels, extent of any physical disabilities, and geographical location of home when delivering hygiene.

Implications for Patient-Centered Care

- Maintain privacy, especially for women from cultures that value female modesty, and provide gender-congruent caregivers as requested (Giger, 2017).

- Collaborate with community leaders when providing health education for a diverse community (LaFleur et al., 2017).
- Allow family members to participate in care if desired by adapting the schedule of hygiene activities.
- Recognize that some cultures prohibit or restrict touching. Incorporate awareness that people from different cultural backgrounds have differing preferences regarding personal space. In some cases touch is considered magical and healing; others view it as evil or anxiety producing (Giger, 2017).
- Recognize cultural hair practices, and do not cut or shave hair without prior discussion with patient or family (Bowen and O'Brien-Richardson, 2017).
- Be aware that toileting practices vary by culture (Giger, 2017).
- Recognize that different cultures have preferences about hot and cold water and their effects on healing or diseases (Morgan-Consoli and Unzueta, 2018).

Body Image

Body image is a person's subjective concept of his or her body, including physical appearance, structure, or function (see [Chapter 33](#)). Body image affects the way in which individuals maintain personal hygiene. If a patient maintains a neatly groomed appearance, be sure to consider the details of grooming when planning care, and consult with the patient before making decisions about how to provide hygiene. Patients who appear unkempt or uninterested in hygiene sometimes need education about its importance or further assessment regarding their ability to participate with daily hygiene.

Surgery, illness, or a change in emotional or functional status often affects a patient's body image. Discomfort and pain, emotional stress, and fatigue diminish the ability or desire to perform hygiene self-care and require extra effort to promote hygiene and grooming.

Socioeconomic Status

A person's economic resources influence the type and extent of hygiene practices used. Be sensitive in considering that a patient's economic status influences the ability to regularly maintain hygiene. He or she may not be able to afford desired basic supplies such as deodorant, shampoo, and toothpaste. A patient may need to modify the home environment by adding safety devices such as nonskid surfaces and grab bars in the bath to perform hygiene self-care safely. When patients lack socioeconomic resources, it becomes difficult for them to participate and take responsible roles in health promotion activities such as basic hygiene.

Health Beliefs and Motivation

Knowledge about the importance of hygiene and its implications for well-being influences hygiene practices. However, knowledge alone is not enough. Motivation also plays a key role in a patient's hygiene practices. Motivational interviewing can assist you in identifying how a patient perceives benefit in performing hygiene and his or her willingness to change behavior (see [Chapter 25](#)). Adapt what you learn about a patient's willingness to change into your patient teaching approach. Provide information that focuses on a patient's personal health-related issues relevant to the desired hygiene care behaviors. Patient perceptions of the benefits of hygiene care and the susceptibility to and seriousness of developing a problem affect the motivation to change behavior. For example, do patients perceive that they are at risk for dental disease, or that dental disease is serious, and that brushing and flossing are effective in reducing risk? When they recognize that there is a risk and that they can take reasonable action without negative consequences, they are more likely to be receptive to modify health behaviors ([Broadbent et al., 2016](#)).

Cultural Variables

Cultural beliefs, religious practices, and personal values influence hygiene care (see [Box 40.1](#)). People from diverse cultural backgrounds (e.g., level of education, gender preference, geographic location) frequently follow different self-care practices (see [Chapter](#)

9). For example, maintaining cleanliness does not hold the same importance for some ethnic or social groups as it does for others (Giger, 2017). In North America many are fortunate to be able to bathe or shower daily and use deodorant to prevent body odors. However, people from some socioeconomic or cultural groups are not sensitive to body odors, prefer to bathe less frequently, and do not use deodorant. Avoid expressing disapproval or forcing changes in hygienic practices unless the practices affect a patient's health. In these situations, use tact, provide information, and allow choices.

Developmental Stage

The normal process of aging affects the condition of body tissues and structures. Apply your knowledge of physical and psychosocial developmental changes as you assess your patients and plan, implement, and evaluate hygiene care. A patient's developmental stage affects the ability of a patient to perform hygiene care and the type of care needed. Use your knowledge of developmental changes when planning hygiene care.

Skin

The neonate's skin is relatively immature at birth. The epidermis and dermis are bound together loosely, and the skin is very thin. Friction against the skin layers causes bruising. Handle a neonate carefully during bathing. Any break in the skin easily results in an infection.

A toddler's skin layers become more tightly bound together. Thus, the child has a greater resistance to infection and skin irritation. However, because of his or her more active play and the absence of established hygiene habits, parents and caregivers need to provide thorough hygiene and teach good hygiene habits.

During adolescence the growth and maturation of the integument increase. In girls, estrogen secretion causes the skin to become soft, smooth, and thicker with increased vascularity. In boys, male hormones produce an increased thickness of the skin with some darkening in color. Sebaceous glands become more active, predisposing adolescents to acne (i.e., active inflammation of the sebaceous glands accompanied by pimples). Sweat glands become

fully functional during puberty. Adolescents usually begin to use antiperspirants. More frequent bathing and shampooing also become necessary to reduce body odors and eliminate oily hair.

The condition of the adult's skin depends on bathing practices and exposure to environmental irritants. Normally the skin is elastic, well hydrated, firm, and smooth. When an adult bathes frequently or is exposed to an environment with low humidity, it becomes dry and flaky. With aging the rate of epidermal cell replacement slows, and the skin thins and loses resiliency. Moisture leaves the skin, increasing the risk for bruising and other types of injury. As the production of lubricating substances from skin glands decreases, the skin becomes dry and itchy ([Touhy and Jett, 2018](#)). These changes warrant caution when bathing, turning, and repositioning older adults. Too-frequent bathing and bathing with hot water or harsh soap cause the skin to become excessively dry ([American Academy of Dermatology, 2018](#)).

Feet and Nails

Foot health is a key component to a person's mobility, health, and overall well-being. With aging and continued exposure to the trauma of walking and weight-bearing, a patient is more likely to develop chronic foot problems compounded as a result of poor foot care, improper fit of footwear, and local abnormalities and systemic disease ([Persaud et al., 2018](#)). For example, Morton's neuroma, a common condition in middle-age women, affects health-related quality of life by causing burning, numbness, and pain of the foot on weight-bearing ([Park et al., 2018](#)).

Older adults do not always have the strength, flexibility, visual acuity, or manual dexterity to care for their feet and nails. Foot problems may be overlooked and impact a patient's comfort, mobility, and quality of life ([Persaud et al., 2018](#)). Older adults frequently complain of foot pain. They also often have dry feet because of a decrease in sebaceous gland secretion and dehydration of epidermal cells. Common problems of the feet affecting older adults include corns, calluses, bunions, hammertoes, maceration between toes, and fungal infections ([Arthritis Foundation, 2017](#)).

The Mouth

At approximately 6 to 8 months of age, infants begin teething. The first permanent (secondary) teeth erupt at about 6 years of age ([Hockenberry et al., 2019](#)). From adolescence, when all the permanent teeth are in place, through middle adulthood, the teeth and gums remain healthy if a person follows healthy eating patterns and dental care. Avoiding fermentable carbohydrates and sticky sweets helps to keep the teeth free of dental caries. In addition, regular brushing (twice a day) and flossing reduce caries and periodontal disease.

As a person ages, numerous factors result in poor oral health, including age-related changes of the mouth, changes resulting from chronic disease such as diabetes, physical disabilities involving hand grasp or strength affecting the ability to perform oral care, lack of attention to oral care, and prescribed medications that have oral side effects. Gums lose vascularity and tissue elasticity, which may cause dentures to fit poorly.

Hair

Throughout life, changes in the growth, distribution, and condition of the hair influence hair hygiene. As males reach adolescence, shaving becomes a part of routine grooming. Young girls who reach puberty often begin to shave their legs and axillae. With aging, as scalp hair becomes thinner and drier, shampooing is usually performed less frequently.

Eyes, Ears, and Nose

[Chapter 49](#) addresses changes in hearing, vision, and olfaction across the life span as a result of growth and development. Alterations in sensory function often require modifications in hygiene care. Hygiene of sensory structures must be provided in a way to prevent injury to sensitive tissues such as the cornea of the eye and the internal ear canal.

Physical Condition

Patients with certain types of physical limitations or disabilities associated with disease and injury lack the physical energy and dexterity to perform hygiene self-care safely. A patient whose arm is in a cast or who has an IV line needs help with hygiene care. A weakened grasp resulting from arthritis, stroke, or muscular disorders makes using a toothbrush, washcloth, or hairbrush difficult or ineffective. Sensory deficits not only alter a patient's ability to perform care but also place the patient at risk for injury. Safety is a priority for a patient with a sensory deficit. For example, a patient with paresthesia who is unable to feel that bath water is too hot can incur a burn injury during bathing.

Chronic illnesses such as cardiac, pulmonary, and neurological diseases; cancer; dementia; and some mental health illnesses often exhaust or incapacitate patients. Patients who become tired or short of breath frequently need to have complete hygiene care provided. Include periods of rest during care to allow patients who are tired the opportunity to participate in their care. Pain often accompanies illness and injury, limiting a patient's ability to tolerate hygiene and grooming activities or perform self-care. Pain frequently limits ROM, resulting in impaired use of the arms or hands or limited ability to move about in the environment, impairing the ability to perform hygiene self-care. Sedation and drowsiness associated with analgesics used for pain management also limit a patient's ability to safely participate in care.

Limited mobility caused by a variety of factors (e.g., obesity, physical injury, weakness, surgery, pain, prolonged inactivity, medication effect, and presence of medical devices [e.g., indwelling catheter, feeding tube, or IV line]) decreases a patient's ability to perform hygiene self-care activities safely. Individualized care considers a patient's ability to perform care, the amount of assistance needed, and the need for assistive and safety devices to facilitate safe hygiene care.

Acute and chronic cognitive impairments resulting from conditions such as stroke, brain injury, psychoses, and dementia often result in the inability to perform self-care independently. Patients with dementia often forget to attend to their basic hygiene needs. When people with cognitive impairments are unaware of

their hygiene and grooming needs, they may become fearful and agitated during hygiene care, resulting in aggressive behavior ([Mendes, 2018](#)). Safe, effective patient-centered care takes the effect of cognitive impairment on personal care into consideration and provides appropriate modifications.

Critical Thinking

Successful critical thinking requires a synthesis of knowledge, experience, information gathered from patients, critical thinking attitudes, and intellectual and professional standards. Clinical judgments require you to anticipate the information, analyze the data, and make decisions regarding your patient's care. During assessment consider all elements that build toward making appropriate nursing diagnoses ([Fig. 40.1](#)).

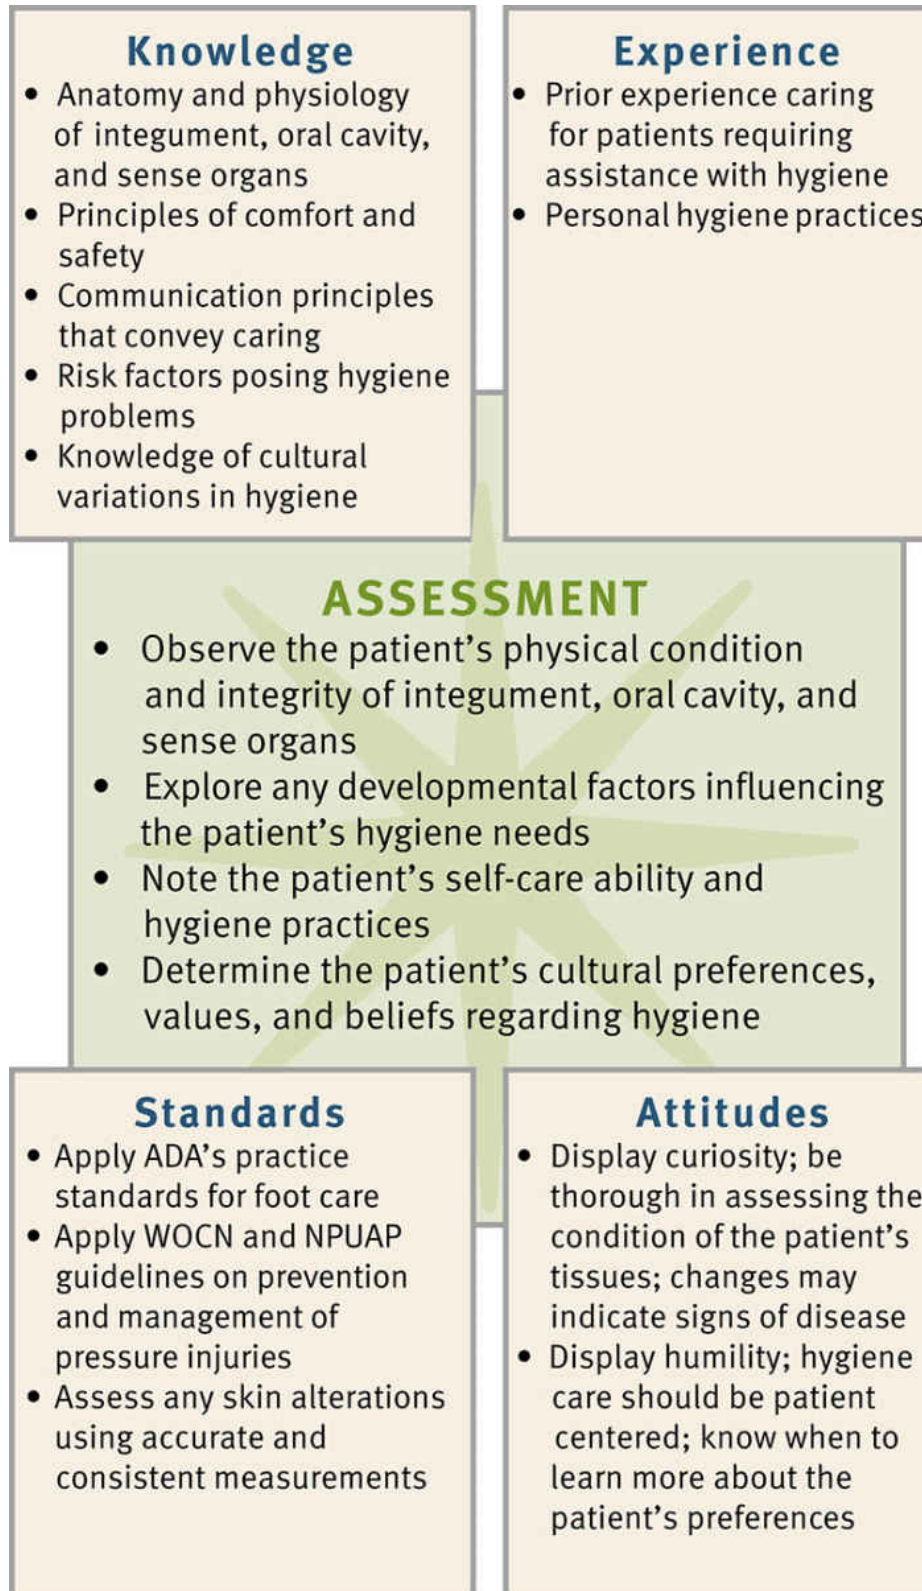

FIG. 40.1 Critical thinking model for hygiene assessment. *ADA*, American Diabetes Association; *NPUAP*, National Pressure Ulcer Advisory Panel; *WOCN*, Wound, Ostomy and Continence Nurses Society.

Integrate nursing knowledge with knowledge from other disciplines. For example, a patient with diabetes mellitus has special needs for nail and foot care to prevent injury and infection. Knowledge about the pathophysiology of diabetes and its potential effects on his or her peripheral circulation and sensory status provides the scientific knowledge base needed to implement safe and effective foot care. In addition, integrate knowledge about developmental and cultural influences as you identify and meet hygiene needs.

Be aware of the impact of critical thinking attitudes as you plan and implement care. For example, think creatively to help patients adapt existing hygiene practices or develop new ones when illness, loss of function, or decreased activity tolerance impairs self-care abilities. Be nonjudgmental and confident when providing care. Because of variations in individual patients' physical status and hygiene practices, you need to approach care with an attitude of flexibility. For example, when caring for a patient with decreased activity tolerance, pace activities and plan rest periods during bathing and other hygiene measures.

Draw on your own experiences as you help with your patients' hygiene care. Reflect on times when you helped family members or others close to you with their hygiene. Usually an early clinical experience involves providing or helping with hygiene care for a patient. Finally, rely on professional standards such as those for skin and foot care from the American Diabetes Association (ADA) and specialty nursing groups such as the Wound Ostomy and Continence Nurses Society (WOCN) when planning care to meet a patient's hygiene needs. As your experience and knowledge grow, your comfort and expertise in meeting the individualized hygiene needs of your patients increase.

REFLECT NOW

You know that people and cultures differ in the types and frequencies of hygiene practices. Think about how you might address your own personal biases, so you can provide more patient-centered hygiene care in the future.

◆ Nursing Process

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care.

◆ Assessment

Thoroughly assess each patient and critically analyze your findings to ensure you make patient-centered clinical decisions required for safe and effective hygiene. Assessment of a patient's hygiene status and self-care abilities requires you to complete a nursing history and perform a physical assessment (see [Chapter 30](#)). You do not assess all body regions routinely before providing hygiene. However, conduct a brief history to determine priority areas (e.g., diabetic patient with foot ulcers, an overweight patient's skinfolds, an immobilized patient's skin condition) and help you plan relevant and individualized hygiene care. Assessment of a patient's ability to provide hygiene self-care helps you decide about the type and amount of hygiene care to provide and how much the patient can be encouraged to participate in care.

Through the Patient's Eyes

Providing safe, quality hygiene care requires a complete awareness of the patient's hygiene preferences and needs. Because patients have varying expectations, you need to avoid making personal hygiene care a simple routine. Complete a nursing history that not only elicits personal preferences but also addresses the patient's cultural or religious customs and beliefs.

Explore a patient's perspective regarding hygiene care by asking him or her about preferred personal hygiene and grooming practices. Ask about personal care products desired and preferences such as frequency, time of day, and amount of assistance needed. Also ask questions such as "To make you most comfortable and feel at home, how can I best perform your bath and personal care?" Determine the patient's awareness of any hygiene-related problems and his or her knowledge and ability to perform hygiene care measures ([Box 40.2](#)). Learning a patient's expectations and applying them in practice fosters a caring relationship. Fully individualizing hygiene care shows your respect for the patient's needs.

As you learn what the patient expects, you incorporate this information into a plan of care.

Box 40.2 Nursing Assessment Questions

Cultural and/or Religious Practices

- Do you have preferences for how you bathe, shampoo your hair, brush your teeth, or care for your feet?
- How comfortable are you with someone helping you with your bathing?
- In what way can I best help you with your bath, hair care ...?

Tolerance of Hygiene Activities

- Tell me about any symptoms, such as shortness of breath, pain, or fatigue, that you have during bathing.
- What can I do to minimize these symptoms?
- Which aspects of bathing, toothbrushing, or foot care cause discomfort or fatigue?

Assistance with Hygiene

- Do you use any aids to help you with your bath such as grab bars in your tub or shower?
- Do you prefer someone of the same gender to help in your hygiene care?
- Which parts of the bath, toothbrushing, and foot care can you do for yourself? With which parts of hygiene care do you need help?

Skin Care

- Which type of bath do you prefer?
- How often and when do you usually bathe?

- What kind of soap and lotion do you use?
- Have you noticed any skin changes or irritation?
- Do you have any known allergies or reactions to soaps, cosmetics, or skin care products?

Mouth Care

- Do you have any mouth pain or toothaches? Have you noticed any sores in your mouth? Do your gums bleed during brushing or flossing?
- Do you wear dentures or a partial plate?

Foot and Nail Care

- How do you usually care for your feet and nails? Do you soak your feet?
- Do you file or trim your own fingernails and toenails?

Hair and Scalp Care

- Have you recently experienced itching of the scalp or noticed flaking or dandruff?
- Have you noticed any changes in the texture or thickness of your hair?

Assessment of Self-Care Ability

Assess a patient's physical ability to perform or assist with hygiene care safely and efficiently; include assessment of the patient's muscle strength, flexibility, balance, visual acuity, and ability to detect thermal and tactile stimuli. Determine your patient's mental status, including orientation and cognitive function (see [Chapter 30](#)). A patient with impaired cognitive function may be less able to follow instructions and help with care. Observe the patient performing hygiene care, noting complaints or physical manifestations that suggest activity intolerance. Assess respiratory rate and effort, skin color, and pulse rate. Ask questions to assess the patient for dizziness, weakness, or fatigue. To determine the

amount of assistance the patient needs, observe him or her performing care activities such as brushing teeth or combing hair (Fig. 40.2). Patients who have limited upper-extremity mobility and strength, reduced vision, fatigue, or inability to grasp small objects require help. Patients having difficulty with manual dexterity and cognitive function are likely to show deterioration in physical or oral health. Poor oral care increases the risk for aspiration pneumonia in patients recovering from a stroke or who have dementia (Murray and Scholten, 2018). Also note the presence of medical devices such as feeding tubes, IV lines, or urinary catheters. These devices require special hygiene measures.

FIG. 40.2 Nurse observes patient brushing teeth. During such observations the nurse can determine how much assistance the patient may need.

When patients have self-care limitations, family may help with care. Work with the family to design patient-centered care. Determine how the family can help the patient, how often they can provide this assistance, and their feelings about being caregivers (Pinkert et al., 2018). In addition, assess the home environment and its influence on the patient's hygiene practices. Are there barriers in the home that affect his or her self-care abilities (e.g., water faucets that are too tight to adjust easily, bathtubs with

high sides, a bathroom too small to fit a chair in front of a sink, and lack of adjustable bed or adaptive equipment available for assisting with bathing)?

Assessment of the Skin

Perform an assessment of the skin (see [Chapter 30](#)), noting color, texture, thickness, turgor, temperature, and hydration. In the healthy person the skin is smooth, warm, and supple with good turgor. Pay special attention to the presence and condition of any lesions. Note dryness indicated by flaking, redness, scaling, and cracking. Also carefully inspect areas of the skin in contact with any medical device at least daily (e.g., skin under an oxygen cannula or the nasal mucosa under an endotracheal or feeding tube) ([NPUAP, 2013](#)) (see [Chapter 48](#)). Look for edema under the sites. Discovering manifestations of common skin problems influences how you administer hygiene care ([Table 40.2](#)).

TABLE 40.2**Common Skin Problems**

Characteristics	Implications	Interventions
Dry Skin		
Flaky, rough texture on exposed areas such as hands, arms, legs, or face	Skin becomes infected if epidermal layer cracks.	Bathe less frequently. Rinse body of all soap because residue left on skin can cause irritation and breakdown. Add moisture to air with use of humidifier. Increase fluid intake when skin is dry. Use moisturizing cream to aid healing. (Cream forms protective barrier and helps maintain fluid within skin.) Use creams to clean skin that is dry or allergic to soaps and detergents.
Acne		
Inflammatory, papulopustular skin eruption, usually involving bacterial breakdown of sebum; appears on face, neck, shoulders, and back	Infected material within pustule spreads if area is squeezed or picked. Permanent scarring can result.	Wash hair and skin thoroughly each day with warm water and soap to remove oil. Use cosmetics sparingly. Oily cosmetics or creams accumulate in pores and make condition worse. Implement dietary restrictions if necessary. (Eliminate foods that aggravate condition from diet.) Use prescribed topical antibiotics for severe forms of acne.
Skin Rashes		
Skin eruptions that result from overexposure to sun or moisture or from allergic reaction (flat or raised, localized or systemic, pruritic or nonpruritic)	If skin is scratched continually, inflammation and infection may occur. Rashes also cause discomfort.	Wash area thoroughly and apply antiseptic spray or lotion to prevent further itching and aid in healing process. Apply warm or cold soaks to relieve inflammation if indicated.
Contact Dermatitis		
Inflammation of skin characterized by abrupt onset with erythema; pruritus; pain; and appearance of scaly, oozing lesions (seen on face, neck, hands, forearms, and genitalia)	Dermatitis is often difficult to eliminate because person is usually in continual contact with substance causing skin reaction. Substance is often hard to identify.	Avoid causative agents (e.g., cleansers and soaps).
Abrasion		
Scraping or rubbing away of epidermis that results in localized bleeding and later weeping of serous fluid	Infection occurs easily because of loss of protective skin layer.	Be careful not to scratch patient with jewelry or fingernails. Wash abrasions with mild soap and water; dry thoroughly and gently. Observe dressing or bandage for retained moisture because it increases risk of infection.

Determine a patient's level of cleanliness by observing the appearance of the skin and detecting body odors that can indicate inadequate cleansing or excessive perspiration caused by fever or pain. Inspect less obvious or difficult-to-reach skin surfaces such as under the breasts or scrotum, around the female patient's perineum, or in the groin for redness, excessive moisture, and soiling or debris. Separate skinfolds for observation and palpation. It is important to keep these areas dry, especially in patients who are overweight. Cornstarch may be used to decrease friction and absorb moisture (Dial et al., 2018; Cowell and Radley, 2014).

Be attentive to characteristics of skin problems most influenced by hygiene measures. Is the skin dry from too much bathing or from use of hot water or irritating soap? Does the patient have a rash caused by an allergic reaction to a skin care product? Certain conditions place patients at risk for impaired skin integrity ([Table 40.3](#)). Because of increased risk be particularly alert when assessing patients with reduced sensation, impaired circulation, nutrition or hydration alterations, body secretions, incontinence, altered cognition, external medical devices, and decreased mobility. Patients may be unaware of skin problems because they are unable to feel pain or pressure or see their skin in some places (e.g., the back or the feet). Carefully assess the skin under orthopedic devices (braces, splints, casts) and beneath items such as antiembolic stockings and tape. Assess the condition and cleanliness of the perineal and anal areas during hygiene care and when the patient requires toileting assistance. When prolonged contact of urine or feces occurs such as with diarrhea or incontinence, skin breakdown often results. Most people consider these areas private; therefore, be sensitive in your approach ([Touhy and Jett, 2018](#)).

TABLE 40.3**Risk Factors for Hygiene Care**

Risks	Hygiene Implications
Oral Problems	
Inability to use upper extremities because of paralysis, weakness, or restriction (e.g., cast, dressing)	Patient lacks upper-extremity strength or dexterity needed to brush teeth (Harding et al., 2020).
Dehydration, inability to take fluids or food by mouth (NPO)	Causes excess drying and fragility of mucosa; increases accumulation of secretions on tongue and gums.
Presence of nasogastric or oxygen tubes; mouth breathers	Tubes cause pressure, friction, and drying of mucosa and/or lips.
Chemotherapeutic drugs	Drugs kill rapidly multiplying cells, including normal cells lining oral cavity. Ulcers and inflammation develop.
Lozenges, cough drops, antacids, and chewable over-the-counter vitamins	Medications contain large amounts of sugar. Repeated use increases sugar or acid content in mouth, causing dental caries.
Radiation therapy to head and neck	Reduces salivary flow and lowers pH of saliva; leads to stomatitis and tooth decay (Harding et al., 2020).
Oral surgery, trauma to mouth, placement of oral airway	These cause trauma to oral cavity with swelling, ulcerations, inflammation, and bleeding.
Immunosuppression; altered blood clotting	Predispose to inflammation and bleeding gums.
Diabetes mellitus	Patients are prone to dryness of mouth, gingivitis, periodontal disease, and loss of teeth.
Endotracheal intubation with mechanical ventilation	Potential for ventilator-associated pneumonia (VAP) exists. Chlorhexidine gluconate (CHG) 0.12% is an inexpensive effective agent for reducing VAP, especially in patients who have heart surgery (Nicolosi et al., 2014).
Dialysis	Oral problems commonly found in these patients include halitosis, xerostomia (dry mouth), gingivitis, stomatitis, tooth decay, tooth loss, and jaw problems. Causes may include micronutrient deficiencies, elevated blood sugar, rheumatoid arthritis, weight control, and smoking (Chapple et al., 2017).
Cognitive impairment	Patients are prone to poor oral health and are at risk for aspiration pneumonia (Murray and Scholten, 2017).
Skin Problems	
Immobilization	Dependent body parts are exposed to pressure from underlying surfaces. The inability to turn or change position increases risk for pressure injuries.
Bariatric patient	Patient cannot visualize skin properly and keep it clean and dry. Excessive adipose tissue creates pressure from weight, lack of air circulation, and an increase in moisture with poor tissue perfusion (Dial et al., 2018). Increases risk for pressure injuries.
Reduced sensation caused by stroke, spinal cord injury, diabetes, local nerve damage	Patient unable to sense skin injury. Does not receive normal transmission of nerve impulses when applying excessive heat or cold, pressure, friction, or chemical irritants to skin. Increases risk for pressure injuries.
Altered cognition resulting from dementia, psychological disorders, or temporary delirium	Patient unable to verbalize skin care needs. Does not realize effect of pressure or prolonged contact with excretions or secretions, requiring more vigilant assessment.
Limited protein or caloric intake and reduced hydration (e.g., fever, burns, gastrointestinal alterations, poorly fitting dentures)	Predispose to impaired tissue synthesis. Skin becomes thinner, less elastic, and smoother with loss of subcutaneous tissue. Poor wound healing results. Reduced hydration impairs skin turgor.
Excessive secretions or excretions on skin from perspiration, urine, watery fecal material, and wound drainage	Moisture is medium for bacterial growth and causes local skin irritation, softening of epidermal cells, and skin maceration.
Presence of external medical devices (e.g., cast, restraint, bandage, dressing)	Devices such as casts, cloth restraints, bandages, tubing, and orthopedic devices exert pressure or friction against surface of skin (NPUAP, 2013).
Vascular insufficiency	Arterial blood supply to tissues is inadequate, or venous return is impaired, causing decreased circulation to extremities. Tissue ischemia and breakdown often occur. Risk for infection is high.
Foot Problems	
Patient unable to bend over or has reduced visual acuity	Patient is unable to fully visualize entire surface of each foot, impairing ability to adequately assess condition of skin and nails.
Eye Care Problems	
Reduced dexterity and hand coordination	Physical limitations create inability to safely insert or remove contact lenses.

When caring for patients with dark skin pigmentation, be aware of assessment techniques and skin characteristics unique to highly

pigmented skin (Ball et al., 2019). Several skin conditions are more common in persons with skin of color, including certain dermatoses, inflammation of hair follicles, acne keloidalis nuchae, and keloids (Kundu and Patterson, 2013). These conditions require special approaches to skin care. Also be very careful in assessing the skin in dark-skinned patients at risk for pressure injuries (see Chapter 48).

Assessment of the Feet and Nails

A variety of common foot and nail problems can be caused by inadequate hygiene and are actually detected during hygiene care. Problems sometimes result from abuse or poor care of the feet and hands such as nail biting or trimming nails improperly, exposure to harsh chemicals, and wearing poorly fitting shoes. Question the patient to determine type of footwear and usual foot and nail care practices.

Examine all skin surfaces of the feet, including the areas between the toes and over the entire sole of the foot. Poorly fitting shoes often irritate the heels, soles, and sides of the feet. Inspection of the feet for lesions includes noting areas of dryness, inflammation, or cracking. (Chapman, 2017). Chronic foot problems are common in older adults, who often experience dry feet because of a decrease in sebaceous gland secretion, dehydration, or poor condition of footwear.

People are often unaware of foot or nail problems until pain or discomfort occurs. Assess patients with diseases that affect peripheral circulation and sensation for the adequacy of circulation and sensation of the feet. Diabetic neuropathy and decreased peripheral circulation put people with diabetes at greater risk for foot problems. Daily inspection and preventive foot care help maintain ulcer-free feet (Chapman, 2017). Inspect a patient's shoes and inspect feet for areas of blistering or abrasion from improper shoes or fit (Jeffcoate et al., 2018). Palpate the dorsalis pedis and posterior tibial pulses, and assess for intact sensation to light touch, pinprick, and temperature (Ball et al., 2019).

Observe a patient's gait. Painful foot disorders or decreased sensation cause limping or an unnatural gait. Ask whether the patient has foot discomfort, and determine factors that aggravate the pain. Foot problems sometimes result from bone or muscular alterations or wearing poorly fitting footwear.

Inspect the condition of the fingernails and toenails, looking for lesions, dryness, inflammation, or cracking, which are often associated with a variety of common foot and nail problems (Table 40.4). The cuticle that surrounds the nail can grow over it and become inflamed if nail care is not

performed correctly and periodically. Ask women whether they polish their nails and use polish remover frequently because chemicals in these products cause excessive nail dryness. Disease changes the shape and curvature of the nails ([Ball et al., 2019](#)). Inflammatory lesions and fungus of the nail bed cause thickened, horny nails that separate from the nail bed.

TABLE 40.4

Common Foot and Nail Problems

Problem	Characteristics	Implications	Interventions
<p>Callus</p> 	<p>Thickened portion of epidermis, consisting of mass of horny, keratotic cells; usually flat and painless; found on undersurface of foot or on palm of hand; caused by local friction or pressure</p>	<p>Foot calluses often cause discomfort when wearing tight-fitting shoes.</p>	<p>Refer patient to podiatrist; do not self-treat. The use of orthotic devices cushions and redistributes weight to relieve pressure on calluses.</p>
<p>Corns</p>  <p>From Weston WL, Lane AT: <i>Color textbook of pediatric dermatology</i>, ed 4, St Louis, 2007, Mosby.</p>	<p>Keratinosis caused by friction and pressure from shoes; mainly on toes, over bony prominence; usually cone shaped, round, and raised; calluses with painful core</p>	<p>Conical shape compresses underlying dermis, making it thin and tender. Tight shoes aggravate pain. Tissue attaches to bone if allowed to grow. Patient may suffer alteration in gait because of pain.</p>	<p>Refer patient to podiatrist. Avoid use of oval corn pads, which increase pressure on toes. Use wider, softer shoes.</p>
<p>Plantar warts</p>  <p>From Zitelli BJ, Davis HW: <i>Atlas of pediatric physical diagnosis</i>, ed 3, St Louis, 1997, Mosby.</p>	<p>Fungating lesion that appears on sole of foot; caused by papillomavirus</p>	<p>Warts are sometimes contagious, are painful, and make walking difficult.</p>	<p>Refer patient to podiatrist.</p>
<p>Athlete's foot (tinea pedis)</p> 	<p>Fungal infection of foot; scaliness and cracking of skin between toes and on soles of feet; small blisters containing fluid appear, apparently induced by constricting footwear (e.g., sneakers)</p>	<p>Athlete's foot can spread to other body parts, especially hands. It is contagious and often recurs.</p>	<p>Feet should be well ventilated. Drying feet well after bathing and applying powder help prevent infection. Wearing clean socks or stockings reduces incidence. Health care provider orders application of griseofulvin, miconazole nitrate, or tolnaftate.</p>
<p>Ingrown nails</p>  <p>From Habif TP: <i>Clinical dermatology: a color guide to diagnosis and therapy</i>, ed 2, St Louis, 1990, Mosby.</p>	<p>Toenail or fingernail growing inward into soft tissue around nail; results from improper nail trimming, poor shoe fit, or heredity</p>	<p>Ingrown nails cause localized pain in presence of pressure; some become infected.</p>	<p>Treatment is frequent warm soaks (<i>exception: patient with diabetes or other vascular diseases, such as Berger's disease</i>) in antiseptic solution and removal of part of nail that has grown into skin. Teach patient proper nail-trimming techniques. Refer to podiatrist.</p>
<p>Paronychia</p> 	<p>Inflammation of tissue surrounding nail after hangnail or other injury; occurs in people who frequently have their hands in water; common in patients with diabetes</p>	<p>Area sometimes becomes infected.</p>	<p>Treatment is warm compresses or soaks (<i>exception: patient with diabetes</i>) and local application of antibiotic ointments. Paronychia can be prevented by careful manicuring.</p>
<p>Foot odors</p>	<p>Result of excess perspiration promoting microorganism growth; faulty foot hygiene or improper footwear causes foot odor</p>	<p>Odor frequently embarrasses patient.</p>	<p>Frequent washing, use of foot deodorants and powders, and clean footwear prevent or reduce this problem.</p>

Assessment of the Oral Cavity

The condition of the oral cavity reflects overall health and also indicates oral hygiene needs. Inspect all areas of the mouth carefully for color, hydration, texture, and lesions (see [Chapter 30](#)). Patients frequently develop common oral problems as a result of inadequate oral care or disease (e.g., oral malignancy) or as a side effect of treatments such as radiation and chemotherapy. These problems include receding gum tissue, inflamed gums (gingivitis), a coated tongue, **glossitis** (inflamed tongue), discolored teeth (particularly along gum margins), **cheilitis** (cracked lips), dental caries, missing teeth, and **halitosis** (foul-smelling breath). Localized pain and infection commonly accompany oral problems.

Apply clean gloves to palpate any tender areas or lesions. Observe for cleanliness and use olfaction to detect halitosis. If you identify any oral problems, notify the patient's health care provider. Early identification of poor oral hygiene practices and common oral problems reduces the risk for gum disease and dental caries ([USDHHS, 2018](#)). If the older adult becomes **edentulous** (i.e., without teeth) and wears complete or partial dentures, include an assessment of underlying gums and palate.

Assessment of the Hair

Assess the condition of a patient's hair and scalp before performing hair care. Findings help determine the frequency and type of care needed. You can anticipate certain patients who might require a more focused assessment, such as a patient who has had head trauma or a homeless patient unable to perform regular hygiene. Normally the hair is clean, shiny, and untangled, and the scalp is clear of lesions. [Table 40.5](#) summarizes hair and scalp problems with implications and interventions.

TABLE 40.5**Hair and Scalp Problems**

Characteristics	Implications	Interventions
Dandruff		
Scaling of scalp is accompanied by itching. In severe cases dandruff is on eyebrows.	Dandruff causes embarrassment. If it enters eyes, conjunctivitis often develops.	Shampoo regularly with medicated shampoo. In severe cases obtain health care provider's advice.
Ticks		
Small, gray-brown parasites burrow into skin and suck blood.	Ticks may transmit disease to people, including Rocky Mountain spotted fever, tularemia, and Lyme disease.	Use fine-tipped tweezers to grasp tick as close to the skin's surface as possible. Pull upward with steady, even pressure. Don't twist or jerk the tick; this can cause the mouth-parts to break off and remain in the skin. If this happens, remove the mouth-parts with tweezers. If you are unable to remove the mouth easily with clean tweezers, leave it alone and let the skin heal. After removing the tick, thoroughly clean the bite areas and your hands with rubbing alcohol and iodine scrub, or soap and water. Dispose of a live tick by putting it in alcohol, placing it in a sealed bag/container, wrapping it tightly in tape, or flushing it down the toilet (CDC, 2018). Follow-up: If you develop a rash or fever within several weeks of tick removal, contact your health care provider and inform about your tick bite.
Pediculosis (Lice)		
Pediculosis Capitis (Head Lice)		
Parasite resides on scalp attached to hair strands. Eggs look like oval particles, similar to dandruff. Bites or pustules may be observed behind ears and at hairline.	Head lice are difficult to remove and spread to furniture and other people if not treated. They do not carry disease, cannot fly or jump, and are carried by animals.	Wearing gloves, check entire scalp by using tongue depressor or special lice comb. Use medicated shampoo for eliminating lice. <i>Caution against use of products containing lindane because the ingredient is toxic and known to cause adverse reactions (CDC, 2016).</i> Check hair for nits and comb with a nit comb for 2 to 3 days until all lice and nits have been removed. Vacuum infested areas of home.
Pediculosis Corporis (Body Lice)		
Parasites tend to cling to clothing; thus, they are not always easy to see. Body lice suck blood and lay eggs on clothing and furniture.	Patient itches constantly. Scratches seen on skin become infected. Hemorrhagic spots appear on skin where lice are sucking blood.	Bathe or shower thoroughly. After skin is dried, apply recommended pediculicide lotion. After 12 to 24 hours take another bath or shower. Bag infested clothing or linen until laundered in hot water. Vacuum rooms thoroughly and throw away bag after completion.
Pediculosis Pubis (Crab Lice)		
Parasites are in pubic hair. Crab lice are gray-white with red legs.	Lice spread through bed linen, clothing, or furniture or between people via sexual contact.	Shave hair off affected area. Clean as for body lice. If lice were sexually transmitted, notify partner.
Hair Loss (Alopecia)		
Alopecia occurs in all races. Balding patches are in periphery of hair line. Hair becomes brittle and broken.	Patches of uneven hair growth and loss alter patient's appearance.	Stop hair-care practices that damage hair (e.g., teasing hair, hair picks, tight braiding, excessive heat when blow-drying).

Observe a patient's ability to perform hair care. A person's appearance and feeling of well-being often are related to the way the hair looks and feels. Illness, disability, and conditions such as arthritis, fatigue, obesity, and the presence of physical barriers (e.g., cast or IV access) alter a patient's ability to maintain daily hair care.

In community health and home care settings it is particularly important to inspect the hair for lice so that you can provide appropriate hygienic treatment. If you suspect **pediculosis capitis** (head lice), guard against self-infestation by hand hygiene and the use of gloves or tongue blades to inspect the patient's hair.

The loss of hair (**alopecia**) results from the effects of chemotherapy medications, hormonal changes, or improper hair care practices. Alopecia often appears as brittle and broken hair in the hair line that progresses to bald patches. If noted, be sure to question the patient about specific hair care practices, especially the use of chemicals and heat application during hair care.

Assessment of the Eyes, Ears, and Nose

Examine the condition and function of the eyes, ears, and nose (see [Chapter 30](#)). The healthy eye is not inflamed and is without drainage. The presence of redness indicates allergic or infectious conjunctivitis, which can be highly contagious. The crusty drainage associated with conjunctivitis easily spreads from one eye to the other. Wear clean gloves to examine the eyes and perform proper hand hygiene before and after the examination. Determine whether a patient wears contact lenses, especially when he or she enters the health care agency in an unresponsive or confused state. To determine whether a contact lens is present, stand to the side of the patient's eyes and observe the corneas for the presence of a soft or rigid lens. Also observe the sclera because the lens may have shifted off the cornea. An undetected contact lens causes corneal injury when left in place too long.

Assessment of the external ear structures includes inspection of the auricle and external ear canal (see [Chapter 30](#)). Observe for the presence of accumulated **cerumen** (earwax) or drainage in the ear canal and local inflammation. Question patients about tenderness on palpation or the presence of pain and ask how they usually clean their ears.

Inspect the nares for signs of inflammation, discharge, lesions, edema, and deformity (see [Chapter 30](#)). The nasal mucosa is normally pink and clear and has little or no discharge. Allergies cause a clear, watery discharge. If patients have any form of tubing exiting the nose (e.g., nasogastric), observe for edema, skin ulceration, localized tenderness, inflammation, drainage, and bleeding where the tubing comes in contact with the nares.

Use of Sensory Aids

For patients who wear eyeglasses, contact lenses, artificial eyes, or hearing aids, assess their knowledge and methods used for care, and have them describe the typical approach used in routine care (see [Chapter 49](#)). When possible, observe a patient perform care. Compare information gathered from him or her with the proper care technique for these devices. Any difference between a patient's practice and standard practice provides an opportunity for patient education.

Assessment of Hygiene Care Practices

Assessment of hygiene practices reveals a patient's preferences for grooming. For example, a patient chooses to groom the hair in a certain style or trim nails in a certain way. When a patient has a physical disability, special safety precautions are often necessary when grooming. For example, teach patients with loss of sensation to file nails instead of clipping. By observing a patient perform hygiene care, you can detect any needed areas of teaching or assistance while maintaining the patient's maximal level of independence.

Assessment of Cultural Influences

Ask what makes a patient feel most comfortable during a bath or other hygiene measures. Because personal hygiene is very private, this question may help reveal normal cultural practices. Perhaps he or she prefers a partial instead of a full bath from a nurse, with a family member completing the bathing of more private body parts.

Some patients also defer part of hygiene. For example, if you believe that frequent skin care is critical to prevent skin breakdown, take the time to understand the patient's concerns and then offer an explanation that helps him or her accept your intervention. Many institutions are using chlorhexidine gluconate (CHG) for daily bathing. CHG can leave the skin feeling sticky. If patients complain about its use, you need to explain their vulnerability to infection and how CHG helps reduce occurrence of health care–associated infection (HAI). Consider a patient's level of literacy, and be sure that you have adapted your assessment questions to a level the patient can understand.

Patients at Risk for Hygiene Problems

Some patients present risks that require more attentive and rigorous hygiene care (see [Table 40.3](#)). These risks may result from side effects of medications or other medical therapy; a lack of knowledge;

immobilization; an inability to perform hygiene; or a physical condition that potentially injures the skin, mouth, feet and nails, or hair. Anticipate whether a patient is predisposed to risks and follow through with a complete assessment. For example, if a patient is receiving cancer chemotherapy, there is a risk of the medication producing mouth ulcerations, which are painful and create a risk for infection and impaired nutrition because of reluctance to eat and drink. A patient who receives broad-spectrum antibiotics may develop an opportunistic infection when the normal flora of the mouth is disrupted by the antibiotic. Be thorough and detailed during the oral examination, checking all surfaces of the tongue and mucosa. For a bariatric patient or a patient who is diaphoretic, provide special attention to body areas such as beneath the woman's breasts and in the groin, skinfolds, and perineal area, where moisture collects and irritates skin surfaces (Cowell and Radley, 2014). Assessment should include a review of a patient's medical and surgical history, medications, and the specific risk factors that the patient presents.

REFLECT NOW

Think about how you would modify your nursing assessment to correctly identify a patient's risks for hygiene problems.

• Nursing Diagnosis

Data interpretation of your patient's hygiene status and self-care abilities involves recognizing assessment patterns or clusters of data to clearly identify and label the patient's health problems related to hygiene. For example, when caring for an older adult with degenerative arthritis, you observe swollen joints, weakness, and limited ROM in the dominant hand along with a generally unkempt appearance. Closer review of data reveals a pattern that confirms that your patient has difficulty turning and regulating a water faucet and is unable to completely wash body parts. The nursing diagnosis of *Impaired Ability to Bath* becomes part of the plan of care. Accurate selection of nursing diagnoses requires critical thinking

to identify actual or potential problems. Be thorough in assessment to reveal all appropriate assessment findings or risk factors so you can make an accurate diagnosis (Box 40.3).

Box 40.3 Nursing Diagnostic Process Self-Care **Deficit: Impaired Ability to Bath**

Assessment activities	Assessment findings
Observe patient attempt to bathe self.	Patient is unable to change position in order to wash lower body, back, or perineal area.
Assess patient's upper-extremity strength and range of motion.	Patient has restricted upper-extremity range of motion in elbow and weakness of hand. Patient has difficulty turning in bed by self or reaching items needed. Patient is unable to turn water faucets on and off without hand pain.
Observe patient's ability to move from bed to bathroom and maneuver in bathroom.	Patient cannot transfer from bed to chair without assistance, cannot ambulate, relies on wheelchair to move around, is unable to maneuver wheelchair in bathroom without help or to transfer to shower seat unassisted. Patient needs lift equipment for transfers.

Use a patient's actual alteration (e.g., *Impaired Tissue Integrity*) or one for which the patient is at risk (e.g., *Risk for Infection*) to determine the focus of nursing interventions. A patient with an actual alteration requires extensive hygiene care, often more thorough than routine hygiene. For example, if a patient has the nursing diagnosis *Impaired Tissue Integrity*, initiate care more frequently to keep skin surfaces clean and dry and eliminate factors such as moisture or drainage. Also provide care to promote healing of injured tissue and skin surfaces (see Chapter 48). If a patient is at risk for a problem, take preventive measures. For example, if a patient is at risk for developing an infection in his or her mouth and has the nursing diagnosis *Risk for Infection*, keep the mucosa well hydrated, minimize foods irritating to tissues, and provide cleaning that soothes and reduces tissue inflammation.

Completing a nursing diagnosis requires identification of the related factor, which will guide your selection of nursing interventions. A diagnosis of *Impaired Oral Mucous Membrane related to malnutrition* and a diagnosis of *Impaired Oral Mucous Membrane related to chemical trauma* require different interventions. When poor nutrition is a causal factor, you need to consult with a registered dietitian for appropriate dietary

supplements and incorporate patient education into the plan. When chemotherapy injures the oral mucosa, you follow cancer nursing guidelines regarding care for oral **mucositis** (i.e., painful inflammation of oral mucous membranes), including frequent gentle brushing with a soft toothbrush, flossing, rinsing with bland rinse, limiting diet to soft foods, and applying water-based moisturizer to lips (USDHHS, 2018). While there are many possible nursing diagnoses for patients in need of supportive hygiene care, the nursing diagnoses in the preceding paragraphs and the following list represent examples of diagnoses commonly associated with hygiene-related problems:

- *Activity Intolerance*
- *Impaired Dressing and Grooming*
- *Impaired Mobility*
- *Impaired Health Maintenance*
- *Impaired Skin Integrity*

• Planning

During planning synthesize information from multiple resources (Fig. 40.3). Critical thinking ensures that a patient's plan of care integrates all that is known about the individual patient and key critical thinking elements. In many situations patients present with multiple nursing diagnoses. Use a concept map (Fig. 40.4) to visualize and understand how nursing diagnoses interrelate. Rely on knowledge, experience, and established standards of care when developing a care plan. Remember critical thinking attitudes such as creativity when developing a patient-centered plan for hygiene care. Partner with a patient to identify patient goals and outcomes, set priorities for care, and select evidence-based interventions. Consider continuity of care and involve other health care team members (e.g., occupational or physical therapy) when developing the plan.

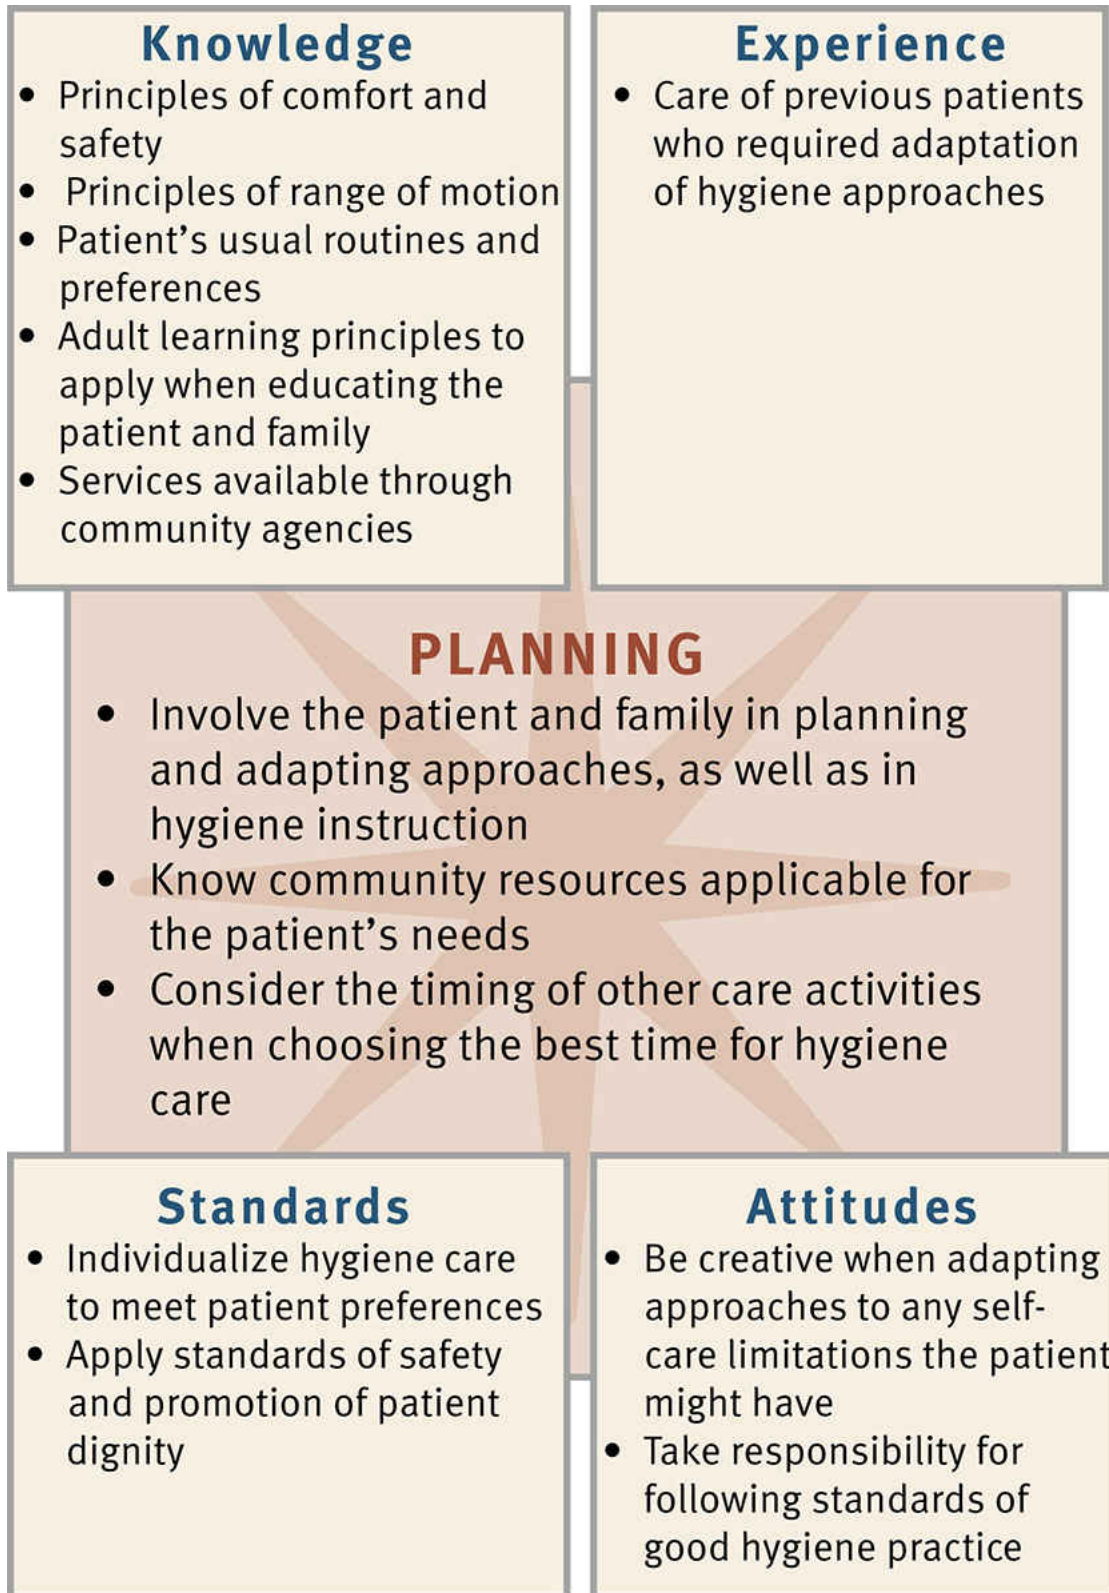

FIG. 40.3 Critical thinking model for hygiene planning.

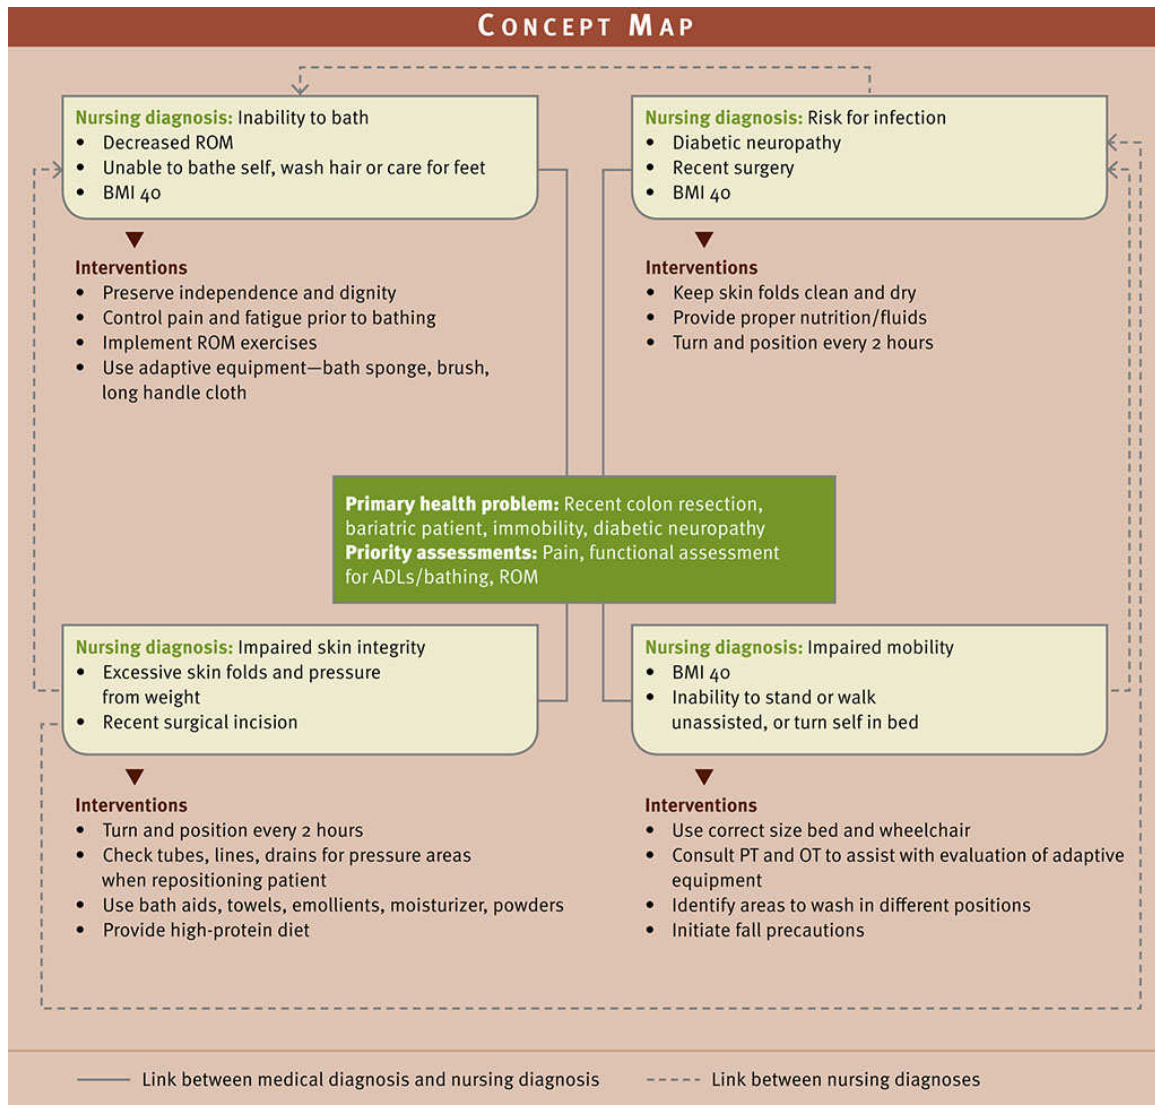

FIG. 40.4 Concept map for Mrs. White. *ADLs*, Activities of daily living; *BMI*, body mass index; *OT*, occupational therapist; *PT*, physical therapist; *ROM*, range of motion.

Previous experience with other patients is useful in knowing how to adapt hygiene techniques for special needs. Professional standards guide selection of the most effective nursing interventions. These standards often establish evidence-based guidelines for care.

Goals and Outcomes

Partner with the patient and family to identify goals and expected outcomes to develop a mutually agreed-on plan of care based on the patient's nursing diagnoses (see the [Nursing Care Plan](#)). Establish goals that are realistic for the patient's self-care abilities and resources and focus

on maintaining or improving the patient's overall hygiene. Make outcomes measurable and achievable within patient limitations. In addition, work with the patient to select individualized hygiene measures. For example, a nurse and a patient who has one-sided paralysis following a cerebral vascular accident develop the following goal: "Patient will be able to groom self (dress and bathe) before discharge." The nurse establishes realistic, individualized expected outcomes to measure the patient's progress toward meeting this goal. These outcomes may include the following:

- Patient is able to bathe in front of sink.
- Patient uses assist devices (bathing mitt and long-handled sponge) for bathing.
- Patient dresses self, using dressing stick and sock aid.

Setting Priorities

A patient's condition influences your priorities for hygiene care. Set priorities based on the necessary assistance required by the patient, the extent of the hygiene-related problems, and the nature of the patient's nursing diagnoses. For example, a seriously ill patient usually needs a daily bath because body secretions accumulate, and the patient is unable to maintain cleanliness independently. Some older patients at home require a visit from a home care aide to help with a tub bath or shower. Patients who are normally inactive during the day and have skin that tends to be dry may need to bathe only twice a week, whereas a patient with urinary and bowel incontinence needs perineal cleaning with each episode of soiling. Plan to help patients who are weakened or possess poor coordination. For example, a patient who is partially paralyzed and has difficulty getting out of a tub needs a tub chair, handrails, or extra personnel available for help.

Timing is also important in planning hygiene care. Being interrupted in the middle of a bath often frustrates and embarrasses a patient. Assess for cultural preferences on time of day or who may help patient with hygiene care.

Teamwork and Collaboration

During hospitalization, know a patient's schedule for therapy or diagnostic procedures and plan hygiene care accordingly. If a patient is hospitalized, plan care before discharge to home, a rehabilitation center, or

extended care. Be sure that family caregivers know any physical or cognitive limitations that will affect their ability to provide safe, effective hygiene care. For example, does the patient require assistance to get into a tub or shower, does the patient have reduced sensation making him or her at risk for burns from hot water, and can the patient remember steps to follow for proper foot care? Collaborate with other health team members as indicated (e.g., work with physical and occupational therapy to enhance the patient's independence with self-care activities).

When a patient needs assistance as a result of a self-care limitation and family caregivers are the ones to provide it, proper education and preparation should be included in the plan of care. Give clear directions on how to perform hygiene and how to obtain appropriate equipment and hygiene supplies. Family members also need guidance in providing safety and adapting techniques to fit patient limitations. Be aware of equipment and procedures used in the agency, and support the patient and family to make them knowledgeable about making necessary adaptations. Depending on a patient's limitations, some insurance plans provide home care assistants to help with basic hygiene needs. Explore this option with the patient and family members.

Collaborate with community agencies as needed. For example, the nurse involved in the care of a homeless patient needs to be aware of the location of clothing distribution centers for basic hygiene supplies, a shelter where bathing facilities are available, and any organization that offers free health care or reduced fees. Partner with social workers or staff in local area churches, not-for-profit organizations, and schools to be sure that patients have the resources they need to maintain hygiene.

• Implementation

Hygiene is an essential part of basic patient care. When you use caring practices to perform hygiene measures, you reduce the patient's anxiety and promote comfort and relaxation. For example, use a gentle approach when giving patients their baths and changing gowns as you turn and reposition them. A soft, gentle voice when conversing with patients relieves fears or concerns. For patients suffering symptoms such as pain or nausea, administering medications to relieve the symptoms before providing hygiene helps to maintain patient comfort during hygiene procedures.

Consider the stress that hygiene care can cause and be alert for any cues of embarrassment or anxiety. Some patients fear pain or are frightened

about falling or sustaining injury when assisting them to a bathroom.

Implementation also focuses on assisting and preparing patients to perform much of their hygiene care independently. Discuss any signs and symptoms of hygiene problems. Teach patients proper hygiene techniques and how their use is associated with better health. Inform patients about available resources in the community.

Health Promotion

In primary health care situations educate and counsel patients and family caregivers on why proper hygiene techniques are necessary. For example, a new mother needs to learn how to bathe her newborn to reduce risk of skin irritation and infection, whereas an older adult needs information on the importance of regular ear care to avoid accumulated cerumen and hearing impairment. The hygiene skills described throughout this chapter provide standards for excellent physical care. When caring for patients in primary health care settings, maintain these standards and incorporate adaptations as needed to meet the patient's lifestyle, functional status, living arrangements, and preferences. Key points when teaching patients about hygiene include the following:

- Make any instruction relevant based on your assessment of the patient's knowledge, motivation, preferences, and health beliefs. For example, when teaching a patient who has diabetes, include risks for impaired foot circulation and how this causes a risk for infection and poor healing, especially when the skin is injured or broken.
- Adapt instruction to a patient's personal bathing facilities and resources. Not all patients have the ideal situation that exists in a health care setting (e.g., easily accessible shower or a bedside table to place over a bed). Adapt available resources so that the patient can reach and use needed items comfortably and safely. For example, a

Nursing Care Plan

Self-Care Deficit: Impaired Ability to Bath

Assessment

Mrs. White is 70 years old and is post-op day 2 after a colon resection. She has diabetes, a history of hypertension, and body mass index of 40. Her mobility is limited because of her abdominal discomfort, although she can walk short distances. She prefers to stay in

bed because she states that she feels tired, weak, and sore. She has begun an early mobility protocol and will ambulate this morning. Physical therapy is helping her learn to use a walker. Mrs. White states that her buttocks, thighs, and skinfolds feel inflamed with a pain score of 7/10. She lives alone, but her granddaughter is going to nursing school and has offered to help her at home.

Assessment Activities	Assessment Findings ^a
Ask Mrs. White what hygiene care is important this morning.	Mrs. White says, "I want to feel clean and smell good. "
Assess Mrs. White's skin condition.	Visual inspection reveals redness at elbows and under breasts and thighs. The abdominal incision is dry and pink, and the sutures are well approximated.
Assess Mrs. White's ability to bathe, including an assessment of her range of motion (ROM) and upper- and lower-extremity strength.	Mrs. White is unable to gather bath supplies because of her immobility. She can stand and walk to the bathroom sink but is unable to wash her entire body. Mrs. White states that she has difficulty visualizing areas of her body. Her arms are restricted with decreased ROM and have decreased sensation.

^a **Assessment findings** are shown in bold type.

Nursing Diagnosis

Self-care deficit: Impaired ability to bath related to immobility associated with obesity and limited ROM

Planning

Goals	Expected Outcomes (NOC) ^b
	Self-Care: Bathing
Mrs. White will remain free of body odor.	Mrs. White self-reports feeling clean and refreshed after bathing each day.
Mrs. White will maintain intact skin during hospitalization.	Skin is clean and dry without skin breakdown between skinfolds. Mrs. White describes personal risk factors for impaired skin integrity.
Mrs. White will describe best method to bathe using adaptive devices by discharge.	Mrs. White states two ways to use adaptive equipment during her bath by discharge. She bathes herself, using a bath mitt and mirror.
Mrs. White will accept help from a family caregiver to assist with hygiene care within the next week.	Mrs. White reports satisfaction with assistance in bathing by family caregiver.

^b Outcome classification labels from Moorhead S, et al: *Nursing Outcomes Classification (NOC)*, ed 6, St Louis, 2018, Elsevier.

Interventions (Nic) ^c	Rationale
Self-Care Assistance: Bathing/Hygiene	
Administer prn ordered oral analgesic before bath; begin bath 30 minutes later.	Patient participation in bathing or other self-care activities will improve with pain control. Give prn pain medication before pain is severe (Butcher et al., 2018).
Help patient shower and place her on a shower seat. Demonstrate for patient use of grab bar, and use wash mitt with soap pocket. Stay close by to prevent an accidental fall.	Proper education on use of shower seats, grab bars in showers/baths, and assistive devices reduces the risk for injuries while bathing (King et al., 2018). Using a wash mitt with a soap pocket or a wall-mounted soap dispenser minimizes difficulty of manipulating soap and a washcloth. A shower seat or bath bench makes it easier for patient to focus on washing rather than on balance required for standing (King et al., 2018).
Teach patient and granddaughter (as needed) how to use adaptive equipment for bathing and safe patient-handling skills and how to perform skin assessments. Help Mrs. White plan hygiene schedule with granddaughter.	Family members who are taught methods to meet patient's bathing needs increase patient satisfaction, making the experience safe, easy, and successful (King et al., 2018). Appropriate assistive devices encourage independence.

^c Intervention classification labels from Butcher HK, et al: *Nursing Interventions Classifications (NIC)*, ed 7, St Louis, 2018, Elsevier.

Evaluation

Evaluation Activity	Patient Response/Finding	Outcome Status
Ask Mrs. White why it is important for her to inspect skin and have regular bathing.	Mrs. White states that she now knows she is at risk for infection because she is overweight and has diabetes. She also knows her risk for infection is higher in the hospital.	Mrs. White is able to identify her personal risk factors for infection if she does not bathe properly.
Inspect Mrs. White's skin after she bathes in shower and assess for any remaining body odor.	Mrs. White's skin is clear without irritation under breasts and perineum. Had difficulty cleansing back and bottom of feet, but no signs of irritation. No apparent odor. Patient expresses sense of feeling clean. Is able to describe how to use adaptive devices.	Mrs. White requires assistance with bathing in areas of body she could not reach. Will refer to occupational therapy for an appropriate assistive device with long handle.
Observe how the granddaughter assists Mrs. White on to a shower seat; observe their use of adaptive equipment.	Mrs. White and her granddaughter have planned to shower every 3 days in the evening after granddaughter returns from work. Granddaughter is able to explain correct technique for helping patient with walker and transferring to and from shower seat.	Mrs. White has a realistic plan for bathing at home. During a home visit the granddaughter demonstrates knowledge of safe patient handling.

young mother has more room and believes that bathing her infant is safer if she uses her kitchen sink and counter rather than her bathroom sink.

- Teach patients ways to avoid injury. Almost any hygiene procedure poses risks (e.g., cutting a nail too close to the skin or failing to adjust the water temperature of the bath). Include safety risks and tips with all instructions.
- Reinforce infection control practices. Damage to the skin, mucosa, eyes, or other tissues creates an immediate risk for infection. Determine that a patient understands the relationship among healthy and intact skin and tissues, hand hygiene practices, and the prevention of infection (see [Chapter 28](#)).

Acute, Restorative, and Continuing Care

Nursing knowledge and skills needed for performing hygiene care are consistent across all health care settings. In addition, some of the skills in this section are applicable in areas of health promotion. The variety, frequency, and timing of hygiene measures vary across health care settings and according to individual patient needs. In the acute care setting factors such as more frequent diagnostic and treatment plans and the need for more extensive hygiene care resulting from acute illness or injury affect scheduling. In extended-care facilities and nursing homes, bathing may be scheduled less frequently.

Bathing and Skin Care

Individualize your care on the basis of the patient's hygiene preferences. The extent, type, and timing or frequency of bathing and the methods used depend on a patient's physical abilities, health problems, and the degree of hygiene required (Boxes 40.4 and 40.5). In addition to cleansing baths, the health care provider may prescribe therapeutic baths, including sitz baths. Medicated baths (e.g., oatmeal, cornstarch, or Aveeno) may be recommended in the home setting. A sitz bath cleans and reduces pain and inflammation of perineal and anal areas (see Chapter 48). Medicated baths relieve skin irritation and create an antibacterial and drying effect.

Box 40.4 Hygiene Care Schedule in Acute and Long-Term Care Settings

Early Morning Care

Nursing personnel on the night shift provide basic hygiene to patients getting ready for breakfast, scheduled tests, or early morning surgery. "AM care" includes offering a bedpan or urinal if the patient is not ambulatory, washing the patient's hands and face, and helping with oral care.

Routine Morning Care

After breakfast help by offering a bedpan or urinal to patients confined to bed; provide a full or partial bath or a shower, including perineal care and oral, foot, nail, and hair care; give a back rub; change a patient's gown or pajamas; change the bed linens; and straighten a patient's bedside unit and room. This is often referred to as "complete AM care."

Afternoon Care

Hospitalized patients often undergo many exhausting diagnostic tests or procedures in the morning. In rehabilitation centers patients participate in physical therapy in the morning. Afternoon hygiene care includes washing the hands and face, helping with oral care, offering a bedpan or urinal, and straightening bed linen.

Evening, or Hour-before-Sleep, Care

Before bedtime offer personal hygiene care that helps patients relax and promotes sleep. “PM care” often includes changing soiled bed linens, gowns, or pajamas; helping patients wash the face and hands; providing oral hygiene; giving a back massage; and offering the bedpan or urinal to nonambulatory patients. Some patients enjoy a beverage such as juice; check diet to determine which beverages are allowed.

Box 40.5 Types of Baths

Complete bed bath: Bath administered to totally dependent patient in bed (see Skill 40.1).

Partial bed bath: Bed bath that consists of bathing only body parts that would cause discomfort if left unbathed such as the hands, face, axillae, and perineal area. Partial bath may also include washing back and providing back rub. Provide a partial bath to dependent patients in need of partial hygiene or self-sufficient bedridden patients who are unable to reach all body parts.

Sponge bath at the sink: Involves bathing from a bath basin or sink with patient sitting in a chair. Patient is able to perform part of the bath independently. Assistance is needed for hard-to-reach areas.

Tub bath: Involves immersion in a tub of water that allows more thorough washing and rinsing than a bed bath. Commonly used in long-term care. A patient may require the nurse’s help. Some institutions have tubs equipped with lifting devices that facilitate positioning dependent patients in the tub.

Shower: Patient sits or stands under a continuous stream of water. The shower provides more thorough cleaning than a bed bath but can cause fatigue.

Bag bath/travel bath: Contains several soft, nonwoven cotton cloths that are premoistened in a solution of no-rinse surfactant cleanser

and emollient. The bag bath offers an alternative because of the ease of use, reduced time bathing, and patient comfort.

Chlorhexidine gluconate (CHG) bath: Antimicrobial agent used to reduce incidence of hospital-acquired infections on skin, invasive lines, and catheters (Cassir et al., 2015; Boonyasiri et al., 2016; Shah et al., 2016).

If a patient is physically dependent or cognitively impaired, increase the frequency of skin assessment and provide skin care directed toward reducing the risk for skin breakdown. When bathing patients with cognitive impairments, consider their special needs and challenges (Wilson, 2018). These patients easily become afraid. Patients with dementia often refuse, withdraw, or fight during a bath or shower. A person-centered approach can assist in managing their physical limitations and aggressive behaviors (Box 40.6). Use assessment and communication skills to learn possible triggers that affect participation with hygiene care (Yevchak et al., 2017; Konno et al., 2014). For example, unmanaged pain; being cold; feeling frightened, vulnerable, and exposed; feeling embarrassed; feeling a loss of control; or not understanding what is happening often causes aggressive behavior. Adapt your bathing procedures and the environment to reduce the triggers. For example, administer any ordered analgesic 30 minutes before a bath and be gentle in your approach. Keep the patient's body as warm as possible with warm towels, and be sure that the room temperature is comfortable. Reduce fear by making sure that all safety devices (e.g., grab bars in a shower, bath mats) are available. Ask for permission to conduct the bath and give the patient options for making decisions (e.g., choice of soap, timing of when to wash face). Use comforting words during bathing to enhance a patient's relaxation. Collaborate and communicate to teach family members how to communicate with and how to help bathe cognitively impaired patients for optimal outcomes once the patient is discharged (Vaingankar et al., 2016).

Box 40.6 Evidence-Based Practice Improving Hygiene Care for Patients with Cognitive Impairments

PICOT Question: Does implementing a person-centered approach for hygiene care improve patient cooperation and nurse satisfaction in adults with cognitive impairments?

Evidence Summary

Noisy and unfamiliar surroundings are very distressing to patients with cognitive impairments, such as confusion or dementia. In addition, this distress is worsened by the patient's physical illness, pain, dehydration, toileting needs, medications, and stimulation from the hospital environment (Mendes, 2018). A person-centered care approach can work with the family caregiver, the patient, and the health care team to design hygiene measures and routines that are congruent with the patient's usual practices (Shelton et al., 2018). Research supports the use of nurse-facilitated person-centered care interventions when caring for patients with cognitive disorders (Yevchak et al., 2017).

Application to Nursing Practice

- Designing person-centered care helps nurses meet the individual needs of their patients and minimize some agency-based constraints on care routines (Pinkert et al., 2018).
- Work with family and patient to determine factors that may trigger anxiety or reduced cooperation. These triggers may vary from person to person and can include (but are not limited to) new nursing staff, a full bladder, the time of day, or too much environmental noise (Hirschman and Hodgson, 2018; Yevchak et al., 2017).
- Avoiding incongruent care preferences between the patient and the agency caregiver reduces patient anxiety (Shelton et al., 2018).
- Whenever possible, involve the patient in the hygiene care plan and maintain prehospital routines (Villar et al., 2018; Mendes, 2018).
- Communicating the patient's preferences related to hygiene and activities of daily living (ADL) with all agency caregivers promotes patient comfort, reduces patient anxiety, and improves nurse satisfaction (Rokstad et al., 2017; Shelton et al., 2018).

Complete Bed Bath

A **complete bed bath** (see Skill 40.1), tub bath, or shower often exhausts a patient. Turning during a complete bed bath and receiving back care increase oxygen consumption and demand. Getting out of a low tub requires considerable exertion. Assess and be alert for a patient's activity intolerance during hygiene care. Assessing heart rate before, during, and after a bath provides a measure of his or her physical tolerance. Provide a **partial bed bath** (see Skill 40.1) to patients who are aging, dependent, in

need of only partial hygiene, or bedridden and unable to reach all body parts. Wear gloves when there is a risk of coming in contact with body fluids. Control environmental factors that alter skin integrity, including moisture, heat, and external sources of pressure such as wrinkled bed linen and improperly placed drainage tubing.

Traditionally baths have been given using soap and warm water. The question of whether to use bath basins with soap and water is an issue because bath basins provide a reservoir for bacteria and are a possible source of transmission of hospital-acquired infections (HAIs) ([Alserehi et al., 2018](#); [Powers et al., 2012](#)). There is a link between waterborne pathogens and the development of biofilm (multiple colonies of microorganisms attached to a surface such as a bath basin). The formation of a biofilm combined with transmission of organisms through contact with unwashed hands can create a reservoir of bacteria. The bacteria can be transferred to and maintained in a patient's bath basin. In contrast, the use of chlorhexidine gluconate (CHG) 4% solution in place of standard soap and water in washbasins has been shown to decrease bacterial growth in basins ([Powers et al., 2012](#)) and reduce critical care unit-acquired methicillin-resistant *Staphylococcus aureus* (MRSA) ([Petlin et al., 2014](#)). It is important to air-dry bath basins completely and not to use a basin for storing supplies.

Another option to using CHG in bath basins is the use of CHG 2% in impregnated washcloths. The CHG in the cloths is fast acting, has broad-spectrum microorganism coverage, continues antimicrobial activity up to 24 hours after application, and is rinse free and disposable ([AHRQ, 2013](#)). Daily bathing with 2% CHG-impregnated cloths versus nonantimicrobial washcloths reduces cross-contamination and colonization of multidrug-resistant organisms (MDROs) ([Ruiz et al., 2017](#); [Climo et al., 2013](#)). Daily bathing with some form of CHG is becoming more of a standard practice across hospitals. Patients often describe their skin as feeling a bit sticky. Be sure to explain to patients the importance of using CHG to protect them against serious infection.

- When using CHG solution in bath water or impregnated cloths, use a clean CHG washcloth/cloth for each area of the body.
 - Do not use above a patient's jawline as it can be irritating to the eyes and ears ([AHRQ, 2013](#)).
 - Use a regular washcloth moistened in warm water for the face.

- Do not rinse the CHG off the body; this interferes with its antibacterial effects.
- There are precautions to follow in using CHG. CHG is safe to use on superficial wounds, abrasions, and rashes ([AHRQ, 2013](#)). In the case of open or deep wounds such as stage III or IV pressure injuries, bathe with CHG around a dressing or wound. Do not use CHG on third- or fourth-degree burns ([AHRQ, 2013](#)).

Use a tub bath or shower (see Skill 40.1) to give a more thorough bath than a bed bath. CHG 4% solution can be used in showers, but instruct patients to exit the shower after application, and do not rinse the CHG off. Implement safety measures to prevent fall injuries because the surface of a tub or shower stall is slippery. In some settings a health care provider's order for a shower or tub bath is necessary. Place a chair in the shower for patients with weakness or poor balance. Both tubs and showers need to have grab bars for patients to hold during entry and exit and maneuvering during the bath or shower. Patients vary in how much physical assistance they need from care providers. Regardless of the type of bath a patient receives, use the following guidelines:

- *Provide privacy.* Close the door and/or pull room curtains around the bathing area. While bathing a patient, expose only the areas being bathed by using proper draping.
- *Maintain safety.* Keep side rails up when away from a patient's bedside when patients are dependent or unconscious. **Note:** When side rails serve as a restraint, you need a health care provider's order (see agency-specific policy for restraint usage) (see [Chapter 27](#)). Place the nurse call system in the patient's reach if leaving the bedside even temporarily.
- *Maintain warmth.* Keep the room warm because the patient is partially uncovered and easily chilled. Wet skin causes an excessive loss of heat through evaporation. Control drafts and keep windows closed. Keep the patient covered. Expose only the body part being washed during the bath.
- *Promote independence.* Encourage the patient to participate in as much of the bathing activities as possible. Offer assistance when needed.
- *Anticipate needs.* Bring a new set of clothing and hygiene products to the bedside or bathroom.

Teach patients to follow a few general rules for skin health. Encourage them to routinely inspect their skin for changes in color or texture and report abnormalities to their health care provider. Instruct them to handle the skin gently, avoiding excessive rubbing. Patients with excessively dry skin are predisposed to skin impairment. If patients use bar soap at home, recommend that they choose one that contains emollients to hydrate dry skin. Avoid overly hot water because it can dry the skin by removing natural oils. Lubricate the skin with emollient lotions to reduce dryness.

Good skin health requires patients to eat nutritious foods from all food groups, including those rich in vitamins and minerals, and to consume adequate fluids. Stress safety concerns such as failing to adjust or check the water temperature and slipping on wet surfaces. Ensure that patients understand that healthy and intact skin and tissues protect them from infection. Reinforce infection control practices, including proper hand hygiene.

Perineal Care

Cleansing patients' genital and anal areas is called **perineal care**. It usually occurs as part of a complete bed bath; however, it must be provided at least once a day and more often (see agency policy) if a patient has a urinary catheter (see Skill 40.1). Patients most in need of perineal care include those at greatest risk for acquiring an infection (e.g., uncircumcised males, patients who have indwelling urinary catheters, or those who are recovering from rectal or genital surgery or childbirth). In addition, women who are having a menstrual period require perineal care. CHG is safe to use on the perineum and external mucosa for thorough cleansing ([AHRQ, 2013](#)).

When the patient's condition allows, encourage the patient to perform perineal care. Sometimes you are embarrassed about providing perineal care, particularly to patients of the opposite sex. Similarly, the patient may feel embarrassed. Do not let embarrassment cause you to overlook the patient's hygiene needs. When staffing levels permit, use a gender-congruent caregiver. A professional, dignified, and sensitive approach reduces embarrassment and helps put the patient at ease.

If a patient performs self-care, various problems such as vaginal and urethral discharge, skin irritation, and unpleasant odors often go unnoticed. Stress the importance of perineal care in preventing skin breakdown and infection. Be alert for complaints of burning during urination or localized soreness, excoriation, or pain in the perineum. Inspect vaginal and perineal areas and the patient's bed linen for signs of

discharge, and use your sense of smell to detect abnormal odors. Risk factors for skin breakdown in the perineal area include urinary or fecal incontinence, rectal and perineal surgical dressings, indwelling urinary catheters, and morbid obesity.

Back Rub

A back rub or back massage usually follows a patient's bath. It promotes relaxation, relieves muscular tension, and decreases perception of pain. **Effleurage** (i.e., long, slow, gliding strokes of a massage) is associated with reduced measured anxiety, heart rate, and respiratory rate. Studies show that slow-stroke back massages of 3 minutes and hand massages of 10 minutes significantly improve both physiological and psychological indicators of relaxation in older people (Touhy and Jett, 2018).

When providing a back rub, enhance relaxation by reducing noise and ensuring that the patient is comfortable. It is important to ask whether a patient would like a back rub, because some individuals dislike physical contact. Consult the medical record for any contraindications to a massage (e.g., fractured ribs, burns, heart surgery). [Chapter 44](#) describes steps for back massage.

REFLECT NOW

You had your first clinical experience providing hygiene to a patient with a diagnosis of Alzheimer's disease who became frightened and uncooperative during bathing. Using information in this section and Box 40.6, think about strategies you might use to help make hygiene a more satisfying experience.

Foot and Nail Care

Routine nail and foot care involves soaking the hands and feet to soften cuticles and layers of horny cells, thorough cleaning, drying, and proper nail trimming. The one exception is patients with diabetes mellitus or peripheral vascular disease, who are at risk for tissue ulceration or infection because soaking causes skin softening or **maceration** of tissue.

When providing nail care, have the patient remain in bed or sit in a chair (see Skill 40.2). In some settings or with specific patients such as a person with diabetes mellitus, you need a health care provider's order to trim toenails. The risk of accidentally cutting skin around a nail and predisposing a patient to infection is the reason orders are required. Check agency policy to determine whether an order is necessary.

Take time during the procedure to teach the patient and family proper techniques for cleaning and nail trimming. Stress the importance of how thorough nail care prevents infection and promotes good circulation. All patients must learn to protect the feet from injury, never walk barefoot, keep feet clean and dry, and wear footwear that fits properly. Instruct patients in the proper way to inspect all surfaces of the feet and hands for redness, lesions, dryness, or signs of infection. Teach foot care to family caregivers for patients who need regular foot care and have peripheral vascular disease, visual difficulties, physical constraints that prevent movement, or cognitive problems.

Certain conditions place patients with diabetes at increased risk for amputation (ADA, 2016). These factors include peripheral neuropathy, limited joint mobility, bony deformity, peripheral vascular disease, and a history of skin ulcers or previous amputation. Observe for changes that indicate peripheral neuropathy or vascular insufficiency (Box 40.7). Advise patients to use the following guidelines in a routine foot and nail care program (ADA, 2020):

Box 40.7 Signs of Peripheral Neuropathy or Vascular Insufficiency

Peripheral Neuropathy

- Muscle wasting of lower extremities
- Foot deformities
- Soft tissue infection in lower extremities
- Abnormal gait
- Absent or decreased deep tendon reflexes and/or response to vibratory, touch, or painful stimuli

Vascular Insufficiency

- Decreased hair growth on legs and feet
- Absent or decreased pulses
- Infection of the foot
- Poor wound healing
- Thickened nails
- Shiny appearance of the skin
- Blanching of skin on elevation

Data from Ball J, et al: *Seidel's guide to physical examination*, ed 9, St Louis, 2019, Mosby.

- Inspect the feet daily, including the bottoms and tops, heels, and areas between the toes. Use a mirror to help inspect the feet thoroughly, or ask a family member to check daily.
- Wash feet daily in lukewarm water. Dry thoroughly, especially between the toes. Avoid harsh chemicals or long soaks, which can cause skin softening or maceration of tissue, causing ulceration or infection.
- Wear well-fitting shoes and clean, dry socks at all times; never go barefoot. Check inside shoes before wearing them for rough areas or objects that may rub against the foot.
- Keep skin soft and smooth by applying an emollient lotion over all surfaces of the feet but not between the toes.
- If you can see and reach your toenails, trim them straight across and square file the edges smooth.
- Keep the blood flowing to your feet by putting them up when sitting and wiggling your toes and moving your ankles up and down for 5 minutes, 2 or 3 times a day. Do not cross your legs for long periods and don't smoke.
- Protect the feet from hot and cold. Do not use heating pads or electric blankets and always wear shoes at the beach or on hot pavement.

Oral Hygiene

Regular oral hygiene, including brushing, flossing, and rinsing, prevents and controls plaque-associated oral diseases. Brushing cleans the teeth of food particles, plaque, and bacteria. It also massages the gums and relieves discomfort resulting from unpleasant odors and tastes. Daily flossing removes food particles, plaque, and tartar that collect between teeth and at the gum line. Rinsing removes dislodged food particles and excess toothpaste. Complete oral hygiene enhances well-being and comfort and stimulates the appetite.

When patients become ill, many factors influence their need for oral hygiene, such as their ability to take fluids orally, presence of oral lesions or trauma, and level of consciousness. Patients who are unconscious or have artificial airways, such as tracheostomy or endotracheal tube, have special precautions for oral care because they do not have a gag reflex. Patients in hospitals or long-term care facilities do not always receive the aggressive oral care they need. Base the frequency of care on the condition of the oral cavity, risk for aspiration of saliva, and the patient's level of

comfort. Some patients (e.g., stroke, trauma to oral cavity, patient with endotracheal tube) require oral care as often as every 1 to 2 hours.

Brushing

The [American Dental Association guidelines \(2018\)](#) for effective oral hygiene include brushing the teeth at least twice a day with American Dental Association–approved fluoride toothpaste. Fluoride and antimicrobial mouth rinses help prevent tooth decay. Do not use fluoride rinse in children ages 6 or under because of the risk of swallowing the rinse. Use antimicrobial toothpastes and 0.12% CHG oral rinses for patients at increased risk for poor oral hygiene (e.g., older adults and patients with cognitive impairments and who are immunocompromised) ([Jenson et al., 2018](#)). The toothbrush needs to have a straight handle and a brush small enough to reach all areas of the mouth. Rounded soft bristles stimulate the gums without causing abrasion and bleeding. Any patient who has decreased dexterity as a result of a medical condition or the aging process requires an enlarged handle with an easier grip ([Box 40.8](#)).

Box 40.8 Focus on Older Adults Oral Health

- Many older adults are edentulous (without teeth), and the teeth that are present are often diseased or decayed (Touhy and Jett, 2018).
- The periodontal membrane weakens with aging, making it more prone to infection. Periodontal disease predisposes older adults to systemic infection.
- Dentures or partial plates do not always fit properly, causing pain and discomfort, which in turn affects chewing, digestive processes, enjoyment of food, and nutritional status.
- An age-related decline in saliva secretion and some medications (e.g., antihypertensives, diuretics, antiinflammatories, antidepressants) cause dry mouth (Touhy and Jett, 2018).
- Financial limitations and the belief that dentures eliminate the need for routine dental care are some of the reasons why older adults do not seek dental care (Touhy and Jett, 2018).

Brush all tooth surfaces thoroughly (Box 40.9). Commercially made foam swabs are ineffective in removing plaque. Electric or battery-powered toothbrushes improve the quality of cleaning and may be easier to use than manual brushes when nurses provide care for dependent patients. Do not use lemon-glycerin sponges because they dry mucous membranes and erode tooth enamel.

Box 40.9 Procedural Guidelines Providing Oral

Hygiene

Delegation and Collaboration

The skill of oral hygiene (including tooth brushing, flossing, and rinsing) can be delegated to assistive personnel (AP). However, the nurse is responsible for assessing the patient's gag reflex to determine whether the patient is at risk for aspiration. The nurse instructs the AP about:

- Types of changes in oral mucosa (e.g., presence of lesions or open sores) to report to the nurse.
- Positioning the patient to avoid aspiration.
 - Keeping head of bed (HOB) raised 30-45 degrees.
 - Explaining the need to immediately report to the nurse excessive patient coughing or choking during or after oral hygiene.
- Reporting ulcerations, lesions, or bleeding of oral mucosa or gums and patient report of pain.
- Not flossing when the patient has a bleeding tendency.

Equipment

Soft-bristle toothbrush; nonabrasive fluoride toothpaste; dental floss; chlorhexidine gluconate (CHG) solution (*optional*; see agency policy); tongue depressor; water glass with cool water, normal saline, or an antiseptic mouth rinse (*optional depending on patient preference*); moisturizing lubricant for lips (*optional*); emesis basin; face towel; paper towels; clean gloves; penlight; linen bag or hamper

Steps

1. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy (TJC, 2020).
2. Review medical record and identify presence of common oral hygiene problems.
3. Determine patient's or family caregiver's knowledge, experience, and health literacy
4. Assess patient's oral hygiene practices, such as frequency of brushing and flossing, type of toothpaste and mouthwash used, last and frequency of dental visits.
5. Perform hand hygiene and apply clean gloves.
6. Using tongue depressor and penlight, inspect integrity of lips, teeth, buccal mucosa, gums, palate, and tongue; also assess for gag reflex and ability to swallow (see Chapter 30). Note presence of dental caries—chalky white discoloration of tooth or presence of brown or black discoloration; gingivitis—inflammation of gums; periodontitis—receding gum lines, inflammation, gaps between teeth; halitosis—bad breath; cheilitis—cracked lips; dry, cracked, and coated tongue.
7. Remove and dispose of gloves and perform hand hygiene.
8. Explain procedure to patient, discussing patient's preferences; assess patient's ability to grasp and manipulate toothbrush and willingness to help with oral care.
9. Place paper towels on over-bed table and arrange other equipment within easy reach.
10. Provide privacy by closing room doors and drawing room divider curtain. Raise bed to comfortable working position.
11. Raise head of bed (if allowed) and lower near side rail. Move patient or help him or her move closer to side. Place patient in side-lying position if needed (if aspiration risk). Place towel over patient's chest.
12. Apply clean gloves. Apply enough toothpaste to brush to cover length of bristles. Hold brush over emesis basin. Pour small amount of water over toothpaste.
13. Patient may help with brushing. Hold toothbrush bristles at 45-degree angle to gum line (see illustration A). Be sure that tips of bristles rest against and penetrate under gum line. Brush inner and outer surfaces of upper and lower teeth by brushing from gum to crown of each tooth. Clean biting surfaces of teeth by holding top of bristles parallel with teeth and brushing gently back and forth (see

illustration B). Brush sides of teeth by moving bristles back and forth (see illustration C).

STEP 13 Direction of brushing for tooth brushing.

14. Have patient hold brush at 45-degree angle and lightly brush over surface and sides of tongue. Avoid initiating gag reflex.
15. Allow patient to rinse mouth thoroughly by taking several sips of cool water, swishing water across all tooth surfaces, and spitting into emesis basin. Use this time to observe patient's brushing technique and teach the importance of regular hygiene (see Fig. 40.2).
16. Have patient rinse mouth with antiseptic rinse for 30 seconds. Then have patient spit rinse into emesis basin. Help wipe patient's mouth.
17. Floss or allow patient to floss between all teeth (see illustration).

STEP 17 Flossing. **A**, Dental floss is held between middle fingers to floss upper teeth. **B**, Floss is moved in up-and-down motions between teeth. Floss is moved up and down from crown to gum line. **C**, Floss is held with index fingers to floss lower teeth.

18. Allow patient to rinse mouth thoroughly with cool water and spit into emesis basin. Help wipe his or her mouth.

19. Inspect oral cavity to determine effectiveness of oral hygiene and rinsing. Ask patient whether mouth feels clean or if there are any sore or tender areas. Remove towel and place in linen bag.
20. Remove and dispose of gloves and perform hand hygiene. Help patient to comfortable position, raise side rail, and lower bed to original position.
21. **Use Teach-Back:** “I want to be sure you know how often to floss your teeth. Show me how you will floss your teeth.” Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly.
22. Record and Report bleeding, pain, or presence of lesions to nurse in charge or health care provider.

To prevent cross-contamination, teach patients to avoid sharing toothbrushes with family members or drinking directly from a bottle of mouthwash. Disclosure tablets or drops to stain the plaque that collects at the gum line are useful for showing patients how effectively they brush. Instruct patients to obtain a new toothbrush every 3 months or following a cold or upper respiratory infection to minimize growth of microorganisms on the brush surfaces ([American Dental Association, 2018](#)).

Flossing

Dental flossing removes plaque and tartar between teeth. Flossing involves inserting waxed or unwaxed dental floss between all tooth surfaces, one at a time. The seesaw motion used to pull floss between teeth removes plaque and tartar from tooth enamel. Use unwaxed floss and avoid vigorous flossing near the gum line on patients who are receiving chemotherapy, radiation, or anticoagulant therapy to prevent bleeding. If toothpaste is applied to the teeth before flossing, fluoride comes in direct contact with tooth surfaces, aiding in cavity prevention. According to [American Dental Association \(2018\)](#) recommendations, flossing once a day is sufficient. Because it is important to clean all teeth surfaces thoroughly, do not rush to complete flossing. Placing a mirror in front of a patient helps you demonstrate the proper method for holding the floss and cleaning between the teeth. Flossing a patient’s teeth is not realistic or appropriate in all care settings.

Patients With Special Needs

Some patients require special oral hygiene methods. For example, patients with diabetes mellitus and who are on chemotherapy frequently experience periodontal disease. Therefore, they need to visit a dentist every 3 to 4 months, clean their teeth up to 4 times a day, and handle oral tissues gently with a minimum of trauma. Xerostomia, bruxism, and dental caries may be present with patients who are methamphetamine users. Cravings for sugary sweets may cause decay and gum disease.

Patients may depend on their caregivers for oral care. Being unconscious or having an artificial airway (e.g., endotracheal or tracheal tubes) increases the susceptibility for patients to have drying of salivary secretions because they are unable to eat or drink, unable to swallow, and frequently breathe through the mouth. Unconscious patients often have a reduced gag reflex, or they cannot swallow salivary secretions that accumulate in the mouth. Pooling of salivary secretions in the back of the throat harbors microorganism growth. These secretions often contain gram-negative bacteria that cause pneumonia if aspirated into the lungs. Proper oral hygiene requires keeping the mucosa moist and removing secretions that contribute to infection. While providing hygiene, protect the patient from choking and aspiration and use topical CHG, especially in ventilated patients (see Skill 40.3). Current evidence shows that use of CHG with oral hygiene reduces the risk for ventilator-associated pneumonia (IHI, 2018; El-Rabbany et al., 2015).

Have two nurses provide the care; turn the patient's head toward you and place the bed in semi-Fowler's position. You can delegate assistive personnel to participate. One nurse does the actual cleaning, and the other caregiver removes secretions with suction equipment. Some agencies use equipment that combines a mouth swab with the suction device; you can use this equipment safely by yourself. While cleansing the oral cavity, use a small oral airway or a padded tongue blade to hold the mouth open. Never use your fingers to hold a patient's mouth open. A human bite contains multiple pathogenic microorganisms. Even though the patient is not awake or alert, explain the steps of mouth care and the sensations that he or she will feel. Also tell the patient when the procedure is completed.

Some treatments such as chemotherapy, immunosuppressive agents, head and neck radiation, and nasogastric intubation place patients at higher risk of experiencing stomatitis or inflammation of the oral mucosa. **Stomatitis** causes burning, pain, and change in food and fluid tolerance. When caring for patients with stomatitis, brush with a soft toothbrush and floss gently to prevent bleeding of the gums. In some cases, flossing needs to be omitted temporarily from oral care. Advise patients to avoid alcohol

and commercial mouthwash and to stop smoking. Normal saline rinses (approximately 30 mL) on awakening in the morning, after each meal, and at bedtime help clean the oral cavity. Patients can increase the rinses to every 2 hours if necessary. Consult with the health care provider to obtain topical or oral analgesics for pain control.

Denture Care

Encourage patients to clean their dentures on a regular basis to avoid gingival infection and irritation. When patients become disabled, someone else assumes responsibility for denture care (Box 40.10). Dentures are a patient's personal property and must be handled with care because they break easily. They must be removed at night to rest the gums and prevent bacterial buildup. To prevent warping, keep dentures covered in water when they are not worn and always store them in an enclosed, labeled cup with the cup placed on the patient's bedside stand. Discourage patients from removing their dentures and placing them on a napkin or tissue because they could easily be thrown away.

Box 40.10 Procedural Guidelines Care of Dentures

Delegation and Collaboration

The skill of denture care can be delegated to assistive personnel (AP). The nurse instructs the AP to:

- Not use hot or excessively cold water when caring for dentures.
- Inform the nurse if there are cracks in dentures.
- Inform the nurse if the patient has any oral discomfort.

Equipment

Soft-bristled toothbrush or denture toothbrush; denture dentifrice or toothpaste, denture adhesive (*optional*); glass of water; emesis basin or sink; 4 × 4-inch gauze; washcloth; denture cup (for storage); clean gloves

Steps

1. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency

- policy (TJC, 2019).
2. Assess environment for safety (e.g., check room for spills; make sure that bed is in locked, low position) (QSEN, 2018).
 3. Perform hand hygiene.
 4. Determine patient's or family caregiver's knowledge, experience, and health literacy.
 5. Ask patient whether dentures fit and whether he or she is experiencing any gum or mucous membrane tenderness or irritation. Ask patient about denture care and product preferences.
 6. Determine whether patient has necessary dexterity to clean dentures independently or requires help.
 7. Lower side rail. Position patient comfortably sitting up in bed, or help him or her walk from bed to chair placed in front of sink.
 8. Fill emesis basin with tepid water. (If using sink, place washcloth in bottom of sink and fill sink with approximately 2.5 cm [1 inch] of water.)
 9. Perform hand hygiene again and apply clean gloves.
 10. Ask patient to remove dentures. If patient is unable to do this independently, grasp upper plate at front with thumb and index finger wrapped in gauze and pull downward. Gently lift lower denture from jaw and rotate one side downward to remove from patient's mouth. Place dentures in emesis basin or sink lined with washcloth and 2.5 cm (1 inch) of water.
 11. Inspect oral cavity, paying attention to gums, tongue, and upper palate. Observe for lesions, plaques, and areas of irritation. Palpate areas as needed.

Clinical Decision: Oral mucosal lesions are common in older adults, especially those with dentures. These lesions are associated with local and systemic factors, and tongue lesions may be the first to appear (*Pedersen et al., 2015*).

12. Apply cleaning agent to brush and brush surfaces of dentures (see illustration). Hold dentures close to water. Hold brush horizontally and use back-and-forth motion to clean biting surfaces. Use short strokes from top of denture to biting surfaces to clean outer teeth surfaces. Hold brush vertically and use short strokes to clean inner teeth surfaces. Hold brush horizontally and use back-and-forth motion to clean undersurface of dentures (see Procedural Guideline Box 40.9).

STEP 12 Brushing surface of dentures.

13. Rinse thoroughly in tepid water. If water is too cold, dentures can crack. If it is too hot, dentures can become warped and no longer fit.
14. When necessary, apply a thin layer of denture adhesive to undersurface before inserting.
15. Reinsert dentures as soon as possible. If patient needs help with inserting dentures, moisten upper denture and press firmly to seal it in place. Insert moistened lower denture (if applicable). Ask whether denture(s) feels comfortable. **Note:** It is common for patients to choose not to wear their dentures during an acute illness.
16. Some patients prefer to store their dentures to give gums a rest and reduce risk for infection. Store in tepid water in enclosed, labeled denture cup. Keep denture cup in a secure place labeled with patient's name to prevent loss when not worn (e.g., at night, during surgery).
17. Dispose of supplies. Remove and discard gloves and perform hand hygiene.
18. Return patient to a comfortable position with bed in low position. Leave nurse call system in reach.
19. Record and report any abnormalities noted involving oral mucosa.

Implement measures to prevent denture-induced stomatitis when caring for patients who wear dentures. Poorly fitting dentures, wearing dentures while sleeping, and poor dental hygiene habits contribute to denture-induced stomatitis (Maciag et al., 2017; Martori et al., 2014). Signs and symptoms range from redness and swelling under the dentures to painful red sores on the roof of the mouth and infection with the yeast *Candida albicans*. Some patients deny pain, and others complain of pain worsened by wearing dentures. To prevent denture-induced stomatitis, rinse the mouth and dentures after meals, clean them carefully and regularly, remove and soak them overnight, brush and floss (if appropriate) any remaining teeth, and visit a dentist regularly for examination (American Dental Association, 2018).

Hair and Scalp Care

A person's appearance and feeling of well-being often depend on the way the hair looks and feels. Illness or disability often prevents a patient from maintaining daily hair care. When patients are immobilized, their hair soon becomes tangled. Some dressings or diagnostic procedures leave sticky residue on the hair. Basic hair and scalp care includes brushing, combing, and shampooing.

Brushing and Combing

Frequent brushing helps keep hair clean and distributes oil evenly along hair shafts. Combing prevents hair from tangling. Encourage patients to maintain routine hair care and provide help for patients with limited mobility or weakness and those who are confused or weakened by illness. Patients in a hospital or extended-care facility appreciate the opportunity to have their hair brushed and combed before being seen by others.

When caring for patients from different cultures, learn as much as possible from them or their family about preferred hair care practices. For example, the hair of African-Americans tends to be quite dry. Use special lanolin conditioners for conditioning. Cultural preferences also affect how hair is combed and styled and whether it can be cut.

Long hair becomes matted easily when a patient is confined to bed, even for a short period. When lacerations or incisions involve the scalp, blood and topical medications also cause tangling. Frequent brushing and combing keep long hair neatly groomed. Braiding helps to avoid repeated tangles; however, patients need to unbraid hair periodically and comb it to

ensure good hygiene. Braids that are too tight lead to bald patches. Obtain permission from the patient before braiding the hair.

To brush hair part it into two sections and separate each section into two more sections. Brushing from the scalp toward the hair ends minimizes pulling. Moistening the hair with water or an alcohol-free detangle product makes it easier to comb. Never cut a patient's hair without consent.

Patients who develop head lice require special considerations in the way combing is performed (Box 40.11). The lice are small, about the size of a sesame seed; thus, you need bright light or natural sunlight to see them. Thorough combing is more effective than use of pediculicidal shampoos, which are often toxic and ineffective against resistant lice.

Box 40.11 Hygiene Care for Head Lice

- Perform hand hygiene and apply disposable gown and gloves.
- Use a grooming comb or hairbrush to remove tangles.
- Divide patient's hair in sections, and fasten off hair that is not being combed.
- Comb out from scalp to the end of the hair (special combs are available in drugstores).
- Dip comb in a cup of water or use a paper towel to remove lice between each passing.
- After combing, look through hair carefully for attached lice; you can catch live lice with a tweezers or comb.
- After combing thoroughly, move to next section of hair.
- Instruct family to clean the comb with an old toothbrush and dental floss. Then boil the comb. The ideal is to discard the comb after each use, but some patients' financial situations prevent the purchase of multiple combs.
- Instruct family to comb and screen for lice daily.
- Instruct family to contain patient's clothes and wash them in hot water.
- Instruct family to vacuum the home and patient's room and immediately empty vacuum bag or bagless collection device.

- Instruct caregivers on how to prevent transmission of lice: Do not share bed linens or hair care products. Avoid placing bare hand on patient's head. Immediately wash hands after providing hair care.

If a pediculicidal shampoo is ordered, review pertinent information and instruct the patient and caregiver in its proper use. Use with caution because these shampoos may have severe neurological side effects. Make sure to thoroughly rinse shampoo from hair to avoid itching.

Shampooing

Frequency of shampooing depends on a person's daily routines and the condition of the hair. Remind patients in hospitals or extended-care facilities that staying in bed, excess perspiration, or treatments that leave blood or solutions in the hair require more frequent shampooing. In some agencies you need a health care provider's order to shampoo a patient who is dependent or has limited mobility because it is challenging to find ways to shampoo the hair without causing injury.

The patient who can shower or tub bathe usually shampoos the hair without difficulty. A shower or tub chair facilitates shampooing for patients who are ambulatory and weight-bearing and become tired or faint. Handheld shower nozzles allow patients to easily wash the hair in the tub or shower. Some patients allowed to sit in a chair choose to be shampooed in front of a sink or over a washbasin; however, certain conditions (e.g., eye surgery or neck injury) limit bending. In these situations, teach the patient and family the degree of bending allowed.

If a patient is unable to sit but can be moved, transfer him or her to a stretcher for transportation to a sink or shower equipped with a handheld nozzle. Use caution when positioning the patient's head and neck, particularly in patients with any form of head or neck injury.

If a patient is unable to sit in a chair or be transferred to a stretcher, shampoo the hair with him or her in bed ([Box 40.12](#)). Position a special shampoo trough under his or her head to catch water and suds. After shampooing, patients like having their hair styled and dried. Most health care centers have portable hair dryers. Dry shampoos that reduce the need to wet the patient's hair are also available but are not highly effective. Shampoo caps provide a warm, wet massage to the scalp while cleaning the hair.

o Box 40.12 Procedural Guidelines Hair Care:

Shampooing and Shaving

Delegation and Collaboration

The skills of combing, shampooing, and shaving can be delegated to assistive personnel (AP). The nurse instructs the AP to:

- Properly position a patient with head or neck mobility restrictions.
- Provide the proper care in cases of head lice, stressing steps to take to prevent transmission to other patients.
- Report how the patient tolerated the procedure and any concerns (e.g., neck pain).
- Use an electric razor for any patient at risk for bleeding tendencies.

Equipment

Hair Care

- Wide-tooth comb and hairbrush

Regular Shampoo

- Washcloth; shampoo, hair conditioner (*optional*), hydrogen peroxide and saline 50/50 mixture (*optional if blood in hair*); water pitcher with warm water; plastic shampoo board, washbasin; bath blanket, waterproof pad.

Disposable Shampoo

- Disposable shampoo cap product

Shaving with Razor

- New disposable or electric razor; clean gloves; bath towel(s), mirror, washcloth, washbasin; shaving cream or soap, aftershave lotion (if patient desires and not contraindicated)

Mustache Care

- Scissors, brush or comb; bath towel; gooseneck lamp or overhead light

Steps

1. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy (TJC, 2020).
2. Assess whether patient has bleeding tendency. Review medical history, medications, and laboratory values (e.g., platelet count, anticoagulation studies).

CLINICAL DECISION: Have any patient on anticoagulants or who has low platelets use an electric razor.

3. Review medical record to determine that there are no contraindications to procedure. Check agency policy for health care provider order as needed. Certain medical conditions such as head and neck injuries, spinal cord injuries, and arthritis place patient at risk for injury during shampooing because of positioning and manipulation of patient's head and neck
4. Assess environment for safety (e.g., check room for spills; make sure that bed is in locked, low position) (QSEN, 2018).
5. Perform hand hygiene. Inspect condition of hair and scalp (this can also be done just before starting shampoo or combing). Inspect for presence of any infestation (e.g., pediculosis). Inspect for drainage from any head wounds. **Note:** Apply clean gloves if drainage or infestation is suspected. Apply a gown if infestation is suspected (National Pediculosis Association, 2017).
6. Remove and discard gloves and perform hand hygiene.
7. Determine patient's or family caregiver's knowledge, experience, and health literacy.
8. Assess patient's hair-care and shaving product preferences (e.g., shampoo, aftershave lotion, skin conditioner).
9. Assess patient's ability to manipulate comb, brush, or razor.
10. Gather equipment and supplies at patient's bedside. Explain your intent to provide hair/beard care. Ask patient to explain during

procedure the steps that he or she uses to comb hair and/or shave. Ask patient to indicate if he or she becomes uncomfortable during procedure.

11. Position patient sitting in chair or up in bed with head elevated 45 to 90 degrees (as tolerated).
12. Provide privacy; close door or pull curtain. Arrange supplies at bedside table and adjust lighting.
13. Perform hand hygiene.
14. Combing and brushing hair:
 - a. Apply clean gloves if necessary. Part hair into two sections and then separate it into two more sections (see illustrations).

A

B

STEP 14a Parting hair. **A**, Part hair down the middle and divide it into two main sections. **B**, Part main section into two smaller sections.

- b. Brush or comb from scalp toward hair ends.
- c. Moisten hair lightly with water, conditioner, or alcohol-free detangle product before combing.

- d. Move fingers through hair to loosen any larger tangles.
 - e. Using a wide-tooth comb, start on either side of head and insert comb with teeth upward to hair near scalp. Comb through hair in circular motion by turning wrist while lifting up and out. Continue until all hair is combed through, and comb into place to shape and style.
15. Shampooing bed-bound patient with shampoo board:
- a. Apply clean gloves. Place waterproof pad under patient's shoulders, neck, and head.
 - b. Position patient supine with head and shoulders at top edge of bed. Place shampoo board under patient's head and washbasin under end of trough spout (see illustration). Be sure that trough spout extends beyond edge of mattress.

STEP 15b Patient positioned over shampoo board.
Copyright © Mosby's Clinical Skills: Essentials Collection.

- c. Place rolled towel under patient's neck and bath towel over patient's shoulders.
- d. Brush and comb patient's hair.
- e. Ask patient to hold towel or washcloth over eyes.
- f. Test water temperature. Slowly pour water from pitcher over hair until it is completely wet (see illustration). If hair contains matted blood, apply hydrogen peroxide to

dissolve clots and rinse with saline. Apply small amount of shampoo.

STEP 15f Nurse pouring water over patient's hair.
Copyright © Mosby's Clinical Skills: Essentials Collection.

- g. Work up lather with both hands. Start at hairline and work toward back of neck. Lift head slightly with one hand to wash back of head. Shampoo sides of head. Massage scalp by applying pressure with fingertips.
- h. Rinse hair with water. Make sure that water drains into basin. Repeat rinsing until hair is free of soap. (If you need to refill pitcher, raise side rail when leaving bedside.)
- i. Apply conditioner or crème rinse if requested, and rinse hair thoroughly.
- j. Wrap patient's head in bath towel. Dry face with cloth used to protect eyes. Dry off any moisture along neck or shoulders.
- k. Dry patient's hair and scalp. Use second towel if first one becomes saturated.
- l. Comb hair to remove tangles and dry with dryer if desired.
- m. Apply oil preparation or conditioning product to hair if desired by patient.
- n. Variation for patients with coarse, curly hair: Condition hair after washing. To untangle hair, use wide teeth of

comb. Beginning at nape of neck, comb small subsections of hair, starting at hair ends. Continue to work through small sections until hair is free of tangles.

16. Shampooing with disposable shampoo product:

- a. Patient can be sitting on chair or in bed. Apply clean gloves.
- b. Comb hair to remove any tangles or debris (see Step 14 above).
- c. Open package, apply cap, and secure all hair beneath cap (see illustration).

STEP 16c Patient wearing disposable shampoo cap.

- d. Massage head through cap. Check fitting around head to maintain correct fit.
- e. Massage 2 to 4 minutes according to directions on package; additional time may be required for longer hair or hair

matted with blood.

- f. Discard cap in trash; do not dispose of in toilet because it may clog plumbing.
- g. If patient desires, towel-dry hair. Brush or comb patient's hair.

17. Shaving with disposable razor:

- a. Place bath towel over patient's chest and shoulders.
- b. Run warm water in washbasin. Check water temperature.
- c. Place washcloth in basin and wring out thoroughly. Apply cloth over patient's entire face for several seconds.
- d. Apply approximately $\frac{1}{4}$ inch shaving cream or soap to patient's face. Smooth cream evenly over sides of face, on chin, and under nose.
- e. Hold razor in dominant hand at 45-degree angle to patient's skin. Begin by shaving across one side of patient's face using short, firm strokes in direction that hair grows (see illustration). Use nondominant hand to gently pull skin taut while shaving. Ask patient whether he feels comfortable.

STEP 17e Shaving patient using short, firm strokes.

- f. Dip razor blade in water because shaving cream accumulates on edge of blade.
 - g. After all facial hair is shaved, rinse face thoroughly with warm, moistened washcloth.
 - h. Dry face thoroughly and apply aftershave lotion if desired. Remove towel.
18. Shaving with electric razor:
- a. Place bath towel over patient's chest and shoulders.
 - b. Apply skin conditioner or preshave preparation.
 - c. Turn razor on and begin by shaving across side of face. Gently hold skin taut while shaving over surface of skin. Use gentle downward stroke of razor in direction of hair growth.
 - d. After completing shave, turn razor off, remove towel and apply aftershave lotion as desired unless contraindicated.
19. Mustache and beard care:
- a. Place bath towel over patient's chest and shoulders.
 - b. If necessary, gently comb mustache or beard. Offer option for patient to shampoo beard.
 - c. Allow patient to use mirror and direct areas to trim with scissors.
 - d. After completing, remove towel.
20. Discard soiled linen in dirty laundry bag. Remove and dispose of gloves. Perform hand hygiene.
21. Help patient to comfortable position with nurse call system in reach, bed in low position.
22. Return reusable equipment to proper place.
23. Inspect condition of hair and scalp, condition of shaved area and skin underneath beard or mustache. Look for areas of localized bleeding from cuts and areas of dryness.
24. Ask patient whether face feels clean and comfortable.
25. **Use Teach-Back:** "Since you are on a blood thinner, I want to be sure I explained to you the risks of using a regular razor at home. What type of razor you should use? Tell me the things to watch for with a bleeding tendency." Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly.
26. Record or report any lesions, presence of lice to healthcare provider.

Shaving

Shave a patient's facial hair after the bath or shampoo. Some women prefer to shave their legs or axillae while bathing. When helping a patient, take care to avoid cutting him or her with the razor blade. Patients prone to bleeding (e.g., those receiving anticoagulants or high doses of aspirin or those with low platelet counts) need to use their personal electric razor. Before using an electric razor, check for frayed cords or other electrical hazards. Use a razor blade on only one patient because of infection control considerations.

When using a razor blade for shaving, soften the skin to prevent pulling, scraping, or cuts. Moisten the skin with lukewarm water and apply shaving cream. Bar soap may leave a film on the blade, resulting in a poorer-quality shave. You need to shave patients when they are unable to shave themselves independently. To avoid causing discomfort or razor cuts, gently pull the skin taut and use long, firm razor strokes in the direction the hair grows ([Fig. 40.5](#)). Short downward strokes work best to remove hair over the upper lip or chin. A patient usually explains the best way to move the razor across the skin.

FIG. 40.5 Shave using short, firm strokes in direction of hair growth.

Facial hair of people of color tends to be curly and becomes ingrown unless shaved close to the skin. However, there are common skin lesions among people of color that require a different shaving technique. An example is the common condition of pseudofolliculitis barbae, commonly referred to as razor bumps and recognized by inflammation of hair

follicles and hyperpigmented papules and pustules ([Kundu and Patterson, 2013](#)). It typically results from cut hairs penetrating the skin. Use the following techniques for this condition: Avoid a close shave, leaving hair at a length of 0.5 to 3 mm; use clippers, a single-blade razor, or depilatories; if depilatories cause skin irritation, discontinue use, shave in the direction of hair growth, and do not pull the skin taut while shaving ([Kundu and Patterson, 2013](#)).

Mustache and Beard Care

Mustaches or beards require daily grooming, including shampooing. Grooming keeps food particles and mucus from collecting in the hair. If a patient is unable to carry out self-care, do so at his or her request. Comb out beards gently, and obtain the patient's permission before trimming or shaving off a mustache or beard.

Care of the Eyes, Ears, and Nose

Give special attention to cleaning the eyes, ears, and nose during a routine bath and when drainage or discharge accumulates. This aspect of hygiene not only makes a patient more comfortable but also improves sensory reception (see [Chapter 49](#)). Care focuses on preventing infection and maintaining normal sensory function. In addition, care of the eyes, ears, and nose requires approaches that consider the patient's special needs.

Medical Devices

If a patient has oxygen tubing, a feeding tube, or a nasotracheal tube, it is essential that you care for the area of the skin around the nose or ears underlying the device. The National Pressure Ulcer Advisory Panel ([NPUAP, 2013](#)) recommends the following: cushion and protect the skin with dressings in high-risk areas (e.g., nasal bridge) (see [Chapter 48](#)), do not place device(s) over sites of prior or existing pressure injury, and be sure to gently cleanse a potential area of irritation that underlies a device at least daily.

Basic Eye Care

Cleaning the eyes involves simply washing with a clean washcloth moistened in water (see Skill 40.1). Soap may cause burning and irritation. Never apply direct pressure over the eyeball because it causes serious injury. When cleaning a patient's eyes, obtain a clean washcloth and clean from inner to outer canthus. Use a different section of the washcloth for each eye. Remember, never use CHG solution or cloths to clean the eyes, ears, or face.

Unconscious patients require more frequent eye care. A complication of sedation and coma is that some patients are unable to maintain effective eye closure, which results in exposure keratopathy. Thus, these patients lose their natural protective mechanisms to protect the cornea. When unprotected, there is an increased risk of corneal dehydration, abrasion,

perforation, and infection (Demirel et al., 2014). Normal protective mechanisms include blinking with lubrication of the eye. Blinking provides a mechanical barrier to injury and prevents dehydration. Secretions collect along the lid margins and inner canthus when the blink reflex is absent or when the eye does not close completely. Prompt assessment of impaired blinking is essential to protect your patient's eyes. When an eye does not close completely, you may need to place an eye patch over it to prevent corneal drying and irritation. Apply lubricating eyedrops according to the health care provider's orders (Kocacal et al., 2018).

Eyeglasses

Eyeglasses are expensive. Be careful when cleaning glasses and protect them from breakage or other damage when they are not worn. Put them in a case in a drawer of the bedside table when not in use. Cool water sufficiently cleans glass lenses. Prevent scratching by using a soft cloth for drying; do not use paper towels. Plastic lenses in particular scratch easily; special cleaning solutions and drying tissues are available.

Contact Lenses

A contact lens is a thin, transparent disk that fits directly over the cornea of the eye. Contact lenses correct refractive errors of the eye or abnormalities in the shape of the cornea. In outpatient or home settings instruct patients on the routines to follow for regular cleansing and care (Box 40.13). Explain that all contact lenses must be removed periodically to prevent ocular infection and corneal ulcers or abrasions from infectious agents such as *Pseudomonas aeruginosa* and staphylococci. Pain, tearing, discomfort, and redness of the conjunctivae indicate lens overwear. Encourage patients to report persistence of these symptoms, even after lens removal, to their health care provider.

Box 40.13 Patient Teaching Contact Lens Care

Objective

- Patient verbalizes and/or demonstrates proper care for contact lenses and common warning signs of problems associated with contact lens wear.

Teaching Strategies

- Instruct patients on the following:
 - Do not use fingernail on lens to remove dirt or debris.
 - Do not use tap water to clean soft lenses.
 - Follow recommendations of lens manufacturer or eye care practitioner when inserting, cleaning, and disinfecting lenses.
 - Keep lenses moist or wet when not worn.
 - Use fresh solution daily when storing and disinfecting lenses.
 - Thoroughly wash and rinse lens storage case on a daily basis. Clean periodically with soap or liquid detergent, rinse thoroughly with warm water, and air dry.
 - If lens is dropped, moisten finger with cleaning or wetting solution and gently touch lens to pick it up. Then clean, rinse, and disinfect it.
- To avoid mix-up, always start with the same lens when removing or inserting lenses.
- Throw away disposable or planned replacement lenses after prescribed wearing period.
- Encourage patient to remember the acronym RSVP: *Redness, Sensitivity, Vision problems, and Pain*. If one of these problems occurs, remove contact lenses immediately. If problems continue, contact a vision care specialist (Harding et al., 2020).

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- Explain to me the warning signs of corneal irritation and eye infection.
- Describe for me the methods of contact lens care that lead to infection.
- I want to make sure that you understand the information on lens cleaning and storage. Show me how you will clean your lenses and store them.

When patients are admitted to the hospital or agency in an unresponsive or confused state, determine whether they normally wear contact lenses

and whether the lenses are in place. If a patient wears contact lenses and no one detects this, severe corneal injury can result. If you find that your patient is wearing contact lenses and cannot remove them, seek help. Once the lenses are removed, document the removal, the condition of the patient's eyes following removal, and the storage of the lenses.

Ear Care

Routine ear care involves cleaning the outer ear with a washcloth and warm water. Cleanse the outer ear canal with the end of a moistened washcloth rotated gently into the canal. Gentle, downward retraction at the entrance of the ear canal usually causes visible cerumen to loosen and slip out. Instruct patients never to use objects such as bobby pins, toothpicks, paper clips, or cotton-tipped applicators to remove earwax. These objects can injure the ear canal and rupture the tympanic membrane. They may also cause cerumen to become impacted within the ear canal.

Children and older adults commonly have impacted cerumen. You can usually remove excessive or impacted cerumen by irrigation, which requires a health care provider's order. Review the order for type of solution and ear(s) to receive the irrigation. Before irrigation question the patient for history of perforated eardrum and inspect his or her tympanic membrane to be sure that it is intact; a perforated tympanic membrane contradicts performing irrigation. Visually inspect the pinna and external meatus for redness, swelling, drainage, and presence of foreign objects. Also determine the patient's ability to hear in the affected ear before irrigation.

To irrigate the ear, have the patient sit or lie on the side with the affected ear up. For adults and children over 3 years of age, gently pull the pinna up and back. In children 3 years of age or younger, the pinna should be pulled down and back. Using a bulb-irrigating syringe, gently wash the ear canal with warm solution (37°C or 98.6°F), being careful not to occlude the canal, which results in pressure on the tympanic membrane. Direct the fluid slowly and gently toward the superior aspect of the ear canal, maintaining the flow in a steady stream. Periodically during the irrigation ask if the patient is experiencing pain, nausea, or vertigo. These symptoms indicate that the solution is too hot or too cold or is being instilled with too much pressure. After the canal is clear, wipe off any moisture from the ear with cotton balls and inspect the canal for remaining earwax.

Hearing Aid Care

A hearing aid amplifies sounds in a controlled manner; the aid receives normal low-intensity sound inputs and delivers them to a patient's ear as louder outputs. Hearing aids come in a variety of types. The new class of hearing aids reduces background noise interference. Computer chips placed in the aids allow for fine adjustments to the specific patient's hearing needs.

There are several popular types of hearing aids. A completely-in-canal (CIC) aid ([Fig. 40.6, A](#)) is the newest, smallest, and least visible and fits entirely in the ear canal. It is used for patients with moderately severe hearing loss. It has cosmetic appeal, is easy to manipulate and place in the ear, and does not interfere with wearing eyeglasses or using the telephone. The patient can wear it during most physical exercise. However, it requires adequate ear diameter and depth for proper fit. It does not accommodate progressive hearing loss, and it requires manual dexterity to operate, insert, remove, and change batteries. In addition, cerumen tends to plug this model more than the others.

FIG. 40.6 Common types of hearing aids. **A**, Completely-in-canal (CIC) hearing aid. **B**, In-the-ear (ITE) hearing aid. **C**, Behind-the-ear (BTE) hearing aid. **D**, Digital hearing aid.

An in-the-ear (ITE, or intraaural) aid (Fig. 40.6, B) fits into the external auditory canal and allows for finer tuning. It is more powerful and stronger and therefore is more useful for mild-to-severe hearing loss than the CIC aid. It is easier to position and adjust and does not interfere with wearing eyeglasses. However, it is more noticeable than the CIC aid and is not for people with moisture or skin problems in the ear canal.

A behind-the-ear (BTE, or postaural) aid (Fig. 40.6, C) hooks around and behind the ear. It is connected by a short, clear, hollow plastic tube to an ear mold inserted into the external auditory canal. A BTE aid allows for fine tuning. It is the largest aid and is useful for patients with mild to profound hearing loss or manual dexterity difficulties or for those who find partial ear occlusion intolerable. The larger size of this type of aid can make the use of eyeglasses and phones difficult; it is more difficult to keep in place during physical exercise.

Digital hearing aids (Fig. 40.6, D) analyze sounds to remove background noise. This aid is beneficial for people with mild to severe hearing loss. Digital hearing aids program for low-frequency and high-frequency sounds and must be programmed and adjusted by a licensed audiologist. [Box 40.14](#) reviews guidelines for the care and cleaning of hearing aids.

Box 40.14 Care and Use of Hearing Aids

- Initially wear hearing aid 15 to 20 minutes; gradually increase time to 10 to 12 hours.
- Once inserted, turn aid slowly to one-third to one-half volume.
- Whistling sound indicates incorrect earmold insertion, improper fit of aid, or buildup of earwax or fluid.
- Adjust volume to comfortable level for talking at distance of 1 yard.
- Do not wear aid under heat lamps or hair dryer or in very wet, cold weather.
- Batteries last 1 week with daily wearing of 10 to 12 hours.
- Remove or disconnect battery when not in use.
- Replace earmolds every 2 or 3 years.
- Routinely check battery compartment: Is it clean? Are batteries inserted properly? Is compartment shut all the way?

- Make sure that dials on hearing aid are clean and easy to rotate, creating no static during adjusting.
- Keep aid clean. See manufacturer instructions. Aids are usually cleaned with a soft cloth.
- Avoid use of hairspray and perfume while wearing hearing aids; residue from spray causes aid to become oily and greasy.
- Do not submerge in water.
- Routinely check cord or tubing (depending on type of aid) for cracking, fraying, and poor connections.
- Routine follow-up with audiologist is recommended to evaluate effectiveness of current aid.

Data from Touhy T, Jett P: *Ebersole and Hess' gerontological nursing & healthy aging*, ed 5, St Louis, 2018, Elsevier.

Nasal Care

If a patient cannot remove nasal secretions, help by using a wet washcloth or a cotton-tipped applicator moistened in water or saline. Never insert the applicator beyond the length of the cotton tip. You also can remove excessive nasal secretions through gentle nasal suctioning (see [Chapter 41](#)).

When nasogastric, feeding, or endotracheal tubes are inserted through a patient's nose, change the tape anchoring the tube at least once a day. When the tape becomes moist from nasal secretions, the skin and mucosa can easily become macerated (softened by soaking). Friction from a tube causes tissue injury. Anchor tubing correctly with tape or fixative devices to minimize tension or friction on the nares (see [Skill 47.2](#)).

Patient's Room Environment

Attempt to make a patient's room as comfortable as the home. It needs to be safe and large enough to allow the patient and visitors to move about freely. Removal of barriers around the bed and along walkways reduces risk of falls. Control room temperature, ventilation, noise, and odors. Keeping the room neat and orderly also contributes to the patient's sense of well-being.

Maintaining Comfort

What makes a comfortable environment depends on a patient's age, severity of illness, and level of normal daily activity. Depending on age and physical condition, maintain the room temperature between 20° and 23°C (68° and 73.4°F). Infants, older adults, and the acutely ill often need a warmer room. However, certain ill patients benefit from cooler room temperatures to lower the metabolic demands of the body.

An effective ventilation system prevents stale air and odors from lingering in the room. Good ventilation reduces lingering odors caused by draining wounds, emesis, bowel movements, and used bedpans and urinals. Always empty and cleanse bedpans and urinals promptly. Room deodorizers help remove many unpleasant odors. Before using room deodorizers, determine that your patient is not allergic or sensitive to the deodorizer itself.

Ill patients seem to be more sensitive to noises and lighting commonly found in health care settings. Try to control the noise level, especially when a patient is trying to sleep. Explain the source of unfamiliar noises such as an IV pump or pulse oximeter alarms.

Proper lighting provides for safety and comfort. A brightly lit room usually stimulates, whereas a darkened room promotes rest and sleep. Adjust room lighting by closing or opening drapes, regulating over-bed and floor lights, and closing or opening room doors. When entering a patient's room at night, refrain from abruptly turning on an overhead light unless necessary.

Room Equipment

Although there are variations across health care settings, a typical hospital room contains the following basic pieces of furniture: over-bed table, bedside stand, chairs, and bed (Fig. 40.7). The over-bed table is an ideal working space for performing procedures. It also serves as a surface for meal trays, toiletry items, and objects that a patient often uses. Clean the top of the over-bed table with an antiseptic cleaner before using it for meals. Do not place a bedpan or urinal on the over-bed table. Use the bedside stand to store a patient's personal possessions and hygiene equipment. Patients often use bedside stands for their telephone, water pitcher, and drinking cup.

FIG. 40.7 Typical hospital room.

Most patient rooms contain a straight-backed chair or an upholstered lounge chair with arms. Armless straight-backed chairs are convenient when temporarily transferring a patient from the bed, such as during bed making. Upholstered lounge chairs or recliners tend to be more comfortable for patients who can sit for longer times.

Each room usually has an over-bed light and floor-level night lighting. Patients need instructions as to how to access lighting and other controls via their nurse call system (Fig. 40.8). Additional portable or built-in examination lighting provides extra light during bedside procedures.

FIG. 40.8 Nurse instructing patient in use of nurse call system and bed controls.

Other equipment usually found in a patient's room includes the nurses' call system (often integrated into side rails), a television, a wall-mounted blood pressure gauge, oxygen and vacuum wall outlets, and personal care items. Special equipment designed for comfort or positioning patients includes foot boots and special mattresses (see [Chapter 48](#)). Whenever you use comfort and positioning equipment, check agency policy and manufacturer directions before application.

Beds

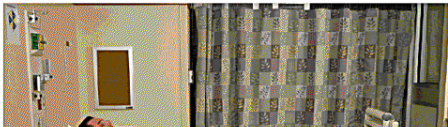

Seriously ill patients often remain in bed for a long time. Because a bed is the piece of equipment used most by a hospitalized patient, it is designed for comfort, safety, and adaptability for changing positions. A typical hospital bed has a firm mattress on a metal frame that you can raise and lower horizontally. More and more hospitals are converting the standard hospital bed to one in which the mattress surface can be adjusted electronically for safety and comfort. For example, low beds are being used to prevent falls, and beds that regulate pressure in the mattress help to reduce pressure injuries. Different bed positions promote patient

comfort, minimize symptoms, promote lung expansion, and improve access during certain procedures ([Table 40.6](#)).

TABLE 40.6

Common Bed Positions

Position	Description	Uses
Fowler's 	Head of bed raised to angle of 45 to 90 degrees; semi-sitting position; foot of bed may also be raised at knee	While patient is eating During nasogastric tube insertion and nasotracheal suction Promotes lung expansion Eases difficult breathing
Semi-Fowler's 	Head of bed raised approximately 30 to 45 degrees; inclination less than Fowler's position; foot of bed may also be raised at knee	Promotes lung expansion, especially with ventilator-assisted patients Used when patients receive oral care and for gastric feedings to reduce regurgitation and risk of aspiration
Trendelenburg's 	Entire bedframe tilted with head of bed down	Used for postural drainage Facilitates venous return in patients with poor peripheral perfusion
Reverse Trendelenburg's 	Entire bedframe tilted with foot of bed down	Used infrequently Promotes gastric emptying Prevents esophageal reflux

Position	Description	Uses
Flat 	Entire bedframe horizontally parallel with floor	Used for patients with vertebral injuries and in cervical traction Used for patients who are hypotensive Patients usually prefer for sleeping

5

You usually change the position of a bed by using electrical controls that are either incorporated into the patient's nurse call system or in a panel on the side or foot of the bed (see [Fig. 40.8](#)). Know how to use the bed controls. Ease in raising and lowering a bed and changing position of the head and foot eliminates undue musculoskeletal strain. Also instruct patients and family members in the proper use of controls and caution them against raising the bed to a position that causes the patient harm. Maintain the bed height at the lowest horizontal position when a patient is unattended.

Beds contain safety features such as locks on the wheels or casters. Lock wheels when a bed is stationary to prevent accidental movement. Side rails allow patients to move more easily in bed and prevent accidents. Do not use side rails to restrict a patient from moving in bed. When using side rails as a restraint, you need a health care provider's order (see [Chapter 27](#)). You can remove the headboard and footboard from most beds. This is important when the medical team needs to have easy access to the patient such as during cardiopulmonary resuscitation.

Bed Making

Keep a patient's bed clean and comfortable. This requires frequent inspection to be sure that linen is clean, dry, and free of wrinkles. When patients are diaphoretic, have draining wounds, or are incontinent, check more frequently for wet or soiled linen.

Usually you make a bed in the morning after patients bathe or while they bathe at a sink or in a shower, while sitting in a chair eating, or when out of the room for procedures or tests. Throughout the day straighten linen that is loose or wrinkled. Also check the bed linen for food particles after meals and for wetness or soiling. Change any linen that becomes soiled or wet.

When changing bed linen, follow principles of medical asepsis by keeping soiled linen away from your uniform ([Fig. 40.9](#)). Place soiled linen

in special linen bags before placing in a hamper. To avoid air currents that spread microorganisms, never shake the linen. To avoid transmitting infection, do not place soiled linen on the floor. If clean linen touches the floor or any unclean surface, immediately place it in the dirty-linen container.

FIG. 40.9 Holding linen away from uniform prevents contact with microorganisms.

During bed making use safe patient-handling procedures (see [Chapter 27](#)). Always raise the bed to the appropriate height before changing linen so that you minimize the extent to which you bend or stretch over the mattress. Move back and forth to opposite sides of the bed while applying new linen. Body mechanics and safe handling are important when turning or repositioning a patient in bed.

When patients are confined to bed, you must make an occupied bed. Organize bed-making activities to conserve time and energy ([Box 40.15](#)). The patient's privacy, comfort, and safety are all important when making a bed. Using side rails to aid positioning and turning, keeping nurse call

systems within the patient's reach, and maintaining the proper bed position help promote comfort and safety. After making a bed, return it to the lowest horizontal position and verify that the wheels are locked to prevent accidental falls when the patient gets in and out of the bed.

Box 40.15 Procedural Guideline Making an Occupied Bed

Delegation and Collaboration

The skill of making an occupied bed can be delegated to assistive personnel (AP). The nurse instructs the AP about:

- Any position or activity restrictions that apply.
- Looking for wound drainage or loosened equipment that might be found in the bed linens.
- When to obtain help from other caregivers for positioning a patient during linen change and the importance of using safe patient handling techniques and supporting patient alignment.
- Using special precautions (e.g., aspiration precautions [see Chapter 45] or positioning for tube-feeding infusion [see Chapter 45) when positioning a patient during bed making.

Equipment

Linen bags: mattress pad (change only when soiled); bottom sheet (flat or fitted); draw sheet (*optional*); top sheet, blanket, bedspread, pillowcases; waterproof pads (*optional*); clean gloves (if linen is soiled or there is risk of exposure to body fluids); antiseptic cleanser; washcloth

Steps

1. Review medical record and assess restrictions in mobility/positioning of patient.
2. Organize supplies and close room door or divider curtain to provide privacy.
3. Assess environment for safety (e.g., check room for spills; make sure that equipment is working properly and that bed is in locked position and appropriate number of side rails are raised) (QSEN, 2018).
4. Perform hand hygiene. Apply clean gloves if patient has been incontinent or if drainage is present on linen.
5. Explain procedure to patient, noting that patient will be asked to turn over layers of linen.
6. Raise bed to a comfortable working height; lower head of bed (HOB) as tolerated, keeping patient comfortable. Remove nurse call system (if separate from bed rails).

CLINICAL DECISION: If patient is on aspiration precautions or receiving tube feeding, keep HOB 30 degrees or higher at all times.

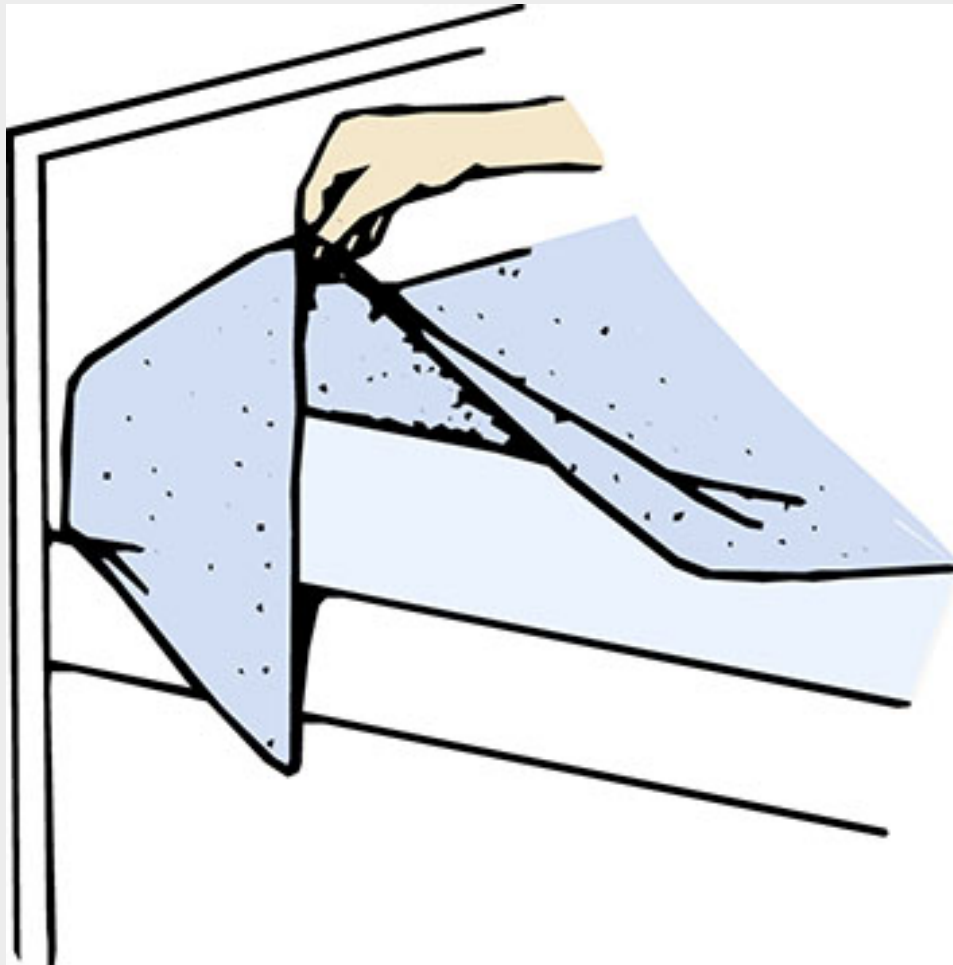

7. Lower side rail on side where you are standing. Loosen all top linen. Remove bedspread and blanket separately, leaving patient covered with top sheet. If blanket or spread is soiled, place in linen bag. If to be reused, fold into square and place over back of chair.
8. Cover patient with clean bath blanket by unfolding it over top sheet. Have patient hold top edge of bath blanket or tuck blanket under shoulders. Grasp top sheet under bath blanket at patient's shoulders and bring sheet down to foot of bed. Remove sheet and discard in dirty laundry bag.
9. Position patient on far side of bed, turned onto side and facing away from you. **Note:** This is when another caregiver can help you by standing at bedside across from you. Encourage patient to use side rail to turn. Adjust pillow under patient's head.
10. Assess to make sure that there is no tension on any external medical devices.
11. Loosen bottom linens, moving from head to foot. Fanfold or roll any cloth incontinence pads, drawsheet (if present), and bottom sheet (in that order) toward patient. Tuck edges of old linen just under patient's buttocks, back, and shoulders (see illustration). Do not fanfold mattress pad (if it is to be reused). Remove any disposable pads and discard in receptacle.

STEP 11 Tuck all soiled linen from one side of bed alongside patient's back.

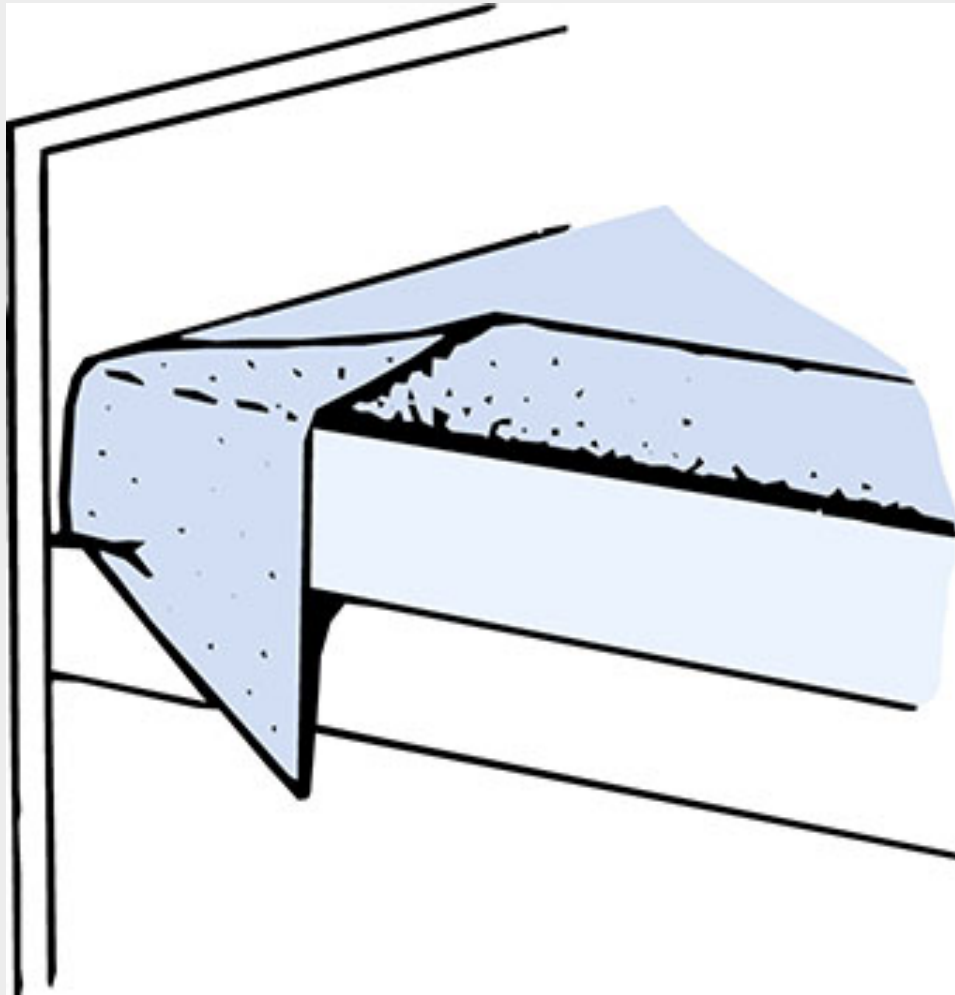

12. Clean, disinfect, and dry mattress surface if it is soiled or has moisture (see agency policy).
13. Apply clean linens to the exposed half of bed in separate layers. When needed, start with a new mattress pad by placing it lengthwise with center crease in middle of bed. Fanfold pad to center of bed alongside patient. Repeat process with bottom sheet.
14. If bottom sheet is fitted, pull corners of new sheet smoothly over mattress corner at top and bottom of bed. Fold remaining portion of sheet across bed surface, toward patient's back.
15. If bottom sheet is flat, place over mattress. Allow edge of sheet closest to you to hang about 25 cm (10 inches) over mattress edge on side and at head of bed (HOB). Be sure that lower hem of bottom sheet lies seam down along bottom edge of mattress. Spread remaining portion of sheet over mattress toward patient's back.
16. For a flat sheet, Miter the top corner at HOB.
 - a. Face HOB diagonally. Place hand away from HOB under top corner of mattress, near mattress edge, and lift.

- b. With other hand, tuck top edge of bottom sheet smoothly under mattress so that side edges of sheet above and below mattress meet when brought together.
- c. To miter a corner, pick up top edge of sheet at about 45 cm (18 inches) from top end of mattress (see illustration).

STEP 16c Top edge of sheet picked up.

- d. Lift sheet and lay it on top of mattress to form a neat triangular fold with lower base of triangle even with mattress side edges (see illustration).

STEP 16d Sheet on top of mattress in a triangular fold.

- e. Tuck lower edge of sheet, which is hanging free below the mattress, under the mattress. Tuck with palms down, without pulling triangular fold.
- f. Hold part of sheet covering side of mattress in place with one hand (see illustrations). With other hand pick up top of triangular linen fold and bring it down over side of mattress. Tuck under mattress with palms down without pulling fold (see illustration).

STEP 16f Triangular fold placed over side of mattress; sheet tucked under mattress.

17. Tuck remaining part of sheet under side of mattress, moving toward foot of bed. Keep linen smooth.
18. Place new drawsheet along middle of bed lengthwise. Fanfold or roll drawsheet on top of clean bottom sheet. Tuck under patient's buttocks and torso without touching old linen.
19. Add waterproof pad (absorbent side up) over drawsheet with seam side down. Fanfold toward patient. Continue to keep clean and soiled linen separate. Also keep linen under patient as flat as possible because patient will need to roll over old and new layers of linen when you are ready to make other side of bed.

20. Advise patient that he or she will be rolling over a thick layer of linens. Keeping patient covered, ask him or her to roll toward you slowly over layers of linen and to not raise the hips (see illustration). Stress the need to roll while staying aligned.

STEP 20 Patient begins rolling over layers of linen.

21. You will now raise side rail and move to opposite side of bed.
Option: The caregiver helping you will help position patient. Have patient roll away from you toward other side of bed, over all of the folds of linen. Again, have patient keep hips still.
22. Lower side rail. Loosen edges of soiled linen from under mattress. Remove soiled linen by folding into a bundle or square.
23. Hold linen away from your body and place it in laundry bag.
24. Clean, disinfect, and dry other half of mattress as needed.
25. Pull clean, fan-folded or rolled mattress pad; sheet; drawsheet; and incontinence pad out from beneath patient toward you. Smooth all linen out over mattress from head to foot of bed. Help patient roll back to supine position and reposition pillow.
26. If bottom sheet is fitted, pull corners over mattress edges. Smooth out sheet.
27. If flat sheet is used, miter top corner of bottom flat sheet (see Steps 16a–f).
28. Facing side of bed, grasp remaining edge of bottom flat sheet. Lean back slightly, keep back straight, and pull while tucking excess linen under mattress from HOB to foot of bed. Avoid lifting mattress during tucking.

29. Smooth fanfolded drawsheets over bottom sheet (tucking is optional). Smooth waterproof incontinence pads, making sure that bed surface is wrinkle free.
30. Place top sheet over patient with vertical centerfold lengthwise down middle of bed and with seam side of hem facing up. Open sheet out from head to foot and unfold over patient. Be sure that top edge of sheet is even with top edge of mattress.
31. Place clean or reused bed blanket on bed over patient. Make sure that top edge is parallel with top edge of sheet and 15 to 20 cm (6 to 8 inches) from edge of top sheet. Raise side rail.
32. Go to other side of bed. Lower side rail. Spread sheet and blanket out evenly.
33. Have patient hold onto sheet and blanket while you remove bath blanket; discard in linen bag.
34. Make cuff by turning edge of top sheet down over top edge of blanket.
35. Make horizontal toe pleat; stand at foot of bed and fanfold in sheet and blanket 5 to 10 cm (2 to 4 inches) across bed. Pull sheet and blanket up from bottom to make fold approximately 15 cm (6 inches) from bottom edge of mattress.
36. Standing at side of bed, tuck in remaining part of sheet and blanket under foot of mattress. Tuck top sheet and blanket together. Be sure that toe pleats are not pulled out.
37. Make modified mitered corner with top sheet and blanket. (Follow Steps 16a–f.) After making triangular fold, do not tuck tip of triangle (see illustration).

STEP 37 Modified mitered corner.

38. Go to other side of bed. Repeat Steps 35 and 36.
39. Change pillowcase. Have patient raise head. While supporting neck with one hand, remove pillow. Allow patient to lower head. Remove soiled case and place in linen bag. Grasp clean pillowcase at center of closed end. Gather case, turning it inside out over the hand holding it. With the same hand, pick up middle of one end of pillow. Pull pillowcase down over pillow with other hand. Do not hold pillow against your uniform. Be sure that pillow corners fit evenly into corners of case. Reposition pillow under patient's head.
40. Place nurse call system within patient's reach on bedrail or pillow; return bed to locked, low position; and raise side rail (as needed).
41. Place all linen in dirty laundry bag. Remove and dispose of gloves.
42. Arrange and organize patient's room and perform hand hygiene.

43. During procedure inspect skin for areas of irritation. Observe patient for signs of fatigue, dyspnea, pain, or other sources of discomfort.

When possible, make the bed while it is unoccupied (Box 40.16). Use judgment to determine the best time for a patient to sit in a chair so you can make the bed. When making an unoccupied bed, follow the same basic principles as for occupied bed making.

Box 40.16 Procedural Guidelines Making an Unoccupied Bed

Delegation and Collaboration

The skill of making an unoccupied bed can be delegated to assistive personnel (AP).

Equipment

Linen bag, mattress pad (change only when soiled), bottom sheet (flat or fitted), drawsheet (*optional*), top sheet, blanket, bedspread, waterproof pads (*optional*), pillowcases, bedside chair or table, clean gloves (if linen is soiled), washcloth or paper towel, and antiseptic cleanser.

Steps

1. Perform hand hygiene. If patient has been incontinent or if excess drainage is on linen, gloves are necessary.
2. Assess activity orders or restrictions in mobility in planning if patient can get out of bed for procedure. Help to bedside chair or recliner.
3. Lower side rails on both sides of bed and raise bed to comfortable working position.
4. Remove soiled linen and place in laundry bag. Avoid shaking or fanning linen.
5. Reposition mattress and wipe off any moisture with a washcloth or paper towel moistened in antiseptic solution. Dry thoroughly.
6. Apply all bottom linen on one side of bed (before moving to opposite side):
 - a. To apply a fitted sheet, be sure it is placed smoothly over mattress.

- b. To apply a flat unfitted sheet, allow about 25 cm (10 inches) to hang over sides of mattress edges (along sides and head of bed). Make sure that lower hem of sheet lies seam down, even with bottom edge of mattress. Pull remaining top part of sheet over top edge of mattress.
7. While standing at head of bed, miter top corner of bottom sheet (see Box 40.15, Steps 16a-f).
8. Tuck remaining part of unfitted sheet under mattress from head to foot of bed.
9. *Optional:* Apply drawsheet and waterproof incontinence pad, laying centerfolds along middle of bed lengthwise. Smooth draw sheet and pad over mattress and tuck excess edge of drawsheet under mattress, keeping palms down. Center position of pad over bottom sheet.
10. Move to opposite side of bed and spread bottom sheet smoothly over edge of mattress from head to foot of bed.
11. Apply fitted sheet smoothly over each mattress corner. For an unfitted sheet, miter top corner of bottom sheet (see Step 7), making sure that corner is taut.
12. Grasp remaining edge of unfitted bottom sheet and tuck tightly under mattress while moving from head to foot of bed.
13. Smooth folded drawsheet over bottom sheet and tuck under mattress, first at middle, then at top, and then at bottom.
14. If needed, apply single waterproof pad over bottom sheet or drawsheet.
15. Place top sheet over bed with vertical centerfold lengthwise down middle of bed. Open sheet out from head to foot, being sure that top edge of sheet is even with top edge of mattress.
16. Make horizontal toe pleat: stand at foot of bed and make fanfold in sheet 5 to 10 cm (2 to 4 inches) across bed. Pull sheet up from bottom to make fold approximately 15 cm (6 inches) from bottom edge of mattress.
17. Tuck in remaining part of sheet under foot of mattress. Place blanket over bed with top edge parallel to top edge of sheet and 15 to 20 cm (6 to 8 inches) down from edge of sheet. (*Optional:* Apply additional spread over bed.)
18. Make cuff by turning edge of top sheet down over top edge of blanket and spread.
19. Standing on one side at foot of bed, lift mattress corner slightly with one hand; with other hand tuck top sheet, blanket, and spread under

- mattress. Be sure that toe pleats are not pulled out.
20. Make modified mitered corner with top sheet, blanket, and spread. After making triangular fold, do not tuck tip of triangle (see Box 40.15, Step 37).
 21. Go to other side of bed. Spread sheet, blanket, and spread out evenly. Make cuff with top sheet and blanket. Make modified corner at foot of bed.
 22. Apply clean pillowcase.
 23. Place nurse call system within patient's reach on bedrail or pillow and return bed to low position allowing for patient transfer. Lock wheels. Help patient to bed.
 24. Arrange patient's room. Remove and discard supplies. Perform hand hygiene.

An unoccupied bed can be made as an open or closed bed. In an open bed the top covers are folded back, so it is easy for a patient to get into bed. Draw up the top sheet, blanket, and bedspread to the head of the mattress and place a pillow at the top to make a closed bed. A closed bed is prepared in a hospital room before a new patient is admitted to that room. A surgical, recovery, or postoperative bed is a modified version of the open bed. The top bed linen is arranged for easy transfer of the patient from a stretcher to the bed. The top sheets and spread are not tucked or mitered at the corners. Instead they are folded to one side or to the bottom third of the bed (Fig. 40.10). This makes patient transfer into the bed easier.

FIG. 40.10 Surgical or recovery bed.

Linens

Many agencies have “nurse servers” either within or just outside a patient’s room to store a daily supply of linen. Because of the importance of cost control in health care, avoid bringing excess linen into a patient’s room. Once you bring linen into a patient’s room, if unused, it must be laundered before being used. Excess linen lying around a patient’s room creates clutter and obstacles for patient care activities.

Before making a bed, collect necessary bed linens and the patient’s personal items. In this way all equipment is accessible to prepare the bed and room. When fitted sheets are not available, flat sheets usually are pressed with a center crease to be placed down the center of the bed. The linens unfold easily to the sides, with creases often fitting over the mattress edge. Apply clean linens whenever there is soiling.

Handle linen properly to minimize the spread of infection (see [Chapter 28](#)). Agency policies provide guidelines for the proper way to bag and dispose of soiled linen. After a patient is discharged, all bed linen goes to

the laundry, and housekeeping cleans the mattress and bed before clean linen is applied.

• Evaluation

Through the Patient's Eyes

During assessment you collected information about a patient's expectations of care. Both during and after hygiene, determine from the patient whether care is being provided in an acceptable manner (Fig. 40.11). For example, while bathing a patient, encourage him or her to verbalize any discomfort such as too-cool water or discomfort with movement. To evaluate a patient's satisfaction with your care, ask questions, such as "Do you think your bath helped you feel more comfortable?" "Tell me ways we can make you feel less tired during your bath?" "Were you pleased with how we bathed and cleaned your feet?" Being aware of and addressing a patient's expectations and any concerns foster a caring therapeutic relationship.

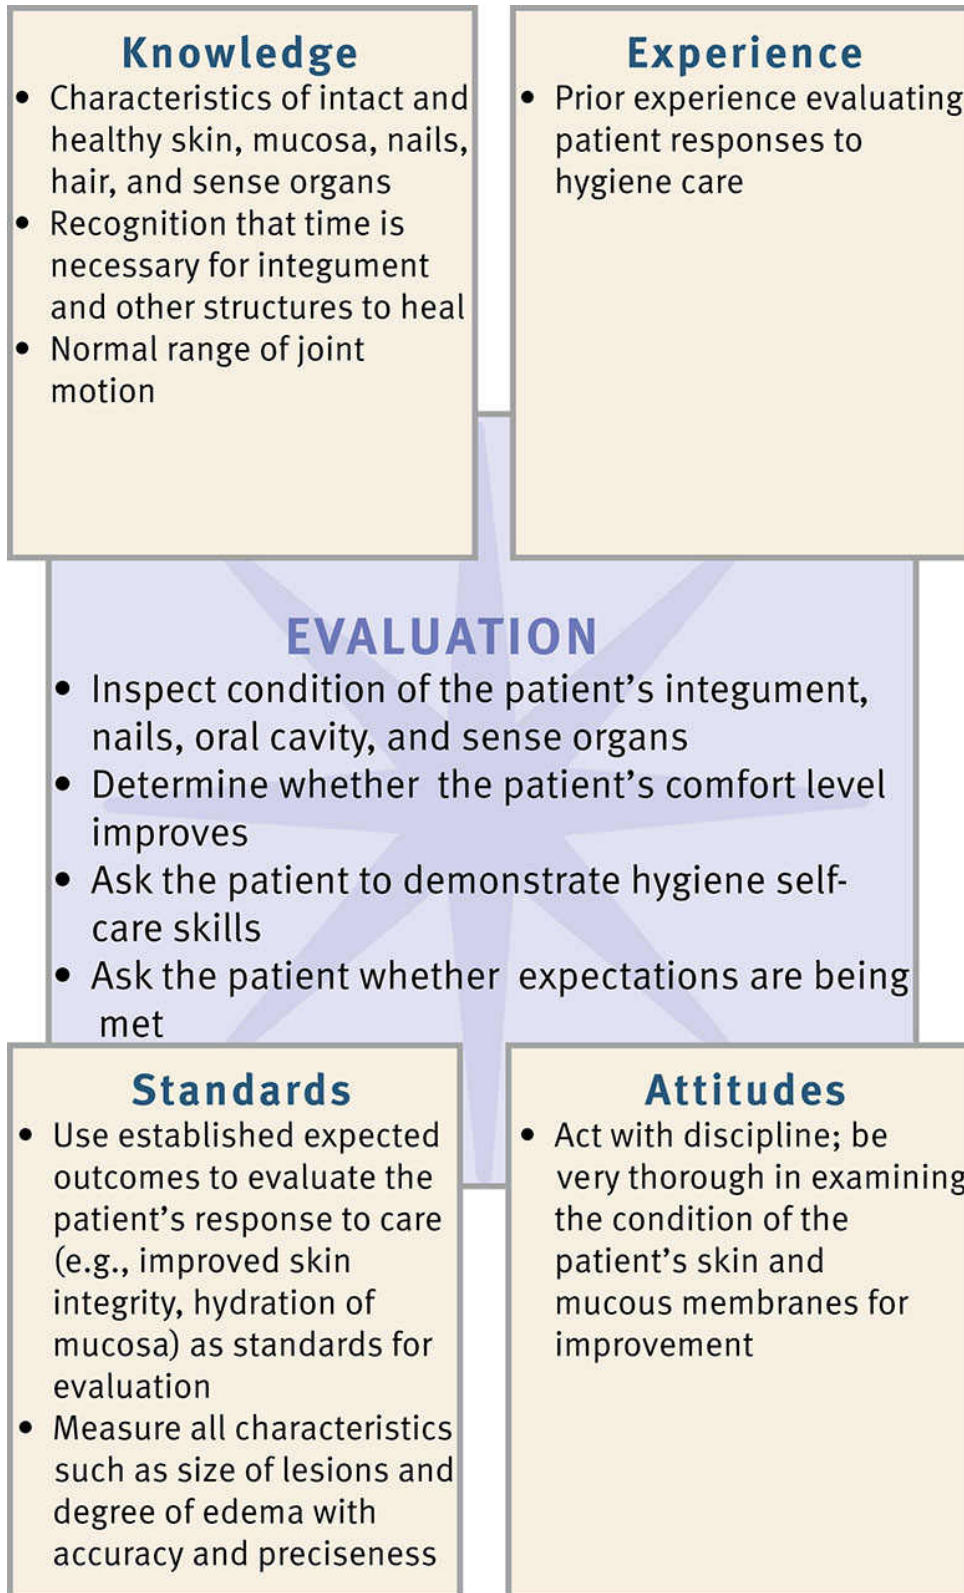

FIG. 40.11 Critical thinking model for hygiene evaluation.

Patient Outcomes

Evaluate patient responses to hygiene measures both during and after each particular hygiene intervention. For example, while bathing a patient, inspect the skin carefully to see whether soiling or drainage is effectively removed. Once a bath is completed, evaluate whether the patient feels more comfortable by asking him or her to rate the level of comfort using a pain scale (see [Chapter 44](#)). Frequently it takes time for hygiene care to result in an improvement in a patient's condition. While the presence of oral lesions, a scalp infestation, or skin excoriation often requires repeated measures and a combination of nursing interventions to fully resolve, you must evaluate these areas following hygiene measures. Your knowledge base and experience provide important perspectives when analyzing ongoing evaluation data about a patient. For example, frequent observation of the skin helps to determine the effectiveness of hygiene practices. Does a rash clear or a pressure injury show signs of healing? Is the patient able to complete hygiene care using adaptive equipment?

To evaluate a patient's or family caregiver's ability to perform self-care hygiene measures use teach-back. For example, say, "I want to be sure you are clear about why foot care is so important for you since you have diabetes. Tell me three things you can do to protect your feet from infection." As another example, say, "We talked about ways to prevent your skin from drying. Describe how you will protect your skin from dryness."

When established outcomes for the care plan are not met, revise it. Continue to apply critical thinking attitudes when considering all evaluation findings. When outcomes are not met, ask questions by involving the patient to determine appropriate changes in interventions. Examples of questions include:

- What is preventing you from being able to perform your foot care at home?
- Which further measures do you think are necessary to keep your mouth feeling clean?
- What do you think would help you be more independent with your hygiene?

Mrs. White is discharged to her home. Her granddaughter and a home care aide will provide care for her over the next few weeks. During evaluation you note that Mrs. White is making progress using the walker and bath-adaptive equipment that have been ordered for home care. Which assessments should be made for her following discharge from the hospital? What teaching needs to be provided to the family member to perform safe hygiene care for her grandmother?

Safety Guidelines for Nursing Skills

Ensuring patient safety is an essential role of the professional nurse. To ensure patient safety, communicate clearly with members of the health care team, assess and incorporate the patient's priorities of care and preferences, and use the best evidence when making decisions about your patient's care. When performing the skills in this chapter, remember the following points to ensure safe, individualized patient care.

- Patients who are totally dependent on a caregiver require help with personal hygiene measures. Always perform hygiene measures while moving from cleanest to less clean or dirty areas. This often requires you to change gloves and perform hand hygiene during care activities.
- Use clean gloves when you anticipate contact with nonintact skin or mucous membranes or when there is or may likely be contact with drainage, secretions, excretions, or blood during hygiene care.
- When using water or solutions for hygiene care, be sure to test the temperature to prevent burn injury.
- Use principles of body mechanics and safe patient handling to avoid injury to patient or self when performing hygiene care (QSEN, 2018).
- You are responsible and accountable for the care provided. Give proper direction to AP when delegating hygiene measures.
- Monitor laboratory findings, such as coagulation studies, before administering oral hygiene.
- Determine patient's or family caregiver's knowledge, experience, and health literacy. Ensures patient or family caregiver has the capacity to obtain, communicate, process, and understand basic health information (CDC, 2019).

Skill 40.1. • Bathing and Perineal Care

Delegation and Collaboration

Assessment of the patient's skin, pain level, and ROM cannot be delegated to assistive personnel (AP). The skill of bathing and perineal care can be delegated to AP. Direct the AP about:

- Avoiding the massage of reddened skin areas during bathing.
- Contraindications to soaking a patient's feet.
- Reporting any signs of impaired skin integrity to the nurse.
- Properly positioning patients with musculoskeletal limitations and indwelling catheters or intravenous (IV) lines.
- Reporting patient fatigue, shortness of breath, or pain during hygiene care.

Equipment

- Washcloths and bath towels
- Bath blanket
- Bar or liquid soap, or 4-oz bottle of 2% to 4% chlorhexidine gluconate (CHG) (dispensed in a single bath-size bottle) (*option: 2% CHG bathing cloths*)
- Toiletry items (deodorant, lotion). **Note:** If using CHG, use a hospital-approved lotion.
- Disposable wipes
- Warm water
- Clean hospital gown or patient's own pajamas or gown
- Laundry bag
- Clean gloves
- Washbasin dedicated for bathing only
- Eye patch/shield and nonallergenic tape (for unconscious patient)

Step	Rationale
Assessment	
1. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2020).
2. Review medical record for orders for specific precautions concerning patient's movement or positioning and whether there is an order for a therapeutic bath.	Prevents accidental injury to patient during bathing activities. Determines level of help that patient needs.
3. Assess patient's or family caregiver's knowledge, experience, and health literacy.	Ensures patient or family caregiver has the capacity to obtain, communicate, process, and understand basic health information (CDC, 2019).
4. Perform hand hygiene. Assess patient's fall risk status (if partial bathing out of bed or self-bath is to be performed).	Reduces transmission of microorganisms. Allows you to anticipate needed precautions such as having patient sit on chair in front of basin.
5. Assess patient's tolerance for bathing: activity tolerance, comfort level during movement, cognitive function, musculoskeletal function, and presence of shortness of breath (see Chapter 30).	Determines patient's comfort level and ability to perform or tolerate bathing and level of assistance required (e.g., tub bath, partial bed bath).
6. If cognitive level is reduced, assess patient's cognitive (Mini-Mental State Examination) and functional status (e.g., Barthel's index or the index of activities of daily living [ADLs] to measure self-care ability). For patients with suspected dementia, observe behavior, especially after telling patient it is bath time; does he or she become agitated?	Every person entering a long-term care setting should be formally assessed for cognitive and functional status (Hirschman et al., 2018; Shelton et al., 2018). Functional status assesses a patient's capacity for self-bathing and how much supervision/help is needed to accomplish daily ADL tasks. Every attempt should be made to avoid bathing people against their will.
CLINICAL DECISION: Patients with dementia may become agitated and aggressive during bathing activities. Consider using alternative bathing procedures such as bag wipes with these patients (Villar et al., 2018). Maintain a calm, nonthreatening, quiet environment using therapeutic communication (see Box 40.6).	
Table Continued	

Step	Rationale
7. Assess patient's visual status, ability to sit without support, hand grasp, ROM of extremities.	Determines degree of assistance patient needs for bathing. ROM may be delegated to assistive personnel.
8. Assess for presence and position of external medical device/equipment (e.g., intravenous [IV] line, oxygen tubing, Foley catheter).	Affects how you plan bathing activities and positioning. Helps determine how to set up supplies.
9. Assess for allergy or sensitivity to bathing products and CHG.	When allergy or sensitivity is present, select another cleansing solution.
10. Assess patient's bathing preferences: frequency and time of day preferred, type of hygiene products used, and other factors related to patient preferences.	Patient participates in plan of care. Promotes patient's comfort and willingness to cooperate. Incorporates cultural or personal hygiene preferences into care.
11. Ask whether patient has noticed any problems related to condition of skin and genitalia: excess moisture, inflammation, drainage or excretions from lesions or body cavities, rashes or other skin lesions.	Provides you with information to direct physical assessment of skin and genitalia during bathing. Also influences selection of skin care products.
12. Before or during bath assess condition of patient's skin. Note presence of dryness, indicated by flaking, redness, scaling, and cracking.	Provides a baseline for comparison over time in determining whether bathing improves condition of skin.
13. Assess patient's knowledge of skin hygiene in terms of its importance, preventive measures to take, and common problems.	Determines patient's learning needs.
Planning	
1. Assess room environment for safety (e.g., check room for spills; make sure that equipment is working properly and that bed brakes are locked and bed is in low position).	Identifies safety hazards in patient environment that could cause or potentially lead to harm (QSEN, 2018).
2. Adjust room temperature and ventilation, close room doors and windows, and draw room divider curtain.	Warm room that is free of drafts prevents rapid loss of body heat during bathing. Privacy provides for patient's mental and physical comfort.
3. Prepare equipment and place supplies on bedside table. If it is necessary to leave room, be sure that nurse call system is within patient's reach, bed is in low position, side rails up (as appropriate) and brakes are locked.	Avoids interrupting procedure or leaving patient unattended to retrieve missing equipment. Provides for patient safety.
4. Explain procedure and ask patient for suggestions on how to prepare supplies. If partial bath, ask how much of bath patient wishes to complete. If using CHG, explain benefit of reducing infection and that solution leaves a sticky feeling on the skin.	Promotes patient's cooperation and participation. Patients who prefer using their own bathing supplies may need to discuss benefits of CHG.
Implementation	
1. Offer patient bedpan or urinal. Apply clean gloves to help patient as needed. Provide toilet tissue and dispose of any excrement properly. Provide patient towel and moist washcloth. Dispose of gloves if applied and perform hand hygiene.	Patient feels more comfortable after voiding. Prevents interruption of bath. Reduces transmission of microorganisms.
2. Complete or partial bed bath	
a. If patient has nonintact skin or skin is soiled with drainage, excretions, or body secretions, apply clean gloves. Ensure that patient is not allergic to latex.	Prevents allergic reaction if latex gloves are used.
b. Verify that bed is in locked position and raise bed to comfortable working height. Lower side rail closest to you and help patient into comfortable supine position, maintaining body alignment. Bring patient toward side closest to you.	Prevents bed from moving. Helps you reach patient without stretching and reaching across bed, thus minimizing strain on back muscles.
c. Place bath blanket over patient and loosen and remove top covers without exposing him or her. If possible, have patient hold top of bath blanket while you remove linen. Place soiled linen in laundry bag. Take care to not allow linen to touch your uniform. <i>Optional:</i> Use top sheet when bath blanket is not available or if patient prefers.	Bath blanket provides warmth and privacy during bath.
d. Remove patient's gown or pajamas. (1). If gown with ties or snaps on sleeves, simply untie or unsnap and remove gown without pulling IV line (if present).	Provides full exposure of body parts during bathing.

Table Continued

Step	Rationale
(2) If regular gown is used and patient has reduced mobility and IV access, remove gown from <i>unaffected side first</i> .	Undressing unaffected side first allows easier manipulation of gown over body part with reduced ROM.
(3) If patient has an IV line and gown with no snaps, remove gown from arm <i>without IV line first</i> . Then remove gown from arm with IV line (see illustration A). Pause IV fluid infusion by pressing appropriate sensor on IV pump. Remove IV tubing from pump; use regulator to slow IV infusion. Remove IV bag from pole (see illustration B) and slide IV bag and tubing through arm of patient's gown (see illustration C). Rehang IV bag (see illustration D), reconnect tubing to pump, open regulator clamp, and restart IV fluid infusion by pressing appropriate sensor on IV pump. If IV fluids are infusing by gravity, check IV flow rate and regulate if necessary. Do not disconnect IV tubing to remove gown.	Manipulation of IV tubing and container may disrupt flow rate. Do not delegate regulation of IV flow rate to AP.
e. Raise side rail. Lower bed temporarily to lowest position. Go and fill washbasin two-thirds full with warm water. Place basin and supplies on over-bed table. Raise bed to comfortable working height. Check water temperature and also have patient place fingers in water to test temperature tolerance. Place plastic container of bath lotion in bath water to warm if desired.	Raising side rail and lowering bed position maintain patient's safety while you leave bedside. Keeping bed at working height during bath prevents back strain. Warm water promotes comfort, relaxes muscles, and prevents unnecessary chilling. CHG is most effective at full strength. Testing temperature prevents accidental burns. Bath water warms lotion for application to patient's skin.
f. Lower side rail, remove pillow if tolerated, and raise head of bed 30 to 45 degrees if allowed. Place bath towel under patient's head. Place second bath towel over patient's chest.	Removal of pillow makes it easier to wash patient's ears and neck. Placing towels prevents bed linen and bath blanket from getting soiled or wet.

g. Wash face.

STEP 26(3) A, Remove patient's gown. B, Remove IV tubing from pole. C, Slide IV tubing through arm of patient's gown. D, Rehang IV bag.

Table Continued

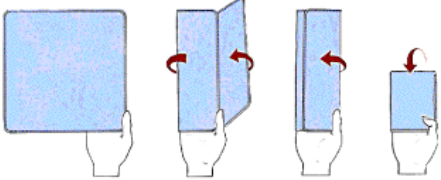

Step	Rationale
CLINICAL DECISION: Do not use bath water with 4% CHG solution or 2% CHG bathing cloths on the eyes or face. Only use clear water or mild soap and water on the face.	
(1) Ask whether patient is wearing contact lenses. You may choose to remove them at this time.	Prevents accidental injury to eyes.
(2) Fold washcloth around fingers of your hand to form a mitt (see illustration). Immerse mitt in water and wring thoroughly.	Mitt retains water and heat better than loosely held washcloth; keeps cold edges from brushing against patient and prevents splashing.
(3) Wash patient's eyes with plain warm water. Use different section of mitt for each eye. Move mitt from inner to outer canthus (see illustration). Soak any crusts on eyelid for 2 to 3 minutes with damp cloth before attempting removal. Dry eyes thoroughly but gently.	Soap irritates eyes. Use of separate sections of mitt reduces infection transmission. Bathing eye from inner to outer canthus prevents secretions from entering nasolacrimal duct. Pressure can cause internal injury.
(4) Ask whether patient prefers to use soap on face. Otherwise wash, rinse, and dry forehead, cheeks, nose, neck, and ears without using soap. (Men may wish to shave at this point or wait until after bath.)	Soap tends to dry face, which is exposed to air more than other body parts.
(5) Provide eye care for unconscious patient.	Patients who are unconscious have lost the normal protective corneal reflex of blinking, increasing the risk for corneal drying, abrasions, and eye infection (Demirel et al., 2014).
(a) Instill eyedrops or ointment per health care provider's order (see Chapter 31).	Keeps cornea lubricated.
(b) In the absence of blink reflex, keep eyelids closed. Close eye gently, using back of your fingertip, before placing eye patch or shield. Place tape over patch or shield. Do not tape eyelid.	When blink reflex is absent, patient loses a protective mechanism. Keeping eyelids closed maintains eye moisture and prevents injury (Kocacal et al., 2018).
h. Wash trunk and upper extremities. <i>Option:</i> Change bath water at this time or, if using 4% CHG solution, pour entire 4 ounce single-use container into basin.	Evidence shows that CHG use in daily bathing can reduce incidence of hospital-acquired infections (Martin et al., 2017; Shah et al., 2016). CHG reduces bacteria for up to 24 hours and prevents infection (AHRQ, 2013).
CLINICAL DECISION: When using CHG in a bath basin of water, use one washcloth for washing each major body part. Then dispose of cloth and use a new cloth for the next body part (Martin et al., 2017). Dipping cloth back into basin contaminates solution and makes CHG less effective. Do not rinse after bathing with CHG solution. Allow CHG to dry on the skin to achieve antimicrobial effects.	
<p>(1) Remove bath blanket from patient's arm that is closest to you. Place bath towel lengthwise under arm. Bathe arm with soap and water using long, firm strokes from distal to proximal areas (fingers to axilla).</p>  <p><small>Step 2g(2) Steps for folding washcloth to form a mitt. From Universal ICU decolonization: An enhanced protocol. Appendix E: Training and educational materials, Pockville, MD, September 2013, Agency for Healthcare Research and Quality.</small></p>	<p>Towel prevents soiling of bed. Soap lowers surface tension and facilitates removal of debris and bacteria when friction is applied during washing. Long, firm strokes stimulate circulation; moving distal to proximal promotes venous return.</p>  <p><small>Step 2g(3) Wash eye from inner to outer canthus. (Copyright © Mosby's Clinical Skills: Essentials Collection.)</small></p>

Table Continued

Step	Rationale
(2) Raise and support arm above head (if possible) to wash, rinse, and dry axilla thoroughly (see illustration). Apply deodorant or powder to underarms if desired or needed.	Movement of arm exposes axilla and exercises normal ROM of joint. Alkaline residue from soap discourages growth of normal skin bacteria. Drying prevents excess moisture, which can cause skin maceration or softening. Respect patient's preference for use of hygiene products.
(3) Move to other side of bed and repeat Steps (1) and (2) with other arm.	Provides for better access to patient and helps prevent back strain.
(4) Cover patient's chest with bath towel and fold bath blanket down to umbilicus. Bathe chest with long, firm strokes. Take special care with skin under female patient's breasts, lifting breast upward if necessary while bathing underneath breast. Rinse if using soap and water and dry well.	Draping prevents unnecessary exposure of body parts. Towel maintains warmth and privacy. Secretions and dirt collect easily in areas of tight skinfolds. Skin under breasts is vulnerable to excoriation if not kept clean and dry.
i. Wash hands and nails.	
(1) Fold bath towel in half and lay it on bed beside patient. Place basin on towel. Immerse patient's hand in water. Allow hand to soak for 2 to 3 minutes before washing hand and fingernails. Remove basin and dry hand well. Repeat for other hand.	Soaking softens cuticles and calluses of hand, loosens debris beneath nails, and enhances feeling of cleanliness. Thorough drying removes moisture between fingers.
CLINICAL DECISION: Do not routinely soak fingers of patient with diabetes mellitus.	
j. Check temperature of bath water and change water when cool or soapy. (See agency policy regarding changing water when using CHG solution.)	Warm water maintains patient's comfort. Alkaline soap residue is irritating to skin and can decrease the normal protectiveness of acid pH.
CLINICAL DECISION: If patient is at risk for falling, be sure that two side rails are up before obtaining fresh water. In addition, lower bed when it is necessary to leave bedside. Note: Having all side rails raised is considered a restraint. Check agency policy.	
k. Wash abdomen.	
(1) Place bath towel lengthwise over chest and abdomen. (Two towels may be needed.) Fold bath blanket down to just above pubic region. With one hand lift bath towel. With mittened hand bathe and rinse abdomen, giving special attention to umbilicus and skinfolds of abdomen and groin. Stroke from side to side. Keep abdomen covered between washing and rinsing. Rinse and dry well.	Draping prevents unnecessary exposure of body parts. Towel maintains warmth and privacy. Keeping skinfolds clean and dry helps prevent odor and skin irritation. Moisture and sediment that collect in skinfolds predispose skin to maceration.
(2) Apply clean gown or pajama top. If an extremity is injured or immobilized, dress affected side first. (This step may be omitted until completion of bath; gown should not become soiled during remainder of bath.)	Maintains patient's warmth and comfort. Dressing affected side first allows easier manipulation of gown over body part with reduced ROM.
CLINICAL DECISION: If one extremity is injured or immobilized, always dress affected side first.	
l. Wash lower extremities.	
(1) Cover chest and abdomen with top of bath blanket. Expose near leg by folding blanket toward midline. Be sure to keep other leg and perineum draped. Place bath towel under leg as you support patient's knee and ankle.	Prevents unnecessary exposure.  <small>step 2H(2) Positioning arm to wash axilla. (Copyright © Mosby's Clinical Skills: Essentials Collection.)</small>

Table Continued

Step	Rationale
<p>(2) Wash leg using long, firm strokes from ankle to knee and from knee to thigh (see illustration). Rinse and dry well. Remove and discard towel.</p>	<p>Promotes circulation and venous return. Excess massage of calf could loosen deep vein thrombus. Secretions and moisture may be present between toes, predisposing patient to maceration and breakdown.</p> <p>Do Not cut nails of a patient with diabetes. See agency policy for podiatrist care.</p>
<p>CLINICAL DECISION: When bathing lower extremities, assess for signs of warmth, redness, swelling, tenderness, and pain in the lower extremities because these might be early signs of deep vein thrombosis (DVT).</p>	
<p>(3) Clean foot, making sure to bathe between toes. Rinse and dry toes and feet completely. Clean and file nails as needed (see Skill 40.2).</p>	
<p>(4) Raise side rail, move to opposite side of bed, lower side rail, and repeat Steps (2) and (3) for other leg and foot. If skin is dry, apply moisturizer. When finished, cover patient with bath blanket.</p>	<p>Well-lubricated skin is less at risk for breakdown.</p>
<p>(5) Cover patient with bath blanket, raise side rail for patient's safety, remove and dispose of soiled gloves, and perform hand hygiene. Change bath water and/or CHG solution and water.</p>	<p>Decreased bath water temperature causes chilling. Clean water reduces microorganism transmission to perineal structures.</p>
<p>m. Provide perineal hygiene.</p>	
<p>(1) If patient can maneuver and handle washcloth, allow him or her to clean perineum on own.</p>	<p>Maintains patient's dignity and self-care ability.</p>
<p>CLINICAL DECISION: CHG is safe to use on the perineum and external mucosa (AHRQ, 2013).</p>	
<p>(2) Female patient</p>	
<p>(a) Apply pair of clean gloves. Lower side rail. Help patient into dorsal recumbent position. Note restrictions or limitations in patient's positioning. Place waterproof pad under patient's buttocks. Drape patient with bath blanket placed in shape of a diamond. Lift lower edge of bath blanket to expose perineum (see illustration).</p>	<p>Provides full exposure of female genitalia. If patient is totally dependent, provide assistance to support her in side-lying position and raise leg as perineum is bathed. If position causes patient discomfort, reduce degree of abduction in her hips.</p>
<p>(b) Fold lower corner of bath blanket up between patient's legs onto abdomen. Wash and dry patient's upper thighs.</p>	<p>Keeping patient draped until procedure begins minimizes anxiety. Buildup of perineal secretions soils surrounding skin surfaces.</p>
<div style="text-align: right;">  <p>Step 2(2) Washing leg. (Copyright © Mosby's Clinical Skills: Essentials Collection.)</p> </div> <div style="text-align: right;">  <p>Step 2m(2)(a) Drape patient for perineal care.</p> </div> <div style="text-align: right;">  <p>Step 2m(2)(d) Cleanse from perineum to rectum (front to back).</p> </div>	

Step	Rationale
Table Continued	

Step	Rationale
(c) Wash labia majora. Use nondominant hand to gently retract labia from thigh; with dominant hand wash carefully in skinfolds. Wipe in direction from perineum to rectum. Repeat on opposite side with separate section of washcloth. Rinse and dry area thoroughly.	Perineal care involves thorough cleaning of patient's external genitalia and surrounding skin. Skinfolds may contain body secretions that harbor microorganisms. Wiping front to back reduces chance of transmitting fecal organisms to urinary meatus.
(d) Gently separate labia with nondominant hand to expose urethral meatus and vaginal orifice. With dominant hand, wash downward from pubic area toward rectum in one smooth stroke (see illustration). Wash middle and both sides of perineum. Use separate section of cloth for each stroke. Clean thoroughly around labia minora, clitoris, and vaginal orifice. Avoid placing tension on indwelling catheter if present and clean area around it thoroughly.	Cleansing method reduces transfer of microorganisms to urinary meatus. (For menstruating women or patients with indwelling catheters, clean with cotton balls.)
(e) Provide catheter care as needed per agency requirements (see Chapter 46).	Proper cleansing around periurethral area and catheter reduces the risk for catheter-associated urinary tract infections (CAUTI) (CDC, 2015).
(f) Rinse area thoroughly. May use bedpan and pour warm water over perineal area. Dry thoroughly from front to back.	Rinsing removes soap and microorganisms more effectively than wiping. Retained moisture harbors microorganisms.
(g) Fold lower corner of bath blanket back between patient's legs and over perineum. Ask patient to lower legs and assume comfortable position.	
(3) Male patient	
(a) Apply pair of clean gloves. Lower side rail. Help patient to supine position. Note any restriction in mobility.	Provides full exposure of male genitalia. Position patients who are unable to lie supine on their side.
(b) Fold lower half of bath blanket up to expose upper thighs. Wash and dry thighs.	Buildup of perineal secretions soils surrounding skin surfaces.
(c) Cover thighs with bath towels. Raise bath blanket up to expose genitalia. Gently raise penis and place bath towel underneath. Gently grasp shaft of penis. If patient is uncircumcised, retract foreskin (see illustration). If patient has an erection, defer procedure until later.	Draping minimizes patient anxiety. Towel prevents moisture from collecting in inguinal area. Gentle but firm handling of penis reduces chance of an erection. Secretions capable of harboring microorganisms collect underneath foreskin.
(d) Wash tip of penis at urethral meatus first. Using circular motion, clean from meatus outward (see illustration). Discard washcloth and repeat with clean cloth until penis is clean. Rinse and dry gently.	Direction of cleaning moves from area of least contamination to area of most contamination, preventing microorganisms from entering urethra.
(e) Return foreskin to its natural position. This is extremely important in patients with decreased sensation in their lower extremities.	Tightening of foreskin around shaft of penis causes local edema and discomfort. Patients with reduced sensation do not feel tightening of foreskin.
(f) Gently clean shaft of penis and scrotum by having patient abduct legs. Pay special attention to underlying surface of penis. Lift scrotum carefully and wash underlying skinfolds. Rinse and dry thoroughly.	Vigorous massage of penis may cause an erection. Underlying surface of penis is an area where secretions accumulate. Abduction of legs provides easier access to scrotal tissues. Secretions collect easily between skinfolds.
(g) Avoid placing tension on indwelling catheter if present and clean area around it thoroughly. Provide catheter care (see Chapter 46).	Cleaning along catheter from exit site reduces incidence of nosocomial urinary infection.
(4) Remove soiled gloves and discard in trash; raise side rail before leaving bedside to dispose of water and obtain fresh water.	Prevents transmission of infection. Protects patient from injury.
n. Wash back. (This follows both female and male perineal care.)	

Step	Rationale
(1) Perform hand hygiene and apply clean pair of gloves. Lower side rail. Help patient into prone or side-lying position (as applicable). Place towel lengthwise along patient's side and keep him or her covered with bath blanket.	Exposes back and buttocks for bathing while limiting exposure.

Step 2n(3)(c) Retract foreskin.

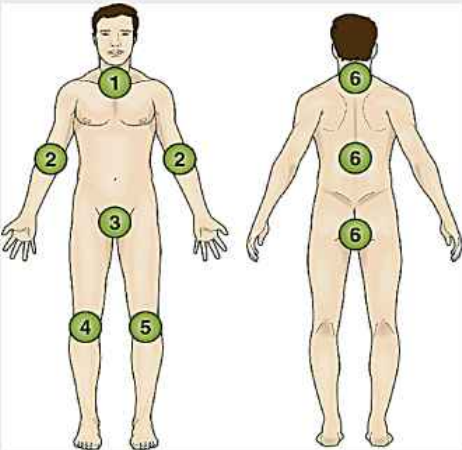

Step 2n(3)(d) Use circular motion to clean tip of penis.

STEP 2n(5) Cleanse buttocks from front to back.

Table Continued

Step	Rationale
(2) Keep patient draped by sliding bath blanket over shoulders and thighs during bathing. Wash, rinse, and dry back from neck to buttocks using long, firm strokes.	Cleaning back before buttocks and anus prevents contamination of water.
(3) Next move from back to buttocks and anus. Have patient remain in prone or side-lying position and keep covered to avoid chilling. Clean anus and buttocks area.	Exposes back and buttocks for bathing while limiting exposure.
(4) If fecal material is present, enclose in fold of underpad or toilet tissue and remove with disposable wipes.	Skinfolds near buttocks and anus may contain fecal secretions that harbor microorganisms.
(5) Clean buttocks and anus, washing front to back (see illustration). Clean, rinse, and dry area thoroughly. If needed, place a clean absorbent pad under patient's buttocks. Remove contaminated gloves. Raise side rail and perform hand hygiene.	Cleaning motion prevents contaminating perineal area with fecal material or microorganisms.
3. Return to bed and lower side rail; give a back rub (see Chapter 44).	Promotes patient relaxation. Make sure that back rub is appropriate for your patient. Back rubs are contraindicated in some cardiac patients.
a. Apply additional body lotion or oil to patient's skin as needed. When finished, raise side rail.	Moisturizing lotion prevents dry, chapped skin.
4. Remove soiled linen and place in dirty-linen bag. Clean and replace bathing equipment. Perform hand hygiene.	Reduces transmission of microorganisms.
5. Help patient dress. Comb patient's hair. If a woman wants to apply makeup, help as needed.	Promotes patient's body image.
6. Make patient's bed (see Boxes 40.15 and 40.16).	Provides clean, comfortable environment.
7. Check function and position of external devices (e.g., indwelling urethral catheters, nasogastric tubes, IV lines).	Ensures that systems remain functional after bathing activities.
8. Place bed in lowest position. Wheels locked. Side rails up as appropriate.	Maintains patient's safety by decreasing height of bedframe from floor.
9. Replace nurse call system and personal possessions. Leave room as clean and comfortable as possible. Perform hand hygiene.	Prevents transmission of infection. Clean environment promotes patient's comfort. Keeping nurse call system and articles of care within reach promotes patient's safety.
10. Optional Bathing Methods	
a. Commercial bag bath or CHG cleansing pack:	
(1) A cleansing pack contains six to eight premoistened towels for cleaning. Warm package contents in microwave following package directions. If you are bathing patient using warm commercial or CHG cloth, check temperature of cloth before use. Gloves diminish sense of heat.	Provides warm, soothing heat. CHG reduces bacteria for up to 24 hours and prevents infection (AHRQ, 2013). Prevents burn to skin.
(2) Use all six CHG cloths in the following order (see illustration): <ul style="list-style-type: none"> • Cloth 1: Neck, shoulders, and chest • Cloth 2: Both arms, both hands, web spaces, and axilla • Cloth 3: Abdomen and then groin/perineum • Cloth 4: Right leg, right foot, and web spaces • Cloth 5: Left leg, left foot, and web spaces • Cloth 6: Back of neck, back, and buttocks 	Reduces transmission of microorganisms.
 <p>Step 10a(2) Using CHG bathing cloths.</p>	
(3) Firmly massage skin when using cloth. Allow skin to air-dry for 30 seconds. Do not rinse. It is permissible to lightly cover patient with bath towel to prevent chilling.	Drying skin with towel removes emollient that is left behind after water/cleaner solution evaporates.
(4) Note: If there is excessive soiling (e.g., in perineal region), use an extra cloth or conventional washcloths, soap, water, and towels.	
Step	
Rationale	
b. Tub bath or shower:	
(1) Consider patient's condition and review orders for precautions concerning his or her movement or positioning.	Prevents accidental injury to patient during bathing.
(2) Schedule use of shower or tub.	Prevents unnecessary waiting, which causes fatigue.

(3) Check tub or shower for cleanliness. Use cleaning techniques outlined in an agency policy. Place rubber mat on tub or shower bottom. Place disposable bath mat or towel on floor in front of tub or shower.	Cleaning prevents transmission of microorganisms. Mats prevent slipping and falling.
(4) Collect all hygienic aids, toiletry items, and linens requested by patient. Place within easy reach of tub or shower.	Placing items close at hand prevents possible falls when patient reaches for equipment.
(5) Help patient to bathroom if necessary. Have him or her wear robe and slippers.	Assistance prevents accidental falls. Wearing robe and slippers prevents chilling.
(6) Demonstrate how to use call signal in bathroom for assistance.	Bathrooms are equipped with signaling devices in case patient feels faint or weak or needs immediate assistance. Patients prefer privacy during bath if safety is not jeopardized.
(7) Place "occupied" sign on bathroom door.	Maintains patient's privacy.
(8) Fill bathtub halfway with warm water. Check temperature of bath water, have patient test water, and adjust temperature if water is too warm. Explain which faucet controls hot water. If patient is taking shower, turn shower on and adjust water temperature before he or she enters shower stall. Use shower seat or tub chair if needed (see illustration).	Adjusting water temperature prevents accidental burns. Older adults and patients with neurological alterations (e.g., diabetes, spinal cord injury) are at high risk for burn as a result of reduced sensation. Use of assistive devices facilitates bathing and minimizes physical exertion.
(9) Instruct patient to use safety bars when getting in and out of tub or shower to pull cord to summon assistance (if available). Caution patient against use of bath oil in tub water.	Prevents slipping and falling. Oil causes tub surfaces to become slippery.
(10) Instruct patient not to remain in tub longer than 10 or 15 minutes. Check on him or her every 5 minutes.	Prolonged exposure to warm water causes vasodilation and pooling of blood in some patients, leading to light-headedness or dizziness.
(11) Return to bathroom when patient signals and knock before entering.	Provides privacy.
(12) For patient who is unsteady, drain tub of water before he or she tries to get out. Place bath towel over patient's shoulders. Help patient out of tub as needed and help with drying.	Prevents accidental falls. Patient may become chilled as water drains.

CLINICAL DECISION: Weak or unstable patients need extra assistance in getting out of a tub. Planning for additional personnel is essential before attempting to help the patient. Lift equipment may be used for transfer. See agency policy.

Step 10b(8) Shower seat for patient safety.

Table Continued

Step	Rationale
c. Help patient as needed with getting dressed in clean gown or pajamas, slippers, and robe. (In home setting patient may put on regular clothing.)	Maintains warmth to prevent chilling.
d. Help patient to room and comfortable position in bed or chair.	Maintains relaxation gained from bathing.
e. Clean tub or shower according to agency policy.	Prevents transmission of infection through soiled linen and moisture.
f. Remove soiled linen and place in dirty-linen bag. Discard disposable equipment in proper receptacle. Place "unoccupied" sign on bathroom door. Return supplies to storage area.	Reduces transmission of infection.
g. Perform hand hygiene.	Reduces transfer of microorganisms.
Evaluation	
1. Observe skin, paying particular attention to areas previously soiled, reddened, dry, or showing early signs of pressure or pressure injuries.	Techniques used during bathing leave skin clean and clear. Over time dry skin diminishes. If patient shows areas of redness, use Braden scale to measure risk for pressure injury (see Chapter 48).
2. Observe ROM during bath.	Measures joint mobility.
3. Ask patient to rate level of comfort (on a scale of 0-10).	Determines patient's tolerance of bathing activities.
4. Ask patient to rate level of fatigue (on a scale of 0-10).	Determines patient's tolerance of bathing activities.
5. Use Teach-Back: "We talked about the importance of keeping your skin clean with these special bathing cloths. Explain to me why we are using bathing cloths for your bath." Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly.	Determines patient's/family caregiver's level of understanding of instructional topic.
Unexpected Outcomes and Related Interventions	
<p>1. Areas of excessive dryness, rashes, or pressure injuries appear on skin.</p> <ul style="list-style-type: none"> • Complete pressure injury assessment (see Chapter 48). • Apply moisturizing lotions or topical skin applications per agency policy. • Limit frequency of complete baths. It may become necessary (if patient has a sensitivity to CHG) to switch to plain soap and water. • Obtain special bed surface if patient is at risk for skin breakdown. <p>2. Patient becomes excessively tired or unable to cooperate or participate in bathing.</p> <ul style="list-style-type: none"> • Reschedule bathing to a time when patient is more rested. • Provide pillow or elevate head of bed during bath for patient with breathing difficulties. • Notify health care provider if this is a change in patient's fatigue level. • Perform hygiene measures in stages between scheduled rest periods. <p>3. The rectum, perineum, or genital area is inflamed or swollen or has foul-smelling odor.</p> <ul style="list-style-type: none"> • Bathe perineal area frequently enough to keep clean and dry. • Obtain an order for a sitz bath. • Apply protective barrier ointment or anti-inflammatory cream. • Report findings to health care provider. 	
Recording and Reporting	
<ul style="list-style-type: none"> • Record procedure, amount of assistance provided, patient's participation in care, condition of skin, and any significant findings (e.g., reddened areas, breaks in skin, inflammation, ulcerations). • Document your evaluation of patient learning. • Report any skin irritations, breaks in skin, or ulcerations to nurse in charge or health care provider. These are serious in patients with altered circulation to the lower extremities. • Report intolerance of activity to patient's oncoming nurse. 	
Home Care Considerations	
<ul style="list-style-type: none"> • Assess patient's tub and shower area for need for safety devices (e.g., grab bars, shower chair, handheld shower). • Assess patient for the need for assistive bathing devices (e.g., long-handle sponge, mirrors, or lift equipment). 	

Skill 40.2. Performing Nail and Foot Care Delegation and Collaboration

The skill of nail and foot care of patients *without diabetes mellitus* or *peripheral vascular disease* can be delegated to assistive personnel (AP). The nurse instructs the AP about:

- Not trimming patient's nails (unless permitted by agency or health care provider).
- Special considerations for patient positioning.

- Reporting any breaks in skin, redness, numbness, swelling, or pain to the nurse.

Equipment

- Washbasin
- Emesis basin
- Washcloth and towel
- Nail clippers (check agency policy)
- Soft nail or cuticle brush
- Plastic applicator stick
- Emery board or nail file
- Body lotion
- Disposable bath mat
- Clean gloves

Step	Rationale
Assessment	
1. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2020).
2. Verify health care provider's order for cutting nails (check agency policy).	Patients with diabetes or reduced peripheral circulation are more at risk for infection. Accidental cutting of skin increases risk for infection.
3. Perform hand hygiene. Apply clean gloves if drainage is present. Inspect all surfaces of fingers, toes, feet, and nails. Pay particular attention to areas of dryness, inflammation, or cracking. Also inspect areas between toes, heels, and soles of feet.	Integrity of feet and nails determines frequency and level of hygiene required. Heels, soles, and sides of feet are prone to irritation from ill-fitting shoes.
CLINICAL DECISION: <i>Patients with peripheral vascular diseases or diabetes mellitus, older adults, and patients whose immune system is suppressed often require nail care from a specialist to reduce the risk of tissue injury and infection. Defer care other than washing the feet in these cases until patient has been evaluated.</i>	
4. Assess color and temperature of toes, feet, and fingers. Assess capillary refill of nails. Palpate radial and ulnar pulse of each hand and dorsalis pedis pulse of each foot; note character of pulses (see Chapter 30). Remove and dispose of gloves. Perform hand hygiene.	Assesses adequacy of blood flow to extremities. Circulatory alterations often change integrity of nails and increase patient's chance of localized infection when break in skin integrity occurs.
5. Assess patient's or family caregiver's knowledge, experience, and health literacy.	Ensures patient or family caregiver has the capacity to obtain, communicate, process, and understand basic health information (CDC, 2019).
6. Assess type of footwear worn by patients, including type and cleanliness of socks worn, type and fit of shoes, and whether restrictive garters or knee-high hose are worn.	Types of shoes and footwear predispose patient to foot and nail problems (e.g., infection, areas of friction, ulcerations). These conditions decrease mobility and increase risk for amputation in patient with diabetes (Chapman, 2017).
7. If possible, observe patients walking to assess their gait.	Alterations in bony structures of the foot or sores cause pain, imbalance, and unsteady gait.
8. Ask female patients whether they use nail polish and polish remover frequently.	Chemicals in these products cause excessive dryness.
9. Identify patients at risk for foot or nail problems.	Certain conditions increase risk for foot or nail problems.
a. Older adult	Normal physiological changes such as poor vision, lack of coordination, or inability to bend over contribute to difficulty in performing foot and nail care (Touhy and Jett, 2018).
b. Diabetes mellitus, peripheral vascular disease	Vascular changes associated with diabetes mellitus reduce blood flow to peripheral tissues. Break in skin integrity places patient with diabetes at high risk for skin infection.
c. Heart failure, renal disease	Both conditions increase tissue edema, particularly in dependent areas (e.g., feet). Edema reduces blood flow to neighboring tissues.
d. Cerebrovascular accident (stroke)	Presence of residual foot or leg weakness or paralysis results in altered walking patterns. Altered gait pattern causes increased friction and pressure on feet.
10. Assess type of home remedies that patient or family caregiver uses for existing foot problems (use this time for instruction):	Certain preparations or applications cause more injury to soft tissue than initial foot problem.
a. Over-the-counter liquid preparations to remove corns	Liquid preparations cause burns and ulcerations.
b. Cutting corns or calluses with razor blade or scissors	Cutting corns or calluses sometimes results in infection caused by a break in skin integrity. The patient with diabetes or any patient with decreased peripheral circulation has an increased risk for infection secondary to a break in skin integrity.

Table Continued

Step	Rationale
c. Use of oval corn pads	Oval pads exert pressure on toes, thereby decreasing circulation to surrounding tissues.
d. Application of adhesive tape	Skin of older adult is thin and delicate and prone to tearing when adhesive tape is removed.
11. Assess patient's ability to care for nails or feet: visual alterations, fatigue, and musculoskeletal weakness.	Determines patient's ability to perform self-care and degree of assistance required from nurse.
12. Assess patient's knowledge of foot and nail care practices.	Ensures patient has the capability to obtain, communicate, process, and understand basic health information (CDC, 2019).
Planning	
1. Assess environment for spills on floor and make sure that bed brakes are locked and bed is in low position.	Ensures patient safety.
2. Collect appropriate equipment and arrange on over-bed table.	Provides each access to equipment and promotes an organized procedure.
3. Close room door or pull curtain around patient's bed.	Provides privacy.
4. Explain procedure, including need to soak feet, which requires several minutes.	Patient needs to be able to place fingers and feet in basin for 10 to 20 minutes. Some patients may become tired.
Implementation	
1. Assist ambulatory patient to seated position in bedside chair. Help bed-bound patient to supine position with head of bed elevated. Place disposable bath mat or towel on floor under patient's feet, or place towel on bed.	Sitting in chair facilitates immersion of feet in basin. Bath mat or towel protects feet from exposure to soil or microorganisms on floor; towel lessens chance of splashing water on floor or bed.
CLINICAL DECISION: Soaking the feet of patients with diabetes mellitus or peripheral vascular disease is not recommended. Soaking may lead to maceration (excessive softening of the skin) and drying of the skin (ADA, 2020), leading to tissue breakdown and infection.	
2. Adjust over-bed table to low position and place it over patient's lap. (Patient sits in chair or lies in bed.)	Easy access prevents accidental spills.
3. Fill washbasin with warm water. Test water temperature. Place basin on floor and lower side rail or place basin on waterproof pad on the mattress. Assist patient to immerse feet.	Warm water softens nails and thickened epidermal cells, reduces inflammation of skin, and promotes local circulation. Proper water temperature prevents burns.
4. Instruct patient to place fingers in emesis basin and arms in comfortable position.	Prolonged positioning causes discomfort unless normal anatomical alignment is maintained.
5. Allow patient's feet and fingernails to soak for 10 to 20 minutes. Rewarm water after 10 minutes. Note: If patient is diabetic or has peripheral vascular disease, skip this step.	Softening corns, calluses, and cuticles ensures easy removal of dead cells and easy manipulation of cuticle. <i>Do not soak if patient has diabetes.</i>
6. Perform hand hygiene and apply clean gloves. Clean gently under nails with plastic applicator stick or soft brush while immersing fingers (see illustration).	Removes debris under nails that harbors microorganisms.
7. Use soft cuticle brush or nail brush to clean around cuticles to decrease overgrowth.	Nail brush helps prevent inflammation and injury to cuticles. The cuticle grows slowly over the nail and must be pushed back with a soft nail brush regularly.
	 <p>Step 6 Clean under fingernails.</p>

Table Continued

Step	Rationale
CLINICAL DECISION: Check agency policy regarding appropriate nail care for cleaning under nail and trimming. Do not use orange stick or end of cotton swab.	
8. Remove hands from basin and dry thoroughly.	Thorough drying impedes fungal nail growth and prevents maceration of tissues.
9. File fingernails straight across and even with tops of fingers. If permitted by agency policy, use nail clippers and clip fingernails straight across and even with tops of fingers (see illustration); then smooth nail, using file. Remove and dispose of gloves and perform hand hygiene.	Reduces tearing or splitting of nails. Shaping corners of nails can damage tissues.
10. Move over-bed table away from patient and begin foot care. Apply clean gloves and scrub callused areas of feet with washcloth.	Provides easier access to patient's feet. Friction removes dead skin layers. Gloves prevent transmission of fungal infection.
11. Clean between toes with washcloth.	Areas between toes harbor debris.
12. Dry feet thoroughly and clean under nails (see Step 6).	Nails harbor debris and dirt and are a source of potential infection from poor care habits (Ball et al., 2019).
13. Trim toenails using procedures in Step 9. Do not file corners of toenails. Check agency policy for trimming patient's nails.	Shaping corners of toenails damages tissues, which increases the risk for infection (Jeffcoate et al., 2018).
14. Apply lotion to hands and feet. Rub in thoroughly. Do not leave excess lotion between toes.	Lotion lubricates dry skin by helping to retain moisture.
15. Assist patient back to bed or into a comfortable chair.	
16. Be sure nurse call system is within reach and patient knows how to use it.	Ensures patient can ask for assistance if needed.
17. Sanitize equipment according to agency policy. Dispose of used equipment, remove and dispose of gloves and perform hand hygiene.	Reduces transmission of infection.
CLINICAL DECISION: Instruct patients to report any of the following to their health care provider: abnormalities or changes in the nail, including changes in nail shape or color; bleeding around the nails; thinning or thickening of the nails; and redness, swelling, or pain around the nails.	
Evaluation	
1. Inspect nails, cuticles, and areas between fingers and toes and surrounding skin surfaces.	Inspection enables you to evaluate condition of skin and nails. Allows you to note any remaining rough nail edges.
2. When possible, observe patient walking after foot and nail care.	Evaluates level of comfort and whether nail care removed excess skin or uneven nail surfaces that caused discomfort or problems with mobility.
3. Use Teach-Back: "I want to be sure you know what problems you can have if you do not trim your nails correctly. Show me how to properly trim your toenails." Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly.	Determines patient's/family caregiver's level of understanding of instructional topic.
Unexpected Outcomes and Related Interventions	

Step	Rationale
1. Cuticles and surrounding tissues are inflamed and tender to touch.	<ul style="list-style-type: none"> • Repeated soakings are necessary to relieve inflammation and loosen layers of skin cells. • Patients with peripheral vascular disease or diabetes often require referral to a podiatrist. • Evaluate need for antifungal cream.

Step 9 Trim nails straight across when using nail clipper.

Step	Rationale
2. Localized areas of tenderness occur on feet with calluses or corns at point of friction.	<ul style="list-style-type: none"> • Recommend a change in footwear if necessary. • Refer to a podiatrist or nurse in charge.
3. Tissue injury appears between toes or other pressure areas in foot.	<ul style="list-style-type: none"> • Notify physician or nurse in charge. • Implement appropriate pressure injury interventions (see Chapter 48).
Recording and Reporting	<ul style="list-style-type: none"> • Record procedure and observations of integument (e.g., breaks in skin, inflammation, ulcerations). • Report any breaks in skin or ulcerations to nurse in charge or physician. These are serious in patients with peripheral vascular disease and illnesses in which patient's circulation is impaired. Special foot-care treatments are often necessary. • Document your evaluation of patient learning.
Home Care Considerations	<ul style="list-style-type: none"> • Instruct family and patient to remove foot hazards from the home, e.g., throw rugs, objects that block pathways, or uneven flooring. • Alternative therapies: moleskin applied to areas of feet that are under friction is less likely to cause pressure to tissues; wrapping small pieces of lamb's wool around toes reduces irritation of soft corns between toes. • Provide contact information for a podiatrist; this is especially important for patients with diabetes or peripheral vascular disease.

Skill 40.3. Performing Mouth Care for an Unconscious or Debilitated Patient

Delegation and Collaboration

The skill of providing oral hygiene to an unconscious or debilitated patient can be delegated to assistive personnel (AP). The nurse is responsible for assessing a patient's gag reflex. The nurse instructs the AP to:

- Have another AP assist and properly position patient for mouth care.
- Be aware of aspiration precautions.
- Use an oral suction catheter for clearing oral secretions (see [Chapter 41](#), [Skill 41.1](#)).
- Report any lesions or bleeding of mucosa or gums, excessive coughing, or choking to the nurse.

Equipment

- Small pediatric, soft-bristled toothbrush, toothette sponges, or suction toothbrushes for patients for whom brushing is contraindicated
- Antibacterial solution per agency policy (e.g., chlorhexidine gluconate [CHG] 0.12%)
- Fluoride toothpaste
- Water-based mouth moisturizer
- Tongue blade
- Penlight

- Oral suction equipment
- Oral airway (uncooperative patient or patient who shows bite reflex)
- Water-soluble lip lubricant
- Water glass with cool water
- Face and bath towel
- Emesis basin
- Clean gloves

Step	Rationale
Assessment	
1. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2020).
2. Assess patient's risk for oral hygiene problems (see Procedural Guideline 40.9).	Certain conditions increase likelihood of alterations in integrity of oral cavity mucosa and structures, necessitating more frequent care.
3. Perform hand hygiene and apply clean gloves.	Reduces transmission of microorganisms in blood or saliva.
4. Assess for presence of gag reflex by placing tongue blade on back half of tongue.	Helps in determining aspiration risk.
CLINICAL DECISION: <i>Patients with impaired gag reflex are unable to clear airway secretions and often accumulate secretions in the back of the oral cavity and have a higher risk for aspiration. Keep suction equipment available when caring for patients who are at risk for aspiration.</i>	
5. Inspect condition of oral cavity. Inspect lips, teeth, gums, buccal mucosa, palate, and tongue using tongue depressor and penlight if necessary (see Chapter 30). Observe for color, moisture, lesions, injury or ulcers, and condition of teeth or dentures.	Determines condition of oral cavity and need for hygiene. Establishes baseline to show improvement following oral care.
CLINICAL DECISION: <i>The critically ill patient with an artificial airway and who is on mechanical ventilation is at risk for ventilator-associated pneumonia (VAP). Once intubated, the artificial airway causes a bypass of normal airway defenses, which also causes a rapid change in the normal oral flora (IHI, 2018; Klompas et al., 2014). Some patients require mouth care as often as every 1 to 2 hours until the mucosa returns to normal.</i>	
6. Assess patient's respirations or oxygen saturation.	Assists in early recognition of aspiration.
7. Remove and dispose of gloves. Perform hand hygiene.	Prevents transmission of infection.
Table Continued	

Step	Rationale
Planning	
1. Assess environment for safety (e.g., check the room for spills, make sure that suction equipment is working properly, and check that bed is in locked, low position).	Identifies safety hazards in patient environment that could cause or potentially lead to harm (QSEN, 2018).
2. Gather equipment and supplies at bedside.	Avoids interrupting procedure or leaving patient unattended to retrieve missing equipment.
3. Close room door or pull curtain around bed	Provides privacy
4. Explain procedure to patient or family caregiver if present.	Even debilitated or intubated patients are usually able to hear. Explanation can reduce anxiety.
Implementation	
1. Perform hand hygiene and apply clean gloves.	Reduces transfer of microorganisms.
2. Raise bed to appropriate working height; lower side rail.	Promotes good body mechanics for caregiver.
3. Unless contraindicated (e.g., head injury, neck trauma), position patient in Sims' or side-lying position. Turn patient's head toward mattress in dependent position with HOB elevated at least 30 degrees.	Position promotes drainage of secretions from mouth instead of collecting in back of pharynx. Prevents aspiration.
4. Place towel on over-bed table and arrange equipment. If needed, turn on suction machine and connect tubing to suction catheter.	Prevents soiling of tabletop. Equipment prepared in advance ensures smooth, safe procedure. Supplies within reach create organized workspace.
5. Place second towel under patient's head and emesis basin under chin.	Prevents soiling of bed linen.
6. Remove dentures or partial plates if present.	Allows for thorough cleaning of prosthetics later. Provides clearer access to oral cavity.
7. If patient is uncooperative or having difficulty keeping mouth open, insert an oral airway. Insert upside down and turn airway sideways and over tongue to keep teeth apart. Insert when patient is relaxed if possible. Do not use force.	Prevents patient from biting down on nurse's fingers and provides access to oral cavity.
CLINICAL DECISION: <i>Never place fingers into the mouth of an unconscious or debilitated patient. This could occlude the airway. Also, the normal patient response is to bite down.</i>	
8. Clean mouth using brush moistened in water. Apply toothpaste or use antibacterial solution first to loosen crusts. Hold toothbrush bristles at 45-degree angle to gum line. Be sure that tips of bristles rest against and penetrate under gum line. Brush inner and outer surfaces of upper and lower teeth by brushing from gum to crown of each tooth; then clean biting surfaces of teeth by holding top of bristles parallel with teeth and brushing gently back and forth (see Box 40.9 Procedural Guidelines). Brush sides of teeth by moving bristles back and forth. Use a toothette sponge if patient has a bleeding tendency or if use of toothbrush is contraindicated (see illustration). Suction any accumulated secretions. Moisten brush with clear water or CHG solution to rinse. Use brush or toothette to clean roof of mouth, gums, and inside cheeks. Gently brush tongue, but avoid stimulating gag reflex (if present). Repeat rinsing several times and use suction to remove secretions. Use towel to dry off lips.	Brushing action removes food particles between teeth and along chewing surfaces and removes crusts and secretions from mucosa. The use of a chlorhexidine gluconate (CHG) oral hygiene protocol as part of daily oral care reduces the incidence of ventilator-associated pneumonia (VAP) (Villar et al., 2015; de Lacerda Vidal et al., 2017). The Institute for Healthcare Improvement (2018) recommends the use of 0.12% chlorhexidine gluconate (CHG) as part of daily oral care in critically ill patients. Repeated rinsing removes all debris and aids in moistening mucosa. Suction removes secretions and fluids that collect in posterior pharynx, thus reducing aspiration risk.

Step	Rationale
9. Apply thin layer of water-soluble moisturizer to lips (see illustration).	Lubricates lips to prevent drying and cracking.
	

Step 8 Cleaning lips and mucosa around oral airway with toothette.

Step 9 Application of water-soluble moisturizer to lips.

Step	Rationale
10. Inform patient that procedure is completed. Return him or her to comfortable and safe position.	Provides meaningful stimulation to unconscious or less-responsive patient.
11. Raise side rails as appropriate and return bed to locked, low position. Leave nurse call system within reach.	Reduces risk of falls from bed.
12. Clean equipment and return to its proper place. Place soiled linen in dirty laundry bag.	Proper disposal of soiled equipment prevents spread of infection.
13. Remove and dispose of gloves in proper receptacle and perform hand hygiene.	Reduces transmission of microorganisms.
Evaluation	
1. Apply clean gloves and use tongue blade and penlight to inspect oral cavity.	Determines efficacy of cleaning. Once thick secretions are removed, underlying inflammation or lesions may be revealed.
2. Ask debilitated patient if mouth feels clean.	Evaluates level of comfort.
3. Use Teach-Back: "I explained what is needed to reduce your husband's risk of choking on secretions in his throat. Tell me the ways to prevent him from choking." Revise your instruction now or develop a plan for revised patient/family caregiver teaching if family caregiver is not able to teach back correctly.	Determines patient's/family caregiver's level of understanding of instructional topic.
Unexpected Outcomes and Related Interventions	
1. Secretions or crusts remain on mucosa, tongue, or gums. • Provide more frequent oral hygiene.	
2. Localized inflammation or bleeding of gums or mucosa is present. • Provide more frequent oral hygiene with toothette sponges. • Apply a water-based mouth moisturizer to provide moisture and maintain integrity of oral mucosa. • Chemotherapy and radiation can cause mucositis (inflammation of mucous membranes in mouth) because of sloughing of epithelial tissue. Room temperature saline rinses, bicarbonate and sterile water rinses, and oral care with a soft-bristled toothbrush decrease severity and duration of mucositis.	
3. Lips are cracked or inflamed. • Apply moisturizing gel or water-soluble lubricant to lips more often.	
4. Patient aspirates secretions. • Suction oral airway to maintain airway patency (see Chapter 41). • Elevate patient's HOB to facilitate breathing. • If aspiration is suspected, notify health care provider immediately. Prepare patient for chest x-ray examination.	
Recording and Reporting • Record procedure, appearance of oral cavity before and after procedure, presence of gag reflex, and patient's response to procedure. • Document your evaluation of patient/family caregiver learning. • Use agency's standardized hand-off communication to communicate specific patient risks for aspiration and dry mouth. Discuss patient-specific interventions taken. • Report any unusual findings (e.g., bleeding, ulceration, lesions, choking response) to nurse in charge or health care provider. • Report immediately to the health care provider if patient aspirates.	
Home Care Considerations • Irrigate oral cavity with bulb syringe; patient can use a gravity baster to remove secretions. • Give mouth care at least twice a day. • Have caregivers demonstrate positioning patient to prevent aspiration.	

Key Points

- Various health beliefs, personal, sociocultural, economic, and developmental factors influence patients' hygiene preferences and practices.
- Hygiene needs, preferences, and the ability to participate in care change as people get older.
- Assess a patient's skin, feet and nails, oral mucosa, hair, and eyes and ears to obtain a complete assessment of the patient's hygiene needs.
- Assess a patient's physical and cognitive ability to perform basic hygiene measures.
- Vascular insufficiency and reduced mobility, cognition, and sensation increase a patient's risk for impaired skin integrity.
- Diabetes and peripheral vascular diseases increase the patient's risk for foot and nail problems.
- Critically thinking about a patient's hygiene preferences, needs, and ability to participate in care results in patient-centered hygiene care matching the patient's needs and preferences.
- Administering therapies to relieve symptoms such as pain or nausea before hygiene better prepares patients for any procedure.
- Position patients and make suction available to reduce the risk for aspiration when providing oral care to unconscious patients.

- A patient's environment needs to be comfortable, safe, and large enough to provide care and allow the patient and visitors to move about freely.
- Evaluation of hygiene procedures is based on outcomes of care; a patient's sense of comfort, relaxation, and well-being; and a patient's understanding of hygiene techniques.

Reflective Learning

- Your patient has diabetes and needs foot care. She asks why foot care is important. What would you tell her about why foot care is important and her associated risks?
- You have been assigned to your first comatose patient, and you notice 0.12% chlorhexidine gluconate (CHG) solution is ordered. Why is this necessary? What is the benefit to the patient?
- Your female patient has a Foley catheter in place. What are the necessary modifications in perineal care to reduce the risks of catheter-associated urinary tract infection (CAUTI)?

Review Questions

1. What is the proper position to use for an unresponsive patient during oral care to prevent aspiration? (Select all that apply.)
 1. Prone position
 2. Sims' position

3. Semi-Fowler's position with head to side
 4. Trendelenburg position
 5. Supine position
2. The student nurse is teaching a family member the importance of foot care for his or her mother, who has diabetes. Which safety precautions are important for the family member to know to prevent infection? (Select all that apply.)
 1. Cut nails frequently.
 2. Assess skin for redness, abrasions, and open areas daily.
 3. Soak feet in water at least 10 minutes before nail care.
 4. Apply lotion to feet daily.
 5. Clean between toes after bathing.
3. Integrity of the oral mucosa depends on salivary secretion. Which of the following factors impairs salivary secretion? (Select all that apply.)
 1. Use of cough drops
 2. Immunosuppression
 3. Radiation therapy
 4. Dehydration
 5. Presence of oral airway
4. A nurse is assigned to care for the following patients. Which patient is most at risk for developing skin problems and thus requiring thorough bathing and skin care?
 1. A 44-year-old female patient who has had removal of a breast lesion and is having her menstrual period

2. A 56-year-old male patient who is homeless and admitted to the emergency department with malnutrition and dehydration and who has an intravenous line
3. A 60-year-old female patient who experienced a stroke with right-sided paralysis and has an orthopedic brace applied to the left leg
4. A 70-year-old patient who has diabetes and dementia and has been incontinent of stool
5. When the nurse is assigned to a patient who has a reduced level of consciousness and requires mouth care, which physical assessment techniques should the nurse perform before the procedure? (Select all that apply.)
 1. Oxygen saturation
 2. Heart rate
 3. Respirations
 4. Gag reflex
 5. Response to painful stimulus
6. The American Dental Association suggests that patients who are at risk for poor hygiene use the following interventions for oral care: (Select all that apply.)
 1. Use antimicrobial toothpaste.
 2. Brush teeth 4 times a day.
 3. Use 0.12% chlorhexidine gluconate (CHG) oral rinses.
 4. Use a soft toothbrush for oral care.
 5. Avoid cleaning the gums and tongue.
7. While planning morning care, which of the following patients would have the highest priority to receive his or

her bath first?

1. A patient who just returned to the nursing unit from a diagnostic test
 2. A patient who prefers a bath in the evening when his wife visits and can help him
 3. A patient who is experiencing frequent incontinent diarrheal stools and urine
 4. A patient who has been awake all night because of pain 8/10
8. A patient with a malignant brain tumor requires oral care. The patient's level of consciousness has declined, with the patient only being able to respond to voice commands. Place the following steps in the correct order for administration of oral care.
1. If patient is uncooperative or having difficulty keeping mouth open, insert an oral airway.
 2. Raise bed, lower side rail, and position patient close to side of bed with head of bed raised up to 30 degrees.
 3. Using a brush moistened with chlorhexidine paste, clean chewing and inner tooth surfaces first.
 4. For patients without teeth, use a toothette moistened in chlorhexidine rinse to clean oral cavity.
 5. Remove partial plate or dentures if present.
 6. Gently brush tongue, but avoid stimulating gag reflex.
9. The nurse delegates needed hygiene care for an alert elderly patient who had a stroke. Which intervention would be appropriate for the assistive personnel to accomplish during the bath? (Select all that apply)

1. Checking distal pulses
 2. Providing range-of-motion (ROM) exercises to extremities
 3. Determining type of treatment for stage 1 pressure injury
 4. Changing the dressing over an intravenous site
 5. Providing special skin care
10. The nurse observes an adult Middle Eastern patient attempting to bathe himself with only his left hand. The nurse recognizes that this behavior likely relates to:
1. Obsessive-compulsive behavior.
 2. Personal preferences.
 3. The patient's cultural norm.
 4. Controlling behaviors.

Answers: 1. 2, 3; 2. 2, 4, 5; 3. 3, 4; 4. 4; 5. 3, 4; 6. 1, 3, 4; 7. 3; 8. 2, 5, 1, 3, 6, 4; 9. 2, 5; 10. 3.

Oxygenation

OBJECTIVES

- Describe the structure and function of the cardiopulmonary system.
- Describe the physiological processes of ventilation, perfusion, and exchange of respiratory gases.
- Differentiate among the physiological processes of cardiac output, myocardial blood flow, and systemic circulation.
- Describe the relationship of cardiac output (preload, afterload, contractility, and heart rate) to the process of oxygenation.
- Identify the potential clinical outcomes occurring as a result of hyperventilation, hypoventilation, and/or hypoxemia.
- Identify the potential clinical outcomes occurring as a result of disturbances in conduction, altered cardiac output, impaired valvular function, myocardial ischemia, and/or impaired tissue perfusion.
- Describe the effect of a patient's level of health, age, lifestyle, and environment on oxygenation.
- Describe how to assess for the risk factors affecting a patient's oxygenation.
- Describe how to assess for the physical manifestations that occur with alterations in oxygenation.
- Develop a plan of care for a patient with altered oxygenation.
- Describe nursing care interventions used to promote oxygenation in the primary care, acute care, and restorative and continuing care settings.
- Describe strategies to use to maintain a patient's airway.
- Evaluate a patient's responses to oxygenation therapies.

Disturbances in oxygenation often result from ineffective gas exchange (lungs) or an ineffective pump (heart). You will learn about the physiology of the cardiopulmonary system and how the heart and the lungs work together to provide oxygen to the tissues of the body. This chapter describes how to assess and care for a patient with a disturbance in oxygenation.

Scientific Knowledge Base

Oxygen is a basic human need. The cardiac and respiratory systems work together to supply the body with oxygen necessary for carrying out the respiratory and metabolic processes needed to sustain life. Blood is oxygenated through the mechanisms of ventilation, perfusion, and transport of respiratory gases. Neural and chemical regulators control the rate and depth of respiration in response to changing tissue oxygen demands. The cardiovascular system provides the transport mechanisms to distribute oxygen to cells and tissues of the body ([McCance and Huether, 2019](#)).

Respiratory Physiology

Respiration is the exchange of oxygen and carbon dioxide during cellular metabolism. It is commonly confused as the act of air moving in and out of the lungs, which is actually ventilation. The airways of the lung transfer oxygen from the atmosphere to the alveoli, where the oxygen is exchanged for carbon dioxide (CO₂). Through the alveolar capillary membrane, oxygen transfers to the blood, and CO₂ transfers from the blood to the alveoli. There are three steps in the process of oxygenation: ventilation, perfusion, and diffusion ([McCance and Huether, 2019](#)).

Structure and Function

The respiratory muscles, pleural space, lungs, and alveoli are essential for ventilation, perfusion, and exchange of respiratory gases. Gases move into and out of the lungs through pressure changes. Intrapleural pressure is negative, or less than atmospheric pressure, which is 760 mm Hg at sea level. For air to flow into the lungs, intrapleural pressure becomes more negative, setting up a pressure gradient between the atmosphere and the alveoli. The diaphragm and external intercostal muscles contract (move downward and outward) to create a negative pleural pressure and increase the size of the thorax for inspiration. Relaxation of the diaphragm and contraction of the internal intercostal muscles allow air to escape from the lungs ([Cedar, 2018](#); [McCance and Huether, 2019](#)).

Ventilation is the process of moving gases into and out of the lungs with air flowing into the lungs during inhalation (inspiration) and out of the lungs during exhalation (expiration). It requires coordination of the muscular and elastic properties of the lungs and thorax. The major

inspiratory muscle of respiration is the diaphragm. It is innervated by the phrenic nerve, which exits the spinal cord at the fourth cervical vertebra. **Perfusion** relates to the ability of the cardiovascular system to pump oxygenated blood to the tissues and return deoxygenated blood to the lungs. Finally, **diffusion** is responsible for moving the respiratory gases from one area to another by concentration gradients. For the exchange of respiratory gases to occur, the organs, nerves, and muscles of respiration need to be intact and the central nervous system needs to be able to regulate the respiratory cycle (Cedar, 2018; McCance and Huether, 2019).

Conditions or diseases that change the structure and function of the pulmonary system alter respiration. Some of these conditions include chronic obstructive pulmonary disease (COPD), asthma, lung cancer, and cystic fibrosis. In these conditions, you could find increased respiratory rate, decreased oxygen saturation levels, or adventitious lung sounds (McCance and Huether, 2019).

Work of Breathing

Work of breathing (WOB) is the effort required to expand and contract the lungs. In the healthy individual breathing is quiet and accomplished with minimal effort. The amount of energy expended on breathing depends on the rate and depth of breathing, the ease in which the lungs can be expanded (compliance), and airway resistance (McCance and Huether, 2019).

Inspiration is an active process, stimulated by chemical receptors in the aorta. Expiration is a passive process that depends on the elastic recoil properties of the lungs, requiring little or no muscle work. Surfactant is a chemical produced in the lungs to maintain the surface tension of the alveoli and keep them from collapsing. Patients with advanced COPD lose the elastic recoil of the lungs and thorax. As a result, the patient's work of breathing increases. In addition, patients with certain pulmonary diseases have decreased surfactant production and sometimes develop atelectasis. Atelectasis is a collapse of the alveoli that prevents normal exchange of oxygen and carbon dioxide (McCance and Huether, 2019).

Accessory muscles of respiration (the intercostal muscles in the rib cage and abdominal muscles) can increase lung volume during inspiration. Patients with COPD, especially emphysema, frequently use these muscles to increase lung volume. Prolonged use of the accessory muscles does not promote effective ventilation and eventually causes fatigue. During assessment a patient's clavicles may elevate during inspiration, which can

indicate ventilatory fatigue, air hunger, or decreased lung expansion (McCance and Huether, 2019).

Compliance is the ability of the lungs to distend or expand in response to increased intra-alveolar pressure. Compliance decreases in diseases such as pulmonary edema, interstitial and pleural fibrosis, and congenital or traumatic structural abnormalities such as kyphosis or fractured ribs (McCance and Huether, 2019).

Airway resistance is the increase in pressure that occurs as the diameter of the airways decreases from mouth/nose to alveoli. Any further decrease in airway diameter by bronchoconstriction or the presences of excess mucus can increase airway resistance. Diseases causing airway obstruction, such as asthma, tracheal edema, or COPD, increase airway resistance. When airway resistance increases, the amount of oxygen delivered to the alveoli decreases (McCance and Huether, 2019).

Decreased lung compliance, increased airway resistance, and the increased use of accessory muscles increase the WOB, resulting in increased energy expenditure. Therefore, the body increases its metabolic rate and the need for more oxygen. The need for elimination of carbon dioxide also increases. This sequence is a vicious cycle for a patient with impaired ventilation, causing further deterioration of respiratory status and the ability to oxygenate adequately (McCance and Huether, 2019).

Lung Volumes

The normal lung volumes are determined by age, gender, and height. Tidal volume is the amount of air exhaled following a normal inspiration. Residual volume is the amount of air left in the alveoli after a full expiration. Forced vital capacity is the maximum amount of air that can be removed from the lungs during forced expiration (McCance and Huether, 2019). Variations in tidal volume and other lung volumes are associated with alterations in patients' health status or activity, such as pregnancy, exercise, obesity, or obstructive and restrictive conditions of the lungs.

Pulmonary Circulation

The primary function of pulmonary circulation is to move blood to and from the alveolar capillary membrane for gas exchange. Pulmonary circulation begins at the pulmonary artery, which receives poorly oxygenated mixed venous blood from the right ventricle. Blood flow through this system depends on the pumping ability of the right ventricle. The flow continues from the pulmonary artery through the pulmonary

arterioles to the pulmonary capillaries, where blood comes in contact with the alveolar capillary membrane and the exchange of respiratory gases occurs. The oxygen-rich blood then circulates through the pulmonary venules and pulmonary veins, returning to the left atrium (McCance and Huether, 2019).

Respiratory Gas Exchange

Diffusion is the process for the exchange of respiratory gases in the alveoli of the lungs and the capillaries of the body tissues. Diffusion of respiratory gases occurs at the alveolar capillary membrane (Fig. 41.1). The thickness of the membrane affects the rate of diffusion. Increased thickness of the membrane impedes diffusion because gases take longer to transfer across the membrane. Patients with pulmonary edema, pulmonary infiltrates, or pulmonary effusion have a thickened membrane, resulting in slow diffusion, slow exchange of respiratory gases, and decreased delivery of oxygen to tissues. Chronic diseases (e.g., emphysema), acute diseases (e.g., pneumothorax), and surgical processes (e.g., lobectomy) often alter the amount of alveolar capillary membrane surface area (McCance and Huether, 2019).

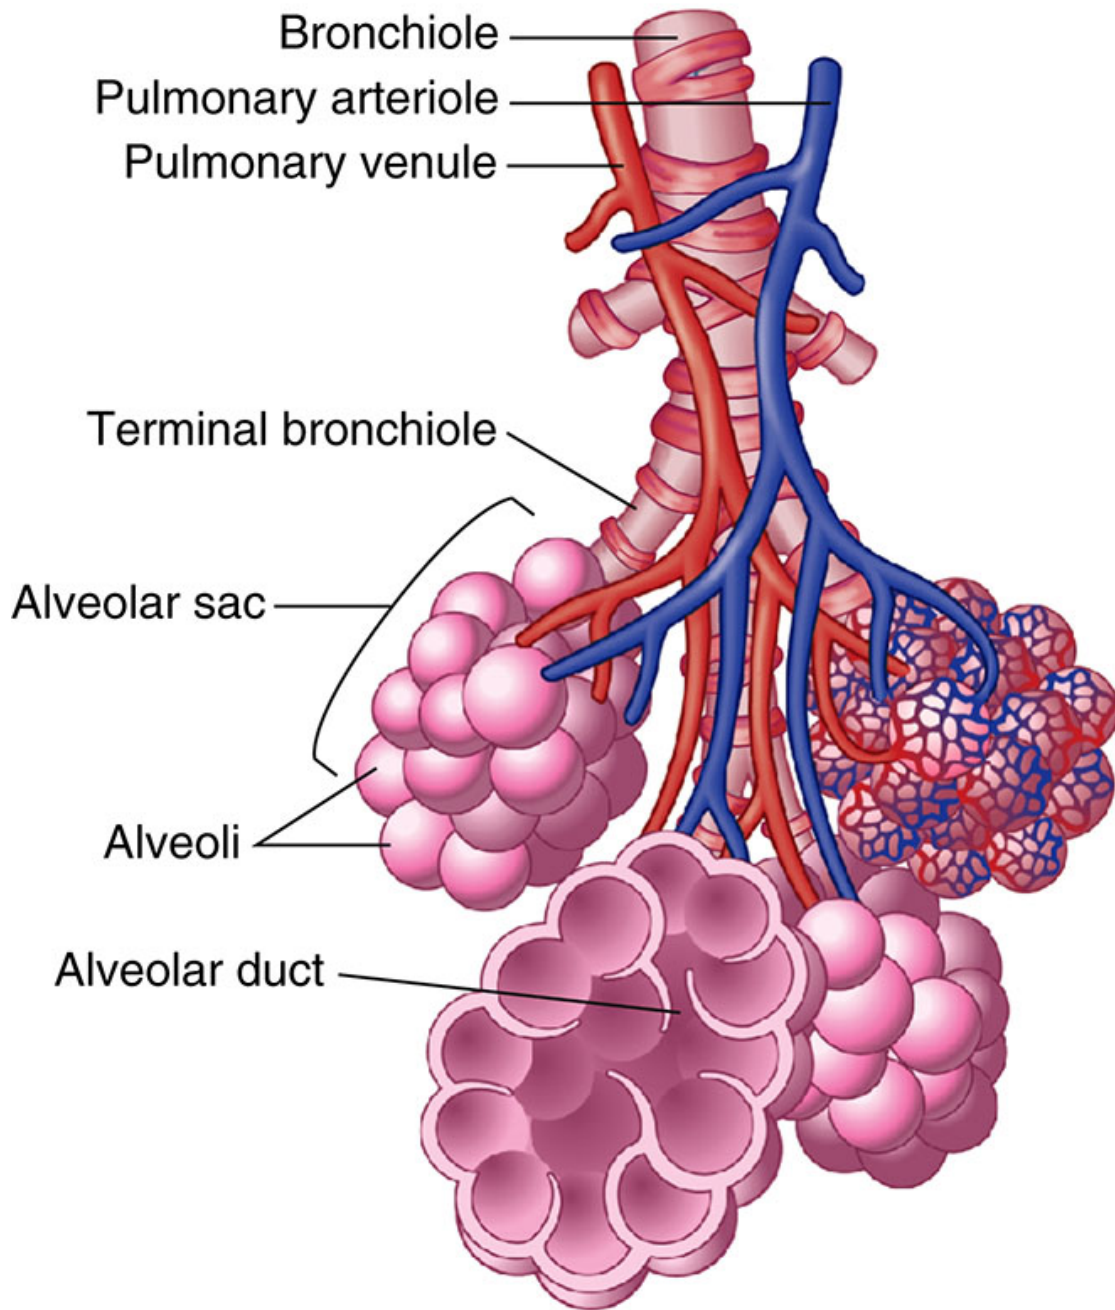

FIG. 41.1 Alveoli at terminal end of lower airway.
From Patton KT, Thibodeau GA: *Human body in health and disease*, ed 7, St Louis, 2018, Elsevier.

Oxygen Transport

The oxygen-transport system consists of the lungs and cardiovascular system. Delivery depends on the amount of oxygen entering the lungs (ventilation), blood flow to the lungs and tissues (perfusion), rate of

diffusion, and oxygen-carrying capacity. Three things influence the capacity of the blood to carry oxygen: the amount of dissolved oxygen in the plasma, the amount of hemoglobin, and the ability of hemoglobin to bind with oxygen. Hemoglobin, which is a carrier for oxygen and carbon dioxide, transports most oxygen (approximately 97%). The hemoglobin molecule combines with oxygen to form oxyhemoglobin. The formation of oxyhemoglobin is easily reversible, allowing hemoglobin and oxygen to dissociate (deoxyhemoglobin), which frees oxygen to enter tissues. Patients who are acidotic (pH less than 7.35; seen in patients with sepsis or diabetic ketoacidosis), hypercapnic (elevated PaCO₂ levels; seen in patients with COPD), or who have low hemoglobin levels (seen in patients with anemia or excess blood loss) have decreased ability to carry oxygen and therefore to deliver oxygen to the tissues ([McCance and Huether, 2019](#)).

Carbon Dioxide Transport

Carbon dioxide, a product of cellular metabolism, diffuses into red blood cells and is rapidly hydrated into carbonic acid (H₂CO₃). The carbonic acid then dissociates into hydrogen (H) and bicarbonate (HCO₃⁻) ions.

Hemoglobin buffers the hydrogen ion, and the HCO₃⁻ diffuses into the plasma. Reduced hemoglobin (deoxyhemoglobin) combines with carbon dioxide, and the venous blood transports the majority of carbon dioxide back to the lungs to be exhaled ([McCance and Huether, 2019](#)).

Regulation of Ventilation

Regulation of ventilation is necessary to ensure sufficient oxygen intake and carbon dioxide elimination to meet the demands of the body (e.g., during exercise, infection, or pregnancy). Neural and chemical regulators control the process of ventilation. Neural regulation includes the CNS control of respiratory rate, depth, and rhythm. The cerebral cortex regulates the voluntary control of respiration by delivering impulses to the respiratory motor neurons by way of the spinal cord. Chemical regulation maintains the appropriate rate and depth of respirations based on changes in the carbon dioxide (CO₂), oxygen (O₂), and hydrogen ion (H⁺) concentration (pH) in the blood. Changes in levels of O₂, CO₂, and H⁺ (pH) stimulate the chemoreceptors located in the medulla, aortic body, and carotid body, which in turn stimulate neural regulators to adjust the rate and depth of ventilation to maintain normal arterial blood gas levels ([McCance and Huether, 2019](#)).

Cardiovascular Physiology

Cardiopulmonary physiology involves delivery of deoxygenated blood (blood high in carbon dioxide and low in oxygen) to the right side of the heart and then to the lungs, where it is oxygenated. Oxygenated blood (blood high in oxygen and low in carbon dioxide) then travels from the lungs to the left side of the heart and the tissues. The cardiac system delivers oxygen, nutrients, and other substances to the tissues and facilitates the removal of cellular metabolism waste products by way of blood flow through other body systems such as respiratory, digestive, and renal (McCance and Huether, 2019).

Structure and Function

The right ventricle pumps deoxygenated blood through the pulmonary circulation (Fig. 41.2). The left ventricle pumps oxygenated blood through the systemic circulation. As blood passes through the circulatory system, there is an exchange of respiratory gases, nutrients, and waste products between the blood and the tissues. Alterations in structure and function of the heart can lead to a variety of symptoms, including but not limited to dyspnea, edema, and weak pulses. Nurses hear abnormal heart sounds, such as murmurs or rubs, when the structure of the heart is altered (McCance and Huether, 2019).

FIG. 41.2 Schematic representation of blood flow through the heart. Arrows indicate direction of flow and pulmonary circulation.

Modified from Lewis SM, et al: *Medical surgical nursing: assessment and management of clinical problems*, ed 10, St Louis, 2017, Mosby.

Myocardial Pump

The pumping action of the heart is essential to oxygen delivery. There are four cardiac chambers: two atria and two ventricles. The ventricles fill with blood during diastole and empty during systole. The volume of blood ejected from the ventricles during systole is the **stroke volume**.

Hemorrhage and dehydration cause a decrease in circulating blood volume and a decrease in stroke volume (McCance and Huether, 2019).

Myocardial fibers have contractile properties that allow them to stretch during cardiac filling. In a healthy heart this stretch is proportionally related to the strength of contraction. As the myocardium stretches, the strength of the subsequent contraction increases; this is known as the *Frank-Starling (Starling's) law of the heart*. In the diseased heart

(cardiomyopathy), Starling's law does not apply because the increased stretch of the myocardium is beyond the physiological limits of the heart. The subsequent contractile response results in insufficient stroke volume, and blood begins to "back up" in the pulmonary (left heart failure) or systemic (right heart failure) circulation (McCance and Huether, 2019).

Myocardial Blood Flow

To maintain adequate blood flow to the pulmonary and systemic circulation, myocardial blood flow must supply sufficient oxygen and nutrients to the myocardium itself. Blood flow through the heart is unidirectional. The four heart valves ensure this forward blood flow (see Fig. 41.2). During ventricular diastole the atrioventricular (mitral and tricuspid) valves open, and blood flows from the higher-pressure atria into the relaxed ventricles. As systole begins, ventricular pressure rises and the mitral and tricuspid valves close. Valve closure causes the first heart sound (S_1) (McCance and Huether, 2019) (see Chapter 30).

During the systolic phase the semilunar (aortic and pulmonic) valves open, and blood flows from the ventricles into the aorta and pulmonary artery. The mitral and tricuspid valves stay closed during systole, so all of the blood is moved forward into the pulmonary artery and aorta. As the ventricles empty, the ventricular pressures decrease, allowing closure of the aortic and pulmonic valves. Valve closure causes the second heart sound (S_2). Some patients with valvular disease have backflow or regurgitation of blood through the incompetent valve, causing a murmur that you can hear on auscultation (see Chapter 30) (McCance and Huether, 2019).

Coronary Artery Circulation

The coronary circulation is the branch of the systemic circulation that supplies the myocardium with oxygen and nutrients and removes waste. The coronary arteries fill during ventricular diastole. The left coronary artery has the most abundant blood supply and feeds the more muscular left ventricular myocardium, which does most of the work of the heart (McCance and Huether, 2019).

Systemic Circulation

The arteries of the systemic circulation deliver nutrients and oxygen to tissues, and the veins remove waste from tissues. Oxygenated blood flows from the left ventricle through the aorta and into large systemic arteries.

These arteries branch into smaller arteries; then arterioles; and finally, the smallest vessels, the capillaries. The exchange of respiratory gases occurs at the capillary level, where the tissues are oxygenated. The waste products exit the capillary network through venules that join to form veins. These veins become larger and form the vena cava, which carry deoxygenated blood back to the right side of the heart, where it then returns to the pulmonary circulation ([McCance and Huether, 2019](#)).

Blood Flow Regulation

The amount of blood ejected from the left ventricle each minute is the **cardiac output**. The normal cardiac output is 4 to 8 L/min in the healthy adult at rest. The circulating volume of blood changes according to the oxygen and metabolic needs of the body. For example, cardiac output increases during exercise, pregnancy, and fever but decreases during sleep. The following formula represents cardiac output:

$$\text{Cardiac output (CO)} = \text{Stroke volume (SV)} \times \text{Heart rate (HR)}$$

Stroke volume is the amount of blood ejected from the ventricle with each contraction. The normal range for a healthy adult is 50 to 75 mL per contraction. Preload, afterload, and myocardial contractility all affect stroke volume. **Preload** is the amount of blood in the left ventricle at the end of diastole, before the next contraction. It is often referred to as end-diastolic volume. The ventricles stretch when filling with blood. The more stretch on the ventricular muscle, the greater the contraction and the greater the stroke volume (Starling's law). In certain clinical situations, medical treatment alters preload and subsequent stroke volumes by changing the amount of circulating blood volume. For example, when treating a patient who is hemorrhaging, increased fluid therapy and replacement of blood increase circulating volume, thus increasing the preload and stroke volume, which in turn increases cardiac output. If volume is not replaced, preload, stroke volume, and the subsequent cardiac output decrease ([McCance and Huether, 2019](#)).

Afterload is the resistance to the ejection of blood from the left ventricle. The heart works harder to overcome the resistance so that blood can be ejected from the left ventricle. The diastolic aortic pressure is a good

clinical measure of afterload. In hypertension, the afterload increases, causing an increase in cardiac workload (McCance and Huether, 2019).

Myocardial contractility is the ability of the heart to squeeze blood from the ventricles. It also affects stroke volume and cardiac output. Poor ventricular contraction decreases the amount of blood ejected. Injury to the myocardial muscle, such as an acute MI, causes a decrease in myocardial contractility (McCance and Huether, 2019). The myocardium in some older adults is stiffer with a slower ventricular filling rate and prolonged contraction time (Touhy and Jett, 2018).

Heart rate affects blood flow because of the relationship between heart rate and diastolic filling time. For example, a sustained heart rate greater than 160 beats/min decreases diastolic filling time, which decreases stroke volume and cardiac output (McCance and Huether, 2019). The heart rate of the older adult is slow to increase under stress, but studies have found that this may be caused more by lack of conditioning than age. Exercise is beneficial in maintaining function at any age (Touhy and Jett, 2018).

Conduction System

The rhythmic relaxation and contraction of the atria and ventricles depend on continuous, organized transmission of electrical impulses. The cardiac conduction system generates and transmits these impulses (Fig. 41.3).

FIG. 41.3 Conduction system of the heart. AV, Atrioventricular; SA, sinoatrial.

From Lewis SL et al: *Medical-surgical nursing: assessment and management of clinical problems*, ed 10, St Louis, 2017, Mosby.

The conduction system of the heart generates the impulses needed to initiate the electrical chain of events for a normal heartbeat. The autonomic nervous system influences the rate of impulse generation and the speed of transmission through the conductive pathway and the strength of atrial and ventricular contractions. Sympathetic and parasympathetic nerve fibers innervate all parts of the atria and ventricles and the sinoatrial (SA) and atrioventricular (AV) nodes. Sympathetic fibers increase the rate of impulse generation and speed of transmission. The parasympathetic fibers originating from the vagus nerve decrease the rate (McCance and Huether, 2019).

The conduction system originates with the SA node, the “pacemaker” of the heart. The SA node is in the right atrium next to the entrance of the superior vena cava. Impulses are initiated at the SA node at an intrinsic rate of 60 to 100 cardiac action potentials per minute in an adult at rest. The electrical impulses are transmitted through the atria along intraatrial and internodal pathways to the AV node. The AV node mediates impulses between the atria and the ventricles. It assists atrial emptying by delaying the impulse before transmitting it through the bundle of His and the ventricular Purkinje network. A normal sinus rhythm is necessary to ensure optimal perfusion of the tissues in the body (McCance and Huether, 2019).

An **electrocardiogram (ECG)** is a measurement of the electrical activity of the conduction system. An ECG monitors the regularity and path of the electrical impulse through the conduction system; however, it does not reflect the muscular work of the heart. The normal sequence on the ECG is called the normal sinus rhythm (NSR) (see [Fig. 41.3](#)) ([Urden et al., 2020](#)).

NSR implies that the impulse originates at the SA node and follows the normal sequence through the conduction system. The P wave (atrial depolarization) represents the electrical conduction through both atria. Atrial contraction follows the P wave. The PR interval represents the impulse travel time from the SA node through the AV node, through the bundle of His, and to the Purkinje fibers. The normal length for the PR interval is 0.12 to 0.2 seconds. An increase in the time greater than 0.2 seconds indicates a block in the impulse transmission through the AV node, whereas a decrease, less than 0.12 seconds, indicates the initiation of the electrical impulse from a source other than the SA node ([Urden et al., 2020](#)).

The QRS complex (ventricular depolarization) indicates that the electrical impulse traveled through the ventricles. Normal QRS duration is 0.06 to 0.1 seconds. An increase in QRS duration indicates a delay in conduction time through the ventricles. Ventricular contraction usually follows the QRS complex ([Urden et al., 2020](#)).

The QT interval represents the time needed for ventricular depolarization and repolarization. The normal QT interval is 0.12 to 0.42 seconds. This interval varies inversely with changes in heart rate. Changes in electrolyte values, such as hypocalcemia or hypomagnesemia, or therapy with medications (disopyramide, amiodarone, haloperidol, and azithromycin are examples) increases the QT interval. An increased QT interval increases the person's risk for lethal dysrhythmias ([Urden et al., 2020](#)).

Factors Affecting Oxygenation

Four factors influence adequacy of circulation, ventilation, perfusion, and transport of respiratory gases to the tissues: (1) physiological, (2) developmental, (3) lifestyle, and (4) environmental. The physiological factors are discussed here, and the others are discussed in the Nursing Knowledge Base section that follows.

Physiological Factors

Any condition affecting cardiopulmonary functioning directly affects the ability of the body to meet oxygen demands. Respiratory disorders include hyperventilation, hypoventilation, and hypoxia. Cardiac disorders include disturbances in conduction, impaired valvular function, myocardial hypoxia, cardiomyopathy conditions, and peripheral tissue hypoxia. Other physiological processes affecting a patient's oxygenation include alterations affecting the oxygen-carrying capacity of blood (anemia), decreased inspired oxygen concentration, increases in the metabolic demand of the body (fever), and alterations affecting chest wall movement caused by musculoskeletal abnormalities or neuromuscular alterations (muscular dystrophy) (McCance and Huether, 2019; Urden et al., 2020).

Decreased Oxygen-Carrying Capacity

Hemoglobin carries the majority of oxygen to tissues. Anemia and inhalation of toxic substances decrease the oxygen-carrying capacity of blood by reducing the amount of available hemoglobin to transport oxygen. Anemia (e.g., a lower-than-normal hemoglobin level) is a result of decreased hemoglobin production, increased red blood cell destruction, and/or blood loss. Patients have fatigue, decreased activity tolerance, increased breathlessness, increased heart rate, and pallor (especially seen in the conjunctiva of the eye). Oxygenation decreases as a secondary effect with anemia. The physiological response to chronic hypoxemia is the development of increased red blood cells (polycythemia). This is the adaptive response of the body to increase the amount of hemoglobin and the available oxygen-binding sites (Lewis et al., 2017; McCance and Huether, 2019).

Carbon monoxide (CO) is a colorless, odorless gas that causes decreased oxygen-carrying capacity of blood. In CO toxicity, hemoglobin strongly binds with CO, creating a functional anemia. Because of the strength of the bond, CO does not easily dissociate from hemoglobin, making hemoglobin unavailable for oxygen transport. People with CO poisoning are often unaware of their exposure to this gas, and the symptoms of CO poisoning (headache, dizziness, nausea, vomiting, and dyspnea) mimic other illnesses (Urden et al., 2020).

Hypovolemia

Conditions such as shock and severe dehydration cause extracellular fluid loss and reduced circulating blood volume, or **hypovolemia**. Decreased circulating blood volume results in hypoxia to body tissues. With

significant fluid loss, the body tries to adapt by peripheral vasoconstriction and by increasing the heart rate to increase the volume of blood returned to the heart, thus increasing the cardiac output ([McCance and Huether, 2019](#)).

Decreased Inspired Oxygen Concentration

With the decline of the concentration of inspired oxygen, the oxygen-carrying capacity of the blood decreases. Decreases in the fraction of inspired oxygen concentration (FiO_2) are caused by upper or lower airway obstruction, which limits delivery of inspired oxygen to alveoli; decreased environmental oxygen (at high altitudes); or hypoventilation (occurs in opiate overdoses) ([Lewis et al., 2017](#)).

Increased Metabolic Rate

Increased metabolic activity increases oxygen demand. The level of oxygenation declines when body systems are unable to meet this demand. An increased metabolic rate is normal in pregnancy, wound healing, and exercise because the body is using energy for building tissue. Most people are able to meet the increased oxygen demand and do not display signs of oxygen deprivation. Fever increases the tissues' need for oxygen; as a result, carbon dioxide production increases. When fever persists, the metabolic rate remains high, and the body begins to break down protein stores. This causes muscle wasting and decreased muscle mass, including respiratory muscles such as the diaphragm and intercostal muscles. The body attempts to adapt to the increased carbon dioxide levels by increasing the rate and depth of respiration. The patient's WOB increases, and the patient eventually displays signs and symptoms of hypoxemia. Patients with pulmonary diseases are at greater risk for hypoxemia ([McCance and Huether, 2019](#)).

Conditions Affecting Chest Wall Movement

Any condition reducing chest wall movement results in decreased ventilation. If the diaphragm does not fully descend with breathing, the volume of inspired air decreases, delivering less oxygen to the alveoli and tissues ([McCance and Huether, 2019](#)).

Pregnancy

As the fetus grows during pregnancy, the enlarging uterus pushes abdominal contents upward against the diaphragm. In the last trimester of

pregnancy, the inspiratory capacity declines, resulting in dyspnea on exertion and increased fatigue ([Ball et al., 2019](#)).

Obesity

Patients who are morbidly obese have reduced lung volumes from the heavy lower thorax and abdomen, particularly when in the recumbent and supine positions. Many morbidly obese patients suffer from obstructive sleep apnea. Morbidly obese patients have a reduction in lung and chest wall compliance as a result of encroachment of the abdomen into the chest, increased WOB, and decreased lung volumes. In some patients an obesity-hypoventilation syndrome develops in which oxygenation is decreased and carbon dioxide is retained. The obese patient is also susceptible to atelectasis or pneumonia after surgery because the lungs do not expand fully and the lower lobes retain pulmonary secretions ([McCance and Huether, 2019](#)).

Musculoskeletal Abnormalities

Musculoskeletal impairments in the thoracic region reduce oxygenation. Such impairments result from abnormal structural configurations, trauma, muscular diseases, and diseases of the central nervous system. Abnormal structural configurations impairing oxygenation include those affecting the rib cage, such as pectus excavatum, and the vertebral column, such as kyphosis, lordosis, or scoliosis ([Ball et al., 2019](#); [McCance and Huether, 2019](#)).

Trauma

Flail chest is a condition in which multiple rib fractures cause chest wall instability. This instability allows the lung under the injured area to contract on inspiration and bulge on expiration, resulting in hypoxia. Patients with thoracic or upper abdominal surgical incisions use shallow respirations to avoid pain, which also decreases chest wall movement. Opioids used to treat pain depress the respiratory center, further decreasing respiratory rate and chest wall expansion ([Urden et al., 2020](#)).

Neuromuscular Diseases

Neuromuscular diseases affect tissue oxygenation by decreasing a patient's ability to expand and contract the chest wall. Ventilation is impaired, resulting in atelectasis, hypercapnia, and hypoxemia. Examples of conditions causing hypoventilation include myasthenia gravis and Guillain-Barré syndrome ([McCance and Huether, 2019](#)).

Central Nervous System Alterations

Diseases or trauma of the medulla oblongata and/or spinal cord result in impaired ventilation. When the medulla oblongata is affected, neural regulation of ventilation is impaired, and abnormal breathing patterns develop. Cervical trauma at C3 to C5 usually results in paralysis of the phrenic nerve. When the phrenic nerve is damaged, the diaphragm does not descend properly, thus reducing inspiratory lung volumes and causing hypoxemia. Spinal cord trauma below the C5 vertebra usually leaves the phrenic nerve intact but damages nerves that innervate the intercostal muscles, preventing anteroposterior chest expansion.

Influences of Chronic Lung Disease

Oxygenation decreases as a direct consequence of chronic lung disease. Changes in the anteroposterior diameter of the chest wall (barrel chest) occur because of overuse of accessory muscles and air trapping in COPD or cystic fibrosis. Chronic lung disease often results in varying degrees of dyspnea, tachypnea, hypoxemia and/or hypercapnia ([Ball et al., 2019](#); [Lewis et al., 2017](#); [McCance and Huether, 2019](#)).

Alterations in Respiratory Functioning

Illnesses and conditions affecting ventilation or oxygen transport alter respiratory functioning. The three primary alterations are hypoventilation, hyperventilation, and hypoxia.

The goal of ventilation is to produce a normal arterial carbon dioxide tension (PaCO_2) between 35 and 45 mm Hg and a normal arterial oxygen tension (PaO_2) between 80 and 100 mm Hg. Hypoventilation and hyperventilation are often determined by arterial blood gas analysis ([McCance and Huether, 2019](#)). Hypoxemia refers to a decrease in the amount of arterial oxygen. Nurses monitor arterial oxygen saturation (SpO_2) using a pulse oximeter, a noninvasive oxygen saturation monitor. Normally SpO_2 is greater than or equal to 95% (see [Chapter 30](#)).

Hypoventilation

Hypoventilation occurs when alveolar ventilation is inadequate to meet the oxygen demand of the body or eliminate sufficient carbon dioxide. As alveolar ventilation decreases, the body retains carbon dioxide. For example, atelectasis, a collapse of the alveoli, prevents normal exchange of

oxygen and carbon dioxide. As more alveoli collapse, less of the lung is ventilated, and hypoventilation occurs.

In patients with COPD, the administration of excessive oxygen results in hypoventilation. These patients have adapted to a high carbon dioxide level, so their carbon dioxide–sensitive chemoreceptors do not function normally. Their peripheral chemoreceptors of the aortic arch and carotid bodies are primarily sensitive to lower oxygen levels, causing increased ventilation. Because the stimulus to breathe is a decreased arterial oxygen (PaO_2) level (hypoxic drive to breathe), administration of oxygen greater than 24% to 28% (1 to 3 L/min) prevents the PaO_2 from falling to a level (60 mm Hg) that stimulates the peripheral receptors, thus destroying the stimulus to breathe. The resulting hypoventilation causes excessive retention of carbon dioxide, which can lead to respiratory acidosis and respiratory arrest. Signs and symptoms of hypoventilation include mental status changes, dysrhythmias, and potential cardiac arrest. If untreated, the patient's status rapidly declines, leading to convulsions, unconsciousness, and death (McCance and Huether, 2019).

Hyperventilation

Hyperventilation is a state of ventilation in which the lungs remove carbon dioxide faster than it is produced by cellular metabolism. Severe anxiety, infection, drugs, or an acid-base imbalance induces hyperventilation (see Chapter 42). Acute anxiety leads to hyperventilation and exhalation of excessive amounts of carbon dioxide. Increased body temperature (fever) increases the metabolic rate, thereby increasing carbon dioxide production. The increased carbon dioxide level stimulates an increase in the patient's rate and depth of respiration, causing hyperventilation (McCance and Huether, 2019).

Hyperventilation is sometimes chemically induced. For example, salicylate (aspirin) poisoning and amphetamine use result in excess carbon dioxide production, stimulating the respiratory center to compensate by increasing the rate and depth of respiration. It also occurs as the body tries to compensate for metabolic acidosis. For example, the patient with diabetes in ketoacidosis produces large amounts of metabolic acids. The respiratory system tries to correct the acid-base balance by overbreathing. Ventilation increases to reduce the amount of carbon dioxide available to form carbonic acid (see Chapter 42). This can also result in the patient developing respiratory alkalosis. Signs and symptoms of hyperventilation include rapid respirations, sighing breaths, numbness and tingling of

hands/feet, light-headedness, and loss of consciousness ([McCance and Huether, 2019](#)).

Hypoxia

Hypoxia is inadequate tissue oxygenation at the cellular level. It results from a deficiency in oxygen delivery or oxygen use at the cellular level. It is a life-threatening condition. Untreated, it has the potential to produce fatal cardiac dysrhythmias ([McCance and Huether, 2019](#)).

Causes of hypoxia include (1) a decreased hemoglobin level and lowered oxygen-carrying capacity of the blood; (2) a diminished concentration of inspired oxygen, which occurs at high altitudes; (3) the inability of the tissues to extract oxygen from the blood, as with cyanide poisoning; (4) decreased diffusion of oxygen from the alveoli to the blood, as in pneumonia; (5) poor tissue perfusion with oxygenated blood, as with shock; and (6) impaired ventilation, as with multiple rib fractures or chest trauma ([McCance and Huether, 2019](#)).

The clinical signs and symptoms of hypoxia include apprehension, restlessness (often an early sign), inability to concentrate, decreased level of consciousness, dizziness, and behavioral changes. The patient with hypoxia is unable to lie flat and appears both fatigued and agitated. Vital sign changes include an increased pulse rate and increased rate and depth of respiration. During early stages of hypoxia the blood pressure is elevated unless the condition is caused by shock. As the hypoxia worsens, the respiratory rate declines as a result of respiratory muscle fatigue ([Lewis et al., 2017](#)).

Cyanosis, blue discoloration of the skin and mucous membranes caused by the presence of desaturated hemoglobin in capillaries, is a late sign of hypoxia. The presence or absence of cyanosis is not a reliable measure of oxygen status. Central cyanosis, observed in the tongue, soft palate, and conjunctiva of the eye where blood flow is high, indicates hypoxemia. Peripheral cyanosis, seen in the extremities, nail beds, and earlobes, is often a result of vasoconstriction and stagnant blood flow ([Ball et al., 2019](#); [Lewis et al., 2017](#)).

Alterations in Cardiac Functioning

Illnesses and conditions affecting cardiac rhythm, strength of contraction, blood flow through the heart or to the heart muscle, and decreased peripheral circulation alter cardiac function. Older adults have structural changes in the heart, including vascular and valve stiffening, increased left

ventricular wall thickness, and fibrosis. In addition, there are changes in the conduction system. Fat accumulates around the SA node, sometimes creating a partial or complete separation of the node from the atrial tissue. A pronounced decline in the number of pacemaker cells occurs after 60 years of age ([Strait and Lakatta, 2012](#); [Touhy and Jett, 2018](#)).

Disturbances in Conduction

Electrical impulses that do not originate from the SA node cause conduction disturbances. These rhythm disturbances are called dysrhythmias, meaning a deviation from the normal sinus heart rhythm. Dysrhythmias occur as a primary conduction disturbance such as in response to ischemia; valvular abnormality; anxiety; drug toxicity; caffeine, alcohol, or tobacco use; or a complication of acid-base or electrolyte imbalance (see [Chapter 42](#)).

Dysrhythmias are classified by cardiac response and site of impulse origin. Cardiac response is tachycardia (greater than 100 beats/min), bradycardia (less than 60 beats/min), a premature (early) beat, or a blocked (delayed or absent) beat. Tachydysrhythmias and bradydysrhythmias lower cardiac output and blood pressure. Tachydysrhythmias reduce cardiac output by decreasing diastolic filling time. Bradydysrhythmias lower cardiac output because of the decreased heart rate ([McCance and Huether, 2019](#); [Urden et al., 2020](#)).

Atrial fibrillation is a common dysrhythmia in older adults. The electrical impulse in the atria is chaotic and originates from multiple sites. The rhythm is irregular because of the multiple pacemaker sites and the unpredictable conduction to the ventricles. The QRS complex is normal; however, it occurs at irregular intervals. Atrial fibrillation is often described as an irregularly irregular rhythm. It decreases cardiac output by altering preload and contractility ([Hartjes, 2018](#); [McCance and Huether, 2019](#); [Urden et al., 2020](#)).

Abnormal impulses originating above the ventricles are supraventricular dysrhythmias. The abnormality on the waveform is the configuration and placement of the P wave. Ventricular conduction usually remains normal, and there is a normal QRS complex. Paroxysmal supraventricular tachycardia is a sudden, rapid onset of tachycardia originating above the AV node. It often begins and ends spontaneously. Sometimes excitement, fatigue, caffeine, smoking, or alcohol use precipitates paroxysmal supraventricular tachycardia ([McCance and Huether, 2019](#); [Urden et al., 2020](#)).

Ventricular dysrhythmias represent an ectopic site of impulse formation within the ventricles. It is ectopic in that the impulse originates in the ventricle, not the SA node. The configuration of the QRS complex is usually widened and bizarre. P waves are not always present; often they are buried in the QRS complex. **Ventricular tachycardia** and **ventricular fibrillation** are life-threatening rhythms that require immediate intervention. Ventricular tachycardia is a life-threatening dysrhythmia because of the decreased cardiac output and the potential to deteriorate into ventricular fibrillation or sudden cardiac death ([Hartjes, 2018](#); [Urden et al., 2020](#)).

Altered Cardiac Output

Failure of the myocardium to eject sufficient volume to the systemic and pulmonary circulations occurs in heart failure. Primary coronary artery disease, cardiomyopathy, valvular disorders, and pulmonary disease lead to myocardial pump failure ([McCance and Huether, 2019](#); [Urden et al., 2020](#)).

Left-Sided Heart Failure

Left-sided heart failure is an abnormal condition characterized by decreased functioning of the left ventricle. If left ventricular failure is significant, the amount of blood ejected from the left ventricle drops greatly, resulting in decreased cardiac output. Signs and symptoms include fatigue, breathlessness, dizziness, and confusion as a result of tissue hypoxia from the diminished cardiac output. As the left ventricle continues to fail, blood begins to pool in the pulmonary circulation, causing pulmonary congestion. Clinical findings include crackles in the bases of the lungs on auscultation, hypoxia, shortness of breath on exertion, cough, and paroxysmal nocturnal dyspnea ([Hartjes, 2018](#); [McCance and Huether, 2019](#)).

Right-Sided Heart Failure

Right-sided heart failure results from impaired functioning of the right ventricle. It more commonly results from pulmonary disease or as a result of long-term left-sided failure. The primary pathological factor in right-sided failure is elevated pulmonary vascular resistance (PVR). As the PVR continues to rise, the right ventricle works harder, and the oxygen demand of the heart increases. As the failure continues, the amount of blood ejected from the right ventricle declines, and blood begins to “back up” in the

systemic circulation. Clinically the patient has systemic symptoms, such as weight gain, distended neck veins, hepatomegaly and splenomegaly, and dependent peripheral edema (Hartjes, 2018; McCance and Huether, 2019).

Impaired Valvular Function

Valvular heart disease is an acquired or congenital disorder of a cardiac valve that causes either hardening (stenosis) or impaired closure (regurgitation) of the valves. When stenosis occurs, the flow of blood through the valves is obstructed. For example, when stenosis occurs in the semilunar valves (aortic and pulmonic valves), the adjacent ventricles have to work harder to move the ventricular blood volume beyond the stenotic valve. Over time the stenosis causes the ventricle to hypertrophy (enlarge), and if the condition is untreated, left- or right-sided heart failure occurs. When regurgitation occurs, there is a backflow of blood into an adjacent chamber. For example, in mitral regurgitation the mitral leaflets do not close completely. When the ventricles contract, blood escapes back into the atria, causing a murmur, or “whooshing” sound (see Chapter 30) (Hartjes, 2018; McCance and Huether, 2019).

Myocardial Ischemia

Myocardial ischemia results when the supply of blood to the myocardium from the coronary arteries is insufficient to meet myocardial oxygen demands. Two common outcomes of this ischemia are angina pectoris and myocardial infarction (Hartjes, 2018; McCance and Huether, 2019).

Angina

Angina pectoris is a transient imbalance between myocardial oxygen supply and demand. The condition results in chest pain that is aching, sharp, tingling, or burning or that feels like pressure. Typically, chest pain is left sided or substernal and often radiates to the left or both arms, the jaw, neck, and back. In some patients, angina pain does not radiate. It usually lasts from 3 to 5 minutes. Patients report that it is often precipitated by activities that increase myocardial oxygen demand (e.g., eating heavy meals, exercise, or stress). It is usually relieved with rest and coronary vasodilators, the most common being a nitroglycerin preparation (McCance and Huether, 2019).

Myocardial Infarction

Myocardial infarction (MI) or acute coronary syndrome (ACS) results from sudden decreases in coronary blood flow or an increase in myocardial oxygen demand without adequate coronary perfusion. Infarction occurs because ischemia is not reversed. Cellular death occurs after 20 minutes of myocardial ischemia (McCance and Huether, 2019).

Chest pain associated with MI in men is usually described as crushing, squeezing, or stabbing. The pain is often in the left chest and sternal area; may be felt in the back; and radiates down the left arm to the neck, jaws, teeth, epigastric area, and back. It occurs at rest or exertion and lasts more than 20 minutes. Rest, position change, or sublingual nitroglycerin administration does not relieve the pain (Hartjes, 2018; McCance and Huether, 2019).

There are differences between men and women in relation to coronary artery disease. As women get older, their risk of heart disease begins to rise, making it the leading cause of death for women in the United States. Women on average have greater blood cholesterol and triglyceride levels than men. Obesity in women is more prevalent, which also increases risk for diabetes and cardiac disease. Women's symptoms differ from those of men. The most common initial symptom in women is angina, but they also present with atypical symptoms such as fatigue, indigestion, shortness of breath, and back or jaw pain. Women have twice the risk of dying within the first year after a heart attack than men (CDC, 2019a; 2017Ball et al., 2019; Lewis et al.,).

REFLECT NOW

You are caring for a patient who was recently told he has decreased cardiac output due to atrial fibrillation. How would you describe cardiac output, the conduction system, and this dysrhythmia to the patient?

Nursing Knowledge Base

Factors Influencing Oxygenation

In addition to physiological factors, multiple developmental, lifestyle, and environmental factors affect patients' oxygenation status. It is important to recognize these as possible risks or factors that impact their health care goals.

Developmental Factors

The developmental stage of a patient and the normal aging process affect tissue oxygenation.

Infants and Toddlers

Healthy full-term infants younger than 3 months of age are presumed to have a lower infection rate because of the protective function of maternal antibodies. The infection rate increases in infants from 3 to 6 months of age. Infants and toddlers are at risk for upper respiratory tract infections, especially when they are exposed to secondhand smoke or other children. Upper respiratory tract infections are usually not dangerous, and infants and toddlers recover with little difficulty. Infants and toddlers are also at risk for airway obstruction because of their anatomically smaller airways and their tendency to place foreign objects in their mouths ([Hockenberry et al., 2019](#)).

School-Age Children and Adolescents

School-age children and adolescents are exposed to respiratory infections and respiratory risk factors such as cigarette smoking or secondhand smoke. This age-group is also at risk for experimenting with cigarette smoking and other recreational inhalants. A healthy child usually does not have adverse pulmonary effects from respiratory infections. The [CDC \(2018b\)](#) reported that 5.6% of middle school-age children and 19.6% of high school-age children use tobacco products, with electronic cigarettes being the most commonly used tobacco product among these age-groups. However,

current cigarette smoking among middle school- and high school-age children has declined (CDC, 2018b). School-age children and adolescents possess other cardiopulmonary disease risk factors such as obesity, inactive lifestyles, unhealthy diets, and excessive use of caffeinated beverages or other energy drinks (Hockenberry et al., 2019).

Young and Middle-Age Adults

Young and middle-age adults are exposed to multiple cardiopulmonary risk factors: an unhealthy diet, lack of exercise, stress, over-the-counter and prescription drugs not used as intended, illegal substances, and smoking. Reducing these modifiable factors decreases a patient's risk for cardiac or pulmonary diseases. This is also the time when individuals establish lifelong habits and lifestyles. It is important to help your patients make good choices and informed decisions about their health care practices. The increased cost of cigarettes plus the states' smoke-free air policies, laws that reduce smoking in public places, and access to cessation programs and medications have proven to be helpful in smoking cessation (CDC, 2018a).

Older Adults

The cardiac and respiratory systems undergo changes throughout the aging process (Box 41.1). The changes are associated with calcification of the heart valves, vascular stiffening and increased left ventricular wall thickness, fewer SA nodes, and costal cartilage stiffening. The arterial system develops atherosclerotic plaques.

Box 41.1 Focus on Older Adults **Cardiopulmonary Implication in Older Adults**

- The tuberculin skin test is an unreliable indicator of tuberculosis in older patients. They frequently display false-positive or false-negative skin test reactions.

- Older patients are at an increased risk for reactivation of dormant organisms that were present for decades as a result of age-related changes in the immune system.
- The standard 5-TU Mantoux test is given and repeated or repeated with the 250-TU strength to create a booster effect. If the older patient has a positive reaction, a complete history is necessary to determine any risk factors.
- Cardiac problems differ from other chronic conditions in that when they become acute, symptoms worsen rapidly and necessitate hospitalization, whereas other chronic conditions can be managed in the home (Touhy and Jett, 2018).
- Controlling blood pressure in older adults results in 30% fewer strokes, 64% less heart failure, 23% fewer fatal cardiac events, and 21% fewer cardiac-related deaths (Touhy and Jett, 2018).
- Mental status changes are often the first signs of cardiac and/or respiratory problems and often include forgetfulness and irritability.
- Changes in the older adult's cough mechanism lead to retention of pulmonary secretions, airway plugging, and atelectasis if patients do not use cough suppressants with caution.
- Age-related changes in the immune system lead to a decline of both cell-mediated and humoral immunity, resulting in an increased risk of respiratory infections (McCance and Huether, 2019).
- Changes in the thorax that occur from ossification of costal cartilage, decreased space between vertebrae, and diminished respiratory muscle strength lead to problems with chest expansion and oxygenation (Touhy and Jett, 2018).

Osteoporosis leads to changes in the size and shape of the thorax. The trachea and large bronchi become enlarged from calcification of the airways. The alveoli enlarge, decreasing the surface area available for gas exchange. The number of functional cilia is reduced, causing a decrease in the effectiveness of the cough mechanism, putting the older adult at increased risk for respiratory infections (Touhy and Jett, 2018).

Lifestyle Factors

Lifestyle modifications are difficult for patients because they often have to change an enjoyable habit such as cigarette smoking or eating certain foods. Risk-factor modification is important and includes smoking cessation, weight reduction, a low-cholesterol and low-sodium diet, management of hypertension, and moderate exercise (see [Chapter 6](#)). Although it is difficult to change long-term behavior, helping patients acquire healthy behaviors reduces the risk for or slows or halts the progression of cardiopulmonary diseases.

Nutrition

Good nutrition affects cardiopulmonary function by supporting normal metabolic functions. A poor diet leads to risk factors affecting the heart and lungs. Without essential nutrients, a patient may experience respiratory muscle wasting, resulting in decreased muscle strength and respiratory excursion. Cough efficiency is reduced secondary to respiratory muscle weakness, putting a patient at risk for retention of pulmonary secretions. A patient with chronic lung disease often requires a diet higher in calories and smaller, more frequent meals due to the increased work of breathing. A diet with a moderate amount of carbohydrates is recommended to prevent an increase in carbon dioxide production. Obesity affects the respiratory and cardiovascular systems. It can lead to a decrease in lung expansion and an increase in oxygen demand to meet metabolic demands ([Lewis et al., 2017](#)).

Dietary practices also influence the prevalence of cardiovascular diseases (see [Chapter 45](#)). Patients with nutritional alterations are at risk for anemia, which reduces the oxygen-carrying capacity of the blood and can alter cardiac output. Cardioprotective nutrition includes diets rich in fiber; whole grains; fresh fruits and vegetables; nuts; antioxidants; lean meats, fish, and chicken; and omega-3 fatty acids. A diet of fruits, vegetables, and low-fat dairy foods that are high in fiber, potassium, calcium, and magnesium and low in saturated and total fat helps prevent and reduce the effects of hypertension ([Lewis et al., 2017](#)).

Hydration

Fluid intake is essential for cellular health. Fluid volume overload may lead to vascular congestion in patients with heart, kidney, or lung diseases and impair the body's ability to deliver oxygen to the tissues. Dehydration or fluid volume deficit may result in dizziness, fainting, hypotension, or a thickening of respiratory secretions, which makes it difficult for a patient to expectorate secretions (Lewis et al., 2017).

Exercise

Exercise increases the metabolic activity and oxygen demand of the body. The rate and depth of respiration increase, enabling the person to inhale more oxygen and exhale excess carbon dioxide. A physical exercise program has many benefits (see Chapter 38). People who exercise for 30 to 60 minutes daily have a lower pulse rate and blood pressure, decreased cholesterol level, increased blood flow, and greater oxygen extraction by working muscles (Lewis et al., 2017).

Smoking

Cigarette smoking and secondhand smoke are associated with a number of diseases, including heart disease, COPD, and lung cancer. Cigarette smoking worsens peripheral vascular and coronary artery diseases. Inhaled nicotine causes vasoconstriction of peripheral and coronary blood vessels, increasing blood pressure and decreasing blood flow to peripheral vessels (McCance and Huether, 2019).

Women who take birth control pills and smoke cigarettes have an increased risk for thrombophlebitis and pulmonary emboli. Smoking during pregnancy can result in low-birth-weight babies, preterm delivery, and babies with reduced lung function (CDC, 2018c).

Smoking accounts for approximately 30% of all cancer deaths in the United States, including 80% of all lung cancer deaths. Smoking has been linked to the development of other cancers, including mouth, esophagus, liver, bladder, kidney, cervix, and myeloid leukemia (ACS, 2018). Nicotine patches, gum, and lozenges are available over the counter, and nicotine nasal spray and inhalers can be obtained by prescription. Prescription drugs such as bupropion

and varenicline are also available to help people quit smoking ([ACS, 2017](#)).

Exposure to environmental tobacco smoke (secondhand smoke) increases the risk of lung cancer and cardiovascular disease in the nonsmoker. Children with parents who smoke have a higher incidence of asthma, pneumonia, and ear infections. Infants exposed to secondhand smoke are at higher risk for sudden infant death syndrome ([NCI, 2018](#)).

Substance Abuse

Excessive use of alcohol and other illicit drugs impairs tissue oxygenation in two ways. First, the person who chronically abuses substances often has a poor nutritional intake. With the resultant decrease in intake of iron-rich foods, hemoglobin production declines. Second, excessive use of alcohol and certain other drugs depresses the respiratory center, reducing the rate and depth of respiration and the amount of inhaled oxygen. Substance abuse by either smoking or inhaling substances such as crack cocaine or fumes from paint or glue cans causes direct injury to lung tissue that leads to permanent lung damage ([McCance and Huether, 2019](#)). The report on inhalant abuse (huffing) by teenagers to get a euphoric effect includes use of a wide variety of substances such as paint thinner, nail polish remover, glue, spray paint, nitrous oxide, and other common household products. Sudden death can occur from cardiac arrhythmias, or chronic abuse can cause damage to heart, lungs, and kidneys ([NIDA, 2017](#)).

Stress

Stress is a perceived threat that results in sympathetic stimulation. Continuous stress adversely affects a patient's health and well-being (see [Chapter 37](#)). A continuous state of stress increases the metabolic rate and oxygen demand of the body. The body responds to stress with an increased rate and depth of respiration and increased cardiac output. Stress causes an increased release of cortisol, which affects the metabolism of fat and creates a risk for CAD and hypertension. Stressors can be a trigger for asthma exacerbations.

Patients with chronic illnesses or life-threatening illnesses cannot tolerate the oxygen demands associated with stress (Huether and McCance, 2017).

Environmental Factors

The environment influences oxygenation. The prevalence of COPD is higher in rural areas versus those who live in urban areas (CDC, 2018f). In addition, a patient's workplace sometimes increases the risk for pulmonary disease. Occupational pollutants include asbestos, talcum powder, dust, and airborne fibers. For example, farm workers in dry regions of the southwestern United States are at risk for coccidioidomycosis, a fungal disease caused by inhalation of spores of the airborne bacterium *Coccidioides immitis* (CDC, 2019b). Asbestosis is an occupational lung disease that develops after exposure to asbestos. The lung with asbestosis often has diffuse interstitial fibrosis, creating a restrictive lung disease. Patients exposed to asbestos are at risk for developing lung cancer, and this risk increases with exposure to tobacco smoke (McCance and Huether, 2019).

Critical Thinking

Successful critical thinking requires a synthesis of knowledge, experience, information gathered from patients, critical thinking attitudes, and intellectual and professional standards. Clinical judgments require you to anticipate information, analyze the data, and make decisions regarding your patient's care. During assessment consider all elements that build toward making an appropriate nursing diagnosis ([Fig. 41.4](#)).

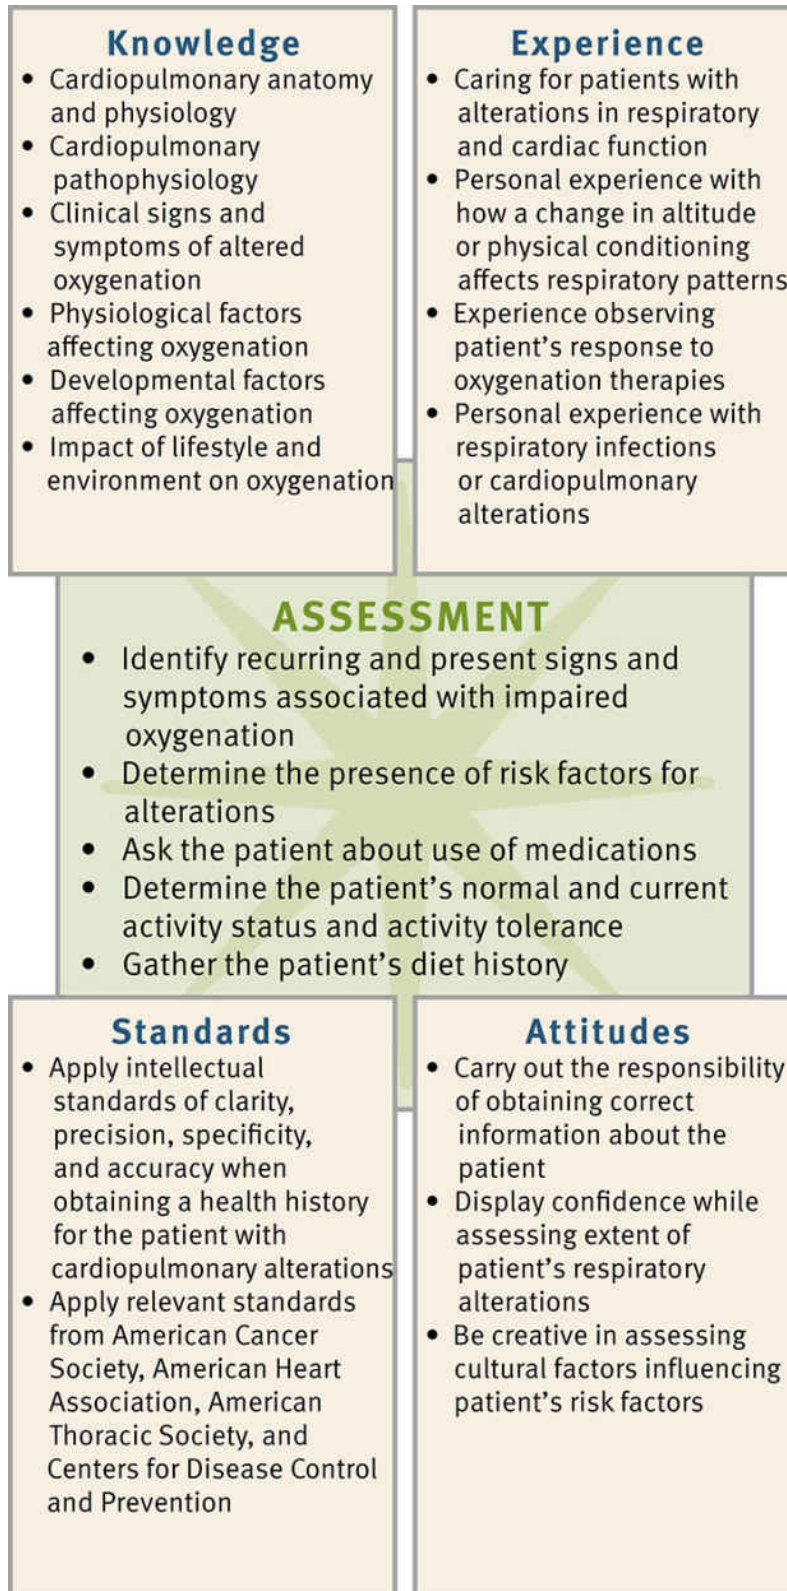

FIG. 41.4 Critical thinking model for oxygenation assessment.

To understand how alterations in oxygenation affect patients and your selection of appropriate interventions, you need to integrate knowledge from nursing and other disciplines and information gathered from patients. Critical thinking attitudes ensure that you approach patient care in a methodical and logical way. The use of professional standards such as The American Association for Respiratory Care (AARC) and the American Nurses Association (ANA) provide valuable guidelines for care and management of patients (see [Fig. 41.4](#)).

REFLECT NOW

You are preparing to teach a group of young adults about lifestyle and its correlation to heart and lung disease. What information would you include in the teaching plan specific to this population? Compare this teaching plan to education that you would provide to a group of middle-age adults. How would it differ? Would content change?

◆ Nursing Process

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care.

◆ Assessment

During the assessment process, thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care. Nursing assessment of cardiopulmonary functioning includes an in-depth history of a patient's normal and present cardiopulmonary function, past impairments in circulatory or respiratory functioning, and methods that a patient uses to optimize oxygenation. The nursing history includes a review of drug, food, and other allergies. Physical examination of a patient's cardiopulmonary status reveals the extent of existing signs and symptoms (Ball et al., 2019) (see Chapter 30). Utilizing assessment values of pulse oximetry and capnography aids in the assessment of patients with spontaneous breathing, intubated patients, and patients requiring oxygen therapy or mechanical ventilation. Pulse oximetry provides an instant feedback about the patient's level of oxygenation. **Capnography**, also known as *end-tidal CO₂ monitoring*, provides instant information about the patient's ventilation (how effectively CO₂ is being eliminated by the pulmonary system), perfusion (how effectively CO₂ is being transported through the vascular system), and how effectively CO₂ is produced by cellular metabolism (Hartjes, 2018; Urden et al., 2020). Capnography is measured near the end of exhalation. Finally, a review of laboratory and diagnostic test results provides valuable assessment data.

Through the Patient's Eyes

Ask patients about their priorities and what they expect from their health care visit. Identifying their expectations regarding their health, symptoms, and treatment plan involves patients in the decision-making process and helps them participate in their care. For example, planning a smoking-cessation program for a patient who is not ready for the change is frustrating for both the patient and you. Establish realistic, short-term outcomes that build to a larger goal. For example, tobacco-cessation

treatments are effective, but a patient needs to be willing to participate in the program and may need to use several strategies to be successful. Educating the patient on the opportunities for individual, group, or telephone counseling and identifying a social support system give more individual choices when developing the cessation plan. After this is determined, the various nicotine and non-nicotine medications for treatment of tobacco dependence can be discussed to find one that may fit the patient's lifestyle. A combination of counseling and medication is more effective than either one alone (CDC, 2017a).

Remember that your goals and expectations do not always coincide with those of your patient. By addressing a patient's concerns and expectations, you establish a relationship that addresses other health care goals and expected outcomes. Knowing your patients' mind-sets and respecting their wishes go a long way in helping them make significant beneficial lifestyle changes.

Nursing History

The nursing history focuses on the patient's ability to meet oxygen needs and maintain cardiorespiratory health. The nursing history for respiratory function includes the presence of a cough, shortness of breath, dyspnea, wheezing, pain, environmental exposures, frequency of respiratory tract infections, pulmonary risk factors, past respiratory problems, current medication use, and smoking history or secondhand smoke exposure. The nursing history for cardiac function includes pain and characteristics of pain, fatigue, peripheral circulation, cardiac risk factors, diet, and the presence of past or concurrent cardiac conditions. Ask specific questions related to cardiopulmonary disease (Box 41.2).

Box 41.2 Nursing Assessment Questions

Nature of the Cardiopulmonary Problem

- Describe the problem that you're having with your heart.
- Does the problem (e.g., chest pain, rapid heart rate) occur at a specific time of the day, during or after exercise, or all the time?
- Do you notice abnormal beats?
- If you have chest pain, what relieves or makes the pain worse?

Questions to Ask Associated With Breathing

- Describe the breathing problems you are having.
- How has your breathing pattern changed?
- Do you have a cough? Is the coughing increasing? Is it worse at a certain time of day?
- Describe your cough. Is it dry or moist? Do you have sputum with coughing? Is this different in color, volume, or thickness?
- On a scale of 0 to 10, with 10 being the most severe, rate your shortness of breath. What helps your shortness of breath?

Questions to Ask Related to Chest Pain

- If you are having chest pain, what causes the pain and how long does it last? Is this a different type of pain? Can you show me where the pain is located?
- Does the chest pain occur with coughing?
- On a scale of 0 to 10, with 0 being no pain and 10 being the most severe pain, rate your chest pain at its worst. Is the pain different today?

Questions to Ask Regarding Predisposing Factors

- Have you been exposed to a cold or flu or other respiratory illnesses?
- Tell me the medications you are taking. Are you taking over-the-counter medications or supplements? If so, what are they?
- Do you smoke? Have you been exposed to secondhand smoke?
- Have you been doing any unusual exercises?

Questions to Ask Regarding Effect of Symptoms

- Describe for me a typical daily diet.
- Tell me how your symptoms affect daily activities, your appetite, sleeping, and exercise routine.

Health Risks

Determine familial risk factors such as a family history of lung cancer or cardiovascular disease. Documentation includes blood relatives who had cardiopulmonary disease and their present level of health or age at time of death. Assess for an exposure to infectious organisms, such as tuberculosis (TB). Occupational and environment risk factors (e.g., asbestos exposure) should also be addressed ([Ball et al., 2019](#); [McCance and Huether, 2019](#)).

Pain

The presence of chest pain requires an immediate thorough assessment, including location, duration, radiation, and frequency. In addition, it is important to note any other symptoms associated with chest pain, such as nausea, diaphoresis, extreme fatigue, or weakness. Cardiac pain does not occur with respiratory variations. Chest pain in men is most often on the left side of the chest and radiates to the left arm. Chest pain in women is much less definitive and is often a sensation of breathlessness, jaw or back pain, nausea, and/or fatigue (CDC, 2019a). Pericardial pain results from inflammation of the pericardial sac, occurs on inspiration, and does not usually radiate ([Ball et al., 2019](#)).

Pleuritic chest pain results from inflammation of the pleural space of the lungs; the pain is peripheral and radiates to the scapular regions. Inspiratory maneuvers such as coughing, yawning, and sighing worsen pleuritic chest pain. Patients usually describe it as knifelike, lasting from a minute to hours and always in association with inspiration. Musculoskeletal pain is often present following exercise, rib trauma, and prolonged coughing episodes. Inspiration worsens this pain, and patients often confuse it with pleuritic chest pain ([Ball et al., 2019](#)).

Fatigue

Fatigue is a subjective sensation in which a patient reports a loss of endurance. Fatigue in the patient with cardiopulmonary alterations is often an early sign of a worsening of the chronic underlying process. To provide an objective measure of fatigue, ask the patient to rate it on a scale of 0 to 10, with 10 being the worst level and 0 representing no fatigue. Ask your patients when they noticed the fatigue, what makes it better or worse, if the onset was sudden or gradual, if it is worse in the morning or later in the day, and how the fatigue affects what they want to do ([Ball et al., 2019](#); [Lewis et al., 2017](#)).

Dyspnea

Dyspnea is associated with hypoxia. It is the subjective sensation of difficult or uncomfortable breathing or observed labored breathing with shortness of breath. Dyspnea is usually associated with exercise or excitement, but in some patients, it is present without any relation to activity or exercise. It is associated with many conditions, such as pulmonary diseases, cardiovascular diseases, neuromuscular conditions, and anemia. In addition, it occurs in the pregnant woman in the final months of pregnancy. Finally, environmental factors such as pollution, cold air, and smoking also cause or worsen dyspnea (Ball et al., 2019).

When gathering information about a patient's sensation of dyspnea, ask the patient when the dyspnea occurs (such as with exertion, stress, or respiratory tract infection) and what improves the dyspnea (e.g., rest, inhaled medication, or position change). Determine whether the patient's dyspnea affects the ability to lie flat. **Orthopnea** is an abnormal condition in which a patient uses multiple pillows when reclining to breathe easier or sits leaning forward with arms elevated. The number of pillows used usually helps to quantify the orthopnea (e.g., two- or three-pillow orthopnea). Also ask whether the patient must sleep in a recliner chair to breathe easier. Paroxysmal nocturnal dyspnea (PND) occurs when a patient is sleeping. The patient often awakens in a panic, feels as if he or she is suffocating, and has a strong need to sit up to relieve the breathlessness (Ball et al., 2019).

Cough

Coughing is a protective reflex to clear the trachea, bronchi, and lungs of irritants and secretions. Patients with a chronic cough tend to deny, underestimate, or minimize their coughing, often because they are so accustomed to it that they are unaware of its frequency (Ball et al., 2019).

If a patient has a cough, determine the onset of the cough, how frequently it occurs, and whether it is productive or nonproductive. Chronic coughs are often a sign of chronic lung disease, whereas acute coughs can be a sign of infection or an inhaled irritant. A nonproductive cough is often associated with allergies or gastroesophageal reflux disease. A productive cough results in sputum production (e.g., material coughed up from the lungs that a patient swallows or expectorates). Sputum contains mucus, cellular debris, microorganisms, and sometimes pus or blood. Collect data about the type and quantity of sputum. Instruct patients to try to cough up some sputum and not to simply clear the

throat, which produces only saliva. Have the patient cough into a specimen cup. Inspect the sputum for color (such as green or blood tinged), consistency (such as thin or thick), odor (none or foul), and amount in tablespoons or milliliters (Ball et al., 2019).

If **hemoptysis** (bloody sputum) is present, determine whether it is associated with coughing and bleeding from the upper respiratory tract, sinus drainage, or the gastrointestinal tract (**hematemesis**). Hemoptysis has an alkaline pH, and hematemesis has an acidic pH; thus, pH testing of the specimen may help to determine the source (McCance and Huether, 2019). Describe hemoptysis according to amount and color and whether it is mixed with sputum. Note whether the patient is on anticoagulant therapy. When there is bloody or blood-tinged sputum, health care providers frequently perform diagnostic tests such as examination of sputum specimens, chest x-ray examinations, **bronchoscopy**, and other scans.

Environmental and Occupational Exposures

Environmental exposure to inhaled substances, such as smog, dust, silicon, mold, cockroaches, pet dander, and asbestos, is closely linked with respiratory disease. Investigate exposures in the patient's home, workplace, and recent travel. In addition, determine whether a patient who is a nonsmoker is exposed to secondhand smoke (ATSDR, 2016; McCance and Huether, 2019).

Carbon monoxide (CO) poisoning often results from an improperly vented furnace flue or fireplace. The patient will have vague complaints of general malaise, flulike symptoms, and excessive sleepiness. Patients are particularly at risk in the late fall when they turn the furnace on or begin to use the fireplace again (CDC, 2018d). Ask whether there is a CO detector in the home.

Radon gas is a radioactive substance from the breakdown of uranium in soil, rock, and water that enters homes through the ground or well water. When homes are poorly ventilated, this gas is unable to escape and becomes trapped. If a patient who smokes also lives in a home with a high radon level, the risk for lung cancer is very high (EPA, 2016). Ask whether the patient has any radon detectors in the home.

Smoking

It is important to determine a patient's direct and secondary exposure to tobacco. Ask about any history of smoking; include the number of years

smoked and the number of packages smoked per day. This is recorded as pack-year history (packages per day × years smoked). For example, if a patient smoked two packs a day for 20 years, the patient has a 40 pack-year history. Determine exposure to secondhand smoke, because any form of tobacco exposure increases a patient's risk for cardiopulmonary diseases ([ALA, 2019a](#)).

Respiratory Infections

Obtain information about a patient's frequency and duration of respiratory tract infections. Although everyone occasionally has a cold, for some people it results in bronchitis or pneumonia. On average, patients have four colds per year. Determine if and when a patient has had a pneumococcal or influenza (flu) vaccine. This is especially important when assessing older adults because of their increased risk for respiratory disease ([Touhy and Jett, 2018](#)). Ask about any known exposure to tuberculosis (TB) and the date and results of the last tuberculin skin test.

Determine a patient's risk for human immunodeficiency virus (HIV) infection. Patients with a history of intravenous (IV) drug use and multiple unprotected sex partners are at risk of developing HIV infection. Patients do not always display symptoms of HIV infection until they present with *Pneumocystis* or *Mycoplasma pneumoniae*. Patients with HIV/AIDS (acquired immunodeficiency syndrome) or other immunocompromised states are at increased risk for respiratory infections ([McCance and Huether, 2019](#)).

Allergies

Inquire about your patient's exposure to airborne allergens (e.g., pet dander, pollen, or mold). The allergic response is often watery eyes, sneezing, runny nose, or respiratory symptoms such as cough or wheezing. When obtaining information from the patient, ask specific questions about the type of allergens, response to these allergens, and successful and unsuccessful relief measures. In addition, determine the effect of environmental air quality and secondhand smoke exposure on the patient's allergy and symptoms. Safe nursing practice also includes obtaining information about food, drug, or insect sting allergies on the initial history and physical. However, always double-check this information with the patient on any subsequent assessment, especially concerning respiratory allergens ([Ball et al., 2019](#)).

Medications

Another component of the nursing history includes determining all the medications that a patient is using. These include prescribed medications, over-the-counter medications, folk medicine, herbal medicines, alternative therapies, and illicit drugs and substances. Some of these preparations have adverse effects by themselves or because of interactions with other drugs (Ball et al., 2019). For example, a person using a prescribed bronchodilator drug may choose to use an over-the-counter inhalant as well. Many of these contain ephedrine or *ma huang*, a natural ephedrine, which acts like epinephrine. This product reacts with the prescribed medication by potentiating or decreasing the effect of the prescribed medication. Patients taking warfarin (Coumadin) for blood thinning prolong the prothrombin time (PT)/international normalized ratio (INR) results if they are taking ginkgo biloba, garlic, or ginseng with the anticoagulant. The drug interaction can precipitate a life-threatening bleed (Lewis et al., 2017).

It is important to determine whether a patient uses illicit drugs. Inhaled opioids, which are often diluted with talcum powder, cause pulmonary disorders resulting from the irritant effect of the powder on lung tissues. Marijuana is usually smoked in the form of a joint or pipe. Marijuana smoke is an irritant to the lungs, putting users at higher risk for respiratory illnesses (NIDA, 2018a). Cocaine is snorted through the nose, placed on the gums, smoked, or injected. Cocaine abusers can have acute cardiovascular changes such as constricted blood vessels and increased heart rate and blood pressure. People who use the inhaled form of cocaine often develop respiratory infections such as pneumonia. Cocaine deaths are often caused by heart attack or stroke (NIDA, 2018b).

As with all medications, assess the patient's knowledge and ability to self-administer medications correctly (see Chapter 31). Of particular importance is the assessment that the patient understands the potential side effects of medications. Patients need to recognize adverse reactions and be aware of the dangers in combining prescribed medications with over-the-counter drugs.

Physical Examination

The physical examination includes assessment of the cardiopulmonary system (see Chapter 30). Give special consideration when assessing an older adult patient for changes that occur with the aging process (Table 41.1). These changes affect the patient's activity tolerance and level of fatigue or cause transient changes in vital signs and are not always associated with a specific cardiopulmonary disease.

TABLE 41.1**Effects of Aging on Cardiopulmonary Assessment Findings**

Function	Pathophysiological Change	Key Clinical Findings
Heart		
Muscle contraction	Thickening of the ventricular wall, increased collagen and decreased elastin in the heart muscle	Decreased cardiac output (edema, dyspnea, activity intolerance, inability to lie flat for extended time)
Blood flow	Heart valves become thicker and stiffer, more often in the mitral and aortic valves	Systolic ejection murmur
Conduction system	SA node becomes fibrotic from calcification; decrease in number of pacemaker cells in SA node	Increased P-R, QRS, and Q-T intervals, decreased amplitude of QRS complex; tachycardia more poorly tolerated
Arterial vessel compliance	Calcified vessels, loss of arterial distensibility, decreased elastin in vessel walls, more tortuous vessels	Hypertension with an increase in systolic blood pressure.
Lungs		
Breathing mechanics	Decreased chest wall compliance, loss of elastic recoil Decreased respiratory muscle mass/strength	Prolonged exhalation phase Decreased vital capacity Activity intolerance
Oxygenation	Decreased alveolar surface area Decreased carbon dioxide diffusion capacity	Decreased PaO ₂ Slightly increased PaCO ₂
Breathing control/breathing pattern	Decreased responsiveness of central and peripheral chemoreceptors to hypoxemia and hypercapnia	Increased respiratory rate Decreased tidal volume
Lung defense mechanisms	Decreased number of cilia Decreased IgA production and humoral and cellular immunity Drier mucus membranes	Decreased airway clearance Diminished cough reflex Increased risk for infection
Sleep and breathing	Decreased respiratory drive Decreased tone of upper airway muscles	Increased risk of aspiration and respiratory infection Snoring, obstructive sleep apnea

IgA, Immunoglobulin A; PaCO₂, arterial carbon dioxide tension; PaO₂, arterial oxygen tension; SA, sinoatrial. (Data from Ball J, et al: *Seidel's guide to physical examination*, ed 9, St Louis, 2019, Elsevier, and Touhy T, Jett K: *Gerontological nursing and healthy aging*, ed 5, St Louis, 2018, Elsevier.)

Inspection

Using inspection techniques, perform a head-to-toe observation of the patient for skin and mucous membrane color, general appearance, level of consciousness, adequacy of systemic circulation, breathing patterns, and chest wall movement (Table 41.2). Investigate any abnormalities further during palpation, percussion, and auscultation.

TABLE 41.2**Inspection of Cardiopulmonary Status**

Abnormality	Cause
Eyes	
Xanthelasma (yellow lipid lesions on eyelids)	Hyperlipidemia
Pale conjunctivae	Anemia
Cyanotic conjunctivae	Hypoxemia
Petechiae on conjunctivae	Fat embolus or bacterial endocarditis
Nose	
Flaring nares	Air hunger, dyspnea
Mouth and Lips	
Cyanotic mucous membranes	Decreased oxygenation (hypoxia)
Pursed-lip breathing	Associated with chronic lung disease
Pallor	Anemia
Neck Veins	
Distention	Associated with right-sided heart failure
Chest	
Retractions	Increased work of breathing, dyspnea
Asymmetry	Chest wall injury
Barrel chest	COPD; may be normal in some older adults.
Fingertips and Nail Beds	
Cyanosis	Decreased cardiac output or hypoxia
Splinter hemorrhages	Infective endocarditis
Clubbing of nail beds	Chronic hypoxemia
Skin	
Peripheral cyanosis	Vasoconstriction and diminished blood flow; cold environment
Central cyanosis	Hypoxemia
Decreased skin turgor	Dehydration (normal finding in older adults as a result of decreased skin elasticity)
Dependent edema	Associated with right- and left-sided heart failure
Periorbital edema	Associated with kidney disease

From Ball JW et al: *Seidel's Physical examination handbook*, ed 9, St Louis, 2019, Elsevier; and Lewis, S, et al: *Medical-surgical nursing assessment and management of clinical problems*, ed 9, St Louis, 2017, Mosby.

Inspection includes observations of the nails for clubbing (see [Chapter 30](#)). Clubbed nails often occur in patients with chronic oxygen deficiency, such as cystic fibrosis and congenital heart defects. Also note the shape of the chest wall. Conditions such as advancing age and chronic obstructive pulmonary disease (COPD) cause the chest to assume a rounded “barrel” shape ([Ball et al., 2019](#); [Lewis et al., 2017](#)).

Observe chest wall movement for retraction (e.g., sinking in of soft tissues of the chest between the intercostal spaces) and use of accessory

muscles. Elevation of a patient's clavicles at rest reveals increased work of breathing. Also observe the patient's breathing pattern and assess for paradoxical breathing (the chest wall contracts during inspiration and expands during exhalation) or asynchronous breathing. At rest the normal adult respiratory rate is 12 to 20 breaths/min. Bradypnea is less than 12 breaths/min, and tachypnea is greater than 20 breaths/min (see [Chapter 29](#)). In some conditions, such as metabolic acidosis, the acidic pH stimulates an increase in rate, usually greater than 35 breaths/min, and depth of respirations (**Kussmaul respiration**) to compensate by decreasing carbon dioxide levels. Apnea is the absence of respirations for 15 to 20 seconds or longer. **Cheyne-Stokes respiration** occurs when there is decreased blood flow or injury to the brainstem. This type of breathing is an abnormal respiratory pattern, with periods of apnea followed by periods of deep breathing and then shallow breathing followed by more apnea (Huether and McCance, 2020; [Lewis et al., 2017](#)).

Palpation

Palpation of the chest provides assessment data in several areas. It documents the type and amount of thoracic excursion; elicits any areas of tenderness; and helps to identify tactile fremitus, thrills, heaves, and the cardiac point of maximal impulse (PMI). Palpation of the extremities provides data about the peripheral circulation (e.g., the presence and quality of peripheral pulses, skin temperature, color, and capillary refill) (see [Chapter 30](#)).

Palpation of the feet and legs determines the presence or absence of peripheral edema. Patients with alterations in cardiac function, such as those with heart failure or hypertension, often have pedal or lower-extremity edema. Edema is graded from 1+ to 4+, depending on the depth of visible indentation after firm finger pressure (see [Chapter 30](#)).

Palpate the pulses in the neck and extremities to assess arterial blood flow (see [Chapter 30](#)). Use a scale of 0 (absent pulse) to 4+ (full, bounding pulse) to describe what you feel. The normal pulse is 2+; a weak, thready pulse is 1+. Never palpate both carotid arteries at the same time as doing so may cause the patient to lose consciousness ([Ball et al., 2019](#)).

Percussion

Percussion detects the presence of abnormal fluid or air in the lungs. It also determines diaphragmatic excursion (see [Chapter 30](#)).

Auscultation

Auscultation helps identify normal and abnormal heart and lung sounds (see [Chapter 30](#)). Auscultation of the cardiovascular system includes assessing for normal S_1 and S_2 sounds and the presence of abnormal S_3 and S_4 sounds (gallops), murmurs, or rubs. Identify the location, intensity, pitch, and quality of a murmur. Auscultation also identifies any bruits over the carotid, abdominal aorta, and femoral arteries ([Ball et al., 2019](#)).

“Adventitious breath sounds” is another term for abnormal breath sounds. They include wheezing, crackles, and rhonchi. Wheezing is a continuous, high-pitched musical sound caused by high-velocity movement of air through a narrowed airway. It is associated with asthma, acute bronchitis, or pneumonia. It occurs during inspiration, expiration, or both. Determine whether there are any precipitating factors, such as respiratory infection, allergens, exercise, or stress. Crackles are discontinuous sounds of various pitch most often heard during inspiration. They are a result of the disruption of the small respiratory passages and cannot be cleared by coughing. They are often heard in patients with pneumonia or emphysema or chronic bronchitis. Rhonchi, or sonorous wheezes, are deeper sounding in pitch than crackles and are often heard during expiration. They reflect the presence of thick secretions or muscle spasms in the airway. Rhonchi can often be cleared by coughing and are most commonly heard in patients with asthma or pneumonia ([Ball et al., 2019](#)).

Diagnostic Tests

A variety of diagnostic tests are used to monitor and assess cardiopulmonary function. Some of these tests are noninvasive, while others are more invasive. Diagnostic testing used in the assessment and evaluation of the patient with cardiopulmonary alterations is summarized in [Tables 41.3 through 41.5](#). When reviewing results of pulmonary function studies, be aware of expected variations in patients from different cultures ([Box 41.3](#)).

TABLE 41.3**Cardiopulmonary Diagnostic Blood Studies**

Test and Normal Values	Interpretation
Complete Blood Count	
Normal values for a complete blood count (CBC) vary with age and gender	A CBC determines the number and type of red and white blood cells per cubic millimeter of blood. White blood cells assess for presence of infection. Red blood cells and hemoglobin assess for presence of anemia and ability of the blood to carry oxygen to the tissues.
Cardiac Enzymes	
Creatine kinase (CK-MB): Cardio specific enzyme released from cells when myocardial tissue is damaged. If greater than 4%-6% of total CK, then highly indicative of MI; levels increase within 4-6 hours of MI	Providers use cardiac enzymes, along with troponin, to diagnose acute myocardial infarcts.
Cardiac Troponins	
Plasma cardiac troponin I <0.03 ng/mL	Value elevates as early as 3 hours after myocardial injury.
Plasma cardiac troponin T <0.1 ng/mL	Value often remains elevated for 10-14 days.
Serum Electrolytes	
Potassium (K⁺) 3.5-5 mEq/L or 3.5-5 mmol/L	Patients on diuretic therapy are at risk for hypokalemia (low potassium). Patients receiving angiotensin-converting enzyme (ACE) inhibitors are at risk for hyperkalemia (elevated potassium). Since potassium has an effect on cardiac rhythm, it is important to keep this value as close to normal as possible.
Cholesterol	
Fasting cholesterol less than 200 mg/dL or less than 5.2 mmol/L (SI units)	Contributing factors include sedentary lifestyle with intake of saturated fatty acids, familial hypercholesterolemia.
Low-density lipoproteins (LDLs) (bad cholesterol) <130 mg/dL Very low-density lipoproteins (VLDLs) 7-32 mg/dl	High LDL cholesterol (hypercholesterolemia) is caused by excessive intake of saturated fatty acids, dietary cholesterol intake, and obesity. Familial hypercholesterolemia and hyperlipidemia, hypothyroidism, nephrotic syndrome, and diabetes mellitus are also contributing factors. VLDLs are predominant carriers of triglycerides and can be converted to LDL by lipoprotein lipase. Levels in excess of 25%-50% indicate increased risk of cardiac disease.
High-density lipoproteins (HDLs) (good cholesterol) Male: > 45 mg/dL; female: > 55 mg/dL	Factors such as cigarette smoking, obesity, lack of regular exercise, beta-adrenergic blocking agents, genetic disorders of HDL metabolism, hypertriglyceridemia, and type 2 diabetes cause low HDL cholesterol.
Triglycerides Male: 40-160 mg/dL; female: 35-135 mg/dL	Obesity, excessive alcohol intake, diabetes mellitus, beta-adrenergic blocking agents, and familial hypertriglyceridemia cause hypertriglyceridemia.
Additional Tests	
Brain natriuretic peptide <100 pg/mL	Increased levels may be used to help determine severity of congestive heart failure.
C-reactive protein <0.1/dL or <10 mg/L	Test used by clinicians to detect inflammation if there is a high suspicion of tissue injury or infection somewhere in the body. It can also be used to evaluate a patient's risk of developing coronary artery disease and stroke. Used to help evaluate patient for sepsis.

Data from Pagana KD et al: *Mosby's diagnostic and laboratory test reference*, ed 14, St Louis, 2019, Mosby.

TABLE 41.4**Cardiac Function Diagnostic Tests**

Test	Significance
Holter monitor	Portable ECG worn by a patient at home or work or school. The test produces a continuous ECG tracing over a period of time. Patients keep a diary of activity, noting when they experience rapid heartbeats or dizziness. Evaluation of the ECG recording along with the diary provides information about the electrical activity of the heart during activities of daily living.
ECG exercise stress test	ECG is monitored while a patient walks on a treadmill at a specified speed and duration of time. Test evaluates the cardiac response to physical stress. It is not a valuable tool for evaluation of cardiac response in women because of an increased false-positive finding.
Thallium stress test	ECG stress test with the addition of thallium-201 injected intravenously. It determines coronary blood flow changes with increased activity. Often used for people who cannot walk on the treadmill.
Electrophysiological study (EPS)	EPS is an invasive measure of intracardiac electrical pathways. It provides more specific information about difficult-to-treat dysrhythmias and assesses adequacy of antidysrhythmic medication.
Transthoracic echocardiography	This is a noninvasive measure of heart structure and heart wall motion. It graphically demonstrates overall cardiac performance.
Scintigraphy	Scintigraphy is radionuclide angiography; used to evaluate cardiac structure, myocardial perfusion, and contractility.
Cardiac catheterization and angiography	These are used to visualize cardiac chambers, valves, the great vessels, and coronary arteries. Pressures and volumes within the four chambers of the heart are also measured.

ECG, Electrocardiogram.

Data from Pagana KD, et al: *Mosby's diagnostic and laboratory test reference*, ed 14, St Louis, 2019, Mosby.

TABLE 41.5

Ventilation and Oxygenation Diagnostic Studies

Measurement and Normal Values	Interpretation/Purpose
Arterial Blood Gases	
pH 7.35-7.45	Provides important information for assessment of patient's respiratory and metabolic acid/base balance and adequacy of oxygenation (see Chapter 42)
PCO ₂ 35-45 mm Hg	
HCO ₃ 21-28 mEq/L	
PO ₂ 80-100 mm Hg	
SaO ₂ saturation 95%-100% Older adult: 95%	
Base excess 0 ± 2 mEq/L	
Pulmonary Function Tests	
Basic ventilation studies (Pulmonary functions vary by ethnic group.)	Determines ability of the lungs to efficiently exchange oxygen and carbon dioxide Used to differentiate pulmonary obstructive from restrictive disease
Peak Expiratory Flow Rate (PEFR)	
The point of highest flow during maximal expiration (Normal in adults is based on age and body weight.)	Reflects changes in large airway sizes; an excellent predictor of overall airway resistance in a patient with asthma Daily measurement for early detection of asthma exacerbations
Bronchoscopy	
Normal airways without masses, pus, or foreign bodies	Visual examination of the tracheobronchial tree through a narrow, flexible fiberoptic bronchoscope Performed to obtain fluid, sputum, or biopsy samples; remove mucus plugs or foreign bodies
Lung Scan	
Normal lung structure without masses	Nuclear scanning test used to identify abnormal masses by size and location Identification of masses used in planning therapy and treatments Also used to find a blood clot preventing normal perfusion or ventilation (<input type="checkbox"/> scan)
Thoracentesis	
Surgical perforation of chest wall and pleural space with a needle to aspirate fluid for diagnostic or therapeutic purposes or to remove a specimen for biopsy; performed using aseptic technique and local anesthetic (Patient usually sits upright with the anterior thorax supported by pillows or an over-bed table.)	Specimen of pleural fluid obtained for cytological examination Results may indicate an infection or neoplastic disease Identification of infection or a type of cancer important in determining a plan of care
Sputum specimens	Nasal aspirate/swabs for respiratory syncytial virus, influenza; sometimes are obtained while patient expectorates into specimen container; true sputum cultures are obtained via airway suctioning or through bronchoscopy
• Normal: negative	
• Sputum culture and sensitivity	Obtained to identify a specific microorganism or organism growing in sputum Identifies drug resistance and sensitivities to determine appropriate antibiotic therapy
• Sputum for acid-fast bacillus (AFB)	Screens for presence of AFB for detection of tuberculosis by early-morning specimens on 3 consecutive days
• Sputum for cytology	Obtained to identify lung cancer Differentiates type of cancer cells (small cell, oat cell, large cell)

Data from Pagana KD, et al: *Mosby's diagnostic and laboratory test reference*, ed 14, St Louis, 2019, Mosby.

Box 41.3 Cultural Aspects of Care **Cultural Impact on Pulmonary Diseases**

The impact of pulmonary diseases on patients and their families varies among cultures. It is important to understand these variations in terms of assessing for and providing care in patients with lung diseases. In 2018, approximately two-thirds of the new cases of TB diagnosed in the United States occurred in people who were not born in the United States. The countries where these patients were most likely to be born were Mexico, the Philippines, India, Vietnam, and China (CDC, 2019c).

The cigarette smoking rate in the United States is highest in American Indian/Alaskan Natives (24.6%), followed by Caucasians (15.3%), African-Americans (15.1%), Hispanics (9.9%), and Asians (7.0%). Smoking rates are also highest in those who have less than a high school education (22%) than in those who have a baccalaureate degree or higher (5.8%). Smoking increases the risk for a number of cancer types, chronic obstructive pulmonary disease (COPD), and heart disease (ALA, 2019b).

People of certain ethnic or cultural backgrounds tend to live in the same area, which can affect their exposure to certain environmental pollutants or triggers of respiratory exacerbations. Their location of living can also affect their socioeconomic status and their access to health care, which can also have a great impact on their pulmonary health (Celedon et al., 2017).

While ethnic and cultural differences can contribute to overall health, it should be noted that in today's globalization, health care providers should look more at acculturation (cultural exchange of beliefs, values, or behaviors as a result of interacting with people of other cultures) as an influence on a person's or a family's health. For example, smoking rates are higher in females of Mexican descent who have lived in the United States (Celedon et al., 2017).

The American Thoracic Society and the National Heart, Lung, and Blood Institute recommend looking more at the individual person and less at the person's race or ethnicity when trying to develop a plan of care. There is discussion about looking at a person's genetic makeup to develop a plan of care as genetic testing could help determine actual risk of disease and which medications would work best for that particular patient (Celedon et al., 2017).

Implications for Patient-Centered Care

- If your patients are foreign born, ask whether they have had the bacille Calmette-Guérin (BCG) vaccine, which can cause a positive reaction to the TB skin test. Also assess their exposure to people with known TB or other pulmonary infectious diseases (CDC, 2019c).
- Immunization clinics should concentrate on the underserved urban communities, especially those with large numbers of older adults. Provide TB skin testing, flu vaccines, and pneumonia vaccines as needed.
- Community health departments need to target at-risk populations for flu and pneumonia vaccine clinics.
- Public health programs for those at highest risk for pulmonary diseases should focus on pollution prevention, immunizations, and smoking-cessation programs.

One screening test is TB Mantoux skin testing ([Box 41.4](#)). This is a simple test and is recommended for health care workers who care for patients at increased risk for TB disease. Those patients at greater risk include people from countries where TB disease is common (most countries in Latin America, Africa, and Asia, for example), prisoners and correctional facility employees, and residents of long-term care facilities ([CDC, 2016a](#)).

Box 41.4 Tuberculosis Skin Testing

- Skin testing determines whether a person is infected with *Mycobacterium tuberculosis*.
- Tuberculosis (TB) skin testing (TST) is performed by an intradermal injection of 0.1 mL of tuberculin purified protein derivative (PPD) on the inner surface of the forearm (see Chapter 31). The injection produces a pale elevation of the skin (a wheal) 6 to 10 mm in diameter. Afterward the injection site is circled, and the patient is instructed not to wash the circle off.
- Read tuberculin skin tests between 48 and 72 hours after the test. If the site is not read within 72 hours, a patient must have another skin test.
- *Positive results:* A palpable elevated, hardened area around the injection site, caused by edema and inflammation from the antigen-

antibody reaction, measured in millimeters. (See Chapter 31 for evaluation of positive results by millimeters.)

- People born outside the United States may have had bacille Calmette-Guérin (BCG) vaccine for TB disease, which results in a positive reaction to the TST and may complicate the treatment plan. The positive skin reaction does not indicate that the BCG vaccine provided protection against the disease (CDC, 2016a, b).
- Reddened flat areas are *not* positive reactions and are not measured.
- TST is less reliable in older adults (see Box 41.1) and in those with an altered immune function, such as a human immunodeficiency virus (HIV)-positive patient or someone receiving chemotherapy.

Invasive diagnostic tests, such as a thoracentesis, are painful. How painful a diagnostic procedure is depends on the patient's tolerance for pain (see [Chapter 44](#)). Reduce the patient's anxiety by explaining the procedure and telling him or her what to expect. Be sure that he or she understands the importance of following instructions related to the procedure. For example, a patient undergoing a thoracentesis will need to understand the importance of not coughing during the procedure. Provide appropriate pain management 30 to 60 minutes before procedures, as ordered, to reduce the perception of pain. After any procedure monitor the patient for signs of changes in cardiopulmonary functioning such as sudden shortness of breath, pain, oxygen desaturation, and anxiety.

REFLECT NOW

You are preparing to assess a patient with COPD. What would be important questions to ask this patient when gathering a health history? What are your expected physical assessment findings? What diagnostic tests would you expect the health care provider to order for this patient?

• Nursing Diagnosis

Based upon your assessment findings, you develop nursing diagnoses (see [Chapter 17](#)) for patients with oxygenation problems by clustering specific assessment findings and identifying the related etiology ([Box 41.5](#)). The assessment findings for diagnoses related to oxygenation can be similar. For example, both *Impaired Gas Exchange* and *Impaired Breathing* have dyspnea and nasal flaring. A closer review of assessment findings, as well as an analysis of the patient’s history, will help you clarify and select the correct diagnosis. For example, a trauma patient who has rib pain and is showing an increased respiratory rate is more likely to have *Impaired Breathing*. The clustered assessment findings and related factors support a problem or negative nursing diagnosis. If assessment results in the clustering of risk factors, a risk nursing diagnosis will be made.

Box 41.5 Nursing Diagnostic Process Impaired Gas Exchange Related to Decreased Lung Expansion

Assessment Activities	Assessment Findings
Ask patient or family about patient’s mood, attentiveness, memory, and activity level.	Confusion Decreased activity Fatigue Irritability Restlessness Sleepiness
Observe patient’s respirations for rate, rhythm, depth.	Dyspnea Nasal flaring Tachypnea Use of accessory muscles
Inspect skin and mucous membranes.	Diaphoresis Pallor Cyanosis
Auscultate chest.	Decreased respiratory excursion Abnormal, distant lung sounds

These additional nursing diagnosis examples may apply when planning care for the patient with alterations in oxygenation:

- *Impaired Cardiac Output*
- *Acute Pain*
- *Activity Intolerance*

- *Risk for Activity Intolerance*
- *Impaired Airway Clearance*

• **Planning**

During planning, use critical thinking skills to synthesize information from multiple sources (Fig. 41.5). Critical thinking ensures that your plan of care integrates individualized patient needs. Professional standards are especially important to consider when developing a plan of care. These standards often establish scientifically proven guidelines for selecting effective nursing interventions.

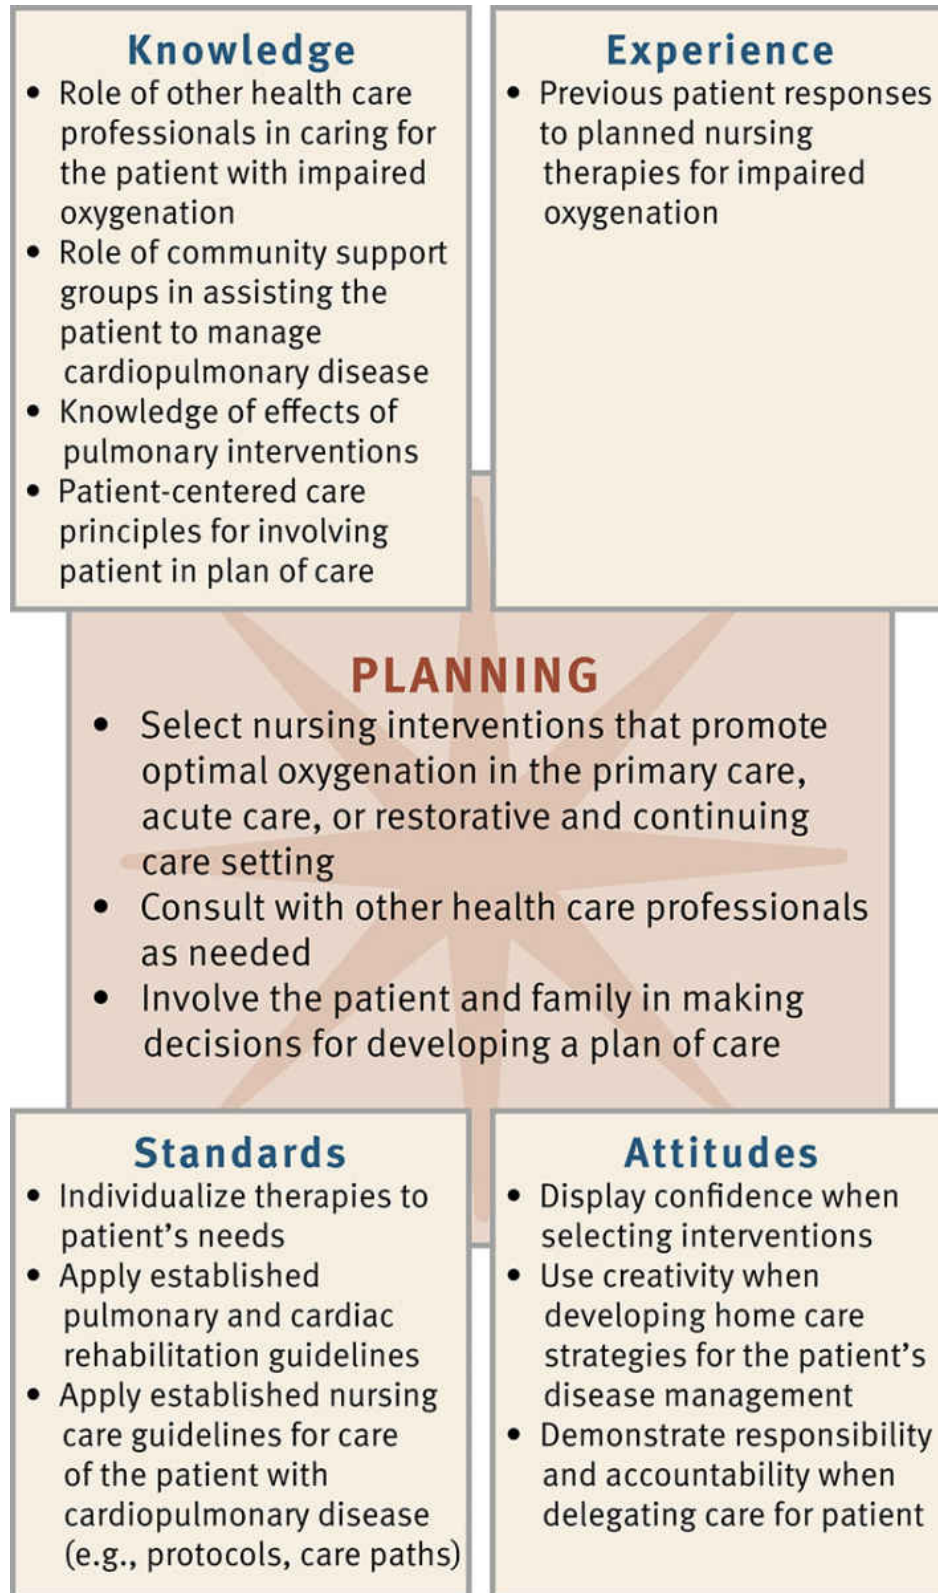

FIG. 41.5 Critical thinking model for oxygenation planning.

Goals and Outcomes

Develop an individualized plan of care for each nursing diagnosis (see the [Nursing Care Plan](#)). Together, with your patient, set realistic expectations, relevant goals, and measurable outcomes of care.

Patients with impaired oxygenation require a nursing care plan directed toward meeting actual or potential oxygenation needs. Allow patients to collaborate with you. Develop individual outcomes based on patient-centered goals. For example, for the goal of an improved breathing pattern, select specific expected outcomes, such as the following:

- Patient's respiratory rate is between 12 and 20 breaths/minute.
- Patient achieves bilateral lung expansion.
- Patient breathes without the use of accessory muscles.

Often a patient with cardiopulmonary disease has multiple nursing diagnoses ([Fig. 41.6](#)). In this case, identify when goals or outcomes apply to more than one diagnosis. The presence of multiple diagnoses also makes priority setting a critical activity.

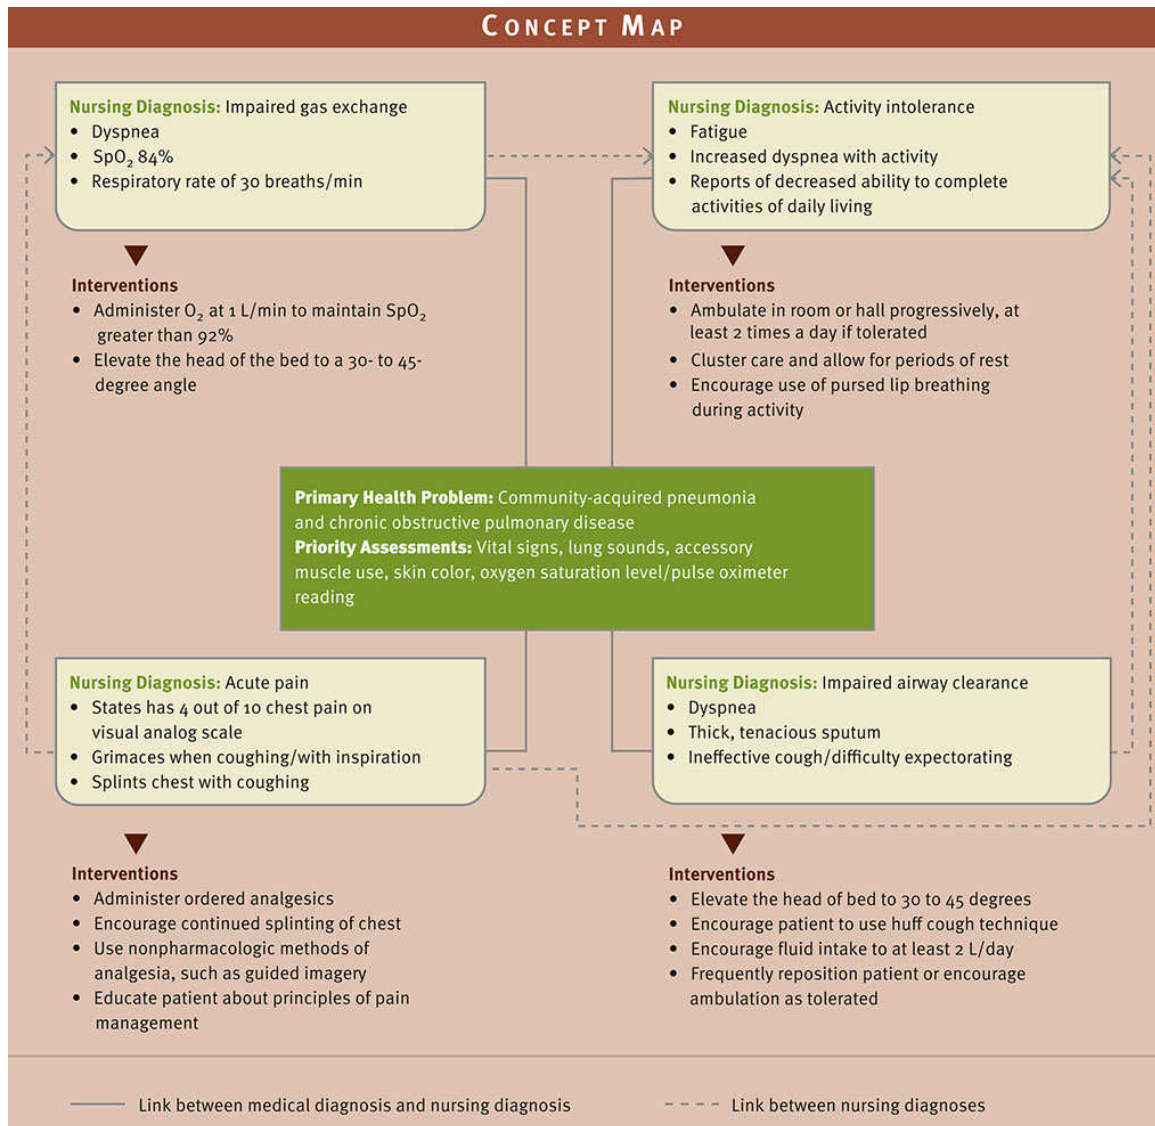

FIG. 41.6 Concept map for Mr. Edwards.

Setting Priorities

A patient's level of health, age, lifestyle, and environmental risk factors affect tissue oxygenation. Patients with severe impairments in oxygenation frequently require nursing interventions in multiple areas. Consider which goal/outcome is the most important to achieve while the patient is in the hospital or primary care setting. For example, in an acute care setting, maintaining a patent airway has a higher priority than improving the patient's exercise tolerance. The need for a patent airway is immediate; as the patient's level of oxygen improves, activity tolerance increases (Urden et al., 2020). In a second example, when caring for a patient who has an

abdominal incision, pain control is a priority. In this situation, controlling the patient's pain facilitates coughing and deep breathing and activity (Lewis et al., 2017).

However, in a community-based or primary care setting, priorities often focus on primary or tertiary health promotion activities, such as smoking cessation, exercise, and/or diet modifications. Both you and the patient need to focus on the same goal and expected outcomes. In addition to individualizing each goal, be sure that the goals are realistic, have reasonable time frames, and are attainable for the patient. In addition, be sure to respect the patient's preferences for his or her degree of active engagement in the care process. Some will choose to be very active and desire to make day-to-day decisions. Others may choose to assume a more passive role, preferring you to choose a course of action while keeping them informed (Lewis et al., 2017).

Teamwork and Collaboration

The time spent with a patient in any setting is limited. Therefore, collaborate with family members, colleagues, and other health care specialists to achieve the established goals and expected outcomes. Some patients need to improve their exercise and activity tolerance; for other patients, continuing care involves participating in a community-based cardiopulmonary rehabilitation program. Some patients need home physical therapy.

Collaboration with physical therapists, nutritionists, respiratory therapists, and community-based nurses is valuable for patients with heart failure or chronic lung conditions. These professionals work with patients and their caregivers using resources in the community to assist them in attaining and maintaining the highest possible level of wellness. In addition, professionals identify community resources and support systems to help prevent and manage symptoms related to cardiopulmonary diseases. Communication among everyone on the patient's health care team and recognition of everyone's contributions in achieving the health care goals for the patient are imperative.

Implementation

There are interventions for promoting and maintaining adequate oxygenation across the continuum of care. As a nurse, you will be responsible for independent interventions such as positioning, coughing techniques, and health education for disease prevention. In addition, you

will provide physician-initiated interventions such as oxygen therapy, lung inflation techniques, and chest physiotherapy.

Health Promotion

Maintaining a patient's optimal level of health reduces the number and/or severity of respiratory symptoms. Prevention of respiratory infections is foremost in maintaining optimal health (Box 41.6). Providing cardiopulmonary-related health information is an important nursing responsibility.

Box 41.6 Patient Teaching **Prevention of Recurrent Respiratory Infections**

Objective

- The patient will be able to describe how to reduce the risk factors for recurring respiratory infections.

Teaching Strategies

- Adapt teaching strategies to the patient's health literacy, educational background, reading level, and cultural preferences (CDC, 2019c).
- Communicate with patient and family to identify collaborative goals for reducing risk factors.
- Explain the link between smoking and increased risk for respiratory infections (CDC, 2018a; McCance and Huether, 2019).
- Refer to smoking cessation programs and discuss appropriate medication to support smoking cessation from the primary health provider (ACS, 2017).
- If a patient does not smoke, teach the importance of avoiding secondhand smoke and areas of high air pollution.
- Instruct patient and family about appropriate hand hygiene techniques to reduce transmission of microorganisms.
- Explain to patient and family why annual influenza vaccines and appropriate pneumonia vaccines are needed (CDC, 2018e; CDC, 2017b).

- Instruct patient and family about signs and symptoms of respiratory infection that should be reported to health care provider, such as increased coughing, shortness of breath, change of color of sputum, fever, and fatigue.

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- Ask patient to state benefits of smoking cessation and the risks for secondhand smoke.
- Ask patient about plans for flu and pneumonia vaccines.
- Ask patient to describe in simple terms the symptoms of respiratory infection and when to call the health care provider.

The health information that your patients and their families bring to the situation varies. Some patients have a lot of exposure to health care information and understand their treatment plans. Other families might have a lot of exposure to health care information but are unable to understand and follow treatment plans. Last, you might encounter families who are experiencing their first exposure to health care information and are very unsure of their interpretation of the information. When providing health information, be sure to assess a patient's health literacy level and then individualize findings into an individualized education session (see [Chapter 25](#)).

Vaccinations

Seasonal flu vaccine protects against influenza viruses that research indicates will be the most common during that year. The vaccines are formulated annually based on worldwide surveillance data. Annual flu vaccines are recommended for all people 6 months and older. Patients with chronic illnesses (heart, lung, kidney, or immunocompromised), infants, older adults, and pregnant women can get very sick; thus, they should be immunized ([CDC, 2018e](#)). The vaccine is also recommended for people in close or frequent contact with anyone in the high-risk groups, including infants and health care workers. It is effective in reducing the severity of illness and the risk of serious complications and death. It is important to assess a patient's allergies and any allergic response to

vaccines or any components. People with a known hypersensitivity to eggs or other components of the vaccine should consult their physician before being vaccinated (CDC, 2018e). Adults with an acute febrile illness should schedule the vaccination after they have recovered. The live, attenuated nasal spray vaccine is given to healthy people from 2 through 49 years of age if they are not pregnant. The live vaccine is also not indicated in people who are immunocompromised or have certain chronic health conditions such as asthma or heart disease (CDC, 2018e).

Pneumococcal vaccine (PCV13) is routinely given to children younger than 2 years of age and is recommended for patients with certain medical conditions (such as heart disease) that are at risk of complications from pneumococcal disease. Adults over 65 years of age and any adult who smokes may receive the pneumococcal polysaccharide vaccine (PPSV23). These vaccines should not be administered if the patient has had an allergic reaction to the vaccine in

Nursing Care Plan

Impaired Airway Clearance

Assessment

Mr. Edwards is a 75-year-old currently lying in a semi-Fowler's position in bed, talking with his wife. He is admitted with community-acquired right upper lobe pneumonia and has a 2-year history of COPD. He has an intermittent productive cough with occasional thick, yellow sputum. Lying flat makes the cough worse.

Assessment Activities	Assessment Findings ^a
Ask Mr. Edwards how long he has had this cough and how frequently he coughs.	He replies, "I have a morning cough every day, but this cough is different. It started about a week ago. It is worse when I lie flat. "
Ask Mr. Edwards what is different about this cough.	He replies, "It is difficult to cough up anything, my mouth is dry , and I have become more fatigued . My ribs are starting to get sore."
Assess Mr. Edwards' respiratory rate, work of breathing, and whether he is using accessory muscles.	There is minor use of abdominal muscles while breathing. He replies, "I feel short of breath when I walk."
Obtain vital signs.	Temperature: 101.4 F (38.5 C); pulse 102 beats/min; respirations 30 breaths/min; BP 130/90 mm Hg, and SpO ₂ 84%. He states he has a pain score of 4 out of 10 on visual analog scale.
Auscultate lung fields.	Abnormal lung sounds (crackles) are heard in the right upper lobe and left and right lower lobes.
Ask Mr. Edwards to produce a sputum sample.	Sputum is thick and discolored yellow to yellow-green and difficult to cough up and expectorate.

^a Assessment findings are shown in **bold** type.

Nursing Diagnosis:

Impaired airway clearance related to retained thick pulmonary secretions

Planning

Goals	Expected Outcomes (NOC) ^b
	Respiratory Status: Airway Patency
Mr. Edwards will be able to effectively clear secretions by discharge.	Mr. Edwards will state an increased ease in coughing and expectorating within 48 hours.
	Lung sounds will improve with fewer crackles within 48 hours.

^b Outcome classification labels from Moorhead S, et al.: *Nursing Outcomes Classification (NOC)*, ed 6, St Louis, 2018, Elsevier.

Interventions (Nic) ^c	Rationale
Airway Management	
Position Mr. Edwards with head elevated at least 30-45 degrees.	Increases depth of breathing and decreases the airway resistance during inspiration, thereby improving respiratory gas exchange (Elliott and Morrell-Scott, 2017).
Ambulate in room or hall progressively as tolerated at least 2 times a day. If unable to ambulate, reposition from side to side every 2 hours or more.	Body movement helps patients take bigger breaths, increasing their tidal volume and preventing atelectasis. Movement and repositioning help to mobilize secretions, making them easier to expectorate (Urden et al., 2020; Atkins and Kautz, 2014).
Have Mr. Edwards deep-breathe and cough every hour. Teach him to take a deep breath, hold it for several seconds, open his mouth, tighten his abdominal muscles, and cough 2 to 3 times with his mouth open.	Retained secretions predispose patient to atelectasis and worsening of the pneumonia. Controlled coughing improves effectiveness of cough and removal of airway secretions (Urden et al., 2020; Borge et al., 2014).
Increase fluids to 2500 mL in 24 hours if not contraindicated by cardiac or renal status. Offer fluids Mr. Edwards prefers.	Fluids help to liquefy or thin the sputum, which may help promote secretion removal and relieve oral mucosa and skin dryness (Lewis et al., 2017).

^c Intervention classification labels from Butcher HK, et al: *Nursing Interventions Classification (NIC)*, ed 7, St Louis, 2018, Elsevier.

Evaluation

Evaluation Activity	Patient Response/Finding	Outcome Status
Auscultate the lungs.	Lung sounds are clear in left lung, crackles present in right lower lobe.	Lung sounds clear to auscultation.
Ask Mr. Edwards whether he can cough and expectorate sputum; observe him perform this action.	Mr. Edwards reports that it is easier to cough up his secretions; Mr. Edwards is observed expectorating thin, pale yellow sputum.	Mr. Edwards clears airway with coughing.

the past or while the patient is recovering from a febrile illness. Women should not receive the vaccine while pregnant; instead, they should try to receive the vaccine before pregnancy (CDC, 2017b).

Healthy Lifestyle

Identification and elimination of risk factors for cardiopulmonary disease are important parts of primary care. The risk factors for cardiac disease are lower when total cholesterol levels are less than 200 mg/dL, high-density lipoprotein (HDL) levels are greater than 40 mg/dL in men and 50 mg/dL in women, and low-density lipoprotein (LDL) levels are less than 160 mg/dL (Lewis et al., 2017). Encourage patients to eat a healthy low-fat, high-fiber diet and maintain a body weight in proportion to their height (see Chapter 45). The Dietary Approaches to Stop Hypertension (DASH) diet, along with exercise, stress reduction, and limiting alcohol intake, has been shown to decrease a patient's risk of hypertension (NHLBI, n.d.a). Eliminating cigarettes and other tobacco and adequately hydrating are additional healthy behaviors. Encourage patients to examine their habits

and make appropriate changes. Patients with cardiopulmonary alterations need to minimize their risk for infection, especially during the winter months (see [Box 41.6](#)).

Exercise is a key factor in promoting and maintaining a healthy heart and lungs. Encourage patients to have at least 150 minutes a week of moderate intensity exercise and at least 2 days a week of muscle strengthening activity ([USDHHS, 2018](#)). Aerobic exercise is necessary to improve lung and heart function and strengthen muscles. Walking is an efficient way to achieve a good aerobic workout. Many shopping malls have programs allowing people to walk in the enclosed mall before the shops open. During the hot summer months, teach patients to limit activities to early in the day or late in the evening, when temperatures are lower. In addition, teach the importance of maintaining adequate hydration and sodium intake, especially if they are taking diuretics. Patients with known cardiac disease and those with multiple risk factors are cautioned to avoid exertion in cold weather. Shoveling snow is especially risky and often precipitates a cardiac event. Other activities, such as hanging holiday lights and decorations in the extreme cold, can precipitate chest pain and bronchospasm. Please refer to [Chapter 38](#) for further discussion on activity and exercise.

Environmental Pollutants

Avoiding exposure to secondhand smoke is essential to maintaining optimal cardiopulmonary function. Most public places, such as businesses or restaurants, ban smoking or have separate areas designated as smoking areas. Provide counseling and support so that a patient who lives with secondhand smoke in the home understands its effects. If the patient is a smoker who wants to quit smoking, the patient's family should be told to encourage and support the patient in the attempt to quit.

Patients should try to avoid environmental hazards in their home or work environments. For example, patients who know that pollen triggers an asthma exacerbation should be taught to keep windows closed and use air filters when air pollen counts are high ([Hockenberry et al., 2019](#); [Lewis et al., 2017](#)). Many health care agency dress codes prohibit the use of perfumes or colognes because they often affect patient breathing patterns and allergies. Farmers, painters, and carpenters may benefit from the use of particulate filter masks to reduce the inhalation of particles.

Acute Care

Patients with acute pulmonary illnesses require nursing interventions directed toward halting the pathological process (e.g., respiratory tract infection), shortening the duration and severity of an illness (e.g., hospitalization with pneumonia), and preventing complications from the illness or treatments (e.g., hospital-acquired infection resulting from invasive procedures) (Lewis et al., 2017; Urden et al., 2020).

Dyspnea Management

Dyspnea is difficult to treat. Health care providers individualize treatments for each patient and usually implement more than one therapy. Treatment of the underlying process causing dyspnea is then followed with other therapies (e.g., pharmacological measures, oxygen therapy, physical techniques, and psychosocial techniques). Pharmacological agents include bronchodilators, inhaled steroids, mucolytics, and low-dose antianxiety medications. Oxygen therapy reduces dyspnea associated with exercise and hypoxemia. Physical and psychological techniques such as cardiopulmonary reconditioning (e.g., exercise, breathing techniques, and cough control), relaxation techniques, biofeedback, and meditation are also beneficial (Lewis et al., 2017).

Airway Maintenance

The airway is patent when the trachea, bronchi, and large airways are free from obstructions. Airway maintenance requires adequate hydration to prevent thick, tenacious secretions. Proper coughing techniques remove secretions and keep the airway open. A variety of interventions such as suctioning, chest physiotherapy, and nebulizer therapy assist patients in managing alterations in airway clearance (Urden et al., 2020).

Mobilization of Pulmonary Secretions

The ability of a patient to mobilize pulmonary secretions makes the difference between a short-term illness and a long recovery involving complications. Nursing interventions promoting removal of pulmonary secretions such as repositioning and suctioning assist in achieving and maintaining a clear airway and help to promote lung expansion and gas exchange (Lewis et al., 2017; Morrow et al., 2016).

Hydration

Maintenance of adequate systemic hydration keeps mucociliary clearance normal. In patients with adequate hydration, pulmonary secretions are

thin, white, watery, and easily removable with minimal coughing. Excessive coughing to clear thick, tenacious secretions is fatiguing and energy depleting. It can also cause pain in the chest muscles and ribs, which further decreases the patient's ability to cough and clear secretions. The best way to maintain thin secretions is to provide a fluid intake of 1500 to 2500 mL/day unless contraindicated by cardiac or renal status. The color, consistency, and ease of mucus expectoration determines adequacy of hydration (Lewis et al., 2017).

Humidification

Humidification is the process of adding water to gas to keep airways moist. It is necessary for patients receiving oxygen therapy at high flow rates, typically greater than 4 L/minute (see agency protocols). Oxygen humidification via nasal cannula or face mask is achieved by bubbling oxygen through sterile water (see Skill 41.4). Sterile water should be used to decrease the risk of hospital-acquired infection; agency protocols must be followed for changing the solution (Wen et al., 2017).

When caring for pediatric patients, humidity may be applied to all oxygen devices, regardless of flow rates. Infants and children have smaller airways than adults, and secretions are more likely to obstruct airways in the younger population. Humidity is added to help ease the ability of infants and children to clear their airways (Hockenberry et al., 2019; Walsh and Smallwood, 2017).

Nebulization

Nebulization adds moisture to inspired air by mixing particles of varying sizes with the air. Aerosolization suspends the maximum number of water drops or particles of the desired size in inspired air. When the thin layer of fluid supporting the mucous layer over the cilia dries, the cilia are damaged and unable to adequately clear the airway. Humidification through nebulization enhances mucociliary clearance, the natural mechanism of the body for removing mucus and cellular debris from the respiratory tract. This, in turn, improves the clearance of pulmonary secretions. Nebulization is also a method of administration for certain medications, such as bronchodilators and mucolytic agents (Grindrod, 2015; Lewis et al., 2017).

Coughing and Deep-Breathing Techniques

Coughing is an effective technique for maintaining a patent airway. Directed coughing is a deliberate maneuver that is effective when spontaneous coughing is inadequate (Borge et al., 2014). It permits a patient to remove secretions from both the upper and lower airways. The normal series of events in the directed cough are deep inhalation, closure of the glottis, active contraction of the expiratory muscles, and glottis opening. Deep inhalation increases the lung volume and airway diameter, allowing the air to pass through partially obstructing mucus plugs or other foreign matter. Contraction of the expiratory muscles against the closed glottis causes a high intrathoracic pressure to develop. When the glottis opens, a large flow of air is expelled at a high speed, providing momentum for mucus to move to the upper airways where the patient can expectorate or swallow it.

The *huff cough* stimulates a natural cough reflex and is generally used to help move secretions to the larger airways. The patient inhales deeply and then holds his or her breath for 2 to 3 seconds. While forcefully exhaling, the patient opens the glottis by saying the word *huff*. With practice he or she inhales more air and is able to progress to the cascade cough. When using a cascade cough, the patient takes a slow deep breath, holds it for 1 to 2 seconds, then opens the mouth and performs a series of coughs throughout exhalation. This technique is often used in patients with large amounts of sputum, such as those with cystic fibrosis (CFF, 2015a).

The *quad cough*, or *manually assisted cough* technique, is for patients without abdominal muscle control, such as those with spinal cord injuries. While the patient breathes out with a maximal expiratory effort, the patient or nurse pushes inward and upward on the abdominal muscles toward the diaphragm, causing the cough (Chatwin et al., 2018).

Diaphragmatic breathing is a technique that encourages deep breathing to increase air to the lower lungs. The diaphragm descends (belly moves out) when breathing in and ascends (belly sinks in) when breathing out. This technique has been shown to decrease dyspnea for a short period of time, particularly in patients with COPD, by increasing diaphragmatic excursion and reducing accessory muscle use (Morrow et al., 2016).

Evaluate the effectiveness of coughing by the patient's ability to expectorate sputum, the patient's report of swallowed sputum, or clearing of adventitious sounds by auscultation. Encourage patients with chronic pulmonary diseases, upper respiratory tract infections, and lower respiratory tract infections to deep breathe and cough at least every 2 hours while awake. Encourage patients with a large amount of sputum to cough every hour while awake. After some surgeries, it is recommended

that patients perform deep breathing and coughing techniques every 2 to 4 hours while awake to prevent accumulation of secretions. Offer postoperative patients support devices (folded blanket, pillow, or palmed hands) to splint an abdominal or thoracic incision to minimize pain during directed coughing. Cough is a source of droplet transmission of pulmonary pathogens; thus, the health care provider should follow Standard Precautions ([Lewis et al., 2017](#)).

Chest Physiotherapy

Chest physiotherapy (CPT) is external chest wall manipulation using percussion, vibration, or high-frequency chest wall compression (HFCWC) ([Fig. 41.7](#)). It is often used in conjunction with postural drainage and can help mobilize pulmonary secretions in a select group of patients. [Box 41.7](#) describes the guidelines to determine whether CPT is indicated. The American Association for Respiratory Care (AARC) does not support the routine use of CPT with all patients. There is no evidence to support its routine use in all patient populations, instead reserving its use for patients with retained secretions who cannot expectorate those secretions, such as patients with cystic fibrosis (CF) ([Strickland, 2015](#); [Strickland et al., 2013](#)).

FIG. 41.7 High-frequency chest wall compression (HFCWC).
Copyright © 2019 Hill-Rom Services, Inc. Reprinted with permission. All rights reserved.

Box 41.7 Guidelines for Chest Physiotherapy

Nursing and respiratory therapy collaborate with the health care provider to determine whether chest physiotherapy (CPT) is best for a patient. The following guidelines help in physical assessment and subsequent decision making:

- Conduct a complete respiratory assessment to confirm need for CPT, including sputum production, effectiveness of cough, history of

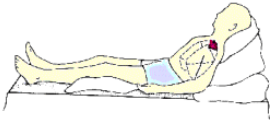

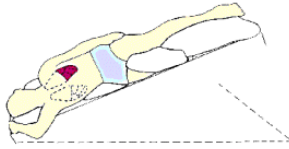

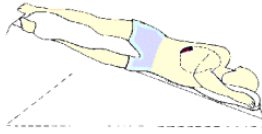

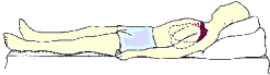

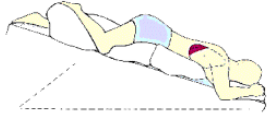

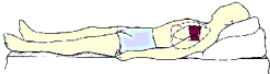

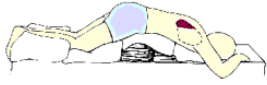

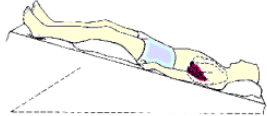

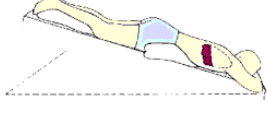

pulmonary problems successfully relieved with CPT, abnormal lung sounds, and documented conditions such as atelectasis, complicated pneumonia, vital signs, or changes in oxygenation status (Lewis et al., 2017; Strickland, 2013).

- Know the patient's medications. Certain medications, particularly diuretics and antihypertensives, cause fluid and hemodynamic changes. These decrease a patient's tolerance to positional changes and postural drainage. Long-term steroid use increases a patient's risk of pathological rib fractures and often contraindicates vibration.
- Know the patient's medical history. Certain conditions such as increased intracranial pressure, spinal cord injuries, and abdominal aneurysm resection contraindicate the positional changes of postural drainage. Thoracic trauma or surgery contraindicates percussion and vibration.
- Know the patient's level of cognitive function. Participation in controlled coughing techniques requires him or her to follow instructions. Congenital or acquired cognitive limitations alter a patient's ability to learn and participate in these techniques.
- Be aware of the patient's exercise tolerance. CPT maneuvers are fatiguing (Strickland, 2015).

Postural drainage is a component of pulmonary hygiene; it consists of drainage, positioning, and turning and is sometimes accompanied by chest percussion and vibration. It aids in improving secretion clearance and oxygenation. Positioning involves draining affected lung segments ([Table 41.6](#)) and helps to drain secretions from those segments of the lungs and bronchi into the trachea. Some patients do not require postural drainage of all lung segments, and clinical assessment is crucial in identifying specific lung segments requiring it. For example, patients with left lower lobe atelectasis require postural drainage of only the affected region, whereas a child with CF often requires postural drainage of all lung segments ([CFF, n.d.](#); [Hockenberry et al., 2019](#); [Lewis et al., 2017](#)).

TABLE 41.6

Positions for Postural Drainage

Lung Segment	Position of Patient	Lung Segment	Position of Patient
Adult – Make sure to assess patient prior to positioning. Some patients, such as those with head injuries, heart failure, or pulmonary embolus, should not be placed in the Trendelenburg position (Lewis et al., 2017).			
Bilateral 	High-Fowler's	Left lower lobe—lateral segment 	Right side-lying in Trendelenburg's position
Apical segments 	Sitting on side of bed	Right lower lobe—lateral segment 	Left side-lying in Trendelenburg's position
Right upper lobe—anterior segment 	Supine with head elevated	Right lower lobe—posterior segment 	Prone with right side of chest elevated in Trendelenburg's position
Left upper lobe—anterior segment 	Supine with head elevated	Right middle lobe—posterior segment 	Prone with thorax and abdomen elevated
Right upper lobe—posterior segment 	Side-lying with right side of chest elevated on pillows	Both lower lobes—anterior segments 	Supine in Trendelenburg's position
Left upper lobe—posterior segment 	Side-lying with left side of chest elevated on pillows	Both lower lobes—posterior segments 	Prone in Trendelenburg's position
Right middle lobe—anterior segment 	Three-fourths supine position with dependent lung in Trendelenburg's position		

Manual chest percussion involves rhythmically clapping on the chest wall over the area being drained to force secretions into larger airways for expectoration (Strickland et al., 2013). It is commonly performed by respiratory therapists in larger health care settings. Position your hand so that the fingers and thumb touch and the hands are cupped. The cupping makes the hand conform to the chest wall while trapping a cushion of air to soften the intensity of the clapping. The procedure should produce a hollow sound and should not be painful. Perform chest percussion by vigorously striking the chest wall alternately with cupped hands (Fig. 41.8). Perform percussion over a single layer of clothing, not over buttons, snaps, or zippers. The single layer of clothing prevents slapping the patient's skin. Thicker or multiple layers of material dampen the vibrations. Percussion is contraindicated in patients with bleeding disorders, osteoporosis, or fractured ribs. Avoid percussion over burns, open wounds, or skin infections of the thorax. Take caution to percuss the lung fields under the ribs and not over the spine, breastbone, stomach, or lower back or trauma can occur to the spleen, liver, or kidneys. Commercial devices that are shaped similar to cups are also available to use to perform manual chest percussion (CFF, n.d.).

FIG. 41.8 Chest wall percussion, alternating hand clapping against patient's chest wall.

Vibration is a gentle shaking pressure applied to the chest wall only during exhalation to shake secretions into larger airways. This pressure can be applied either manually or with a commercially available device. Vibration may be tolerated better than percussion. You use vibration most often with patients with CF (CFF, n.d.).

High-frequency chest wall compression (HFCWC) consists of an inflatable vest that is attached to an air-pulse generator (Fig. 41.9). HFCWC loosens and removes secretions from the airway by delivering high-frequency, small-volume expiratory pulses to a patient's external chest wall. The vest can be worn over clothes. This therapy is beneficial for patients with neuromuscular diseases and for patients with chronic lung diseases with thick sputum, such as CF (Strickland, 2014; Strickland et al., 2013).

FIG. 41.9 High-frequency chest wall oscillation vest for home use. Copyright © 2012 Hill-Rom Services, Inc. Reprinted with permission. All rights reserved.

Positive Expiratory Pressure

Positive expiratory pressure (PEP) is an airway clearance technique that can be used with and without oscillation. Its use is typically reserved for patients with CF or other lung diseases in which sputum is retained (Franks et al., 2019; Strickland, 2015). The Acapella and Flutter devices are commonly used PEP devices (Fig. 41.10). PEP allows air to be inhaled easily but forces the patient to exhale against resistance. This action helps air get behind the mucus, which then makes it easier to expectorate the mucus (CFF, 2015b; Franks et al., 2019). The patient must be physically capable of maintaining a seal with their mouth around the device.

FIG. 41.10 Acapella airway clearance device.

Maintenance and Promotion of Lung Expansion

Nursing interventions to maintain or promote lung expansion include noninvasive techniques such as ambulation, positioning, incentive spirometry, and noninvasive ventilation. Invasive medical interventions, such as chest tube insertion and management, assist in restoring lung expansion.

Ambulation

Immobility is a major factor in developing atelectasis, ventilator-associated pneumonia (VAP), and functional limitations, including muscle weakness and fatigue (Nuwi and Irwan, 2018). This decline in status is often referred to as deconditioning. Early ambulation studies indicate that the therapeutic benefits of activity include an increase in general strength and lung expansion. Even the patient who requires invasive mechanical ventilation benefits by an early mobility program. Such mobility programs should include input from both respiratory and physical therapists in the treatment plan. Progressive mobilization from dangling the legs to standing and then walking is safe for intubated patients (Atkins and Kautz, 2014; Hartjes, 2018) (see Chapter 38).

Positioning

The healthy, completely mobile person maintains adequate ventilation and oxygenation by frequent position changes during daily activities. However, when a person's illness or injury restricts mobility, the risk for

respiratory impairment is increased. Frequent changes of position are simple and cost-effective methods for reducing stasis of pulmonary secretions and decreased chest wall expansion, both of which increase the risk of pneumonia.

The 45-degree semi-Fowler's is the most effective position to promote lung expansion and reduce pressure from the abdomen on the diaphragm. When a patient is in this position, be sure that he or she does not slide down in bed, which can reduce lung expansion. Sliding also increases the risk of pressure injuries. A patient with unilateral lung disease, such as pneumothorax, atelectasis, or pneumonia of one lung, should be positioned in a manner to promote perfusion of the healthy lung and improve oxygenation. In most cases, position the patient with the good lung down. In the presence of pulmonary abscess or hemorrhage, position the patient with the affected lung down to prevent drainage toward the healthy lung. For bilateral lung disease, the best position depends on the severity of the disease ([Lewis et al., 2017](#); [Urden et al., 2020](#)).

Incentive Spirometry

Incentive spirometry encourages voluntary deep breathing by providing visual feedback to patients about inspiratory volume. It is a commonly used intervention that promotes deep breathing and is thought to prevent or treat atelectasis in the postoperative patient. Recent evidence suggests that the use of the incentive spirometer is not as effective at preventing postoperative pulmonary complications as it once was thought to be. The AARC recommends that its use be reserved for patients with existing atelectasis or those with risk factors for developing atelectasis, such as those who have undergone thoracic or abdominal surgery, patients with prolonged bed rest, or patients with neuromuscular disease or spinal cord injuries ([AARC, 2011](#); [Eltorai et al., 2018](#)).

There are two types of incentive spirometers. Flow-oriented incentive spirometers consist of one or more plastic chambers that contain freely moving colored balls. A patient inhales slowly and with an even flow to elevate the balls and keep them floating as long as possible to ensure a maximally sustained inhalation. Volume-oriented incentive spirometry devices have a bellows that is raised to a predetermined volume by an inhaled breath ([Fig. 41.11](#)). An achievement light or counter provides visual feedback. Some devices are constructed so the light does not turn on unless the bellows is held at a minimum desired volume for a specified period to enhance lung expansion (see [Chapter 50](#)).

FIG. 41.11 Volume-oriented incentive spirometer.

The [AARC guidelines \(2011\)](#) recommend 5 to 10 breaths per session every hour while awake. Administration of pain medications before incentive spirometry helps a patient achieve deep breathing by reducing pain and splinting. Use incentive spirometry in combination with other pulmonary measures, such as deep breathing and coughing and early mobilization in patients who are at risk for atelectasis ([do Nascimento et al., 2014](#)).

Suctioning Techniques

Suctioning is necessary when patients are unable to clear respiratory secretions from the airways by coughing or other less invasive procedures. Suctioning techniques include oropharyngeal and nasopharyngeal suctioning, orotracheal and nasotracheal suctioning, and suctioning an artificial airway.

In most cases, use sterile technique for suctioning because the oropharynx and trachea are considered sterile. The mouth is considered clean, so it only requires clean technique. When suctioning both the oral pharynx and the trachea, always suction the nasotracheal and/or trachea (sterile) before the oral pharynx (clean) (AARC, 2004, 2010a; Wiegand, 2017).

Each type of suctioning requires the use of a round-tipped, flexible catheter with holes on the sides and end of the catheter. When suctioning, you apply negative pressures (100-150 mm Hg for adults) during withdrawal of the catheter and **never** on insertion (Myatt, 2015; Wiegand, 2017). Patient assessment determines the frequency of suctioning. It is indicated when rhonchi, gurgling breath sounds, and diminished breath sounds are audible on auscultation or visible secretions are present after other methods to remove airway secretions have failed. You may also use suctioning to obtain a sputum specimen for culture or cytology if the patient is unable to cough productively. There is no evidence to support suctioning on a scheduled basis. Too-frequent suctioning puts patients at risk for development of hypoxemia, hypotension, arrhythmias, and possible trauma to the mucosa of the lungs (Myatt, 2015; Wiegand, 2017).

Oropharyngeal and Nasopharyngeal Suctioning

Perform oropharyngeal or nasopharyngeal suctioning when a patient is able to cough effectively but is unable to clear secretions by expectorating. Apply suction after a patient has coughed (see Skill 41.1). Once the pulmonary secretions decrease and a patient is less fatigued, he or she is then able to expectorate or swallow the mucus, and suctioning is no longer necessary.

Orotracheal and Nasotracheal Suctioning

Perform oro-tracheal or nasotracheal suctioning is necessary when a patient with pulmonary secretions is unable to manage secretions by coughing and does not have an artificial airway present (see Skill 41.1). You pass a sterile catheter through the mouth or nose into the trachea. The nose is the preferred route because stimulation of the gag reflex is minimal. The procedure is similar to nasopharyngeal suctioning, but you advance the catheter tip farther into the patient's trachea. The entire procedure from catheter passage to its removal is done quickly, lasting no longer than 10 seconds (AARC, 2010a; Wiegand, 2017). Allow the patient to rest between passes of the catheter. If the patient develops respiratory distress, stop suctioning unless the collection of secretions is causing distress. If the

patient is using supplemental oxygen, replace the oxygen cannula or mask during rest periods.

Tracheal Suctioning

Perform tracheal suctioning through an artificial airway such as an endotracheal (ET) or tracheostomy tube. The size of a catheter should be as small as possible but large enough to remove secretions. Never apply suction pressure while inserting the catheter to avoid traumatizing the lung mucosa. Once you insert a catheter the necessary distance, maintain suction pressure between 80 and 120 mm Hg ([Wiegand, 2017](#)) as you withdraw. Apply suction intermittently only while withdrawing the catheter. Rotating the catheter enhances removal of secretions that have adhered to the sides of the airway.

The practice of normal saline instillation (NSI) into artificial airways to improve secretion removal may be harmful and is not recommended. Clinical studies comparing the results of suctioning following NSI with standard suctioning have not shown any clinical or significant results ([AARC, 2010a](#); [Wang et al., 2017](#)).

The two current methods of suctioning are the open and closed methods. Open suctioning involves using a new sterile catheter for each suction session ([Wiegand, 2017](#)). Wear sterile gloves and follow Standard Precautions during the suction procedure. Closed suctioning involves using a reusable sterile suction catheter that is encased in a plastic sheath to protect it between suction sessions ([Fig. 41.12](#)). Closed suctioning is most often used on patients who require invasive mechanical ventilation to support their respiratory efforts because it permits continuous delivery of oxygen while suction is performed and reduces the risk of oxygen desaturation. It is also associated with a decrease in the development of late-onset ventilator-associated pneumonia ([Letchford and Bench, 2018](#)). Although sterile gloves are not used in this procedure, nonsterile gloves are recommended to prevent contact with splashes from body fluids (see [Skill 41.1](#)).

FIG. 41.12 Ballard tracheal care, closed suction catheter.

REFLECT NOW

You are caring for a patient with cystic fibrosis. When entering the room, you note the patient to be in a supine position and complaining of a frequent, nonproductive cough. What are interventions that you can perform to help increase the patient's ability to expectorate the sputum?

Artificial Airways

An artificial airway is for a patient with a decreased level of consciousness or airway obstruction or who is in need of prolonged ventilatory support and aids in removal of tracheobronchial secretions and maintaining a patent airway. The presence of an artificial airway places a patient at high risk for infection and airway injury. Use clean technique for oral airways, but use sterile technique in caring for and maintaining endotracheal and

tracheal airways to prevent health care–associated infections (HAIs). Artificial airways need to stay in the correct position to prevent airway damage (Higginson et al., 2016; Wiegand, 2017) (see Skill 41.2).

Oral Airway

The oral airway, the simplest type of artificial airway, prevents obstruction of the trachea by displacement of the tongue into the oropharynx (Fig. 41.13). The oral airway extends from the teeth to the oropharynx, maintaining the tongue in the normal position. Determine the proper oral airway size by measuring the distance from the corner of the mouth to the angle of the jaw just below the ear. The length is equal to the distance from the flange of the airway to the tip. Use only the correct size airway. If the airway is too small, the tongue does not stay in the anterior portion of the mouth; if the airway is too large, it forces the tongue toward the epiglottis and obstructs the airway (Wiegand, 2017).

FIG. 41.13 Artificial oral airways.

Insert the airway upside down, then turn the curve of the airway toward the cheek and place it over the tongue. When the airway is in the

oropharynx, turn it so that the opening points downward. Correctly placed, the airway moves the tongue forward away from the oropharynx, and the flange (e.g., the flat portion of the airway) rests against the patient's teeth. Incorrect insertion merely forces the tongue back into the oropharynx ([Wiegand, 2017](#)).

Endotracheal and Tracheal Airways

An **endotracheal (ET) tube** is a short-term artificial airway used to administer invasive mechanical ventilation, relieve upper airway obstruction, protect against aspiration, or clear secretions. A physician or specially trained clinician inserts the ET tube. The tube is passed through the patient's mouth, past the pharynx, and into the trachea ([Fig. 41.14](#)). It is generally removed within 14 days; however, it is sometimes used for a longer period of time if the patient is still showing progress toward weaning from invasive mechanical ventilation and extubation (removal of the endotracheal tube) ([Urden et al., 2020](#); [Wiegand, 2017](#)).

FIG. 41.14 Endotracheal tube inserted into trachea. Cuff inflated to maintain position.

Copyright © 2015 Medtronic. All rights reserved. Used with the permission of Medtronic.

If a patient requires long-term assistance from an artificial airway, a **tracheostomy** is considered. A surgical incision is made into the inferior border of the cricoid cartilage of the trachea, and a short tracheostomy tube is inserted. Most tracheostomies have a small plastic inner tube that fits inside a larger one (the inner cannula). The most common complication of a tracheostomy tube is partial or total airway obstruction caused by buildup of respiratory secretions. If this occurs, the inner tube can be

removed and cleaned or replaced with a temporary spare inner tube that should be kept at the patient's bedside. Keep tracheal dilators at the bedside to have available for emergency tube replacement or reinsertion. Humidification from air humidifiers or humidified oxygen tracheostomy collars can help prevent drying of secretions that cause occlusion. Tracheostomy suctioning should be done as necessary to clear secretions. The majority of patients with a tracheostomy tube cannot speak because the tube is inserted below the vocal cords. It is important to use written or nonverbal communication (lipreading) strategies to help patients communicate. Be sure to assess patients for anxiety caused by the inability to speak. Care and cleaning of the tracheostomy tube is discussed in Skill 41.2 (Urden et al., 2020; Wiegand, 2017).

Invasive Mechanical Ventilation

Invasive mechanical ventilation, also referred to as positive-pressure ventilation, is a lifesaving technique used with artificial airways (ET or tracheostomy) for various physiological and clinical indications. Physiological indications for invasive mechanical ventilation include supporting cardiopulmonary gas exchange (alveolar ventilation and arterial oxygenation), increasing lung volume, and reducing the work of breathing (Urden et al., 2020). Clinical indications for invasive mechanical ventilation include reversing hypoxia and acute respiratory acidosis; relieving respiratory distress; preventing or reversing atelectasis and respiratory muscle fatigue; allowing for sedation and/or other neuromuscular blockade, thereby decreasing oxygen consumption; and stabilizing the chest wall (Urden et al., 2020). It can be used to either fully or partially replace spontaneous breathing, depending on the need of the patient. Invasive mechanical ventilation also redistributes oxygen demand from working respiratory muscles to other vital organs.

Ventilator-associated pneumonia (VAP) is a significant potential complication because the artificial airway tube bypasses many of the airway's and lung's normal defense mechanisms. Ventilator associated pneumonia (VAP) is a health care-acquired infection (HAI) that develops 48 hours or more after endotracheal intubation and mechanical ventilation (Letchford and Bench, 2018). It is a potentially serious complication in patients who are already critically ill. VAP mortality rates range from 10% to 55% among ventilated patients; VAP increases patient time in the ICU by 4 to 6 days and is estimated to add an additional \$40,000 to the cost of a hospital admission (Chahoud et al., 2015; Larrow and Klich-Heartt, 2016) (Box 41.8). Hospitals are not reimbursed for costs associated with VAP.

Box 41.8 Evidence-Based Practice Adherence to a Ventilator Care Bundle on Reducing Ventilator-Associated Pneumonia

PICOT Question: In patients requiring invasive mechanical ventilation, does adhering to an evidenced-based ventilator care bundle contribute to a reduction of ventilator-associated pneumonia (VAP)?

Evidence Summary

Ventilator associated pneumonia (VAP) is a health care–acquired infection (HAI) that develops in a person requiring invasive mechanical ventilation (via endotracheal intubation or tracheostomy tube) for at least 48 hours (Bassi et al., 2017). *Pseudomonas*, *Acinetobacter*, and methicillin-resistant *Staphylococcus aureus* are frequent bacterial causes of VAP (Chacko et al., 2017). Patients with VAP have fever, increased secretions, and pulmonary infiltrates seen on chest radiograph. Over time these infiltrates progressively increase, and the patient’s lung functions decline. VAP increases length of stay in the intensive care unit, is associated with increased morbidity and mortality, and increases the patient’s cost of hospitalization (Chacko et al., 2017; Larrow and Klich-Heartt, 2016).

In 2012, the Institute for Healthcare Improvement published an evidence-based how-to guide for the prevention of VAP (IHI, 2012). This guide was the beginning of a series of evidenced-based interventions related to ventilator care that, when implemented together, achieve significantly better outcomes than when implemented individually (Bassi et al., 2017). The key components of the VAP bundle include:

- Elevation of the head of the bed (HOB) greater than 30 degrees
- Daily “sedation vacations” and assessment of readiness to extubate
- Peptic ulcer disease prophylaxis
- Venous thromboembolism prophylaxis
- Daily oral care with chlorhexidine (Hua et al., 2016)
- Delirium monitoring
- Early mobilization (Bassi et al., 2017; Larrow and Klich-Heartt, 2016)

The use of the bundle (known as the VAP bundle or the ABCDE bundle) has been known to decrease rates of VAP (Kram et al., 2015; AACN, 2017a,b).

Application to Nursing Practice

- Implement the VAP bundle when mechanical ventilation is initiated (Anand et al., 2018).
- Avoid prolonged supine positioning. Pulmonary aspiration is increased by supine positioning and pooling of secretions above the ET tube cuff (AACN, 2018).
- Position with HOB elevation to 45 degrees or higher significantly reduces gastric reflux and VAP.
- Orotracheal and orogastric tubes are preferred over nasal devices to reduce the risk of VAP (Rouzé et al., 2017).
- Suction frequently to remove oropharyngeal and subglottic secretions to reduce the risk of early-onset VAP. Utilize subglottic suctioning to decrease the amount of secretions that pool in the oropharyngeal cavity (Bassi et al., 2017; Li et al., 2017) .
- Perform endotracheal and tracheostomy tube suctioning only when indicated by patient assessment findings and not on a scheduled basis.
- Monitor cuff pressure of the endotracheal and tracheostomy tubes frequently to ensure that there is an adequate seal to prevent aspiration of secretions.
- Always drain ventilator circuit condensation away from patient and into the appropriate receptacle. Drain the tubing hourly to prevent accumulation.
- Assess for and treat delirium.
- Change ventilator circuits only when visibly soiled.
- Ensure that humidity is added to the ventilator circuit.

Noninvasive Ventilation

Noninvasive positive-pressure ventilation (NPPV), a form of noninvasive ventilation (NIV), maintains positive airway pressure and improves alveolar ventilation without the need for an artificial airway. It is used for the treatment of obstructive sleep apnea, in patients with respiratory failure, and following extubation of an ET tube (Gale et al., 2015). This alternative to invasive ventilation reduces and reverses atelectasis; improves oxygenation; reduces pulmonary edema; and improves cardiac function. Positive-pressure ventilation keeps the alveoli partially inflated,

reducing the risk of atelectasis. Because the alveoli remain partially inflated, there is a continuous exchange of respiratory gas, which leads to improved oxygenation. In patients with obstructive sleep apnea, the NPPV helps to keep the airway open (Hortal et al., 2016; Xu et al., 2015). Goals of this type of ventilation include improved gas exchange, improved sleep, enhanced quality of life, reduction of morbidity, and improved physical function. The most common modes of NPPV are **continuous positive airway pressure (CPAP)** and **bilevel positive airway pressure (BiPAP)**.

CPAP maintains a steady stream of pressure throughout a patient's breathing cycle. It benefits patients with obstructive sleep apnea (OSA), patients with heart failure, and preterm infants with underdeveloped lungs. In obstructive sleep apnea (OSA), the upper airway collapses, causing obstruction that leads to shallow or absent breathing. Any air moving past the obstruction results in loud snoring. An overnight sleep study may be needed to determine the need and the correct settings for a CPAP machine (see Chapter 43). Equipment includes a mask (Fig. 41.15) that fits over the nose or both nose and mouth and a CPAP machine that delivers air to the mask (Hortal et al., 2016). The smallest mask with the proper fit is the most effective. It must be tight enough to form a seal on the face so that the air does not escape but not so tight as to cause pressure injury formation or necrosis where the mask is against the face (Schallom et al., 2015).

FIG. 41.15 CPAP mask.
Courtesy ResMed.

BiPAP works by providing assistance during inspiration and preventing alveolar closure during expiration. It provides both inspiratory positive airway pressure (IPAP) and expiratory airway pressure (EPAP), also known as *positive end-expiratory pressure (PEEP)*. During inhalation the positive pressure increases the patient's tidal volume and alveolar ventilation. The pressure support decreases when the patient exhales, allowing for easier exhalation. The overall result of BiPAP is an increased amount of air in the lungs at the end of expiration (functional residual

capacity), reduced airway closure, expansion of areas of atelectasis, and improved oxygenation ([Hartjes, 2018](#); [Urden et al., 2020](#)).

Complications of noninvasive ventilation include facial and nasal injury and skin breakdown, dry mucous membranes and thick secretions, and aspiration of gastric contents if vomiting occurs ([AACN, 2018](#)).

Complications avoided by noninvasive ventilation are VAP, sinusitis, and the effects of large-dose sedative agents. Use of noninvasive ventilation results in shorter intensive care unit (ICU) and hospital stays ([Gale et al., 2015](#); [Schallom et al., 2015](#)). Perform good oral hygiene every few hours while a patient is on NPPV to relieve dryness.

Chest Tubes

A **chest tube** ([Fig. 41.16](#)) is a catheter inserted through the rib cage into the pleural space to remove air, fluids, or blood; to prevent air or fluid from reentering the pleural space; or to reestablish normal intrapleural and intrapulmonic pressures after trauma or surgery ([Chotai and Mosenifar, 2018](#)). Chest tubes are common after chest surgery and chest trauma and are used for treatment of pneumothorax or hemothorax to promote lung reexpansion (see [Skill 41.3](#)).

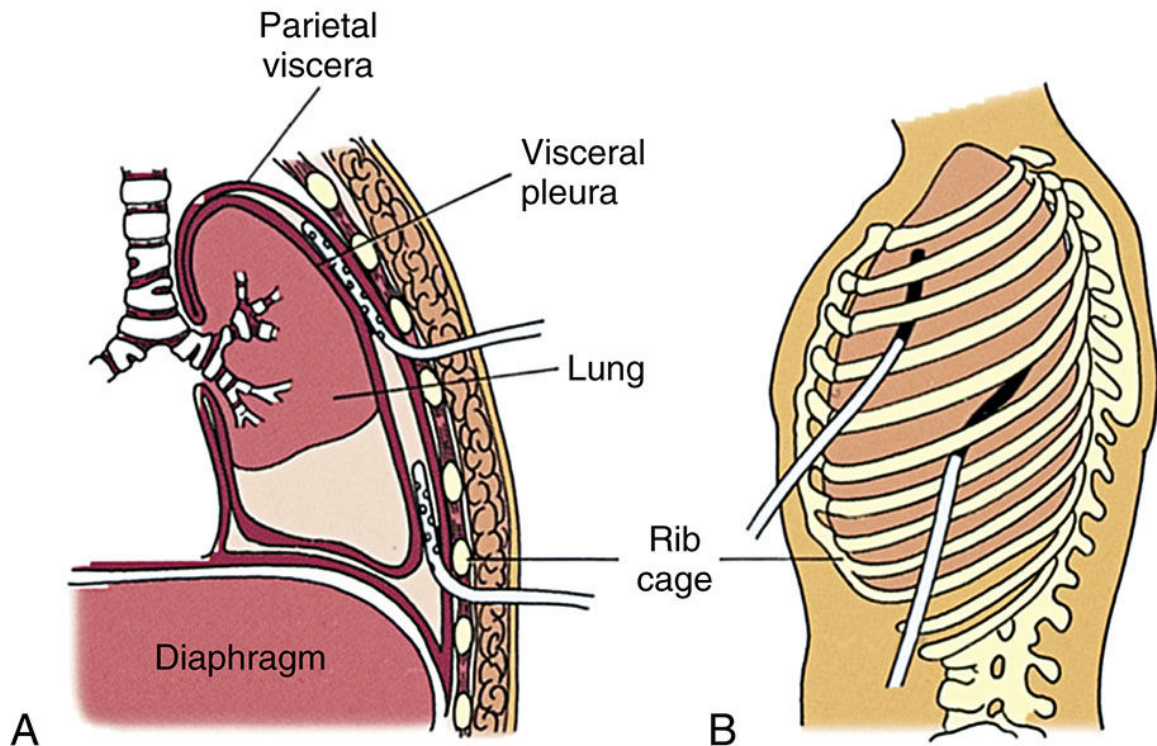

FIG. 41.16 Diagram of sites for chest tube placement. **A**, Anatomical drawing of upper tube placement for removal of air and lower tube placement for blood and fluid. **B**, View of tubes exiting through intracostal sites.

A **pneumothorax** is a collection of air in the pleural space. The loss of negative intrapleural pressure causes the lung to collapse. There are a variety of causes for a pneumothorax. A pneumothorax can occur as a result of chest trauma (e.g., stabbing, gunshot wound, or rib fracture). Other causes of pneumothorax are the rupture of an emphysematous bleb on the surface of the lung (the destruction caused by emphysema), tearing of the pleura from an invasive procedure such as surgery, insertion of a subclavian IV line, and invasive mechanical ventilation, including PEEP. Spontaneous pneumothorax occurs due to the rupture of small blebs (air-filled sacs). A spontaneous pneumothorax can occur in young, healthy individuals or in patients with a history of lung disease such as COPD or CF (Lewis et al., 2017). A patient with a pneumothorax usually feels sharp pain that is pleuritic and worsens on inspiration. Dyspnea is common and worsens as the size of the pneumothorax increases.

A tension pneumothorax is a life-threatening condition in which air enters the pleural space and cannot escape. The accumulation of air eventually leads to compression of the affected lung and pressure on the heart, causing the heart and great vessels to shift to the unaffected side. This shift then leads to compression of the unaffected lung, leading to

decreased oxygenation and decreased cardiac output. Clinical manifestations include dyspnea, tachycardia, tracheal deviation laterally, and absent breath sounds on the affected side. A tension pneumothorax is a medical emergency and requires immediate intervention, including needle decompression and chest tube placement ([Zardo et al., 2015](#); [Urden et al., 2020](#)).

A **hemothorax** is an accumulation of blood and fluid in the pleural space, usually as a result of trauma. It produces a counter pressure and prevents the lung from full expansion. A rupture of small blood vessels from inflammatory processes such as pneumonia or TB can cause a hemothorax, as can trauma. In addition to pain and dyspnea, signs and symptoms of shock develop if blood loss is severe ([Lewis et al., 2017](#); [Urden et al., 2020](#)).

A variety of chest tubes are available to drain air or excess fluid from the pleural space to relieve respiratory distress. Typically, a small-bore chest tube (12 to 20 Fr) is used to remove a small amount of air, and a larger-bore chest tube (greater than 20 Fr) is used to remove large amounts of fluid or blood ([Zardo et al., 2015](#)).

After a chest tube is inserted, it is attached to a drainage system. A traditional chest drainage unit (CDU) has three chambers for collection of drainage, water seal, and suction control. This unit can drain a large amount of both fluid and air. Disposable chest drainage systems, such as the Codman, Pleur-evac, or Atrium, allow for more mobility than previous bottle systems and are now more commonly used. The disposable systems also allow for increased ability to maintain sterility of the system ([Chotai and Mosenifar, 2018](#)). Nonventilated patients and patients who had thoracoscopic lung surgery or minimally invasive cardiac surgery do well with these mobile chest drains.

Special Considerations

Keep a chest tube drainage system closed and below the chest (see Skill 41.3). The chest tube should be secured to the chest wall. Watch for slow, steady bubbling in the water seal chamber and keep it filled with sterile water at the prescribed level. A constant or intermittent bubbling in the water-seal chamber, or new more vigorous bubbling, indicates a leak in the drainage system or another pneumothorax, and you must assess the system and the patient to accurately identify the source of the leak. Watch for fluctuation (tailing) of the fluid level to ensure that the chest tube and system are working. Mark the level on the outside of the collection chambers every shift. Report any unexpected cloudy or bloody drainage.

Avoid kinks and dependent loops in the tubing. Ideally, it should lie horizontally across the bed or chair before dropping vertically into the drainage device. Encourage your patient to cough, breathe deeply, and use the incentive spirometer. Make sure that he or she is in a semi-Fowler or high-Fowler (45-90 degrees) position and is ambulated if not contraindicated. Routinely evaluate respiratory rate, breath sounds, SpO₂ levels, and the insertion site for subcutaneous emphysema ([Chotai and Mosenifar, 2018](#)). Subcutaneous emphysema is the presence of air under the skin, and crepitus is palpated in the area where it is located ([Hartjes, 2018](#)).

Clamping a chest tube is contraindicated when ambulating or transporting a patient. Clamping can result in a tension pneumothorax. Air pressure builds in the pleural space, collapsing the lung and creating a life-threatening event. A chest tube is clamped only when replacing the chest drainage system, assessing for an air leak, or as a trial before removal to assess whether the air leak has stopped. Stripping or milking chest tubes to keep them patent is based on nursing assessment and may be necessary to remove clots in the tube ([Chotai and Mosenifar, 2018](#)). Routine milking or stripping of the chest tubes is not recommended as it can cause increased intrathoracic pressure and tissue damage ([Wiegand, 2017](#); [Makic et al., 2015](#)).

Handle the chest drainage unit carefully, and maintain the drainage device below the patient's chest. The drainage unit should always be maintained in an upright position. If it is knocked over, replacement of the unit is needed ([Chotai and Mosenifar, 2018](#)).

Removal of chest tubes requires patient preparation. The most frequent sensations reported by patients during chest tube removal include burning, pain, and a pulling sensation. Make sure that the patient is given pain medication at least 30 minutes before removal. The nurse assists the health care provider in removing the chest tube and monitors the dressing placed over the insertion site and the patient's respiratory status after tube removal ([Wiegand, 2017](#)). An unplanned removal of the chest tube, such as the tube being accidentally removed while repositioning the patient, requires the nurse to cover the site with a gloved hand and ask for help in retrieving supplies to cover the site. Petrolatum gauze, dry gauze, and tape will be needed to dress the site. If the chest tube becomes disconnected from the drainage system, clamp the tubing with the shodded hemostat or crimp the tubing with a gloved hand to prevent air from entering the pleural space. Ask for someone to get a new chest drainage system and attach it to the chest tube in a sterile manner. Regardless of how the tube

comes out, monitor the patient for signs of respiratory distress and auscultate lung sounds ([Muzzy and Butler, 2015](#)).

Maintenance and Promotion of Oxygenation

Promotion of lung expansion, mobilization of secretions, and maintenance of a patent airway assist patients in meeting their oxygenation needs. However, some patients also require oxygen therapy to keep a healthy level of tissue oxygenation.

Oxygen Therapy

Oxygen therapy is widely available and used in a variety of settings to relieve or prevent hypoxia, which can lead to hypoxemia. The goal of oxygen therapy is to prevent or relieve hypoxemia by delivering the lowest amount of oxygen possible and achieve adequate tissue oxygenation ([Walsh and Smallwood, 2017](#)). The dosage or concentration of oxygen is monitored continuously. Routinely check the health care provider's orders to verify that the patient is receiving the prescribed oxygen concentration. The seven rights of medication administration also pertain to oxygen administration (see [Chapter 31](#)).

Supplemental oxygen therapy offers many benefits to patients with acute and/or chronic cardiopulmonary diseases. This therapy reduces mortality, increases exercise tolerance, decreases pulmonary hypertension, and improves a patient's quality of life ([Franchini et al., 2016](#); [Wen et al., 2017](#)). It is important to reinforce to your patients why they may require supplemental oxygen in the acute care setting, as well as possible home use ([Box 41.9](#)).

Box 41.9 Procedural Guidelines Applying a Nasal Cannula or Oxygen Mask

Delegation and Collaboration

The skill of applying a nasal cannula or oxygen mask can be delegated to assistive personnel (AP) after the method of delivery and percentage of oxygen needed by a patient is determined. The nurse is responsible for assessing the patient's respiratory system and the response to oxygen therapy. The nurse, in some agencies, may collaborate with the respiratory therapist in the setup of oxygen therapy, including adjustment of oxygen flow rate. The nurse instructs the AP to:

- Safely adjust the device (e.g., loosening the strap on the oxygen cannula or mask) and clarify its correct placement and positioning.
- Inform the nurse immediately about any changes in vital signs; changes in pulse oximetry (SpO₂); changes in level of consciousness (LOC); skin irritation from the cannula, mask, or straps; or patient complaints of pain or shortness of breath.
- Provide extra skin care around patient's ears and nose or other parts of the patient's body that might be irritated by the device.

Equipment

(Note: If device is used in the home, the home care equipment vendor provides the equipment.)

Oxygen delivery device as ordered by health care provider; oxygen tubing (consider extension tubing as needed); humidifier, if indicated; sterile water for humidifier; oxygen source; oxygen flowmeter; "oxygen in use" sign; pulse oximeter; stethoscope; clean gloves; face shield, if risk of splash from secretions is present

Steps

1. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy. Compare identifiers with information on patient's MAR or medical record.
2. Review accuracy of health care provider's order for oxygen, noting delivery method, flow rate, duration of oxygen therapy, and parameters for titration of oxygen settings.
3. Obtain data from patient's electronic health record (vital signs, pulse oximetry, arterial blood gas values).
4. Perform hand hygiene and apply gloves. Perform respiratory assessment, including symmetry of chest wall expansion, chest wall abnormalities (e.g., kyphosis), temporary conditions (e.g., pregnancy, trauma) affecting ventilation, respiratory rate and depth, sputum production, lung sounds, and signs and symptoms associated with hypoxia.
5. Observe for cognitive and/or behavioral changes (e.g., apprehension, anxiety, confusion, decreased ability to concentrate, decreased LOC, fatigue, and dizziness).

CLINICAL DECISION: Patients with sudden changes in their vital signs, LOC, or behavior may be experiencing profound hypoxia. Patients who demonstrate subtle changes over time may have worsening of a chronic or existing condition or a new medical condition (Lewis et al., 2017).

6. Assess airway patency and remove airway secretions by having patient cough and expectorate mucus or by suctioning (see Skill 41.1). **Note:** Continue wearing gloves. However, remove and dispose of gloves and perform hand hygiene if there is contact with mucus. Then reapply gloves if contact with mucus is likely.

CLINICAL DECISION: Excessive amounts of secretions, signs of respiratory distress (increased work of breathing, increased respiratory rate), presence of rhonchi on auscultation, excessive coughing, or decrease in patient pulse oximeter indicate need for suctioning.

7. Inspect condition of skin around nose and ears.
8. Assess patient's or family caregiver's knowledge, experience, and health literacy level.
9. Apply face shield if risk of exposure to splashing mucus exists.
10. Attach oxygen-delivery device (e.g., cannula, mask) to oxygen tubing and attach end of tubing to humidified oxygen source adjusted to prescribed flow rate (see illustration).

STEP 10 Flowmeter attached to oxygen source.

11. Apply oxygen device:

- a. Place tips of the cannula into patient's nares. If tips are curved, they should point downward inside nostrils. Then loop cannula tubing up and over patient's ears. Adjust lanyard so that cannula fits snugly but not too tight and without pressure to patient nares and ears (see illustration).

STEP 11a Nasal cannula adjusted for proper fit.

- b. Apply a mask by placing it over patient's mouth and nose. Then bring straps over patient's head and adjust to form a comfortable but tight seal.
 - c. Maintain sufficient slack on oxygen tubing and secure to patient's clothes.
12. Observe for proper function of oxygen-delivery device:
- a. *Nasal cannula*: Cannula is positioned properly in nares; oxygen flows through tips.
 - b. *Partial nonrebreather mask*: Mask seals tightly around mouth. Reservoir fills on exhalation and almost collapses on inspiration. Reservoir should not collapse completely (see illustration).

STEP 12b Plastic face mask with reservoir bag.

- c. *Oxygen-conserving cannula (Oxymizer)*: Fit as for nasal cannula. Reservoir is located under patient's nose or worn as a pendant.
- d. *Nonrebreather mask*: Apply as regular mask. Contains one-way valves with reservoir; exhaled air does not enter reservoir bag. Can be combined with nasal cannula to provide higher inspired oxygen concentration (FiO_2).
- e. *Simple face mask*: Select appropriate flow rate (see illustration).

STEP 12e Simple face mask.

f. *Venturi* mask (see illustration): Apply as regular mask. Select appropriate flow rate (see Table 41.7).

STEP 12f Venturi mask.

g. *High-flow nasal cannula* (see illustration).

STEP 12g High-flow nasal cannula.
Courtesy Fischer & Paykel Healthcare.

13. Verify setting on flowmeter and oxygen source for proper setup and prescribed flow rate.
14. Check cannula/mask every 8 hours or as agency policy indicates. Keep humidification container filled at all times.
15. Post "Oxygen in use" signs on wall behind bed and at entrance to room.
16. Properly dispose of gloves (if used) and perform hand hygiene.
17. Be sure nurse call system is accessible and within patient's reach. Instruct the patient on its use.
18. Monitor patient's response to changes in oxygen flow rate with SpO₂. **Note:** Monitor ABGs when ordered; however, obtaining ABG measurement is an invasive procedure, and ABGs are not measured frequently.
19. Perform physical assessment, auscultating lung sounds; palpating chest excursion; inspecting color and condition of skin; and observing for decreased anxiety, improved LOC and cognitive abilities, decreased fatigue, and absence of dizziness. Measure vital signs.

20. Assess adequacy of oxygen flow each shift or as agency policy dictates.
21. Observe patient's external ears, bridge of nose, nares, and nasal mucous membranes for evidence of skin breakdown.
22. **Use Teach-Back:** "I want to be sure I explained how oxygen will help you. Tell me why oxygen is beneficial for you." Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly.

Safety Precautions

Oxygen is a highly combustible gas. Although it does not burn spontaneously or cause an explosion, it can easily cause a fire in a patient's room if it contacts a spark from an open flame or electrical equipment. With increasing use of home oxygen therapy, patients and health care professionals need to be aware of the dangers of combustion ([AARC, 2007](#)). Be cognizant of agency procedures for managing a fire or know the local emergency response phone number (often 911) in case of a fire at a patient's home.

Follow these oxygen safety precautions:

- Oxygen is a therapeutic gas and must be prescribed and adjusted only with a health care provider's order. Distribution must be in accordance with federal, state, and local regulations ([Jacobs et al., 2018](#)).
- Keep oxygen-delivery systems 10 feet from any open flames.
- Oxygen is a combustible substance. Determine that all electrical equipment in the room is functioning correctly and properly grounded (see [Chapter 27](#)). An electrical spark in the presence of oxygen can result in a serious fire as oxygen supports combustion.
- When using oxygen cylinders, secure them so that they do not fall over. Store them upright and either chained or secured in appropriate holders.
- Check the oxygen level of portable tanks before transporting a patient to ensure that there is enough oxygen in the tank.
- Ensure that patients have adequate oxygen tubing to safely move around their agency or home environment.

Supply of Oxygen

Oxygen is supplied to a patient's bedside either by oxygen tanks or through a permanent wall-piped system. Oxygen tanks are transported on wide-based carriers that allow the tank to be placed upright at the bedside. Regulators control the amount of oxygen delivered. One common type is an upright flowmeter with a flow adjustment valve at the top. A second type is a cylinder indicator with a flow adjustment handle.

Methods of Oxygen Delivery

The nasal cannula and oxygen masks are the most common devices to deliver oxygen to patients. These devices deliver different levels of oxygen to patients (see [Box 41.9](#); [Table 41.7](#)).

TABLE 41.7

Oxygen Delivery Systems

Delivery System	FiO ₂ Delivered	Advantages	Disadvantages
Low-Flow Delivery Devices			
Nasal cannula	1-6 L/min: 24%-44%	Safe and simple Easily tolerated Effective for low concentrations Does not impede eating or talking Inexpensive, disposable	Unable to use with nasal obstruction Drying to mucous membranes Can dislodge easily May cause skin irritation or breakdown around ears or nares Patient's breathing pattern (mouth or nasal) affects exact FiO ₂
Oxygen-conserving cannula (<i>Oxymizer</i>)	8 L/min: up to 30%-50%	Indicated for long-term O ₂ use in the home Allows increased O ₂ concentration and lower flow	Cannula cannot be cleaned More expensive than standard cannula
Simple face mask	6-12 L/min: 35%-50%	Useful for short periods such as patient transportation	Contraindicated for patients who retain CO ₂ May induce feelings of claustrophobia Therapy interrupted with eating and drinking Increased risk of aspiration
Partial and nonrebreather masks (Note: Reservoir bag should always remain partially inflated.)	10-15 L/min: 60%-90%	Useful for short periods Delivers increased FiO ₂ Easily humidifies O ₂ Does not dry mucous membranes	Hot and confining; may irritate skin; tight seal necessary Interferes with eating and talking Bag may twist or kink; should not totally deflate
High-Flow Delivery Devices			
Venturi mask	24%-50%	Provides specific amount of oxygen with humidity added Administers low, constant O ₂	Mask and added humidity may irritate skin Therapy interrupted with eating and drinking Specific flow rate must be followed
High-flow nasal cannula	Adjustable FiO ₂ (0.21-1) with modifiable flow (up to 60 L/min)	Wide range of FiO ₂ Can use on adults, children, and infants	FiO ₂ dependent on patient respiratory pattern and input flow Risk for infection (Urden et al., 2020)
Noninvasive Ventilation			
Continuous positive airway pressure (CPAP) and bilevel positive airway pressure (BiPAP)	21%-100%	Avoids the use of an artificial airway in some patients with acute respiratory distress, postextubation respiratory failure, or neuromuscular disorders Successfully treats obstructive sleep apnea	Nasal pillows/face masks can cause skin breakdown May cause claustrophobia in some patients

CO₂, Carbon dioxide; FiO₂, fraction of inspired oxygen concentration. FiO₂ delivered may differ by manufacturer; check manufacturer's guidelines.

Data for high-flow cannula: Walsh BK, Smallwood CD: Pediatric oxygen therapy: a review and update, *Respir Care* 62(6):645, 2017. Source for noninvasive ventilation: Wiegand D: *AACN procedure manual for high acuity, progressive, and critical care*, ed 7, St Louis, 2017, Elsevier.

Nasal Cannula

A **nasal cannula** has two nasal prongs that are slightly curved and inserted in a patient's nostrils. To keep the nasal prongs in place, fit the attached tubing over the patient's ears and secure it under the chin using the sliding connector. Be alert for skin breakdown over the ears and in the nostrils from too tight an application. Attach the nasal cannula to an oxygen source with a flow rate of 1 to 6 L/min (24% to 44% oxygen). Flow rates equal to or greater than 4 L/min have a drying effect on the mucosa and thus need to be humidified ([AARC, 2007](#); [Hartjes, 2018](#)). Know which flow rate produces a given percentage of inspired oxygen concentration (FiO₂).

High-Flow Nasal Cannula

High-flow nasal cannula (HFNC) is a relatively new method of oxygen delivery. It provides heated, humidified oxygen through a nasal cannula at flow rates as high as 60 L/minute while an air-oxygen blender allows for the titration of the FiO₂. The cannula is typically larger in diameter than the standard nasal cannula. HFNC is used to treat respiratory failure, and early evidence indicates that there is less need for invasive ventilation in patients who are initially treated with HFNC ([Walsh and Smallwood, 2017](#); [Xu et al., 2018](#)).

Oxygen Masks

An oxygen mask is a plastic device that fits snugly over the mouth and nose and is secured in place with a strap. It delivers oxygen as the patient breathes through either the mouth or nose by way of a plastic tubing at the base of the mask that is attached to an oxygen source. An adjustable elastic band is attached to either side of the mask that slides over the head to above the ears to hold the mask in place. There are two primary types of oxygen masks: those delivering low concentrations of oxygen and those delivering high concentrations.

The simple face mask is used for short-term oxygen therapy. It fits loosely and delivers oxygen concentrations from 6 to 12 L/min (35% to 50% oxygen). The mask is contraindicated for patients with carbon dioxide retention because retention can be worsened, leading to decreased levels of consciousness. Flow rates should be 6 L or more to avoid rebreathing exhaled carbon dioxide retained in the mask. Be alert to skin breakdown under the mask with long-term use (Hartjes, 2018).

Partial rebreather and nonrebreather masks are simple masks with a reservoir bag that are capable of delivering higher concentrations of oxygen for a short period of time (60% to 90% oxygen at a flow rate of 10 to 15 L/min). Frequently inspect the reservoir bag to make sure that it is inflated. If it is deflated, the patient is breathing large amounts of exhaled carbon dioxide. (Hartjes, 2018; Lewis et al., 2017).

The Venturi mask delivers high flow, more precise oxygen concentrations of 24% to 60% and usually requires oxygen flow rates of 4 to 12 L/min, depending on the flow-control meter selected. Its use is typically reserved for patients with COPD who need low, constant oxygen concentrations (Hartjes, 2018; Lewis et al., 2017).

Building Competency in Safety

Mr. Edwards, a 75-year-old man with COPD, is receiving oxygen therapy via nasal cannula. What are ways you can prevent complications from this type of oxygen delivery device?

Restoration of Cardiopulmonary Functioning

If a patient's hypoxia is severe and prolonged, cardiac arrest results. A cardiac arrest is a sudden cessation of cardiac output and circulation. When this occurs, oxygen is not delivered to tissues, carbon dioxide is not transported from tissues, tissue metabolism becomes anaerobic, and metabolic and respiratory acidosis occur. Permanent damage to the heart, brain, and other tissue occurs within 4 to 6 minutes.

Cardiopulmonary Resuscitation

During cardiac arrest there is an absence of pulse and respiration. Patients in cardiac arrest require immediate **cardiopulmonary resuscitation** (CPR), a basic emergency procedure of artificial respiration and manual external cardiac massage. The sequence for CPR is C-A-B: chest compression, early defibrillation, establishing an airway, and rescue breathing ([Link et al., 2015](#)).

The American Heart Association ([AHA, 2015](#)) continues to research cardiac arrest treatment and outcomes. In adults (the majority of cardiac arrests) the critical initial elements found to be essential for survival were adequate chest compressions and early defibrillation. Adequate compressions in adults need to occur at a rate of 100 to 120/minute with a depth of at least 2 inches and allowance for time for the chest to recoil. Passive ventilation is no longer recommended in patients undergoing conventional CPR in the community setting, although it may be used in emergency medical service settings ([Neumar et al., 2015](#)).

Defibrillation delivers an electrical current to the myocardium that stops all electrical activity and allows the heart's normal pacemaker to resume its normal activity ([Wiegand, 2017](#)). It is recommended that defibrillation occur within 5 minutes for an out-of-hospital sudden cardiac arrest and within 3 minutes for a patient in a hospital. An automated external defibrillator (AED) ([Box 41.10](#)), available in many public places, such as schools, airports, and workplaces, can be used by health care providers and lay individuals alike to defibrillate people with cardiac arrest ([AHA, 2018](#); [Neumar et al., 2015](#)).

Box 41.10 Automated External Defibrillator

- The automated external defibrillator (AED) is a device used to administer an electrical shock through the chest wall to the heart to stop the abnormal rhythm and restore a normal heart rhythm.
- The AED has built-in computers that assess a patient's heart rhythm and determine whether defibrillation is necessary. New technology has made them user friendly, with audio and visual cues telling users what to do when using them. The AED delivers a shock to the patient after announcing, "Everyone stand clear of patient." A shock is delivered only if the patient needs it (NHLBI, n.d.b).
- Lay rescuer AED programs train lay personnel on the use of the AED (AHA, 2018).
- The AED is used to strengthen the chain of survival. Patients who received a shock from an AED available in the public had a higher survival rate and rate of discharge from the hospital than those who did not (AHA, 2018).
- For witnessed ventricular fibrillation, early cardiopulmonary resuscitation with defibrillation within the first 3 to 5 minutes results in greater survival rates (Lewis et al., 2017).

If a person is choking and has an obstructed airway, perform abdominal thrusts until the person is able to speak and breathe unassisted or becomes unconscious. Then you perform CPR. You may sweep the mouth and remove the foreign body if you can see it ([AHA, 2015](#)).

Restorative and Continuing Care

Restorative and continuing care emphasizes cardiopulmonary reconditioning as a structured rehabilitation program.

Cardiopulmonary rehabilitation helps patients achieve and maintain an optimal level of health through controlled physical exercise, nutritional counseling, relaxation and stress-management techniques,

and prescribed medications and oxygen. As physical reconditioning occurs, a patient's complaints of dyspnea, chest pain, fatigue, and activity intolerance decrease. In addition, the patient's anxiety, depression, or somatic concerns often decrease. The patient and the rehabilitation team define the goals of rehabilitation.

Respiratory Muscle Training

Respiratory muscle training improves muscle strength and endurance, resulting in improved activity tolerance. It typically consists of repetitive breathing exercises performed against some external force or load. Respiratory muscle training prevents respiratory failure in patients with COPD. There are several devices and methods available for this type of training. One method for respiratory muscle training is the incentive spirometer ([Ahmadi et al., 2016](#); [Menzes et al., 2018](#)).

Breathing Exercises

Breathing exercises include techniques to improve ventilation and oxygenation. The three basic techniques are deep-breathing and coughing exercises, pursed-lip breathing, and diaphragmatic breathing. Deep-breathing and coughing exercises, previously discussed, are routine interventions used by postoperative patients (see [Chapter 50](#)).

Pursed-Lip Breathing

Pursed-lip breathing involves deep inspiration and prolonged expiration through pursed lips to prevent alveolar collapse. While sitting up, instruct the patient to take a deep breath and exhale slowly through pursed lips as if blowing out a candle. Patients need to gain control of the exhalation phase so that it is longer than inhalation. The patient is usually able to perfect this technique by counting the inhalation time and gradually increasing the count during exhalation ([COPD Foundation, 2019](#)). In studies using pursed-lip breathing as a method to improve exercise tolerance in patients with COPD, patients were able to demonstrate increases in their exercise tolerance, breathing pattern, and arterial oxygen saturation ([Cabral et al., 2015](#)).

Diaphragmatic Breathing

Diaphragmatic breathing is useful for patients with pulmonary disease and dyspnea secondary to heart failure. This type of breathing increases tidal volume and decreases respiratory rate, which leads to an overall improved breathing pattern and quality of life (Morrow et al., 2016; Seo et al., 2016).

Diaphragmatic breathing is more difficult than other breathing methods because it requires a patient to relax intercostal and accessory respiratory muscles while taking deep inspirations, which takes practice. The patient places one hand flat below the breastbone (upper hand) and the other hand (lower hand) flat on the abdomen. Ask him or her to inhale slowly, making the abdomen push out (as the diaphragm flattens, the abdomen should extend out) and moving the lower hand outward. When the patient exhales, the abdomen goes in (the diaphragm ascends and pushes on lungs to help expel trapped air). The patient practices these exercises initially in the supine position and then while sitting and standing. The exercise is often used with the pursed-lip breathing technique.

Home Oxygen Therapy

Indications for home oxygen therapy include an arterial partial pressure (PaO_2) of 55 mm Hg or less or an arterial oxygen saturation (SaO_2) of 88% or less on room air at rest, on exertion, or with exercise (CMS, 2017). Home oxygen therapy is administered via nasal cannula or face mask. Patients with permanent tracheostomies use either a T tube or tracheostomy collar (AARC, 2007; Wiegand, 2017). Home oxygen therapy has beneficial effects for patients with chronic cardiopulmonary diseases. This therapy improves patients' exercise tolerance and fatigue levels and, in some situations, assists in the management of dyspnea (see Skill 41.4).

There are three types of oxygen-delivery systems: compressed gas cylinders, liquid oxygen, and oxygen concentrators. Before placing a certain delivery system in a home, assess the advantages and disadvantages (Table 41.8) of each type, along with the patient's needs and community resources. In the home the major consideration is the oxygen-delivery source.

TABLE 41.8**Home Oxygen Storage Systems**

Primary Use	Advantages	Disadvantages
Compressed Gas Cylinders		
Stationary and portable systems designed for intermittent therapy such as for exercise or sleep or as a backup system for a concentrator only.	100% oxygen stored in steel or aluminum cylinders; relatively inexpensive, no loss of gas during storage, relatively portable, delivery of up to 15 L/min; does not require electrical source; smaller tanks available for portability.	Bulky and heavy; must be secured safely to prevent them from falling over; frequent refilling necessary with continuous use; patient must know how to read regulator and understand when to call supplier; portable cylinders weigh 15 lb.
Liquid Oxygen Systems		
Stationary and portable system of choice for high-volume users and active patients.	100% oxygen; more oxygen occupies a smaller space; patient carries convenient ambulatory units refilled at home as shoulder bag, backpack, or wheeled luggage cart; delivery of up to 6 L/min; they come with a battery pack or electrical connections for cars; patient can safely refill ambulatory units from larger reservoir; quiet and easy operation; minimal maintenance; does not require electricity for operation; requires relatively fewer deliveries of oxygen.	Evaporates, especially in warmer temperatures and when not in use; potential for connections to freeze together or form frost at connections if tight connection not maintained during filling; costly setup and delivery fees. The liquid oxygen is very cold and can harm the skin instantly upon contact.
Oxygen Concentrators		
Stationary system; cost-effective for patients requiring low-flow continuous oxygen and patients with limited mobility inside or outside the home.	Provide a large source of oxygen, inexpensive, fixed monthly costs; most units with delivery of 1 to 5 L/min; good choice for people who do not leave their homes frequently; no cylinders or tanks to refill; delivery up to 10 L/min with specific makes and models. They must be placed in an open, well-ventilated area away from heat and flames. They work by removing nitrogen from room air to make the air 94% to 98% oxygen. They can be small and can weigh from 22 to 70 lb.	Oxygen concentration decreases as liter flow increases; power supply needed; increased electric costs; is not an ambulatory unit; therefore, it requires second system for portability; requires regular maintenance and backup system.
Compressed Gas		
Small cylinders with compressed gas that allow for portability.	Different models allow from 1 to 5 hours of portable oxygen. Cylinders can be easily wheeled on a cart or a stroller. Smaller tanks can be carried in backpacks, fanny packs, or shoulder bags. Each cylinder is fitted with a regulator used for adjusting the flow rate. At a rate of 2 L/min, they last only a few hours. The most common cylinder used is the E-cylinder; it lasts about 5 hours at a rate of 2 L/min.	They last only a few hours. E-cylinders are not appropriate as a sole source of oxygen for continuous, long-term therapy.

American Thoracic Society (ATS): *Oxygen therapy*, updated 2016, <http://www.thoracic.org/patients/patient-resources/resources/oxygen-therapy.pdf>, accessed May 2019, and McCoy RW: Options for home oxygen therapy equipment: storage and metering of oxygen in the home, *Resp Care* 58(1):65, 2013.

Patients and their family caregivers need extensive teaching to be able to manage oxygen therapy efficiently and safely (see Skill 41.4). Teach the patient and family about home oxygen delivery (e.g., oxygen safety, regulation of the amount of oxygen, and how to use the prescribed home oxygen-delivery system) to ensure their ability to maintain the oxygen-delivery system. The home health nurse coordinates the efforts of the patient and family, home respiratory

therapist, and home oxygen equipment vendor. The social worker usually assists initially with arranging for the home care nurse and oxygen vendor.

• **Evaluation**

Evaluate nursing interventions and therapies by evaluating whether patient expectations have been met and by comparing the patient's progress with the goals and expected outcomes of the nursing care plan (Fig. 41.17).

Knowledge

- Characteristics of adequate oxygenation status
- Understanding of patient's care expectations

Experience

- Previous patient responses to planned nursing therapies for impaired oxygenation

EVALUATION

- Evaluate signs and symptoms of the patient's oxygenation status after nursing interventions
- Ask for the patient's perception of oxygenation status after interventions
- Ask whether the patient's expectations are being met

Standards

- Use established expected outcomes to evaluate the patient's response to care (e.g., pulse oximetry remains above 92%, respiratory rate remains between 20 and 24 breaths/min)
- Apply intellectual standards of clarity, precision, specificity, and accuracy when evaluating outcomes of care

Attitudes

- Demonstrate perseverance when an intervention is unsuccessful and must be revised
- Use discipline to reassess and evaluate the patient's signs and symptoms to determine the true success of interventions

FIG. 41.17 Critical thinking model for oxygenation evaluation.

Through the Patient's Eyes

It is important to determine a patient's perceptions of his or her care. Does the home care patient feel that interventions have improved the ability to maintain a more normal lifestyle? Does the acute care patient feel more at ease breathing? Focus on evaluating how a disease is affecting day-to-day activities and the patient's perceived response to treatment. Patients who have chronic heart and lung problems often must be motivated to participate in necessary therapies. Evaluate the patient's motivation and emotional readiness to adhere to treatments provided. Be aware of the need to change a treatment plan to be culturally sensitive to improve adherence. Determine whether the patient and family caregiver feel more in control of their health situation after you have provided instruction. There are a considerable number of surveys that health care team members can utilize to determine the patient's quality of life.

Patient Outcomes

Compare the patient's actual progress with the goals and expected outcomes of the nursing care plan to determine his or her health status. If the nursing measures used are unsuccessful in improving oxygenation, modify the care plan and reevaluate. Continuous evaluation helps to determine whether new or revised therapies are required and whether new nursing diagnoses have developed and require a new plan of care. Do not hesitate to notify the health care provider about a patient's deteriorating oxygenation status. Prompt notification helps avoid an emergency situation or even the need for CPR. Examples of evaluative measures include:

- Ask the patient about his or her degree of breathlessness. Observe respiratory rate before, during, and after any activity or procedure.
- Ask the patient about fatigue during ambulation. Monitor pulse oximetry and pulse rate before, during, and after any activity or procedure.

- Ask the patient to rate breathlessness on a scale of 0 to 10, with 0 being no shortness of breath and 10 being severe shortness of breath.
- Ask the patient which interventions help reduce dyspnea.
- Ask the patient about frequency of cough and sputum production, and assess any sputum produced.
- Auscultate lung sounds for improvement in adventitious sounds.
- When needed, monitor arterial blood gas levels, pulmonary function tests, chest x-ray films, ECG tracings, and physical assessment data to provide objective measurement of the success of therapies and treatments.

Safety Guidelines for Nursing Skills

Ensuring patient safety is an essential role of the professional nurse. To ensure patient safety, communicate clearly with members of the health care team, assess and incorporate the patient's priorities of care and preferences, and use the best evidence when making decisions about your patient's care. When performing the skills in this chapter, remember the following points to ensure safe, individualized patient care.

- Know a patient's baseline range of vital signs. Patients with sudden changes in their vital signs, level of consciousness, or behavior are possibly experiencing profound hypoxemia. Patients who demonstrate subtle changes over time have worsening of a chronic or existing condition or a new medical condition. (Hartjes, 2018).
- Limit the introduction of the catheter to 2 times with each suctioning procedure (Wiegand, 2017).
- Perform tracheal suctioning before pharyngeal suctioning whenever possible. The mouth and pharynx contain more bacteria than the trachea. If there is an abundance of oral secretions present before beginning the procedure, suction mouth with separate oral suction device.

- Use caution when suctioning patients with a head injury. Suctioning elevates the intracranial pressure (ICP). Reduce this risk by hyperventilating on a ventilator prior to suctioning. This results in hypocarbia that in turn induces vasoconstriction. Vasoconstriction reduces the potential increase in ICP.
- The routine use of normal saline instillation (NSI) into the airway before endotracheal and tracheostomy suctioning is not recommended. Use of NSI is associated with the adverse effects of excessive coughing, bronchospasm, spread of organisms to the lower respiratory tract, and decreased oxygen saturation (AARC, 2010b, Wang et al., 2017). In certain circumstances, if it is necessary to stimulate a cough, normal saline may be indicated. This requires collaboration with the health care team.
- Review institutional policy before stripping or milking chest tubes. Most institutions have stopped using this practice because stripping the tube greatly increases intrapleural pressure, which can damage the pleural tissue and cause pneumothorax or worsen an existing pneumothorax.
- The most serious tracheostomy complication is airway obstruction, which can result in cardiac arrest. Most tracheostomy tubes are designed with a small plastic inner tube/cannula that sits inside the larger one. If the airway becomes occluded, the smaller one can be removed and replaced with a temporary spare. It is important to always have a spare at the bedside for emergency replacement.
- Patients with COPD who are breathing spontaneously should cautiously receive high levels of oxygen therapy because it results in a decreased stimulus to breathe (Grindrod, 2015).

Skill 41.1. • Suctioning

Delegation and Collaboration

The skill of artificial airway suctioning of newly inserted artificial airways cannot be delegated to assistive personnel (AP). However, when a patient has been assessed by the nurse as stable, oropharyngeal and well-established tracheostomy tube suctioning can be delegated. The nurse directs the AP about:

- Any modifications of the skill such as the need for supplemental oxygen.
- Appropriate suction limits for suctioning nasotracheally and for suctioning ETTs and TTs and risks of applying excessive or inadequate suction pressure.
- Reporting any changes in patient's respiratory status, level of consciousness, restlessness, secretion color and amount, and unresolved coughing or gagging.
- Reporting any changes in patient's color, vital signs, or complaints of pain.

The nurse may need to collaborate with the respiratory therapist as respiratory therapists are also allowed to perform this procedure at certain health care agencies.

Equipment

Oropharyngeal Suctioning

- Clean, nonsterile suction catheter or Yankauer suction tip catheter
- Clean gloves
- Clean towel or paper drape
- Mask, goggles, or face shield if indicated; gown if isolation procedures dictate
- Disposable cup or basin
- Tap water or normal saline (about 100 mL)
- Suction machine or wall suction device with regulator
- Connecting tubing (6 feet)
- Stethoscope
- Pulse oximeter
- Oral airway (if indicated)
- Washcloth
- Manual self-inflating resuscitation bag (bag-valve-mask) with oxygen connecting tubing

Nasotracheal Suctioning

- Sterile suction catheter (12 to 16 Fr) (smallest diameter that effectively removes secretions)
- Two sterile gloves or one sterile and one clean glove
- Sterile basin (e.g., sterile disposable cup)
- Sterile water or normal saline (about 100 mL)
- Clean towel or paper drape
- Mask, goggles, or face shield if indicated; gown if isolation procedures dictate
- Stethoscope
- Pulse oximeter
- Suction machine or wall suction device with regulator
- Connecting tubing (6 feet)
- Manual self-inflating resuscitation bag (bag-valve-mask) with oxygen connecting tubing

Endotracheal or Tracheostomy Suctioning

- Appropriate-size suction catheter, usually 12 to 16 Fr (smallest diameter that will remove secretions effectively, preferably one that is no more than half of the internal diameter of the artificial airway to minimize decrease in PaO₂) (AARC, 2010a; Branson et al., 2014)
- Suction machine or wall suction device with regulator
- Two sterile gloves or one sterile and one clean glove
- Sterile basin
- Sterile normal saline (about 100 mL)
- Clean towel or sterile drape
- Mask, goggles, or face shield, if indicated; gown if isolation procedures dictate
- Small Y-adapter (if catheter does not have a suction control port)

- Pulse oximeter, stethoscope and end-tidal CO₂ detector
- Manual self-inflating resuscitation bag (bag-valve-mask) with oxygen connecting tubing
- PEEP valve for resuscitation bag

Closed-System on In-Line Suctioning

- Closed-system or in-line suction catheter
- 5- to 10-mL normal saline in syringe or vials
- Two clean gloves
- Suction machine or wall suction device with regulator
- Connecting tubing (6 feet)
- Oral suction kit/supplies for oropharyngeal suctioning
- Mask, goggles, or face shield if indicated; gown if isolation procedures dictate
- Pulse oximeter and stethoscope
- Manual self-inflating resuscitation bag (bag-valve-mask) with oxygen connecting tubing, while not necessary for the procedure, is safe to have on hand.

Step	Rationale
Assessment	
<p>1. Identify patient using at least two identifiers (e.g., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's MAR or medical record.</p>	<p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2020).</p>
<p>2. Review medical record to identify contraindications to nasotracheal suctioning: occluded nasal passages; nasal bleeding; epiglottitis or croup; acute head, facial, or neck injury or surgery; coagulopathy or bleeding disorder; irritable airway; laryngospasm or bronchospasm; gastric surgery with high anastomosis; myocardial infarction (AARC, 2004; Hockenberry et al., 2019; Wiegand, 2017).</p>	<p>These conditions are contraindicated because passage of suction catheter through nasal route causes trauma to existing facial trauma/surgery, increases nasal bleeding, or causes severe bleeding in presence of coagulopathy or bleeding disorders. In presence of epiglottitis or croup, laryngospasm, or irritable airway, passage of suction catheter through nose causes intractable coughing, hypoxemia, and severe bronchospasm, necessitating emergency intubation or tracheostomy. Hypoxemia could worsen cardiac damage in myocardial infarction (AARC, 2004; Hockenberry et al., 2019; Wiegand, 2017).</p>
Table Continued	

Step	Rationale
3. Review sputum microbiology data in laboratory report.	Certain bacteria are easier to transmit or require isolation because of virulence or antibiotic resistance.
4. Perform hand hygiene and apply gloves. Assess for signs and symptoms of upper and lower airway obstruction requiring suctioning: abnormal respiratory rate, adventitious lung sounds, nasal secretions, gurgling, drooling, restlessness, gastric secretions or vomitus in mouth, and coughing without clearing airway secretions and/or improving adventitious lung sounds.	Physical signs and symptoms result from secretions in upper and lower airways and decreased oxygen to the tissues. Presuction assessment provides baseline data to identify need for suctioning and measures the effectiveness of suction procedures (Wiegand, 2017; Branson et al., 2014).
5. Assess vital signs and signs and symptoms associated with hypoxia and hypercapnia: decreased pulse oximetry (SpO ₂), increased pulse and blood pressure, apprehension, anxiety, lack of concentration, lethargy, decreased level of consciousness, confusion, dizziness, behavioral changes (e.g., irritability), irregular heart pulse, pallor, and cyanosis (a very late sign of hypoxia). Keep pulse oximeter on patient.	Physical signs and symptoms resulting from decreased tissue oxygenation. Provides presuction baseline to measure patient tolerance to suctioning and effectiveness of suctioning on SpO ₂ levels.
6. Assess for risk factors for upper and lower airway obstruction, including chronic obstructive pulmonary disease, impaired mobility, decreased level of consciousness, nasal feeding tube, decreased cough or gag reflex, and decreased swallowing ability.	Risk factors can impair patient's ability to clear secretions from airway, increase risk for retaining secretions, and necessitate nasopharyngeal or nasotracheal suctioning (Urden et al., 2020).
7. Identify patients with an increased risk for ineffective airway clearance (e.g., patients with decreased level of consciousness, neuromuscular or neurological impairment, or anatomical factors that influence upper or lower airway function, such as recent surgery; head, chest, or neck trauma; tumors).	Changes in neurological status and neuromuscular impairment increase likelihood that patient is unable to clear respiratory secretions. Abnormal anatomy or head and neck surgery/trauma and tumors in and around lower airway impair normal secretion clearance. Accumulating pulmonary secretions impede patient's ability to effectively clear airway through cough mechanism (Urden et al., 2020).
8. Assess for excessive amounts of secretions or secretions visible in the oral cavity or artificial airway, signs of respiratory distress (increased work of breathing, increased respiratory rate), presence of rhonchi on auscultation, excessive coughing, increased peak inspiratory pressures (if on mechanical ventilator), sawtooth pattern on ventilator monitor, or changes in capnography waveform (if patient on mechanical ventilator) or decrease in patient pulse oximeter (Branson et al., 2014; Sole et al., 2015).	Suctioning should be performed only as patient condition indicates and not in a scheduled fashion such as hourly (Lewis et al., 2017; Myatt, 2015).
9. Assess patency of ETT (if present) with capnography/end-tidal carbon dioxide (CO ₂) detector.	ETT may become displaced or blocked by secretions. Capnography allows for the detection of secretions by visualizing the sawtooth pattern on the capnography monitor (Sole et al., 2015; Wiegand, 2017).
10. Assess factors that may affect volume and consistency of secretions.	Thickened or copious secretions increase risk for airway obstruction.
a. Fluid balance	Fluid overload increases amount of secretions. Dehydration can cause thicker secretions.
b. Lack of humidity	Environment influences secretion formation and gas exchange. Lack of humidity, particularly in patients with artificial airways, can lead to atelectasis or airway obstruction (Hanon, 2016).
c. Infection (e.g., pneumonia)	Patients with respiratory infections are prone to increased secretions that are thicker and sometimes more difficult to expectorate.
11. For endotracheal suctioning, assess patient's peak inspiratory pressure when on volume-controlled ventilation or tidal volume during pressure-controlled ventilation. Remove gloves and perform hand hygiene.	Increased peak inspiratory pressure or decreased tidal volume may indicate airway obstruction (Urden et al., 2020). Prevents transmission of microorganisms.
CLINICAL DECISION: The patient's vital signs, pulse oximetry, end-tidal CO ₂ , and respiratory status will be assessed before and continuously throughout the procedure (Wiegand, 2017).	
12. Determine presence of apprehension, anxiety, decreased ability to concentrate, lethargy, decreased level of consciousness (especially acute), increased fatigue, dizziness, behavioral changes (especially irritability), pallor, cyanosis, dyspnea, or use of accessory muscles.	These are signs and symptoms of hypoxia and/or hypercapnia, which can indicate need for suction. These signs can also help to identify patient's ability to cooperate with procedure.
13. Assess patient's or family caregiver's knowledge, experience, and health literacy.	Ensures patient or family caregiver has the capacity to obtain, communicate, process, and understand basic health information (CDC, 2019c).
14. Assess for patient's understanding of procedure and presence of any apprehension.	Reveals need for instruction or psychosocial support.

Table Continued

Step	Rationale
Planning	
1. Provide privacy and assist patient to comfortable position, typically semi-Fowler's or high Fowler's.	Reduces stimulation of gag reflex, promotes patient comfort and secretion drainage, and prevents aspiration.
2. If not already present, place pulse oximeter on patient's finger. Take reading and leave oximeter in place.	Provides continuous SpO ₂ value to determine patient's response to suctioning.
3. Prepare and organize equipment. Place towel across patient's chest.	Ensures that you have the necessary equipment in place to complete procedure.
4. Explain to patient how procedure will help clear airway and relieve some breathing difficulty. Explain that temporary coughing, sneezing, gagging, or shortness of breath is normal during procedure.	Encourages cooperation and minimizes anxiety and pain of procedure.
Implementation	
1. Perform hand hygiene and apply appropriate personal protective equipment (mask with face shield or goggles; gown if necessary).	Reduces transmission of microorganisms.
2. Adjust bed to appropriate height (if not already done) and lower side rail on side nearest you. Check locks on bed wheel.	Minimizes caregiver's muscle strain and prevents injury. Prevents bed from moving.
3. Connect one end of connecting tubing to wall suction device and place other end in convenient location near patient. Turn suction device on and set suction pressure to as low a level as possible and yet able to effectively clear secretions. This value is typically between 80 and 120 mm Hg in adults (between 60 and 100 mm Hg in neonates) (AARC, 2010a). Suction pressure should not exceed 180 mm Hg (Branson et al., 2014). Occlude end of suction tubing to check pressure.	Ensures equipment function. Excessive negative pressure damages tracheal mucosa and induces greater hypoxia (Wiegand, 2017).
4. Prepare suction catheter for all types of open suctioning.	
a. Onetime use catheter (open suction technique).	
(1) Using aseptic technique, open suction kit or catheter package. If sterile drape is available, place it across patient's chest or on bedside table. Do not allow suction catheter to touch any nonsterile surfaces. Note: When performing oropharyngeal suction only, there is no need to place a sterile drape; it is a clean procedure, not sterile.	Prepares catheter, maintains asepsis, and reduces transmission of microorganisms. Provides sterile surface on which to lay catheter between passes.
(2) Unwrap or open sterile basin and place on bedside table. Be careful not to touch inside of basin. Fill with about 100 mL sterile normal saline solution or water (see illustration).	Saline or water is used to clean tubing after each suction pass.
(3) If performing nasotracheal suctioning, open packet of water-soluble lubricant and apply small amount (about 1 inch) along catheter tip. Note: Lubricant is not necessary for artificial airway suctioning.	Water-soluble lubricant helps avoid lipid aspiration pneumonia. Excessive amount of lubricant occludes catheter.
5. Apply gloves: Note that oropharyngeal suctioning is a clean technique and clean gloves are appropriate. For nasotracheal, endotracheal tube, or tracheal tube suctioning, sterile gloves are required. When this is the case, apply sterile gloves to each hand or nonsterile glove to nondominant hand and sterile glove to dominant hand.	<p>Reduces transmission of microorganisms and maintains sterility of suction catheter.</p>  <p>Step 4a(2) Pouring sterile saline into tray. Copyright © Mosby's Clinical Nursing Essentials Collection.</p>
Table Continued	

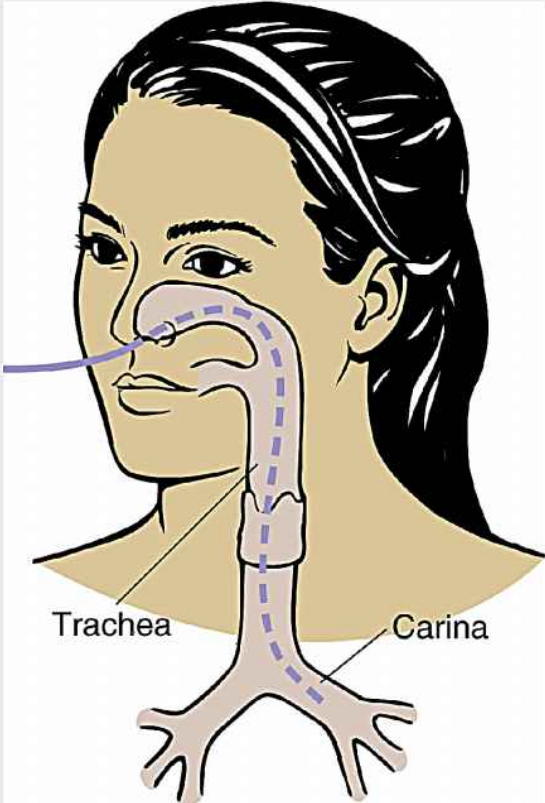

Step	Rationale
<p>6. Pick up suction catheter with dominant hand without touching nonsterile surfaces. Pick up connecting tubing with nondominant hand. Secure catheter to tubing (see illustration).</p>  <p>Step 6 Attaching suction catheter to suction tubing.</p>	<p>Maintains catheter sterility. Connects catheter to suction.</p>
<p>7. Place tip of catheter into sterile basin and suction small amount of normal saline solution from basin by occluding suction vent.</p>	<p>Ensures equipment function. Lubricates internal catheter and tubing.</p>
<p>8. Suction airway.</p>	
<p>a. Nasopharyngeal and nasotracheal suctioning:</p>	
<p>(1) Have patient take deep breaths, if able, or increase oxygen flow rate with delivery device through cannula or mask (if ordered).</p>	<p>May help to decrease risks of hypoxemia.</p>
<p>(2) Lightly coat distal 6 to 8 cm (2–3 inches) of catheter with water-soluble lubricant.</p>	<p>Lubricates catheter for easier insertion.</p>
<p>(3) Remove oxygen-delivery device, if applicable, with nondominant hand.</p>	<p>Allows access to nares and catheter.</p>
<p>CLINICAL DECISION: Be sure to insert catheter during patient inhalation, especially if inserting it into trachea, because epiglottis is open. Do not insert during swallowing or catheter will most likely enter esophagus. Never apply suction during insertion. Patient should cough. If patient gags or becomes nauseated, catheter is most likely in esophagus, and you need to remove it.</p>	
<p>(4) Apply suction.</p>	
<p>(a) <i>Nasopharyngeal</i> (without applying suction): As patient takes deep breath, insert catheter following natural course of nares; slightly slant catheter downward and advance to back of pharynx. Do not force through nares. In adults insert catheter approximately 16 cm (6.5 inches); in older children, 8–12 cm (3–5 inches); in infants and young children, 4–7.5 cm (1.5–3 inches). Rule of thumb is to insert catheter distance from tip of nose (or mouth) to angle of mandible.</p>	<p>Ensure that catheter tip reaches pharynx for suctioning.</p>
<p>CLINICAL DECISION: If resistance is met during insertion, you may need to try the other naris. Do not force the catheter up the nares because this will cause mucosal damage.</p>	
<p>i. Apply intermittent suction for no more than 10 seconds by placing and releasing nondominant thumb over catheter vent (Wiegand, 2017). Slowly withdraw catheter while rotating it back and forth between thumb and forefinger.</p>	<p>Intermittent suction up to 10 seconds safely removes pharyngeal secretions. Suction time greater than 10 seconds increases risk for suction-induced hypoxemia (AARC, 2010a; Branson et al., 2014; Wiegand, 2017).</p>

Table Continued

Step	Rationale
<p>(b) <i>Nasotracheal</i> (without applying suction): As patient takes deep breath, advance catheter following natural course of naris. Advance catheter slightly slanted and downward to just above entrance into larynx and then trachea. While patient takes deep breath, quickly insert catheter: for adults insert approximately 16–20 cm (6–8 inches) into trachea (see illustration). Patient will begin to cough; then pull back catheter 1–2 cm (½ inch) before applying suction. <i>Note:</i> In older children, 16–20 cm (6–8 inches); in infants and young children, 8–14 cm (3–5½ inches).</p>  <p style="text-align: center; font-size: small;">Step 6a(4)(b) Distance of insertion of nasotracheal catheter.</p>	<p>Ensure that catheter tip reaches trachea for suctioning.</p>
<p>CLINICAL DECISION: When using the nasal approach, perform tracheal suctioning before pharyngeal suctioning whenever possible. The mouth and pharynx contain more bacteria than the trachea.</p>	
<p>CLINICAL DECISION: When there is difficulty passing the catheter, ask patient to cough or say “ahh” or try to advance the catheter during inspiration. Both measures help to open the glottis to permit passage of the catheter into the trachea.</p>	
<p>(c) <i>Positioning option:</i> In some instances, turning patient’s head helps you suction more effectively. If you feel resistance after insertion of catheter, use caution; it has probably hit the carina. Pull catheter back 1–2 cm (0.4–0.8 inches) before applying suction (AARC, 2004; Wiegand, 2017).</p>	<p>Turning patient’s head to side elevates bronchial passage on opposite side. Turning head to right helps with suctioning of left mainstem bronchus; turning head to left helps you suction right mainstem bronchus. Suctioning too deep may cause tracheal mucosa trauma.</p>
<p>i. Apply intermittent suction for no more than 10 seconds by placing and releasing nondominant thumb over catheter vent (Wiegand, 2017). Slowly withdraw catheter while rotating it back and forth between thumb and forefinger.</p>	<p>Suction time greater than 15 seconds increases risk for suction-induced hypoxemia (AARC, 2010a; Branson et al., 2014; Wiegand, 2017). Intermittent suction and rotation of catheter prevents injury to tracheal mucosa. If catheter “grabs” mucosa, remove thumb to release suction.</p>
<p>CLINICAL DECISION: Monitor patient’s vital signs and oxygen saturation throughout suctioning process. Stop suctioning if there is a 20 beats/min change (increase or decrease) in pulse rate or if SpO₂ falls below 90% or 5% from baseline.</p>	
<p>(5) Reapply oxygen-delivery device and encourage patient to take some deep breaths, if able.</p>	<p>Helps to decrease risk of hypoxia. Increases patient comfort.</p>
<p>(6) Rinse catheter and connecting tubing with normal saline or water until cleared.</p>	<p>Secretions that remain in suction catheter or connecting tubing decrease suctioning efficiency.</p>

Step	Rationale
<p>(7) Assess for need to repeat suctioning. Do not perform more than two passes with catheter. Allow patient to rest at least 1 minute (AARC, 2010a; Wiegand, 2017). Ask patient to deep breathe and</p>	<p>Observe for alterations in cardiopulmonary status. Suctioning induces hypoxemia, irregular pulse</p>

patient to rest at least 1 minute (AARC, 2010a; Wiegand, 2017). Ask patient to deep breathe and cough.

Suctioning induces hypoxemia, laryngospasm, and bronchospasm (AARC, 2010a; Wiegand, 2017). Hyperoxygenation is recommended before, during, and after open suctioning to reduce suction-induced hypoxemia (Galbiati and Paola, 2015).

Table Continued

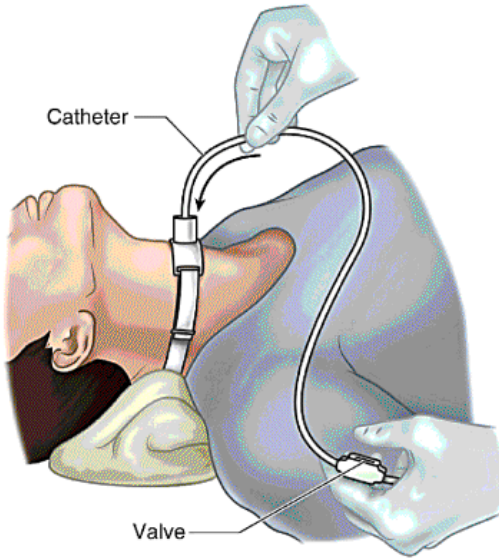

Step	Rationale
<p>b. Artificial airway:</p>	
<p>(1) When patient has an artificial airway, hyperoxygenate him or her with 100% oxygen for at least 30 to 60 seconds before suctioning by (1) pressing suction hyperoxygenation button on ventilator OR (2) increasing baseline fraction of inspired oxygen (FIO₂) level on mechanical ventilator OR (3) disconnecting ventilator, attaching self-inflating resuscitation bag-valve device to tube with nondominant hand (or have assistant do this), and administering 5–6 breaths over 30 seconds (or have assistant do this) (Wiegand, 2017). Note: Some mechanical ventilators have a button that, when pushed, delivers 100% oxygen for a few minutes and then resets to previous setting.</p>	<p>Preoxygenation decreases risk of decreased arterial oxygen levels while ventilation or oxygenation is interrupted and volume is lost during suctioning. Some models of resuscitation bags do not deliver 100% oxygen; therefore, this is not the best way to oxygenate patient (Wiegand, 2017).</p>
<p>(2) If patient is receiving mechanical ventilation, open swivel adapter or, if necessary, remove oxygen- or humidity-delivery device with nondominant hand.</p>	<p>Exposes artificial airway.</p>
<p>CLINICAL DECISION: Suctioning can cause elevations in intracranial pressure (ICP) in patients with head injuries. Reduce this risk by presuction hyperoxygenation, which results in hypocarbia, which in turn induces vasoconstriction. Vasoconstriction reduces the potential for an increase in ICP (Urden et al., 2020).</p>	
<p>(3) Advise patient that you are about to begin suctioning. Without applying suction, gently but quickly insert catheter into artificial airway using dominant thumb and forefinger (it is best to try to time catheter insertion into artificial airway with inspiration) (see illustration). Advance catheter until you meet resistance or patient coughs; then pull back 1 cm (0.4 inch) (Wiegand, 2017).</p>  <p>Step 8b(3) Suctioning tracheostomy.</p>	<p>Application of suction pressure while introducing catheter into trachea increases risk for damage to tracheal mucosa and increased hypoxia. Pulling back stimulates cough and removes catheter from mucosal wall so that catheter is not resting against tracheal mucosa during suctioning. Shallow suctioning is recommended to prevent tracheal mucosa trauma (AARC, 2010a; Wiegand, 2017).</p>
<p>CLINICAL DECISION: If unable to insert catheter past the end of the ETT, the catheter is probably caught in the Murphy eye (i.e., side hole at the distal end of the ETT that allows for collateral airflow in the event of tracheal mainstem intubation). If this happens, rotate the catheter to reposition it away from the Murphy eye or withdraw it slightly and reinsert with the next inhalation. Usually the catheter meets resistance at the carina. One indication that the catheter is at the carina is acute onset of coughing because the carina contains many cough receptors. Pull the catheter back 1 cm (½ inch).</p>	

Table Continued

Step	Rationale
<p>(4) Apply intermittent suction for 10 seconds (AARC, 2010a; Wiegand, 2017). Place and release nondominant thumb over vent of catheter; slowly withdraw catheter while rotating it back and forth between dominant thumb and forefinger. Do not use suction for greater than 15 seconds. Encourage patient to cough. Watch for respiratory distress.</p>	<p>Suction time greater than 10 seconds increases risk for suction-induced hypoxemia (AARC, 2010a; Branson et al., 2014; Wiegand, 2017). Intermittent suction and rotation of catheter prevent injury to tracheal mucosa. If catheter "grabs" mucosa, remove thumb to release suction.</p>
<p>CLINICAL DECISION: If patient develops respiratory distress during the suction procedure, immediately withdraw catheter and supply additional oxygen and breaths as needed. In an emergency administer oxygen directly through the catheter. Disconnect suction and attach oxygen at prescribed flow rate through the catheter. If the patient does not tolerate the suctioning procedure, you may need to consider switching to closed (in-line) suctioning or allowing longer recovery times. Notify health care provider if patient develops significant cardiopulmonary compromise during suctioning (Urden et al., 2020; Wiegand, 2017).</p>	
<p>(5) If patient is receiving mechanical ventilation, close swivel adapter or replace oxygen-delivery device. Hyperoxygenate patient for 30–60 seconds.</p>	<p>Reestablishes artificial airway. Helps to decrease risks of hypoxia.</p>
<p>(6) Rinse catheter and connecting tubing with normal saline until clear. Use continuous suction.</p>	<p>Removes catheter secretions. Secretions left in tubing decrease suctioning efficiency and provide environment for microorganism growth.</p>
<p>(7) Assess patient's vital signs, cardiopulmonary status, and ventilator measures for secretion clearance. Repeat Steps (1) through (6) once or twice more to clear secretions. Unless the patient is in respiratory distress, allow adequate time (at least 1 full minute) between suction passes (Wiegand, 2017).</p>	<p>Suctioning can induce dysrhythmias, hypoxia, and bronchospasm and impair cerebral circulation or adversely affect hemodynamic stability (Wiegand, 2017).</p>
<p>CLINICAL DECISION: The number of suction passes should be based on patient assessment and presence of secretions. If secretions persist after two passes, reapply oxygen source and allow patient more time to rest and recover from these procedures (Wiegand, 2017).</p>	
<p>(8) When pharynx and trachea are sufficiently cleared of secretions, perform oropharyngeal suctioning (see Step 8d) to clear mouth of secretions. Do not suction nose again after suctioning mouth.</p>	<p>Removes upper airway secretions. More microorganisms generally are present in mouth. Upper airway is considered "clean," and lower airway is considered "sterile." You can use same catheter to suction from sterile to clean areas (e.g., tracheal suctioning to oropharyngeal suctioning) but not from clean to sterile areas.</p>
<p>c. Artificial airway using in-line or closed suctioning</p>	
<p>(1) Open suction catheter package using aseptic technique and attach closed suction catheter unit to ventilator circuit. In many agencies, a respiratory therapist attaches the catheter to the mechanical ventilator circuit.</p>	<p>Attaches the suction catheter to the ETT or tracheostomy tube in order to perform in-line or closed suctioning.</p>
<p>(2) Connect one end of connecting tubing to suction machine; connect other end to the end of the closed-system or in-line suction catheter. Turn suction device on, set vacuum regulator to appropriate negative pressure, and check pressure.</p>	<p>Prepares the system for suction.</p>
<p>(3) When patient has an artificial airway, hyperoxygenate with 100% oxygen for at least 30 seconds before suctioning by (1) pressing suction hyperoxygenation button on ventilator OR (2) increasing baseline fraction of inspired oxygen (FIO₂) level on mechanical ventilator. <i>Note:</i> Some mechanical ventilators have a button that, when pushed, delivers 100% oxygen for a few minutes and then resets to previous setting.</p>	<p>Preoxygenation decreases risk of decreased arterial oxygen levels while ventilation or oxygenation is interrupted and volume is lost during suctioning (AARC, 2010a; Wiegand, 2020).</p>
<p>CLINICAL DECISION: Suctioning can cause elevations in intracranial pressure (ICP) in patients with head injuries. Reduce this risk by presuction hyperoxygenation, which results in hypocarbia, which in turn induces vasoconstriction. Vasoconstriction reduces the potential for an increase in ICP (Urden et al., 2020).</p>	
<p>(4) Unlock suction control mechanism, if required by manufacturer. Open saline port and attach saline syringe or vial.</p>	<p>Allows for suctioning and prepares the saline that is used to rinse the catheter between suction attempts.</p>
<p>(5) Pick up suction catheter enclosed in plastic sleeve with dominant hand.</p>	
<p>(6) Advise patient that you are about to begin suctioning. Without applying suction, gently but quickly insert catheter into artificial airway using dominant thumb and forefinger (it is best to try to time catheter insertion into artificial airway with inspiration). Advance catheter until you meet resistance or patient coughs; then pull back 1 cm (0.4 inch) (Wiegand, 2017).</p>	<p>Application of suction pressure while introducing catheter into trachea increases risk for damage to tracheal mucosa and increased hypoxia. Pulling back stimulates cough and removes catheter from mucosal wall so that catheter is not resting against tracheal mucosa during suctioning. Shallow suctioning is recommended to prevent tracheal mucosa trauma (AARC, 2010a; Wiegand, 2017).</p>

Table Continued

Step	Rationale
(7) Encourage patient to cough, and apply suction by squeezing on suction control mechanism while withdrawing catheter. Be sure to withdraw catheter completely into plastic sheath and past the tip of the airway so that it does not obstruct airflow.	
CLINICAL DECISION: It is difficult to apply intermittent pulses of suction and nearly impossible to rotate the catheter compared to the standard catheter. Apply continuous suction for 10 seconds but no longer as you remove the suction catheter (AARC, 2010a; Branson et al., 2014; Wiegand, 2017).	
(8) Assess patient's vital signs, cardiopulmonary status, and ventilator measures for secretion clearance. Repeat Steps (1) through (7) once or twice more to clear secretions. Allow adequate time (at least 1 full minute) between suction passes.	Suctioning can induce dysrhythmias, hypoxia, and bronchospasm and impair cerebral circulation or adversely affect hemodynamic stability (Wiegand, 2017).
(9) When airway is clear, withdraw catheter completely into sheath. Be sure that colored indicator line on catheter is visible in the sheath. Squeeze saline vial or push syringe while applying suction to rinse inner lumen of catheter. Use at least 5 to 10 mL of saline to rinse the catheter until it is clear of retained secretions.	Cleans the suction catheter, thereby reducing risk of bacterial growth and infection.
(10) Lock the suction mechanism, if applicable. Perform oropharyngeal suctioning if patient requires.	Prevents migration of the suction catheter into the airway, which could lead to obstruction.
d. Oropharyngeal suctioning	In patients who require sterile suctioning of the airways, oropharyngeal suction is performed <i>after</i> the sterile suctioning to prevent contamination of the suction catheters or tubing with bacteria present in the oral cavity (Wiegand, 2017). If the patient does not require sterile suctioning, use oropharyngeal suctioning to remove oral secretions.
(1) Apply clean gloves.	Reduces transmission of microorganisms.
(2) Connect the Yankauer suction catheter to the connecting tubing.	Prepares the suction apparatus.
(3) Remove patient's oxygen mask, if present, but keep it close. Nasal cannula may remain in place.	Allows access to mouth. Reduces chance of hypoxia.
CLINICAL DECISION: If patient has been suctioned prior to oropharyngeal suctioning, they may require some recovery from the suctioning procedure before oropharyngeal suctioning is performed. Allow for that recovery to happen by reapplying the oxygen mask until just before oropharyngeal suctioning.	
(4) Insert catheter into mouth along gum line to pharynx. Move catheter around mouth until secretions have cleared. Encourage patient to cough. Replace oxygen mask.	Movement of catheter prevents suction tip from invaginating oral mucosal surfaces and causing trauma. Coughing moves secretions from lower airway into mouth and upper airway.
CLINICAL DECISION: If ETT is present, be careful when moving the catheter so as not to dislodge the ETT. Be careful when suctioning a patient who had recent oral or head/neck surgery. Aggressive suctioning and excessive coughing should not be used or encouraged in patients who have undergone throat surgery, such as a tonsillectomy. Aggressive suctioning in these patient populations can aggravate the operative site, increasing the risk of bleeding or infection (Urden, 2020).	
(5) Rinse catheter with water or normal saline in cup or basin until connecting tubing is cleared of secretions. Turn off suction. Place catheter in clean, dry area.	Rinses catheter and reduces probability of transmission of microorganisms. Clean suction tubing enhances delivery of set suction pressure. Catheter may be reused.
9. When suctioning is complete, disconnect catheter from connecting tubing. Roll catheter around fingers of dominant hand. Pull off other glove over first glove in same way. Discard in appropriate receptacle.	Seals contaminants in gloves. Reduces transmission of microorganisms.
10. Remove towel, place in laundry or appropriate receptacle, and reposition patient.	Reduces transmission of microorganisms.
11. If oxygen level was changed during procedure, readjust oxygen to original ordered level because patient's blood oxygen level should have returned to baseline.	Prevents absorption atelectasis (i.e., tendency for airways to collapse if proximally obstructed by secretions). Prevents oxygen toxicity while allowing patient time to reoxygenate blood.
12. Apply clean gloves to continue personal care, such as washing the patient's face or performing oral hygiene.	Promotes comfort.
13. Discard remainder of normal saline into appropriate receptacle. If basin is disposable, discard into appropriate receptacle. If basin is reusable, rinse it out and place it in soiled utility room.	Reduces transmission of microorganisms.

Table Continued

Step	Rationale
14. Remove personal protective equipment and discard into appropriate receptacle. Perform hand hygiene.	Reduces transmission of microorganisms.
15. Place unopened suction kit on suction machine table or at head of bed.	Provides immediate access to suction catheter for next procedure.
16. Help patient to comfortable position and provide oral hygiene as needed.	
17. Raise side rails (as appropriate), lower bed to lowest position. Place nurse call system in an accessible location within patient's reach.	Ensures patient safety and patient's ability to call for assistance.
Evaluation	
1. Compare patient's vital signs, cardiopulmonary assessments, E_tCO_2 and SpO_2 values before and after suctioning. If on ventilator, compare FiO_2 and tidal volumes and peak inspiratory pressures.	Identifies physiological effects of suction procedure to restore airway patency.
2. Ask patient whether breathing is easier and congestion is decreased.	Provides subjective confirmation that suctioning procedure has relieved airway.
3. Auscultate lungs and compare patient's respiratory assessment before and after suctioning.	Provides objective information about any change in lung sounds.
4. Observe character of airway secretions.	Provides data to document presence or absence of respiratory tract infection or thickened secretions.
5. Use Teach-Back: "I need to suction your father, and I want to be sure that I explained the suctioning procedure and when I need to do it. Please tell me in your own words why suctioning is beneficial." Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly.	Determines patient's/family caregiver's level of understanding of instructional topic.
Unexpected Outcomes and Related Interventions	
<p>1. Patient has decrease in overall cardiopulmonary status as evidenced by decreased SpO_2, increased E_tCO_2, continued tachypnea, continued increased work of breathing, and cardiac dysrhythmias.</p> <ul style="list-style-type: none"> • Limit length of suctioning. • Determine need for more frequent suctioning, possibly of shorter duration. • Determine need for supplemental or increase in supplemental oxygen. Supply oxygen between suctioning passes. • Notify health care provider. <p>2. Bloody secretions are returned after suctioning.</p> <ul style="list-style-type: none"> • Determine amount of suction pressure used. May need to be decreased. • Ensure that suction is completed correctly using intermittent suction and catheter rotation. Do not apply suction until after catheter has been pulled back 1 cm (0.4 inches) to prevent applying suction while catheter is touching carina. • Evaluate suctioning frequency. • Provide more frequent oral hygiene. <p>3. Inability to obtain secretions during suction procedure</p> <ul style="list-style-type: none"> • Evaluate patient's fluid status and adequacy of humidification on oxygen-delivery device. • Assess for signs of infection. • Determine need for chest physiotherapy. 	
Recording and Reporting	
<ul style="list-style-type: none"> • Respiratory assessments before and after suctioning; size of catheter used; suctioning route; amount, consistency, and color of secretions obtained; frequency of suctioning; patient tolerance of suctioning procedure, including changes in vital signs, pulse oximetry values, and E_tCO_2 values (if applicable), and oxygen requirement after procedure. • Note which naris was used/should be used and why for nasopharyngeal/tracheal suctioning. • Quantity and quality of sputum obtained during suction procedure, including whether blood was present. • Document your evaluation of patient learning. 	
Home Care Considerations	
<ul style="list-style-type: none"> • Adhere to best practices for infection control while weighing cost-effectiveness in the presence of a chronic situation. If a patient has an established tracheostomy or requires long-term nasotracheal suctioning and infection is not present, clean suction technique may be deemed appropriate. • Although most patients with airway clearance problems at home have a tracheostomy, some also require nasal pharyngeal suctioning. Catheters are often used for a 24-hour period and then cleaned and disinfected, or they are cleaned with soapy water after each use and discarded after 24 hours. • Stress to family caregivers the importance of brief intervals of applying suction pressure. Instruct those performing suction to hold their breath during the application of negative suction pressure to help them remember to not suction too long. • Instruct patient and family caregiver about infection control practices (e.g., to clean and disinfect or change the secretion collection container every 24 hours according to home care or institutional protocol and to avoid splash when emptying the suction container jar in the toilet). Instruct caregiver to apply mask (shield if available) and gloves and bring the jar as close to the toilet bowl as possible to decrease the risk of splash. • Power companies should be notified of homes in which there are patients receiving home suction or ventilation. In the event of a power outage, these homes would be the priority for receiving power. 	

Skill 41.2. Care of an Artificial Airway

Delegation and Collaboration

This skill of performing ETT care cannot be delegated to assistive personnel (AP). AP may assist the nurse with ETT care. Often, the nurse collaborates with a respiratory therapist in performing this care. In some settings, the skill of TT care for patients with a well-established TT can be delegated to AP. The nurse directs the AP to:

- Immediately report any signs of respiratory problems or increased airway secretions.
- Immediately report if the ETT or TT appears to have moved or become obstructed or dislodged.
- Immediately report changes in patient's mood, level of consciousness, irritability, vital signs, decreased pulse oximetry value, or changes in end-tidal CO₂ values.
- Immediately report abnormal color of the tracheal stoma and drainage.

Equipment

- Towel
- Stethoscope
- Pulse oximeter and end-tidal CO₂ detector
- Personal protective equipment: goggles/mask/face shield; gloves; gown
- Oral and artificial airway suction supplies
- Oxygen source
- Self-inflating manual resuscitation bag-valve device and appropriate-size mask
- Oral hygiene supplies (e.g., pediatric-size toothbrush, sponge toothette for edentulous patients, toothpaste, cleaning solution, and nonalcohol-based mouthwash)
- Communication device—*optional* (letter or picture board, tablet, pen and paper)

- Reintubation equipment should be available at bedside in case of accidental tube dislodgment

Endotracheal Tube Care

- Additional health care team member (two people are needed to safely complete some of the ETT care steps)
- ETT and oropharyngeal suction equipment
- 1- to 1½-inch adhesive or waterproof tape (not paper tape) or commercial ETT stabilizer (follow manufacturer's or health care agencies' instructions for securing the ETT)
- Two pairs of clean gloves
- Adhesive remover swab
- Face cleanser (e.g., wet washcloth, towel, soap, shaving supplies)
- Clean 2 × 2-inch gauze
- Tincture of benzoin or liquid adhesive
- Oral airway or bite block
- Tongue blade (*optional*)

Tracheostomy Care

- Additional health care team member (two people are needed to safely complete some of the TT care steps)
- Sterile tracheostomy care kit, if available, or:
 - Three sterile 4 × 4-inch gauze pads
 - Sterile cotton-tipped applicators
 - Sterile tracheostomy dressing
 - Sterile basin
 - Small sterile brush (or disposable cannula)
 - Tracheostomy ties (e.g., twill tape, manufactured tracheostomy ties, Velcro tracheostomy ties)
- Sterile normal saline or water
- TT and oropharyngeal suction equipment

- Scissors
- Pair of sterile and clean gloves
- Disposable inner cannula, if patient has one
- Extra sterile tracheostomy kit
- Cuff pressure manometer

Step	Rationale
Assessment	
1. Identify patient using at least two identifiers (e.g., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's MAR or medical record.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2020).
2. Review medical record to assess patient's hydration status, humidity delivered to airway/ventilator circuit, status of any existing infection, patient's nutritional status, and ability to cough.	Determines factors that affect amount and consistency of secretions in ETT/TT and patient's ability to clear airway.
3. Perform hand hygiene, apply gloves, and perform complete assessment of patient's cardiopulmonary status, including lung sounds, pulse oximetry, E _t CO ₂ , vital signs, and level of consciousness. Keep pulse oximeter in place.	Provides baseline to determine status of ventilation and patient response to and tolerance of therapy.
4. Observe condition of tissues surrounding ETT/TT for impaired skin integrity (e.g., blistering, abrasions, pressure injuries) on nares, lips, cheeks, corner of mouth, or neck; excess nasal or oral secretions; patient moving tube with tongue or biting tube or tongue; or foul-smelling mouth.	Increased risk for developing pressure areas around ETT or TT from impaired circulation as tube is pulled or pressed against mucosal tissues (Pittman et al., 2015). Presence of ETT or TT impairs ability of patient to swallow oral secretions.
5. Observe patency of airway: excess peristomal, intratracheal, or endotracheal secretions; diminished airflow; or signs and symptoms of airway obstruction.	Buildup of secretions in ETT/TT impairs oxygen delivery and subsequent tissue oxygenation. Excess secretions in the artificial airways may indicate need for suctioning before performing any other airway care.
6. Observe for signs and symptoms of gurgling on expiration, decreased exhaled tidal volume (mechanically ventilated patient), signs and symptoms of inadequate ventilation (rising end-tidal carbon dioxide concentration [E _t CO ₂], patient-ventilator desynchrony, or dyspnea), spasmodic coughing, tense test balloon on tube, flaccid test balloon on tube, and ability to speak or vocalize.	Cuff underinflation increases risk for aspiration, allows secretions to enter the trachea, and permits vocalization. Cuff overinflation may cause ischemia or necrosis of tracheal tissue from obstruction of capillary bed, resulting in tracheomalacia or tracheoesophageal fistula (Myatt, 2015; Rouzé et al., 2017). End-tidal carbon dioxide concentration [E _t CO ₂] validates the correct placement of the ETT by analyzing the exhaled gas for carbon dioxide levels (Wiegand, 2017).
CLINICAL DECISION: For possible overinflation or underinflation of ETT/TT cuff, notify respiratory therapy and follow agency policy for correcting cuff pressures. Most sources agree that 20 cm H ₂ O is the lowest accepted pressure, but some sources recommend that the highest pressure to maintain the cuff is 25 cm H ₂ O (Myatt, 2015).	
Table Continued	

Step	Rationale
7. Observe for factors that increase risk for complications from ETT/TT: type and size of tube, movement of tube up and down trachea (in and out), duration of tube placement, presence of facial trauma, malnutrition, and neck or thoracic radiation.	Tube pressure can cause medical device-related pressure injuries. Tube can become dislodged from lower airway (incidental extubation), or it can enter right mainstem bronchus.
8. FOR ETT: Determine proper ETT depth as noted by centimeters at lip or gum line. This line is marked on tube and recorded in patient's record at time of intubation and every shift. Remove and dispose of gloves. Perform hand hygiene.	Ensures that tube is at proper depth to adequately ventilate both lungs and that it is not too high, which causes vocal cord damage, or too low, which results in right mainstem intubation, in which only the right lung is ventilated. Reduces transmission of microorganisms.
9. Determine when oral and airway care were last performed. Know the health care agency protocols and procedures, but be aware of patient-specific needs for more frequent care.	Oral care is performed every 2-4 hours. TT care is performed every 4-8 hours (Wiegand, 2017).
10. Assess patient's or family caregiver's knowledge of procedure, literacy level, and ability to provide own care, as allowed.	Ensures patient or caregiver has the capacity to obtain, communicate process, and understand basic health information (CDC, 2019c).
Planning	
1. Gather equipment/supplies and arrange at bedside. Close room curtain or door.	Ensures the necessary equipment is available to implement all interventions that should be completed for the patient. Ensures patient privacy.
2. Obtain assistance from available staff.	Reduces risk for accidental extubation of ETT or dislodgment of the TT.
3. Assist patient in assuming comfortable position for both patient and staff. Elevate patient's head to at least 30 degrees, unless contraindicated.	Provides access to site and facilitates completion of procedure. Prepares patient for any suctioning that may be required. Position may decrease risk of aspiration (AACN, 2018).
4. Explain procedure and patient's need to participate, including not biting or moving ETT with tongue, trying not to cough when tape or holder is off ETT/TT, keeping hands down, and not pulling on tubing.	Reduces anxiety, encourages cooperation, and reduces risk of accidental extubation or tube dislodgment.
CLINICAL DECISION: For patients with TT: at some agencies, it is standard practice to have an extra TT that is the same size as the patient's current TT and a TT one size smaller at the bedside at all times in case there is an emergent need to replace the TT because of obstruction or dislodgment.	
Implementation	
1. Perform hand hygiene. Apply clean gloves and mask, goggles, or face shield if indicated. Have assistant do so as well.	Reduces transmission of microorganisms.
2. Place clean towel across patient's chest.	Reduces soiling of bedclothes and linen.
3. Perform airway suctioning if indicated.	Removes secretions. Diminishes patient's need to cough during procedure.
4. Perform ETT care	
a. Connect Yankauer suction catheter to suction source and have it ready to use. Ensure that suction source/machine for oral suctioning is on and functioning properly.	Need to have functioning equipment to perform oral care appropriately. Prepares suction apparatus.
b. Remove oral airway or bite block, if present, and place on towel.	Provides access to and complete observation of patient's oral cavity.
CLINICAL DECISION: If patient is biting the tube, do not remove bite block until absolutely necessary. This prevents obstruction of the ETT and occlusion of the artificial airway.	
c. Brush teeth with soft toothbrush, using solution or toothpaste that helps to break down plaque buildup on teeth. Suction oropharyngeal secretions as necessary.	There may be need for pediatric toothbrush, depending on size of patient's oral cavity. It is recommended to brush teeth at least twice a day (AACN, 2017a; Wiegand, 2017).
d. Use chlorhexidine solution and oral swabs to clean mouth. Suction oropharyngeal secretions as necessary. Apply mouth moisturizer to oral mucosa and lips after each cleaning.	This step should be completed every 2 to 4 hours (AACN, 2017a; Wiegand, 2017). The swabs, solution, and moisturizer may come in a prepackaged kit from manufacturer. The use of chlorhexidine mouthwash or gel is effective in reducing VAP (AACN, 2017b; Hua et al., 2016; Munro and Ruggiero, 2014).

Table Continued

Step	Rationale
<p>e. Prepare ETT securement options:</p>	
<p>(1) Tape method: Prepare tape by cutting piece of tape long enough to go completely around patient's head from naris to naris plus 15 cm (6 inches). This is typically 30–60 cm (12–24 inches) in total length. Lay tape adhesive-side up on bedside table. Cut and lay 8–15 cm (3–6 inches) of second piece of tape, adhesive sides together, in center of the long strip to prevent tape from sticking to hair. Smaller strip of tape should cover area between ears around back of head (see illustration).</p>	<p>Preparing tape ahead decreases amount of time one must manually hold ETT throughout procedure, therefore decreasing risk of tube dislodgment. Adhesive tape needs to encircle head below ears with sufficient tape left to wrap around tube.</p>
<p>STEP 4a(1) Methods of securing adhesive tape. From Wiegand's AACN procedure manual for high acuity, progressive and acuity care (St Louis, 2017, Elsevier).</p>	
<p>(2) Commercially available ET holder: Open package per manufacturer's instructions. Set device aside with head guard in place and Velcro strips open.</p>	<p>Commercial devices are latex free, fast, convenient, and disposable.</p>
<p>CLINICAL DECISION: It is a nursing decision whether to use tape or a commercially available ET holder. There are advantages and disadvantages to both. The commercial tube holders allow for less slippage of the ETT and easier access for oral care but have an increased risk of the formation of pressure injuries (Branson et al., 2014; Smith and Pietrantonio, 2016).</p>	
<p>f. Remove old tape or device.</p>	
<p>(1) Tape: While one person is holding and stabilizing ETT, the other person should remove tape from patient, using adhesive tape remover. The tape will also need to be removed from ETT itself.</p>	<p>Provides access to skin under tape for assessment and hygiene. Adhesive tape remover ensures easier, less traumatic removal of the tape.</p>
<p>CLINICAL DECISION: Clean outside of ETT tube with soap and water or saline as needed. Do not apply adhesive tape remover to the ETT itself. This action will make it nearly impossible for the new tape to appropriately stick to the ETT, which increases risk of tube dislodgment. Do not allow assistant to hold the tube away from the lips or nares. Doing so allows too much movement in the tube and increases the risk for tube movement and accidental extubation. Never let go of the ETT because it could become dislodged (Lewis et al., 2017; Wiegand, 2017).</p>	
<p>(2) Commercially available device: Remove Velcro strips from ETT and remove ETT holder from patient.</p>	<p>Velcro adhesive strips hold ETT in place and provide marker to measure distance to patient's lips or gums. These devices all permit access to patient's mouth and lips for ease in oropharyngeal suctioning and oral hygiene.</p>

Table Continued

Step	Rationale
<p>g. Remove excess secretions or adhesive from patient's face. Clean facial skin with mild soap and water and dry thoroughly. May need to apply tape adherence product such as tincture of benzoin to face. Note: Determine if patient needs face shaved and complete before re-taping ET tube.</p>	<p>Application of tape adherence product allows for new tape or device to stay on patient's face (Wiegand, 2017).</p>
<p>CLINICAL DECISION: When shaving patients, take great care to keep the cuff inflation port away from the razor. The razor can inadvertently cut or nick the tubing, causing air loss from the cuff and the possible need for reintubation.</p>	
<p>CLINICAL DECISION: Do not remove oral airway or bite block if patient is still actively biting. Wait until the new tape or commercial device is partially or completely secured to ETT.</p>	
<p>h. Note level of ETT by looking at mark or noting centimeter value on tube itself. Move oral ETT to other side of mouth and ensure that tube marking at lip is unchanged. Perform oral care as needed on side where tube was initially positioned. Clean oral airway or bite block with warm soapy water and rinse well. Reinsert as necessary.</p>	<p>Changing sides of ETT removes pressure and decreases risk of breakdown at corners of mouth and oral mucosa (Pittman et al., 2015; Wiegand, 2017).</p>
<p>CLINICAL DECISION: The patient may cough excessively when the tube is being moved. The person who is holding the tube in place should be prepared for this and take extra caution while holding. In some instances, the ETT may need to be secured with the tape before the rest of the oral care is performed. In some cases, the patient may need to be administered a dose of an antianxiety or sedating medication. The cuff of the ETT may need to be deflated before changing its position. If cuff deflation is necessary, perform deep oral suctioning before deflation of the cuff, then provide oral care after the cuff is properly reinflated (Wiegand, 2017).</p>	
<p>i. Secure tube (assistant continues to hold ET tube).</p>	
<p>(1) Tape method:</p>	
<p>(a) Slip tape under patient's head and neck, adhesive side up. Take care not to twist tape or catch hair. Do not allow tape to stick to itself. It helps to gently stick end of tape to a tongue blade, which serves as guide. Then slide tongue blade under patient's neck. Center tape so double-faced tape extends around back of neck from ear to ear.</p>	<p>Positions tape to secure ETT in proper position. Don't allow tape to go on or over earlobe.</p>
<p>(b) On one side of face secure tape from ear to naris (nasal ETT) or over lip to ETT (oral ETT). Tear remaining tape in half lengthwise, forming two pieces that are 1–1.5 cm (0.4–0.6 inch) wide. Secure bottom half of tape across upper lip (oral ETT) or across top of nose (nasal ETT) to opposite ear (see illustration A). Wrap top half of tape around tube and up from bottom (see illustration B). Tape should encircle tube at least 2 times for security.</p>	<p>Secures tape to face. Using top tape to wrap prevents downward drag on ETT.</p>
<p>(c) Gently pull other side of tape firmly to pick up slack and secure to opposite side of face and ETT same as first piece. Note: ETT is secured. Assistant can release hold. Check depth mark at lips or gum line.</p>	<p>Secures tape to face and tube. ETT should be at same depth at lips or gum line. Check earlier assessment for verification of tube depth in centimeters.</p>
<p>(2) Commercially available ETT tube securement device:</p>	
<div style="display: flex; justify-content: space-around;">   </div>	
<p>STEP 4(1)(b) A, Securing bottom half of tape across patient's upper lip. B, Securing top half of tape around tube.</p>	

Table Continued

Step	Rationale
CLINICAL DECISION: This step will only need to be completed if the device is visibly soiled and cannot be cleaned or if it is no longer adhering to the face and keeping the ETT secure.	
(a) Thread ETT through opening designed to secure it. Be sure that pilot balloon is accessible.	Commercially available holders have a slit in front of holder designed to secure ETT.
(b) Place strips of ETT holder under patient at occipital region of head.	
(c) Verify that ETT is at established depth using lip or gum line marker as guide.	Ensures that ETT remains at correct depth as determined during assessment.
(d) Attach Velcro strips at base of patient's head. Leave 1 cm (0.4 inch) slack in strips.	
(e) Verify that tube is secure, that it does not move forward from patient's mouth or backward down into patient's throat, and that there are no pressure areas on oral mucosa or occipital region of head (see illustration).	Tube must be secure, so it remains at correct depth. It can be secured without being tight and causing pressure.
j. For unconscious patient, reinsert oral airway without pushing tongue into oropharynx, and secure with tape.	Prevents patient from biting ETT and allows access for oropharyngeal suctioning. An oral airway is not used in a conscious, cooperative patient because it causes excessive gagging and pressure areas to mouth and tongue.
k. Clean rest of face and neck with soapy washcloth, rinse, and dry. Shave male patient as necessary.	Moisture and beard growth prevent adhesive tape adherence.
CLINICAL DECISION: If a nasotracheal tube is in place, all the preceding steps will be completed, except that the tube will not be moved, nor its position changed. It is out of the scope of nurse practice to move the ETT from one naris to another and could cause great harm to the patient.	
5. Perform tracheostomy tube care:	
a. Preoxygenate patient for 30 seconds or ask patient to take 5 to 6 deep breaths. Then suction tracheostomy (see Skill 41.1). Before removing gloves, remove soiled tracheostomy dressing and discard in glove with coiled catheter.	Removes secretions to avoid occluding outer cannula while inner cannula is removed. Reduces need for patient to cough.
b. Perform hand hygiene. Open sterile tracheostomy kit (if available). Open two 4 × 4-inch gauze packages using aseptic technique and pour normal saline on one package. Leave second package dry. Open two cotton-tipped swab packages and pour normal saline on one package. Do not recap normal saline.	Decreases risk of infection. Prepares equipment and allows for smooth, organized completion of tracheostomy care. Tracheostomy care should be performed every 4 to 8 hours or per agency protocol (Wiegand, 2017).
c. Open sterile tracheostomy dressing package.	 <p data-bbox="1015 1243 1291 1285">STEP 41(2)(e) Commercial endotracheal tube holder. Modified from Silis JR. Entry-level respiratory therapist exam guide. St. Louis, 2000, Mosby.</p>

Table Continued

Step	Rationale
d. Unwrap sterile basin and pour about 0.5-2 cm (0.2-1 inch) of normal saline into it.	
e. Prepare TT fixation device.	
(1) If using twill tape: Prepare length of twill tape long enough to go around patient's neck 2 times, about 60-75 cm (24-30 inches) for an adult. Cut ends on diagonal. Lay aside in dry area.	Cutting ends of tie on diagonal aids in inserting tie through eyelet.
(2) If using commercially available TT holder, open package according to manufacturer's directions.	
f. Open inner cannula package (If new one is to be inserted such as with disposable inner cannulas or if patient does not tolerate being disconnected from oxygen source while cleaning reusable inner cannula).	
g. Apply sterile gloves. Keep dominant hand sterile throughout procedure.	Reduces transmission of microorganisms.
h. Remove oxygen source if present.	
CLINICAL DECISION: It is always important to stabilize TT during tracheostomy care to prevent injury, unnecessary discomfort, or accidental dislodgment. Have an assistant such as an AP, nurse, or respiratory therapist help during the procedure. Instruct assistant to apply clean gloves.	
i. Care of tracheostomy with reusable inner cannula:	
(1) While touching only outer aspect of tube, unlock and remove inner cannula with nondominant hand following line of tracheostomy. Drop inner cannula into normal saline basin.	Removes inner cannula for cleaning. Normal saline loosens secretions from inner cannula.
CLINICAL DECISION: If patient is receiving mechanical ventilation, you may want the person assisting you to hold the TT stable and remove the ventilator tube from the connection while you remove the inner cannula. This action helps to ensure that the TT itself is not removed accidentally if difficulties removing the ventilator from the TT or removing the inner cannula from the TT occur.	
(2) Place tracheostomy collar, T tube, or ventilator oxygen source over outer cannula. (Note: May not be able to attach T tube and ventilator oxygen devices to all outer cannulas when inner cannula is removed.)	Maintains supply of oxygen to patient as needed.
CLINICAL DECISION: If patient is unable to tolerate being disconnected from the ventilator, replace the inner cannula with a clean new one and reattach the ventilator to the tracheostomy. Then proceed with cleaning the original inner cannula as described in the next steps and store it in a sterile container until the next inner cannula change (Wiegand, 2017).	
(3) To prevent oxygen desaturation if patient is affected, quickly pick up inner cannula and use small brush to remove secretions inside and outside inner cannula (see illustration).	Tracheostomy brush provides mechanical force to remove thick or dried secretions.
 <p data-bbox="370 1333 584 1350">STEP 5(3) Cleaning tracheostomy inner cannula.</p>	

Table Continued

Step	Rationale
(4) Hold inner cannula over basin and rinse with sterile normal saline, using nondominant (clean) hand to pour normal saline.	Removes secretions and normal saline from inner cannula.
(5) Remove oxygen source, replace inner cannula (see illustration), and secure "locking" mechanism. Reapply ventilator, tracheostomy collar, or T tube. Hyperoxygenate patient if needed.	Secures inner cannula and reestablishes oxygen supply.
j. Tracheostomy with disposable inner cannula:	
(1) Remove new cannula from manufacturer packaging.	Prepares you for change of inner cannula.
(2) While touching only outer aspect of tube, withdraw inner cannula and replace with new cannula by inserting it at a 90-degree angle then rotate downward. Lock into position.	Provides clean, sterile inner cannula for patient.
CLINICAL DECISION: If patient is receiving mechanical ventilation, you may want the person assisting you to hold the TT stable and remove the ventilator tube from the connection while you remove the inner cannula. This action helps to ensure that the TT itself is not accidentally removed if difficulties removing the ventilator or the inner cannula from the TT occur.	
(3) Dispose of contaminated cannula in appropriate receptacle and reconnect to ventilator or oxygen supply.	Prevents transmission of infection. Restores oxygen delivery.
k. Using normal saline-saturated cotton-tipped swabs and 4 × 4-inch gauze, clean exposed outer cannula surfaces and stoma under faceplate extending 5–10 cm (2–4 inches) in all directions from stoma (see illustration). Clean in circular motion from stoma site outward with dominant hand to handle sterile supplies. Do not go over previously cleaned area.	Aseptically removes secretions from stoma site. Moving in outward circle pulls mucus and other contaminants from stoma to periphery.
l. Using dry 4 × 4-inch gauze, pat lightly at skin and exposed outer cannula surfaces.	Dry surfaces prohibit formation of moist environment for microorganism growth and skin excoriation (Wiegand, 2017).
m. Secure tracheostomy.	
CLINICAL DECISION: Some agencies do not recommend changing the securement device for the first 72 hours after insertion of the TT because of risk of stoma closure if the tube were to become dislodged accidentally (Wiegand, 2017).	
(1) Tracheostomy tie method:	
(a) Instruct assistant, if available, to apply clean gloves and securely hold TT in place. With assistant holding TT, cut old ties. Do not cut pilot balloon of cuff.	Prevents transmission of infection. Secures TT to prevent incidental dislodgment. If pilot balloon is cut, there is no ability to inflate cuff (Wiegand, 2017).

Step	Rationale
CLINICAL DECISION: Assistant must not release hold on TT until new ties are firmly tied. If working without an assistant, do not cut old ties until new ties are in place and securely tied (Lewis et al., 2017). When ties are off, this is a good time to clean the back of the patient's neck and assess patient's skin under TT flange and under the ties	

or tube holder, making sure that skin is intact, free of pressure, and dry before applying assessment device.

STEP 5(b) Fastening inner collar.

STEP 5(c) Cleaning around stoma.

Table Continued

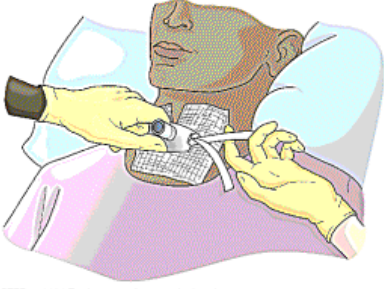

Step	Rationale
(b) Take prepared twill tape, insert one end of tie through faceplate eyelet, and pull ends even (see illustration).	Diagonal cuts ensure ease of threading end of tie through holes of eyelet (Wiegand, 2017).
(c) Slide both ends of tie behind head and around neck to other eyelet and insert one tie through second eyelet.	
(d) Pull snugly	Secures TT.
(e) Tie ends securely in double square knot, allowing space for insertion of only one loose or two snug finger widths between tie and neck (see illustration).	One finger width of slack prevents ties from being too tight when tracheostomy dressing is in place and prevents movement of tracheostomy tube into lower airway (Wiegand, 2017).
(f) Insert fresh 4 × 4-inch tracheostomy dressing under clean ties and faceplate (see illustration).	Absorbs drainage. Dressing prevents pressure on clavicle heads (Wiegand, 2017).
CLINICAL DECISION: Never cut a 2 × 2-inch or 4 × 4-inch gauze pad because the cut edges fray and increase the risk of infection (Wiegand, 2017).	
(2) Tracheostomy tube holder method:	
(a) Instruct assistant, if available, to apply clean gloves and securely hold TT in place. When an assistant is unavailable, leave old TT holder in place until new device is secure.	Ensures that tracheostomy stays in correct position. Prevents incidental dislodgment of tube.
(b) Align strap under patient's neck. Be sure that Velcro attachments are on either side of TT.	Ensures proper securement of TT.
(c) Place narrow end of ties under and through faceplate eyelets. Pull ends even and secure with Velcro closures (see illustration).	
(d) Verify that there is space for only one loose or two snug finger widths to be inserted under neck strap.	Ensures proper securement of TT without securement device being too tight.
n. Discard soiled items in appropriate receptacle. Remove towel and place in laundry.	Reduces transmission of microorganisms.
o. Perform oral care with toothbrush or oral swabs and chlorhexidine rinse.	Use of chlorhexidine may decrease patient risk of developing a ventilator-associated event (VAE)/ventilator-associated pneumonia (VAP) and promotes patient comfort (AACN, 2017b; Hua et al., 2016).
p. Measure TT cuff pressure.	Cuff pressures should be measured every 8 hours and following any tracheostomy-related intervention or after the patient has been repositioned (Intensive Care Society [ICS], 2018).
(1) Attach a commercial pressure gauge/manometer to the tracheal cuff.	<p>Allows for measurement of the pressure of TT cuff.</p>  <p>STEP 05(1)(b) Replacing tracheostomy ties. Do not remove old tracheostomy tie until new ones are secure.</p>  <p>STEP 05(1)(e) Tracheostomy ties properly placed. From Sommers SA. Mosby's textbook for nursing assistants, ed 8. St. Louis, 2013. Mosby.</p>

Table Continued

Step	Rationale
(2) Read the measurement. If the cuff pressure is greater than 25 cm H ₂ O, then release some air from the cuff (using the pressure gauge on the manometer) until the pressure reaches between 20 and 25 cm H ₂ O. If the pressure is less than 20 cm H ₂ O, add air by squeezing the bulb on the manometer until the pressure is between 20 and 25 cm H ₂ O.	Overinflated cuffs can lead to tracheal stenosis, necrosis, tracheomalacia, and fistula formation. Underinflated cuffs can lead to ineffective mechanical ventilation and increase risk of aspiration (Myatt, 2015; Wiegand, 2017)
6. Discard soiled items in appropriate receptacle; remove towel and place in laundry. Remove gloves and mask, goggles, or face shield or gown; discard in receptacle; and perform hand hygiene. (Assistant performs same steps.) Place clean items (e.g., tincture of benzoin, oral care solution, excess swabs) in place of storage.	Reduces transmission of microorganisms. Ensures that contaminated gloves and hands do not touch clean items.
7. Reposition patient and ask him or her what else he or she needs.	Promotes comfort; gives patients opportunity to communicate their needs.
8. Be sure nurse call system is in an accessible location within patient's reach.	Ensures patient can call for assistance if needed.
9. Raise side rails (as appropriate) and lower bed to lowest position.	Ensures patient safety.
10. Be sure that oxygen and/or humidification delivery sources are in place and set at correct levels.	Humidification helps prevent airway obstruction and atelectasis (Hanlon, 2016).
Evaluation	
1. Compare respiratory assessments before and after ETT/TT care.	Identifies any physiological changes, including presence and quality of breath sounds after procedure.
2. Observe depth and position of ETT according to health care provider recommendation.	Position of ETT should not be altered.
3. Assess security of tape by gently tugging at tube.	Tape should remain attached to face. Patient may cough during tugging.
4. Assess skin around mouth, oral mucous membranes, and/or tracheal stoma for intactness and pressure sores.	Tape should not tear skin. Pressure areas should be absent.
5. Compare pulse oximeter and E _t CO ₂ values from before and after ETT/TT care.	Changes in oxygen saturation and E _t CO ₂ can help identify displacement or dislodgment of ETT/TT.
6. Observe for excessive phonation or presence of gastric secretions in airway secretions.	Occurs with inadequate or excessive cuff inflation.
7. Use Teach-Back: "I want to be sure I explained why we need to clean your breathing tube routinely. Tell me why the cleaning of your tube is important for your breathing." Revise your instruction now or develop plan for patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly.	<p data-bbox="951 909 1352 961">Determines patient's/family caregiver's level of understanding of instructional topic.</p> <div data-bbox="1036 989 1289 1161">  <p data-bbox="1036 1163 1289 1182">STEP 5m(1)f) Applying tracheostomy dressing.</p> </div> <div data-bbox="1036 1230 1289 1486">  <p data-bbox="1036 1488 1289 1518">STEP 5m(2)(c) Tracheostomy tube holder in place. Table Continued

Step	Rationale
<p>Unexpected Outcomes and Related Interventions</p> <ol style="list-style-type: none"> 1. Tube is dislodged or misplaced accidentally, including extubation. <ul style="list-style-type: none"> • Remain with patient while calling for help. • Ventilate with bag-valve-mask as needed. • Assess patient for airway patency, spontaneous breathing, and vital signs. • Prepare for retaping or securing procedure or reintubation. 2. Patient has pressure injury in mouth, lips, nares, or tracheal stoma. <ul style="list-style-type: none"> • Increase frequency of ETT care. • Apply antimicrobial ointment per agency protocol. • Align oxygen and humidity supply tubing so that they do not pull ETT, creating pressure sores. • Monitor for infection. If skin tear is present on cheeks or over nose or upper lip, apply protective barrier such as stoma adhesive patch or hydrocolloid dressing and apply tape to it. 3. Cuff leak develops. <ul style="list-style-type: none"> • Verify position of tube, notify respiratory therapy, and follow agency policy. 	
<p>Recording and Reporting</p> <ul style="list-style-type: none"> • Record respiratory assessments before and after tube care, depth of ETT or type and size of tracheostomy tube, frequency and extent of care, patient tolerance, and any complications related to presence of the tube. • Document your evaluation of patient learning. • Report signs of infection or displacement of ETT or tracheostomy tube immediately. • Report time of care and patient tolerance, including vital sign changes or any changes in pulse oximeter, E_tCO₂, or respiratory status, and presence of any areas of impaired skin integrity on face or neck, in the mouth, or around the nares or tracheal stoma. 	
<p>Home Care Considerations</p> <ul style="list-style-type: none"> • Instruct family caregivers in how to obtain supplies. Routine tracheostomy care should be done at least once a day after discharge from hospital. At home, clean technique with nonsterile gloves is usually used. • Patients with tracheostomies may need to communicate with others by writing or use of computer. Ensure that they have communication devices that meet their needs. • Instruct family caregivers in signs and symptoms of respiratory distress, tube dysfunction, and respiratory and stoma infections. Call health care provider if patient feels pain or discomfort longer than a week after insertion, if breathing does not improve after usual method of clearing secretions, or if secretions become thick or mucus plugs are present. • When outside, use tracheostomy covers to protect from dust or cold air. • Never remove the outer cannula unless instructed by health care provider to do so. 	

Skill 41.3. Care of Patients with Chest Tubes Delegation and Collaboration

The skill of chest tube management cannot be delegated to assistive personnel (AP). The nurse directs the AP about:

- Proper positioning of the patient with chest tubes to facilitate chest tube drainage and optimal functioning of the system, including maintaining the drainage system at a level lower than the insertion site and not lying on tubing.
- Ambulating and transferring patient with chest drainage.
- Reporting changes in vital signs, complaints of chest pain or sudden shortness of breath, or excessive bubbling in water-seal chamber to the nurse immediately.
- Danger of any disconnection of drainage system, change in type and amount of drainage, sudden bleeding, or sudden cessation of bubbling.

Equipment

- Local anesthetic, if not an emergent procedure
- Prescribed chest drainage system
- Water-seal system versus waterless system: sterile water or normal saline per manufacturer's directions
- Clean gloves
- Suction source and setup
- Sterile skin preparation solution (povidone-iodine or chlorhexidine solutions)
- Chest tube tray (all items are sterile), typically: knife handle, clamps, small sponge forceps, needle holder, knife blade No. 10, 3-0 silk sutures, sterile drape, two clamps, 4 × 4-inch sponges, suture scissors, and sterile gloves
- Dressings: Petroleum or Xeroform gauze, large dressing of choice, split chest tube dressing, additional 4 × 4-inch dressings, 4-inch tape or elastic bandage
- Two rubber-tipped hemostats (shodded) for each chest tube
- 1-inch waterproof adhesive tape for taping connections
- Face mask, face shield, or head cover
- Sterile gloves
- 1-inch adhesive tape or zip tie for securing connections
- Stethoscope, sphygmomanometer, and pulse oximeter

Step	Rationale
Assessment	
1. Identify patient using at least two identifiers (e.g., name and birthday or name and account number) according to agency policy. Compare identifiers with information on the patient's MAR or medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2020).
2. Review health care provider's order for chest tube placement.	Insertion of chest tube requires health care provider order.
3. Review patient's medication record for anticoagulant therapy, including aspirin, warfarin, heparin, or platelet aggregation inhibitors such as ticlopidine or dipyridamole.	Anticoagulation therapy can increase procedure-related blood loss.
4. Review patient's hemoglobin and hematocrit levels.	Parameters reflect whether blood loss is occurring, which may affect oxygenation.
5. Assess patient's or family caregiver's knowledge, experience, and health literacy.	Ensures patient or family caregiver has the capacity to obtain, communicate, process, and understand basic health information (CDC, 2019c).
6. Assess patient for known allergies. Ask patient whether he or she has had a problem with medications, latex, or anything applied to skin.	Povidone-iodine or chlorhexidine are antiseptic solutions often used to clean skin before tube insertion. Lidocaine is a local anesthetic administered to reduce pain. The chest tube will be held in place with tape and sutures (Wiegand, 2017).
7. Perform hand hygiene and perform a complete respiratory assessment, baseline vital signs, and pulse oximetry (SpO ₂).	Baseline assessment and vital signs are essential for any invasive procedure. Chest tube insertion often relieves respiratory distress.
a. Assess for signs and symptoms of increased respiratory distress and hypoxia (e.g., decreased breath sounds over affected and unaffected lungs, marked cyanosis, asymmetrical chest movements, displaced trachea, shortness of breath, and confusion).	Signs and symptoms associated with respiratory distress are related to type and size of pneumothorax, hemothorax, or preexisting illness. Signs of hypoxia are related to inadequate oxygen to tissues.
b. Assess for sharp, stabbing chest pain or chest pain on inspiration, hypotension, and tachycardia. If possible, ask patient to rate level of comfort on a scale of 0 to 10.	Sharp, stabbing chest pain with or without decreased blood pressure and increased heart rate may indicate tension pneumothorax. Presence of pneumothorax or hemothorax is painful, frequently causing sharp inspiratory pain. In addition, discomfort is associated with presence of a chest tube, not just with its insertion. Adequate pain control promotes better patient participation in activity (Chotai and Mosenifar, 2018).
8. For patients who have existing chest tubes, observe:	
a. Chest tube dressing and site surrounding tube insertion.	Ensures that dressing is intact and occlusive seal remains without air or fluid leaks and that area surrounding insertion site is free of drainage or skin irritation (Chotai and Mosenifar, 2018).
b. Tubing for kinks, dependent loops, or clots.	Maintains a patent, freely draining system, preventing fluid accumulation in chest cavity. When tubing is coiled, looped, or clotted, drainage is impeded, and there is an increased risk for tension pneumothorax or surgical emphysema (Chotai and Mosenifar, 2018).
c. Chest drainage system should remain upright and below level of tube insertion.	An upright drainage system facilitates drainage and maintains water seal.
9. Remove and dispose of gloves. Perform hand hygiene.	
10. Assess patient's comfort level on a scale of 0 to 10.	Provides a baseline to compare after chest tube insertion.
11. Determine patient's knowledge of procedure.	Encourages cooperation, minimizes risks and anxiety. Identifies teaching needs.
Planning	
1. Gather equipment/supplies and arrange at bedside. Close room curtain or door.	Ensures the necessary equipment is available to implement all interventions that should be completed for the patient. Ensures patient privacy.
2. Assist patient in assuming appropriate position for insertion of the chest tube, or a position of optimal comfort during other chest tube care.	Appropriate positioning is important for the proper insertion of the chest tube. Position of optimal comfort, once tube is inserted, will allow for increase in physical activity, including deep breathing, coughing, and use of the incentive spirometer.
3. Be available while provider explains insertion procedure to the patient. Once tube is inserted and during normal management, explain the care that you will be providing.	Reduces anxiety and encourages cooperation.
Implementation	
1. Check agency policy and determine whether informed consent is needed. Complete "Time Out" procedure.	Invasive medical procedures typically require informed consent. "Time Out" is completed to determine right patient, procedure, and location of insertion or incision site (Wiegand, 2017).
2. Perform hand hygiene.	Reduces transmission of microorganisms.

Table Continued

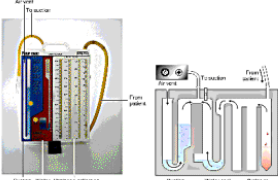

Step	Rationale
3. Set up water-seal system (or dry system with suction); see manufacturer guidelines.	The water-seal system contains two or three compartments or chambers (see illustration). Fluid drains into the first chamber. The second chamber contains the water seal, which allows air to escape because of the force of expiration but not to reenter on inspiration. If suction is needed, a third chamber is used.
a. Obtain chest drainage system. Remove wrappers and prepare to set up two- or three-chamber system.	Maintains sterility of system for use under sterile operating room conditions.
b. While maintaining sterility of drainage tubing, stand system upright and add sterile water or normal saline (NS) to appropriate compartments.	Reduces possibility of contamination.
(1) <i>Two-chamber system (without suction)</i> : Add sterile solution to water-seal chamber (second chamber), bringing fluid to required level as indicated.	Water-seal chamber acts as one-way valve, so air cannot enter pleural space (Chotali and Mosenifar, 2018).
(2) <i>Three-chamber system (with suction)</i> : Add sterile solution to water-seal chamber (second chamber). Add amount of sterile solution prescribed by health care provider to suction-control chamber (third chamber), usually 20 cm H ₂ O pressure. Connect tubing from suction-control chamber to suction source. Tailor length of drainage tube to patient. Note: Suction control chamber vent must not be occluded when using suction (see illustration).	Depth of fluid level dictates highest amount of negative pressure that can be present within system. For example, 20 cm of water is approximately 20 cm of water pressure. After chest tube is inserted, turn up the wall or portable suction device until water in suction-control bottle exhibits continuous, gentle bubbling.
CLINICAL DECISION: When increasing suction, remember that increased bubbling does not result in more suction to the chest cavity, but only serves to evaporate the water more quickly. The suction pressure should not exceed -20 cm H ₂ O because lung tissue damage may occur (Chotali and Mosenifar, 2018).	
(3) <i>Dry suction system</i> : Fill water-seal chamber with sterile solution. Adjust suction-control dial to prescribed level of suction; suction ranges from -10 to -40 cm of water pressure. Suction-control chamber vent is never occluded when suction is used. Note: On dry suction system, DO NOT obstruct positive-pressure relief valve. This allows air to escape.	Automatic control valve on dry suction-control device adjusts to changes in patient air leaks and fluctuation in suction source and vacuum to deliver prescribed amount of suction.  <p>Step 38(2) Left, Pleur-Evac three-chamber drainage system. Right, Schematic of drainage device.</p>

Table Continued

Step	Rationale
4. Set up waterless system (see manufacturer guidelines).	A waterless system is like a water seal system except that sterile water is not required for suction. The suction-control chamber is replaced by a one-way valve located near the top of the system. The suction-control chamber contains a suction-control float ball that is set by a suction-control dial (between -10 and -40 cm H ₂ O after the suction is connected and turned on) (Zisis et al., 2015).
a. Remove sterile wrappers and prepare to set up.	Maintains sterility of system for use under sterile operating room conditions.
b. For two-chamber system (without suction), nothing is added or needs to be done to system.	Waterless two-chamber system is ready for connecting to patient's chest tube after opening wrappers.
c. For three-chamber system (with suction), connect tubing from suction-control chamber to suction source.	Suction source provides additional negative pressure to system.
d. Instill 15 mL of sterile water or NS into diagnostic indicator injection port located on top of system.	Allows observation of rise and fall of water in diagnostic air leak window. Constant left-to-right bubbling or rocking is abnormal and indicates air leak. This is not necessary for mediastinal drainage because there is no tidaling. In an emergency, system <i>does not</i> require water for setup.
5. Secure all tubing connections with tape applied in double-spiral fashion using 2.5-cm (1-inch) adhesive tape or zip ties (nylon cable) with a clamp. Check system for patency by: a. Clamping drainage tubing that will connect to patient's chest tube. b. Connecting tubing from float ball chamber to suction source. c. Turning on suction to prescribed level.	Prevents atmospheric air from leaking into system and patient's intrapleural space. Provides chance to ensure airtight system before connection to patient.
6. Turn off suction source and unclamp drainage tubing before connecting patient to system. Suction source is turned on again after patient is connected.	Having patient connected to suction when it is initiated could damage pleural tissues from sudden increase in negative pressure. Tubing that is coiled or looped prevents adequate drainage and may cause tension pneumothorax (Wiegand, 2017).
7. Administer procedure medications such as sedatives or analgesics as ordered. (Give medications 30 minutes before procedure.)	Reduces patient anxiety and pain during procedure.
CLINICAL DECISION: During procedure, carefully monitor patient for changes in level of sedation.	
8. Provide psychological support to patient.	
a. Reinforce preprocedure explanation.	Reduces patient anxiety and helps complete procedure efficiently.
b. Coach and support patient throughout procedure.	
9. Perform hand hygiene and apply clean gloves. Position patient for tube insertion so that side in which tube is to be inserted is accessible to health care provider.	Reduces transmission of microorganisms. Allows ease of access for insertion of the tube.
10. Assist health care provider with chest tube insertion by providing needed equipment and local analgesic. Health care provider anesthetizes skin over insertion site, makes small skin incision, inserts clamped tube, sutures it in place, and applies occlusive dressing.	Ensures smooth insertion.
11. Help health care provider attach drainage tube to chest tube; remove clamp. Turn on suction to prescribed level.	Connects drainage system and suction (if ordered) to chest tube.
12. Tape or zip-tie all connections between chest tube and drainage tube. (Note: Chest tube is usually taped by health care provider at time of tube placement; check agency policy.)	Secures chest tube to drainage system and reduces risk for air leak that causes breaks in airtight system (Chotai and Mosenifar, 2018; Wiegand, 2017).
13. Check systems for proper functioning. Health care provider orders chest x-ray film.	Verifies intrapleural placement of tube.
14. After tube placement position patient: a. Semi-Fowler's or high-Fowler's position to evacuate air (pneumothorax) (Chotai and Mosenifar, 2018) b. High-Fowler's position to drain fluid (hemothorax) (Chotai and Mosenifar, 2018)	Permits optimum drainage of fluid and/or air.
15. Check patency of air vents in system.	
a. Water-seal vent must have no occlusion.	Permits displaced air to pass into atmosphere.
b. Suction-control chamber vent is not occluded when suction is used.	Provides safety factor of releasing excess negative pressure into atmosphere.
c. Waterless systems have relief valves without caps.	Provides safety factor of releasing excess negative pressure.
16. Position excess tubing horizontally on mattress next to patient. Secure with clamp provided so that it does not obstruct tubing.	Prevents excess tubing from hanging over edge of mattress in dependent loop. Drainage collected in loop can occlude drainage system, which predisposes patient to tension pneumothorax (Wiegand, 2017).
17. Adjust tubing to hang in straight line from chest tube to drainage chamber.	Promotes drainage and prevents fluid or blood from accumulating in pleural cavity.

Step	Rationale

Table Continued

Step	Rationale
CLINICAL DECISION: Gentle lifting of the drainage tubing allows gravity to help blood and other viscous material to move to the drainage bottle and avoid stasis in the tubing, which can lead to obstruction of the system and increased pressure in the thoracic cavity. Patients with recent chest surgery or trauma may need to have the chest drain tubing lifted more frequently, based on assessment of the amount of drainage (Wiegand, 2017).	
18. Place two rubber-tipped hemostats (for each chest tube) in easily accessible position (e.g., taped to top of patient's headboard). These should remain with patient when ambulating.	Chest tubes are double clamped under specific circumstances: (1) to assess for air leak, (2) to empty or quickly change disposable systems, (3) to assess whether patient is ready to have tube removed, or (4) if chest tube becomes accidentally disconnected from drainage system (Muzzy and Butler, 2015).
CLINICAL DECISION: In the event of a chest tube disconnection or if the drainage system breaks, submerge the distal part of the tube 2 to 4 cm (1 to 2 inches) below the surface of a 250-ml. bottle of sterile water or NS until a new chest tube unit can be set up (Lewis et al., 2017; Muzzy and Butler, 2015).	
19. Dispose of sharps in proper container, dispose of used supplies, and perform hand hygiene.	Reduces transmission of microorganisms.
20. Care of patient after chest tube insertion/existing chest tube:	
a. Perform hand hygiene and apply clean gloves. Assess vital signs; oxygen saturation; skin color; breath sounds; rate, depth, and ease of respirations; and insertion site every 15 minutes for first 2 hours, and then at least every shift (see agency policy).	Provides immediate information about procedure-related complications such as respiratory distress and leakage. Provides information about status of patient with existing chest tube.
b. Monitor color, consistency, and amount of chest tube drainage every 15 minutes for first 2 hours after insertion. Indicate level of drainage fluid, date, and time on write-on surface of chamber.	Provides baseline for continuous assessment of type and quantity of drainage. Ensures early detection of complications.
(1) From mediastinal tube, expect less than 100 mL/hr immediately after surgery and no more than 500 mL in first 24 hours.	Sudden gush of drainage may result from coughing or changing patient's position (i.e., releasing pooled/collected blood rather than indicating active bleeding). Acute bleeding indicates hemorrhage. Health care provider should be notified if there is more than 100-200 mL of bloody drainage in an hour (Lewis et al., 2017; Wiegand, 2017).
(2) Expect little or no output from anterior chest tube that is inserted for a pneumothorax (Wiegand, 2017).	
CLINICAL DECISION: Routine stripping or milking of the chest tube is not a recommended practice. Doing so can result in increased pressure in the thoracic cavity, causing damage to the lungs or the pleural tissues. If there is a visible clot in the tubing, gentle milking of the tubing (manual squeezing and releasing of parts of the tubing) may be indicated, but only if the patient is at risk of further harm from the clot, such as the development of a tension pneumothorax (Makic et al., 2015; Wiegand, 2017).	
c. Observe chest dressing for drainage and determine whether it is still occlusive.	Drainage around tube may indicate blockage of the tube. Many health care agencies require the chest tube dressings to be occlusive in nature.
CLINICAL DECISION: If the dressing is not occlusive or is saturated with drainage, it may need to be changed. There is no standard for how chest tube dressings should be performed, such as sterile versus a nonsterile dressing change. Know the health care agency standards for this procedure. Some health care agencies require the use of petrolatum gauze around the chest tube while others do not (Gross et al., 2016).	
d. Palpate around tube for swelling and crepitus (subcutaneous emphysema) as noted by crackling.	Indicates presence of air trapping in subcutaneous tissues. Small amounts are commonly absorbed. Large amounts are potentially dangerous. Most occurrences of crepitus are minor (Mao et al., 2015).
CLINICAL DECISION: Some patients may develop subcutaneous emphysema (i.e., a collection of air under the skin after chest tube placement), which can occur if tubing is blocked or kinked. When this occurs, a crepitus (a crackling sensation) is felt with tactile fremitus on palpation.	
e. Check tubing to ensure that it is free of kinks and dependent loops.	Promotes drainage and prevents the development of a tension pneumothorax.

Table Continued

Step	Rationale
f. Observe for fluctuation of water-seal chamber and drainage in tubing during inspiration and expiration. Observe for clots or debris in tubing.	If fluctuation or tidaling stops, it means that either the lung is fully expanded or system is obstructed (Wiegand, 2017). In spontaneously breathing patient, fluid rises in water-seal or diagnostic indicator (waterless system) with inspiration and falls with expiration. The opposite occurs in patient who is mechanically ventilated. This indicates that system is functioning properly (Atrium, 2015).
g. Keep drainage system upright and below level of patient's chest.	Promotes gravity drainage and prevents backflow of fluid and air into pleural space.
h. Check for air leaks by monitoring bubbling in water-seal chamber. Intermittent bubbling is normal during expiration when air is being evacuated from pleural cavity, but continuous bubbling during both inspiration and expiration indicates leak in system.	Absence of bubbling may indicate that lung is fully expanded in patient with pneumothorax. Check all connections and locate sources of air leak.
i. Remove and dispose of gloves and dispose of used soiled equipment in appropriate biohazard container. Perform hand hygiene.	Prevents accidents involving contaminated equipment.
21. Instruct patient how to regularly take deep breaths, and reposition as often as possible.	Facilitates and maintains lung expansion.
22. Be sure nurse call system is in an accessible location within patient's reach.	Ensures patient can call for assistance if needed.
23. Raise side rails (as appropriate) and lower bed to lowest position.	Ensures patient safety.
Evaluation	
1. Evaluate patient for decreased respiratory distress and chest pain. Auscultate patient's lungs and observe chest expansion.	Determines status of lung expansion.
2. Monitor vital signs and SpO ₂ .	Determines whether level of oxygenation has improved.
3. Reassess patient's level of comfort on scale of 0 to 10, comparing level with comfort before chest tube insertion and/or pain medication administration.	Indicates need for analgesia. Patient with chest tube discomfort hesitates to take deep breaths and as a result is at risk for pneumonia and atelectasis.
4. Evaluate patient's ability to use deep-breathing exercises and reposition self while maintaining comfort.	Indicates patient's ability to promote lung expansion and prevent complications. Patients need to be repositioned every 2 hours when a chest tube is in place (Wiegand, 2017).
5. Monitor continued functioning of system as indicated by reduction in amount of drainage, resolution of air leak, and complete reexpansion of the lung.	Detects early signs of system complications or indicates possible removal of chest tube.
6. Use Teach-Back: "I want to be sure I explained why you have a chest tube. Explain to me why you have this tube and what we are doing to keep the system functioning." Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly.	Determines patient's/family caregiver's level of understanding of instructional topic.
Unexpected Outcomes and Related Interventions	
<p>1. Patient develops respiratory distress. Chest pain, decrease in breath sounds over affected and unaffected lungs, marked cyanosis, asymmetrical chest movements, presence of subcutaneous emphysema around tube insertion site or neck, hypotension, tachycardia, and/or mediastinal shift are critical and indicate severe change in patient status, such as excessive blood loss or tension pneumothorax.</p> <ul style="list-style-type: none"> • Notify health care provider immediately. • Collect set of vital signs and SpO₂. • Prepare for chest x-ray film. • Provide oxygen as ordered. • Be sure patient has head of bed elevated. 	
<p>2. Air leak is unrelated to patient's respirations.</p> <ul style="list-style-type: none"> • Locate leak by clamping chest tube with two rubber-shodded or toothless clamps close to the chest wall. If bubbling stops, air leak is inside patient's thorax or at the insertion site, and the health care provider should be notified. • If bubbling continues with the clamps near the chest wall, gradually move one clamp at a time down the drainage tubing away from the patient and toward the drainage chamber. When the bubbling stops, the leak is in the section of the tubing between the 2 clamps. If the leak occurs when the clamps are near the drainage system, then the leak is in the drainage system itself. If there is a leak in the tubing or the drainage system, the nurse can replace the tubing or the drainage system (Muzzy and Butler, 2015). 	
<p>3. Chest tube is disconnected/dislodged.</p> <ul style="list-style-type: none"> • Check connections and reattach using sterile technique (Chotal and Mosemfar, 2018). • Immediately apply dressing and/or pressure over chest tube insertion site (Muzzy and Butler, 2015). • Notify health care provider. 	

Table Continued

Step	Rationale
Recording and Reporting	<ul style="list-style-type: none"> Record and report respiratory assessment; amount of suction, if used; amount of drainage since the previous assessment; type and amount of drainage in chest tubing; and presence or absence of an air leak, including amount if present, and patient comfort level. Record integrity of dressing and presence of drainage on dressing. Document your evaluation of patient learning. Record and report patient tolerance to new chest tube insertion; comfort level and any analgesia; respiratory assessment before and after insertion; quantity and quality of chest tube drainage.
Home Care Considerations	<ul style="list-style-type: none"> Patients with chronic conditions (e.g., uncomplicated pneumothorax, effusions, empyema) that require long-term chest tube therapy may be discharged with smaller mobile drains. These systems do not have a suction-control chamber and use a mechanical one-way valve instead of a water-seal chamber. Instruct patient in how to ambulate and remain active with a mobile chest tube drainage system. Provide patient with information as to when to contact health care professionals regarding changes in health status or drainage system (e.g., chest pain, breathlessness, change in drainage).

Skill 41.4. Using Home Oxygen Equipment Delegation and Collaboration

The skill of administering home oxygen equipment cannot be delegated to assistive personnel (AP). Instruct the AP about:

- The unique needs of patient (e.g., amount of assistance in applying nasal cannula or mask) and any assistance needed in filling liquid canisters.
- The type of equipment patient should have in the home and the oxygen flow rate.
- Immediately reporting to the nurse increased rate of breathing, decreased level of consciousness, increased confusion, and pain.

Equipment

- Nasal cannula equipment (see Procedural Guideline, Box 41.9, for required equipment)
- Humidification device if oxygen delivery greater than 4 L/min
- Oxygen tubing available in lengths of 50 feet
- Home low-flow oxygen-delivery system with appropriate equipment

Step	Rationale
Assessment	
1. Identify patient using at least two identifiers (e.g., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's MAR or medical record.	Ensures correct patient. Complies with The Joint Commission Standards and improves patient safety (TJC, 2020).
2. Review health care provider's order for home oxygen equipment.	A health care provider's order is required for home oxygen use.
3. Assess patient's or family caregiver's knowledge, experience, and health literacy.	Ensures patient or family caregiver has the capacity to obtain, communicate, process, and understand basic health information (CDC, 2019c).
4. While patient is still in the hospital, determine patient's or family caregiver's ability to use oxygen equipment correctly. In home setting, reassess for access to and appropriate use of equipment.	Physical or cognitive impairments necessitate instructing family member or significant other how to operate home oxygen equipment. Ongoing assessment enables you to determine specific components of skill that patient or family can complete easily.
5. Inform the patient/family caregiver that the home oxygen vendor will assess home environment for adequate electrical service if oxygen concentrator is ordered.	Oxygen concentrators require electricity to work. Continuous oxygen therapy must not be interrupted.
6. Assess patient's and family's knowledge of home oxygen use, their ability to understand safety precautions, and their ability to observe for signs and symptoms of hypoxia: apprehension, anxiety, decreased ability to concentrate, decreased level of consciousness, increased fatigue, dizziness, behavioral changes, increased pulse, increased respiratory rate, pallor, or cyanosis of the mucous membranes.	Hypoxia occurs at home despite use of oxygen therapy. Worsening of patient's physical condition or another underlying condition such as a change in the respiratory status can cause hypoxia.
Planning	
1. Explain need for and use of home oxygen therapy.	Improves adherence to the treatment regimen. Decreases anxiety and the need for home oxygen.
2. Determine appropriate resources in community for equipment and assistance, including maintenance and repair services and medical equipment supplier.	Ensures readily available assistance for patients with home oxygen systems. Delivery and setup with basic instruction on how to use and maintain home oxygen equipment must be in accordance with federal, state, and local laws (CMS, 2017; Jacobs, 2018).
Table Continued	

Step	Rationale
3. Provide family resources to investigate municipal requirements for home medical equipment, especially oxygen.	Many municipalities require that patients with home oxygen equipment notify emergency medical service (EMS) before bringing equipment home. When there is a power outage, EMS calls the home, and in some cases the home is on a priority list for power restoration.
4. Obtain appropriate referrals to determine whether patient meets standards for third-party reimbursement.	Indications for home oxygen therapy include (1) a PaO ₂ less than or equal to 55 mm Hg or SaO ₂ less than or equal to 88% breathing room air; (2) PaO ₂ less than or equal to 56-59 mm Hg or SaO ₂ less than or equal to 89% with conditions such as cor pulmonale, heart failure, or hematocrit greater than 56%; or (3) oxygen therapy is needed during activities that cause hypoxia such as ambulation, sleep, or exercise causing an SaO ₂ of less than or equal to 88% (CMS, 2017). Providing evidence of inclusion criteria is often necessary for third-party reimbursement.
Implementation	
1. Perform hand hygiene.	Reduces transmission of infection.
2. Place oxygen-delivery system in clutter-free environment that is well ventilated; away from walls, drapes, bedding, and combustible materials; and at least 8 feet from heat source.	Prevents injury from improper placement of oxygen equipment (ATS, 2016).
3. Demonstrate each step for preparation and completion of oxygen therapy.	Teaches psychomotor skills and enables patient to ask questions. When patients and family caregivers are adequately informed about supplemental oxygen therapy, the patient's consistent use of the therapy is enhanced (Lewis et al., 2017).
a. Compressed oxygen system—available in large cylinders as stationary units or smaller, lightweight cylinders in carrying bags and/or wheel carts.	Smaller units are used for ambulation and as a backup of stationary unit if there is power failure or equipment malfunction (ATS, 2016).
(1) Turn cylinder valve counterclockwise two or three turns with wrench. Store wrench with oxygen tank.	Turns on oxygen. Keeps wrench available.
(2) Check cylinders by reading amount on pressure gauge. Store wrench in a safe place near the system.	Verifies adequate oxygen supply for patient use.
b. Oxygen concentrator system—available as stationary unit or portable device.	Extracts oxygen from other gases in atmospheric air (ATS, 2016).
(1) Plug concentrator into appropriate outlet.	Provides power source. Make sure that it is in an open area and never in a closet or other closed space
(2) Turn on power switch.	Starts concentrator motor.
(3) Alarm sounds for a few seconds.	Alarm turns off when desired pressure inside concentrator is reached.
c. Liquid oxygen systems—available in large-reservoir canisters that can be used to refill a smaller portable unit (ATS, 2016). Portable unit weighs around 11 pounds and can be carried with a shoulder strap or pulled on a cart.	When liquid oxygen is warmed, it goes from liquid to gas. More oxygen can be stored as a liquid than gas.
(1) Check liquid system by depressing button, often located in lower right corner, and reading dial on stationary oxygen reservoir or ambulatory tank.	Verifies amount of oxygen supply for patient use.
(2) Collaborate with durable medical equipment (DME) vendor to provide instruction in refilling ambulatory tank.	Ensures continuation of home oxygen therapy.
(3) Refill oxygen tank.	
(a) Wipe both filling connectors with clean, dry, lint-free cloth.	Removes dust and moisture from system.
(b) Turn off flow selector of ambulatory unit.	

Table Continued

Step	Rationale
(c) Attach ambulatory unit to stationary reservoir by inserting adapter from ambulatory tank into adapter of stationary reservoir (see illustration).	
(d) Open fill valve on ambulatory tank and apply firm pressure to top of stationary reservoir. Stay with unit while it is filling. You will hear a loud hissing noise. Tank fills in about 2 minutes (see illustration).	Prevents leaking of oxygen during filling process. If oxygen leaks during filling process, connection between ambulatory tank and reservoir ices up and valves stick together.
(e) Disconnect ambulatory unit from stationary reservoir when hissing noise changes and vapor cloud begins to form from stationary unit.	Overfilling causes ambulatory unit to malfunction, caused by high pressure in tank.
CLINICAL DECISION: If ambulatory unit does not separate easily, valves from reservoir and ambulatory unit may be frozen together. Wait until valves warm to disengage (about 5 to 10 minutes). Do not touch any frosted areas because contact with skin causes skin damage from frostbite.	
(f) Wipe both filling connectors with clean, dry, lint-free cloth.	Ice sometimes forms during filling. Removes moisture from oxygen system.
4. Connect oxygen-delivery device to oxygen system. (see illustration).	Connects oxygen source to delivery system.
5. Adjust to prescribed flow rate (L/min).	Ensures appropriate oxygen prescription.
6. Have patient or family caregiver apply oxygen-delivery device. Ensure that patient knows to have two sets of oxygen-delivery devices and tubing.	Verifies that patient or family caregiver can apply device. Extra set of equipment is necessary for cleaning or in case of equipment malfunction.
7. Instruct patient and family caregiver not to change oxygen flow rate.	Exceeding prescribed amount of oxygen is harmful in some patients, such as those with chronic obstructive pulmonary disease (COPD).
8. Guide patient and family caregiver as they perform each step. Provide written material for reinforcement and review.	Allows you to correct for errors in technique and discuss their implications.
<p data-bbox="261 747 889 831">9. Instruct patient and family caregiver to notify health care provider if signs or symptoms of hypoxia or respiratory tract infection (e.g., fever, increased sputum, change in color of sputum, or odor) occur.</p> <div data-bbox="365 867 816 1146">  <p data-bbox="365 1150 568 1167">Step 3c(3)(e) Top view of stationary reservoir.</p> </div>	Respiratory tract infections increase oxygen demand and affect oxygen transfer from lungs to blood. Can create severe exacerbation of patient's pulmonary disease.
Step	Rationale

Step 3c(3)(d) Fill valve on ambulatory tank is opened while applying firm pressure to top of ambulatory unit.

Step 4 Oxygen delivery device (nasal cannulas) and tubing attached to ambulatory oxygen tanks.

Step	Rationale
10. Discuss emergency plan for power loss, natural disaster, and acute respiratory distress. Have patient or family caregiver call 911 and notify health care provider and home care agency.	Ensures appropriate response and prevents worsening of patient's condition. Power companies will often work to supply power to houses requiring oxygen therapy first.
11. Instruct patient and family caregiver in safe home oxygen practices, including not allowing smoking in the house, keeping oxygen tanks away from open flame, and storing tanks upright.	Ensures safe use of oxygen in the home and prevents injury to patient and family.
12. Instruct patient and family caregiver that home oxygen-delivery equipment must be maintained and serviced routinely according to manufacturer's guidelines (CMS, 2017).	Routine maintenance ensures proper function of equipment.
Evaluation	
1. During each home visit monitor oxygen delivery rate.	Verifies whether patient or family caregiver is using oxygen at prescribed rate.
2. Ask patient and family caregiver about any problems or concerns with the home oxygen equipment.	Determines whether patient and family caregivers are able to safely use the equipment and solve minor problems.
3. Ask patient and family about ease of administering or any problems with the home oxygen delivery system.	Determines ability of patient and family to deal with stressors associated with home oxygen use.
4. Ask patient and family caregiver to state safety guidelines, emergency precautions, and emergency plan.	Determines patient's knowledge of what to do if power fails, if equipment fails, or if patient's status worsens.
5. Use Teach-Back: "I want to be sure I explained how to administer and use the home oxygen equipment. Show me how to apply your nasal cannula and regulate the oxygen source." Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly.	Determines patient's/family caregiver's level of understanding of instructional topic.
Unexpected Outcomes and Related Interventions	
<p>1. Patient reports no oxygen flow.</p> <ul style="list-style-type: none"> • Check tank pressure gauge. If level of oxygen is low, refill tank if portable or provide alternate source of oxygen such as concentrator. • Notify home oxygen supplier of need for refill. • Reassure patient and family. 	
<p>2. Patient or family caregiver is unable to fill portable liquid oxygen from main source.</p> <ul style="list-style-type: none"> • Check to see that portable tank is connected correctly. • Determine whether valve is frozen. • Contact home oxygen supplier for service visit. • Provide alternate oxygen source if necessary. 	
<p>Recording and Reporting</p> <ul style="list-style-type: none"> • Record teaching plan and describe patient's and family caregiver's ability to safely use home oxygen equipment. • Record type of home oxygen equipment being used and oxygen flow rate, knowledge of safety guidelines, how to use equipment, unexpected outcomes to observe, and ability to return demonstrate proper use of oxygen-delivery device. <p>Home Care Considerations</p> <ul style="list-style-type: none"> • Ensure emergency numbers are programmed into a phone or are readily available for use in case of an emergency. These numbers include health care provider, supplier of medical equipment, and utility company. • Power companies should be notified of homes in which there are patients receiving home oxygen. In the event of a power outage, these homes would be the priority for receiving power. 	

Key Points

- Cardiopulmonary system consists of heart, lungs, airways, and blood vessels. They function to provide and deliver oxygen to the tissues and to remove carbon dioxide from the body.
- Ventilation, diffusion, respiration, and perfusion are processes for providing adequate oxygenation from the alveoli to the blood.
- Cardiac output is determined by the patient's heart rate, strength of contraction, amount of blood in the ventricle, and amount of resistance the heart has to overcome to eject the blood.
- Myocardial blood flow is the path the blood takes to perfuse the muscles of the heart.
- Systemic circulation allows for the perfusion of tissues, delivering oxygen to the tissues and taking carbon dioxide and other waste substances away from the tissues.
- Patients with decreased cardiac output have difficulties in delivering oxygen to the tissues.
- Patients who are hypoxic are at risk for decreased cardiac output.
- Altered level of consciousness, tachypnea, dyspnea, and anxiety are all signs of hypoxemia.
- Electrical disturbances, dysrhythmias, and mechanical dysfunction of the heart (impaired valve function) can lead to decreased cardiac output, leading to decreased delivery of oxygen to the tissues.
- Myocardial ischemia can damage the cardiac muscle, thereby decreasing cardiac output, which leads to decreased oxygen

delivery to the tissues.

- Decreased hemoglobin levels, seen in patients with anemia or blood loss, alter a patient's ability to transport oxygen, causing disturbances in oxygenation.
- Age (both young and the elderly), nutritional intake, hydration status, level of exercise, exposure to smoke or other environmental pollutants, and stress can all have a negative impact on a patient's oxygenation status.
- Nurses and health care providers should ask patients about their risk factors for altered oxygenation, such as smoking history, substance abuse, exposure to pollutants and environmental substances, exercise patterns, diet patterns, and other chronic illnesses.
- Nursing assessment includes respiratory rate and pattern, presence of cough and/or secretions, fatigue, dyspnea, wheezing, chest pain, oxygen saturation, VS, and signs of respiratory infection.
- Assess for signs of chronic hypoxemia, such as clubbed fingers or barrel chest.
- Nursing plan of care should include positioning, medication administration, oxygen administration, respiratory muscle training, and airway suctioning.
- Oxygen therapy, either by nasal cannula, mask or mechanical ventilation, helps to improve tissue oxygenation by increasing the amount of oxygen available to the patient.
- Breathing exercises, such as diaphragmatic breathing and pursed-lip breathing, benefit patients with chronic pulmonary disease.
- Chest physiotherapy is reserved for use in patients with thick secretions to help them mobilize those secretions.

- Vaccinations, smoking-cessation programs, exercise programs, and nutritional support are health promotion strategies to utilize when working with patients and their families.
- Mobilization of secretions through positioning and adequate hydration helps to maintain the airway.
- Suctioning may be necessary to maintain airway patency in patients who have difficulties in maintaining their own airway.
- Artificial airways may be used in patients who cannot maintain their own airway.
- Assess breath sounds, SpO₂ levels, breathing rate and patterns, activity tolerance, level of fatigue, and ability to maintain airway to determine a patient's response to therapies.

Reflective Learning

- Consider a patient experience you have had. What clinical assessments did you find that indicated the patient had a disturbance in oxygenation?
- Reflect upon past clinical experiences in which your patient was receiving therapy for a disturbance in oxygenation. What therapies were the health care providers prescribing for that patient, and how did the patient respond to the therapies?
- Think about a patient with a disturbance in oxygenation that you have cared for during your clinical experience. How did you know that your interventions were working and that the patient was progressing toward meeting his or her expected outcomes? What would you have done if the patient were not making progress toward those outcomes?

Review Questions

1. The nurse is preparing to perform nasotracheal suctioning on a patient. Arrange the steps in order.
 1. Apply suction.
 2. Assist patient to semi-Fowler's or high Fowler's position, if able.
 3. Advance catheter through nares and into trachea.
 4. Have patient take deep breaths.
 5. Lubricate catheter with water-soluble lubricant.
 6. Apply sterile gloves.
 7. Perform hand hygiene.
 8. Withdraw catheter.
2. Which skills can the nurse delegate to assistive personnel (AP)? (Select all that apply.)
 1. Initiate oxygen therapy via nasal cannula.
 2. Perform nasotracheal suctioning of a patient.
 3. Educate the patient about the use of an incentive spirometer.
 4. Assist with care of an established tracheostomy tube.
 5. Reposition a patient with a chest tube.
3. The nurse is caring for a patient with pneumonia. On entering the room, the nurse finds the patient lying in bed, coughing, and unable to clear secretions. What should the nurse do first?
 1. Start oxygen at 2 L/min via nasal cannula.
 2. Elevate the head of the bed to 45 degrees.
 3. Encourage the patient to use the incentive spirometer.
 4. Notify the health care provider.
4. The nurse is performing discharge teaching for a patient with chronic obstructive pulmonary disease (COPD). What statement, made by the patient, indicates the need for further teaching?

1. "Pursed-lip breathing is like exercise for my lungs and will help me strengthen my breathing muscles."
 2. "When I am sick, I should limit the amount of fluids I drink so that I don't produce excess mucus."
 3. "I will ensure that I receive an influenza vaccine every year, preferably in the fall."
 4. "I will look for a smoking-cessation support group in my neighborhood."
5. Which assessment findings indicate that the patient is experiencing an acute disturbance in oxygenation and requires immediate intervention? (Select all that apply.)
1. SpO₂ value of 95%
 2. Retractions
 3. Respiratory rate of 28 breaths per minute
 4. Nasal flaring
 5. Clubbing of fingers
6. The nurse is caring for a patient with an artificial airway. What are reasons to suction the patient? (Select all that apply.)
1. The patient has visible secretions in the airway.
 2. There is a sawtooth pattern on the patient's E_tCO₂ monitor.
 3. The patient has clear breath sounds.
 4. It has been 3 hours since the patient was last suctioned.
 5. The patient has excessive coughing.
7. The nurse is caring for a patient with a chest tube for treatment of a right pneumothorax. Which assessment finding necessitates immediate notification of the health care provider?
1. New, vigorous bubbling in the water seal chamber.
 2. Scant amount of sanguineous drainage noted on the dressing.

3. Clear but slightly diminished breath sounds on the right side of the chest.
4. Pain score of 2 one hour after the administration of the prescribed analgesic.
8. The nurse has just witnessed her patient go into cardiac arrest. What priority interventions should the nurse perform at this time? (Select all that apply.)
 1. Perform chest compressions.
 2. Ask someone to bring the defibrillator to the room for immediate defibrillation.
 3. Apply oxygen via nasal cannula.
 4. Place the patient in the high Fowler's position.
 5. Educate the family about the need for CPR.
9. The nurse is performing tracheostomy care on a patient. What finding would indicate that the tracheostomy tube has become dislodged?
 1. Clear breath sounds
 2. Patient speaking to nurse
 3. SpO₂ reading of 96%
 4. Respiratory rate of 18 breaths/minute
10. Which number corresponds to the spot where you would assess for an air leak in the patient with a chest tube?

Fluid, Electrolyte, and Acid-Base Balance

OBJECTIVES

- Describe processes that regulate fluid distribution, extracellular fluid volume, and body fluid osmolality.
- Describe processes that regulate electrolyte balance.
- Describe processes that regulate acid-base balance.
- Describe common fluid, electrolyte, and acid-base imbalances.
- Identify risk factors for fluid, electrolyte, and acid-base imbalances.
- Apply the nursing process when caring for patients with fluid, electrolyte, and acid-base imbalances.
- Choose appropriate clinical assessments for specific fluid, electrolyte, and acid-base imbalances.
- Describe purpose and procedures for measuring and recording daily weights and fluid intake and output.
- Explain rationale and procedures for initiating an intravenous line; maintaining the system; changing intravenous solution containers, tubing, and dressings; and discontinuing peripheral venous access.
- Describe potential complications of intravenous therapy and what to do if they occur.
- Discuss the procedure for initiating and monitoring a blood transfusion and the appropriate nursing actions to take if transfusion reactions occur.
- Identify how to evaluate the outcomes of care of patients with fluid, electrolyte, and acid-base imbalances.

Fluid is inside and surrounds all the cells in the body. Cellular fluids contain electrolytes such as sodium and potassium and also have a degree of acidity. Fluid, electrolyte, and acid-base balances within the body maintain the health and function of all body systems. The characteristics of body fluids influence body system function because of their effects on cell function. These characteristics include the fluid amount (volume), concentration (osmolality), composition (electrolyte concentration), and degree of acidity (pH). All of these characteristics have regulatory mechanisms that keep them in balance for normal cellular function. It is important to understand how the body normally maintains fluid, electrolyte, and acid-base balance. You also need to understand how imbalances develop; how various fluid, electrolyte, and acid-base imbalances affect patients; and ways to help patients maintain or restore balance safely.

Scientific Knowledge Base

This section provides the foundation of scientific knowledge for your critical thinking regarding patients who have or are at risk of having fluid, electrolyte, or acid-base imbalances.

Location and Movement of Water and Electrolytes

Water is a substantial proportion of body weight. In fact, about 60% of the body weight of an adult man is water. This proportion decreases with age; approximately 50% of an older man's weight is water. Women typically have less water content than men. People who are obese have less water in their bodies than people who are lean because fat contains less water than muscle (Hall, 2016). The term **fluid** means water that contains dissolved or suspended substances such as glucose, mineral salts, and proteins.

Fluid Distribution

Body fluids are located in two distinct compartments: **extracellular fluid (ECF)** outside the cells and **intracellular fluid (ICF)** inside the cells (Fig. 42.1). In adults ICF is approximately two-thirds of total body water. ECF is approximately one-third of total body water. ECF has two major divisions (**intravascular fluid** and **interstitial fluid**) and a minor division (transcellular fluids). Intravascular fluid is the liquid part of the blood (i.e., the plasma). Interstitial fluid is located between the cells and outside the blood vessels. Transcellular fluids such as cerebrospinal, pleural, peritoneal, and synovial fluids are secreted by epithelial cells (Hall, 2016).

FIG. 42.1 Body fluid compartments.

From Hall JE: *Guyton and Hall textbook of medical physiology*, ed 13, Philadelphia, 2016, Saunders.

Composition of Body Fluids

Fluid in the body compartments contains mineral salts known technically as electrolytes. An electrolyte is a compound that separates into ions (charged particles) when it dissolves in water. Ions that are positively charged are called cations; ions that are negatively charged are called

anions. Cations in body fluids are sodium (Na^+), potassium (K^+), calcium (Ca^{2+}), and magnesium ions (Mg^{2+}). Anions in body fluids are chloride (Cl^-) and bicarbonate (HCO_3^-). Anions and cations combine to make salts. If you put table salt (NaCl) in water, it separates into Na^+ and Cl^- . Other combinations of anions and cations do the same. Clinical laboratories usually report electrolyte measurements in milliequivalents per liter (mEq/L) or millimoles per liter (mmol/L), which are two different units of concentration (Table 42.1). Millimoles per liter represent the number of milligrams of the electrolyte divided by its molecular weight that are contained in a liter of the fluid being measured (usually blood plasma or serum). Milliequivalents per liter are the millimoles per liter multiplied by the electrolyte charge (e.g., 1 for Na^+ , 2 for Ca^{2+}). One milliequivalent of one electrolyte can combine with one milliequivalent of another electrolyte, which is why this measurement unit is used.

TABLE 42.1

Normal Laboratory Values for Adults

Item Measured	Normal Value in Serum or Blood
Osmolality	285-295 mOsm/kg H_2O (285-295 mmol/kg H_2O)
Electrolytes	
Sodium (Na^+)	136-145 mEq/L (136-145 mmol/L)
Potassium (K^+)	3.5-5.0 mEq/L (3.5-5 mmol/L)
Chloride (Cl^-)	98-106 mEq/L (98-106 mmol/L)
Total CO_2 (CO_2 total content)	22-30 mEq/L (22-30 mmol/L)
Bicarbonate (HCO_3^-)	Arterial 21-28 mEq/L (21-28 mmol/L) Venous 24-30 mEq/L (24-30 mmol/L)
Total calcium (Ca^{2+})	9.0-10.5 mg/dL (2.25-2.62 mmol/L)
Ionized calcium (Ca^{2+})	4.5-5.6 mg/dL (1.05-1.3 mmol/L)
Magnesium (Mg^{2+})	1.3-2.1 mEq/L (0.65-1.05 mmol/L)
Phosphate	3.0-4.5 mg/dL (0.97-1.45 mmol/L)
Anion gap	6 +/- 4 mEq/L (6 +/- 4 mmol/L)
Arterial Blood Gases	
pH	7.35-7.45
PaCO_2	35-45 mm Hg (4.7-6 kPa)
PaO_2	80-100 mm Hg (10.7-13.3 kPa)
O_2 saturation	95%-100% (0.95-1.00)
Base excess	- 2 to + 2 mm Eq/L (mmol/L)

Fluid that contains a large number of dissolved particles is more concentrated than the same amount of fluid that contains only a few particles. **Osmolality** of a fluid is a measure of the number of particles per kilogram of water. Some particles (e.g., urea) pass easily through cell

membranes; others such as Na^+ cannot cross easily. The particles that cannot cross cell membranes easily determine the tonicity (effective concentration) of a fluid. A fluid with the same tonicity as normal blood is called **isotonic**. A **hypotonic** solution is more dilute than the blood, and a **hypertonic** solution is more concentrated than normal blood (Fig. 42.2).

FIG. 42.2 Effects of isotonic, hypotonic, and hypertonic solutions.

Philadelphia, 2016, Saunders.

Movement of Water and Electrolytes

Active transport, diffusion, osmosis, and filtration are processes that move water and electrolytes between body compartments. These processes maintain equal osmolality in all compartments while allowing for different electrolyte concentrations.

Active Transport

Fluids in different body compartments have different concentrations of electrolytes that are necessary for normal function. For example, concentrations of Na^+ , Cl^- , and HCO_3^- are higher in the ECF, whereas the concentrations of K^+ , Mg^{2+} , and phosphate are higher in the ICF. Cells maintain their high intracellular electrolyte concentration by active transport. Active transport requires energy in the form of adenosine triphosphate (ATP) to move electrolytes across cell membranes against the concentration gradient (from areas of lower concentration to areas of higher concentration). One example of active transport is the sodium-potassium pump, which moves Na^+ out of a cell and K^+ into it, keeping ICF lower in Na^+ and higher in K^+ than the ECF.

Diffusion

Diffusion is passive movement of electrolytes or other particles down a concentration gradient (from areas of higher concentration to areas of lower concentration). Within a body compartment electrolytes diffuse easily by random movements until the concentration is the same in all areas. However, diffusion of electrolytes across cell membranes requires proteins that serve as ion channels. For example, when a sodium channel in a cell membrane is open, Na^+ diffuses passively across the cell membrane into the ICF because concentration is lower in the ICF. Opening of ion channels is tightly controlled and plays an important part in muscle and nerve function.

Osmosis

Water moves across cell membranes by **osmosis**, a process by which water moves through a membrane that separates fluids with different particle concentrations (Fig. 42.3). Cell membranes are semipermeable, which means that water crosses them easily but they are not freely permeable to many types of particles, including electrolytes such as sodium and potassium. These semipermeable cell membranes separate interstitial fluid from ICF. The fluid in each of these compartments exerts **osmotic pressure**,

an inward-pulling force caused by particles in the fluid. The particles already inside the cell exert ICF osmotic pressure, which tends to pull water into the cell. The particles in the interstitial fluid exert interstitial fluid osmotic pressure, which tends to pull water out of the cell. Water moves into the compartment that has a higher osmotic pressure (inward-pulling force) until the particle concentration is equal in the two compartments.

FIG. 42.3 Osmosis moves water through semipermeable membrane. From Patton KT, Thibodeau GA: *The human body in health and disease*, ed 7, St Louis, 2018, Elsevier.

If the particle concentration in the interstitial compartment changes, osmosis occurs rapidly and moves water into or out of cells to equalize the osmotic pressures. For example, when a hypotonic solution (more dilute than normal body fluids) is administered intravenously, it dilutes the interstitial fluid, decreasing its osmotic pressure below intracellular osmotic pressure. Water moves rapidly into cells until the two osmotic pressures are equal again. On the other hand, infusion of a hypertonic intravenous (IV) solution (more concentrated than normal body fluids) causes water to leave cells by osmosis to equalize the osmolality between interstitial and intracellular compartments.

Filtration

Fluid moves into and out of capillaries (between the vascular and interstitial compartments) by the process of **filtration** (Fig. 42.4). Filtration is the net effect of four forces, two that tend to move fluid out of capillaries and small venules and two that tend to move fluid back into them. **Hydrostatic pressure** is the force of the fluid pressing outward against a surface. Similarly, capillary hydrostatic pressure is a relatively strong outward-pushing force that helps move fluid from capillaries into the interstitial area. Interstitial fluid hydrostatic pressure is a weaker opposing force that tends to push fluid back into capillaries (Hall, 2016).

FIG. 42.4 Capillary filtration moves fluid between vascular and interstitial compartments.

From Banasik JL, Copstead LC: *Pathophysiology*, ed 6, St Louis, 2019, Saunders.

Blood contains albumin and other proteins known as **colloids**. These proteins are much larger than electrolytes, glucose, and other molecules that dissolve easily. Most colloids are too large to leave capillaries in the fluid that is filtered; thus they remain in the blood. Because they are particles, colloids exert osmotic pressure. Blood **colloid osmotic pressure**, also called **oncotic pressure**, is an inward-pulling force caused by blood proteins that helps move fluid from the interstitial area back into capillaries. Interstitial fluid colloid osmotic pressure normally is a very small opposing force.

Capillary hydrostatic pressure is strongest at the arterial end of a normal capillary. Fluid moves from the capillary into the interstitial area, bringing nutrients to cells. At the venous end capillary hydrostatic pressure is weaker, and the colloid osmotic pressure of the blood is stronger. Thus fluid moves into the capillary at the venous end, removing waste products

from cellular metabolism. Lymph vessels remove any extra fluid and proteins that have leaked into the interstitial fluid.

Disease processes and other factors that alter these forces may cause accumulation of excess fluid in the interstitial space, known as *edema*. For example, people with heart failure often develop edema. In this situation, venous congestion from a weakened heart that no longer pumps effectively increases capillary hydrostatic pressure, causing edema by moving excessive fluid into the interstitial space. Inflammation is another cause of edema. It increases capillary blood flow and allows capillaries to leak colloids into the interstitial space. The resulting increased capillary hydrostatic pressure and increased interstitial colloid osmotic pressure produce localized edema in the inflamed tissues.

Fluid Balance

Fluid homeostasis is the dynamic interplay of three processes: fluid intake and absorption, fluid distribution, and fluid output ([Felver, 2019d](#)). To maintain fluid balance, fluid intake must equal output. Because some of the normal daily fluid output (e.g., urine, sweat) is a hypotonic salt solution, people must have an equivalent fluid intake of hypotonic sodium-containing fluid (or water plus foods with some salt) to maintain fluid balance (intake equal to output).

Fluid Intake

Fluid intake occurs orally through drinking but also through eating because most foods contain some water. Food metabolism creates additional water. Average fluid intake from these routes for healthy adults is about 2300 mL, although this amount can vary widely, depending on exercise habits, preferences, and the environment ([Table 42.2](#)). Other routes of fluid intake include IV, rectal (e.g., enemas), and irrigation of body cavities that can absorb fluid.

TABLE 42.2**Healthy Adult Average Fluid Intake and Output**

	Normal (per Day)	Prolonged Heavy Exercise (per Hour)
Fluid Intake		
Fluids Ingested		
Oral	1100-1400 mL	280-1100 mL/hr
Foods	800-1000 mL	Highly variable
Metabolism	300 mL	16-50 mL/hr
TOTAL	2200-2700 mL	300-1150 mL/hr
Fluid Output		
Skin (insensible and sweat)	500-600 mL	300-2100 mL/hr
Insensible lungs	400 mL	20 mL/hr
Gastrointestinal	100-200 mL	Negligible, unless diarrhea during exercise
Urine	1200-1500 mL	20-1000 mL/hr, depending on hydration status
TOTAL	2200-2700 mL	340-3120 mL/hr Rehydration with Na ⁺ -containing fluid necessary after prolonged vigorous exercise

Data from Hall JE: *Guyton and Hall textbook of medical physiology*, ed 13, Philadelphia, 2016, Saunders.

Although you might think that the major regulator of oral fluid intake is thirst, habit and social reasons also play major roles in fluid intake. Thirst, the conscious desire for water, is an important regulator of fluid intake when plasma osmolality increases (osmoreceptor-mediated thirst) or the blood volume decreases (baroreceptor-mediated thirst and angiotensin II- and III-mediated thirst) (Gizowski and Bourgue, 2018). The thirst-control mechanism is located within the hypothalamus in the brain (Fig. 42.5). Osmoreceptors continually monitor plasma osmolality; when it increases, they cause thirst by stimulating neurons in the hypothalamus. People who are alert can obtain fluid or communicate their thirst to others, and fluid intake restores fluid balance. Infants, patients with neurological or psychological problems, and some older adults who are unable to perceive or communicate their thirst are at risk for dehydration.

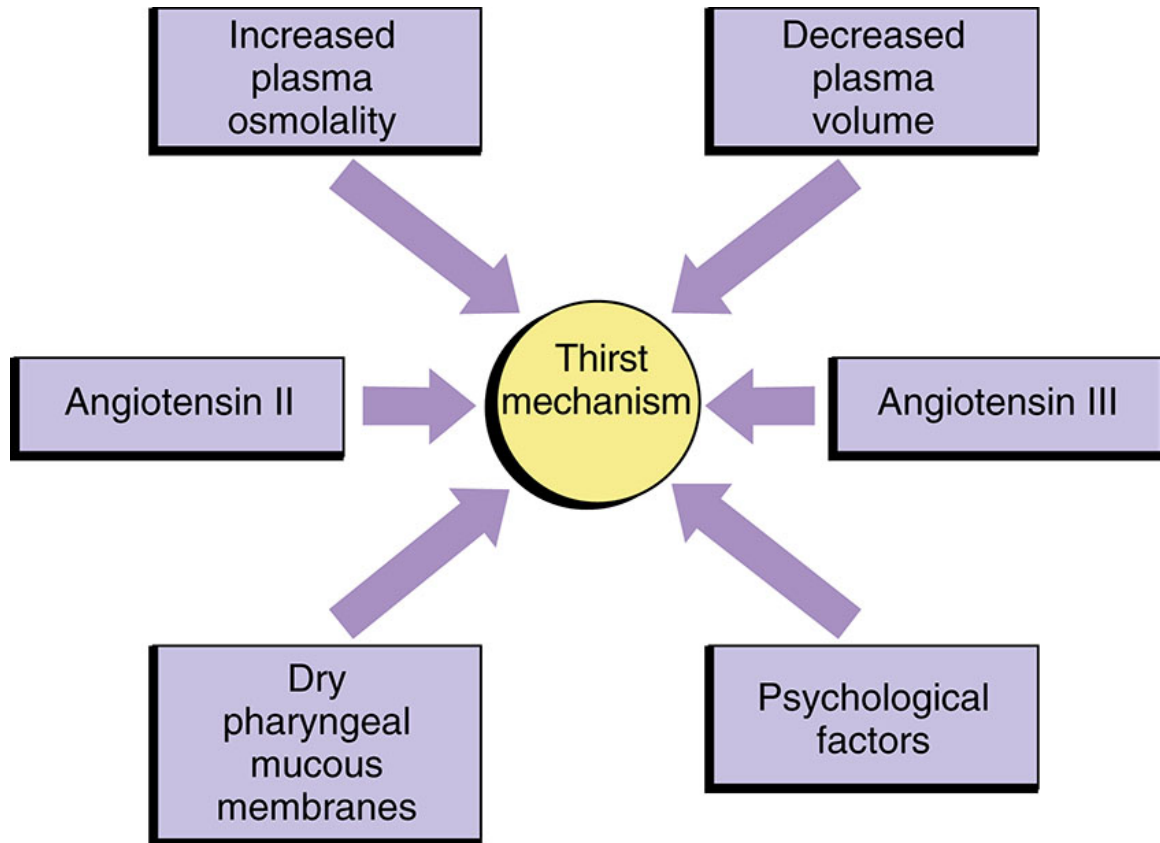

FIG. 42.5 Stimuli affecting thirst mechanism.

Fluid Distribution

The term *fluid distribution* means the movement of fluid among its various compartments. Fluid distribution between the extracellular and intracellular compartments occurs by osmosis. Fluid distribution between the vascular and interstitial parts of the ECF occurs by filtration.

Fluid Output

Fluid output normally occurs through four organs: the skin, lungs, gastrointestinal (GI) tract, and kidneys. Examples of abnormal fluid output include vomiting, wound drainage, or hemorrhage (Felver, 2019d). Table 42.2 shows average amounts of fluid excretion for healthy adults, although urine output varies greatly, depending on fluid intake. Insensible (not visible) water loss through the skin and lungs is continuous. It increases when a person has a fever or a recent burn to the skin (Kamel and Halperin, 2017). Sweat, which is visible and contains sodium, occurs intermittently and increases fluid output substantially. The GI tract plays a vital role in fluid balance. Approximately 3 to 6 L of fluid moves into the

GI tract daily and returns to the ECF. The average adult normally excretes only 100 mL of fluid each day through feces. However, diarrhea causes a large fluid output from the GI tract (Kear, 2017).

The kidneys are the major regulator of fluid output because they respond to hormones that influence urine production. When healthy adults drink more water, they increase urine production to maintain fluid balance. If they drink less water, sweat a lot, or lose fluid by vomiting, their urine volume decreases to maintain fluid balance. These adjustments primarily are caused by the actions of antidiuretic hormone (ADH), the renin-angiotensin-aldosterone system (RAAS), and atrial natriuretic peptides (ANPs) (Hall, 2016) (Fig. 42.6).

FIG. 42.6 Major hormones that influence renal fluid excretion. **A**, Antidiuretic hormone (ADH). **B**, Aldosterone. **C**, Atrial natriuretic peptide (ANP).

Antidiuretic Hormone

ADH regulates the osmolality of the body fluids by influencing how much water is excreted in urine. It is synthesized by neurons in the hypothalamus that release it from the posterior pituitary gland. ADH circulates in the blood to the kidneys, where it acts on the collecting ducts (Hall, 2016). Its name—antidiuretic hormone—tells you what it does. It

causes renal cells to resorb water, taking water from the renal tubular fluid and putting it back in the blood. This action decreases urine volume, concentrating the urine while diluting the blood by adding water to it (see [Fig. 42.6A](#)).

People normally have some ADH release to maintain fluid balance. More ADH is released if body fluids become more concentrated. Factors that increase ADH levels include severely decreased blood volume (e.g., dehydration, hemorrhage), pain, stressors, and some medications.

ADH levels decrease if body fluids become too dilute. This allows more water to be excreted in urine, creating a larger volume of dilute urine and concentrating the body fluids back to normal osmolality. For example, ethyl alcohol decreases ADH release, which causes people to urinate frequently when they drink alcoholic beverages ([Hall, 2016](#)).

Renin-Angiotensin-Aldosterone System

The renin-angiotensin-aldosterone system (RAAS) regulates ECF volume by influencing how much sodium and water are excreted in urine. It also contributes to regulation of blood pressure. Specialized cells in the kidneys release the enzyme renin, which acts on angiotensinogen, an inactive protein secreted by the liver that circulates in the blood. Renin converts angiotensinogen to angiotensin I, which is converted to angiotensin II by other enzymes in the lung capillaries ([Hall, 2016](#)). Angiotensin II has several functions, one of which is vasoconstriction in some vascular beds. The important fluid homeostasis functions of angiotensin II include stimulation of aldosterone release from the adrenal cortex.

Aldosterone circulates to the kidneys, where it causes resorption of sodium and water in isotonic proportion in the distal renal tubules. Removing sodium and water from the renal tubules and returning it to the blood increases the volume of the ECF (see [Fig. 42.6B](#)). Aldosterone also contributes to electrolyte and acid-base balance by increasing urinary excretion of potassium and hydrogen ions.

To maintain fluid balance, normally some action of the RAAS occurs. Certain stimuli increase or decrease the activity of this system to restore fluid balance. For example, if hemorrhage or vomiting decreases the extracellular fluid volume (ECV), blood flow decreases through the renal arteries, and more renin is released. This increased RAAS activity causes more sodium and water retention, helping to restore ECV.

Atrial Natriuretic Peptide

ANP also regulates ECV by influencing how much sodium and water are excreted in urine. Cells in the atria of the heart release ANP when they are stretched (e.g., by an increased ECV). ANP is a weak hormone that increases the loss of sodium and water in the urine (see [Fig. 42.6C](#)). Thus ANP opposes the effect of aldosterone ([Hall, 2016](#)).

Fluid Imbalances

If disease processes, medications, or other factors disrupt fluid intake or output, imbalances sometimes occur ([Felver, 2019d](#)). For example, with diarrhea there is an increase in fluid output, and a fluid imbalance (dehydration) occurs if fluid intake does not increase appropriately. There are two major types of fluid imbalances: volume imbalances and osmolality imbalances ([Fig. 42.7](#)). Volume imbalances are disturbances of the *amount of fluid in the extracellular compartment*. Osmolality imbalances are disturbances of the *concentration of body fluids*. Volume and osmolality imbalances occur separately or in combination.

FIG. 42.7 Fluid volume and osmolality imbalances.

From Banasik JL, Copstead LC: *Pathophysiology online for pathophysiology*, ed 6, St Louis, 2019, Mosby.

Extracellular Fluid Volume Imbalances

In an ECV imbalance there is either too little (ECV deficit) or too much (ECV excess) isotonic fluid. **Extracellular volume deficit** is present when there is insufficient isotonic fluid in the extracellular compartment. Remember that there is a lot of sodium in normal ECF. With ECV deficit, output of isotonic fluid exceeds intake of sodium-containing fluid. Because ECF is both vascular and interstitial, signs and symptoms arise from lack of volume in both of these compartments. [Table 42.3](#) lists specific causes and signs and symptoms of ECV deficit. The term **hypovolemia** means decreased vascular volume and often is used when discussing ECV deficit ([Kamel and Halperin, 2017](#)).

TABLE 42.3

Fluid Imbalances

Imbalance and Related Causes	Signs and Symptoms
Isotonic Imbalances—Water and Sodium Lost or Gained in Equal or Isotonic Proportions	
Extracellular Fluid Volume Deficit—Body Fluids Have Decreased Volume but Normal Osmolality	
<p>Sodium and Water Intake Less Than Output, Causing Isotonic Loss:</p> <p>Severely decreased oral intake of water and salt</p> <p>Increased GI output: vomiting, diarrhea, laxative overuse, drainage from fistulas or tubes</p> <p>Increased renal output: use of diuretics, adrenal insufficiency (deficit of cortisol and aldosterone)</p> <p>Loss of blood or plasma: hemorrhage, burns</p> <p>Massive sweating without water and salt intake</p>	<p><i>Physical examination:</i> Sudden weight loss (overnight), postural hypotension, tachycardia, thready pulse, dry mucous membranes, poor skin turgor, slow vein filling, flat neck veins when supine, dark yellow urine</p> <p>If severe: thirst, restlessness, confusion, hypotension; oliguria (urine output below 30 mL/hr); cold, clammy skin; hypovolemic shock</p> <p><i>Laboratory findings:</i> Increased hematocrit; increased BUN above 20 mg/dL (7.1 mmol/L) (hemoconcentration); urine specific gravity usually above 1.030, unless renal cause</p>
Extracellular Fluid Volume Excess—Body Fluids Have Increased Volume but Normal Osmolality	
<p>Sodium and Water Intake Greater Than Output, Causing Isotonic Gain:</p> <p>Excessive administration of Na⁺-containing isotonic IV fluids or oral intake of salty foods and water</p> <p>Renal retention of Na⁺ and water: heart failure, cirrhosis, aldosterone or glucocorticoid excess, acute or chronic oliguric renal disease</p>	<p><i>Physical examination:</i> Sudden weight gain (overnight), edema (especially in dependent areas), full neck veins when upright or semi-upright, crackles in lungs</p> <p>If severe: confusion, pulmonary edema</p> <p><i>Laboratory findings:</i> Decreased hematocrit, decreased BUN below 10 mg/dL (3.6 mmol/L) (hemodilution)</p>
Osmolality Imbalances	
Hypernatremia (Water Deficit; Hyperosmolar Imbalance)—Body Fluids Too Concentrated	
<p>Loss of Relatively More Water Than Salt:</p> <p>Diabetes insipidus (ADH deficiency)</p> <p>Osmotic diuresis</p> <p>Large insensible perspiration and respiratory water output without increased water intake</p> <p>Gain of Relatively More Salt Than Water:</p> <p>Administration of tube feedings, hypertonic parenteral fluids, or salt tablets</p> <p>Lack of access to water, deliberate water deprivation, inability to respond to thirst (e.g., immobility, aphasia)</p> <p>Dysfunction of osmoreceptor-driven thirst drive</p>	<p><i>Physical examination:</i> Decreased level of consciousness (confusion, lethargy, coma), perhaps thirst, seizures if develops rapidly or is very severe</p> <p><i>Laboratory findings:</i> Serum Na⁺ level above 145 mEq/L (145 mmol/L), serum osmolality above 295 mOsm/kg (295 mmol/kg)</p>
Hyponatremia (Water Excess; Water Intoxication; Hypoosmolar Imbalance)—Body Fluids Too Dilute	
<p>Gain of Relatively More Water Than Salt:</p> <p>Excessive ADH (SIADH)</p> <p>Psychogenic polydipsia or forced excessive water intake</p> <p>Excessive IV administration of D₅W</p> <p>Use of hypotonic irrigating solutions</p> <p>Tap-water enemas</p> <p>Loss of Relatively More Salt Than Water:</p> <p>Replacement of large body fluid output (e.g., diarrhea, vomiting) with water but no salt</p>	<p><i>Physical examination:</i> Decreased level of consciousness (confusion, lethargy, coma), seizures if develops rapidly or is very severe</p> <p><i>Laboratory findings:</i> Serum Na⁺ level below 136 mEq/L (136 mmol/L), serum osmolality below 285 mOsm/kg (285 mmol/kg)</p>
Combined Volume and Osmolality Imbalance	
Clinical Dehydration (ECV Deficit plus Hypernatremia)—Body Fluids Have Decreased Volume and Are Too Concentrated	
<p>Sodium and Water Intake Less Than Output, With Loss of Relatively More Water Than Salt:</p> <p>All of the causes of ECV deficit (see previous causes) plus poor or no water intake, often with fever causing increased insensible water output</p>	<p><i>Physical examination and laboratory findings:</i> Combination of those for ECV deficit plus those for hypernatremia (see previous signs)</p>

ADH, Antidiuretic hormone; BUN, blood urea nitrogen; ECV, extracellular fluid volume; GI, gastrointestinal; D₅W, 5% dextrose in water; IV, intravenous; SIADH, syndrome of inappropriate secretion of antidiuretic hormone.

Extracellular volume excess occurs when there is too much isotonic fluid in the extracellular compartment. Intake of sodium-containing isotonic fluid has exceeded fluid output. For example, when you eat more salty foods than usual and drink water, you may notice that your ankles swell or rings on your fingers feel tight and you gain 2 lb (1 kg) or more overnight. These are manifestations of mild ECV excess. See [Table 42.3](#) for other specific causes and signs and symptoms.

Osmolality Imbalances

In an osmolality imbalance body fluids become hypertonic or hypotonic, which causes osmotic shifts of water across cell membranes. The osmolality imbalances are called *hypernatremia* and *hyponatremia*.

Hypernatremia, also called *water deficit*, is a hypertonic condition. Two general causes make body fluids too concentrated: loss of relatively more water than salt or gain of relatively more salt than water ([Felver, 2019d](#)). [Table 42.3](#) lists specific causes under these categories. When the interstitial fluid becomes hypertonic, water leaves cells by osmosis, and they shrivel. Signs and symptoms of hypernatremia are those of cerebral dysfunction, which arise when brain cells shrivel. Hypernatremia may occur in combination with ECV deficit; this combined disorder is called clinical dehydration.

Hyponatremia, also called *water excess* or *water intoxication*, is a hypotonic condition. It arises from gain of relatively more water than salt or loss of relatively more salt than water ([Felver, 2019d](#)) (see [Table 42.3](#)). The excessively dilute condition of interstitial fluid causes water to enter cells by osmosis, causing the cells to swell. Signs and symptoms of cerebral dysfunction occur when brain cells swell ([Hoorn et al., 2017](#)).

Clinical Dehydration

ECV deficit and hypernatremia often occur at the same time; this combination is called *clinical dehydration*. The ECV is too low, and the body fluids are too concentrated. Clinical dehydration is common with gastroenteritis or other causes of severe vomiting and diarrhea when people are unable to replace their fluid output with enough intake of dilute sodium-containing fluids. Signs and symptoms of clinical dehydration are those of both ECV deficit and hypernatremia (see [Table 42.3](#)).

Electrolyte Balance

You can best understand electrolyte balance by considering the three processes involved in electrolyte homeostasis: electrolyte intake and absorption, electrolyte distribution, and electrolyte output (Table 42.4) (Felver, 2019d). Although sodium is an electrolyte, it is not included here because serum sodium imbalances are the osmolality imbalances discussed previously.

TABLE 42.4

Electrolyte Intake and Absorption, Distribution, and Output

Electrolyte	Intake and Absorption	Distribution	Output/Loss	Important Function
Potassium (K⁺)	Fruits Potatoes Instant coffee Molasses Brazil nuts Absorbs easily	Low in ECF, high in ICF. Insulin, epinephrine, and alkalosis shift K ⁺ into cells. Some types of acidosis shift K ⁺ out of cells.	Aldosterone, black licorice, hypomagnesemia, and polyuria increase renal excretion; oliguria decreases renal excretion. Acute or chronic diarrhea increases fecal excretion.	Maintains resting membrane potential of skeletal, smooth, and cardiac muscle, allowing normal muscle function
Calcium (Ca²⁺)	Dairy products Canned fish with bones Broccoli Oranges Requires vitamin D for best absorption Undigested fat prevents absorption	Ca ²⁺ is low in ECF, mostly in bones and intracellular. Some Ca ²⁺ in blood is bound and inactive; only ionized Ca ²⁺ is active. Parathyroid hormone shifts Ca ²⁺ out of bone; calcitonin shifts Ca ²⁺ into bone. Ca ²⁺ decreases in blood if phosphate rises and vice versa.	Thiazide diuretics decrease renal excretion. Chronic diarrhea and undigested fat increase fecal excretion.	Influences excitability of nerve and muscle cells; necessary for muscle contraction
Magnesium (Mg²⁺)	Dark green leafy vegetables Whole grains Mg ²⁺ -containing laxatives and antacids Undigested fat prevents absorption	Mg ²⁺ is low in ECF, mostly in bones and intracellular. Some Mg ²⁺ in blood is bound and inactive; only free Mg ²⁺ is active.	Rising blood ethanol increases renal excretion; oliguria decreases renal excretion. Chronic diarrhea and undigested fat increase fecal excretion.	Influences function of neuromuscular junctions; is a cofactor for numerous enzymes
Phosphate	Milk Processed foods Aluminum antacids prevent absorption	Phosphate is low in ECF; it is higher in ICF and in bones. Insulin and epinephrine shift phosphate into cells. Decreases in blood if calcium rises and vice versa.	Oliguria and elevated fibroblast growth factor 23 (FGF-23) decrease renal excretion.	Necessary for production of ATP, the energy source for cellular metabolism

ATP, Adenosine triphosphate; ECF, extracellular fluid volume; ICF, intracellular fluid.

Electrolyte distribution is an important issue. Plasma concentrations of K⁺, Ca²⁺, Mg²⁺, and phosphate are very low compared with their concentrations in cells and bone (Hall, 2016). These concentration

differences are necessary for normal muscle and nerve function. The electrolyte values that you review from laboratory reports are measured in blood serum and do not measure intracellular levels.

Electrolyte output occurs through normal excretion in urine, feces, and sweat. Output also occurs through vomiting, drainage tubes, or fistulas. When electrolyte output increases, electrolyte intake must increase to maintain electrolyte balance. Similarly, if electrolyte output decreases such as with oliguria, electrolyte intake must also decrease to maintain balance (Felver, 2019c).

Electrolyte Imbalances

Factors such as diarrhea, endocrine disorders, and medications that disrupt electrolyte homeostasis cause electrolyte imbalances. Electrolyte intake greater than electrolyte output or a shift of electrolytes from cells or bone into the ECF causes plasma electrolyte excess. Electrolyte intake less than electrolyte output or shift of electrolyte from the ECF into cells or bone causes plasma electrolyte deficit (Felver, 2019c).

Potassium Imbalances

Hypokalemia is abnormally low potassium concentration in the blood. It results from decreased potassium intake and absorption, a shift of potassium from the ECF into cells, and an increased potassium output (Table 42.5). Common causes of hypokalemia from increased potassium output include diarrhea, repeated vomiting, and use of potassium-wasting diuretics (Kovesdy et al., 2017). People who have these conditions need to increase their potassium intake to reduce their risk of hypokalemia. Hypokalemia causes muscle weakness, which becomes life threatening if it includes respiratory muscles. It can also cause potentially life-threatening cardiac dysrhythmias.

TABLE 42.5

Electrolyte Imbalances

Imbalance and Related Causes	Signs and Symptoms
Hypokalemia—Low Serum Potassium (K⁺) Concentration	
<p>Decreased K⁺ Intake: Excessive use of K⁺-free IV solutions</p> <p>Shift of K⁺ into Cells: Alkalosis; treatment of diabetic ketoacidosis with insulin</p> <p>Increased K⁺ Output: Acute or chronic diarrhea; vomiting; other GI losses (e.g., nasogastric or fistula drainage); use of potassium-wasting diuretics; aldosterone excess; polyuria; glucocorticoid therapy</p>	<p><i>Physical examination:</i> Bilateral muscle weakness that begins in quadriceps and may ascend to respiratory muscles, abdominal distention, decreased bowel sounds, constipation, dysrhythmias</p> <p><i>Laboratory findings:</i> Serum K⁺ level below 3.5 mEq/L (3.5 mmol/L);</p> <p>ECG abnormalities: U waves, flattened or inverted T waves; ST segment depression</p>
Hyperkalemia—High Serum Potassium (K⁺) Concentration	
<p>Increased K⁺ Intake: Iatrogenic administration of large amounts of IV K⁺; rapid infusion of stored blood; excess ingestion of K⁺ salt substitutes</p> <p>Shift of K⁺ out of Cells: Massive cellular damage (e.g., crushing trauma, cytotoxic chemotherapy); insufficient insulin (e.g., diabetic ketoacidosis); some types of acidosis</p> <p>Decreased K⁺ Output: Acute or chronic oliguria (e.g., severe ECV deficit, end-stage renal disease); use of potassium-sparing diuretics; adrenal insufficiency (deficit of cortisol and aldosterone)</p>	<p><i>Physical examination:</i> Bilateral muscle weakness in quadriceps, transient abdominal cramps, diarrhea, dysrhythmias, cardiac arrest if severe</p> <p><i>Laboratory findings:</i> Serum K⁺ level above 5 mEq/L (5 mmol/L);</p> <p>ECG abnormalities: peaked T waves; widened QRS complex; PR prolongation; terminal sine-wave pattern</p>
Hypocalcemia—Low Serum Calcium (Ca²⁺) Concentration	
<p>Decreased Ca²⁺ Intake and Absorption: Calcium-deficient diet; vitamin D deficiency (includes end-stage renal disease); chronic diarrhea; laxative misuse; steatorrhea</p> <p>Shift of Ca²⁺ into Bone or Inactive Form: Hypoparathyroidism; rapid administration of citrated blood; hypoalbuminemia; alkalosis; pancreatitis; hyperphosphatemia (includes end-stage renal disease)</p> <p>Increased Ca²⁺ Output: Chronic diarrhea; steatorrhea</p>	<p><i>Physical examination:</i> Numbness and tingling of fingers, toes, and circumoral (around mouth) region, positive Chvostek's sign (contraction of facial muscles when facial nerve is tapped), hyperactive reflexes, muscle twitching and cramping; carpal and pedal spasms, tetany, seizures, laryngospasm, dysrhythmias</p> <p><i>Laboratory findings:</i> Total serum Ca²⁺ level below 9.0 mg/dL (2.25 mmol/L) or serum ionized Ca²⁺ level below 4.5 mg/dL (1.05 mmol/L);</p> <p>ECG abnormalities: prolonged ST segments</p>
Hypercalcemia—High Serum Calcium (Ca²⁺) Concentration	
<p>Increased Ca²⁺ Intake and Absorption: Milk-alkali syndrome</p> <p>Shift of Ca²⁺ out of Bone: Prolonged immobilization; hyperparathyroidism; bone tumors; nonosseous cancers that secrete bone-resorbing factors</p> <p>Decreased Ca²⁺ Output: Use of thiazide diuretics</p>	<p><i>Physical examination:</i> Anorexia, nausea and vomiting, constipation, fatigue, diminished reflexes, lethargy, decreased level of consciousness, confusion, personality change, cardiac arrest if severe</p> <p><i>Laboratory findings:</i> Total serum Ca²⁺ level above 10.5 mg/dL (2.62 mmol/L) or serum ionized Ca²⁺ level above 5.6 mg/dL (1.3 mmol/L);</p> <p>ECG abnormalities: heart block, shortened ST segments</p>
Hypomagnesemia—Low Serum Magnesium (Mg²⁺) Concentration	
<p>Decreased Mg²⁺ Intake and Absorption: Malnutrition; chronic alcoholism; chronic diarrhea; laxative misuse; steatorrhea</p> <p>Shift of Mg²⁺ into Inactive Form: Rapid administration of citrated blood</p> <p>Increased Mg²⁺ Output: Chronic diarrhea; steatorrhea; other GI losses (e.g., vomiting, nasogastric or fistula drainage); use of thiazide or loop diuretics; aldosterone excess</p>	<p><i>Physical examination:</i> Positive Chvostek's sign, hyperactive deep tendon reflexes, muscle cramps and twitching, grimacing, dysphagia, tetany, seizures, insomnia, tachycardia, hypertension, dysrhythmias</p> <p><i>Laboratory findings:</i> Serum Mg²⁺ level below 1.3 mEq/L (0.65 mmol/L);</p> <p>ECG abnormalities: prolonged QT interval</p>
Hypermagnesemia—High Serum Magnesium (Mg²⁺) Concentration	
<p>Increased Mg²⁺ Intake and Absorption: Excessive use of Mg²⁺-containing laxatives and antacids; parenteral overload of magnesium</p> <p>Decreased Mg²⁺ Output: Oliguric end-stage renal disease; adrenal insufficiency</p>	<p><i>Physical examination:</i> Lethargy, hypoactive deep tendon reflexes, bradycardia, hypotension</p> <p>Acute elevation in Mg²⁺ levels: Flushing, sensation of warmth</p> <p>Severe acute hypermagnesemia: Decreased rate and depth of respirations, dysrhythmias, cardiac arrest</p> <p><i>Laboratory findings:</i> Serum Mg²⁺ level above 2.1 mEq/L (1.05 mmol/L);</p> <p>ECG abnormalities: prolonged PR interval</p>

ECG, Electrocardiogram, ECV, extracellular fluid volume, GI, gastrointestinal, IV, intravenous.

Data from Felver L: Fluid and electrolyte homeostasis and imbalances. In Banasik JL, Copstead LC, editors: *Pathophysiology*, ed 6, St Louis, 2019,

Saunders.

Hyperkalemia is abnormally high potassium ion concentration in the blood. Its general causes are increased potassium intake and absorption, shift of potassium from cells into the ECF, and decreased potassium output (see [Table 42.5](#)). People who have oliguria (decreased urine output) are at high risk of hyperkalemia from the resultant decreased potassium output unless their potassium intake also decreases substantially. Understanding this principle helps you remember to check urine output before you administer IV solutions containing potassium. Hyperkalemia can cause muscle weakness, potentially life-threatening cardiac dysrhythmias, and cardiac arrest ([Heckle et al., 2018](#)).

Calcium Imbalances

Hypocalcemia is abnormally low calcium concentration in the blood (see [Table 42.5](#)). The physiologically active form of calcium in the blood is ionized calcium. Total blood calcium also contains inactive forms that are bound to plasma proteins and small anions such as citrate. Factors that cause too much ionized calcium to shift to the bound forms cause symptomatic *ionized hypocalcemia* ([Kyle et al., 2018](#)). People who have acute pancreatitis frequently develop hypocalcemia because calcium binds to undigested fat in their feces and is excreted. This process decreases absorption of dietary calcium and also increases calcium output by preventing reabsorption of calcium contained in GI fluids. Hypocalcemia increases neuromuscular excitability, the basis for its signs and symptoms.

Hypercalcemia is abnormally high calcium concentration in the blood. Hypercalcemia results from increased calcium intake and absorption, shift of calcium from bones into the ECF, and decreased calcium output (see [Table 42.5](#)). Patients with some types of cancers such as lung and breast cancers often develop hypercalcemia because some cancer cells secrete chemicals into the blood that are related to parathyroid hormone. When these chemicals reach the bones, they cause shift of calcium from bones into the ECF. This weakens bones, and the person sometimes develops pathological fractures (i.e., bone breakage caused by forces that would not break a healthy bone). Hypercalcemia decreases neuromuscular excitability, the basis for its other signs and symptoms, the most common of which is lethargy ([Turner, 2017](#)).

Magnesium Imbalances

Hypomagnesemia is abnormally low magnesium concentration in the blood. Its general causes are decreased magnesium intake and absorption, shift of plasma magnesium to its inactive bound form, and increased magnesium output (see [Table 42.5](#)). Signs and symptoms are similar to those of hypocalcemia because hypomagnesemia also increases neuromuscular excitability (Eberhard et al., 2017).

Hypermagnesemia is abnormally high magnesium concentration in the blood (see [Table 42.5](#)). End-stage renal disease causes hypermagnesemia unless the person decreases magnesium intake to match the decreased output. Signs and symptoms are caused by decreased neuromuscular excitability, with lethargy and decreased deep tendon reflexes being most common (Kala and Abudayyeh, 2017).

Acid-Base Balance

For optimal cell function the body maintains a balance between acids and bases. Acid-base homeostasis is the dynamic interplay of three processes: acid production, acid buffering, and acid excretion (Felver, 2019a). Normal acid-base balance is maintained with acid excretion equal to acid production. Acids release hydrogen (H^+) ions; bases (alkaline substances) take up H^+ ions. The more H^+ ions that are present, the more acidic is a solution.

The degree of acidity in blood and other body fluids is reported from the clinical laboratory as pH. The pH scale goes from 1.0 (very acid) to 14.0 (very alkaline; basic). A pH of 7.0 is considered neutral. The normal pH range of adult arterial blood is 7.35 to 7.45. Maintaining pH within this normal range is very important for optimal cell function. If the pH goes outside the normal range, enzymes within cells do not function properly, hemoglobin does not manage oxygen properly, and serious physiological problems occur, including death. Laboratory tests of a sample of arterial blood called **arterial blood gases (ABGs)** are used to monitor a patient's acid-base balance (Felver, 2019a) ([Table 42.6](#)).

TABLE 42.6**Arterial Blood Gas Measures**

Laboratory Measure	Normal Range in Adult Arterial Blood	Definition and Interpretation
pH	7.35-7.45	pH is a negative logarithm of the free H ⁺ concentration, a measure of the blood's acidity or alkalinity. Values below 7.35 indicate abnormally acid; above 7.45 they indicate abnormally alkaline. Small changes in pH denote large changes in H ⁺ concentration and are clinically important.
PaCO ₂	35-45 mm Hg (4.7-6 kPa)	PaCO ₂ is partial pressure of carbon dioxide (CO ₂), a measure of how well the lungs are excreting CO ₂ produced by cells. Increased PaCO ₂ indicates CO ₂ accumulation in blood (more carbonic acid) caused by hypoventilation; decreased PaCO ₂ indicates excessive CO ₂ excretion (less carbonic acid) through hyperventilation.
HCO ₃ ⁻	21-28 mEq/L (21-28 mmol/L)	HCO ₃ ⁻ is concentration of the base (alkaline substance) bicarbonate, a measure of how well the kidneys are excreting metabolic acids. Increased HCO ₃ ⁻ indicates that the blood has too few metabolic acids; decreased HCO ₃ ⁻ indicates that the blood has too many metabolic acids.
PaO ₂	80-100 mm Hg (10.7-13.3 kPa)	PaO ₂ is partial pressure of oxygen (O ₂), a measure of how well gas exchange is occurring in the alveoli of the lungs. Values below normal indicate poor oxygenation of the blood.
SaO ₂	95%-100%	SaO ₂ is oxygen saturation, the percentage of hemoglobin that is carrying as much O ₂ as possible. It is influenced by pH, PaCO ₂ , and body temperature. It drops rapidly when PaO ₂ falls below 60 mm Hg (8 kPa).
Base excess	-2 to +2 mEq/L (mmol/L)	Base excess is observed buffering capacity minus the normal buffering capacity, a measure of how well the blood buffers are managing metabolic acids. Values below -2 (negative base excess) indicate excessive metabolic acids; values above +2 indicate excessive amounts of bicarbonate.

Acid Production

Cellular metabolism constantly creates two types of acids: carbonic acid and metabolic acids (Fig. 42.8).

FIG. 42.8 Acid production and excretion.

Reviewing the formula below, cells produce carbon dioxide (CO₂), which combine with water to produce carbonic acid (H₂CO₃). The carbonic acid (H₂CO₃) can then separate to a hydrogen ion (H⁺) and a bicarbonate ion (HCO₃⁻):

Carbon dioxide + Water ↔ Carbonic acid ↔ Hydrogen ion + Bicarbonate

Metabolic acids are any acids that are not carbonic acid. They include citric acid, lactic acid, and many others.

Acid Buffering

Buffers are pairs of chemicals that work together to maintain normal pH of body fluids. If there are too many free H⁺ ions, a buffer takes them up so that they no longer are free. If there are too few, a buffer can release H⁺ ions to prevent an acid-base imbalance. Buffers work rapidly, within seconds.

All body fluids contain buffers. The major buffer in the ECF is the bicarbonate (HCO₃⁻) buffer system, which buffers metabolic acids. It consists of a lot of bicarbonate and a small amount of carbonic acid (normally a 20 to 1 ratio). Addition of H⁺ released by a metabolic acid to a bicarbonate ion makes more carbonic acid. Now the H⁺ is no longer free and will not decrease the blood pH:

Bicarbonate ion + Hydrogen ion \leftrightarrow Carbonic acid

If there are too few H⁺ions, the carbonic acid part of the buffer pair releases some, increasing the bicarbonate, again returning pH to normal.

Carbonic acid \leftrightarrow Bicarbonate ion + Hydrogen ion

Other buffers include hemoglobin, protein buffers, and phosphate buffers. Cellular and bone buffers also contribute to acid-base balance. Buffers normally keep the blood from becoming too acid when acids that are produced by cells circulate to the lungs and kidneys for excretion.

Acid Excretion

The body has two acid-excretion systems: lungs and kidneys. The lungs excrete carbonic acid; the kidneys excrete metabolic acids (see [Fig. 42.8](#)).

Excretion of Carbonic Acid

When you exhale, you excrete carbonic acid in the form of CO₂ and water. If the PaCO₂ (i.e., level of CO₂ in the blood) rises, the chemoreceptors trigger faster and deeper respirations to excrete the excess. If the PaCO₂ falls, the chemoreceptors trigger slower and shallower respirations so that more of the CO₂ produced by cells remains in the blood and makes up the deficit. These alterations in respiratory rate and depth maintain the carbonic acid part of acid-base balance ([Kamel and Halperin, 2017](#)). People who have respiratory disease may be unable to excrete enough carbonic acid, which causes the blood to become more acidic and blood CO₂ to

increase. If an increased respiratory rate is unable to correct the problem, the kidneys begin some compensatory excretion of metabolic acid.

Excretion of Metabolic Acids

The kidneys excrete all acids except carbonic acid. They secrete H^+ into the renal tubular fluid, putting HCO_3^- back into the blood at the same time. If there are too many H^+ ions in the blood, renal cells move more H^+ ions into the renal tubules for excretion, retaining more HCO_3^- in the process. If there are too few H^+ ions in the blood, renal cells secrete fewer H^+ ions.

Phosphate buffers in the renal tubular fluid keep the urine from becoming too acidic when the kidneys excrete H^+ ions. If the kidneys need to excrete a lot of H^+ , renal tubular cells secrete ammonia, which combines with the H^+ ions in the tubules to make NH_4^+ , ammonium ions. Buffering by phosphate and the creation of NH_4^+ turn free H^+ ions into other molecules in the renal tubular fluid (Kamel and Halperin, 2017). This process enables metabolic acid excretion in urine without making urine too acidic. People who have oliguric kidney disease often are unable to excrete metabolic acids normally, and these acids accumulate, making the blood too acidic (Nagami and Hamm, 2017). If the kidneys are unable to correct this problem, respiratory rate and depth increase, causing compensatory excretion of carbonic acid.

Acid-Base Imbalances

People develop acid-base imbalances when their normal homeostatic mechanisms are dysfunctional or overwhelmed. The term **acidosis** describes a condition that tends to make the blood relatively too acidic. Because our cells produce two types of acid, there are two different types of acidosis: respiratory acidosis and metabolic acidosis. The term **alkalosis** describes a condition that tends to make the blood relatively too basic (alkaline). There are two types of alkalosis: respiratory alkalosis and metabolic alkalosis.

The body has compensatory mechanisms that limit the extent of pH change with acid-base imbalances (Kamel and Halperin, 2017). Compensation involves physiological changes that help normalize the pH but do not correct the cause of the problem. If the problem is a respiratory acid-base imbalance, only the lungs can correct the problem, but the kidneys can compensate by changing the amount of metabolic acid in the blood. If the problem is a metabolic acid-base imbalance, only the kidneys

can correct the problem, but the lungs can compensate by changing the amount of carbonic acid in the blood. Thus the kidneys compensate for respiratory acid-base imbalances; the respiratory system compensates for metabolic acid-base imbalances. These compensatory mechanisms do not correct the problem, but they help the body survive by moving the blood pH toward normal. However, if the underlying condition is not corrected, these compensatory mechanisms eventually will fail.

Respiratory Acidosis

Respiratory acidosis arises from alveolar hypoventilation; the lungs are unable to excrete enough CO_2 . The PaCO_2 rises, creating an excess of carbonic acid in the blood, which decreases pH (Table 42.7). The kidneys compensate by increasing excretion of metabolic acids in the urine, which increases blood bicarbonate. This compensatory process is slow, often taking 24 hours to show clinical effect and 3 to 5 days to reach steady state. Decreased cerebrospinal fluid (CSF) pH and intracellular pH of brain cells cause decreased level of consciousness.

TABLE 42.7

Acid-Base Imbalances

Imbalance and Related Causes	Signs and Symptoms
Respiratory Acidosis—Excessive Carbonic Acid Caused by Alveolar Hypoventilation	
<p>Impaired Gas Exchange: Type B COPD (chronic bronchitis) or end-stage type A COPD (emphysema) Bacterial pneumonia Airway obstruction Extensive atelectasis (collapsed alveoli) Severe acute asthma episode</p> <p>Impaired Neuromuscular Function: Respiratory muscle weakness or paralysis from hypokalemia or neurological dysfunction Respiratory muscle fatigue, respiratory failure Chest wall injury or surgery causing pain with respiration</p> <p>Dysfunction of Brainstem Respiratory Control: Drug overdose with a respiratory depressant Some types of head injury</p>	<p><i>Physical examination:</i> Headache, light-headedness, decreased level of consciousness (confusion, lethargy, coma), dysrhythmias</p> <p><i>Laboratory findings:</i> Arterial blood gas alterations: pH below 7.35, PaCO₂ above 45 mm Hg (6 kPa), HCO₃⁻ level normal if uncompensated or above 28 mEq/L (28 mmol/L) if compensated</p>
Respiratory Alkalosis—Deficient Carbonic Acid Caused by Alveolar Hyperventilation	
<p>Hypoxemia from any cause (e.g., initial part of asthma episode, pneumonia) Acute pain Anxiety, psychological distress, sobbing Inappropriate mechanical ventilator settings Stimulation of brainstem respiratory control (e.g., meningitis, gram-negative sepsis, head injury, aspirin overdose)</p>	<p><i>Physical examination:</i> Light-headedness, numbness and tingling of fingers, toes, and circumoral region, increased rate and depth of respirations, excitement and confusion possibly followed by decreased level of consciousness, dysrhythmias</p> <p><i>Laboratory findings:</i> Arterial blood gas alterations: pH above 7.45, PaCO₂ below 35 mm Hg (4.7 kPa), HCO₃⁻ level normal if short lived or uncompensated or below 21 mEq/L (21 mmol/L) if compensated</p>
Metabolic Acidosis—Excessive Metabolic Acids	
<p>Increase of Metabolic Acids (High Anion Gap): Ketoacidosis (diabetes, starvation, alcoholism) Hypermetabolic state (severe hyperthyroidism, burns, severe infection) Oliguric renal disease (acute kidney injury, end-stage renal disease) Circulatory shock (lactic acidosis) Ingestion of acid or acid precursors (e.g., methanol, ethylene glycol, boric acid)</p> <p>Loss of Bicarbonate (Normal Anion Gap): Diarrhea Pancreatic fistula or intestinal decompression Renal tubular acidosis</p>	<p><i>Physical examination:</i> Decreased level of consciousness (lethargy, confusion, coma), abdominal pain, dysrhythmias, increased rate and depth of respirations (compensatory hyperventilation)</p> <p><i>Laboratory findings:</i> Arterial blood gas alterations: pH below 7.35, PaCO₂ normal if uncompensated or below 35 mm Hg (4.7 kPa) if compensated, HCO₃⁻ level below 21 mEq/L (21 mmol/L)</p>
Metabolic Alkalosis—Deficient Metabolic Acids	
<p>Increase of Bicarbonate: Excessive administration of sodium bicarbonate Massive blood transfusion (liver converts citrate to HCO₃⁻) Mild or moderate ECV deficit (contraction alkalosis)</p> <p>Loss of Metabolic Acid: Excessive vomiting or gastric suctioning Hypokalemia Excess aldosterone</p>	<p><i>Physical examination:</i> Light-headedness, numbness and tingling of fingers, toes, and circumoral region; muscle cramps; possible excitement and confusion followed by decreased level of consciousness, dysrhythmias (may be caused by concurrent hypokalemia)</p> <p><i>Laboratory findings:</i> Arterial blood gas alterations: pH above 7.45, PaCO₂ normal if uncompensated or above 45 mm Hg (6.0 kPa) if compensated, HCO₃⁻ above 28 mEq/L (28 mmol/L)</p>

COPD, Chronic obstructive pulmonary disease, ECV, extracellular fluid volume.

Data from Felver L: Acid-base homeostasis and imbalances. In Banasik JL, Copstead LC, editors: *Pathophysiology*, ed 6, St Louis, 2019, Saunders.

Respiratory Alkalosis

Respiratory alkalosis arises from alveolar hyperventilation; the lungs excrete too much carbonic acid (CO_2 and water). The PaCO_2 falls, creating a deficit of carbonic acid in the blood, which increases pH (see [Table 42.7](#)). Respiratory alkalosis usually is short lived; thus the kidneys do not have time to compensate. When the pH of blood, CSF, and ICF increases acutely, cell membrane excitability also increases, which can cause neurological symptoms such as excitement, confusion, and paresthesia. If the pH rises high enough, central nervous system (CNS) depression can occur.

Metabolic Acidosis

Metabolic acidosis occurs from an increase of metabolic acid or a decrease of base (bicarbonate). The kidneys are unable to excrete enough metabolic acids, which accumulate in the blood, or bicarbonate is removed from the body directly as with diarrhea (see [Table 42.7](#)). In either case the blood HCO_3^- decreases, and the pH falls ([Ferrari et al., 2017](#)). With an increase of metabolic acids, blood HCO_3^- decreases because it is used to buffer metabolic acids. Similarly, when patients have conditions that cause the removal of HCO_3^- , the amount of HCO_3^- in the blood decreases. To help identify the specific cause, health care providers and the laboratory calculate the **anion gap**, a reflection of unmeasured anions in plasma. You calculate anion gap by subtracting the sum of plasma concentrations of the anions Cl^- and HCO_3^- from the plasma concentration of the cation Na^+ ([Kamel and Halperin, 2017](#)). When reviewing laboratory reports, check the reference values from the laboratory that measured the electrolyte concentrations ([Table 42.8](#)).

TABLE 42.8**Anion Gap in Metabolic Acidosis**

Anion Gap Type	Values (Without K ⁺)	Causes
Normal anion gap	6 +/- 4 mEq/L (6 +/- 4 mmol/L) Varies, depending on laboratory	<i>Excess output of bicarbonate:</i> Diarrhea, pancreatic fistula, intestinal decompression, renal tubular acidosis <i>Increase of chloride-containing acid:</i> Parenteral HCl therapy
High anion gap	Greater than 5 mEq/L (5 mmol/L) above the laboratory reference range	<i>Increase of any acid except HCl:</i> Ketoacids (DKA, starvation, alcoholism), lactic acid (circulatory shock, extreme exercise), excessive normal metabolic acids (oliguric acute kidney injury, end-stage renal disease, severe hyperthyroidism, burns, severe infection), unusual organic acids (salicylate overdose, acids metabolized from methanol, ethylene glycol, paraldehyde)

DKA, Diabetic ketoacidosis.

Data from Kamel K, Halperin M: *Fluid, electrolyte, and acid–base physiology*, ed 5, St Louis, 2017, Elsevier.

The abnormally low pH in metabolic acidosis stimulates the chemoreceptors, so the respiratory system compensates for the acidosis by hyperventilation. Compensatory hyperventilation begins in a few minutes and removes carbonic acid from the body. This process does not correct the problem, but it helps limit the pH decrease. Metabolic acidosis decreases a person’s level of consciousness (see [Table 42.7](#)).

Metabolic Alkalosis

Metabolic alkalosis occurs from a direct increase of base HCO_3^- or a decrease of metabolic acid, which increases blood HCO_3^- by releasing it from its buffering function. Common causes include vomiting and gastric suction (see [Table 42.7](#)). The respiratory compensation for metabolic alkalosis is hypoventilation. The decreased rate and depth of respiration allow carbonic acid to increase in the blood, as seen by an increased PaCO_2 . The need for oxygen may limit the degree of respiratory compensation for metabolic alkalosis. Because HCO_3^- crosses the blood-brain barrier with difficulty, neurological signs and symptoms are less severe or even absent with metabolic alkalosis ([Kamel and Halperin, 2017](#)).

REFLECT NOW

Think about the risk for specific fluid, electrolyte, and acid-base imbalance when caring for a patient with chronic diarrhea. What types of imbalances is the patient likely to have?

Nursing Knowledge Base

You will apply knowledge about fluid, electrolyte, and acid-base imbalance in many clinical settings. In addition to scientific knowledge, there is a nursing knowledge base established from research and nursing practice, such as the Infusion Nurses Society standards of practice. Nursing knowledge also includes risk factors for fluid imbalances. For example, incorporate this knowledge along with physiology of normal aging when assessing older adults, knowing that this age-group has high risk of fluid imbalances ([Touhy and Jett, 2016](#)). Your nursing knowledge helps you formulate assessment questions to determine patients' risk factors for fluid, electrolyte, and acid-base imbalance; assess for signs and symptoms of these imbalances; and implement nursing and collaborative interventions to maintain or restore fluid and electrolyte and acid-base balance ([Felver, 2019a,b,c](#)). Skills and techniques for safe IV therapy are a vital area of the nursing knowledge base and the focus of nursing research to support evidence-based practice.

Critical Thinking

Successful critical thinking requires a synthesis of knowledge, experience, information gathered from patients, critical thinking attitudes, and intellectual and professional standards. Clinical judgments require you to anticipate the information necessary to analyze the data and make decisions regarding patient care. During assessment consider all elements that build toward making an appropriate nursing diagnosis ([Fig. 42.9](#)).

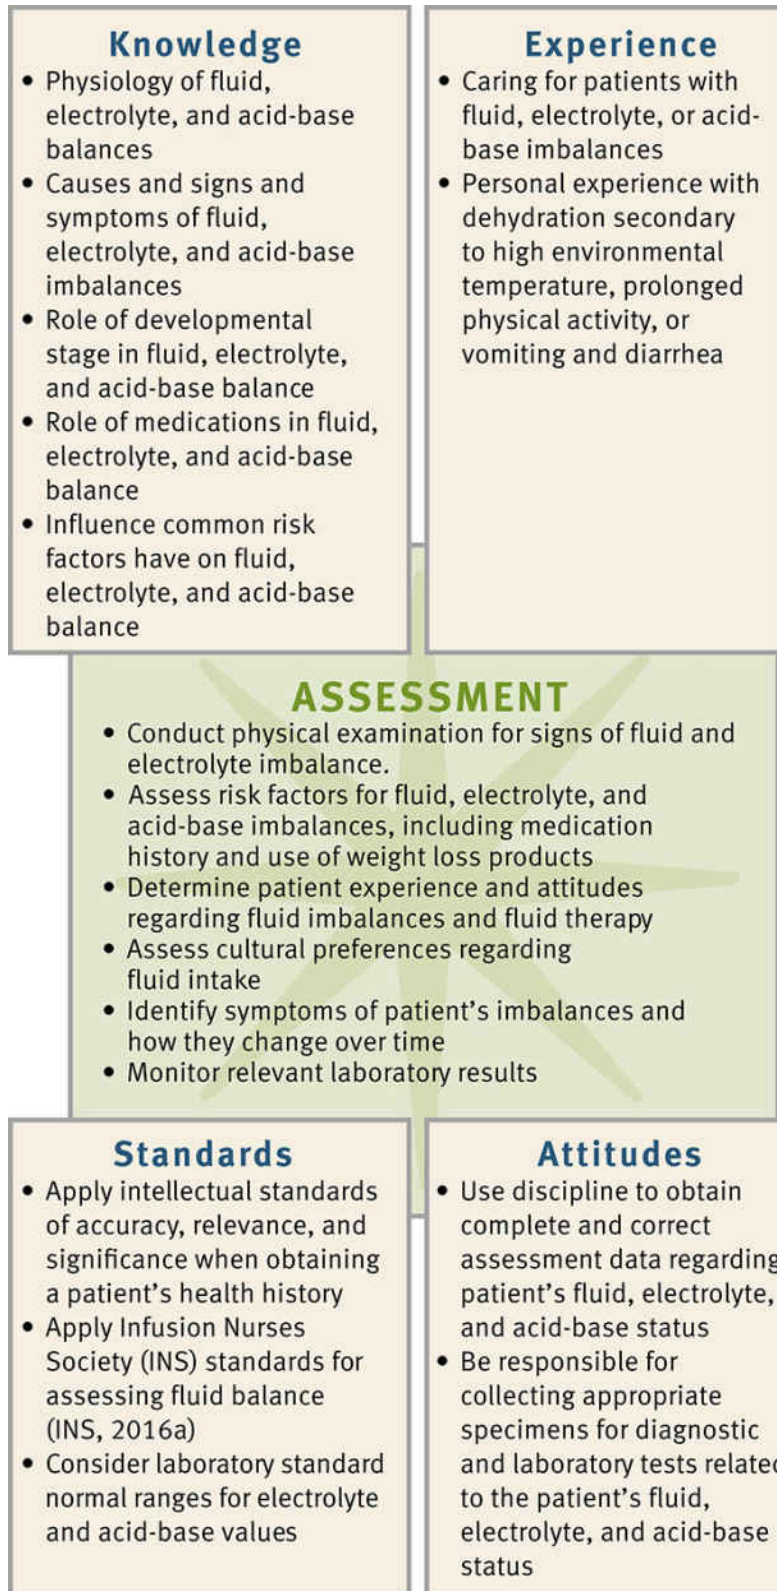

FIG. 42.9 Critical thinking model for fluid, electrolyte, and acid-base balance assessment.

In the case of fluid, electrolyte, and acid-base balance, you integrate knowledge of physiology, pathophysiology, and pharmacology and previous experiences and information gathered from patients. Critical analysis of data enables an understanding of how fluid, electrolyte, and acid-base imbalances affect a specific patient and his or her family. In addition, critical thinking attitudes such as accountability, discipline, and integrity, applied during assessment, help you identify appropriate nursing diagnoses and plan successful interventions. Professional standards such as the Infusion Nurses Society (INS) standards of practice (INS, 2016a) provide valuable guidance for appropriate assessment.

REFLECT NOW

You are preparing to care for a patient with dehydration. What scientific concepts and standards will guide you in obtaining accurate assessment data regarding a patient's fluid, electrolyte, and acid-base status?

◆ Nursing Process

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care. For patients at high risk for fluid, electrolyte, and/or acid-base imbalances or those who already have these imbalances, an individualized approach is the foundation for safe and effective patient-centered nursing care.

◆ Assessment

During the assessment process thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care. Using a systematic approach in assessment enables you to help patients maintain or restore fluid, electrolyte, and acid-base balances safely (see [Fig. 42.9](#)).

Through the Patient's Eyes

A patient's fluid, electrolyte, or acid-base imbalance is sometimes so severe that it is difficult to determine a patient's needs, values, and preferences. However, when a patient is alert enough to discuss care, be sure to conduct a thorough patient-centered assessment. Focus on the patient's experience with fluid, electrolyte, or acid-base alterations and his or her perceptions of the illness. For example, for a patient who is hospitalized for clinical dehydration from diarrhea, ask whether he or she has experienced dehydration previously, and assess his or her interpretation of the signs and symptoms experienced and possible causes. Did the patient require IV therapy in the past? If so, what was that like? Also ask how the person managed diarrhea at home to assess an understanding of how to prevent the imbalances from occurring in the future. Assess potential barriers to rehydration, such as concerns regarding IV therapy. Ask about the patient's greatest concerns regarding fluid status to build the basis for active partnership in planning, implementing, and evaluating patient-centered care.

Nursing History

Clinical assessment begins with a patient history designed to reveal risk factors that cause or contribute to fluid, electrolyte, and acid-base

imbalances (Table 42.9). Ask specific, focused questions to identify factors that contribute to a patient’s potential imbalances (Box 42.1).

TABLE 42.9

Risk Factors for Fluid, Electrolyte, and Acid-Base Imbalances

Age	<i>Very young</i> :ECV deficit, osmolality imbalances, clinical dehydration <i>Very old</i> :ECV excess or deficit, osmolality imbalances
Environment	<i>Sodium-rich diet</i> :ECV excess <i>Electrolyte-poor diet</i> :Electrolyte deficits <i>Hot weather</i> :Clinical dehydration
Gastrointestinal output	<i>Diarrhea</i> :ECV deficit, clinical dehydration, hypokalemia, hypocalcemia (if chronic), hypomagnesemia (if chronic), metabolic acidosis <i>Drainage (e.g., nasogastric suctioning, fistulas)</i> :ECV deficit, hypokalemia; metabolic acidosis if intestinal or pancreatic drainage <i>Vomiting</i> :ECV deficit, clinical dehydration, hypokalemia, hypomagnesemia, metabolic alkalosis
Chronic diseases	<i>Cancer</i> :Hypercalcemia; with tumor lysis syndrome: hyperkalemia, hypocalcemia, hyperphosphatemia; other imbalances, depending on side effects of therapy <i>Chronic obstructive pulmonary disease</i> :Respiratory acidosis <i>Cirrhosis</i> :ECV excess, hypokalemia <i>Heart failure</i> :ECV excess; other imbalances, depending on therapy <i>Oliguric renal disease</i> :ECV excess, hyperkalemia, hypermagnesemia, hyperphosphatemia, metabolic acidosis
Trauma	<i>Burns</i> :ECV deficit, metabolic acidosis <i>Crush injuries</i> : Hyperkalemia <i>Head injuries</i> :Hyponatremia or hypernatremia, depending on ADH response <i>Hemorrhage</i> :ECV deficit, hyperkalemia if circulatory shock
Therapies	<i>Diuretics and other medications</i> (seeBox 42.3) <i>IV therapy</i> :ECV excess, osmolality imbalances, electrolyte excesses <i>PN</i> :Any fluid or electrolyte imbalance, depending on components of solution

ADH, Antidiuretic hormone;ECV,extracellular fluid volume;IV,intravenous;PN,parenteral nutrition.

Box 42.1 Nursing Assessment Questions

Environment

- Do you work or exercise in a hot environment?
- If so, which type of fluid do you drink during that time?

Dietary Intake

- About how many glasses of fluids do you usually drink every day? Which type of fluids do you normally drink?
- Tell me what you usually eat in a day.
- In the past month, was there any day when you went hungry because you did not have enough money for food?
- Which snacks do you usually eat?
- Are you on a special diet because of a medical problem? How does that work for you?
- Are you following any weight-loss program?
- Do you use a salt substitute?
- Do you take calcium, magnesium, or potassium supplements? If so, how often?
- Do you have any difficulties chewing or swallowing?

Lifestyle

- How much alcohol do you drink in a typical week?

Gastrointestinal Output

- Have you had recent vomiting or diarrhea? If so, for how long? How many times per day?

Medications and Other Therapies

- Which medicines/herbal remedies do you use regularly? Occasionally?
- Do you take diuretics? Drugs for high blood pressure?
- Do you use antacids? If so, which ones? How often? Do you ever use baking soda as an antacid? Do you use fizzy (effervescent) medications for colds?
- Do you use laxatives? If so, how often? Which type of stool do you get when you use them?
- What do you use for an upset stomach?

Signs and Symptoms

- If you weigh yourself every day, how has your weight changed over the past few days?
- Do you get light-headed when you stand up?
- Do you feel thirsty, have a dry mouth, or notice a lack of tears?
- Have you noticed a change in your urine output: decreased volume, dark color, or concentrated appearance?
- Are you experiencing swelling of your fingers, feet, or ankles?
- Do you have difficulty breathing when you lie down at night?
- Are you having difficulty concentrating, or do you feel confused? What is normal for you?
- Are you having more difficulty than usual standing up from a sofa or soft chair? Do your legs feel unusually heavy when you climb stairs? Do you have muscle weakness that is unusual for you?
- Have you noticed any muscle cramps or unusual sensations such as numbness or tingling fingers?

Age

First assess a patient's age. An infant's proportion of total body water (70% to 80% total body weight) is greater than that of children or adults. Infants and young children have greater water needs and immature kidneys (Hockenberry et al., 2019; Kear, 2017). They are at greater risk for ECV deficit and hypernatremia because body water loss is proportionately greater per kilogram of weight (Box 42.2).

Box 42.2 Focus on Older Adults Factors Affecting Fluid, Electrolyte, and Acid-Base Balance

- During aging, body composition changes, causing a decreased percentage of body weight as water (50%), which increases risk of extracellular fluid volume (ECV) deficit and dehydration (Felver, 2019d).
- The combined effects of age (neonates, infants, and older adults), chronic diseases, and multiple medications often pose challenges to

maintaining fluid and electrolyte balance.

- Patients with impaired mobility or bladder control issues may restrict fluid intake, which increases the risk of hypernatremia and ECV deficit.
- Decreased thirst sensation increases risk of hypernatremia and dehydration; do not rely on thirst to assess hypernatremia, ECV deficit, or dehydration in patients who are confused, patients with altered level of consciousness, the very young, and older adults.
- Severe dehydration can result in postural hypotension; have patients, especially older adults, arise slowly when you take orthostatic blood pressure measurements.
- Cardiovascular illnesses can decrease the body's ability to adapt to a sudden increase in vascular volume, increasing risk of pulmonary edema with rapid infusion of isotonic intravenous fluids.
- Chronic renal disease results in a decrease in the kidneys' ability to concentrate urine, thus increasing the risk for hypernatremia, ECV deficit, and dehydration.
- Kidney changes of normal aging make it more difficult to excrete a large acid load, increasing the risk of metabolic acidosis (Touhy and Jett, 2016).

Children who are between the ages of 2 and 12 frequently respond to illnesses with fevers of higher temperatures and longer duration than those of adults (Hockenberry et al., 2019). At any age fever increases the rate of insensible water loss. Adolescents have increased metabolism and water production because of their rapid growth changes. Fluctuations in fluid balance are greater in adolescent girls because of hormonal changes associated with the menstrual cycle.

Older adults experience a number of age-related changes that potentially affect fluid, electrolyte, and acid-base balances (see [Box 42.2](#)). They often have more difficulty recovering from imbalances resulting from the combined effects of normal aging, various disease conditions, and multiple medications (Kear, 2017).

Environment

Hot environments increase fluid output through sweating. Sweat is a hypotonic sodium-containing fluid. Excessive sweating without adequate replacement of salt and water can lead to ECV deficit, hypernatremia, or clinical dehydration (McDermott et al., 2017). Ask patients about their

normal level of physical work and whether they engage in vigorous exercise in hot environments. Do the patients have fluid replacements containing salt available during exercise and activity?

Dietary Intake

Assess dietary intake of fluids; salt; and foods rich in potassium, calcium, and magnesium (see [Table 42.4](#)). Ask patients if they follow weight-loss diets. Starvation diets or those with high fat and no carbohydrate content often lead to metabolic acidosis (see [Table 42.7](#)). In addition, assess a patient's ability to chew and swallow, which, if altered, interferes with adequate intake of electrolyte-rich foods and fluids.

Lifestyle

Assess your patient's alcohol intake. How many days does a person have an alcoholic drink each week, and how many drinks does he or she have at any one time? Chronic alcohol abuse commonly causes hypomagnesemia, in part because it increases renal magnesium excretion ([Palmer and Clegg, 2017](#)).

Medications

Obtain a complete list of your patient's current medications, including over-the-counter (OTC) and herbal preparations, to assess the risk for fluid, electrolyte, and acid-base imbalances ([Box 42.3](#)). Use a drug reference book or reputable online database to check the potential effects of other medications. Ask specifically about the use of baking soda as an antacid, which can cause ECV excess because of its high sodium content that holds water in the extracellular compartments. For an individual who uses laxatives, ask about the type of laxative, the frequency of use, and the consistency and frequency of stools. Multiple loose stools remove fluid and electrolytes from the body, thus causing numerous imbalances.

Box 42.3 Commonly Used Medications That Cause Fluid, Electrolyte, and Acid-Base Imbalances

ACE, Angiotensin-converting enzyme; ECV, extracellular fluid

volume;SSRI,selective serotonin reuptake inhibitor.

- ACE inhibitors (e.g., captopril) and angiotensin II receptor blockers (e.g., losartan):Hyperkalemia
- Antidepressants, SSRI (e.g., fluoxetine [Prozac]):Hyponatremia
- Calcium carbonate antacids:Hypercalcemia, mild metabolic alkalosis
- Corticosteroids (e.g., prednisone):Hypokalemia, metabolic alkalosis
- Diuretics, potassium-wasting (e.g., furosemide [Lasix], thiazides):ECV deficit, hyponatremia (thiazides), hypokalemia, hypomagnesemia, mild metabolic alkalosis
- Diuretics, potassium-sparing (e.g., spironolactone):Hyperkalemia, mild metabolic acidosis
- Effervescent (fizzy) antacids and cold medications (high Na⁺ content):ECV excess
- Laxatives:ECV deficit, hypokalemia, hypocalcemia, hypomagnesemia, metabolic acidosis
- Magnesium hydroxide (e.g., Milk of Magnesia):Hypermagnesemia
- Nonsteroidal antiinflammatory drugs (e.g., ibuprofen):Mild ECV excess, hyponatremia
- Penicillins, high-dose (e.g., carbenicillin):Hypokalemia, metabolic alkalosis; hyperkalemia with penicillin G (contains K⁺)

Data from Burchum JR, Rosenthal LD:*Lehne's pharmacology for nursing care*, ed 10, St Louis, 2019, Elsevier.

Medical History

Recent Surgery

Surgery causes a physiological stress response, which increases with extensive surgery and blood loss. In the first 24 to 48 hours after surgery, increased secretion of aldosterone, glucocorticoids, and ADH cause increased ECV, decreased osmolality, and increased potassium excretion (Lewis et al., 2017). In otherwise healthy patients these imbalances resolve without difficulty, but patients who have preexisting illnesses or additional risk factors often need treatment during this period.

Gastrointestinal Output

Increased output of fluid through the GI tract is a common and important cause of fluid, electrolyte, and acid-base imbalances that requires careful assessment. Vomiting and diarrhea, either acute or chronic, can cause ECV deficit, hypernatremia, clinical dehydration, and hypokalemia by increasing the output of fluid, Na^+ , and K^+ . In addition, chronic diarrhea can cause hypocalcemia and hypomagnesemia by decreasing electrolyte absorption. Removal of gastric acid from the body through vomiting or nasogastric suction can cause metabolic alkalosis. In contrast, removal of the bicarbonate-rich intestinal or pancreatic fluids through diarrhea, intestinal suction, or fistula can cause metabolic acidosis (Ferrari et al., 2017).

Acute Illness or Trauma

Acute conditions that place patients at high risk for fluid, electrolyte, and acid-base alterations include respiratory diseases, burns, trauma, GI alterations, and acute oliguric renal disease.

Respiratory Disorders

Many acute respiratory disorders predispose patients to respiratory acidosis. For example, bacterial pneumonia causes alveoli to fill with exudate that impairs gas exchange, causing the patient to retain carbon dioxide, which leads to increased PaCO_2 and respiratory acidosis.

Burns

Burns place patients at high risk for ECV deficit from numerous mechanisms, including plasma-to-interstitial fluid shift and increased evaporative and exudate output. Fluid loss increases with the percentage of body surface burned (Lewis et al., 2017). Patients with burns have cellular damage that releases potassium into the blood, and they may become hyperkalemic. In addition, these patients often develop metabolic acidosis because of greatly increased cellular metabolism, which produces more metabolic acids than their kidneys are able to excrete.

Trauma

Hemorrhage from any type of trauma causes ECV deficit from blood loss. Some types of trauma create additional risks. For example, crush injuries destroy cellular structure, causing hyperkalemia by massive release of intracellular K^+ into the blood.

Head injury typically alters ADH secretion. It may cause diabetes insipidus (deficit of ADH), in which patients excrete large volumes of very dilute urine and develop hypernatremia. In contrast, head injury may cause the syndrome of inappropriate antidiuretic hormone (SIADH), in which excess secretion of ADH causes hyponatremia by retaining too much water and concentrating the urine ([Lewis et al., 2017](#)).

Chronic Illness

Many chronic diseases create ongoing risk of fluid, electrolyte, and acid-base imbalances. For example, type B chronic obstructive pulmonary disease (COPD) often causes chronic respiratory acidosis. In addition, the treatment regimens for chronic disease often cause imbalances. Assess patients for the presence of these conditions (see [Box 42.2](#)).

Cancer

The specific fluid and electrolyte imbalances that occur with cancer depend on the type and progression of the cancer and the treatment regimen. Many patients with cancer develop hypercalcemia when their cancer cells secrete chemicals that circulate to bones and cause calcium to enter the blood. Other fluid and electrolyte imbalances occur in cancer because some types of tumors cause metabolic and endocrine abnormalities ([Wagner and Arora, 2017](#)). In addition, patients with cancer are at risk for fluid and electrolyte imbalances as a result of the side effects (e.g., anorexia, diarrhea) of chemotherapy, biological response modifiers, or radiation ([Lewis et al., 2017](#)).

Heart Failure

Patients who have chronic heart failure have diminished cardiac output, which reduces kidney perfusion and activates the RAAS. The action of aldosterone on the kidneys causes ECV excess and risk of hypokalemia. Most diuretics used to treat heart failure increase the risk of hypokalemia while reducing the ECV excess. Dietary sodium restriction is important with heart failure because Na^+ holds water in the ECF, making the ECV excess worse. In severe heart failure a restriction of both fluid and sodium may be prescribed to decrease the workload of the heart by reducing excess circulating fluid volume ([Lewis et al., 2017](#)).

Oliguric Renal Disease

Oliguria occurs when the kidneys have a reduced capacity to make urine. Some conditions such as acute nephritis cause sudden onset of oliguria, whereas other problems such as chronic kidney disease lead to chronic oliguria. Oliguric renal disease prevents normal excretion of fluid, electrolytes, and metabolic acids, resulting in ECV excess, hyperkalemia, hypermagnesemia, hyperphosphatemia, and metabolic acidosis. The severity of these imbalances is proportional to the degree of renal failure. Although chronic kidney disease is progressive, successful management of imbalances is possible with dietary restriction of sodium and other electrolytes, fluid restriction in severe cases, and eventually dialysis or renal transplant (Lewis et al., 2017).

Physical Assessment

Data gathered through a focused physical assessment validates and extends the information collected in the patient history. [Table 42.10](#) summarizes focused assessments for patients with fluid, electrolyte, and acid-base imbalances. Focus your assessment on the areas pertinent to each patient situation. For example, for patients at risk of fluid imbalances, focus your assessment on body weight changes, clinical markers of vascular and interstitial volume, thirst, behavioral changes, and level of consciousness. Additional focused assessments for patients at high risk of electrolyte and acid-base imbalances include specific cardiac, respiratory, neuromuscular, and GI markers. Grouping your assessments under these categories helps you know which assessments to prioritize and enables you to assess effectively.

TABLE 42.10

Focused Nursing Assessments for Patients with Fluid, Electrolyte, and Acid-Base Imbalances

Assessment	Imbalances
Body Weight Changes from Previous Day	
Loss of 2.2 lb (1 kg) or more in 24 hours for adults	ECV deficit
Gain of 2.2 lb (1 kg) or more in 24 hours for adults	ECV excess
Clinical Markers of Vascular Volume	
<i>Blood pressure:</i>	
Hypotension or orthostatic hypotension	ECV deficit
Light-headedness on sitting upright or standing	ECV deficit
<i>Pulse rate and character:</i>	
Rapid, thready	ECV deficit
Bounding	ECV excess
<i>Fullness of neck veins:</i>	
Flat or collapsing with inhalation when supine	ECV deficit
Full or distended when upright or semi-upright	ECV excess
<i>Other assessments of vascular volume:</i>	
Capillary refill: Sluggish	ECV deficit
Lung auscultation, dependent lobe: Crackles or rhonchi with progressive dyspnea	ECV excess
Urine output: Small volume of dark yellow urine	ECV deficit
Clinical Markers of Interstitial Volume	
<i>Inspection and Palpation</i>	
<i>Presence of edema:</i> Present in dependent areas (ankles or sacrum) and possibly fingers or around eyes	ECV excess
<i>Mucous membranes:</i> Dry between cheek and gum, decreased or absent tearing	ECV deficit
<i>Skin turgor:</i> Pinched skin fails to return to normal position within 3 seconds	ECV deficit
<i>Presence of thirst:</i> Thirst present	Hypnatremia, severe ECV deficit
<i>Behavior and level of consciousness</i>	
Restlessness and mild confusion	Severe ECV deficit
Decreased level of consciousness (lethargy, confusion, coma)	Hyponatremia, hypnatremia, hypercalcemia, acid-base imbalances
Cardiac and Respiratory Signs of Electrolyte or Acid-Base Imbalances	
<i>Pulse rhythm and ECG:</i> Irregular pulse and ECG changes	K ⁺ , Ca ²⁺ , Mg ²⁺ , and/or acid-base imbalances
<i>Rate and depth of respirations:</i>	
Increased rate and depth	Metabolic acidosis (compensatory mechanism); respiratory alkalosis (cause)
Decreased rate and depth	Metabolic alkalosis (compensatory mechanism); respiratory acidosis (cause)
Neuromuscular Markers of Electrolyte or Acid-Base Imbalances	
<i>Muscle strength bilaterally, especially quadriceps muscles:</i>	
Muscle weakness	Hypokalemia, hyperkalemia
<i>Reflexes and sensations:</i>	
Decreased deep tendon reflexes	Hypercalcemia, hypermagnesemia
Hyperactive reflexes, muscle twitching and cramps, tetany	Hypocalcemia, hypomagnesemia
Numbness, tingling in fingertips, around mouth	Hypocalcemia, hypomagnesemia, respiratory alkalosis
Muscle cramps, tetany	Hypocalcemia, hypomagnesemia, respiratory alkalosis
Tremors	Hypomagnesemia
Gastrointestinal Signs of Electrolyte Imbalances	
<i>Inspection and auscultation:</i>	
Abdominal distention	Hypokalemia, third-spacing of fluid
Decreased bowel sounds	Hypokalemia
<i>Motility:</i> Constipation	Hypokalemia, hypercalcemia

ECG, Electrocardiogram; ECV, extracellular fluid volume.

Daily Weights and Fluid Intake and Output Measurement

Daily weights are an important indicator of fluid status (Felver, 2019c). Each kilogram (2.2 lb) of weight gained or lost overnight is equal to 1 L of fluid retained or lost. These fluid gains or losses indicate changes in the amount of total body fluid, usually ECF, but do not indicate shift between body compartments. Weigh patients with heart failure and those who are at high risk for or actually have ECV excess daily. Daily weights are also useful for patients with clinical dehydration or other causes or risks for ECV deficit. Weigh the patient at the same time each day with the same scale after a patient voids. Calibrate the scale each day or routinely. The patient needs to wear the same clothes or clothes that weigh the same; if using a bed scale, use the same number of sheets on the scale with each weighing. Compare the weight of each day with that of the previous day to determine fluid gains or losses. Look at the weights over several days to recognize trends. Interpretation of daily weights guides medical therapy and nursing care.

Teach patients with heart failure to take and record their daily weights at home and to contact their health care provider if their weight increases suddenly by a set amount (obtain parameters from their health care providers). Recognizing trends in daily weights taken at home is important (Park et al., 2017). Patients who are hospitalized for decompensated heart failure often experience steady increases in daily weights during the week before hospitalization.

Measuring and recording all liquid intake and output (I&O) during a 24-hour period is an important aspect of fluid balance assessment. Compare a patient's 24-hour intake with his or her 24-hour output. The two measures should be approximately equal if the person has normal fluid balance (Felver, 2019c). To interpret situations in which I&O are substantially different, consider the individual patient. For example, if intake is substantially greater than output, there are two possibilities: the patient may be gaining excessive fluid or returning to normal fluid status by replacing fluid lost previously from the body. Similarly, if intake is substantially smaller than output, there are also two possibilities: the patient may be losing needed fluid from the body and developing ECV deficit and/or hypernatremia or returning to normal fluid status by excreting excessive fluid gained previously.

In most health care settings I&O measurement is a nursing assessment. Some agencies require a health care provider's order for I&O. If you want to measure I&O for a patient with compromised fluid status, check your

agency policies to determine whether you can set it up or if you need a health care provider's order.

Fluid intake includes all liquids that a person eats (e.g., gelatin, ice cream, soup), drinks (e.g., water, coffee, juice), or receives through nasogastric or jejunostomy feeding tubes (see [Chapter 45](#)). IV fluids (continuous infusions and intermittent IV piggybacks) and blood components also are sources of intake. Water swallowed while taking pills and liquid medications counts as intake. A patient receiving tube feedings often receives numerous liquid medications, and water is used to flush the tube before and/or after medications. Over a 24-hour period these liquids amount to significant intake and always are recorded on the I&O record. Ask patients who are alert and oriented to help with measuring their oral intake and explain to families why they should not drink or eat from the patient's meal trays or water pitcher.

Fluid output includes urine, diarrhea, vomitus, gastric suction, and drainage from postsurgical wounds or other tubes (see [Chapter 50](#)). Record a patient's urinary output after each voiding. Instruct patients who are alert, oriented, and ambulatory to save their urine in a urinal or a calibrated insert, which attaches to the rim of the toilet bowl ([Fig. 42.10](#)). Teach patients and families the purpose of I&O measurements. Also teach them to notify the nurse or assistive personnel (AP) to empty any container with voided fluid or how to measure and empty the container themselves and report the result appropriately. Patients need to have good vision and motor skills to perform these measurements. Active involvement of patient and family is an aspect of patient-centered care that is essential to maintaining accurate I&O measurements. When a patient has an indwelling urinary catheter, drainage tube, or suction, record output (e.g., at the end of each nursing shift or every hour) as the patient's condition requires.

FIG. 42.10 Containers for measuring urine output.

You can delegate parts of I&O measurement and recording to AP with competent skills in measurement. Actual measurement of fluid volumes is more accurate than visual estimates. In many institutions AP record oral intake but not intake through feeding or IV tubes, which are nursing responsibilities. Similarly AP often record urine, diarrhea, and vomitus output but not drainage through tubes. The responsible registered nurse (RN) or licensed practical nurse/licensed vocational nurse (LPN/LVN) and the AP work as a team to record measurements in the designated location in the electronic health record (EHR), often on a flow sheet with other information. The EHR program usually calculates the 24-hour totals. If an EHR is not used, record I&O on paper forms attached to the bedside chart or room door. You or the AP calculates the 24-hour totals (see agency policy). Accurate I&O facilitates ongoing evaluation of a patient's hydration status.

Laboratory Values

Review the patient's laboratory test results and compare them with the normal ranges to obtain further objective data about fluid, electrolyte, and acid-base balances. Normal and abnormal test results are summarized in Tables 42.1, 42.3, and 42.5 to 42.7. The frequency of electrolyte level

measurements depends on the severity of a patient's illness. Analyzing a patient's laboratory results requires you to be thorough and to apply extensive scientific and nursing knowledge, especially if a person develops an acute imbalance while also having a chronic disease. Serum electrolyte tests usually are performed routinely on patients entering a hospital to screen for imbalances and serve as a baseline for future comparisons.

REFLECT NOW

How would your assessments related to fluid, electrolyte, and acid-base imbalances differ between patients with acute illness and patients with chronic illnesses?

• Nursing Diagnosis

When caring for patients with suspected fluid, electrolyte, and acid-base imbalances, it is particularly important to use critical thinking to formulate nursing diagnoses. The assessment data that establish the risk for or the actual presence of a nursing diagnosis in these areas may be subtle, and patterns and trends emerge only when there has been astute assessment. Multiple body systems often are involved; careful clustering of assessment findings leads to selection of the appropriate diagnoses ([Box 42.4](#)).

Box 42.4 Nursing Diagnostic Process Dehydration Related to Loss of Gastrointestinal Fluids via Vomiting

Assessment Activities	Assessment Findings
Assess postural blood pressure and pulse.	Patient has postural hypotension with increased heart rate; pulse is weak.
Inspect oral mucous membranes for degree of moisture.	Oral mucous membranes between cheek and gum are dry.
Obtain daily weight measurements.	Adult patient loses 2.2 lb (1 kg) or more in 24 hours.
Measure urine output and observe color; if available, measure specific gravity of urine.	Patient produces small volume of dark yellow urine; urine specific gravity is increased.
Test skin turgor (not reliable for older adults).	Decreased skin turgor noted.

In addition to the accurate clustering of assessment data, an important part of formulating nursing diagnoses is identifying the relevant causative or related factor (when a diagnosis is negative or problem focused) or risk factors (when a diagnosis is a risk diagnosis). You choose interventions that treat or modify the related factor or risk for the diagnosis to be resolved. For example, *Dehydration related to loss of GI fluids from vomiting* requires therapies that manage the patients' emesis and restore fluid volume with IV therapy. In contrast, the diagnosis of *Fluid Imbalance related to elevated body temperature* requires therapies to lower the patient's body temperature and replace lost body fluids through oral fluid replacement or possibly IV therapy. Possible nursing diagnoses for patients with fluid, electrolyte, and acid-base alterations include the following:

- *Fluid Imbalance*
- *Dehydration*
- *Electrolyte Imbalance*
- *Acid Base Imbalance*
- *Lack of Knowledge of Fluid Regimen*

• Planning

During the planning process use critical thinking to synthesize information from multiple resources (Fig. 42.11). Ensure that a patient's plan of care integrates both scientific and nursing knowledge and all of the information that you collected about the individual patient.

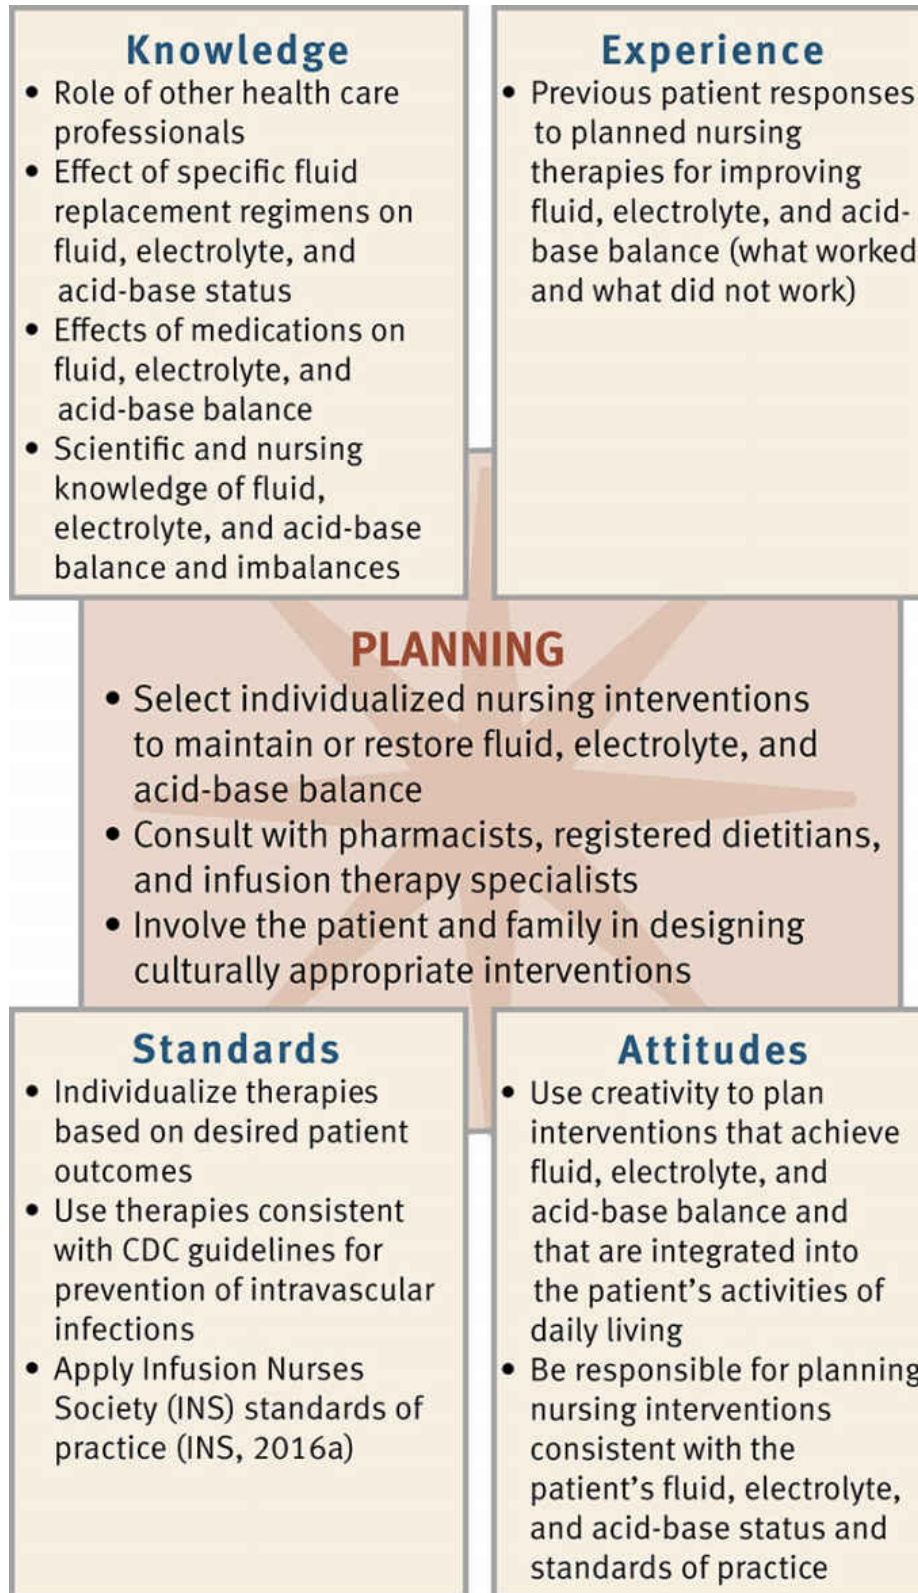

FIG. 42.11 Critical thinking model for fluid, electrolyte, and acid-base balance planning. CDC, Centers for Disease Control and Prevention.

Goals and Outcomes

Establish an individual patient plan of care for each nursing diagnosis (see the [Nursing Care Plan](#)) that includes mutually established patient goals for each diagnosis. Collaborate with and inform patients as you individualize goals with realistic, measurable outcomes. For example, with a nursing diagnosis of *Dehydration*, the following related outcomes might be established for the goal “The patient achieves normal hydration status at discharge”:

- The patient is free of complications associated with the IV device throughout the duration of IV therapy.
- The patient demonstrates balanced I&O measurements within 48 hours.

Setting Priorities

The patient’s clinical condition determines which of the nursing diagnoses takes the greatest priority. Many nursing diagnoses in the area of fluid, electrolyte, and acid-base balances are of highest priority because the consequences for the patient can be serious or even life threatening. For example, in the concept map ([Fig. 42.12](#)) for Mrs. Mendoza, the occurrence of vomiting and diarrhea created a high-priority nursing diagnosis of *Dehydration*. The priority for Mrs. Mendoza is to restore her fluid balance. To achieve this priority, her vomiting and diarrhea must be controlled and resolved, and her fluid volume replaced. If these goals are unmet, Mrs. Mendoza’s fluid imbalance is likely to worsen.

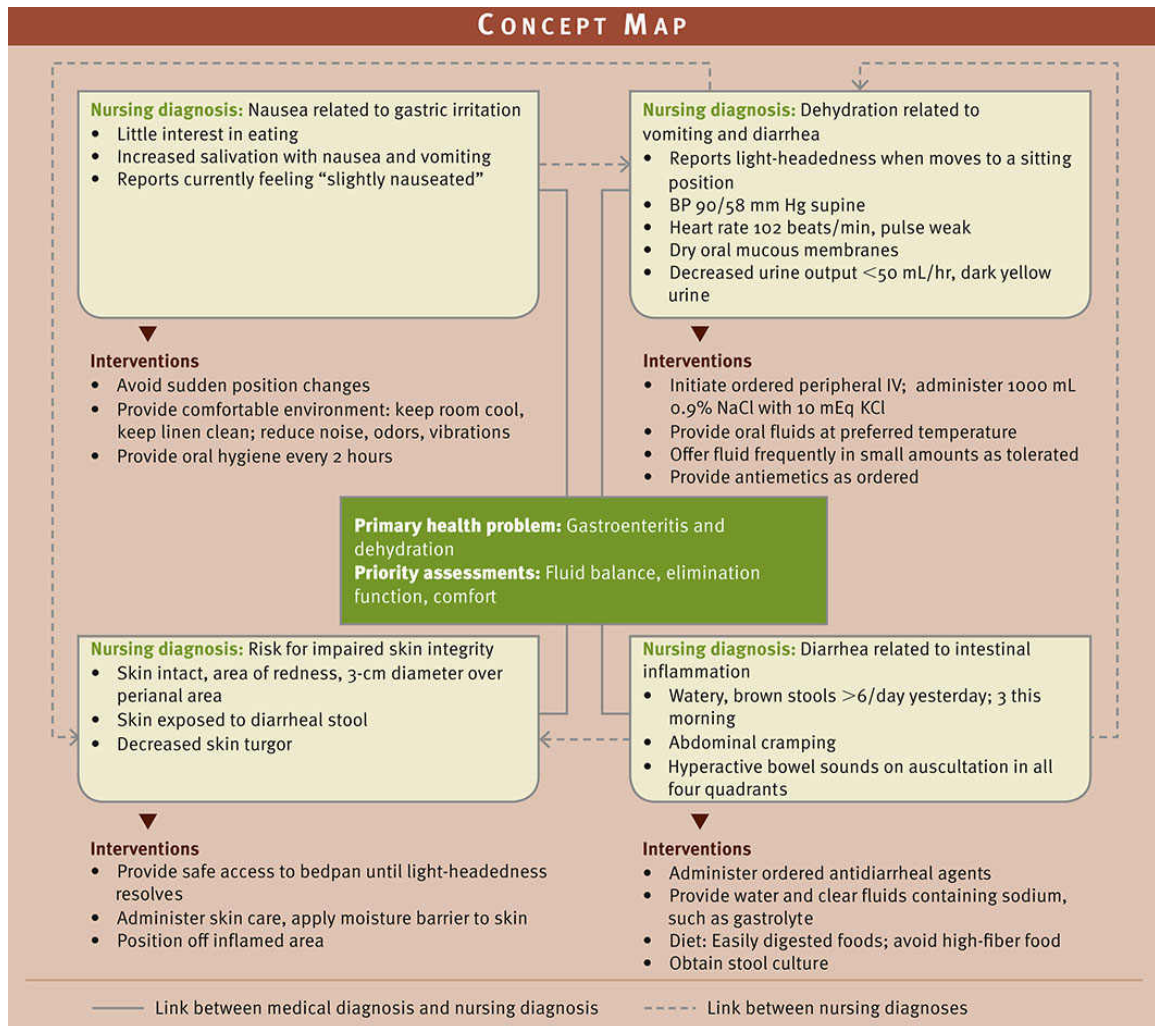

FIG. 42.12 Concept map for Mrs. Mendoza.

Teamwork and Collaboration

Consultation with a patient's health care provider helps to set realistic time frames for the goals of care, particularly when a patient's physiological status is unstable. Ongoing communication and consultation are important because the patient's condition can change quickly. Collaboration with the patient and family and other members of the interprofessional health care team such as IV therapists and pharmacists helps in achieving patient outcomes. Patients and family members are very helpful in identifying approaches for successful therapies such as ways to increase fluid intake. Incorporate patient preferences and resources into the plan of care. Do not delegate administration of IV fluid and hemodynamic assessment to AP. When the patient is stable, you can delegate daily weights, I&O, and direct physical care to AP (INS, 2016a).

Begin discharge planning early for patients with acute or chronic fluid and electrolyte disturbances by anticipating the needs of the patient and family as they transition to another setting. In the hospital collaboration with other members of the health care team ensures that care will continue in the home or long-term care setting with few disruptions. You ensure that therapeutic regimens established in one setting continue through completion at the next setting. For example, for a patient who is discharged on IV therapy, you assess the knowledge and skills of the family member or friend who will assume caregiving responsibilities and initiate a referral to home IV therapy as soon as possible. Close collaboration with members of the health care team such as the patient's health care provider, registered dietitian, and pharmacist is essential to ensure positive patient outcomes. A registered dietitian is a valuable resource in recommending food sources to increase or reduce intake of specific electrolytes, incorporating the patient's preferences when possible (see [Chapter 45](#)). A pharmacist helps identify medications or combinations of medications likely to cause electrolyte or acid-base disturbances and offers information regarding patient education

Nursing Care Plan

Dehydration

Assessment

Mrs. Mendoza, age 77, fell at home after having vomiting and diarrhea for 24 hours. She was admitted to the hospital for oral and intravenous (IV) fluid therapy after x-rays indicated no broken bones. Mrs. Mendoza lives alone in an apartment and has no chronic illnesses except osteoarthritis of her hands.

Assessment Activities	Assessment Findings ^a
Ask Mrs. Mendoza to describe when her vomiting and diarrhea began and any accompanying signs and symptoms.	Gastrointestinal (GI) problems began suddenly yesterday. Reports getting weak and light-headed when she stands or sits upright.
Ask her about current status of vomiting and diarrhea.	Says she was vomiting earlier this morning but not in the past 3 hours. Had three episodes of watery diarrhea this morning and more than six yesterday.
Assess Mrs. Mendoza's vital signs.	Heart rate 110 beats/min; regular, weak pulse ; supine blood pressure (BP) 90/58 mm Hg. Temperature and respirations within normal limits. Postural BP measurement omitted for patient safety.
Evaluate physical signs of extracellular fluid volume (ECV).	Neck veins flat when supine; 100 mL of dark yellow urine in past 4 hours; dry mucous membranes between cheek and gum; prolonged capillary refill time of 5 seconds.
Weigh Mrs. Mendoza using a bed scale.	Weight 120 lb (54.5 kg). States usual weight at home is 127 lb (46.27 kg) (7-lb [3.17-kg] weight loss).

^a Assessment findings are shown in bold type.

Nursing Diagnosis

Dehydration related to prolonged vomiting and diarrhea

Planning

Goals	Expected Outcomes (NOC) ^b
Fluid Balance	
Mrs. Mendoza's fluid volume will return to normal by hospital discharge.	Denies light-headedness when sitting or standing within 24 hours. Daily output of light yellow urine equals intake of at least 1500 mL by discharge.

^b Outcome classification labels from Moorhead S, et al: *Nursing Outcomes Classification (NOC)*, ed 6, St Louis, 2018, Elsevier.

Interventions ^c (Nic)	Rationale
Fluid/Electrolyte Management	
Provide Mrs. Mendoza's favorite fluids at her preferred temperature.	Patient-centered care takes individual preferences into account; types and temperature of oral fluids can influence oral intake (Giger, 2017; Rong et al., 2017).
Provide pitcher and glass of water at Mrs. Mendoza's preferred temperature at her bedside; ensure that she can access and pour from it easily; provide straw if she wishes.	Chronic disease such as osteoarthritis of hands may make it difficult to manipulate a full water pitcher. Make fluid available in form that is easy for patient to access (Felver, 2019c).
Administer IV therapy as prescribed, monitoring closely for early side effects of complications.	IV fluid replacement augments oral replacement when ECV deficit exists. Age-appropriate care is needed because of older adult's anatomical and physiological changes that affect volume delivery (INS, 2016a).

^c Intervention classification labels from Butcher HK, et al.: *Nursing Interventions Classification (NIC)*, ed 7, St Louis, 2018, Elsevier.

Evaluation

Evaluation Activity	Patient Response/Finding	Outcome Status
<p>Monitor vital signs, intake and output (I&O), daily weight, and postural BP when no longer light-headed.</p> <p>Assess intake and output and mucous membranes.</p>	<p>T 37° C (98.6° F), RR 10, HR 72 beats/min, BP 120/78 sitting, 122/78 standing, denies light-headedness</p> <p>Intake 2000 mL, output 2000 mL of light yellow urine</p> <p>Today's weight 129 lb (58.5 kg)</p> <p>Mucous membranes moist</p>	<p>Symptoms of fluid volume deficit are resolving.</p> <p>Patient showing resolution of dehydration.</p>

about side effects to anticipate for prescribed drugs. The patient's health care provider directs the treatment of fluid, electrolyte, or acid-base imbalances.

Implementation

Health Promotion

Health promotion activities focus primarily on patient education, which you provide based on a patient's and family's health literacy. Use plain language to teach patients and caregivers to recognize risk factors for developing imbalances and implement appropriate preventive measures. For example, parents of infants need to understand that GI losses quickly lead to serious imbalances; therefore, when vomiting or diarrhea occurs in an infant, they need to promptly rehydrate with sodium-containing fluid or seek health care to restore normal balance. People of any age need to learn to replace body fluid losses with sodium-containing fluid and water.

Patients with chronic health alterations often are at risk for developing fluid, electrolyte, and acid-base imbalances. They need to understand their own risk factors and the measures they need to take to avoid imbalances. For example, patients with end-stage renal disease often need to restrict intake of fluid, sodium, potassium, magnesium, and phosphate (Norton et al., 2017). Through diet education these patients learn the types of foods to avoid and the suitable volume of fluid that they are permitted daily (see Chapter 45). Teach patients with chronic diseases and their family caregivers the early signs and symptoms of the fluid, electrolyte, and acid-base imbalances for which they are at risk and what to do if these occur.

REFLECT NOW

What should you teach an older adult who has frequent diarrhea about how to replace fluids to avoid dehydration?

Acute Care

Although fluid, electrolyte, and/or acid-base imbalances occur in all settings, they are common in acute care. Acute care nurses administer medications and oral and IV fluids to replace fluid and electrolyte deficits or maintain normal homeostasis; they also help with restricting intake as part of therapy for fluid excesses.

Enteral Replacement of Fluids

Oral replacement of fluids and electrolytes is appropriate as long as the patient is not so physiologically unstable that they cannot be replaced rapidly enough (Carson et al., 2017). Oral replacement of fluids is contraindicated when a patient has a mechanical obstruction of the GI tract, severe nausea, is at high risk for aspiration, or has impaired swallowing. Some patients unable to tolerate solid foods are still able to ingest fluids. Strategies to encourage fluid intake include offering frequent small sips of fluid, popsicles, and ice chips. Record one-half the volume of the ice chips in I&O measurement. For example, if a patient ingests 240 mL of ice chips, you record 120 mL of intake. Encourage patients to keep their own record of intake to involve them actively. Family members who are properly instructed can also help. Pay attention to each patient's preferred temperature of oral fluids. Cultural beliefs regarding appropriate fluids and fluid temperature may become a barrier to achieving adequate fluid intake unless the fluid with the preferred temperature is available (Box 42.5).

Box 42.5 Cultural Aspects of CareFluid Therapy

Cultural and religious beliefs influence how you manage fluid therapy and how patients communicate their needs. For example, a family elder

may be the person who receives explanations and makes health care decisions rather than the patient. A person may refuse therapies because of cultural and religious beliefs. For example, hot-cold beliefs cause some patients to refuse cold oral fluids when they have certain illnesses because they believe that hot fluids are needed to restore balance (Giger, 2017). Religious practices may require modifications of intravenous (IV) tubing length (e.g., when patients need to kneel on the floor and pray several times daily).

Implications for Patient-Centered Care

- Establish communication. If appropriate, determine who makes decisions for the patient and explain fluid restriction or IV therapy procedures.
- Elicit patient/family values and preferences in your clinical interview. Ask specifically about preferred temperature of oral fluids and provide (if oral intake is allowed).
- Determine needed length of IV tubing and incorporate one or more segments of long extension tubing into the IV setup if patient kneels on the floor to pray.
- Determine acceptance of or abstinence from therapeutic regimens and respect patient/family choices regarding therapy (Boucher et al., 2017).
- Know patient's beliefs regarding blood therapy. Although some patients refuse whole blood or packed red blood cells because of religious or personal beliefs, they may accept other blood products or alternatives (Tingle, 2017).

When replacing fluids by mouth in a patient with ECV deficit, choose fluids that contain sodium (e.g., Pedialyte and Gastrolyte). Liquids that contain lactose or have low-sodium content are inappropriate when a patient has diarrhea.

A feeding tube is appropriate when a patient's GI tract is healthy, but he or she cannot ingest fluids (e.g., after oral surgery or with impaired swallowing). Options for administering fluids include gastrostomy or jejunostomy instillations or infusions through small-bore nasogastric feeding tubes (see [Chapter 45](#)).

Restriction of Fluids

Patients who have hyponatremia usually require restricted water intake. Patients who have very severe ECV excess sometimes have both sodium and fluid restrictions. Fluid restriction often is difficult for patients, particularly if they take medications that dry the oral mucous membranes or if they are mouth breathers. Explain the reason that fluids are restricted. Make sure that the patient, family, and visitors know the amount of fluid permitted orally and understand that ice chips, gelatin, and ice cream are fluids. Help the patient decide the amount of fluid to drink with each meal, between meals, before bed, and with medications. It is important to allow patients to choose preferred fluids unless contraindicated. Frequently patients on fluid restriction can swallow a number of pills with as little as 1 oz (30 mL) of liquid.

In acute care settings fluid restrictions usually allot half the total oral fluids between 7AM and 3PM (i.e., the period when patients are more active, receive two meals, and take most of their oral medications). Offer the remainder of the fluids during the evening and night shifts. Patients on fluid restriction need frequent mouth care to moisten mucous membranes, decrease the chance of mucosal drying and cracking, and maintain comfort (see [Chapter 40](#)).

Parenteral Replacement of Fluids and Electrolytes

Fluid and electrolytes may be replaced through infusion of fluids directly into veins (intravenously) rather than via the digestive system. Parenteral replacement includes parenteral nutrition (PN), IV fluid and electrolyte therapy (**crystalloids**), and blood and blood component (colloids) administration. IV devices are called *peripheral IVs* when the catheter tip lies in a vein in one of the extremities; they are called *central venous catheters (CVCs)* or *IVs* when the catheter tip lies in the central circulatory system (e.g., in the vena cava close to the right atrium of the heart) ([Fig. 42.13](#)).

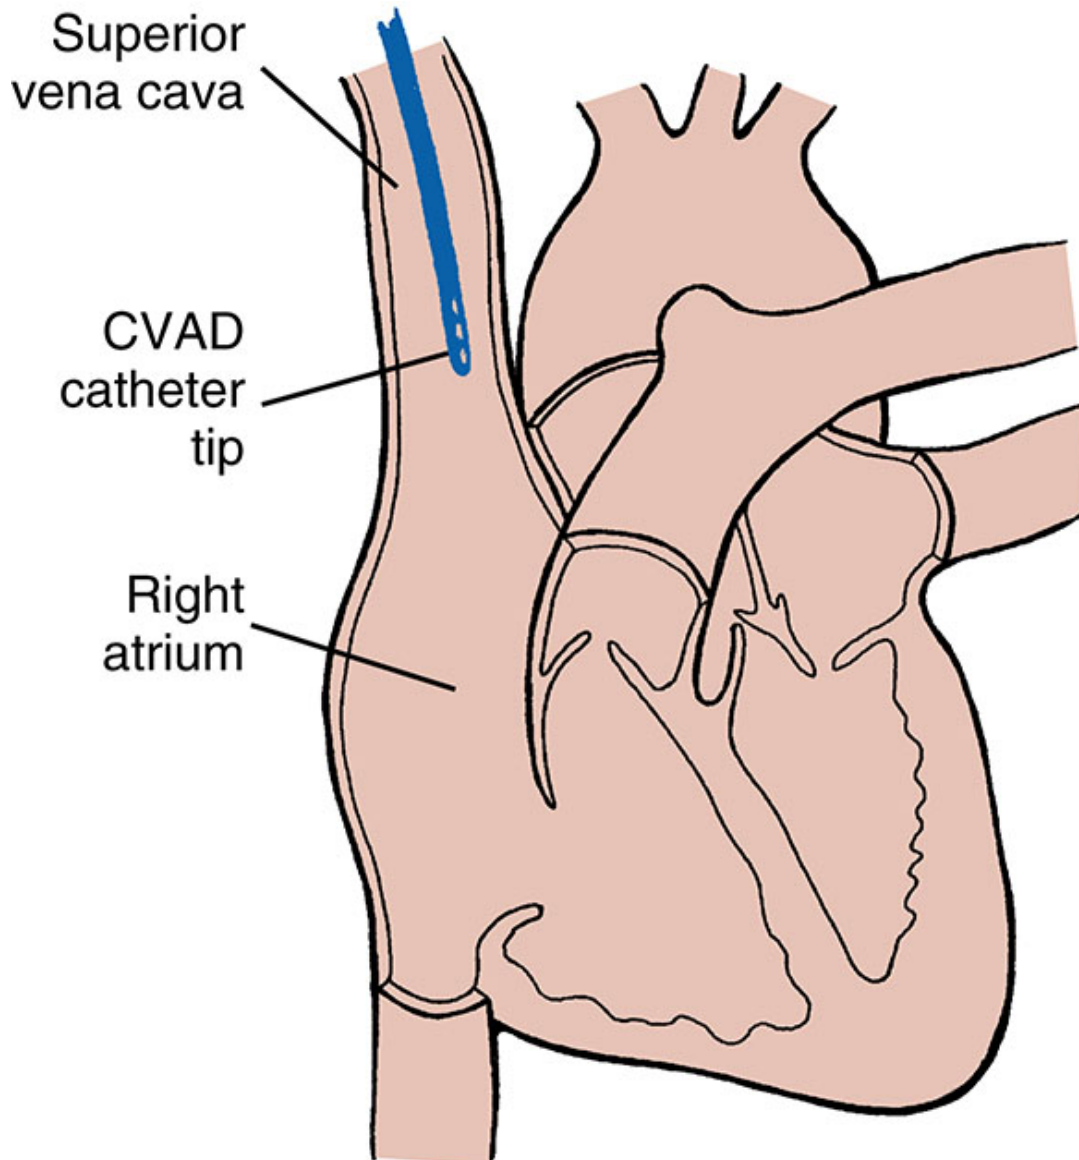

FIG. 42.13 Central venous lines deliver intravenous fluid into superior vena cava near heart. CVAD, Central venous access device.

Practice standard body fluid precautions when preparing and administering parenteral fluids (see [Chapter 28](#)) to minimize your own risk for exposure to bloodborne pathogens. Read and understand the policy and procedures for parenteral infusions at the agency for which you work.

Parenteral Nutrition

Parenteral nutrition (PN), also called *total PN (TPN)*, is IV administration of a complex, highly concentrated solution containing nutrients and electrolytes that is formulated to meet a patient's needs. Depending on their osmolality, PN solutions are administered through a CVC in cases of

high osmolality or through a peripheral intravenous (IV) line for lower osmolality solutions. Safe administration depends on appropriate assessment of nutrition needs, meticulous management of the CVC or IV to prevent infection, and careful monitoring to prevent metabolic complications. [Chapter 45](#) reviews principles and guidelines for PN administration, which is used when patients are unable to receive enough nutrition orally or through enteral feeding.

Intravenous Therapy (Crystalloids)

The goal of IV fluid administration is to correct or prevent fluid and electrolyte disturbances. It allows for direct access to the vascular system, permitting the continuous infusion of fluids over a period of time. IV therapy requires a health care provider's order for type, amount, and speed of administration of a solution. You regulate IV fluid therapy continuously because of ongoing changes in a patient's fluid and electrolyte balance. To provide safe and appropriate therapy to patients who require IV fluids, you need knowledge of the correct ordered solution, the reason the solution was ordered, the equipment needed, the procedures required to initiate an infusion, how to regulate the infusion rate and maintain the system, how to identify and correct problems, and how to discontinue the infusion.

Types of Solutions

Many prepared IV solutions are available for use ([Table 42.11](#)). An IV solution is isotonic, hypotonic, or hypertonic. Isotonic solutions have the same effective osmolality as body fluids. Sodium-containing isotonic solutions such as normal saline are indicated for ECV replacement to prevent or treat ECV deficit. Hypotonic solutions have an effective osmolality less than body fluids, thus decreasing osmolality by diluting body fluids and moving water into cells. Hypertonic solutions have an effective osmolality greater than body fluids. If they are hypertonic sodium-containing solutions, they increase osmolality rapidly and pull water out of cells, causing them to shrivel ([Hall, 2016](#)). The decision to use a hypotonic or hypertonic solution is made on the basis of a patient's specific fluid and electrolyte imbalance. For example, a patient with hypernatremia that cannot be treated with oral water generally receives a hypotonic IV solution to dilute the ECF and rehydrate cells. Too-rapid or excessive infusion of any IV fluid has the potential to cause serious patient problems.

TABLE 42.11**Intravenous Solutions**

Solution	Concentration in IV Container and at Tip of VAD	Effective Concentration in Body	Comments
Dextrose (Glucose) in Water Solutions			
Dextrose 5% in water (D ₅ W)	Isotonic	Hypotonic	Isotonic when first enters vein; dextrose enters cells rapidly, leaving free water, which dilutes ECF; most of the water then enters cells by osmosis.
Dextrose 10% in water (D ₁₀ W)	Hypertonic	Hypotonic	Hypertonic when first enters vein; dextrose enters cells rapidly, leaving free water, which dilutes ECF; most of the water then enters cells by osmosis.
Saline (Sodium Chloride [NaCl] in Water) Solutions			
0.225% NaCl (quarter NS; ¼NS)	Hypotonic	Hypotonic	Expands ECV (vascular and interstitial) and rehydrates cells.
0.45% NaCl (half NS; ½NS)	Hypotonic	Hypotonic	Expands ECV (vascular and interstitial) and rehydrates cells.
0.9% NaCl (NS)	Isotonic	Isotonic	Expands ECV (vascular and interstitial); does not enter cells.
3% or 5% NaCl (hypertonic saline; 3% or 5% NaCl)	Hypertonic	Hypertonic	Draws water from cells into ECF by osmosis.
Dextrose in Saline Solutions			
Dextrose 5% in 0.45% NaCl (½NS; D ₅ 0.45% NaCl)	Hypertonic	Hypotonic	Dextrose enters cells rapidly, leaving 0.45% NaCl.
Dextrose 5% in 0.9% NaCl (D ₅ NS; D ₅ 0.9% NaCl)	Hypertonic	Isotonic	Dextrose enters cells rapidly, leaving 0.9% NaCl.
Multiple Electrolyte Solutions			
Lactated Ringer's (LR) solution	Isotonic	Isotonic	LR contains Na ⁺ , K ⁺ , Ca ²⁺ , Cl ⁻ , and lactate, which liver metabolizes to HCO ₃ ⁻ ; expands ECV (vascular and interstitial); does not enter cells.
Dextrose 5% in LR (D ₅ LR)	Hypertonic	Isotonic	Dextrose enters cells rapidly, leaving LR.

ECF, Extracellular fluid; *ECV*, extracellular fluid volume; *NS*, normal saline; *VAD*, vascular access device.

Additives such as potassium chloride (KCl) are common in IV solutions (e.g., 1000 mL D₅½ NS with 20 mEq KCl at 125 mL/hr). Administer KCl carefully because hyperkalemia can cause fatal cardiac dysrhythmias. **Under no circumstances should KCl be administered by IV push (directly through a port in IV tubing).** Verify that a patient has adequate kidney function and urine output before administering an IV solution containing potassium. Patients with normal renal function who are receiving nothing by mouth should have potassium added to IV solutions. The body cannot conserve potassium, and the kidneys continue to excrete it even when the plasma level falls. Without potassium intake, hypokalemia develops quickly.

Vascular Access Devices

Vascular access devices (VADs) are catheters or infusion ports designed for repeated access to the vascular system. Peripheral catheters are for short-term use (e.g., fluid restoration after surgery and short-term

antibiotic administration). Devices for long-term use include central catheters and implanted ports, which empty into a central vein. Remember that the term *central* applies to the location of the catheter tip, not to the insertion site. Peripherally inserted central catheters (PICC lines) enter a peripheral arm vein and extend through the venous system to the superior vena cava, where they terminate. Other central lines enter a central vein such as the subclavian or jugular vein or are tunneled through subcutaneous tissue before entering a central vein. Central lines are more effective than peripheral catheters for administering large volumes of fluid, PN, and medications or fluids that irritate veins. Proper care of central line insertion sites is critical for the prevention of central line–associated bloodstream infection (CLABSI) (Box 42.6) (CDC, 2017; INS, 2016a). Nurses and health care providers must have specialized education regarding care of CVCs and implanted infusion ports (TJC, 2018). Nursing responsibilities for central lines include careful monitoring, flushing to keep the line patent, and site care and dressing changes to prevent CLABSIs (INS, 2016a).

Box 42.6 Evidence-Based Practice Preventing Central Line–Associated Bloodstream Infections (CLABSI)

PICOT Question: In patients who are hospitalized, do bundled interventions compared with routine central line site care alone prevent central line–associated bloodstream infection (CLABSI)?

Evidence Summary

CLABSI is a serious complication of intravenous (IV) therapy that increases morbidity, hospital length of stay, and health care costs. Research shows that effective strategies for prevention of CLABSI include the use of several evidence-based practices together as a multicomponent “bundle” (Biasucci et al., 2018). Such bundles are effective in reducing CLABSIs at the time of insertion of central lines and also during their maintenance (Biasucci et al., 2018). The Infusion Nursing Standards of Practice (INS, 2016a) and the Centers for Disease Control and Prevention (CDC, 2017) specify a central line bundle: hand hygiene; maximum sterile barrier precautions; chlorhexidine skin antisepsis using chlorhexidine (>0.5%) in alcohol; avoidance of the femoral vein for central venous access for adults; and placement under planned controlled conditions. For the most effective reduction of CLABSIs, The Joint Commission (2018) requires

ongoing staff education to promote consistent adherence to bundle components and attention to institutional support and culture in addition to the use of bundled central line insertion and maintenance practices (Hawes and Lee, 2018; Grover, 2015). Units with a higher proportion of Critical Care Registered Nurse (CCRN) certifications have been shown to have lower rates of CLABSI (Boev et al., 2015).

Application to Nursing Practice

- Verify and use all of the components of the CLABSI prevention bundle (Biasucci et al., 2018; Hawes and Lee, 2018).
- Work with a practice or infection control committee to perform an audit of adherence to CLABSI prevention practices in your unit (INS, 2016a; CDC, 2017).
- If your agency does not have a multidisciplinary CLABSI prevention program, collaborate with infection control personnel and medical and nursing administration to establish one that includes institutional support for education, competency demonstration, use of insertion and maintenance bundles, and daily line audits with feedback to nurses (TJC, 2018; INS, 2016a).

Equipment

Correct selection and preparation of IV equipment helps in safe and rapid placement of an IV line. Because fluids infuse directly into the bloodstream, sterile technique is necessary. Organize all equipment at the bedside for an efficient insertion. IV equipment includes VADs; tourniquet; clean gloves; dressings; IV fluid containers; various types of tubing; and electronic infusion devices (EIDs), also called *infusion pumps*. VADs that are short peripheral IV catheters are available in a variety of gauges, such as the commonly used 20 and 22 gauges. A larger gauge indicates a smaller-diameter catheter. A peripheral VAD is called an over-the-needle catheter; it consists of a small plastic tube or catheter threaded over a sharp stylet (needle). Once you insert a stylet and advance the catheter into the vein, you withdraw the stylet, leaving the catheter in place. These devices have a safety mechanism that covers the sharp stylet when withdrawing it to reduce the risk of needlestick injury (Fig. 42.14). Needleless systems allow you to make connections without using needles, which reduces needlestick injuries.

FIG. 42.14 Over-the-needle catheter for venipuncture.

The main IV fluid used in a continuous infusion flows through tubing called the *primary line*. The primary line connects to the IV catheter. Injectable medications such as antibiotics are usually added to a small IV solution bag and “piggybacked” as a secondary set into the primary line or as a primary intermittent infusion to be administered over a 30- to 60-minute period (Thoele et al., 2018). The type and amount of solution are prescribed by the patient’s health care provider and depend on the medication added and the patient’s physiological status. If an IV infusion is connected to an EID, use the tubing designated for that EID. For gravity-flow IVs (not using an EID), select tubing as described in the equipment list of Skill 42.1. Add IV extension tubing to increase the length of the primary line, which reduces pulling of the tubing and increases a patient’s mobility when changing positions.

Inserting the Intravenous Line

After you collect the equipment at the patient’s bedside, prepare to insert the IV line by assessing the patient for a venipuncture site (see Skill 42.1). The most common IV sites are on the inner arm (Fig. 42.15). Do not use hand veins on older adults or patients who are ambulatory. IV insertion in

a foot vein is common with children but avoid these sites in adults because of the increased risk of thrombophlebitis (INS, 2016a).

FIG. 42.15 Cephalic, basilic, and median cubital veins are best for IV placement in adults.

As you assess a patient for potential venipuncture sites, consider conditions that exclude certain sites. Venipuncture is contraindicated in a site that has signs of infection, infiltration, or thrombosis. An infected site is red, tender, swollen, and possibly warm to the touch. Exudate may be present. Do not use an infected site because of the danger of introducing bacteria from the skin surface into the bloodstream. Avoid using an extremity with a vascular (dialysis) graft/fistula or on the same side as a mastectomy. Avoid areas of flexion if possible and choose the most distal appropriate site (INS, 2016a). Using a distal site first allows for the use of proximal sites later if the patient needs a venipuncture site change.

Venipuncture is a technique in which a vein is punctured through the skin by a sharp rigid stylet (e.g., metal needle). The stylet is partially covered either with a plastic catheter or a needle attached to a syringe. General purposes of venipuncture are to collect a blood specimen, start an IV infusion, provide vascular access for later use, instill a medication, or inject a radiopaque or other tracer for special diagnostic examinations. Skill 42.1 describes venipuncture for peripheral IV fluid infusion,

incorporating INS standards of practice (INS, 2016a). It takes practice to become proficient in venipuncture. Only experienced practitioners should perform it for patients whose veins are fragile or collapse easily such as older adults. Box 42.7 describes principles to follow for venipuncture in older adults.

Box 42.7 Focus on Older Adults Protection of Skin and Veins During Intravenous Therapy

- Use the smallest-gauge catheter or needle possible (e.g., 22 to 24 gauge). Veins are very fragile, and a smaller gauge allows better blood flow to provide increased hemodilution of the intravenous (IV) fluids or medications (INS, 2016a).
- Avoid the back of the hand, which may compromise a patient's need for independence and mobility.
- Avoid placement of an IV line in veins that are easily bumped because older adults have less subcutaneous support tissue (Touhy and Jett, 2016).
- Avoid vigorous friction while cleaning a site to prevent tearing fragile skin.
- If a patient has fragile skin and veins, use minimal or no tourniquet pressure (INS, 2016a).
- If using a tourniquet, place it over the patient's sleeve or use a blood pressure cuff.
- With loss of supportive tissue, veins tend to lie more superficially; lower the insertion angle for venipuncture to 10 to 15 degrees after penetrating the skin.
- Veins roll away from the needle easily because of loss of subcutaneous tissue. To stabilize a vein, apply traction to the skin below the projected insertion site.
- Secure IV site with a catheter stabilization device, avoiding excessive use of tape on fragile skin; consider covering the site additionally with surgical stretch mesh.
- Numerous medications and supplements (e.g., anticoagulants, antibiotics, glucocorticoids, and garlic) increase the likelihood of bruising and bleeding (Burchum et al., 2019).

Nurses require specialized knowledge and education to place PICCs. Some central lines and implanted ports require insertion by physicians or advanced practice nurses. Both types of central catheters require close monitoring and maintenance. This chapter focuses on peripheral catheters.

Regulating the Infusion Flow Rate

After initiating a peripheral IV infusion and checking it for patency, regulate the rate of infusion according to the health care provider's orders (see Skill 42.2). For patient safety avoid uncontrolled flow of IV fluid into a patient. You are responsible for calculating the flow rate (mL/hr) that delivers the IV fluid in the prescribed time frame. The correct IV infusion rate ensures patient safety by preventing too-slow or too-rapid administration of IV fluids. An infusion rate that is too slow often leads to further physiological compromise in a patient who is dehydrated, in circulatory shock, or critically ill. An infusion rate that is too rapid overloads the patient with IV fluid, causing fluid and electrolyte imbalances and cardiac complications in vulnerable patients (e.g., older adults or patients with preexisting heart disease).

Electronic infusion devices (EIDs), also called *IV pumps* or *infusion pumps*, deliver an accurate hourly IV infusion rate. EIDs use positive pressure to deliver a measured amount of fluid during a specified unit of time (e.g., 125 mL/hr). Familiarize yourself with the brand of EID in use at your agency so that you are able to set the flow rate accurately. Many EIDs have capabilities that allow for single- and multiple-solution infusions at different rates. Electronic detectors and alarms respond to air in IV lines, occlusion, completion of infusion, high and low pressure, and low battery power.

When you open a roller clamp or other type of clamp on an infusion tubing that is not yet properly inserted in an EID or on a gravity-flow IV system, the IV fluid infuses very rapidly. Nonelectronic volume-control devices are used occasionally with an IV solution infused by gravity to prevent accidental infusion of a large fluid volume. These devices hang between the IV bag and the patient and hold only a small volume of fluid that can infuse into the patient. Regardless of the device in use, monitor the patient regularly to verify correct infusion of IV fluids.

Patency of an IV catheter means that IV fluid flows easily through it. For patency there must be no clots at the tip of the catheter, and the catheter tip must not be against the vein wall. A blocked catheter slows or stops the rate of infusion of the IV fluids. IV flow rate also can be slowed by infiltration, vasospasm, a knot or kink in the tubing, external pressure on

the tubing, and position changes of the patient's extremity. If the flow decreases or stops and the EID is working correctly, inspect the tubing. Sometimes the patient is lying or sitting on it. The tubing may be kinked or caught in or under equipment. Also inspect the area around the insertion site for anything that obstructs the flow of IV fluids. For gravity flow, the height of the container influences flow rate. Raising the container usually increases the rate because of increased driving pressure.

Flexion of an extremity, particularly at the hand and wrist or elbow, can decrease IV flow rate by compressing the vein. Although VAD placement in areas of flexion is discouraged, occasionally it becomes necessary. In that case INS standards specify use of a hand or arm joint stabilization device to protect the IV site by keeping the joint extended (INS, 2016a). Use padding with arm boards because they may cause skin or nerve damage from pressure. Starting an infusion in a new location rather than relying on a site that causes problems may be more comfortable for a patient. Before discontinuing the current infusion, choose another site and start the infusion to verify that the patient has other accessible veins.

Maintaining the System

After placing an IV line and regulating the flow rate, maintain the IV system. Line maintenance involves (1) keeping the system sterile and intact; (2) changing IV fluid containers, tubing, and contaminated site dressings; (3) helping a patient with self-care activities so as not to disrupt the system; and (4) monitoring for complications of IV therapy. The frequency and options for maintaining the system are identified in agency policies.

An important component of patient care is maintaining the integrity of an IV line to prevent infection. Potential sites for contamination of a VAD are shown in Fig. 42.16. Inserting an IV line under appropriate aseptic technique reduces the chances of contamination from a patient's skin. After insertion, prevent infection by the conscientious use of infection control principles such as thorough hand hygiene before and after handling any part of the IV system and maintaining sterility of the system during tubing and fluid container changes.

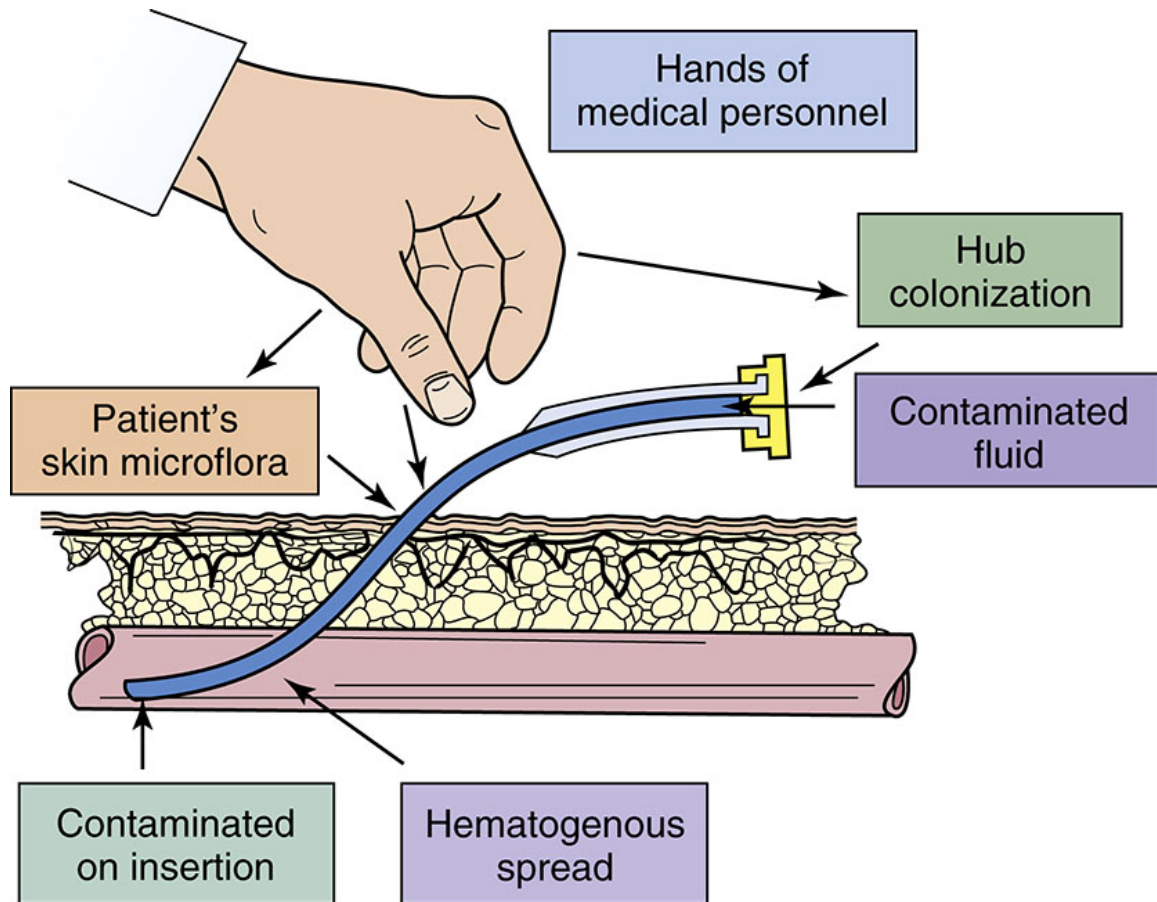

FIG. 42.16 Potential sites for contamination of vascular access device.

Always maintain the integrity of an IV system. Never disconnect tubing because it becomes tangled or it might seem more convenient for positioning or moving a patient or applying a gown. If a patient needs more room to maneuver, use aseptic technique to add extension tubing to an IV line. However, keep the use of extension tubing to a minimum because each connection of tubing provides opportunity for contamination. *Never let IV tubing touch the floor.* Do not use stopcocks for connecting more than one solution to a single IV site because they are sources of contamination (Hadaway, 2018; INS, 2016a). IV tubing contains needless injection ports through which syringes or other adaptors can be inserted for medication administration. Clean an injection port thoroughly with 2% chlorhexidine (preferred), 70% alcohol, or povidone-iodine solution and let it dry before accessing the system (INS, 2016a).

Protective devices designed to prevent movement or accidental dislodgment of a VAD are called *catheter stabilization devices* (Fig. 42.17). These devices are available in many hospitals, and nurses decide whether to use them when starting an IV line. This is a patient safety issue.

Movement of the VAD in a vein can cause phlebitis and infiltration; VAD dislodgment requires using another VAD at a new IV infusion site. INS standards indicate that use of these devices is preferable over taping when feasible (INS, 2016a).

FIG. 42.17 Catheter stabilization device.

Changing Intravenous Fluid Containers, Tubing, and Dressings

Patients receiving IV therapy over several days require periodic changes of IV fluid containers (Skill 42.3). It is important to organize tasks so that you can change containers rapidly before a thrombus forms in a catheter.

Recommended frequency of IV tubing change depends on whether it is used for continuous or intermittent infusion. INS standards (INS, 2016a)

specify that continuous infusion tubing changes occur *no more frequently* than every 96 hours unless the tubing has been compromised or become contaminated, which requires immediate tubing change. In contrast, change tubing for *intermittent* infusion every 24 hours because of the increased risk of contamination from opening the IV system (INS, 2016a). Blood, blood components, and lipids are likely to promote bacterial growth in tubing. INS standards (INS, 2016a) specify tubing changes every 4 hours for blood and blood components and every 24 hours for continuous IV lipids. For lipids use tubing that is free of diethylhexylphthalate (DEHP), a toxin that leaches into lipid solutions (INS, 2016a). Whenever possible, schedule tubing changes when it is time to hang a new IV container to decrease risk of infection. To prevent entry of bacteria into the bloodstream, maintain sterility during tubing and IV fluid container changes (INS, 2016a).

A sterile dressing over an IV site reduces the entrance of bacteria into the insertion site. Transparent dressings, the most common type, help secure the VAD, allow continuous visual inspection of the IV site, and are less easily soiled or moistened than gauze dressings. Leave transparent dressings in place until the IV tubing is replaced (INS, 2016a). If a gauze dressing is used, change it every 48 hours (INS, 2016a). Both types of dressings must be changed when the IV device is removed or replaced or when the dressing becomes damp, loosened, or soiled (INS, 2016a) (see Skill 42.4).

Helping Patients to Protect Intravenous Integrity

To prevent the accidental disruption of an IV system, a patient often needs help with hygiene, comfort measures, meals, and ambulation. Changing gowns is difficult for a patient with an IV in the arm. Teach AP and patients that they must not break the integrity of an IV line to change a gown because it leads to contamination. It helps to use a gown with snaps along the top sleeve seam to facilitate changing the gown without disturbing the venipuncture site. Change regular gowns by following these steps for maximum speed and arm mobility (see also Skill 40.1 for photos):

1. *To remove a gown*, remove the sleeve of the gown from the arm without the IV line, maintaining the patient's privacy.
2. Remove the sleeve of the gown from the arm with the IV line.
3. Remove the IV solution container from its stand and pass it and the tubing through the sleeve. (If this involves removing the tubing

from an EID, use the roller clamp to slow the infusion to prevent the accidental infusion of a large volume of solution or medication).

4. *To apply a gown*, place the IV solution container and tubing through the sleeve of the clean gown and hang it on its stand. (If the IV line is controlled by an EID, reassemble, turn on the pump, and open the roller clamp.)
5. Place the arm with the IV line through the gown sleeve.
6. Place the arm without the IV line through the other gown sleeve.

A patient with an arm or a hand infusion is able to walk unless contraindicated. Offer a rolling IV pole on wheels. Help the patient get out of bed and place the IV pole next to the involved arm. Teach him or her to hold the pole with the involved hand and push it while walking. Check that the IV container is at the proper height, there is no tension on the tubing, and the flow rate is correct. Infusion pumps connect to IV poles and can be used during ambulation because they will function on battery power during the time the patient walks. Instruct the patient to report any blood in the tubing, a stoppage in the flow, or increased discomfort. Once patient returns to a bed or chair, plug in the infusion pump.

Complications of Intravenous Therapy

Carefully assess and monitor your patient's response to IV therapy ([Table 42.12](#)). A severe complication is circulatory overload, which occurs when a patient receives too-rapid administration or an excessive amount of fluids. Assessment findings depend on the type of IV solution that infuses in excess. The signs and symptoms of circulatory overload and other complications often arise rapidly, which highlights the importance of frequent assessment of patients receiving IV therapy.

TABLE 42.12**Complications of Intravenous Therapy with Nursing Interventions**

Complication	Description	Assessment Findings	Nursing Interventions
Circulatory overload of IV solution	IV solution infused too rapidly or in too great an amount	Depends on type of solution ECV excess with Na ⁺ -containing isotonic fluid (crackles in dependent parts of lungs, shortness of breath, dependent edema) Hyponatremia with hypotonic fluid (confusion, seizures) Hypernatremia with Na ⁺ -containing hypertonic fluid (confusion, seizures) Hyperkalemia from K ⁺ -containing fluid (cardiac dysrhythmias, muscle weakness, abdominal distention)	If symptoms appear, reduce IV flow rate and notify patient's health care provider. With ECV excess raise head of bed; administer oxygen and diuretics if ordered. Monitor vital signs and laboratory reports of serum levels. Health care provider may adjust additives in IV solution or type of IV fluid; watch for and implement order.
Infiltration and extravasation	IV fluid entering subcutaneous tissue around venipuncture site Extravasation: technical term used when a vesicant (tissue-damaging) drug (e.g., chemotherapy) enters tissues	Skin around catheter site taut, blanched, cool to touch, edematous; may be painful as infiltration or extravasation increases; infusion may slow or stop	Stop infusion. Discontinue IV infusion if no vesicant drug (see Skill 42.3). If vesicant drug, disconnect IV tubing and aspirate drug from catheter. Agency policy and procedures may require delivery of antidote through catheter before removal. Elevate affected extremity. Avoid applying pressure over site; can force solution into contact with more tissue. Contact health care provider if solution contained KCl, a vasoconstrictor, or other potential vesicant. Apply warm, moist or cold compress according to procedure for type of solution infiltrated. Start new IV line in other extremity. Use standard scale for assessing and documenting infiltration (INS, 2016a).
Phlebitis	Inflammation of inner layer of a vein	Redness, tenderness, pain, warmth along course of vein starting at access site; possible red streak and/or palpable cord along vein	Stop infusion and discontinue IV line (see Skill 42.3). Start new IV line in other extremity or proximal to previous insertion site if continued IV therapy is necessary. Apply warm, moist compress or contact IV therapy team or health care provider if area needs additional treatment. Elevate affected extremity. Document phlebitis using a standardized scale, including nursing interventions per agency policy and procedure.
Local infection	Infection at catheter-skin entry point during infusion or after removal of IV catheter	Redness, heat, swelling at catheter-skin entry point; possible purulent drainage	Culture any drainage (if ordered). Clean skin with alcohol; remove catheter and save for culture; apply sterile dressing. Notify health care provider. Start new IV line in other extremity. Initiate appropriate wound care (see Chapter 48) if needed.
Air embolism	Air in the vein from unpurged syringe or tubing.	Sudden onset of dyspnea, coughing, chest pain, hypotension, tachycardia, decreased level of consciousness, possible signs of stroke	Prevent further air from entering the system by clamping or covering the leak. Place patient on left side, preferably with head of bed raised, to trap air in the lower portion of the left ventricle. Call emergency support team and notify patient's health care provider.
Bleeding at venipuncture site	Oozing or slow, continuous seepage of blood from venipuncture site	Fresh blood evident at venipuncture site, sometimes pooling under extremity	Assess whether IV system is intact. If catheter is within vein, apply pressure dressing over site or change dressing. Start new IV line in other extremity or proximal to previous insertion site if VAD is dislodged, IV is disconnected, or bleeding from site does not stop.

ECV, Extracellular volume; IV, intravenous; VAD, vascular access device.

Building Competency in Safety

A patient who has a peripheral intravenous (IV) infusion wants to wear a special shirt rather than a hospital gown when family members come to celebrate a birthday later today. How can you assist the patient while maintaining patient safety in this situation?

Infiltration occurs when an IV catheter becomes dislodged or a vein ruptures and IV fluids inadvertently enter subcutaneous tissue around the venipuncture site (Major and Huey, 2016). When the IV fluid contains additives that damage tissue, **extravasation** occurs (Matsui et al., 2017). Infiltration and extravasation cause coolness, paleness, and swelling of the area. When infiltration occurs, immediately assess for any additives in the infiltrated fluid to determine the type of action necessary to prevent local tissue damage and sloughing. Vasoconstrictors, high-dose potassium, and other IV additives in subcutaneous tissue need different treatments from those needed for an infiltrated additive-free IV (see Table 42.12). Although the INS does not include an infiltration scale for adults in its 2016 standards, the society does recommend using a scale. Table 42.13 has an infiltration scale, which is commonly used.

TABLE 42.13**Infiltration Scale**

Grade	Clinical Criteria
0	No symptoms
1	Skin blanched Edema <2.54 cm (1 inch) in any direction Cool to touch With or without pain
2	Skin blanched Edema 2.54-15.2 cm (1-6 inches) in any direction Cool to touch With or without pain
3	Skin blanched, translucent Gross edema >15.2 cm (6 inches) in any direction Cool to touch Mild-moderate pain Possible numbness
4	Skin blanched, translucent Skin tight, leaking Skin discolored, bruised, swollen Gross edema >15.2 cm (6 inches) in any direction Deep pitting tissue edema Circulatory impairment Moderate-to-severe pain Infiltration of any amount of blood product, irritant, or vesicant

From Groll D, et al: Evaluation of the psychometric properties of the phlebitis and infiltration scales for the assessment of complications of peripheral vascular access devices, *J Infus Nurs*33(6):385, 2010.

Phlebitis(i.e., inflammation of a vein) results from chemical, mechanical, or bacterial causes. Risk factors for phlebitis include acidic or hypertonic IV solutions; rapid IV rate; IV drugs such as KCl, vancomycin, and penicillin; VAD inserted in area of flexion; poorly secured catheter; poor hand hygiene; and lack of aseptic technique. The typical signs of inflammation (i.e., heat, erythema [redness], tenderness) occur along the course of a vein. [Table 42.14](#) offers a validated scale for assessing severity of phlebitis. When a patient has dark skin, these signs may be less obvious; assess carefully for subtle color changes at the vascular access device site that might indicate phlebitis.

TABLE 42.14**Phlebitis Scale**

Grade	Clinical Criteria
0	No symptoms
1	Erythema at access site with or without pain
2	Pain at access site with erythema and/or edema
3	Pain at access site with erythema and/or edema; streak formation; palpable venous cord
4	Pain at access site with erythema and/or edema; streak formation; palpable venous cord >2.54 cm (1 inch) in length; purulent drainage

From Infusion Nurses Society (INS): Infusion therapy standards of practice. *J Infus Nurs*, 39(1 Suppl):S1, 2016a.

Phlebitis is dangerous because the inflammation of the vein wall can lead to associated blood clots (thrombophlebitis). Clots form along the vein and in some cases cause emboli, which can break off and enter the circulation. This may permanently damage veins. Routine changes of peripheral IV catheters to reduce infection are not recommended (Helton et al., 2016). The INS Standards of Practice (INS, 2016a) recommend avoiding routine replacement of peripheral IV catheters in infants and children and replacement of a peripheral IV catheter in adults only if clinically indicated. The standards provide these guidelines for how frequently to assess a peripheral VAD site to see if its replacement is clinically indicated:

- At least every 4 hours for alert, oriented adults who are able to report problems at the VAD site and are not receiving vesicant (tissue-damaging) infusions
- At least every 1 to 2 hours for adults who are critically ill or sedated or who are cognitively impaired
- At least every hour for neonates and children
- Several times per hour during infusions of vesicants or vasoconstrictors
- During every home or outpatient visit

In the absence of phlebitis, local infection at the venipuncture site is usually caused by poor aseptic technique during catheter insertion, daily monitoring, or catheter removal. Early recognition of local infection and

treatment is important to prevent bacteria from entering the bloodstream (see [Table 42.12](#)). Bloodstream infections may arise from short peripheral IV catheter sites.

Air embolism occurs when air is present inside syringes, IV tubing is not primed with fluid, or connectors are not removed before use and cause air to enter a patient's vein. It also can occur if the VAD is not clamped before changing the tubing or if the IV tubing is punctured inadvertently ([INS, 2016a](#); [Mattox, 2017](#)).

Bleeding can occur around the venipuncture site during the infusion or through the catheter or tubing if these become disconnected inadvertently (see [Table 42.12](#)). Bleeding is more common in patients who receive heparin or other anticoagulants or who have a bleeding disorder (e.g., hemophilia or thrombocytopenia).

Discontinuing Peripheral Intravenous Access

Discontinue IV access after infusion of the prescribed amount of fluid; when infiltration, phlebitis, or local infection occurs; or if the IV infusion slows or stops, indicating the catheter has developed a thrombus at its tip. Skill 42.3 presents the steps for discontinuing peripheral IV access. Help patients and families understand that moving from IV infusion to oral fluid intake is a sign of progress toward recovery.

Blood Transfusion

Blood transfusion, or blood component therapy, is the IV administration of whole blood or a blood component such as packed red blood cells (RBCs), platelets, or plasma. Objectives for administering blood transfusions include (1) increasing circulating blood volume after surgery, trauma, or hemorrhage; (2) increasing the number of RBCs and maintaining hemoglobin levels in patients with severe anemia; and (3) providing selected cellular components as replacement therapy (e.g., clotting factors, platelets, albumin).

Caring for patients receiving blood or blood-product transfusion is a nursing responsibility. You must be thorough in patient assessment, checking the blood product against prescriber's orders, checking it against patient identifiers, and monitoring for any adverse reactions. Blood transfusions are never regarded as routine; overlooking any minor detail can have dangerous and life-threatening events for a patient ([AABB, 2017, 2018](#)).

Blood Groups and Types

Blood transfusions must be matched to each patient to avoid incompatibility. RBCs have antigens in their membranes; the plasma contains antibodies against specific RBC antigens. If incompatible blood is transfused (i.e., a patient's RBC antigens differ from those transfused), the patient's antibodies trigger RBC destruction in a potentially dangerous **transfusion reaction** (i.e., an immune response to the transfused blood components).

The most important grouping for transfusion purposes is the ABO system, which identifies A, B, O, and AB blood types. Determination of blood type is made on the basis of the presence or absence of A and B RBC antigens. Individuals with type A blood have A antigens on their RBCs and anti-B antibodies in their plasma. Individuals with type B blood have B antigens on their RBCs and anti-A antibodies in their plasma. A person who has type AB blood has both A and B antigens on the RBCs and no antibodies against either antigen in the plasma. A type O individual has neither A nor B antigens on RBCs but has both anti-A and anti-B antibodies in the plasma ([Alexander et al., 2014](#)). [Table 42.15](#) shows the compatibilities between blood types of donors and recipients. People with type O-negative blood are considered universal blood donors because they can donate packed RBCs and platelets to people with any ABO blood type. People with type AB-positive blood are called *universal blood recipients* because they can receive packed RBCs and platelets of any ABO type.

TABLE 42.15**ABO Compatibilities for Transfusion Therapy**

Component	Compatibilities	
Whole blood	Give type-specific blood only	
Packed red cells (stored, washed, or frozen/washed)	Donor	Recipient
	O	O, A, B, AB
	A	A, AB
	B	B, AB
	AB	AB
Fresh-frozen plasma	Donor	Recipient
	O	O
	A	A, O
	B	B, O
	AB	AB, B, A, O
Platelets	RBC: ABO and Rh compatible <i>preferred</i>	
	Donor	Recipient
	O	O, A, B, AB
	A	A, AB
	B	B, AB
AB	AB	

ABO, Blood group consisting of groups A, AB, B, and O.

Data from Alexander M et al: *Core curriculum for infusion nursing*, ed 4, Philadelphia, 2014, Lippincott, Williams & Wilkins.

Another consideration when matching blood components for transfusions is the Rh factor, which refers to another antigen in RBC membranes. Most people have this antigen and are Rh positive; a person without it is Rh negative. People who are Rh negative receive only Rh-negative blood components.

Autologous Transfusion

Autologous transfusion (autotransfusion) is the collection and reinfusion of a patient's own blood. Blood for an autologous transfusion most commonly is obtained by preoperative donation up to 6 weeks before a scheduled surgery (e.g., heart, orthopedic, plastic, or gynecological). A patient can donate several units of blood, depending on the type of surgery and his or her ability to maintain an acceptable hematocrit. Blood for autologous transfusion is also obtained at the time of surgery or through blood salvage (e.g., during surgery for liver transplantation, trauma, or vascular and orthopedic conditions). After surgery blood is salvaged from drainage from chest tubes or joint cavities. Autologous

transfusions are safer for patients because they decrease the risk of mismatched blood and exposure to bloodborne infectious agents (Alexander et al., 2014).

Transfusing Blood

Transfusion of blood or blood components is a nursing procedure that requires an order from a health care provider. Patient safety is a nursing priority, and patient assessment, verification of the health care provider's order, and verification of correct blood products for the correct patient are imperative (AABB, 2017, 2018).

Perform a thorough patient assessment before initiating a transfusion, and monitor carefully during and after the transfusion. Assessment is critical because of the risk of transfusion reactions. Pretransfusion assessment includes establishing whether a patient knows the reason for the blood transfusion and whether he or she has ever had a previous transfusion or transfusion reaction. A patient who has had a transfusion reaction is usually at no greater risk for a reaction with a subsequent transfusion. However, he or she may be anxious about the transfusion, requiring nursing intervention. Before beginning a transfusion, explain the procedure and instruct the patient (if alert) to report any side effects (e.g., chills, dizziness, or fever) once the transfusion begins. Have a professional translator available if the patient does not speak English. Ensure that he or she has signed an informed consent. Patients with certain cultural or religious backgrounds may refuse blood transfusions (see Box 42.5).

Because of the danger of transfusion reactions, your pretransfusion assessment always includes the patient's baseline vital signs. These data allow you to identify when vital sign changes occur as a result of a transfusion reaction.

Always follow agency policy and procedures before initiating any blood therapy. For patient safety always verify three things: (1) that blood components delivered are the ones that were ordered, (2) that blood delivered to a patient is compatible with the blood type listed in the medical record, and (3) that the right patient receives the blood. Together two RNs or one RN and an LPN (check agency policy and procedures) must check the label on the blood product against the medical record and the patient's identification number, blood group, and complete name. If even a minor discrepancy exists, do not give the blood; notify the blood bank immediately to prevent infusion errors.

When administering a transfusion, you need an appropriate-size IV catheter and blood administration tubing that has a special in-line filter

([Fig. 42.18](#)). Adults require a large catheter (e.g., 18- or 20-gauge) because blood is more viscous than crystalloid IV fluids. Children with small veins need a smaller catheter. Prime the tubing with 0.9% sodium chloride (normal saline) to prevent hemolysis or breakdown of RBCs. Initiate a transfusion slowly to allow for the early detection of a transfusion reaction. Always have a second IV infusion bag containing 0.9% sodium chloride on standby in case it becomes necessary to stop the blood infusion. Maintain the ordered blood infusion rate, monitor for side effects, assess vital signs, and promptly record all findings. It is important to stay with the patient during the first 15 minutes because this is the time when a reaction is most likely to occur ([DeLisle, 2018](#)). After the initial time period, continue to monitor the patient and obtain vital signs periodically during the transfusion as directed by agency policy. If a transfusion reaction is anticipated or suspected, obtain vital signs more frequently ([Table 42.16](#)).

FIG. 42.18 Filling tubing for blood administration.

TABLE 42.16**Acute Adverse Effects of Transfusions**

Adverse Effect	Cause	Clinical Manifestations	Management	Prevention
Caused by Immune Response to Blood Components				
Acute intravascular hemolytic reaction	Infusion of ABO-incompatible whole blood, RBCs, or components containing 10 mL or more of RBCs Antibodies in recipient's plasma attach to antigens on transfused RBCs, causing RBC destruction	Chills, fever, low back pain, flushing, tachycardia, tachypnea, hypotension, hemoglobinuria, hemoglobinemia, sudden oliguria (acute kidney injury), circulatory shock, cardiac arrest, death	Stop transfusion and save blood bag and administration set for follow-up. Keep IV site open with normal saline infused through new tubing. Maintain BP and treat shock as ordered, if present. Obtain blood samples lowly to avoid hemolysis; send for serological testing. Send urine specimen to laboratory. Give diuretics as prescribed to maintain urine flow. Insert indwelling urinary catheter or measure each voiding to monitor hourly urine output. Dialysis may be required if acute kidney injury occurs. Patient safety alert: Do not transfuse additional RBC-containing components until transfusion service provides newly cross-matched units.	Meticulously verify and document patient identification from sample collection to component infusion.
Febrile nonhemolytic reaction (most common)	Antibodies against donor white blood cells	Sudden shaking chills (rigors), fever (rise in temperature 0.5°C [1°F] or more from start), headache, flushing, anxiety, muscle pain	Stop transfusion. Give antipyretics as prescribed; avoid aspirin in thrombocytopenic patients. Patient safety alert: Do not restart transfusion.	Consider leukocyte-poor blood products (filtered, washed, or frozen). Pretreat with antipyretics if prior history.
Mild allergic reaction	Antibodies against donor plasma proteins	Flushing, itching, urticaria (hives)	Stop transfusion temporarily. Give antihistamine as directed. If symptoms are mild and transient, restart transfusion slowly. Patient safety alert: Do not restart transfusion if fever, pulmonary symptoms, or hypotension develop.	Treat prophylactically with antihistamines.
Anaphylactic reaction	Antibodies to donor plasma, especially anti-IgA	Anxiety, urticaria, dyspnea, wheezing, progressing to cyanosis, severe hypotension, circulatory shock, possible cardiac arrest	Stop transfusion. Have epinephrine ready for injection (0.4 mL of 1:1000 solution subcutaneously or 0.1 mL of 1:1000 solution diluted to 10 mL with saline for IV use). Provide blood pressure support as ordered. Initiate CPR if indicated. Patient safety alert: Do not restart transfusion.	Transfuse extensively washed RBC products from which all plasma has been removed. Alternately use blood from IgA-deficient donor.
Not Caused by Immune Response				
Transfusion-associated circulatory overload (TACO)	Blood administered faster than circulation can accommodate	<i>Dyspnea</i> , cough, crackles, or rales in dependent lobes of lungs; distended neck veins when upright	Turn down transfusion rate or stop transfusion. Place patient upright with feet in dependent position. Administer prescribed diuretics, oxygen, morphine. Phlebotomy may be indicated.	Adjust transfusion volume and flow rate on basis of patient size and clinical status. Have transfusion service divide unit into smaller aliquots for better spacing of fluid input.
Sepsis	Bacterial contamination of transfused blood components	Rapid onset of chills, high fever, severe hypotension, and circulatory shock <i>May occur:</i> Vomiting, diarrhea, sudden oliguria (acute kidney injury), disseminated intravascular coagulation (DIC)	Stop transfusion. Obtain culture of patient's blood and send bag with remaining blood to transfusion service for further study. Treat as ordered: antibiotics, IV fluids, vasopressors, glucocorticoids.	Collect, process, store, and transfuse blood products according to blood-banking standards and infuse within 4 hours of starting time.

ABO, Blood group consisting of groups A, AB, B, and O; BP, blood pressure; CPR, cardiopulmonary resuscitation; DIC, disseminated intravascular coagulation; IgA, immunoglobulin A; IV, intravenous; RBC, red blood cell.

Data from Alexander M, et al: *Core curriculum for infusion nursing*, ed 4, Philadelphia, 2014, Lippincott, Williams & Wilkins; DeLisle J: Is this a blood transfusion reaction? Don't hesitate; check it out, *J Infus Nurs* 41(1):42, 2018.

The transfusion rate usually is specified in the health care provider's orders. Ideally a unit of whole blood or packed RBCs is transfused in 2 hours. This time can be lengthened to 4 hours if the patient is at risk for ECV excess. Beyond 4 hours there is a risk for bacterial contamination of the blood.

When patients have a severe blood loss such as with hemorrhage, they often receive rapid transfusions through a central venous catheter. A blood-warming device often is necessary because the tip of the central venous catheter lies in the superior vena cava, above the right atrium. Rapid administration of cold blood can cause cardiac dysrhythmias. Patients who receive large-volume transfusion of citrated blood have a high risk of hyperkalemia, hypocalcemia, hypomagnesemia, and metabolic alkalosis; therefore they need careful monitoring ([Lim et al., 2017](#)).

Transfusion Reactions

A transfusion reaction is an adverse event that occurs from transfusion of a blood product ([DeLisle, 2018](#)). Many transfusion reactions involve immune system reaction to the transfusion that ranges from a mild response to severe anaphylactic shock or acute intravascular hemolysis, both of which can be fatal. [Table 42.16](#) presents the causes, manifestations, management, and prevention of the most common acute transfusion reactions. Prompt intervention when a transfusion reaction occurs maintains or restores a patient's physiological stability. When you suspect acute intravascular hemolysis, do the following ([Alexander et al., 2014](#); [DeLisle, 2018](#)):

- Stop the transfusion immediately.
- Keep the IV line open by replacing the IV tubing down to the catheter hub with new tubing and running 0.9% sodium chloride (normal saline) at a slow rate.
- **Do not** turn off the blood and simply turn on the 0.9% sodium chloride (normal saline) that is connected to the Y-tubing infusion set. This would cause blood remaining in the IV tubing to infuse

into the patient. Even a small amount of additional blood can make the situation worse. **You must change out all the IV tubing.**

- Immediately notify the health care provider or emergency response team.
- Remain with the patient, observing signs and symptoms and monitoring vital signs as often as every 5 minutes.
- Prepare to administer emergency drugs such as antihistamines, vasopressors, fluids, and corticosteroids per health care provider order or protocol.
- Prepare to perform cardiopulmonary resuscitation.
- Save the blood container, tubing, attached labels, and transfusion record for return to the blood bank.
- Obtain blood and urine specimens per health care provider order or protocol.

Acute transfusion reactions that do not involve an immune response to the blood components also can occur (see [Table 42.16](#)). Transfusion-associated circulatory overload (TACO) is a risk when a patient receives massive whole blood or packed RBC transfusions for massive hemorrhagic shock or when a patient with normal blood volume receives blood. Patients particularly at risk for circulatory overload are older adults and those with cardiopulmonary diseases. Transfusion of blood components that are contaminated with bacteria, especially gram-negative bacteria, can cause sepsis.

Blood from infected donors who are asymptomatic can transmit diseases. Symptoms of these conditions may arise long after a transfusion. Diseases transmitted through transfusions include hepatitis B and C, human immunodeficiency virus (HIV) infection and acquired immunodeficiency syndrome (AIDS), Chagas disease, and cytomegalovirus infection. In the United States all units of blood for blood banks undergo screening for HIV, hepatitis B and C viruses, syphilis, and West Nile virus, which reduces the risk of acquiring these bloodborne infections ([CDC, 2019a](#)).

Interventions for Electrolyte Imbalances

In addition to the administration of prescribed medical therapies, nursing interventions preserve or restore electrolyte imbalance ([Felver, 2019c](#)). For example, people who have hypokalemia or hypercalcemia often need bowel management for constipation. Patient safety interventions to prevent falls are vital for patients who become lethargic from

hypercalcemia and those with muscle weakness. Patients who have hypercalcemia need an increased fluid intake to prevent renal damage; nurses can help them meet the oral fluid intake goals. Teach patients the reasons for their therapies and the importance of balancing electrolyte I&O to prevent imbalances in the future.

Interventions for Acid-Base Imbalances

Nursing interventions to promote acid-base balance support prescribed medical therapies and aim at reversing the existing acid-base imbalance while providing for patient safety (Felver, 2019b). When these imbalances are life threatening, they require rapid treatment. Maintain a functional IV line and check the health care provider's orders frequently for new medications or fluids. Give fluid and electrolyte replacement and prescribed drugs such as insulin promptly. In addition, monitor patients closely for changes in their status. Use protective measures such as side rails for patients with decreased level of consciousness. Support compensatory hyperventilation for patients with metabolic acidosis by keeping their oral mucous membranes moist and positioning them to facilitate chest expansion. Chapter 41 reviews appropriate therapies for patients with respiratory acidosis. Patients with acid-base imbalances often require repeated ABG analysis.

Arterial Blood Gases

Determination of a patient's acid-base status requires obtaining a sample of arterial blood for laboratory testing. ABG analysis reveals acid-base status and the adequacy of ventilation and oxygenation. A qualified RN or other health care provider draws arterial blood from a peripheral artery (usually the radial) or from an existing arterial line (see agency policy and procedures). Before an arterial blood draw, perform an Allen test, which assesses arterial circulation in the hand (Pagana et al., 2018). When performing the Allen test, apply pressure to both the ulnar and radial arteries in the selected hand. The fingers to the hand should be pale and blanched, indicating a lack of arterial blood flow. Release the pressure on the ulnar artery and observe for color to return to the fingers and hand, which indicates that there is adequate circulation to the hand and fingers via the ulnar artery. The Allen test ensures that a patient will have adequate blood flow to the hand if the radial artery is damaged. If color does not return, do not perform radial artery puncture on that arm. After the ABG puncture, apply pressure to the puncture site for at least 5 minutes to reduce the risk of hematoma formation. A longer time is

necessary if the patient takes anticoagulant medications. Reassess the radial pulse after removing the pressure. After obtaining the specimen, take care to prevent air from entering the syringe because this alters the blood gas values. To reduce oxygen usage by blood cells, submerge the syringe in crushed ice and transport it immediately to the laboratory.

Restorative Care

After experiencing acute alterations in fluid, electrolyte, or acid-base balance, patients often require ongoing maintenance to prevent a recurrence of health alterations. Older adults require special considerations to prevent complications from developing (see [Box 42.2](#)).

Home Intravenous Therapy

IV therapy often continues in the home setting for patients requiring long-term hydration, PN, or long-term medication administration. Initiate patient referral for discharge planning to social services, counselors, or a home care coordinator for assessment of patient and community resources. A home IV therapy nurse works closely with a patient to ensure that a sterile IV system is maintained and that complications can be avoided or recognized promptly. [Box 42.8](#) summarizes patient education guidelines for home IV therapy.

Box 42.8 Patient Teaching Home Intravenous Therapy

Objective

- The patient and/or family caregiver will demonstrate competence with administering intravenous (IV) therapy safely in the home.

Teaching Strategies

- Explain the importance of IV therapy in maintaining hydration and access for the delivery of medications.
- Emphasize the risks involved when the IV system is not kept sterile.
- Be sure that the patient and/or family caregiver is able to manipulate the required equipment.

- Instruct in aseptic technique and hand hygiene in the handling of all IV equipment.
- Teach how to change IV solutions, tubing, and dressing when they become soiled or dislodged (INS, 2016a). (Note: As the home care nurse, you may be able to visit frequently enough to perform scheduled tubing changes.)
- Teach procedures for safe disposal in appropriate containers of all sharps and IV materials exposed to blood. Check with the patient's local trash removal services or health department to see which disposal methods are available in the community (US Food and Drug Administration, 2018). Keep sharps containers away from children (see Chapter 28).
- Instruct to apply pressure with sterile gauze if catheter falls out and, if patient is on anticoagulants, to tape pieces of sterile gauze in place for at least 20 minutes with pressure or until bleeding stops.
- Instruct about signs and symptoms of infiltration, phlebitis, and infection and the need to report symptoms immediately.
- Instruct patient and/or family caregiver to report if the infusion slows or stops or if blood is seen in the tubing.
- Teach patient with family caregiver's assistance how to ambulate, perform hygiene, and participate in other activities of daily living without dislodging or disconnecting catheter and tubing:
 - For showering, protect the IV site and dressing from getting wet by covering it completely with plastic. If using an electronic infusion device, unplug around water.
 - Wear clothes that avoid pressure on the IV site, and avoid trauma to the site when changing clothes.
 - Have patient avoid strenuous exercise of the arm with the IV line.

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- I want to be sure I explained how to care for your IV correctly. Please tell and/or show me how you will start and stop your infusion, and change the IV container, tubing and dressing.
- Describe what you would do if your IV infusion stops flowing.

- What would you see if your IV site developed an infection? What would you do next?

Nutritional Support

Most patients who have had electrolyte disorders or metabolic acid-base imbalances require ongoing nutritional support. Depending on the type of disorder, fluid or food intake may be encouraged or restricted (see [Chapter 45](#)). Patients or family members who are responsible for meal preparation need to learn to understand nutritional content of foods and read the labels of commercially prepared foods.

Medication Safety

Numerous medications, OTC drugs, and herbal preparations contain components or create potential side effects that can alter fluid and electrolyte balance. Patients with chronic disease who are receiving multiple medications and those with renal disorders are at significant risk for imbalances. Once patients return to restorative care settings, whether in the home, long-term care, or other setting, drug safety is very important. Patient and family education regarding potential side effects and drug interactions that can alter fluid, electrolyte, or acid-base balance is essential. Review all medications with patients and encourage them to consult with their local pharmacist, especially if they wish to try a new OTC drug or herbal preparation ([Chapter 32](#)).

Evaluation

Through the Patient's Eyes

Review with patients how well their major concerns and expectations regarding fluid, electrolyte, or acid-base management were alleviated or addressed. For example, ask a person admitted with dehydration who was concerned about falling because of light-headedness, "Tell me if you feel we took the precautions necessary to reduce your risk of falling." If the patient's concern was feeling uncomfortable with a very dry mouth, ask, "How does your mouth feel now? Do you feel we made you comfortable?" If the patient's concerns involved having a better understanding of a chronic problem, focus the evaluation on the patient's view of his or her understanding after patient education was provided. A patient's perspectives regarding care often depend in part on involvement of family and friends. If patients have concerns about returning home or to a

different care setting, it is important to evaluate how well prepared they feel for the transition from acute care.

Patient Outcomes

Evaluate the effectiveness of interventions using the goals and outcomes established for the patient's nursing diagnoses. Evaluation of a patient's clinical status is especially important if acute fluid, electrolyte, and/or acid-base imbalances exist. A patient's condition can change very quickly, and it is important to recognize impending problems by integrating information about his or her presenting risk factors, clinical status, effects of the present treatment regimen, and potential causative agent. For evaluation, apply knowledge of how various pathophysiological conditions affect fluid, electrolyte, and acid-base balance; the effects of medications and fluids; and the patient's presenting clinical status when making clinical decisions (Fig. 42.19).

Knowledge

- Characteristics of fluid, electrolyte, and acid-base imbalances
- Effects of pathophysiology on fluid, electrolyte, and acid-base balances
- Effects of nursing and medical interventions on fluid, electrolyte, and acid-base balances

Experience

- Previous patient responses to planned nursing therapies for improving fluid, electrolyte, and acid-base balance (what worked and what did not work)

EVALUATION

- Reassess signs and symptoms of the patient's fluid, electrolyte, and acid-base imbalance
- Ask the patient for perceptions of fluid balance after interventions

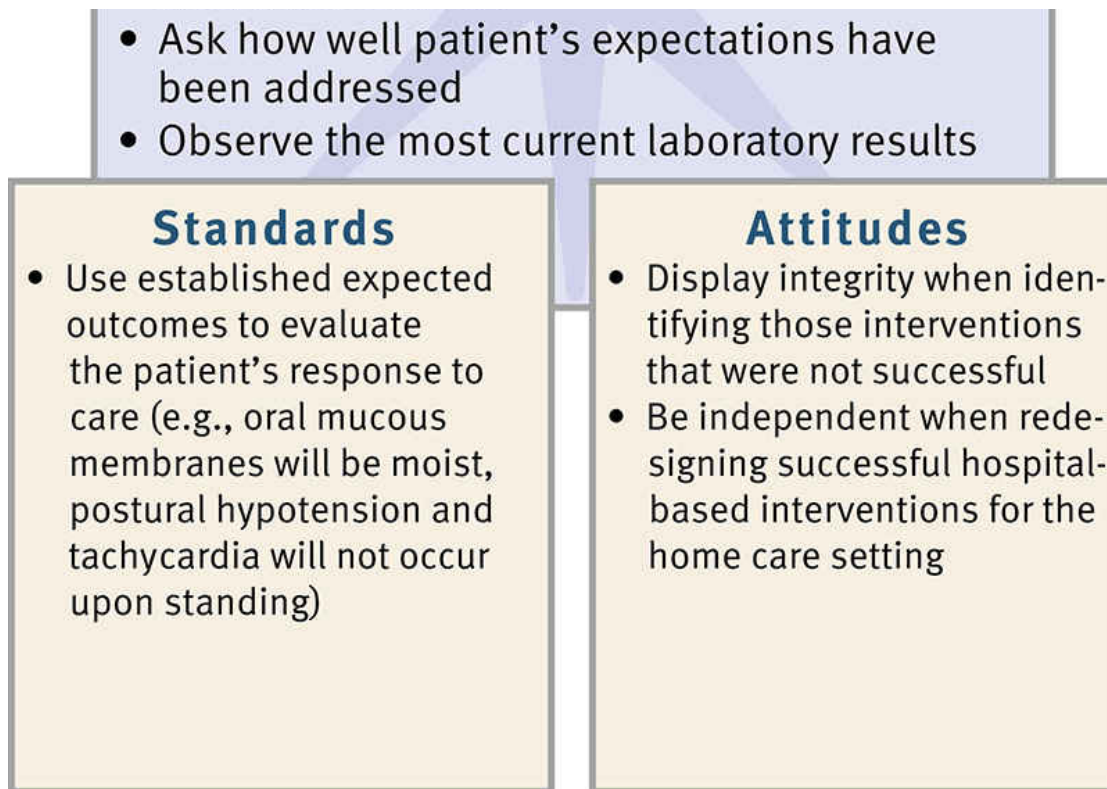

FIG. 42.19 Critical thinking model for fluid, electrolyte, and acid-base balances evaluation.

Compare your current evaluation findings with the previous patient assessment. For example, a patient's hypokalemia demonstrates improvement when the serum potassium is increasing toward normal and the physical signs and symptoms of hypokalemia begin to disappear or lessen in intensity. Specifically, the patient's quadriceps muscles become stronger, normal bowel function returns, and heart rhythm becomes more regular.

For patients with less acute alterations, evaluation is likely to occur over a longer period. In this situation evaluation may be more focused on behavioral changes (e.g., the patient's adherence to dietary restrictions and medication schedules). Another important element of evaluation is the family's ability to anticipate alterations and prevent a recurrence of problems.

The patient's level of progress determines whether the plan of care needs to continue or be revised. If goals are not met, you may need to consult a health care provider to discuss additional methods, such as increasing the frequency of an intervention (e.g., providing more

fluids to a patient experiencing dehydration), introducing a new therapy (e.g., initiating insertion of an IV line), or discontinuing a therapy. Once outcomes are met, the nursing diagnosis is resolved and you are able to focus on other priorities, including maintaining normal fluid, electrolyte, and acid-base balance. If established outcomes are not achieved, explore factors that contributed to why the planned outcomes were not met. Modification of the care plan occurs after this evaluation. If outcomes are not achieved, the questions you ask may include the following:

- “What difficulties are you having with measuring your I&O daily and keeping a record?”
- “What barriers are preventing you from obtaining the potassium-rich foods you need?”
- “Are you continuing to have frequent loose stools or diarrhea?”
- “Have you purchased an antacid, or are you still using baking soda as an antacid?”

Safety Guidelines for Nursing Skills

Ensuring patient safety is an essential role of the professional nurse. To ensure patient safety, communicate clearly with members of the health care team, assess and incorporate the patient’s priorities of care and preferences, and use the best evidence when making decisions about your patient’s care. When performing the skills in this chapter, remember the following points to ensure safe, individualized patient care:

- Check that you have the necessary information, a health care provider’s order if required, and equipment available for the procedure before beginning.
- Before initiation of therapy, check patient identification using two patient identifiers (TJC, 2020) and assess the appropriate

route and rate of infusion and potential incompatibilities between infusing fluids and medications (INS, 2016a).

- Determine whether the patient has a latex allergy and use nonlatex items if allergy is present (INS, 2016a).
- Conduct a complete history and physical assessment, including vital signs, and review laboratory findings before initiating any solutions or medications.
- Know the indications for prescribed therapy before initiating IV therapy. Obtain and review health care provider's order to ensure appropriateness of the prescribed solution of medications (INS, 2016a).
- Use special designated tubing for the brand of EID and for blood transfusions and some medications.
- Review the steps of the procedure mentally before entering a patient's room (i.e., consider modifications that you may need to make for this specific patient and verify that the type of IV solution is appropriate for this patient).
- Maintain strict aseptic and sterile techniques when required and sterility and integrity of the IV system to prevent bloodstream infections (INS, 2016a).
- If you contaminate a sterile object during the procedure, do not use it. Use a new sterile one.
- Use standard body fluid precautions during procedures and place all disposable blood-contaminated items and sharp items in designated puncture-resistant biohazard containers (INS, 2016a).

Skill 42.1. • Insertion of A Short-Peripheral Intravenous Device

Delegation and Collaboration

The skill of inserting a short-peripheral IV access device cannot be delegated to assistive personnel (AP). Delegation to licensed practical nurses (LPNs) varies by State Nurse Practice Act. Instruct the AP to:

- Notify the nurse if the patient complains of any IV site–related complications such as redness, pain, tenderness, swelling, bleeding, drainage, or leaking from under dressing.
- Notify the nurse if the patient’s IV dressing becomes wet or loose.
- Notify the nurse if the level of fluid in the IV bag is low or the electronic infusion device (EID) is alarming.

Equipment

- Short-peripheral IV start kit supplies (available in some agencies): single-use tourniquet, tape, transparent semipermeable membrane (TSM) dressing or sterile gauze and sterile tape, antiseptic solution (alcoholic chlorhexidine solution preferred, 70% alcohol, povidone-iodine, or tincture of iodine), 2 × 2–inch gauze pads, and label
- Appropriate short-peripheral IV catheter with safety mechanism for venipuncture; for adults select 20- to 24- gauge catheter; for neonates, children, and older adults 22- to 24-gauge; for rapid fluid replacement 16- to 20-gauge; based on vein size for blood transfusion 20- to 24- gauge; and for short-term therapy or a single dose, steel-winged device (INS, 2016a)
- Clean gloves (latex free for patients with latex allergy); sterile gloves are needed if palpating the site after skin antiseptics (INS, 2016a)
- Single-use hair clippers or scissors for hair removal if indicated
- Short extension tubing with fused needleless connector or separate needleless connector (also called *injection cap*, *saline lock*, *heparin lock*, *IV plug*, *buff cap*, *buffalo cap*, or *PRN adapter*)
- 10-mL syringe prefilled with preservative-free 0.9% sodium chloride (normal saline [NS]) (INS, 2016a)
- Antiseptic swabs
- Engineered catheter stabilization device (if available) and polymer-based skin protectant swab

- *Option:* IV site protection device
- Prescribed IV solution or medication
- IV administration set (IV tubing), either macrodrip or microdrip , depending on prescribed rate; if using EID, appropriate administration set
- 0.2-micron filter for nonlipid (fat emulsions) solutions (may be incorporated into the infusion set)
- Personal protective equipment: goggles and mask (*optional* based on agency policy)
- Electronic infusion device (EID) and IV pole
- Vein visualization device (*optional* based on agency policy)
- Stethoscope
- Watch with second hand to calculate drip rate
- Special patient gown with snaps at shoulder seams if available
- Needle disposal container (*sharps container* or *biohazard container*)
- *Option:* Hand or arm joint stabilization device

Step	Rationale
Assessment	
1. Review accuracy of health care provider's order: date and time, IV solution, route of administration, volume, rate, duration, and signature of ordering health care provider (Gorski, 2018). Follow the seven rights of medication administration.	Before IV therapy, an order from a health care provider is needed (INS, 2016a). Verification that order is complete prevents medication errors.
a. Check approved online database, drug reference book, or pharmacist about IV solution composition, purpose, potential incompatibilities, adverse reactions, and side effects.	Ensures safe and correct administration of IV therapy and appropriate selection of VAD.
2. Obtain data from patient's electronic health record of clinical factors/conditions that will respond to or be affected by administration of IV solutions.	Provides baseline to determine effectiveness of prescribed therapy. A systems approach is recommended to assess for fluid and electrolyte imbalances (Gorski, 2018).
a. Body weight	Changes in body weight can be an indication of fluid loss or gain (Gorski, 2018).
b. Clinical markers of vascular volume:	
(1) Urine output (decreased, dark yellow)	Kidneys respond to extracellular volume (ECV) deficit by reducing urine production and concentrating urine. Kidney disease can also cause oliguria.
(2) Vital signs: blood pressure, respirations, pulse, temperature	Changes in blood pressure may be associated with fluid volume status (fluid volume deficit [FVD]) seen in postural hypotension. Respirations can be altered in presence of acid-base imbalances. Temperature elevations increase need for fluid requirements (temperature of 38.3°C [101°F] to 39.4°C [103°F] require at least 500 mL of fluid replacement within a 24-hr period) (Gorski, 2018).
(3) Distended neck veins (normally veins are full when person is supine and flat when person is upright)	Indicator of fluid volume status: flat or collapsing with inhalation when supine with ECV deficit; full when upright or semi-upright with ECV excess.
(4) Auscultation of lungs	Crackles or rhonchi in dependent parts of lung may signal fluid buildup caused by ECV excess.
(5) Capillary refill	Indirect measure of tissue perfusion (sluggish with ECV deficit).
c. Clinical markers of interstitial volume:	
(1) Skin turgor (pinch skin over sternum or inside of forearm)	Failure of skin to return to normal position after several seconds indicates FVD (Alexander et al., 2014).
(2) Dependent edema (pitting or nonpitting)	Edema is not usually apparent until 4.4–8.8 lb (2–4 kg) of fluid is retained. A weight gain of 2.2 lb (1 kg) is equivalent to the retention of 1 L of body water (Gorski, 2018).
(3) Oral mucous membrane between cheek and gum	More reliable indicator than dry lips or skin. Dry between cheek and gums indicates ECV deficit.
d. Thirst	Occurs with hypernatremia and severe ECV deficit. Not a reliable indicator for older adults (Kenr, 2017).
e. Behavior and level of consciousness	
(1) Restlessness and mild confusion	Occurs with FVD or acid-base imbalance.
(2) Decreased level of consciousness (lethargy, confusion, coma)	Occurs with severe ECV deficit. May occur with osmolality, fluid and electrolyte, and acid-base imbalances.
3. Determine whether patient is to undergo any planned surgeries or procedures.	Allows anticipation and placement of appropriate VAD for infusion and avoids placement in an area that will interfere with medical procedures (INS, 2016a).
4. Assess available laboratory data (e.g., hematocrit, serum electrolytes, arterial blood gases, and kidney functions [blood urea nitrogen, urine specific gravity, and urine osmolality]).	Helps determine priority assessments and establishes baseline for determining whether therapy is effective. Laboratory values are an assessment of hydration status (Alexander et al., 2014).
5. Assess patient's or family caregiver's knowledge, experience, and health literacy regarding IV therapy.	Ensures patient or family caregiver has the capacity to obtain, communicate, process, and understand basic health information (Centers for Disease Control and Prevention [CDC], 2019).
6. Assess patient's history of allergies, especially to iodine, adhesive, or latex.	Equipment used during VAD insertion may contain substances to which patient is allergic. When a patient has a latex allergy, health care providers will need to use latex-free gloves.
7. Assess patient's arm preference for placement of IV.	Provides patient-centered care by determining level of emotional support and instruction needed.
Planning	
1. Close room door or bedside curtains. Remove clutter from the over-bed or bedside table.	Providing privacy and preparing the environment ensures patient comfort and organizes procedure.

Step	Rationale
2. Perform hand hygiene. Collect and organize equipment on clean bedside table. Verify that you have the correct infusion set for the EID that will be used.	Reduces transmission of microorganisms. Easy access to equipment improves efficiency. Ensures patient safety.

	Table Continued

Step	Rationale
3. Select appropriate-sized catheter; open and prepare sterile packages using sterile aseptic technique (see Chapter 28).	Use smallest-gauge peripheral catheter that will accommodate prescribed therapy and patient needs (INS, 2016a).
4. Help patient to comfortable sitting or supine position. Change patient's gown to one more easily removed with snaps at shoulder if available. Provide adequate lighting.	Promotes comfort and relaxation for patient. Use of this type of gown decreases risk of accidental dislodgment of catheter or administration set. Aids in successful vein location.
5. Explain/instruct patient about rationale for infusion, including solution and medications ordered, procedure for IV insertion, and signs and symptoms of complications (e.g. bleeding, tenderness and swelling) to watch out for.	Provides patient with information about procedure and promotes adherence (INS, 2016a). May minimize anxiety.

Implementation	
1. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy. Compare identifiers with information on patient's MAR or medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2020).
2. Perform hand hygiene. Prepare short extension tubing with fused needleless connector or separate needleless connector (injection cap) to attach to catheter hub.	Needleless connectors protect health care workers by eliminating needles and potential for needlestick injuries when accessing VAD (INS, 2016a).
a. Remove protective cap from needleless connector and attach syringe with 1 to 3 mL 0.9% sodium chloride (normal saline), maintaining sterility. Slowly inject enough saline to prime (fill) short extension tubing and connector, removing all air. Leave syringe attached to tubing.	Replaces air with normal saline, preventing air from entering patient's vein later during VAD insertion.
b. Maintain sterility of end of connector by reapplying end caps and set aside for attaching to catheter hub after successful venipuncture. Do not overtighten end caps.	Prevents touch contamination, which allows microorganisms to enter infusion equipment and bloodstream. Overtightening end caps will make it difficult to remove them.

Clinical Decision: Short extension sets may be used on short-peripheral catheters. Reduces catheter manipulation. For patient safety, all connections should be of Luer-Lok type (INS, 2016a). Luer-Lok connections should be used to prevent accidental disconnection (INS, 2016a). Many agencies use short extension tubing for continuous infusions and stand-alone saline locks (capped catheters).

3. Prepare IV tubing and solution for continuous infusion.	
a. Check IV solution using seven rights of medication administration (see Chapter 31) and review label for name and concentration of solution, type and concentration of any additives, volume, beyond-use and expiration dates, and sterility state. If using bar code, scan code on patient's wristband and then on IV fluid container. Be sure that prescribed additives such as potassium and vitamins have been added. Check solution for color and clarity. Check bag for leaks.	<p>Reviewing label for accuracy reduces risk for medication errors (INS, 2016a).</p> <p>Risk for medication errors can be reduced with safe medication practices, including (INS, 2016a):</p> <ul style="list-style-type: none"> • Do not add medications to infusing containers of IV solutions (INS, 2016a). • Do not use IV solutions that are discolored, contain precipitates, or are expired.
b. Open IV infusion set, maintaining sterility. NOTE: EIDs sometimes have a dedicated administration set; follow manufacturer's instructions.	Prevents touch contamination, which allows microorganisms to enter infusion equipment and bloodstream.
c. Place roller clamp (see illustration A) about 2 to 5 cm (1 to 2 inches) below drip chamber and move roller clamp to "off" position (see illustration B).	Close proximity of roller clamp to drip chamber allows more accurate regulation of flow rate. Moving clamp to "off" prevents accidental spillage of IV solution during priming.

Step		Rationale	

A

STEP 3C A, Close door of control mechanism. B, Select rate and volume to be infused and press start button.

Step

Rationale

Step

STEP3D Removing protective sheath from IV tubing port.

Rationale

Step	Rationale
STEP 3E	Inserting spike into IV bag.
	Table Continued

Step	Rationale
d. Remove protective sheath over IV tubing port on plastic IV solution bag (see illustration) or top of IV solution bottle while maintaining sterility.	Provides access for insertion of IV tubing spike into solution using sterile technique.
e. Remove protective cover from IV tubing spike while maintaining sterility of spike. Insert spike into port of IV bag using a twisting motion (see illustration). If solution container is glass bottle, clean rubber stopper on glass-bottled solution with antiseptic swab and insert spike into rubber stopper of IV bottle. Bottles require vented tubing.	Flat surface on top of bottled solution may contain contaminants, whereas opening to plastic bag is recessed. Prevents contamination of bottled solution during insertion of spike. If sterility of spike is compromised, discard IV tubing and obtain new one.
f. Compress drip chamber and release, allowing it to fill one-third to one-half full (see illustration).	Compression creates suction effect; fluid enters drip chamber to prevent air from entering tubing.
g. Prime air out of IV tubing by filling with IV solution: Remove protective cover on end of IV tubing (some tubing can be primed without removing protective cover) and slowly open roller clamp to allow fluid to flow from drip chamber to distal end of IV tubing. If tubing has a Y connector, invert Y connector when fluid reaches it to displace air. Return roller clamp to "off" position after priming tubing (filled with IV fluid). Replace protective cover on distal end of tubing. Label IV tubing with date according to agency policy and procedure.	Priming ensures that IV tubing is clear of air and filled with IV solution before connecting to VAD. Slowly filling tubing decreases turbulence and chance of bubble formation. Closing clamp prevents accidental loss of fluid. Maintains sterility. Labeling IV tubing allows for recognition of length of time that tubing has been in use and when to change it.
h. Be certain that IV tubing is clear of air and air bubbles. To remove small air bubbles, firmly tap tubing where they are located. Air bubbles will ascend to drip chamber. Check entire length of tubing to ensure that all air bubbles are removed (see illustration).	Large air bubbles act as emboli and should be avoided (Mattox, 2017).
i. If using optional long extension tubing, remove protective cover and attach it to distal end of IV tubing, maintaining sterility. Then prime long extension tubing with IV solution. Insert IV tubing into EID with power off.	Priming removes air from long extension tubing so that it does not enter patient's vascular system. Facilitates starting infusion as soon as IV site is ready.
4. Perform hand hygiene.	Decreases potential risk of microbial contamination and cross-contamination (INS, 2016a).
Clinical Decision: <i>Gloves are not necessary to locate vein but must be applied for VAD insertion using a no-touch technique where the site is not palpated after skin antiseptics (INS, 2016a, 2016b).</i>	
5. Apply tourniquet around upper arm about 10 to 15 cm (4 to 6 inches) above proposed insertion site (see illustration). Do not apply tourniquet too tightly. Check for presence of pulse distal to tourniquet.	Tourniquet should be tight enough to impede venous flow while maintaining arterial circulation (INS, 2016a, 2016b). If patient has fragile veins or bruises easily, tourniquet should be applied loosely or not at all to prevent damage to veins and bruising (INS, 2016a).
<i>Option A:</i> Apply tourniquet on top of thin layer of clothing such as gown sleeve to protect fragile or hairy skin.	
<i>Option B:</i> Blood pressure cuff may be used in place of tourniquet: activate cuff and hold at approximately 50 mm Hg.	Reduces trauma to skin.

Step	Rationale

STEP 3F Squeezing drip chamber to fill with fluid one-third to one-half full.

Step

Rationale

STEP 3H Removing air bubbles from tubing.

Step

Rationale

STEP 5 Tourniquet placed on arm for initial vein selection.

Table Continued

Step	Rationale
6. Select vein for VAD insertion (see Fig. 42.15). Veins on dorsal and ventral surfaces of arms (e.g., metacarpal, cephalic, basilic, or median) are preferred in adults.	Ensures adequate vein that is easy to puncture and less likely to rupture.
a. Use most distal site in nondominant arm if possible.	Patients with VAD placement in their dominant hand have decreased ability to perform self-care.
b. With your fingertip, palpate vein at intended insertion site by pressing downward. Note resilient, soft, bouncy feeling while releasing pressure (see illustration).	Fingertip is more sensitive and better for assessing vein location and condition.
c. Select well-dilated vein. Methods to improve vascular distention:	Increased volume of blood in vein at venipuncture site makes vein more visible.
(1) Position extremity lower than heart, have patient open and close fist slowly, and lightly stroke vein downward.	Use of gravity promotes vascular distention (INS, 2016a).
(2) Apply dry heat to extremity for several minutes.	Dry heat has been found to promote vein dilation and increase successful peripheral catheter insertion (INS, 2016a).

Clinical Decision: Vigorous friction, slapping or hard tapping of a vein, especially in older adults, can cause venous constriction and/or bruising and hematoma (Gorski, 2018).

7. When selecting a vein:	
a. Avoid vein selection in:	
(1) Areas with pain on palpation, compromised areas, sites distal to compromised areas (e.g., open wounds, bruising, infection, infiltration, and extravasation) (INS, 2016a).	It would be difficult to assess for any signs or symptoms of complications if an IV device were inserted in an area already compromised.
(2) Upper extremity on side of breast surgery with axillary node dissection or lymphedema or after radiation, arteriovenous (AV) fistulas/grafts; or affected extremity from cerebrovascular accident (CVA) (INS, 2016a).	Increases risk for complications such as infection, lymphedema, or vessel damage.
(3) Site distal to previous venipuncture site, sclerosed or hardened veins, previous infiltrations or extravasations, areas of venous valves, or phlebotic vessels.	Such sites cause infiltration around newly placed VAD site and vessel damage.
(4) Fragile dorsal hand veins in older adults, veins in lower extremities, and veins in an extremity with poor circulation.	Veins have increased risk for infiltration, tissue damage, and thrombophlebitis (INS, 2016a).
(5) Areas of flexion such as wrist or antecubital area (INS, 2016a).	Veins have increased risk for occlusion, infiltration, phlebitis, or dislodgment.
(6) Ventral surface of wrist (10–12.5 cm [4–5 inches])	Venipuncture in ventral surface of wrist is painful and has potential for nerve damage (INS, 2016a).
b. Choose site that will not interfere with patient's activities of daily living (ADLs), use of assist devices, or planned procedures.	Keeps patient as mobile as possible.
8. Release tourniquet temporarily.	Restores blood flow and prevents venospasm when preparing for venipuncture.

Clinical Decision: If hair removal is needed, do not shave area with a razor. Shaving may increase risk of infection (INS, 2016a). Clip hair with scissors or hair clippers to prepare area for application of transparent semipermeable membrane (TSM) dressing if necessary (explain to patient).

STEP 08 Palpate vein.

Step	Rationale

Table Continued

Step	Rationale
Clinical Decision: Local anesthetic reduces discomfort associated with insertion of a VAD. Both topical and injectable drugs can reduce pain and require a health care provider's order. You may apply topical local anesthetic to intended IV site 30 minutes before procedure. Follow manufacturer recommendations and monitor for allergic reaction (Alexander et al., 2014;INS, 2016a).	
9. Perform hand hygiene and apply clean gloves. Wear eye protection and mask (see agency policy) if splash or spray of blood is possible.	Decreases potential risk of microbial contamination and cross-contamination (INS, 2016a).
10. Place adapter end of short extension set (prepared in Step 2) or needleless connector (injection cap) for saline lock nearby in sterile package.	Permits smooth, quick connection of infusion to short-peripheral catheter once vein is accessed.
11. If area of insertion is visibly soiled, clean site with antiseptic soap and water first and dry. Perform skin antiseptics with alcoholic chlorhexidine solution using friction in back-and-forth motion (see illustration) for 30 seconds and allow to dry completely. If using plain alcohol or povidone-iodine, clean in concentric circle, moving from insertion site outward with swab. Allow drying time between agents if agents are used in combination (alcohol and povidone-iodine).	Mechanical friction in this pattern allows penetration of antiseptic solution to epidermal layer of skin (Alexander et al., 2014). Reduces incidence of catheter-related infections (Alexander et al., 2014). Allow any skin antiseptic agent to fully dry for complete antiseptics—alcoholic chlorhexidine solutions for at least 30 seconds, iodophors for at least 1.5 to 2 minutes (INS, 2016a).
Clinical Decision: If vein palpation is necessary after performing skin antiseptics, use sterile gloves for palpation or perform skin antiseptics again because touching cleaned area introduces microorganisms from your finger to site (INS, 2016a,2016b).	
12. Reapply tourniquet 10 to 15 cm (4 to 6 inches) above anticipated insertion site. Check for presence of pulse distal to tourniquet.	Pressure of tourniquet promotes vein distention. Diminished arterial flow prevents venous filling.
13. Perform venipuncture. Anchor vein below anticipated insertion site by placing thumb over vein 4 to 5 cm (1½ to 2 inches) distal to site (see illustration) and gently stretching skin against direction of insertion. Instruct patient to relax hand.	Stabilizes vein for needle insertion, prevents vein from rolling, and stretches skin taut, decreasing drag during insertion. Some devices require loosening needle (stylet) from catheter before venipuncture. Follow manufacturer directions for use.
a. Warn patient of a sharp stick.	Accessing vein at an angle reduces risk of puncturing posterior vein wall.
b. Hold VAD with needle bevel up. Align catheter on top of vein at 10- to 30-degree angle. Puncture skin and anterior vein wall (see illustration).	Superficial veins require smaller angle. Deeper veins require greater angle.

STEP 11 Clean site with antiseptic swab (alcoholic chlorhexidine solution preferred, 70% alcohol, or povidone-iodine).

Step	Rationale
	

STEP 13 Stabilize vein below insertion site.

STEP 13B Puncture skin with catheter at 10- to 30-degree angle.

Table Continued

Step	Rationale
Clinical Decision: Use each catheter only once for each insertion attempt.	
<p>14. Observe for blood return in catheter or flashback chamber of catheter, indicating that bevel of needle has entered vein (see illustration A). Advance VAD approximately ¼ inch (0.6 cm) into vein and loosen stylet (needle) of ONC. Continue to hold skin taut while stabilizing VAD and, with index finger on push-off tab of VAD, advance catheter off needle into vein until hub rests at venipuncture site (see illustration B). Do not reinsert stylet into catheter once catheter has been advanced into vein. Advance catheter while safety device automatically retracts stylet (techniques for retracting stylet vary with different VADs). Place stylet directly into sharps container.</p>	<p>Increased venous pressure from tourniquet causes backflow of blood into catheter and/or flashback chamber. Some VADs have a notch in the stylet, allowing flash of blood into catheter. Stabilizing VAD allows for placement of catheter into vein and advancement of catheter off stylet. Advancing entire stylet into vein may penetrate wall of vein, resulting in hematoma. Advancing catheter with finger on open hub causes contamination (INS, 2016a). Reinsertion of stylet can cause catheter to shear off and embolize into vein. Devices with safety mechanisms and proper sharps disposal prevent needlestick injuries (OSHA, 2012).</p>
Clinical Decision: A single clinician should not make more than two attempts at initiating IV access and limit total attempts to no more than 4 (INS, 2016a).	
<p>15. Stabilize VAD with nondominant hand and release tourniquet or blood pressure cuff with other. Apply gentle but firm pressure with middle finger of nondominant hand 3 cm (1¼ inches) above insertion site. Keep catheter stable with index finger.</p>	<p>Permits venous flow and reduces backflow of blood. Digital pressure minimizes blood loss and allows attachment of extension set or needleless connector (INS, 2016b).</p>
<p>16. Quickly connect Luer-Lok end of short extension tubing with needleless connector to end of catheter hub. Secure connection. Avoid touching sterile connection ends.</p>	<p>Prompt connection maintains patency of vein, minimizes blood loss, and prevents risk of exposure to blood. Maintains sterility.</p>
Option: IV tubing can be attached directly to catheter hub in place of short extension tubing or needleless connector.	
<p>17. Take the previously attached 10-mL prefilled syringe that contains 0.9% sodium chloride (normal saline [NS]) and is connected to short extension set. Aspirate by pulling back on syringe to remove air and assess blood return. Then, slowly inject NS from syringe into VAD (see illustration A). Remove syringe and discard.</p>	<p>Aspirating air prevents air embolism. Blood return that is color and consistency of whole blood confirms placement of catheter in vein (INS, 2016a). Flushing prevents reflux of blood into catheter and occlusion (INS, 2016b). Initiates flow of fluid through IV catheter, preventing clotting of device. Swelling indicates infiltration, and catheter would need to be removed.</p>
Option: To begin primary infusion, swab needleless connector with antiseptic swab and attach Luer-Lok end of IV tubing to needleless connector (see illustration B). Open roller clamp of IV tubing, turn on EID, and program it. Begin infusion at correct rate. If using gravity flow instead of EID, begin infusion by slowly opening roller clamp to regulate rate.	
<div style="display: flex; justify-content: space-around;">   </div>	
<p>STEP 14 A, Observe for blood return in catheter and/or flashback chamber. B, Advance catheter into vein until hub rests at venipuncture site.</p>	

Table Continued

Step	Rationale
<p>Clinical Decision:Needless connectors protect health care workers and decrease risk for needlestick injuries. They have different internal mechanisms for fluid displacement and vary in the flush-clamp-disconnect sequence to prevent reflux of blood into catheter on disconnection (INS, 2016a). The sequence depends on the type of internal mechanism (Gorski, 2018):</p> <ul style="list-style-type: none"> • Neutral displacement devices do not have a specified flush-clamp-disconnect sequence. • For negative-pressure displacement devices, flush, clamp catheter, then disconnect syringe. • For positive-pressure displacement, flush, disconnect syringe, then clamp catheter. 	
<p>18. Observe insertion site for swelling.</p>	<p>Swelling indicates infiltration, which requires immediate catheter removal.</p>
<p>19. Apply sterile dressing over site.</p>	
<p>a. Transparent semipermeable membrane (TSM) dressing:</p>	
<p>(1) Continue to secure catheter with nondominant hand. Remove adherent backing. Apply one edge of dressing and gently smooth remaining dressing over IV insertion site, leaving Luer-Lok connection between tubing and catheter hub uncovered. Gently press dressing to adhere to skin. Remove outer covering and smooth dressing gently over site (see illustration).</p>	<p>Protects catheter insertion site and minimizes risk for infection (Gorski, 2018). Allows visualization of insertion site and surrounding area for complications (INS, 2016a). Access to Luer-Lok connection between tubing and catheter hub facilitates changing tubing if necessary.</p>
<p>(2) Place 2.5 cm (2-inch) piece of tape over Luer-Lok connection (see illustration). Do not apply tape on top of TSM dressing.</p>	<p>Removal of tape from TSM dressing can tear dressing and cause catheter dislodgement. Tape on top of TSM dressing prevents moisture from being carried away from skin.</p>
<p>b. Sterile gauze dressing:</p>	
<p>(1) Place 5-cm (2-inch) piece of sterile tape over catheter hub (see illustration).</p>	<p>Stabilizes catheter under gauze dressing.</p>
<p>(2) Place 2 × 2-inch gauze pad over insertion site and edge of catheter hub. Secure all edges with tape. Do not place tape over insertion site. Do not cover connection between IV tubing and catheter hub (see illustration).</p>	<p>Use gauze dressings for site drainage, excessive perspiration, or sensitivity/allergic reactions to TSM dressings (INS, 2016a; Gorski, 2018).</p>

STEP 17 A, Flush short extension set after aspirating air and assessing blood return. B, Connect IV tubing to the short extension set that is attached to the catheter.

Step	

STEP 18A(1) Apply transparent semipermeable membrane (TSM) dressing.

STEP 18A(2) Place tape over administration set tubing.

(3) Fold 2 × 2-inch gauze in half and cover with 1 inch-wide tape so about an inch extends on each side. Place under Luer-Lok connection (see illustration). Secure Luer-Lok connection and tubing to tape on folded gauze with 2.5-cm (1-inch) piece of tape. Avoid applying tape or gauze around arm. Do not use rolled bandages with or without elastic to secure VAD. Taping Luer-Lok connection can be eliminated if engineered stabilization device is to be used.

Tape on top of gauze makes it easier to access hub/tubing junction. Gauze pad elevates hub off skin to prevent pressure area. Prevents back-and-forth motion of catheter. Rolled bandages do not secure VAD adequately, can impair circulation or flow of infusion, and obscure visualization for complications (INS, 2016a).

20. *Option:* Secure IV catheter using engineered stabilization device (follow manufacturer directions and agency policy).

Use of engineered stabilization devices that allow visual inspection of insertion site can reduce risk of VAD complications (i.e., phlebitis, infection, migration) and unintentional loss of access (INS, 2016a).

a. Apply polymer-based skin protectant to area of skin around IV site and allow to dry completely.

Risk for medical adhesive-related skin injury (MARSI) is increased as result of age, joint movement, and edema; use of skin protectant can decrease risk (INS, 2016a).

Step	Rationale
(1) Align anchoring pads with directional arrow pointing to insertion site. Press device retainer over top of Luer-Lok connection while supporting underneath connection.	
(2) Stabilize catheter and peel off one side of liner and press to adhere to skin. Repeat on other side (see illustration).	
(3) Monitor for medical adhesive-related skin injury (MARS).	
21. <i>Option:</i> Apply site protection device (e.g., I.V. House UltraDressing®).	Reduces risk of VAD dislodgement (INS, 2016a).
22. Loop extension or IV tubing alongside dressing on arm and secure with second piece of tape directly over tubing (see illustration).	Securing tubing reduces risk for dislodging catheter if IV tubing is pulled (i.e., loop comes apart before catheter dislodges).
23. For continuous infusion, verify ordered rate of infusion and be sure EID is programmed correctly. If infusing by gravity drip, adjust flow rate to correct drops per minute.	Ensures prescribed rate of infusion.
24. Label dressing per agency policy. Include date and time of IV insertion, VAD gauge size and length, and your initials (see illustration).	Allows for recognition of type of device and length of time that device has been in place.
25. Dispose of any remaining sharps in appropriate sharps container. Discard supplies.	Prevents accidental needlestick injuries (OSHA, 2012).
26. Remove and dispose of gloves and perform hand hygiene.	Reduces risk of contamination (INS, 2016b).
 <p data-bbox="358 982 586 997">STEP 19B(1) Place sterile tape over catheter hub.</p>	 <p data-bbox="1062 831 1256 863">STEP 19B(2) Place 2 x 2-inch gauze over insertion site and catheter hub.</p>
 <p data-bbox="358 1577 675 1591">STEP 19B(3) Apply 2 x 2-inch gauze dressing under tubing junction.</p>	 <p data-bbox="1062 1377 1273 1415">STEP 26A(2) Catheter stabilization device in place. (Image Courtesy C.R. Bard, Inc. All rights reserved.)</p>
27. Assist patient to a comfortable position and instruct how to move and turn without dislodging VAD.	Prevents accidental dislodgment of catheter and minimizes risk for falls.
28. Raise bed rails (as appropriate) and lower bed to lowest position.	Minimizes risks for falls and injury
29. Be sure nurse call system is in an accessible location within patient's reach. Instruct patient in its use.	Ensures patient can call for assistance if needed.
Evaluation	

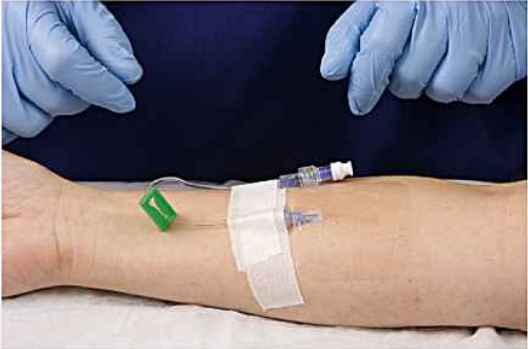

Step	Rationale
(1) Observe patient every 1 to 2 hours, or at established intervals per agency policy and procedure for function, intactness, and patency of IV system and for correct infusion rate and accurate type/amount of IV solution infused by observing level in IV container.	Ensures delivery of prescribed volume over prescribed time and decreases risk for fluid and electrolyte imbalance.
(2) Evaluate patient to determine response to therapy (e.g., laboratory values, input and output [I&O] , weights, vital signs, postprocedure assessments).	Early recognition of complications leads to prompt treatment.
(3) Evaluate patient with a short-peripheral IV at least every 4 hours, or every 1 to 2 hours for patients that are critically ill, sedated, or have cognitive deficits (INS, 2016a), or at established intervals per agency policy and procedure for signs and symptoms of catheter-related complications. Assess the VAD catheter-skin junction site and surrounding area by visually inspecting and palpating through the intact dressing for redness, tenderness, swelling, and drainage.	Identifies complications that compromise integrity of VAD or cause inaccurate IV solution flow rate.
Clinical Decision: <i>If IV is positional, fluid will run slowly or stop, depending on position of patient's arm; if this continues, you may have to restart IV line.</i>	
4. Use Teach-Back: "I want to make sure that I explained the problems that can happen with your IV. Tell me the signs or symptoms that you should tell me or the other nurses about." Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly.	Determines patient's/family caregiver's level of understanding of instructional topic.
Unexpected Outcomes and Related Interventions	
<p>1. Fluid and electrolyte imbalances, including FVD, FVE, and abnormal serum electrolyte levels.</p> <ul style="list-style-type: none"> • Notify health care provider. • Readjust infusion rate based on health care provider order. • Adjust additives in type of IV fluid as ordered. <p>2. IV-related complications including infiltration, phlebitis, local infection, air embolus and bleeding.</p> <ul style="list-style-type: none"> • See Table 42.12 	
<p>3. Catheter occlusion can occur from bent catheter, positional catheter (catheter resting against catheter wall), kink or knot in infusion tubing, clot formation, or precipitate formation from administration of incompatible medications or solutions (Gorski, 2018).</p> <ul style="list-style-type: none"> • Determine cause and consider catheter removal. • Positional catheters can be repositioned to improve IV flow. • Remove occluded IV catheter. Occluded catheters should not be flushed because an embolus can result from dislodging a clot (Gorski, 2018). 	
<p>4. Catheter-related infection can present as redness, swelling around or above IV site, pain, purulent drainage at insertion site, and body temperature elevations (INS, 2016a).</p> <ul style="list-style-type: none"> • Notify health care provider. Obtain order to culture drainage (INS, 2016a). • Remove IV catheter and culture purulent drainage from around IV site (see Chapter 48) (INS, 2016a). 	
 <p data-bbox="358 1423 516 1440">STEP 23 Loop and secure tubing.</p>	 <p data-bbox="1065 1230 1192 1247">STEP 24 Label IV dressing.</p>

Table Continued

Step	Rationale
Recording and Reporting	
<ul style="list-style-type: none"> Record number of attempts at insertion; date and time of insertion; type of solution and additives infusing; precise description of insertion site; catheter gauge, type, length and brand; rate and method of infusion (e.g., gravity or name of EID); purpose of infusion; patient's response to insertion (e.g., what he or she reports); and when infusion was started. Always complete entry with full signature and credentials. After each shift, document patient's status, IV fluid infusing, amount infused, and integrity and patency of system. Record and report signs or symptoms of observed or patient-reported IV-related complications (e.g., redness, tenderness, swelling, drainage, leaking from under dressing, change in flow rate, or infection). Document your evaluation of patient learning. Report to health care provider any adverse events occurring upon VAD placement (e.g., persistent pain or suspected nerve damage, hematoma formation, or arterial puncture). Report to health care provider any signs or symptoms of complications. 	
Home Care Considerations	
<ul style="list-style-type: none"> Ensure that patient is able and willing to self-administer IV therapy or that a reliable family caregiver will provide IV therapy at home. Teach patient and family caregiver information needed to administer IV therapy safely (see Box 42.8). Consider their cultural norms (e.g., health beliefs and comfort with caregivers using touch). 	

Skill 42.2. • Regulating Intravenous Flow Rate Delegation and Collaboration

The skill of regulating IV flow rates cannot be delegated to assistive personnel (AP). Delegation to licensed practical nurses (LPNs) varies by state Nurse Practice Act. The nurse instructs the AP to:

- Inform the nurse when the EID alarm signals.
- Inform the nurse when the fluid container is near completion.
- Report any patient complaints of discomfort related to infusion such as pain, burning, bleeding, or swelling.

Equipment

- Watch with a second hand
- Calculator, paper, and pencil/pen
- Label
- IV solution bag and appropriate administration set
- EID, IV regulating device
- Clean gloves

Step	Rationale
Assessment	
1. Review accuracy and completeness of health care provider order in patient's medical record for patient name, type and volume of IV fluid, additives, infusion rate, and duration of IV therapy. Follow seven rights of medication administration.	Ensures administration of correct IV fluid at proper rate. IV fluids are medications. The seven rights prevent medication administration error.
2. Review medical record and identify patient risk for fluid and electrolyte imbalance given type of IV solution (e.g., neonate, history of cardiac or renal disease).	Helps prioritize assessments. Volume control needs to be strict. Guides choice of infusion device.
3. Perform hand hygiene and apply clean gloves.	Reduces risk of contamination (INS, 2016b).
4. Check infusion system from solution container down to vascular access device (VAD) insertion site for integrity.	Identifies complications that can compromise integrity of VAD and patient safety.
a. Assess IV container for discoloration, cloudiness, leakage, and expiration date.	Incompatibility of solutions or medications compromises integrity of VAD and patient safety (Gorski, 2018).
b. Assess IV tubing for puncture, contamination, or occlusion.	Compromised tubing results in fluid leakage and bacterial contamination.
5. Assess the integrity, patency, and functioning of the existing VAD (according to agency policy). Assess the VAD catheter-skin junction site and surrounding area for catheter-related complications by visually inspecting and palpating through the intact dressing for redness, tenderness, swelling, and drainage.	Identifies complications that compromise integrity of VAD and necessitate replacement of VAD.
6. Remove and dispose of gloves and perform hand hygiene.	Reduces risk of contamination (INS, 2016b).
7. Assess patient's and family caregiver's knowledge, experience, and health literacy regarding how positioning of IV site affects flow rate.	Ensures patient or family caregiver has the capacity to obtain, communicate, process, and understand basic health information (CDC, 2019b).
Planning	
1. Prepare and organize equipment	
a. Gather paper and pencil or calculator to calculate flow rate.	Calculating hourly flow rates ensures that the prescribed amount of fluid to be infused over the prescribed time frame is correct.
b. Check medical order to see how long each liter of fluid should infuse. If hourly rate (mL/hr) is not provided in order, calculate it by dividing volume by hours. For example:	Basis of calculation to ensure infusion of solution over prescribed hourly rate.
Table Continued	

Step	Rationale
Clinical Decision: It is common for health care providers to write an abbreviated IV order such as "D ₅ W with 20 mEq KCl 125 mL/hr continuous." This order implies that IV infusion should be maintained at this rate until an order has been written for IV infusion to be discontinued or changed to another order.	
c. If keep-vein-open (KVO) rate is ordered, check agency policy regarding flow rate.	Prevents catheter clotting, thus preserving venous access while infusing a minimal amount of fluid. An order for KVO rate must specify an infusion rate as required by the seven rights of medication administration (seeChapter 31). Rates may vary from 0.5 mL/hr to 30 mL/hr based on type of VAD, patient-specific therapy, and method of infusion (gravity or EID).
d. Use hourly rate to program EID (see Implementation) or, if gravity-flow infusion, use minute flow rate (drops per minute; gtt/min).	EID automatically delivers correct minute flow rate. Gravity infusion requires calculation of gtt/min.
e. Know calibration (drop factor), in drops per milliliter (gtt/mL) of infusion set used by agency.	Drop factor for macrodrip tubing varies with manufacturer.
(1) <i>Microdrip</i> :60 gtt/mL: used to deliver rates less than 100 mL/hr.	Microdrip tubing universally delivers 60 gtt/mL. Used when small or precise volumes are ordered.
(2) <i>Macrodrip</i> :10 or 15 gtt/mL: used to deliver rates greater than 100 mL/hr.	These are different commercial parenteral administration sets for macrodrip tubing. Used when large volumes or fast rates are necessary. Know drip factor for tubing being used.
f. Select one of the following formulas to calculate minute flow rate (drops/min) based on drop factor of infusion set:	Formulas compute correct flow rate over 1 minute.
(1) mL/hr/60 min = mL/min	
Drop factor × mL/min = gtt/min	
Or	
(2) mL/hr × drop factor/60 min = gtt/min	
g. Calculate minute flow rate for a bag of 1000 mL with 20 mEq of KCl at 125 mL/hr:	Once you determine hourly rate, these formulas compute the correct flow rate.
<i>Microdrip</i> :	When using microdrip, mL/hr always equals gtt/min.
<i>Macrodrip</i> :	Multiply hourly rate (mL/hr) by drop factor and divide product by 60 to convert hours to minutes.
2. Explain/instruct patient and family caregiver on reasons for ongoing IV therapy.	Provides patient and family caregiver with information about procedure and promotes adherence (INS, 2016a).
Implementation	
1. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy. Compare identifiers with information on patient's MAR or medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2020).
Clinical Decision: Manual and mechanical flow-control devices may be used for infusions that do not require strict rate control (INS, 2016b). Fluids run by gravity are adjusted through use of a flow control/regulator. Manual flow regulators (i.e., roller clamp, dial, or barrel-shaped) are not recommended for use in infants and children because accuracy cannot be guaranteed (Alexander et al., 2014; Gorski, 2018) and can be affected by mechanical and patient factors. A calibrated chamber is a volume-controlled flow regulator that uses gravity to deliver only a limited amount of solution. It is placed between the IV container and the insertion spike and drip chamber of an administration set. Mechanical infusion devices (i.e., elastomeric devices, piston-driven pumps) regulate infusion rates with no outside power source (Alexander et al., 2014).	
2. Regulategravityinfusion.	
a. Ensure that IV container is at least 76.2 cm (30 inches) above IV site for adults and increase height for more viscous fluids (Alexander et al., 2014).	Pressure caused by gravity is necessary to overcome venous pressure and resistance from tubing and catheter.

Table Continued

Step	Rationale
b. Slowly open roller clamp on tubing until you can see drops in drip chamber. Hold a watch with second hand at same level as drip chamber and count drip rate for 1 minute (see illustration). Adjust roller clamp to increase or decrease rate of infusion.	Regulates flow to prescribed rate.
c. Monitor drip rate at least hourly.	Many factors influence drip rate; frequent monitoring ensures IV fluid administration as prescribed.
<p>Clinical Decision: An electronic infusion device (EID) uses positive pressure to maintain correct flow rates and catheter patency to deliver a measured amount of fluid over a prescribed period of time (e.g., 100 mL/hr). Infusion pumps are needed for patients requiring low hourly rates, at risk for volume overload, with impaired renal function, or receiving solutions or medications that require a specific hourly volume. EIDs use an electronic sensor and an alarm that signals if pressure in the system changes and the desired flow rate changes. Many EIDs have operating and programming capabilities that allow for infusions of single or multiple solutions at different rates. Various detectors and alarms respond to air in IV lines, completion of infusion, high and low pressure, low battery power, occlusion, and the inability to deliver at a preset rate. The use of an EID still requires you to check to ensure that the pump is functioning and infusing at the prescribed rate.</p>	
3. Regulate EID (infusion pump or smart pump): Follow manufacturer guidelines for setup of EID. Be sure you are using infusion tubing compatible with EID.	Smart pumps with medication safety software are designed for administration of IV fluids that contain medications.
a. Close roller clamp on primed IV infusion tubing. Roller clamp on IV tubing goes between EID and patient.	Prevents fluid leakage.
b. Insert infusion tubing into chamber of control mechanism (see manufacturer directions) (see illustration).	Most EIDs use positive pressure to infuse. Infusion pumps propel fluid through tubing by compressing and milking IV tubing.
c. Secure part of IV tubing through "air in line" alarm system. Close door (see illustration A) and turn on power button, select required drops per minute or volume per hour, close door to control chamber, and press start button (see illustration B). If infusing medication, access the smart pump drug library of medications and set appropriate rate and dose limits. If smart pump alarms immediately and shuts down, your settings were outside unit parameters.	Ensures safe administration of ordered flow rate or medication dose. Smart pumps require additional information such as patient unit and medication. Computer matches pump setting against a drug database and dose error reduction systems (DERSs) provide a means for decreasing IV medication administration errors (Wolf, 2018).
<p>Clinical Decision: An anti-free-flow safeguard (preventing bolus infusion in the event of machine malfunction or when tubing is removed from machine) is an important element of an EID and is required. Always check and follow manufacturer recommendations for specific device features (Alexander et al., 2014; Gorski, 2018).</p>	
d. Open roller clamp on infusion tubing to wide open while EID is in use.	Ensures that pump freely regulates infusion rate.
e. Monitor infusion rate and IV site for complications according to agency policy. Use watch to verify rate of infusion, even when using EID.	Flow controllers and pumps do not replace frequent, accurate nursing evaluation. EIDs can continue to infuse IV solutions after a complication has developed (INS, 2016a).
f. Assess IV system from container to VAD insertion site when alarm signals.	Alarm indicates situation that requires attention. Empty solution container, tubing kinks, closed clamp, infiltration, clotted catheter, air in tubing, and/or low battery can trigger EID alarm.

Step	Rationale

STEP 28 Nurse counting drip rate on gravity infusion.

Step

Rationale

STEP 38 Insert IV tubing into chamber of control mechanism.

Table Continued

Step	Rationale
4. Attach label to IV solution container with date and time container is changed (check agency policy).	Provides reference to determine next time for container change, especially with keep vein open (KVO) rate that contains a specific infusion rate as ordered by health care provider.
5. Teach patient purpose of EID if infusion therapy is delivered by EID, purpose of alarms, to avoid raising hand or arm that affects flow rate, and to avoid touching control clamp.	Information allows patient to protect IV site and informs him or her about rationale for not altering control rate.
6. Dispose of any used supplies. Remove and dispose of gloves and perform hand hygiene.	Reduces risk of contamination (INS, 2016b).
7. Assist patient to a comfortable position and instruct how to move and turn without dislodging VAD.	Prevents accidental dislodgment of catheter and minimizes risk for falls.
8. Raise bed rails (as appropriate) and lower bed to lowest position.	Minimizes risk for falls and injury.
9. Be sure nurse call system is in an accessible location within patient's reach. Instruct patient in its use.	Ensures patient can call for assistance if needed.
Evaluation	
1. Observe patient every 1 to 2 hours (see agency policy), noting volume of IV fluid infused, rate of infusion.	Ensures delivery of prescribed volume over prescribed time and decreases risk for fluid and electrolyte imbalance.
2. Evaluate patient's response to therapy (e.g., laboratory values, input and output [I&O], weights, vital signs, postprocedure assessments).	Provides ongoing evaluation of patient's fluid status, including monitoring for FVE or FVD. Early recognition of complications leads to prompt treatment.
3. Evaluate patient with a short-peripheral IV at least every 4 hours, or every 1 to 2 hours for patients who are critically ill, sedated, or have cognitive deficits (INS, 2016a), or at established intervals per agency policy and procedure. Evaluate IV site for signs and symptoms of IV-related complications.	Prevents complications that compromise integrity of VAD or cause inaccurate IV solution flow rate.
4. Use Teach-Back: "I want to be sure that I explained the importance of your IV fluids running on time at the rate ordered. Tell me what you think may cause the pump to alarm and what you would do." Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly.	Determines patient's/family caregiver's level of understanding of instructional topic.
Unexpected Outcomes and Related Interventions	

Step	Rationale
1. Solution does not infuse at prescribed rate. a. Sudden infusion of large volume of solution occurs; patient develops dyspnea, crackles in lung, dependent edema (edema in legs), and increased urine output.	

indicating FVE.

- Slow infusion rate: KVO rates must have specific rate ordered by health care provider.
- Notify health care provider immediately.
- Place patient in high-Fowler's position.
- Anticipate new IV orders.
- Anticipate administration of oxygen per order.
- Administer diuretics if ordered.

STEP 3C A, Roller clamp in open position. B, Roller clamp in closed position.

Step	Rationale
<p>b. IV solution runs slower than ordered.</p> <ul style="list-style-type: none"> • Check for positional change that affects rate, height of IV container, kinking of tubing, or obstruction. • Check VAD site for complications. • Consult health care provider for new order to provide necessary fluid volume. 	
<p>2. IV is no longer patent.</p> <ul style="list-style-type: none"> • Discontinue present IV infusion and restart new short-peripheral catheter in new site. 	
Recording and Reporting	
<ul style="list-style-type: none"> • Record type and rate of infusion in milliliters per hour (drops per minute in gravity flow) in patient's medical record and any ordered change in fluid rates, rate of infusion, and volume left in infusion. Document use of EID. • Document your evaluation of patient learning. • Report at end of shift current IV flow rate and status of IV site. • Report to provider any signs or symptoms of IV rate-related complication (e.g., fluid and electrolyte imbalances). 	
Home Care Considerations	
<ul style="list-style-type: none"> • Ensure that patient or family caregiver is able and willing to operate infusion pump and administer IV therapy. Assess for any visual or physical limitations with ability to connect and disconnect infusion therapy and problem solve infusion pump malfunction (Alexander et al., 2014). • Home care nurse should be in the home during initiation of infusion therapy to ensure correct pump settings for solution, rate, time, and alarms. The nurse ensures that EID functions properly before use and that patient's electrical outlets are properly grounded. • Provide a 24-hour access telephone number for patient to call for assistance. 	

Skill 42.3. Maintenance Of Intravenous System Delegation and Collaboration

The skill of changing an IV fluid container and tubing cannot be delegated to assistive personnel (AP). Delegation to licensed practical nurses (LPNs) varies by state Nurse Practice Act. Instruct the AP to:

- Inform the nurse when an IV container is near completion.
- Report any cloudiness or precipitate in the IV solution.
- Report any alarm sounding on electronic infusion device (EID).
- Report any patient complaints of discomfort related to infusion such as pain, burning, bleeding, or swelling.
- Report any leakage from or around the IV tubing.
- Report if tubing has become contaminated (lying on the floor).
- Protect the IV dressing during hygiene and activities of daily living (ADL)

Equipment

- Handheld bar code scanner if using bar code system to charge supplies.

Changing Intravenous Container

- Correct volume and type of solution (with additives if indicated) as ordered by health care provider
- Time tape
- Pen

Changing Infusion Tubing

- Clean gloves
- Antiseptic swabs (alcoholic chlorhexidine solution preferred, 70% alcohol, or povidone-iodine)
- Tubing label
- Sterile 2 × 2–inch gauze pads(*optional*)

Continuous IV Infusion

- Microdrip or macrodrip administration set as appropriate
- Add-on device as necessary (e.g., filters, extension set, needleless connector)

Intermittent Extension Set

- Syringe prefilled with preservative-free 0.9% sodium chloride (normal saline [NS]) (INS, 2016a)
- Short extension tubing (if necessary), injection cap

Discontinuing Peripheral IV Access

- Clean gloves
- Sterile 2 × 2– or 4 × 4–inch gauze pad

- Antiseptic swab (alcoholic chlorhexidine solution preferred)
(INS, 2016a)
- Tape

Step	Rationale
Assessment	
1. Review accuracy and completeness of health care provider's order in patient's medical record for patient name and correct solution: type, volume, additives, rate, and duration of IV therapy. Follow seven rights of medication administration.	Ensures delivery of correct IV solution and prescribed volume over prescribed time (INS, 2016a).
2. Check medical record for pertinent laboratory data such as potassium level.	Compare data with baseline to determine ongoing response to IV solution administration.
3. Determine compatibility of all IV solutions and additives by consulting approved online database, drug reference, or pharmacist.	Incompatibilities cause physical, chemical, and therapeutic changes with adverse patient outcomes (Alexander et al., 2014).
4. Perform hand hygiene and apply clean gloves.	Reduces risk of contamination and cross-contamination (INS, 2016b).
5. Note labels on tubing for date and time when IV tubing were last changed.	Ensures correct timing of tubing changes. Decreases risk for infection.
6. Check infusion system from solution container down to vascular access device (VAD) insertion site for integrity.	Identifies complications that can compromise integrity of VAD and patient safety.
a. Assess IV container for discoloration, cloudiness, leakage, and expiration date.	Incompatibility of solutions or medications compromises integrity of VAD and patient safety (Gorski, 2018).
b. Assess IV tubing for puncture, contamination, or occlusion.	Compromised tubing results in fluid leakage and bacterial contamination.
Clinical Decision: If the tubing and/or IV bag becomes damaged, is leaking, or becomes contaminated, it must be changed, regardless of the tubing change schedule. If there has been a break in the integrity of the solution container, a new container is needed (Gorski, 2018).	
7. Determine when dressing on VAD was last changed. Ensure label includes date and time applied, size and type of VAD, and insertion date.	Provides information regarding length of time dressing has been in place and allows planning for dressing change (see Skill 42.4).
8. Assess the integrity, patency and functioning of the existing VAD (check agency policy). Assess the VAD catheter-skin junction site and surrounding area for catheter-related complications by visually inspecting and palpating through the intact dressing for redness, tenderness, swelling, and drainage.	Identifies complications that compromise integrity of VAD and necessitate replacement of VAD.
9. Remove and dispose of gloves and perform hand hygiene.	Reduces risk of contamination (INS, 2016b).
10. Assess patient's and family caregiver's knowledge, experience and health literacy regarding protection of IV site, need to change tubing, or reason for discontinuing IV.	Ensures patient and family caregiver have the capacity to obtain, communicate, process, and understand basic health information (CDC, 2019).
Planning	
1. Close room door or bedside curtains. Remove clutter from the over-bed or bedside table.	Provides privacy. Prepares the setting for the procedure.
2. Perform hand hygiene. Collect and organize equipment on clean, over-bed or bedside table.	Reduces transmission of microorganisms. Keeps procedure organized and provides patient safety.
a. Have next solution prepared at least 1 hour before needed. If prepared in pharmacy, ensure that it has been delivered to patient care unit. Check that solution is correct and properly labeled. Allow solution to warm to room temperature if refrigerated. Follow seven rights of medication administration and verify solution expiration date. Observe for precipitate, discoloration, and leakage.	Adequate planning for changing solution reduces risk of clot formation at catheter tip caused by lack of flow from an empty IV container. Checking that a solution is correct prevents medication error (INS, 2016a).
b. Verify correct administration set for the type of infusion and the electronic infusion device (EID). Coordinate IV tubing changes with solution changes when possible.	Ensures patient safety. Decreasing the number of times the system is open reduces the transmission of infection and contamination of equipment (INS, 2016a).
3. Assist patient to a comfortable position.	Promotes comfort and relaxation.
4. Explain to patient/family member procedure, its purpose, and what is expected of patient. <i>For discontinuing peripheral IV access:</i> Explain that patient must hold extremity still; that he or she may feel burning sensation when you remove catheter; and that procedure will take about 5 minutes.	Provides patient and family caregiver with information about procedure and promotes adherence (INS, 2016a). May also minimize anxiety.
Implementation	
1. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy. Compare identifiers with information on patient's MAR or medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (NPSG, 2020).
2. Changing IV fluid container	Patients receiving intravenous therapy periodically require changes of IV solutions or containers depending on the rate of infusion, volume in the container, and stability of the solution or medication (INS, 2016b). It becomes clinically appropriate to change the type of solution, depending on a patient's fluid and electrolyte balance, response to therapy (e.g., therapeutic drug monitoring), and goals of therapy.

Table Continued

Step	Rationale
<p>a. Change solution when fluid remains only in neck of container (about 50 mL) or when new type of solution has been ordered.</p>	<p>A container is changed when there is an order for a new solution or when it becomes time to add a sequential container to avoid exceeding hang time (Alexander et al., 2014). Prevents waste of solution.</p>
<p>Clinical Decision: <i>The maximum hang time for routine replacement of IV containers is established by agency policy and procedure. Maximum hang time is based upon factors such as the use of strict aseptic technique, whether the system remains closed without injection ports or add-on tubing, stability of the solution or medication being infused, and how long the solution in the IV container will last (Gorski, 2018). It is recommended that each container be changed within 24 hours after the administration set is added (INS, 2016b). Solution and medication containers on ambulatory infusion devices may remain longer than 24 hours if aseptic technique is used, the system remains closed without injection ports or add-on tubing, and the medication is stable for the anticipated infusion time (Gorski, 2018).</i></p>	
<p>b. Perform hand hygiene.</p>	<p>Reduces transmission of microorganisms.</p>
<p>c. Prepare new solution for changing. If using plastic bag, hang on IV pole and remove protective cover from IV tubing port. If using glass bottle, remove metal cap and metal and rubber disks.</p>	<p>Solution and medication containers include plastic bags, plastic bottles, and glass bottles. Permits quick, smooth, organized change from old to new container.</p>
<p>d. Close roller clamp on existing solution to stop flow rate. Remove IV tubing from EID (if used). Then remove old IV solution container from IV pole. Hold container with tubing port pointing upward.</p>	<p>Prevents solution remaining in drip chamber from emptying while changing solutions. Prevents solution in bag from spilling.</p>
<p>e. Quickly remove spike from old solution container and, without touching tip, insert spike into new container (see illustrations).</p>	<p>Reduces risk for solution in drip chamber becoming empty and maintains sterility.</p>
<p>Clinical Decision: <i>If spike becomes contaminated by touching an unsterile object, you will need a new IV tubing set.</i></p>	
<p>f. Hang new container of solution on IV pole.</p>	<p>Gravity helps with delivery of fluid into drip chamber.</p>
<p>g. Check for air in IV tubing. If air bubbles have formed, remove them by closing roller clamp, stretching tubing downward, and tapping tubing with finger (bubbles rise in fluid to drip chamber) (see Skill 42-1, Step 3h).</p>	<p>Reduces risk of air entering tubing. Use of an air-eliminating filter also reduces risk.</p>
<p>h. Make sure that drip chamber is one-third to one-half full. If drip chamber is too full, level can be decreased by removing bag from IV pole, pinching off IV tubing below drip chamber, inverting container, squeezing drip chamber (see illustration), releasing and turning solution container upright, and releasing pinch on tubing.</p>	<p>Reduces risk for air entering IV tubing. If chamber is filled, you cannot observe or regulate drip rate.</p>
<p>i. Regulate flow to ordered rate by opening and adjusting roller clamp on IV tubing or by opening roller clamp and programming and turning on EID.</p>	<p>Maintains measures to restore fluid balance and deliver IV solution as ordered.</p>
<p>j. Place time label on side of container and label with time hung, time of completion, and appropriate intervals. If using plastic bags, mark only on label and not container.</p>	<p>Provides visual comparison of volume infused compared with prescribed rate of infusion.</p>
<p>k. Instruct patient on purpose of new IV solution, additives, flow rate, potential side effects, how to avoid occluding tubing, and what to report.</p>	<p>Information informs patient about purpose for continued IV therapy and what to report and protects VAD patency.</p>

STEP 2E A, Remove spike from old solution container. B, Without touching tip, insert spike into new container.

Step

Rationale

STEP 24 Squeeze drip chamber to fill with fluid. Be sure to leave chamber one-third to one-half full.

Table Continued

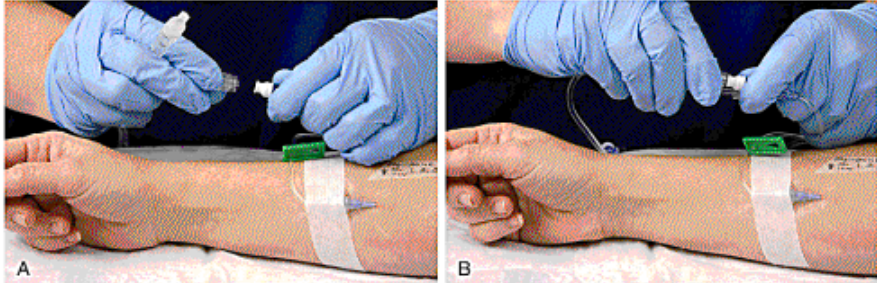

Step	Rationale
3. Changing infusion tubing	
Clinical Decision: Administration sets are the primary method to carry a solution or medication to a patient. These administration sets are considered the primary set. In addition, patients may have add-on devices (e.g., filters, extension sets), which you connect to the primary set as indicated by the prescribed therapy. Secondary sets may be used as a method to administer additional medications in conjunction with the primary infusion (e.g., antibiotics). Follow agency policy and procedures for specific requirements.	
a. Perform hand hygiene. Open new infusion set and connect add-on pieces (e.g., filters, extension tubing) using aseptic technique. Keep protective coverings over infusion spike and distal adapter. Place roller clamp about 2–2.5 cm (1–2 inches) below drip chamber and move roller clamp to “off” position. Secure all connections.	Close proximity of roller clamp to drip chamber allows more accurate regulation of flow rate. Securing connections reduces risk later of air emboli and infection. Protective covers reduce entrance of microorganisms. All connections should be of Luer-Lok type (INS, 2016a).
b. Apply clean gloves. If patient’s IV cannula hub is not visible, remove IV dressing as described in Skill 42.4. Do not remove tape securing cannula to skin.	Cannula hub must be visible to provide smooth transition when removing old and inserting new tubing.
c. To prepare IV tubing with new IV infusion bag (see Skill 42.1, Step 3). Use sterile technique.	
d. Prepare IV tubing with existing continuous IV infusion bag.	
(1) Move roller clamp on new IV tubing to “off” position.	Prevents fluid spillage.
(2) Slow rate of infusion through old tubing to keep vein open (KVO) rate using EID or roller clamp.	Prevents occlusion of VAD.
(3) Compress and fill drip chamber of old tubing.	Ensures that drip chamber remains full until new tubing is changed.
(4) Invert container and remove old tubing. Keep spike sterile and upright.	Solution in drip chamber will continue to run and maintain catheter patency.
(5) Insert spike of new infusion tubing into solution container. Hang solution bag on IV pole, compress drip chamber on new tubing, and release, allowing it to fill one-third to one-half full.	Permits drip chamber to fill and promotes rapid, smooth flow of solution through tubing.
(6) Prime air out of IV tubing by filling with IV solution: Remove protective cover on end of tubing and slowly open roller clamp to allow solution to flow from drip chamber to distal end of IV tubing. If tubing has Y connector, invert Y connector when solution reaches it to displace air. Return roller clamp to “off” position after priming tubing (filled with IV solution). Replace protective cover on end of IV tubing. Place end of adapter near patient’s IV site.	Priming ensures that IV tubing is clear of air before connection with VAD and filled with IV solution. Slow fill of tubing decreases turbulence and chance of bubble formation. Closing clamp prevents accidental loss of fluid. Maintains sterility. Equipment is positioned for quick connection of new tubing.
(7) Stop EID or turn roller clamp on old tubing to “off” position.	Prevents fluid spillage. Prepares EID for insertion of new tubing.
e. Prepare tubing with extension set or saline lock.	Placement of a short extension tubing or loop between a catheter hub and injection cap allows manipulation of the injection cap without moving the catheter.
Clinical Decision: The extension tubing remains attached to the short-peripheral catheter and is changed when the catheter is changed.	
(1) If short extension tubing is needed, use sterile technique to connect new injection cap to new extension set or IV tubing.	Prepares extension set for connecting with IV.
(2) Scrub injection cap with antiseptic swab for at least 15 seconds and allow to dry completely. Attach syringe with 3 to 5 mL of NS flush solution and inject through injection cap into extension set.	Ensures effective disinfection (INS, 2016a). Maintains patency of catheter.
f. Reestablish infusion.	
(1) Gently disconnect old tubing from extension tubing (or from IV catheter hub) and quickly insert Luer-Lok end of new tubing or saline lock into extension tubing connection (or IV catheter hub) (see illustrations for example of connecting tubing to short extension set).	Allows smooth transition from old to new tubing, minimizing time that system is open.
	
STEP 39(1) A, Disconnect old tubing. B, Insert adapter of new tubing.	

Table Continued

Step	Rationale
(2) For continuous infusion, open roller clamp on new tubing and regulate drip rate using roller clamp, or insert tubing into EID, program to desired rate, and push the power button on.	Ensures catheter patency and prevents occlusion.
(3) Attach piece of tape or preprinted label with date and time of IV tubing change onto tubing below drip chamber.	Provides reference to determine next time for tubing change.
(4) Form loop of tubing and secure it to patient's arm with strip of tape.	Avoids accidental pulling against site and stabilizes catheter.
(5) If necessary, apply new dressing (Skill 42.4).	Maintains integrity of VAD site.
Clinical Decision: You may need to assist patients with many aspects of hygiene (e.g., gown changes, bathing) while patients are receiving IV therapy. Never disconnect infusion tubing to change a gown or any article of clothing. Coordinate care so that bathing or hygiene activities are done after discontinuing an IV site and before another venipuncture is performed. If infusion cannot be discontinued, use special "IV gowns" if available.	
4. Discontinuing peripheral IV access	
a. Perform hand hygiene. Apply clean gloves.	Reduces transmission of microorganisms.
b. Observe existing IV site for signs and symptoms of IV-related complications (redness, pain, tenderness, swelling, bleeding, drainage, or leaking from under dressing). Palpate catheter site through intact dressing.	Identifies the need for postprocedure interventions, such as warm compress to site.
c. Assess whether patient is receiving an anticoagulant or has a history of a coagulopathy.	Requires an increase in the time needed to apply pressure to puncture site following catheter removal.
d. Turn off EID and close roller clamp or, if no EID, close roller clamp that controls rate.	Prevents spillage of IV fluid.
e. Remove IV site dressing and catheter engineered stabilization device (see Skill 42.4). Do not use scissors. Avoid tearing patient's skin.	Exposes catheter with minimal discomfort. Scissors might accidentally damage catheter or injure patient (INS, 2016a).
f. Stabilize IV catheter hub and clean site with antiseptic swab. Allow to dry completely.	Removes secretions around skin puncture site.
g. Place clean sterile gauze above insertion site and, using dominant hand, withdraw catheter using a slow, steady motion, keeping the hub parallel to the skin (see illustration). Do not raise or lift catheter before it is completely out of vein. Inspect end of catheter, being sure it is intact after removal.	Dry pad causes less irritation to puncture site. Removal technique avoids trauma to vein or hematoma formation. Inspection determines whether catheter tip is intact. Tip of catheter can break off and embolize, which is an emergency situation.
h. Keep gauze in place and apply continuous pressure to site for 30 seconds or until bleeding has stopped.	Controls bleeding and hematoma formation. Pressure should be applied until hemostasis occurs (INS, 2016a).
Clinical Decision: If patient receives anticoagulants or platelet inhibitors (e.g., low-dose aspirin, warfarin sodium [Coumadin], heparin) or has a low platelet count, apply steady pressure longer (for 5 to 10 minutes) and assess bleeding.	
i. Apply sterile folded gauze dressing over insertion site and secure with tape.	Maintains pressure to prevent bleeding and reduces bacterial entry into puncture site.
5. Dispose of any used supplies. Remove and dispose of gloves and perform hand hygiene.	Reduces transmission of microorganisms (INS, 2016a).
6. Assist patient to a comfortable position and instruct how to move and turn properly with VAD.	Prevents accidental dislodgment of IV catheter.
7. Raise bed rails (as appropriate) and lower bed to lowest position.	Minimizes risk for falls and injury.
8. Be sure nurse call system is in an accessible location within patient's reach. Instruct patient in its use.	Ensures patient can call for assistance if needed.

Step	Rationale

STEP 4G Remove IV catheter slowly, keeping catheter parallel to vein.

Table Continued

Step	Rationale
Evaluation	
1. Observe patient with a short-peripheral IV at least every 4 hours, or every 1 to 2 hours for patients who are critically ill, sedated, or have cognitive deficits (INS, 2016a), or at established intervals per agency policy and procedure for:	Ensures delivery of infusion therapy as ordered.
a. Correct type and amount of solution infused	Ensures delivery of prescribed volume over prescribed time and decreases risk for fluid and electrolyte imbalance.
b. Leaking at connection sites	Minimizes risk of infection caused by breach in system integrity.
c. Function, intactness, and patency of IV system	Validates that IV line is patent and functioning correctly. Manipulation of catheter and tubing may affect rate of infusion.
d. IV-related complications by visually inspecting and gently palpating skin around and above IV site through the intact dressing	Identifies complications that compromise integrity of VAD or cause inaccurate IV solution flow rate.
2. Evaluate patient to determine response to therapy (e.g., laboratory values, input and output [I&O], weights, vital signs, postprocedure assessments).	Provides ongoing evaluation of patient's fluid status.
3. Monitor patient for signs of ECV excess, ECV deficit, or signs and symptoms of electrolyte imbalances.	Early recognition of complications leads to prompt treatment.
4. Use Teach-Back: "We talked about the importance of your IV solutions running as prescribed. I want to be sure I explained this clearly. Tell me in your own words what you should do if you notice that the IV is not dripping or you notice leaking." Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly.	Determines patient's/family caregiver's level of understanding of instructional topic.
5. For discontinuing short-peripheral IV access:	
a. Observe site for bleeding soon after procedure and redness, tenderness, drainage, or swelling during a later evaluation.	Detects bleeding after catheter removal. Detects local infection or postinfusion phlebitis (INS, 2016a).
b. Use Teach-Back: "I want to be sure I explained why I removed the IV. Please tell me why you no longer need an IV." Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly.	Determines patient's/family caregiver's level of understanding of instructional topic.
Unexpected Outcomes and Related Interventions	
<p>1. Flow rate is incorrect; patient receives too little or too much solution.</p> <ul style="list-style-type: none"> • Notify health care provider if patient's anticipated infusion is 100 to 200 ml. less than or greater than anticipated (per agency policy and procedure). • Evaluate patient for signs and symptoms of adverse effects of infusion (e.g., ECV excess or deficit). • Consult health care provider for new order to provide necessary fluid volume. • Check for positional IV site and reposition catheter; apply new dressing if necessary. • Check IV catheter for loss of patency or dislodgment; catheter may require replacement. • Check VAD site for complications. 	
<p>2. Leaking occurs at IV connection.</p> <ul style="list-style-type: none"> • Determine site of leaking and secure connection. • Apply new dressing if necessary (see Skill 42.4). 	
Table Continued	

Step	Rationale
3. IV catheter is removed or dislodged accidentally.	<ul style="list-style-type: none"> Restart new short-peripheral IV line in other extremity or above previous insertion site if continued therapy is necessary (see Skill 42.1).
4. Catheter tip is missing after withdrawal.	<ul style="list-style-type: none"> Apply tourniquet high on extremity to restrict mobility of catheter embolus. Immediately notify health care provider.
Recording and Reporting	
<ul style="list-style-type: none"> Record solution and tubing changes, type of infusion solution including any additives, volume of container, and rate of infusion. Record time of discontinuing solution or IV medication. Record time that peripheral IV access was discontinued, site assessment information, and status of catheter, including gauge, length, and catheter tip integrity. Document your evaluation of patient learning. Report details of tubing and/or equipment change or discontinuing of IV. Report any complications, treatments; report any changes in IV catheter, tubing, and IV fluid type and rate. 	
Home Care Considerations	
<ul style="list-style-type: none"> Ensure that patient is able and willing to self-manage IV therapy (including changing IV containers) or that reliable family caregiver is at home to provide IV care. Instruct patient or family caregiver in procedure for performing an IV solution and tubing change. Consider their cultural norms (e.g., health beliefs and comfort with caregivers using touch). Instruct patient or caregiver to notify health care provider if bleeding or drainage is noted at insertion site or if pain or tenderness occurs up to 4 days after catheter removal. 	

Skill 42.4. Changing A Short-Peripheral Intravenous Dressing

Delegation and Collaboration

The skill of changing a short-peripheral intravenous (IV) dressing cannot be delegated to assistive personnel (AP). Delegation to licensed practical nurses (LPNs) varies by state Nurse Practice Act. Instruct the AP to:

- Report to the nurse if a patient indicates moistness or loosening of an IV dressing.
- Protect the IV dressing during hygiene and activities of daily living (ADLs).

Equipment

- Antiseptic swabs (alcoholic chlorhexidine solution preferred [INS, 2016a], 70% alcohol, or povidone-iodine)
- Adhesive remover(*optional*)
- Polymer-based skin protectant swab(*optional*)
- Clean gloves
- Engineered catheter stabilization device if available or precut strips of sterile nonallergic tape

- Commercially available IV site protector device (see Step 8, *optional*)
- Sterile transparent semipermeable membrane (TSM) dressing or sterile 2 × 2-inch gauze pads and tape

Step	Rationale
Assessment	
<p>1. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy. Compare identifiers with information on patient's MAR or medical record.</p>	<p>Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2020).</p>
<p>2. Determine agency policy regarding peripheral IV dressing changes. Transparent (TSM) dressings usually remain in place until IV site is changed unless dressing becomes wet, visibly soiled, or loose, and at least every 5-7 days. Gauze dressings may be changed every 2 days.</p>	<p>Dressing change increases risk of catheter displacement and is performed only if dressing is compromised or every 5-7 days for transparent dressings or every 2 days for gauze dressings (INS, 2016a).</p>
<p>3. Perform hand hygiene. Observe present dressing for moisture and intactness. Determine whether moisture is from site leakage or external source.</p>	<p>Moisture is a medium for bacterial growth and contaminates dressing. Loose dressing increases risk for bacterial contamination of venipuncture site or displacement of vascular access device (VAD).</p>
Table Continued	

Step	Rationale
4. Observe IV system for proper functioning or complications (see Skill 42.3). Apply clean gloves if dressing is moist. Palpate VAD site through intact dressing, assessing for pain or burning.	Unexplained decrease in flow rate requires investigating VAD placement and patency. Pain is associated with both phlebitis and infiltration.
5. Assess patient's and family caregiver's knowledge, experience and health literacy regarding the needed for continued IV therapy.	Ensures patient and family caregiver has the capacity to obtain, communicate, process, and understand basic health information (CDC, 2019b).
Planning	
1. Close room curtains or door. Prepare environment by removing clutter from bedside and overbed table.	Provides privacy. Prepares environment for efficient procedure.
2. Perform hand hygiene. Collect and organize equipment on clean over-bed or bedside table.	Reduces transmission of microorganisms. Keeps procedure organized and provides patient safety.
3. Explain procedure and purpose to patient and family. Explain that patient must hold affected extremity still and how long procedure will take.	Decreases anxiety, promotes cooperation, and gives patient time frame around which to plan personal activities.
Implementation	
1. Perform hand hygiene and apply clean gloves.	Reduces transmission of microorganisms.
2. Remove existing dressing.	
a. For TSM dressing: Stabilize catheter with nondominant hand (see illustration). Use alcohol swab on edges of TSM dressing next to patient's skin. Remove dressing by pulling up one corner and gently pulling straight out and parallel to skin. Repeat on all sides until dressing has been removed.	Prevents accidental displacement of VAD. Technique minimizes discomfort during removal. Use of alcohol swab loosens dressing.
b. For gauze dressing: Stabilize catheter hub while loosening tape and removing old dressing one layer at a time by pulling toward insertion site. Be cautious if tubing becomes tangled between two layers of dressing.	
3. Assess VAD insertion site for signs and symptoms of IV-related complications (Tables 42.12 to 42.14). If complication exists, determine whether VAD requires removal. Remove catheter if ordered by health care provider (see Skill 42.3).	Presence of complication may require VAD removal.
4. If catheter is to remain in place, assess integrity of engineered stabilization device. Continue to stabilize catheter and remove as recommended by manufacturer directions for use. Inspect for adhesive residue or signs of adhesive-related skin injury from adhesive-based engineered stabilization devices. <i>Note:</i> Some stabilization devices are designed to remain in place for length of time VAD is in as long as adequate stabilization is evident.	Removing stabilization device allows for appropriate skin antisepsis before applying dressing and new stabilization device (INS, 2016a).
<i>Clinical Decision:</i> Keep one finger stabilizing VAD at all times until dressing secures catheter hub. This requires careful planning regarding placing and opening supplies and how to work with one hand. If patient is restless or uncooperative, it is helpful to have another staff member help with procedure.	
5. While stabilizing IV line, use adhesive remover to remove adhesive residue if needed. Then perform skin antisepsis to insertion site with antiseptic wipe using friction in back-and-forth motion for 30 seconds; allow to dry completely. If using alcohol or povidone-iodine, clean in concentric circle, moving from insertion site outward with the swab (see illustration). Allow antiseptic solution to dry completely.	Adhesive residue decreases ability of new tape to adhere securely to skin. Skin antisepsis reduces incidence of catheter-related infections (Alexander, et al., 2014). Allow any skin antiseptic agent to fully dry for complete antisepsis (INS, 2016a).
6. <i>Option:</i> Apply skin protectant to area where you will apply tape, dressing, or engineered stabilization device. Allow to dry.	Coats skin with protective solution to maintain skin integrity, prevents irritation from adhesive, and promotes adherence of dressing.
7. While stabilizing VAD, apply new sterile dressing over site (procedures differ; follow agency policy).	Prevents accidental dislodgment of catheter and protects site from infection (INS, 2016a).
<i>Clinical Decision:</i> Because adhesive Band-Aids are not occlusive and nonsterile tape increases the risk for insertion site infection, do not use either over catheter insertion points.	
a. <i>TSM dressing:</i> Apply as directed in Skill 42.1, Step 19a.	Occlusive dressing protects site from bacterial contamination (INS, 2016a).
b. <i>Gauze dressing:</i> Apply as directed in Skill 42.1, Step 19b.	Less frequently used than transparent dressing.

Table Continued

Step	Rationale
8. <i>Option:</i> Apply polymer-based site protection device (e.g., I.V. House UltraDressing®) or other protective device over area if patient may pick at or bump dressing (see illustration).	Site-protection devices include vented plastic or stretch netting coverings and mitts for hands. Designed to reduce risk of phlebitis, infiltration, or catheter displacement from mechanical motion.
9. Anchor extension tubing or IV tubing alongside dressing on arm, and secure with tape directly over tubing. When using TSM dressing, avoid placing tape over dressing.	Prevents accidental dislodgment of VAD or tubing. More frequent dressing changes due to dislodgment are associated with greater risk of infection (INS, 2016a).
10. Label dressing per agency policy. Label information should include date and time of original IV insertion, VAD gauge and length, and your initials.	Communicates type of device and time interval for dressing change.
11. Dispose of any used supplies. Remove and dispose of gloves and perform hand hygiene.	Reduces transmission of microorganisms (INS, 2016a).
12. Assist patient to a comfortable position and instruct how to move and turn properly with VAD.	Prevents accidental dislodgment of IV catheter.
13. Raise bed rails (as appropriate) and lower bed to lowest position.	Minimizes risk for falls and injury.
14. Be sure nurse call system is in an accessible location within patient's reach. Instruct patient in its use.	Ensures patient can call for assistance if needed.
Evaluation	
1. Observe new dressing to be sure that it is applied, taped, and labeled properly.	Validates quality of completed dressing change.
2. Ensure that flow rate is accurate.	Validates that IV line is patent and functioning correctly. Manipulation of catheter and tubing may affect rate of infusion.

STEP 2A Remove transparent semipermeable membrane (TSM) dressing by pulling side laterally.
Courtesy I.V. House, St. Louis, MO

Step	Rationale

STEP 5 Cleanse peripheral insertion site with antiseptic swab.

STEP 8 I.V. House protective device.

Table Continued

Step	Rationale
<p>3. Use Teach-Back: "I want to be sure I explained why I changed your IV dressing. Tell me why I needed to change your dressing." Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly.</p>	<p>Determines patient's/family caregiver's level of understanding of instructional topic.</p>
<p>Unexpected Outcomes and Related Interventions</p>	
<p>1. VAD is accidentally dislodged or removed.</p> <ul style="list-style-type: none"> • Start new IV line in other extremity or proximal to previous insertion site if continued therapy is necessary. <p>2. IV site develops infiltration, phlebitis, and local infection.</p> <ul style="list-style-type: none"> • See Table 42.12. 	
<p>Recording and Reporting</p>	
<ul style="list-style-type: none"> • Record time that peripheral dressing was changed, reason for change, type of dressing material used, patency of system and IV infusion rate, and description of venipuncture site. • Document any complication of VAD. • Document your evaluation of patient learning. • Report to charge nurse or oncoming nursing shift that dressing was changed and any significant information about integrity of system. • Report any complications to health care provider. 	

Key Points

- Body fluids containing water, Na⁺, and other electrolytes are distributed between ECF and ICF compartments.
- The interplay of fluid intake (thirst, habit, social aspects, nonoral routes), fluid distribution (filtration and osmosis), and fluid output (skin, lungs, GI tract, kidneys) determines the location, volume, and osmolality of body fluid.
- Fluid moves between blood vessels and interstitial fluid by filtration; water moves between ECF and ICF by osmosis.
- The relationship of electrolyte intake and absorption; electrolyte distribution between plasma, cells, and bones; and electrolyte output determines the plasma concentrations of potassium, calcium, magnesium, and phosphate ions.
- Acid production is a product of cellular metabolism. Acid-base imbalances are excesses or deficits of carbonic or metabolic acids.
- ECV deficit and excess are abnormal *volumes* of isotonic fluid in the vascular and interstitial compartments.
- Plasma electrolyte imbalances (e.g., potassium, sodium, calcium, and magnesium) affect body electrolyte content and/or abnormal distribution of electrolytes.
- Risk factors for fluid, electrolyte, and acid-base imbalances include factors that alter the regulatory mechanisms, such as age (very young or very old), environmental factors,

increases in gastrointestinal output, chronic diseases, trauma, and therapies such as medications or IV infusions.

- Clinical assessments for ECV imbalances include sudden changes in body weight and markers of vascular and interstitial volume.
- The osmolality imbalances hyponatremia and hypernatremia manifest as decreased level of consciousness and abnormal serum Na^+ levels.
- Potassium imbalances manifest as bilateral muscle weakness, cardiac dysrhythmias, and abnormal serum K^+ levels.
- Calcium and magnesium imbalances manifest as altered neuromuscular excitability and abnormal serum Ca^{++} or Mg^{++} levels.
- Acid-base imbalances manifest as changes in level of consciousness, abnormal breathing patterns, and abnormalities of PaCO_2 , HCO_3^- , and pH.
- During initiation and maintenance of intravenous therapy, nurses maintain sterility and patency of the system by following safety guidelines and making clinical decisions regarding assessment, organized planning with appropriate equipment, skillful implementation of procedural steps, evaluation of outcomes, and careful recording and reporting.
- Nurses monitor vigilantly and take immediate appropriate action for complications of intravenous therapy, which include circulatory overload of the IV solution, infiltration

and extravasation, phlebitis, local infection, air embolism, and bleeding at the insertion site.

- Blood and blood products must be matched to each patient to avoid incompatibility. Administration involves patient safety steps and use of special equipment, careful monitoring, and rapid knowledgeable action in case of transfusion reaction or other acute adverse events.
- Evaluation of interventions for specific fluid, electrolyte, and acid-base imbalances requires comparison of current clinical signs and symptoms and laboratory status with previous findings, discussion of patient concerns and expectations, and evaluation of patient learning about prevention and treatment of their fluid, electrolyte, or acid-base imbalances.

Reflective Learning

- Consider a patient experience and describe concepts of fluid, electrolyte, and acid-base homeostasis and imbalances that you applied.
- Think about a recent patient and describe that person's risk factors for fluid, electrolyte, and acid-base imbalances.
- Given your clinical setting, what environmental, organizational, or other factors did you see that influence patient intake or output of fluid and electrolytes?

Review Questions

1. An intravenous (IV) fluid is infusing slower than ordered. The infusion pump is set correctly. Which factors could cause this slowing? (Select all that apply.)
 1. Infiltration at vascular access device (VAD) site
 2. Patient lying on tubing
 3. Roller clamp wide open
 4. Tubing kinked in bedrails
 5. Circulatory overload
2. The nurse assesses pain and redness at a vascular access device (VAD) site. Which action is taken first?
 1. Apply a warm, moist compress.
 2. Aspirate the infusing fluid from the VAD.
 3. Report the situation to the health care provider.
 4. Discontinue the intravenous infusion.
3. When delegating input and output (I&O) measurement to assistive personnel, the nurse instructs them to record what information for ice chips?
 1. Two-thirds of the volume
 2. One-half of the volume
 3. One-quarter of the volume
 4. Two times the volume
4. What assessments does a nurse make before hanging an intravenous (IV) fluid that contains potassium? (Select all that apply.)
 1. Urine output
 2. Arterial blood gases
 3. Fullness of neck veins

4. Serum potassium laboratory value in EHR
5. Level of consciousness
5. The health care provider's order is 500 mL 0.9% NaCl intravenously over 4 hours. Which rate does the nurse program into the infusion pump?
 1. 100 mL/hr
 2. 125 mL/hr
 3. 167 mL/hr
 4. 200 mL/hr
6. An older-adult patient is receiving intravenous (IV) 0.9% NaCl. The nurse detects new onset of crackles in the lung bases. What is the priority action?
 1. Notify a health care provider.
 2. Decrease the IV flow rate.
 3. Lower the head of the bed.
 4. Discontinue the IV site.
7. Place the following steps for discontinuing intravenous (IV) access in the correct order:
 1. Perform hand hygiene and apply gloves.
 2. Explain procedure to patient.
 3. Remove IV site dressing and tape.
 4. Use two identifiers to ensure correct patient.
 5. Stop the infusion and clamp the tubing.
 6. Carefully check the health care provider's order.
 7. Clean the site, withdraw the catheter, and apply pressure.

8. A patient has hypokalemia with stable cardiac function. What are the priority nursing interventions? (Select all that apply.)

1. Fall prevention interventions
2. Teaching regarding sodium restriction
3. Encouraging increased fluid intake
4. Monitoring for constipation
5. Explaining how to take daily weights

9. A patient is admitted to the hospital with severe dyspnea and wheezing. Arterial blood gas levels on admission are pH 7.26; PaCO₂, 55 mm Hg; PaO₂, 68 mm Hg; and HCO₃⁻, 24. How does the nurse interpret these laboratory values?

1. Metabolic acidosis
2. Metabolic alkalosis
3. Respiratory acidosis
4. Respiratory alkalosis

10. Which assessment does the nurse use as a clinical marker of vascular volume in a patient at high risk of extracellular fluid volume (ECV) deficit?

1. Dryness of mucous membranes
2. Skin turgor
3. Fullness of neck veins when supine
4. Fullness of neck veins when upright

Sleep

OBJECTIVES

- Explain the effects that the 24-hour sleep-wake cycle has on biological function.
- Discuss mechanisms that regulate sleep.
- Explain the stages of a normal sleep cycle.
- Explain the functions of sleep.
- Compare and contrast the sleep requirements of different age-groups.
- Identify factors that normally promote and disrupt sleep.
- Discuss characteristics of common sleep disorders.
- Conduct a sleep history for a patient.
- Identify nursing interventions designed to promote normal sleep cycles for patients of all ages.
- Explain ways to evaluate the effects of sleep therapies.

Proper rest and sleep are as important to health as good nutrition and adequate exercise. Physical and emotional health depend on the ability to fulfill these basic human needs. Individuals need different amounts of sleep and rest. Without proper amounts, the ability to concentrate, make judgments, and participate in daily activities decreases, and irritability increases.

Identifying and treating patients' sleep pattern disturbances are important goals. To help patients you need to understand the nature of sleep, the factors influencing it, and patients' sleep habits. Patients require individualized approaches based on their personal habits, patterns of sleep, and the particular problem influencing sleep. Nursing interventions are often effective in resolving short- and long-term sleep disturbances.

Sleep provides healing and restoration ([Huether et al., 2017](#)). Achieving the best possible sleep quality is important for the promotion of good health and recovery from illness. Patients who are ill often require more sleep and rest than patients who are healthy. However, the nature of illness often prevents some patients from getting adequate rest and sleep. The environment of a hospital or long-term care facility and the activities of health care personnel often make sleep difficult. Some patients have preexisting sleep disturbances; others develop sleep problems because of an illness or hospitalization.

Scientific Knowledge Base

Physiology of Sleep

Sleep is a cyclical physiological process that alternates with longer periods of wakefulness. The sleep-wake cycle influences and regulates physiological function and behavioral responses.

Circadian Rhythms

People experience cyclical rhythms as part of their everyday lives. The most familiar rhythm is the 24-hour, day-night cycle known as the diurnal or **circadian rhythm** (derived from Latin: *circa*, “about,” and *dies*, “day”). The suprachiasmatic nucleus (SCN) nerve cells in the hypothalamus control the rhythm of the sleep-wake cycle and coordinate this cycle with other circadian rhythms (Huether et al., 2017). Circadian rhythms influence the pattern of major biological and behavioral functions. The predictable changing of body temperature, heart rate, blood pressure, hormone secretion, sensory acuity, and mood depend on the maintenance of the 24-hour circadian cycle (Kryger et al., 2017).

Factors such as light, temperature, social activities, and work routines affect circadian rhythms and daily sleep-wake cycles. All people have **biological clocks** that synchronize their sleep cycles. This explains why some people fall asleep at 8 PM, whereas others go to bed at midnight or early in the morning. Different people also function best at different times of the day.

Hospitals or extended-care centers usually do not adapt care to an individual’s sleep-wake cycle preferences. Typical hospital routines interrupt sleep or prevent patients from falling asleep at their usual time. Poor quality of sleep results when a person’s sleep-wake cycle changes. Reversals in the sleep-wake cycle, such as when a person who is normally awake during the day falls asleep during the day, sometimes indicate a serious illness.

The biological rhythm of sleep frequently becomes synchronized with other body functions. For example, changes in body temperature correlate with sleep patterns. Normally body temperature peaks in the afternoon, decreases gradually, and drops sharply after a person falls asleep. When the sleep-wake cycle becomes disrupted (e.g., by working rotating shifts), other physiological functions usually change as well. For example, a new nurse who starts working the night shift experiences a decreased appetite and loses weight. Anxiety, restlessness, irritability, and impaired judgment

are other common symptoms of sleep cycle disturbances. Failure to maintain an individual's usual sleep-wake cycle negatively influences a patient's overall health.

Sleep Regulation

Sleep involves a sequence of physiological states maintained by highly integrated central nervous system (CNS) activity. It is associated with changes in the peripheral nervous, endocrine, cardiovascular, respiratory, and muscular systems (Huether et al., 2017). Specific physiological responses and patterns of brain activity identify each sequence. Instruments such as the electroencephalogram (EEG), which measures electrical activity in the cerebral cortex; the electromyogram (EMG), which measures muscle tone; and the electrooculogram (EOG), which measures eye movements provide information about some structural physiological aspects of sleep.

The major sleep center in the body is the hypothalamus. It secretes hypocretins (orexins) that promote wakefulness and rapid eye movement (REM) sleep. Prostaglandin D₂, L-tryptophan, and growth factors control sleep (Huether et al., 2017).

Researchers believe that the ascending reticular activating system (RAS) located in the upper brainstem contains special cells that maintain alertness and wakefulness. The RAS receives visual, auditory, pain, and tactile sensory stimuli. Activity from the cerebral cortex (e.g., emotions or thought processes) also stimulates the RAS. Arousal, wakefulness, and maintenance of consciousness result from neurons in the RAS releasing catecholamines such as norepinephrine (Kryger et al., 2017).

Current evidence suggests two processes help to regulate sleep/wake cycles. The homeostatic process (Process S), which primarily regulates the length and depth of sleep; and the circadian rhythms (Process C: "biological time clocks"), which influence the internal organization of sleep and the timing and duration of sleep-wake cycles, operate simultaneously to regulate sleep and wakefulness (Kryger et al., 2017). Time of wake up is defined by the intersection of Process S and Process C (Fig. 43.1).

FIG. 43.1 Two-process model of sleep regulation shows the time course of the homeostatic process (*Process S*) and the circadian process (*Process C*). *Process S* rises during waking and declines during sleep. The intersection of *Process S* and *Process C* defines the time of wake-up.

From Daroff RB, et al: *Bradley's neurology in clinical practice*, ed 7, Philadelphia, 2016, Elsevier.

Stages of Sleep

There are two sleep phases: **nonrapid eye movement (NREM) sleep** and **rapid eye movement (REM) sleep** (Box 43.1). In the classical definition of NREM sleep, people progress through four stages during a typical 90-minute sleep cycle. The American Academy of Sleep Medicine defines three stages in NREM sleep, combining stages 3 and 4 (Kryger et al., 2017). The quality of sleep from stage 1 through stage 4 becomes increasingly deep. Lighter sleep is characteristic of stages 1 and 2, when a person is more easily arousable. Combined stages 3 and 4 involve a deeper sleep called slow-wave sleep, from which a person is more difficult to arouse (Kryger et al., 2017). REM sleep is the phase at the end of each 90-minute sleep cycle. During REM sleep there is increased brain activity associated with rapid eye movements and muscle atonia.

Box 43.1 Stages of the Sleep Cycle

NREM, Nonrapid eye movement; *REM*, rapid eye movement.

NREM (75% of Night)

N1 (Formerly Stage 1)

- Stage of lightest level of sleep, lasting a few minutes.
- Decreased physiological activity begins with gradual fall in vital signs and metabolism.
- Sensory stimuli such as noise easily arouse sleeper.
- If awakened, person feels as though daydreaming has occurred.

N2 (Formerly Stage 2)

- Stage of sound sleep during which relaxation progresses.
- Arousal is still relatively easy.
- Brain and muscle activity continue to slow.

N3 (Formerly Stages 3 and 4)

- Called slow-wave sleep.
- Deepest stage of sleep.
- Sleeper is difficult to arouse and rarely moves.
- Brain and muscle activity are significantly decreased.
- Vital signs are lower than during waking hours.

REM Sleep (25% of Night)

- Vivid, full-color dreaming occurs.
- Stage usually begins about 90 minutes after sleep has begun.
- Stage is typified by autonomic response of rapidly moving eyes, fluctuating heart and respiratory rates, and increased or fluctuating

blood pressure.

- Loss of skeletal muscle tone occurs.
- Gastric secretions increase.
- It is very difficult to arouse sleeper.
- Duration of REM sleep increases with each cycle and averages 20 minutes.

Data from American Sleep Association: *What is sleep?* 2017, <https://sleepassociation.org/patients-general-public/what-is-sleep>, accessed July 29, 2018.; Kryger M, et al: *Principles and practice of sleep medicine*, 6e, St Louis, 2017, Elsevier; National Sleep Foundation: *What happens when you sleep?* 2018, <https://sleepfoundation.org/how-sleep-works/what-happens-when-you-sleep>, accessed July 29, 2018.

Sleep Cycle

Normally an adult's routine sleep pattern begins with a presleep period during which the person is aware only of a gradually developing sleepiness. This period normally lasts 10 to 30 minutes. Individuals who have trouble falling asleep often remain in this stage for an hour or more. Once asleep a person usually passes through four to six complete sleep cycles, each cycle consisting of three stages of NREM sleep and a period of REM sleep, for a total of 90 to 110 minutes (Huether et al., 2017).

With each successive cycle, stage 3 (combined 3 and 4) of NREM sleep shortens, and REM sleep lengthens. REM sleep lasts up to 60 minutes during the last sleep cycle. Not all people progress consistently through the usual stages of sleep. For example, a sleeper fluctuates back and forth for short intervals between NREM stages 2, and 3 before entering REM sleep. The amount of time spent in each stage varies. The number of sleep cycles depends on the total amount of time that the person spends sleeping.

Functions of Sleep

Sleep functions as a time of restoration, memory consolidation, and preparation for the next period of wakefulness (Huether et al., 2017). During NREM sleep biological functions slow. A healthy adult's heart rate decreases from a normal average of 70 to 80 beats/min to 60 beats/min or less during sleep, thus preserving cardiac function. Other biological

functions that decrease during sleep are respirations, temperature, blood pressure, and muscle tone (Kryger et al., 2017).

Sleep restores biological processes. During NREM stage 3 sleep, the body releases human growth hormone for the repair and renewal of epithelial and specialized cells such as brain cells (Huether et al., 2017). Protein synthesis and cell division for the renewal of tissues also occur during rest and sleep. The basal metabolic rate lowers during sleep, which conserves the energy supply of the body (Huether et al., 2017).

REM sleep appears to be important for early brain development, cognition, and memory. Researchers associate REM sleep with changes in the brain, including cerebral blood flow and increased cortical activity. In addition, there is increased oxygen consumption and epinephrine release. These changes are associated with memory storage and learning (Huether et al., 2017).

The benefits of sleep often go unnoticed until a person develops a problem resulting from sleep deprivation. Current estimates show that 50 million to 70 million adults in the United States have some type of sleep-wake problem (American Sleep Association, 2018). Sleep deprivation affects immune function, metabolism, nitrogen balance, and protein catabolism. A loss of REM sleep often leads to confusion and suspicion. Prolonged sleep loss alters various body functions (e.g., mood, motor performance, memory, equilibrium) (National Sleep Foundation, 2018b). Individuals with sleep problems are also more likely to have chronic diseases such as hypertension, diabetes, and obesity. They sometimes also experience poorer quality of life and productivity (Kohansieh and Makaryus, 2015). Millions of health care dollars are spent on indirect costs related to sleep deprivation, such as motor vehicle and industrial accidents, litigation, property damage, hospitalization, medical errors, and death (Liu et al., 2016).

Dreams

Although dreams occur during both NREM and REM sleep, the dreams of REM sleep are more vivid and elaborate, and some believe that they are functionally important to learning, memory processing, and adaptation to stress (Kryger et al., 2017). REM dreams progress in content throughout the night from dreams about current events to emotional dreams of childhood or the past. Personality influences the quality of dreams (e.g., a creative person has elaborate and complex dreams, whereas a depressed person dreams of helplessness).

Most people dream about immediate concerns such as an argument with a spouse or worries over work. Sometimes a person is unaware of fears represented in bizarre dreams. Clinical psychologists try to analyze the symbolic nature of dreams as part of a patient's psychotherapy. The ability to describe a dream and interpret its significance sometimes helps resolve personal concerns or fears.

Another theory suggests that dreams erase certain fantasies or nonsensical memories. Because most people forget their dreams, few have dream recall or do not believe they dream at all. To remember a dream, a person has to consciously think about it on awakening. People who recall dreams vividly usually awake just after a period of REM sleep.

Physical Illness

Any illness that causes pain, physical discomfort, or mood problems such as anxiety or depression often results in sleep problems. People with such alterations frequently have trouble falling or staying asleep. Illnesses also force patients to sleep in unfamiliar positions. For example, it is difficult for a patient with an arm or leg in traction to rest comfortably.

Respiratory disease also interferes with sleep. Patients with chronic lung disease such as emphysema are short of breath and frequently cannot sleep without two or three pillows to raise their heads. Asthma, bronchitis, and allergic rhinitis alter the rhythm of breathing and disturb sleep. A person with a common cold has nasal congestion, sinus drainage, and a sore throat, which impair breathing and the ability to relax.

Connections among heart disease, sleep, and sleep disorders exist. Sleep-related breathing disorders are linked to increased incidence of nocturnal angina (chest pain), increased heart rate, electrocardiogram changes, high blood pressure, and risk of heart diseases and stroke (Huether et al., 2017). Hypertension often causes early-morning awakening and fatigue. Research also identifies an increased risk of sudden cardiac death in the first hours after awakening. Sleep disruptions and frequent arousals occur in people with heart failure because of the apnea, hypercapnia, and hypoxemia that develop as the disease progresses (Kryger et al., 2017). Hypothyroidism decreases the last sleep stage, whereas hyperthyroidism causes people to take more time to fall asleep.

Nocturia, or urination during the night, disrupts sleep and the sleep cycle. After repeated awakenings to urinate, returning to sleep is difficult, and the sleep cycle is incomplete. Although this condition is most common in older people with reduced bladder tone or people with cardiac disease,

diabetes, urethritis, or prostatic disease, it also occurs in a significant number of younger people (Madhu et al., 2015).

Many people experience restless legs syndrome (RLS), which occurs before sleep onset. More common in women, older people, and those with iron deficiency anemia, RLS symptoms include recurrent, rhythmical movements of the feet and legs. Patients feel an itching sensation deep in the muscles. Relief comes only from moving the legs, which prevents relaxation and subsequent sleep. RLS is sometimes a relatively benign condition, depending on how severely sleep is disrupted. Primary RLS is a CNS disorder. Researchers associate secondary RLS with lower levels of iron, pregnancy, renal failure, stress, diet, Parkinson's disease, or a side effect of drugs (Rizek and Kumar, 2017).

Researchers have found a relationship between sleep and gastrointestinal diseases. People with peptic ulcer disease often awaken in the middle of the night. Studies showing a relationship between gastric acid secretion and stages of sleep are conflicting. One consistent finding is that people with duodenal ulcers fail to suppress acid secretion in the first 2 hours of sleep (Kryger et al., 2017). The challenge to researchers is to determine whether sleep disruption impacts gastrointestinal problems such as gastroesophageal reflux and irritable bowel disease or if the diseases disrupt the sleep cycle (Parekh et al., 2018).

Sleep Disorders

Sleep disorders are conditions that, if untreated, generally cause disturbed nighttime sleep that results in one of three problems: insomnia, abnormal movements or sensation during sleep or when waking up at night, or excessive daytime sleepiness (EDS) (Kryger et al., 2017). Many adults in the United States have significant sleep problems from inadequacies in either the quantity or quality of their nighttime sleep and experience **hypersomnolence** daily (National Sleep Foundation, 2018d). Sleep disorders are more common in children and adolescents with either neurologic conditions or neurodevelopmental disabilities (Maski and Owens, 2018). The American Academy of Sleep Medicine developed the International Classification of Sleep Disorders version 2 (ICSD-2), which classifies sleep disorders into eight major categories (Box 43.2).

Box 43.2 Classification of Select Sleep Disorders

REM, Rapid eye movement.

Insomnias

- Adjustment sleep disorder (acute insomnia)
- Inadequate sleep hygiene
- Behavioral insomnia of childhood
- Insomnia caused by medical condition

Sleep-Related Breathing Disorder Central Sleep Apnea Syndromes

- Primary central sleep apnea
- Central sleep apnea caused by medical condition
- Obstructive sleep apnea syndromes

Hypersomnias of Central Origin (Not Caused by a Sleep-Related Breathing Disorder)

- Narcolepsy (four specified types)
- Menstrual-related hypersomnia
- Hypersomnia caused by a medical condition

Parasomnias

Disorders of Arousal

- Sleepwalking
- Sleep terrors

Parasomnias Usually Associated With REM Sleep

- Nightmare disorder
- REM sleep-behavior disorder

Other Parasomnias

- Sleep-related hallucinations
- Sleep-related eating disorder
- Sleep-related enuresis (bed-wetting)

Circadian Rhythm Sleep Disorders

Primary Circadian Rhythm Sleep Disorders

- Delayed–sleep phase type
- Advanced–sleep phase type

Behaviorally-Induced Circadian Rhythm Sleep Disorders

- Jet lag type
- Shift work type
- Drug or substance use

Sleep-Related Movement Disorders

- Restless legs syndrome
- Periodic limb movements
- Sleep-related bruxism (teeth grinding)

Isolated Symptoms, Apparently Normal Variants, and Unresolved Issues

- Long sleeper
- Short sleeper
- Sleep talking

Other Sleep Disorders

- Physiological (organic) sleep disorders
- Environmental sleep disorder

Data from American Academy of Sleep Medicine: International classes of diseases and international classification of sleep disorders. In Kryger HM, et al: *Principles and practice of sleep medicine*, ed 6, St Louis, 2016, Saunders; and Thorpy MJ: Classification of sleep disorders, *Neurotherap* 9 (4): 687, 2012.

Insomnia disorders are related to difficulty falling asleep, frequently awaking from sleep, short periods of sleep, or sleep that is nonrestorative (Kryger et al., 2017). Individuals with sleep-related breathing disorders have changes in respirations during sleep. Hypersomnias are sleep disturbances that result in daytime sleepiness and are not caused by disturbed sleep or alterations in circadian rhythms (Kryger et al., 2017). The circadian rhythm sleep disorders are caused by a misalignment between the timing of sleep and individual desires or the societal norm. The parasomnias are undesirable behaviors that occur usually during sleep. Sleep and wake disturbances are associated with many medical and psychiatric sleep disorders, including psychiatric, neurological, or other medical disorders. In sleep-related movement disorders the person experiences simple stereotyped movements that disturb sleep. The category of “isolated symptoms, apparently normal variants, and unresolved issues” includes sleep-related symptoms that fall between normal and abnormal sleep. The “other sleep disorders” category contains sleep problems that do not fit into other categories.

Sleep laboratory studies diagnose a sleep disorder. A **polysomnogram** involves the use of EEG, EMG, and EOG to monitor stages of sleep and wakefulness during nighttime sleep. The Multiple Sleep Latency Test (MSLT) provides objective information about sleepiness and selected aspects of sleep structure by measuring eye movements, muscle-tone changes, and brain electrical activity during at least four napping opportunities spread throughout the day. The MSLT takes 8 to 10 hours to complete. Patients wear an Actigraph device on the wrist to measure sleep-wake patterns over an extended period of time such as one week. Actigraphy data provide information about sleep time, sleep efficiency, number and duration of awakenings, and levels of activity and rest. An

increasingly popular alternative, particularly among younger adults, is the use of technology in the form of sleep apps for smartphones (Adams et al., 2017). Further study of these sleep apps needs to be conducted to validate the accuracy of measurement of sleep (Lorenz and Williams, 2017).

Insomnia

Insomnia is a symptom that patients experience when they have chronic difficulty in falling asleep, frequent awakenings from sleep, and/or a short sleep or nonrestorative sleep (Kryger et al., 2017). It is the most common sleep-related complaint, with up to 30% of adults suffering from the problem (Haynes et al., 2018). It is commonly experienced by individuals diagnosed with depression (Trauer et al., 2015). People with insomnia experience EDS and insufficient sleep quantity and quality. However, frequently a patient gets more sleep than he or she realizes. Insomnia often signals an underlying physical or psychological disorder. It occurs more frequently in and is the most common sleep problem for women.

People experience transient insomnia because of situational stresses such as family, work, or school problems; jet lag; illness; or loss of a loved one. Insomnia sometimes recurs, but between episodes a patient is able to sleep well. However, a temporary case of insomnia caused by a stressful situation can lead to chronic difficulty in getting enough sleep, perhaps because of the worry and anxiety that develop about getting it.

Insomnia is often associated with poor **sleep hygiene**, or practices that a patient associates with sleep (Badin et al., 2016). If the condition continues, the fear of not being able to sleep is enough to cause wakefulness. During the day people with chronic insomnia feel sleepy, fatigued, depressed, and anxious. Treatment is symptomatic, including improved sleep-hygiene measures, biofeedback, cognitive techniques, and relaxation techniques (Chung et al., 2017). Behavioral and cognitive therapies have few adverse effects and show evidence of sustained improvement in sleep over time (Haynes et al., 2018).

Sleep Apnea

Sleep apnea is a disorder in which an individual is unable to breathe and sleep at the same time. There is a lack of airflow through the nose and mouth for periods from 10 seconds to 1 to 2 minutes in length. There are three types of sleep apnea: obstructive; central; and mixed apnea, which has both an obstructive and a central component.

The most common form is obstructive sleep apnea (OSA), which is a cessation or stopping of airflow despite the effort to breathe. It occurs when muscles or soft structures of the oral cavity or throat relax during sleep. The upper airway becomes partially or completely blocked, and nasal airflow diminishes (hypopnea) or stops (apnea). The person tries to breathe because chest and abdominal movements continue, which often results in loud snoring sounds. When breathing is partially or completely diminished, the person becomes sufficiently hypoxic and must awaken to breathe. Structural abnormalities such as a deviated septum, nasal polyps, narrow lower jaw, or enlarged tonsils sometimes predispose a patient to OSA. It is estimated that 10% to 17% of adults in the United States are affected by OSA (Qaseem et al., 2014). However, a large majority of people are undiagnosed and untreated (Kryger et al., 2017).

Obesity and hypertension are major factors in OSA. Smoking, increasing age (greater than 65 years old), heart failure, alcohol, nasopharyngeal structural abnormalities, large neck circumferences, and menopause are increased risks for OSA (Qaseem et al., 2014; Schub, 2016). Some research indicates that there may be a link between OSA and occupations in which the individual is exposed to and breathes in solvents (Schwartz et al., 2017). The risk for OSA is similar among African Americans, Asians, and Caucasians (Kryger et al., 2017).

Central sleep apnea (CSA) involves dysfunction in the respiratory control center of the brain. The impulse to breathe fails temporarily, and nasal airflow and chest wall movement cease. The oxygen saturation of the blood falls. The condition is common in patients with brainstem injury, stroke, obesity, muscular dystrophy, and encephalitis. Less than 10% of sleep apnea is predominantly central in origin. People with CSA tend to awaken during sleep and therefore complain of insomnia and EDS. Mild and intermittent snoring is also present.

Excessive daytime sleepiness (EDS) is a common complaint in people experiencing OSA and CSA. Other common symptoms of OSA include fatigue, morning headaches, irritability, depression, difficulty concentrating, and a decrease in sex drive (Kryger et al., 2017). Untreated sleep apnea increases the risk of hypertension, diabetes, heart disease, and heart failure. Lifestyle changes, including a weight-reduction program in people who are obese, improved sleep hygiene, bilevel positive airway pressure (BPAP or BiPAP), continuous positive airway pressure (CPAP), surgery, and oral repositioning devices for the jaw and tongue, are treatment options for OSA (Rotenberg et al., 2016; Schub, 2016).

OSA causes a serious decline in arterial oxygen saturation level. Patients are at risk for cardiac dysrhythmias, right heart failure, pulmonary hypertension, angina attacks, stroke, and hypertension.

Patients with sleep apnea rarely achieve deep sleep. In addition to complaints of EDS, sleep attacks, fatigue, morning headaches, irritability, depression, difficulty concentrating, and a decrease in sex drive are common (Kryger et al., 2017). OSA affects quality-of-life issues such as marital relationships and interactions within and outside the family and often is an embarrassment to a patient (Campos-Rodriguez et al., 2016). Treatment includes therapy for underlying cardiac or respiratory complications and any emotional problems that occur as a result of the symptoms of this disorder.

Narcolepsy

Narcolepsy is a dysfunction of the processes that regulate sleep and wake states. Excessive daytime sleepiness is the most common complaint associated with this disorder. During the day a person suddenly feels an overwhelming wave of sleepiness and falls asleep; REM sleep occurs within 15 minutes of falling asleep. **Cataplexy**, or sudden muscle weakness during intense emotions such as anger, sadness, or laughter that occurs at any time during the day, is a symptom of narcolepsy type 1, differentiating it from narcolepsy type 2 (Dauvilliers and Barateau, 2017; Maski and Owens, 2018). Cataplexy usually lasts only a few seconds, but if the cataplectic attack is severe, a patient loses voluntary muscle control and falls to the floor (Maski and Owens, 2018). A person with narcolepsy often has vivid dreams that occur as he or she is falling asleep. These dreams are difficult to distinguish from reality. Sleep paralysis, or the feeling of being unable to move or talk just before waking or falling asleep, is another symptom. Some studies show a genetic link for narcolepsy (Dauvilliers and Barateau, 2017).

A person with narcolepsy falls asleep uncontrollably at inappropriate times. When individuals do not understand this disorder, a sleep attack is easily mistaken for laziness, lack of interest in activities, or drunkenness. Typically, the symptoms first begin to appear in adolescence and are often confused with the EDS that commonly occurs in teens. Patients diagnosed with narcolepsy are treated with stimulants or wakefulness-promoting agents such as modafinil, armodafinil, methylphenidate, or sodium oxybate, which only partially increase wakefulness and reduce sleep attacks (Dauvilliers and Barateau, 2017; Maski and Owens, 2018). Patients also receive antidepressant medications that suppress cataplexy and the

other REM-related symptoms. Brief daytime naps no longer than 20 minutes help reduce subjective feelings of sleepiness. Other management methods that help are following a regular exercise program, practicing good sleep habits, avoiding shifts in sleep, strategically timing daytime naps if possible, eating light meals high in protein, practicing deep breathing, chewing gum, and taking vitamins (Kryger et al., 2017). Patients with narcolepsy need to avoid factors that increase drowsiness (e.g., alcohol, heavy meals, exhausting activities, long-distance driving, and long periods of sitting in hot, stuffy rooms).

Sleep Deprivation

Many patients experience **sleep deprivation** because of a sleep disorder. It can be acute or chronic and results from insufficient or disrupted sleep. Causes include illness (e.g., fever, difficulty breathing, or pain), emotional stress, medications, environmental disturbances (e.g., frequent interruptions in sleep during nursing care, noisy neighbors or pets), and variability in the timing of sleep as a result of shift work. Sleep disorders such as sleep apnea or insomnia can cause sleep deprivation.

With sleep deprivation, there is a decrease in the quantity or quality of sleep and/or an inconsistency in the timing of sleep. When sleep becomes interrupted or fragmented, changes in the normal sequencing of the sleep cycles occur. Cumulative sleep deprivation develops over time.

Individuals respond to sleep deprivation differently. Patients experience a variety of physiological and psychological symptoms (Box 43.3). The severity of symptoms is often related to the duration of sleep deprivation. The most effective treatment for sleep deprivation is elimination or correction of environmental factors and patient care activities that disrupt the sleep pattern. Nurses play an important role in identifying treatable sleep-deprivation problems. Evidence suggests that chronic sleep deprivation is associated with obesity, type 2 diabetes, poor memory, depression, digestive problems, and the development of cardiovascular disease (Kohansieh and Makaryus, 2015).

Box 43.3 Sleep-Deprivation Symptoms

Physiological Symptoms	Psychological Symptoms
<ul style="list-style-type: none"> • Ptosis, blurred vision • Fine-motor clumsiness • Decreased reflexes • Slowed response time • Decreased reasoning and judgment • Decreased auditory and visual alertness • Cardiac arrhythmias 	<ul style="list-style-type: none"> • Confused and disoriented • Increased sensitivity to pain • Irritable, withdrawn, apathetic • Agitated • Hyperactive • Decreased motivation • Excessive sleepiness

Parasomnias

The parasomnias are sleep problems that are more common in children than adults and occur during non-REM or REM sleep (Maski and Owens, 2018). Some have hypothesized that sudden infant death syndrome (SIDS) is thought to be related to apnea, hypoxia, and cardiac arrhythmias caused by abnormalities in the autonomic nervous system that are manifested during sleep (Kryger et al., 2017). Because of an association between the prone position and the occurrence of SIDS, the American Academy of Pediatrics (AAP) recommends that parents place apparently healthy infants in the supine position during sleep to reduce the risk of sudden infant death syndrome (AAP, 2016).

Parasomnias that occur among older children include confusional arousals, somnambulism (sleepwalking), night terrors, nightmares, nocturnal enuresis (bed-wetting), body rocking, and bruxism (teeth grinding). Parasomnias in children are usually benign and the child will “outgrow” the problem (Maski and Owens, 2018). When adults have these problems, it often indicates more serious disorders. Specific treatment varies. However, in all cases it is important to support patients and maintain their safety.

REFLECT NOW

Interview a patient with chronic respiratory, renal, or cardiac disease. Discuss how the disease affects their ability to sleep.

Nursing Knowledge Base

Sleep and Rest

When people are at **rest**, they usually feel mentally relaxed, free from anxiety, and physically calm. Rest does not imply inactivity, although everyone often thinks of it as settling down in a comfortable chair or lying in bed. When people are at rest, they are in a state of mental, physical, and spiritual activity that leaves them feeling refreshed, rejuvenated, and ready to resume the activities of the day. People have their own habits for obtaining rest and can find ways to adjust to new environments or conditions that affect the ability to rest. They rest by reading a book, practicing a relaxation exercise, listening to music, taking a long walk, or sitting quietly.

Illness and unfamiliar health care routines easily affect the usual rest and sleep patterns of people entering a hospital or other health care setting. Nurses frequently care for patients who are on bed rest to reduce physical and psychological demands on the body in a variety of health care settings. However, patients on bed rest do not necessarily feel rested. Some experience emotional distress that prevents complete relaxation. For example, concern over physical limitations or a fear of being unable to return to their usual lifestyle causes such patients to feel stressed and unable to relax. You must always be aware of a patient's need for rest. A lack of rest for long periods causes illness or worsening of existing illness.

Normal Sleep Requirements and Patterns

Sleep duration and quality vary among people of all age-groups. For example, one person feels adequately rested with 4 hours of sleep, whereas another requires 10 hours. Nurses play an important role in identifying treatable sleep-deprivation problems.

Neonates

The neonate up to the age of 3 months averages about 16 hours of sleep a day, sleeping almost constantly during the first week. The sleep cycle is generally 40 to 50 minutes with waking occurring after one to two sleep cycles. Approximately 50% of this sleep is REM sleep, which stimulates the higher brain centers. This is essential for development because the neonate is not awake long enough for significant external stimulation.

Infants

Infants usually develop a nighttime pattern of sleep by 3 months of age. The infant normally takes several naps during the day but usually sleeps an average of 8 to 10 hours during the night for a total daily sleep time of 15 hours. About 30% of sleep time is in the REM cycle. Awakening commonly occurs early in the morning, although it is not unusual for an infant to wake up during the night.

Toddlers

By the age of 2 children usually sleep through the night and take daily naps. Total sleep averages 12 hours a day. After 3 years of age children often give up daytime naps ([Hockenberry and Wilson, 2019](#)). It is common for toddlers to awaken during the night. The percentage of REM sleep continues to fall. During this period toddlers may be unwilling to go to bed at night because they need autonomy or fear separation from their parents.

Preschoolers

On average a preschooler sleeps about 12 hours a night (about 20% is REM). By the age of 5 he or she rarely takes daytime naps except in cultures in which a siesta is the custom ([Hockenberry and Wilson, 2019](#)). The preschooler usually has difficulty relaxing or quieting down after long, active days and has bedtime fears, awakens during the night, or has nightmares. Partial awakening followed by normal return to sleep is frequent ([Hockenberry and Wilson, 2019](#)). In the awake period the child exhibits brief crying, walking around, unintelligible speech, sleepwalking, or bed-wetting.

School-Age Children

The amount of sleep needed varies during the school years. A 6-year-old averages 11 to 12 hours of sleep nightly, whereas an 11-year-old sleeps about 9 to 10 hours ([Hockenberry and Wilson, 2019](#)). The 6- or 7-year-old usually goes to bed with some encouragement or by doing quiet activities. The older child often resists sleeping because he or she is unaware of fatigue or has a need to be independent.

Adolescents

On average the majority of teenagers get about 7 hours or less of sleep per night, although the recommended requirement is 8 to 10 hours (Hirschkowitz et al., 2015; National Sleep Foundation, 2018c). The typical adolescent is subject to many changes, such as school demands, after-school social activities, and part-time jobs, which reduce the time spent sleeping (Bruce et al., 2017). Adolescents typically have electronic devices such as televisions, computers, smartphones, or video games in their rooms, which further contribute to sleep disruption, poor sleep quality, and decreased amount of sleep (Bruce et al., 2017; Shimura et al., 2018). Shortened sleep time often results in EDS, which frequently leads to reduced performance in school, vulnerability to accidents, behavioral and mood problems, and increased use of alcohol (Wiggins and Freeman, 2014).

Young Adults

Most young adults average 6 to 8½ hours of sleep a night. Approximately 20% of sleep time is REM sleep, which remains consistent throughout life. It is common for the stresses of jobs, family relationships, and social activities to frequently lead to insomnia, and some may use medication to help them sleep. Daytime sleepiness contributes to an increased number of accidents, decreased productivity, and interpersonal problems in this age-group.

Pregnancy increases the need for sleep and rest. However, a majority of pregnant women describe variations in sleep habits (Erwin, 2017). Sleep disruption occurs due to pregnancy-related hormone changes and the anatomic and physiological changes that occur in the body to maintain the pregnancy (Erwin, 2017). First-trimester sleep disturbances include a reduction in overall sleep time and quality. Daytime drowsiness, insomnia, and nighttime awakenings also increase because of frequent nocturnal voiding. These disturbances level off in the second trimester. Insomnia, periodic limb movements, RLS, and sleep-disordered breathing are common problems during the third trimester of pregnancy (Kryger et al., 2017).

Middle Adults

The recommended sleep requirement for adults is 7 to 9 hours per night (Hirschkowitz et al., 2015). During middle adulthood the total time spent sleeping at night begins to decline. The amount of stage 4 sleep begins to fall, a decline that continues with advancing age. Insomnia is particularly

common, probably because of the changes and stresses of middle age. Anxiety, depression, or certain physical illnesses cause sleep disturbances. Women experiencing menopausal symptoms often experience insomnia.

Older Adults

Sleeping difficulties increase with age. Approximately 40% of older adults report problems with sleep (Kryger et al., 2017; National Sleep Foundation, 2018a). Older adults spend more time in stage 1 and less time in stages 3 and 4 (NREM sleep); some older adults have almost no NREM stage 4 or deep sleep. Episodes of REM sleep tend to shorten. Older adults experience fewer episodes of deep sleep and more episodes of lighter sleep. They tend to awaken more often during the night, and it takes more time for them to fall asleep. To compensate they increase the number of naps taken during the day.

Older adults who have a chronic illness often experience sleep disturbances. For example, an older adult with arthritis frequently has difficulty sleeping because of painful joints. Changes in sleep pattern are often caused by changes in the CNS that affect the regulation of sleep. Many older adults with insomnia have co-morbid psychiatric illness or medical conditions, take medications that disrupt sleep patterns, or use drugs or alcohol. Sensory impairment reduces an older person's sensitivity to time cues that maintain circadian rhythms.

Factors Influencing Sleep

Many factors affect the quantity and quality of sleep. Often a single factor is not the only cause for a sleep problem. Physiological, psychological, and environmental factors frequently alter the quality and quantity of sleep.

Drugs and Substances

Sleepiness, insomnia, and fatigue often result as a direct effect of commonly prescribed medications (Box 43.4). These medications alter sleep and weaken daytime alertness, which is problematic (Kryger et al., 2017). Medications prescribed for sleep often cause more problems than benefits. Older adults take a variety of drugs to control or treat chronic illness, and the combined effects of their drugs often seriously disrupt sleep. Some substances such as L-tryptophan, a natural protein found in foods such as milk, cheese, and meats, promote sleep.

Box 43.4 Drugs and Their Effects on Sleep

REM, Rapid eye movement.

--	--

Lifestyle

A person’s daily routine influences sleep patterns. An individual working a rotating shift (e.g., 2 weeks of days followed by a week of nights) often has difficulty adjusting to the altered sleep schedule. For example, the body’s internal clock is set at 11 PM, but the work schedule forces sleep at 9 AM instead. The individual is able to sleep only 3 or 4 hours because his or her body clock perceives that it is time to be awake and active. Difficulties maintaining alertness during work time result in decreased and even hazardous performance. After several weeks of working a night shift, a person’s biological clock usually does adjust. Other alterations in routines that disrupt sleep patterns include performing unaccustomed heavy work, engaging in late-night social activities, and changing evening mealtime.

Usual Sleep Patterns

In the past century the amount of sleep obtained nightly by US citizens has decreased, causing many Americans to be sleep deprived and to experience excessive sleepiness during the day. Sleepiness becomes pathological when it occurs at times when individuals need or want to be awake. People who experience temporary sleep deprivation as a result of

an active social evening or lengthened work schedule usually feel sleepy the next day. However, they are able to overcome these feelings even though they have difficulty performing tasks and remaining attentive. Chronic lack of sleep is much more serious and causes serious alterations in the ability to perform daily functions. Sleepiness tends to be most difficult to overcome during sedentary (inactive) tasks such as driving. An increasingly common contributor to EDS is the use of technology close to bedtime, such as watching television, talking or texting on a cellphone, or reading information on electronic devices.

Emotional Stress

Worry over personal problems or a situation frequently disrupts sleep. Emotional stress causes a person to be tense and often leads to frustration when sleep does not occur. Stress also causes a person to try too hard to fall asleep, to awaken frequently during the sleep cycle, or to oversleep. Continued stress causes poor sleep habits.

Older patients frequently experience losses that lead to emotional stress such as retirement, physical impairment, or the death of a loved one. Older adults and other individuals who experience depressive mood problems experience delays in falling asleep, earlier appearance of REM sleep, frequent or early waking, feelings of sleeping poorly, and daytime sleepiness.

Environment

The physical environment in which a person sleeps significantly influences the ability to fall and remain asleep. Good ventilation is essential for restful sleep. The size, firmness, and position of the bed affect the quality of sleep. If a person usually sleeps with another individual, sleeping alone often causes wakefulness. On the other hand, sleeping with a restless or snoring bed partner disrupts sleep.

In hospitals and other inpatient facilities, noise creates a problem for patients. Noise in hospitals is usually new or strange and often loud. Thus patients wake easily. This problem is greatest the first night of hospitalization, when patients often experience increased total wake time, increased awakenings, and decreased REM sleep and total sleep time. People-induced noises (e.g., nursing activities) are sources of increased sound levels. ICUs are sources of high noise levels because of staff, monitor alarms, and equipment. Close proximity of patients, noise from confused and ill patients, ringing alarm systems and telephones, and

disturbances caused by emergencies make the environment unpleasant. Noise causes increased agitation, delayed healing, impaired immune function, and increased blood pressure, heart rate, and stress (Patel et al., 2018).

Light levels affect the ability to fall asleep. Some patients prefer a dark room, whereas others such as children or older adults prefer keeping a soft light on during sleep. Patients also have trouble sleeping because of the room temperature. A room that is too warm or too cold often causes a patient to become restless.

Exercise and Fatigue

A person who is moderately fatigued usually achieves restful sleep, especially if the fatigue is the result of enjoyable work or exercise. Exercising 2 hours or more before bedtime allows the body to cool down and maintain a state of fatigue that promotes relaxation. However, excess fatigue resulting from exhausting or stressful work makes falling asleep difficult. This is often seen in grade-school children and adolescents who keep long, stressful schedules because of school, social activities, and work.

Food and Caloric Intake

Following good eating habits is important for proper sleep. Eating a large, heavy, and/or spicy meal at night often results in indigestion that interferes with sleep. Caffeine, alcohol, and nicotine consumed in the evening produce insomnia. Coffee, tea, cola, and chocolate contain caffeine and xanthines that cause sleeplessness. Thus drastically reducing or avoiding these substances can improve sleep. Some food allergies cause insomnia. A milk allergy sometimes causes nighttime waking and crying or colic in infants.

Weight loss or gain influences sleep patterns. Weight gain contributes to OSA because of increased size of the soft tissue structures in the upper airway (Kryger et al., 2017). Weight loss caused by semi-starvation diets sometimes causes sleep disorders such as reduced sleep and insomnia.

Critical Thinking

Successful critical thinking requires a synthesis of knowledge, experience, information gathered from patients, critical thinking attitudes, and intellectual and professional standards. Clinical judgments require you to anticipate the information necessary, analyze the data, and make decisions regarding patient care. During assessment consider all elements to build toward making an appropriate nursing diagnosis.

In the case of sleep, integrate knowledge from nursing and other disciplines such as pharmacology and psychology. Personal experience with a sleep problem and experience with patients prepares you to know effective forms of sleep therapies. You use critical thinking attitudes such as perseverance, confidence, and discipline to complete a comprehensive assessment and develop a plan of care to provide successful management of the sleep problem. Professional standards such as the *Nursing Scope and Standards of Practice* ([American Nurses Association, 2015](#)), *Clinical Practice Guidelines for the Pharmacologic Treatment of Chronic Insomnia in Adults: An American Academy of Sleep Medicine Clinical Practice Guideline* ([Sateia et al., 2017](#)), and “Excessive Sleepiness” in *Evidence-based Geriatrics Nursing Protocols for Best Practice* ([Chasens and Umlauf, 2012](#)) provide valuable guidelines to assess and address the needs of patients with sleep disorders.

REFLECT NOW

Consider your lifestyle choices. What factors contribute to promoting or disrupting your sleep. What changes can you make that will improve your sleep?

◆ **Nursing Process**

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care.

◆ **Assessment**

During the assessment process thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care ([Fig. 43.2](#)).

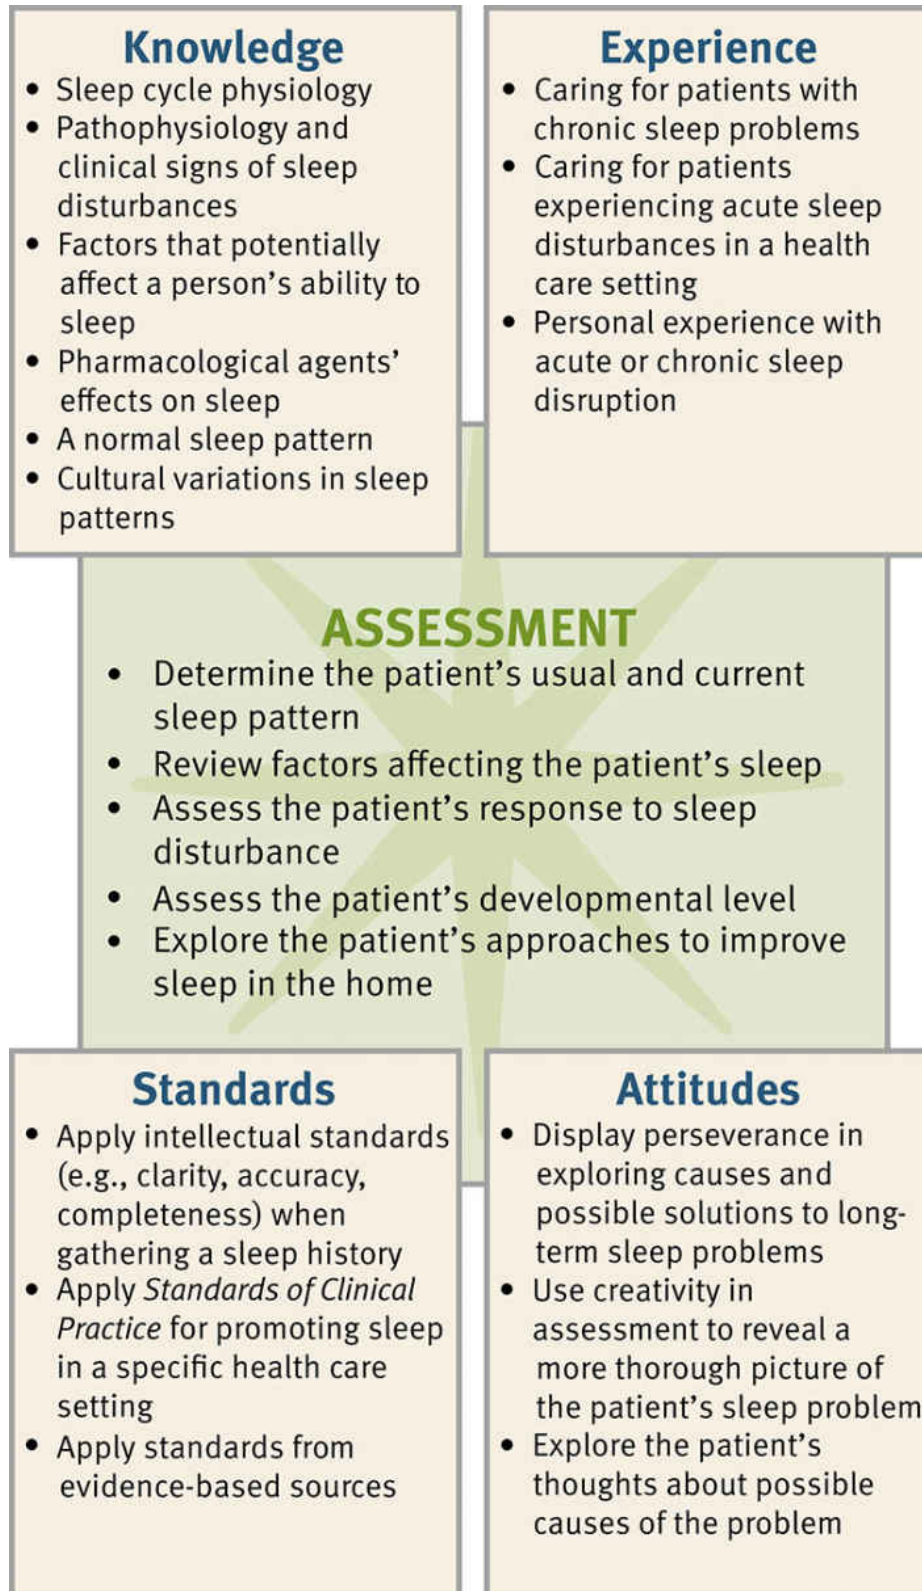

FIG. 43.2 Critical thinking model for sleep assessment.

Through the Patient's Eyes

Sleep is a subjective experience. Only the patient is able to report whether it is sufficient and restful. If the patient is satisfied with the quantity and quality of sleep received, you consider it normal, and the nursing history that you will collect is brief. If a patient admits to or suspects a sleep problem, you will need a detailed history and assessment. If a patient has an obvious sleep problem, consider asking whether his or her sleep partner can be approached for further assessment data.

A poor night's sleep for a patient often starts a vicious cycle of anticipatory anxiety. The patient fears that sleep will again be disturbed while trying harder and harder to sleep. Use a skilled and caring approach to assess the patient's sleep needs. A caring nurse individualizes care for each patient. Always ask patients what they expect regarding sleep. This includes asking about the interventions that they currently use and how successful they are. It is important to understand patients' expectations regarding their sleep pattern. When they ask for help because of sleep disturbances, they typically expect a nurse to respond promptly to help them improve the quantity and quality of their sleep.

Sleep Assessment

Most people are able to provide a reasonably accurate estimate of their sleep patterns, particularly if any changes have occurred. Aim your assessment at first understanding the characteristics of the patient's sleep problem and usual sleep habits so that you incorporate ways for promoting sleep into nursing care. For example, if the nursing history reveals that a patient always reads before falling asleep, it makes sense to offer reading material at bedtime.

Sources for Sleep Assessment

Usually patients are the best resource for describing sleep problems and how they are a change from their usual sleep and waking patterns. Often the patient knows the cause for sleep problems, such as a noisy environment or worry over a relationship.

In addition, bed partners are able to provide information about patients' sleep patterns that help reveal the nature of certain sleep disorders. For example, partners of patients with sleep apnea often complain that the patients' snoring disturbs their sleep. Ask bed partners (if the patient agrees) whether patients have breathing pauses during sleep and how

frequently the apneic attacks occur. Some partners mention becoming fearful when patients apparently stop breathing for periods.

When caring for children, seek information about sleep patterns from parents or guardians because they are usually a reliable source of information. Hunger, excessive warmth, and separation anxiety often contribute to an infant's difficulty in going to sleep or frequent awakenings during the night. Parents of infants need to keep a 24-hour log of their infant's waking and sleeping behavior for several days to determine the cause of the problem. Describing the infant's eating pattern and sleeping environment in the log will help identify which factors are influencing the baby's sleeping behavior. Older children often are able to relate fears or worries that inhibit their ability to fall asleep. If children frequently awaken in the middle of bad dreams, parents are able to identify the problem but perhaps do not understand the meaning of the dreams. Ask parents to describe the typical behavior patterns that foster or impair sleep. For example, excessive stimulation from active play or visiting friends predictably impairs sleep. With chronic sleep problems, parents need to relate the duration of the problem, its progression, and children's responses.

Tools for Sleep Assessment

Two effective subjective measures of sleep are the Epworth Sleepiness Scale and the Pittsburgh Sleep Quality Index. The Epworth Sleepiness Scale contains eight questions about the likeliness of a patient being sleepy during certain activities (e.g., watching television, reading, sitting and talking with someone) on a scale of 0 (would never doze or sleep) to 3 (high chance of dozing or sleeping). A score of 0 to 5 indicates lower normal daytime sleepiness; 6 to 10 is considered higher than normal daytime sleepiness; a score of 11 or 12 is mild excessive daytime sleepiness; 13 to 15 is moderate excessive daytime sleepiness; and a score of 16 to 24 is severe excessive daytime sleepiness (Johns, n.d.). The scale is available at <http://epworthsleepinessscale.com/about-the-ess/>. The second tool, the Pittsburgh Sleep Quality Index assesses sleep quality and patterns (Mollayeva et al., 2016). This scale is available at <https://consultgeri.org/try-this/general-assessment/issue-6.1.pdf>.

Another brief, effective method for assessing sleep quality is the use of a visual analog scale. Draw a straight horizontal line 100 mm (4 inches) long. Opposing statements such as "best night's sleep" and "worst night's sleep" are at opposite ends of the line. Ask patients to place a mark on the horizontal line at the point corresponding to their perceptions of the

previous night's sleep. Measuring the distances of the mark along the line in millimeters offers a numerical value for satisfaction with sleep. Use the scale repeatedly to show change over time. Such a scale is useful to assess an individual patient, not to compare patients.

Another brief, subjective method to assess sleep is a numeric scale with a 0-to-10 sleep rating. Ask individuals to separately rate the quantity and quality of their sleep on the scale. Instruct them to indicate with a number between 0 and 10 their sleep quantity and then their quality of sleep, with 0 being the worst sleep and 10 being the best.

Sleep History

When you suspect a patient has a sleep problem, assess the quality and characteristics of sleep in greater depth by asking the patient to describe the problem. This includes recent changes in sleep pattern, sleep symptoms experienced during waking hours, the use of prescribed or over-the-counter sleep medications, diet and intake of substances such as caffeine or alcohol that influence sleep, and recent life events that have affected the patient's mental and emotional status.

Description of Sleeping Problems

Conduct a more detailed history when a patient has a persistent or what appears to be a serious sleep problem. Open-ended questions help a patient describe a problem more fully. A general description of the problem followed by more focused questions usually reveals specific characteristics that are useful in planning therapies. To begin, you need to understand the nature of the sleep problem, its signs and symptoms, its onset and duration, its severity, any predisposing factors or causes, and the overall effect on the patient. Ask specific questions related to the sleep problem ([Box 43.5](#)).

Box 43.5 Nursing Assessment Questions

Nature of the Problem

- Describe the type of sleep problem you're having.
- Why do you think you're not getting enough sleep?

- Describe a recent night's sleep. How is this sleep different from your usual sleep?

Signs and Symptoms

- Do you have difficulty falling asleep, staying asleep, or waking up?
- Have you been told that you snore loudly?
- Do you have headaches when awakening?

Onset and Duration of Signs and Symptoms

- When did you notice the problem?
- What do you do to relieve the symptom?
- How long has this problem lasted?

Severity

- How long does it take you to fall asleep?
- How often during the week do you have trouble falling asleep?
- On average, how many hours of sleep a night did you get this week?
- How does this compare to your usual amount of sleep?
- What do you do when you awaken during the night or too early in the morning?

Predisposing Factors

- What do you do just before you go to bed?
- Have you recently had any changes at work or at home?
- How is your mood? Have you noticed any changes recently?
- Which medications or recreational drugs do you take on a regular basis?
- Are you taking any new prescriptions or over-the-counter medications?

- Do you eat food (spicy or greasy foods) or drink substances (alcohol or caffeinated beverages) that affect your sleep?
- Do you have a physical illness that affects your sleep?
- Does anyone in your family have a history of sleep problems?

Effect on Patient

- How has the loss of sleep affected you?
- Do you feel excessively sleepy or irritable or have trouble concentrating during waking hours?
- Do you have trouble staying awake? Have you fallen asleep at the wrong times (e.g., while driving, sitting quietly in a meeting)?

Proper questioning helps to determine the type of sleep disturbance and the nature of the problem. [Box 43.6](#) gives examples of additional questions for you to ask a patient when you suspect specific sleep disorders. The STOP-BANG sleep assessment tool is a reliable evidence-based tool used to screen for OSA and is frequently used in preanesthesia and/or preoperative assessments (see [Chapter 50](#)) ([Chung et al., 2016](#)). The questions help to select specific sleep therapies and the best time for implementation.

Box 43.6 Questions to Ask to Assess for Specific Sleep Disorders

Impaired Sleep

- How easily do you fall asleep?
- Do you fall asleep and have difficulty staying asleep? How many times do you awaken?
- What time do you awaken in the morning? What causes you to awaken early?
- What do you do to prepare for sleep? To improve your sleep?
- What do you think about as you try to fall asleep?
- How often do you have trouble sleeping?

Sleep Apnea

- Do you snore loudly? Does anyone else in your family snore loudly?
- Has anyone ever told you that you often stop breathing for short periods during sleep? (Spouse or bed partner/roommate may report this.)
- Do you experience headaches after awakening?
- Do you have difficulty staying awake during the day?

Narcolepsy

- Do you fall asleep at the wrong times? (Friends or relatives may report this.)
- Do you have episodes of losing muscle control or falling to the floor?
- Have you ever had the feeling of being unable to move or talk just before waking or falling asleep?
- Do you have vivid, lifelike dreams when going to sleep or awakening?

To add to the sleep history, have the patient and bed partner keep a sleep-wake log for 1 to 4 weeks. The patient completes the sleep-wake log daily to provide information on day-to-day variations in sleep-wake patterns over extended periods. Entries in the log often include 24-hour information about various waking and sleeping health behaviors such as physical activities, mealtimes, type and amount of intake (alcohol and caffeine), time and length of daytime naps, evening and bedtime routines, the time the patient tries to fall asleep, nighttime awakenings, and the time of morning awakening. A partner helps record the estimated times the patient falls asleep or awakens. Although the log is helpful, the patient needs to be motivated to participate in its completion.

Usual Sleep Pattern

Normal sleep is difficult to define because individuals vary in their perception of adequate quantity and quality of sleep. However, it is important to have patients describe their usual sleep pattern to determine the significance of the changes caused by a sleep disorder. Knowing a patient's usual, preferred sleep pattern allows you to try to match sleeping

conditions in the health care setting with those in the home. Ask the following questions to determine a patient's sleep pattern:

1. What time do you usually get in bed each night?
2. How much time does it usually take to fall asleep? Do you do anything special to help you fall asleep?
3. How many times do you wake up during the night? What do you think is the cause?
4. What time do you typically wake up in the morning?

Compare patient data with their pattern before the sleep problem or with the predominant pattern usually found for other patients of the same age. Use this comparison to assess for identifiable patterns such as insomnia. Patients with sleep problems frequently report sleep patterns that are drastically different from their normal patterns, or sometimes the change is relatively minor. Patients in the hospital usually need or want more sleep as a result of illness. However, some require less sleep because they are less active. Some patients who are ill think that it is important to try to sleep more than usual, eventually making sleeping difficult.

Physical and Psychological Illness

Determine whether the patient has any preexisting health problems that interfere with sleep. Chronic diseases such as chronic obstructive pulmonary disease and painful disorders such as arthritis interfere with sleep. Also assess the patient's medication history, including a description of over-the-counter and prescribed drugs. A history of psychiatric problems also makes a difference. For example, a patient who is living with bipolar disorder sleeps more when depressed than when manic. A patient who is depressed often experiences an inadequate amount of fragmented sleep. If a patient takes medications to aid sleep, gather information about the type and amount of medication and the frequency of its use. Also assess the patient's daily caffeine intake.

If the patient has recently undergone surgery with general anesthesia, expect him or her to experience some sleep disturbance. Patients usually awaken frequently during the first night after surgery and receive little deep or REM sleep. Depending on the type of anesthesia, it takes several days to months for a normal sleep cycle to return.

Current Life Events

In your assessment learn whether the patient is experiencing any changes in lifestyle that disrupt sleep. A person's occupation often offers a clue to the nature of the sleep problem. Changes in job responsibilities, rotating shifts, or long hours contribute to a sleep disturbance. Questions about social activities, recent travel, or mealtime schedules help clarify the assessment.

Emotional and Mental Status

A patient's emotions and mental status affect the ability to sleep. For example, if a patient is experiencing anxiety, emotional stress related to illness, or situational crises such as loss of job or a loved one, he or she often experiences insomnia. When a sleep disturbance is related to an emotional problem, the key is to treat the primary problem; its resolution often improves sleep (Murawski et al., 2017). Patients with mental illnesses may need mild sedation for adequate rest. Assess the effectiveness of any medication and its effect on daytime function.

Bedtime Routines

Ask patients what they do to prepare for sleep. For example, some patients drink a glass of milk, take a sleeping pill, eat a snack, or watch television. Assess habits that are beneficial compared with those that disturb sleep. For example, watching television promotes sleep for one person, whereas it stimulates another to stay awake. Sometimes pointing out that a habit is interfering with sleep helps patients find ways to change or eliminate habits that are disrupting sleep.

Pay special attention to a child's bedtime rituals. For example, the parents need to report whether it is necessary to read a bedtime story, rock the child to sleep, or engage in quiet play. Some young children need a special blanket or stuffed animal when going to sleep.

Bedtime Environment

During assessment ask the patient to describe preferred bedroom conditions, including preferences for lighting in the room, music or television in the background, or needing to have the door open versus closed. Include questions about the presence of electronic devices in the bedroom (e.g., phones, televisions), all of which have small lights that remain on or have a light that blinks when the battery is low. Patients are often surprised how many of these devices are in the sleeping environment.

In addition, some children need the company of a parent to fall asleep. Environmental distractions in a health care setting such as a roommate's television, an electronic monitor in the hallway, a noisy nurses' station, or another patient who cries out at night often interfere with sleep. Modify the environment whenever possible to promote sleep.

Behaviors of Sleep Deprivation

Some patients are unaware of how their sleep problems affect their behavior. Observe for behaviors such as irritability, disorientation (similar to a drunken state), frequent yawning, and slurred speech. If sleep deprivation has lasted a long time, psychotic behavior such as delusions and paranoia sometimes develops. For example, a patient reports seeing strange objects or colors in the room, or he or she acts afraid when the nurse enters the room.

REFLECT NOW

Take either the Epworth Sleepiness Scale or Pittsburgh Sleep Quality Index. After analyzing your results, what does the instrument tell you about your sleep quality?

Nursing Diagnosis

Review your assessment data, looking for clusters that include assessment findings of a sleep pattern disturbance or other health problem. If you identify a sleep problem, specify the condition, such as insomnia or sleep deprivation. By specifying the sleep disturbance diagnosis, you are able to design more effective interventions. For example, you choose different therapies for patients with insomnia who are unable to fall asleep than for those with sleep deprivation. [Box 43.7](#) demonstrates how to use nursing assessment activities to identify and cluster assessment findings to make an accurate nursing diagnosis.

Box 43.7 Nursing Diagnostic Process Impaired Sleep

Assessment Activities	Assessment Findings
Ask patient to explain nature of sleep problem.	Patient reports difficulty falling asleep, taking up to 1 hour. Patient reports waking up two to three times nightly with difficulty returning to sleep.
Observe patient's behavior and ask spouse whether patient is experiencing behavioral changes.	Patient admits to not feeling well rested. Spouse describes times when patient was lethargic and irritable.
Determine whether patient has had recent lifestyle changes.	Spouse reports that patient recently lost job and is concerned about finding new position.

Assessment also identifies the related factor or probable cause of a sleep disturbance such as a noisy environment or a high intake of caffeinated beverages in the evening. These causes become the focus of interventions for minimizing or eliminating a negative or problem-focused diagnosis. For example, if a patient is experiencing insomnia as a result of a noisy health care environment, offer some basic recommendations for helping sleep, such as controlling the noise of hospital equipment, reducing interruptions, or keeping doors closed. If the insomnia is related to anxiety or stress over a threatened marital separation, introduce coping strategies and create an environment for sleep. If you incorrectly define the probable cause or related factors, the patient does not benefit from care.

Sleep problems affect patients in other ways. For example, you find that a patient with sleep apnea has problems with a spouse who is tired and frustrated over the patient's snoring. In addition, the spouse is concerned that the patient is breathing improperly and thus is in danger. Examples of nursing diagnoses for patients with sleep problems include the following:

- *Adequate Sleep*
- *Fatigue*
- *Impaired Sleep*
- *Impaired Alertness*
- *Sleep Deprivation*

Planning

Goals and Outcomes

During planning you again synthesize information from multiple resources to develop an individualized plan of care (Fig. 43.3) (see the [Nursing Care Plan](#)). Professional standards are especially important to consider in developing a care plan. These standards often offer evidence-based guidelines for effective nursing interventions. For example, in *Evidence-Based Geriatrics Nursing Protocols for Best Practice*, the chapter titled “Excessive Sleepiness” ([Chasens and Umlauf, 2012](#)) recommends individualized nursing interventions that maintain and support an older adult’s normal sleep pattern and bedtime ritual. It is important for a plan of care for sleep promotion to include strategies appropriate to the patient’s sleep routines, living environment, and lifestyle.

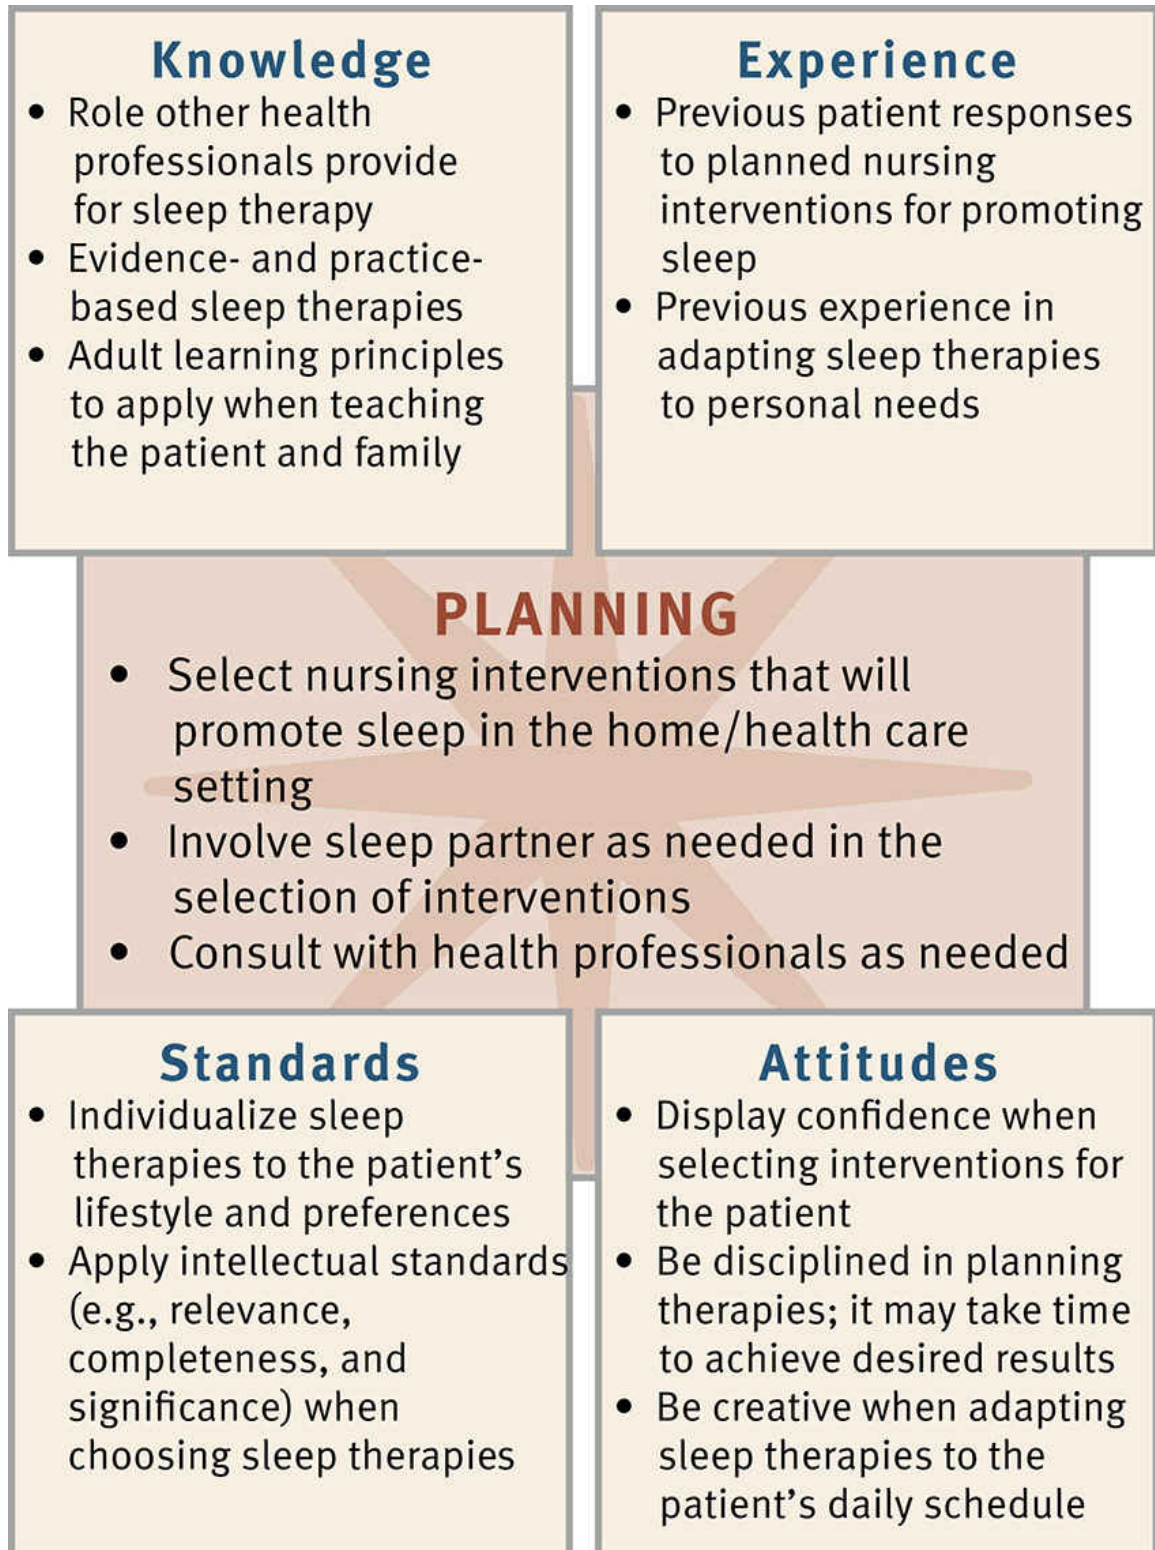

FIG. 43.3 Critical thinking model for sleep planning.

As you plan care for a patient with sleep disturbances, creation of a concept map is another method for developing holistic patient-centered

care (Fig. 43.4). Create the map after identifying relevant nursing diagnoses from the assessment database. In this example the nursing diagnoses are linked to the patient's medical diagnosis of depression and situational stress. The concept map shows the relationships among the nursing diagnoses *Impaired Sleep*, *Caregiver Stress*, *Fatigue*, and *Impaired Health Maintenance*. This approach to planning care helps you recognize relationships among planned interventions. For this patient, interventions and successful outcomes for one nursing diagnosis affect the resolution of another. When developing goals and outcomes, it is important for you to collaborate with your patients. As a result, you are more likely to set realistic goals and measurable outcomes with your patients. An effective plan includes outcomes established over a realistic time frame that focus on the goal of improving the quantity and quality of sleep in the home. Often family members are very helpful in contributing to the plan. A sleep-promotion plan frequently requires many weeks to accomplish.

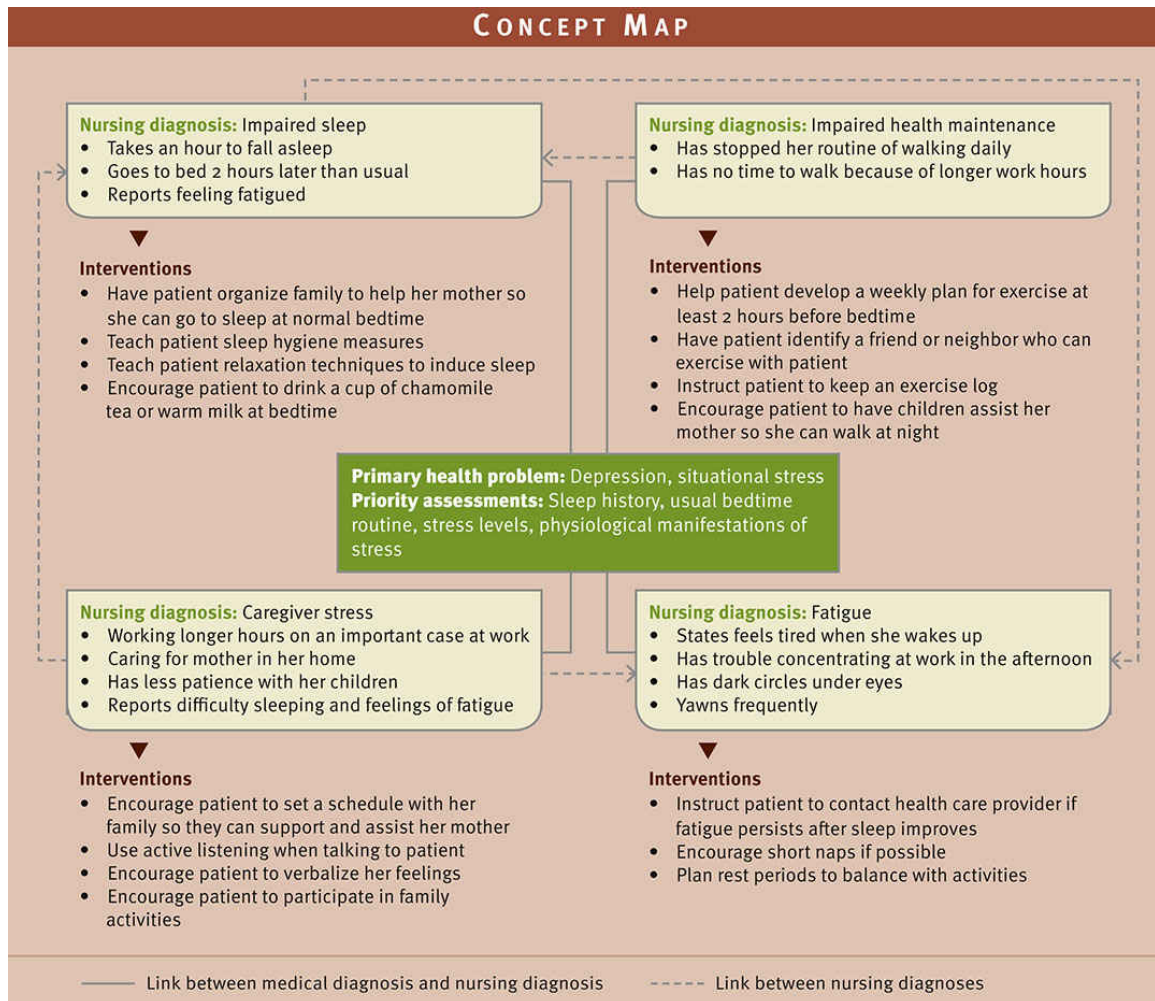

FIG. 43.4 Concept map for Julie Arnold.

Setting Priorities

Work with patients to establish priority outcomes and interventions. Frequently sleep disturbances are the result of other health problems. For example, when physical symptoms interfere with sleep, managing the symptoms is your first priority. After symptoms are relieved, focus on sleep therapies. Patients are a helpful resource in determining which interventions hold priority. For example, once patients understand the factors that disrupt sleep, they make choices about the types of changes they would like to make in their lifestyle or sleeping environment.

Teamwork and Collaboration

Partner closely with the patient and sleep partner to ensure that any therapies such as a change in the sleep schedule or changes to the

bedroom environment are realistic and achievable. In a health care setting, plan treatments or routines so that the patient is able to rest. For example, in the ICU use available electronic monitors to track trends in vital signs without waking a patient each hour. Other staff members need to be aware of the care plan so that they can cluster activities at certain times to reduce awakenings. In a nursing home the focus of the plan involves better planning of rest periods around the activities of the other residents. Roommates often have very different schedules.

When patients have chronic sleep problems, the initial referral for a patient is often to a comprehensive sleep center for assessment of the problem. The nature of the sleep disturbance then determines whether referrals to additional health care providers are necessary. For example, if a sleep problem is related to a situational crisis or emotional problem, refer the patient to a mental health clinical nurse specialist or clinical psychologist for counseling. If the nurse works in an inpatient setting and the patient needs a referral for continued care after discharge, offering information about the sleep problem is useful to the home care nurse. The success of sleep therapy depends on an approach that fits the patient's lifestyle and the nature of the sleep disorder.

REFLECT NOW

Analyze the results of your sleep quality using one of the instruments described in the assessment section. Based on the results, develop one goal and two outcomes for yourself that focus on improving your sleep quality or sleep hygiene habits.

Implementation

Nursing interventions designed to improve the quality of a person's rest and sleep are largely focused on health promotion. Patients need adequate sleep and rest to maintain active and productive lifestyles. During times of illness, rest and sleep promotion are important for recovery. Nursing care in an acute, restorative, or continuing care setting differs from that

provided in a patient's home. The primary differences are in the environment and the nurse's ability to support normal rest and sleep habits. A patient's age also influences the types of therapies that are most effective. [Box 43.8](#) provides principles for promoting sleep in older patients.

Box 43.8 Focus on Older Adults Promoting Sleep

Sleep-Wake Pattern

- Maintain a regular bedtime and wake-up schedule (Taylor et al., 2017).
- Eliminate naps unless they are a routine part of the schedule.
- If naps are taken, limit to 20 minutes or less twice a day (Touhy and Jett, 2018).
- Go to bed when sleepy.
- Use warm bath and relaxation techniques (Touhy and Jett, 2018).
- If unable to sleep in 15 to 30 minutes, do a relaxing activity such as reading (Haynes et al., 2018).
- Avoid stimulating activities such as exercise or watching television before bedtime (Chasens and Umlauf, 2012).

Environment

- Sleep where you sleep best.
- Keep noise to a minimum; use soft music to mask it if necessary.
- Use night-light and keep path to bathroom free of obstacles.
- Set room temperature to preference; use socks to promote warmth.
- Listen to relaxing music (Touhy and Jett, 2018).
- Sit in natural sunlight for two hours each morning if possible (Duzgun and Akyol, 2017).

Medications

- Use sedatives and hypnotics with caution as last resort and then only short term if absolutely necessary (Kryger et al., 2017).
- Adjust medications being taken for other conditions and assess for drug interactions that may cause insomnia or excessive daytime sleepiness.

Diet

- Limit alcohol, caffeine, and nicotine in late afternoon and evening (Touhy and Jett, 2018).
- Consume carbohydrates or milk as a light snack before bedtime (Touhy and Jett, 2018).
- Decrease fluids 2 to 4 hours before sleep (Touhy and Jett, 2018).

Physiological/Illness Factors

- Elevate head of bed and provide extra pillows as preferred.
- Use analgesics 30 minutes before bed to ease aches and pains.
- Use therapeutics to control symptoms of chronic conditions as prescribed (Chasens and Umlauf, 2012).

Health Promotion

In community health and home settings help patients develop behaviors conducive to rest and relaxation. To develop good sleep habits at home, patients and their bed partners need to learn techniques that promote sleep and the conditions that interfere with it (Kryger et al., 2017) (Box 43.9). Parents also learn how to promote good sleep habits for their children. Patients benefit most from instructions based on information about their homes and lifestyles, such as which types of activities promote sleep when a person must work during the night shift or how to make the home environment more conducive to sleep. Patients are more likely to apply information that they find useful and valuable.

Box 43.9 Patient Teaching Sleep-Hygiene Habits

Objective

- Patient will follow proper sleep-hygiene habits at home.

Teaching Strategies

- Instruct patient to try to exercise daily, preferably in the morning or afternoon, and to avoid vigorous exercise in the evening within 2 hours of bedtime.
- Caution patient against sleeping long hours during weekends or holidays to prevent disturbance of normal sleep-wake cycle.
- Explain that, if possible, patients should not use the bedroom for intensive studying, snacking, television watching, or other nonsleep activity besides sex.
- Encourage patients to try to avoid worrisome thinking when going to bed and to use relaxation exercises.
- If patient does not fall asleep within 30 minutes of going to bed, advise him or her to get out of bed and do some quiet activity until feeling sleepy enough to go back to bed.
- Recommend that patients limit caffeine to morning coffee and limit alcohol intake (more than one to two drinks a day interrupts sleep cycle).
- Recommend that patients discontinue use of electronic devices about 30 minutes before going to bed.
- Ask patient to examine environment. Instruct that use of earplugs and eyeshades may be helpful.
- Instruct patient to avoid heavy meals 3 hours before bedtime; a light snack may help.

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- “I want to be sure I explained the important information you need to include in your sleep-wake log. Explain the information you are going to include in your log for the next week.”

- “Tell me about three of the approaches we planned to help you sleep at home.”

Environmental Controls

All patients require a sleeping environment with a comfortable room temperature and proper ventilation, minimal sources of noise, a comfortable bed, and proper lighting (Patel et al., 2018). Children and adults vary more in regard to comfortable room temperature. Instruct parents to place infants on mattresses that are covered by a fitted sheet that meets current safety standards; to clothe babies in sleepers for warmth; to not place pillows, quilts, toys, or anything in cribs; and to position cribs away from open windows or drafts (AAP, 2016; Gaw et al., 2017). Older adults often require extra blankets or covers.

Nursing Care Plan

Impaired Sleep

Assessment

Julie Arnold, a 43-year old attorney, is the first patient of the morning at the neighborhood health clinic where you work. When you ask her how she’s doing, she tells you that she’s having difficulty sleeping. Her health care provider has diagnosed that she’s suffering from depression. Julie is married and has two school-age children. She also tells you that she is caring for her mother, who is staying with them after she was discharged from the hospital following an exacerbation of her heart failure.

Assessment Activities	Assessment Findings ^a
Ask Julie to explain the nature of her sleep problem.	Julie explains that she wakes up once or twice a night . She states, "I feel tired when I wake up, and I have trouble concentrating at work in the afternoon."
Ask Julie if there have been any recent changes in her life.	Julie reports that, because of her heavy work schedule, she has stopped her routine of walking 1 to 2 miles daily. She reports that she has no time for any exercise when she gets home because she needs to take care of her mother and the children .
Ask Julie to describe her bedtime routine.	Julie responds that she is going to bed between 12 AM and 1 AM, which is 2 hours later than her usual bedtime . It takes her an hour to fall asleep . She says that she used to get 7 to 8 hours of sleep a night and now it is more like 5 to 6 hours . She drinks two to three cups of coffee after dinner while she is working on her case before bedtime.
Assess Julie for physical signs of sleep problems.	During the examination you note that Julie has dark circles under her eyes; she shifts her position in the chair multiple times and yawns frequently. She admits to fatigue .

^a **Assessment findings** are shown in bold type.

Nursing Diagnosis:

Impaired Sleep

Planning

Goals	Expected Outcomes (NOC) ^b
	Sleep
Patient will achieve an improved sense of adequate sleep within 4 weeks.	Patient reports waking up less frequently during the night and feeling rested within 4 weeks.
	Patient verbalizes adherence to a regular bedtime routine within 4 weeks.

^b Outcome classification labels from Moorhead S, et al: *Nursing outcomes classification (NOC)*, ed 6, St Louis, 2018, Elsevier.

Interventions (Nic) ^c	Rationale
Sleep Enhancement	
Encourage patient to establish a bedtime routine and a regular sleep pattern.	Maintaining a consistent schedule helps induce sleep (Avidan and Neubauer, 2017).
Instruct patient to avoid caffeine and nicotine before bedtime.	Caffeine and nicotine are stimulants and cause difficulty in falling asleep.
Help patient identify ways to eliminate stressful concerns about work before bedtime (e.g., taking time before actual sleep to read a light novel).	Excess worry and intense activities before bedtime stimulate patient and prevent sleep (Taylor et al., 2017).
Adjust environment; have patient control noise, temperature, and light in the bedroom.	Creates an environment conducive to sleep (Patel et al., 2018).
Relaxation Therapy	
Teach patient how to perform muscle relaxation before bedtime; include demonstration.	Relaxation reduces anxiety, which interferes with sleep (National Sleep Foundation, 2018b; Patel et al., 2018).

Evaluation

Evaluation Activity	Patient Response/Finding	Outcome Status
Ask Julie whether she is able to fall asleep and stay asleep.	Julie responds, "It usually takes 15 to 20 minutes to fall asleep; last week, on two separate nights, I only woke up once each night."	Julie reports fewer awakenings during night and falling asleep within 30 minutes.
Ask Julie to describe her waking behaviors at work and home during the day.	Julie responds that she has completed her case at work and feels less pressure. She has restarted her walking routine and is better able to cope with her children. She can concentrate at work more.	Julie reports feeling more rested.
Observe Julie's waking nonverbal expressions and behavior.	Julie sits in the chair without shifting position. She does not yawn during the conversation. The dark circles under her eyes are almost gone.	Julie's nonverbal behaviors are consistent with improved sleep.

^c Intervention classification labels from Butcher HK, et al: *Nursing interventions classification (NIC)*, ed 7, St Louis, 2018, Elsevier.

Eliminate distracting noise, so the bedroom is as quiet as possible. In the home the television, telephone, or intermittent chiming of a clock often disrupts a patient's sleep. Involve the family in identifying approaches for reducing noise in the home, especially if there are several family members, all with different sleep schedules. It is also important to remember that some patients sleep with familiar inside noises such as the hum of a fan. Some patients benefit from using commercial products that produce a

soothing noise, such as the sounds of ocean waves or rainfall, to create an environment for sleep.

A bed and mattress need to provide support and comfortable firmness. Bed boards placed under mattresses add support. Sometimes extra pillows are important to help a person position comfortably in bed. The position of the bed in the room also makes a difference for some patients.

Patients vary in regard to the amount of light that they prefer at night. Infants and older adults sleep best in softly lit rooms. Light should not shine directly on their eyes. Small table lamps prevent total darkness. For older adults, light reduces the chance of confusion and prevents falls when walking to the bathroom. If streetlights shine through windows or when patients nap during the day, heavy shades, drapes, or slatted blinds are helpful.

Avoid excessive use of smart phones, tablets, and computers in the bedroom. Electronic devices and some smart televisions emit a blue light that affects sleep and circadian rhythms in some patients ([Gronil et al., 2016](#)). These devices increase sleep deprivation in all age-groups, with the greatest impact in children and adolescents ([Glauser, 2018](#)). Encourage patients to not use their electronic devices in bed and, whenever possible, to discontinue use about 30 minutes before sleep.

Promoting Bedtime Routines

Bedtime routines and sleep-hygiene measures relax patients in preparation for sleep. It is always important for people to go to sleep when they feel tired or sleepy. Going to bed while fully awake and thinking about other things often causes insomnia and interferes with the bed as a stimulus for sleep. Newborns and infants sleep through so much of the day that a specific routine is hardly necessary. However, quiet activities such as holding them snugly in blankets, singing or talking softly, and gentle rocking help them fall asleep.

A bedtime routine (e.g., same hour for bedtime, snack, or quiet activity) used consistently helps young children avoid delaying sleep. Parents need to reinforce patterns of preparing for bedtime. Quiet activities such as reading stories, coloring, allowing children to sit in a parent's lap while listening to music or listening to a prayer are routines that are often associated with preparing for bed.

Adults need to avoid excessive mental stimulation just before bedtime. Reading a light novel or listening to music helps a person relax. Relaxation exercises such as slow, deep breathing for 1 or 2 minutes relieve tension

and prepare the body for rest (see [Chapter 44](#)). Guided imagery and praying also promote sleep for some patients.

At home discourage patients from trying to finish office work or resolve family problems before bedtime. The bedroom is not a place to work, and patients need to always associate it with sleep. Working toward a consistent time for sleep and awakening helps most patients gain a healthy sleep pattern and strengthens the rhythm of the sleep-wake cycle.

Promoting Safety

For any patient prone to confusion or falls, safety is critical. A small night-light helps a patient orient to the room environment before going to the bathroom. Beds set lower to the floor can lessen the chance of a person falling when first standing. Instruct patients to remove clutter and throw rugs from the path used to walk from the bed to the bathroom. If a patient needs help to ambulate from a bed to the bathroom, place a small bell at the bedside to call family members. Sleepwalkers are unaware of their surroundings and are slow to react, increasing the risk of falls. Do not startle sleepwalkers but instead gently wake them and lead them back to beds.

Infants' beds need to be safe. To reduce the chance of suffocation, do not place pillows, stuffed toys, or the ends of loose blankets in cribs ([AAP, 2016](#)). Loose-fitting plastic mattress covers are dangerous because infants pull them over their faces and suffocate.

Promoting Comfort

People fall asleep only after feeling comfortable and relaxed. Minor irritants often keep patients awake. Soft cotton nightclothes keep infants or small children warm and comfortable. Instruct patients to wear loose-fitting nightwear. An extra blanket is sometimes all that is necessary to prevent a person from feeling chilled and being unable to fall asleep. Patients need to void before going to bed so they are not kept awake by a full bladder.

Promoting Activity

In the home encourage patients to stay physically active during the day so that they are more likely to sleep at night. Increasing daytime activity lessens problems with falling asleep. Always plan rigorous exercise at least 2 to 3 hours before bedtime because exercise just before bed acts as a stimulant ([Markwald et al., 2018](#)). Research indicates that exercise is

beneficial, particularly for older adults, to improve nighttime sleep. General recommendations include increasing daytime activity or exercise (Meiner and Yeager, 2019). However, older adults with chronic diseases that influence their functional abilities are likely to have limited activity (Touhy and Jett, 2018). Recommend activities that are safe for older patients to perform. Walking, swimming, wheelchair propulsion, and cycling on a stationary bike are excellent for patients with limited physical impairment. Weight lifting using light weights (e.g., 2 to 5 lb) builds upper body strength and endurance. Activity and exercise often prove to be beneficial by improving activity endurance, mobility, and sense of well-being.

Stress Reduction

The inability to sleep because of emotional stress also makes a person feel irritable and tense. When patients are emotionally upset, encourage them to try not to force sleep. Otherwise, insomnia frequently develops, and soon bedtime is associated with the inability to relax. Encourage a patient who has difficulty in falling asleep to get up and pursue a relaxing activity such as sewing or reading rather than staying in bed and thinking about sleep.

Preschoolers have bedtime fears (fear of the dark or strange noises), awaken during the night, or have nightmares. After nightmares encourage the parent to enter the child's room immediately and talk to the child briefly about fears to provide a cooling-down period. One approach is to comfort children and leave them in their own beds so that their fears are not used as excuses to delay bedtime. Keeping a light on in the room also helps some children. Cultural tradition causes families to approach sleep practices differently (Box 43.10). Always respect those practices that differ from traditional recommendations.

Box 43.10 Cultural Aspects of CareCo-sleeping/Bed-sharing

Practices and patterns of sleep and rest vary among cultures. Culture and biology influence the development of sleep problems in children. Sleep patterns, bedtime routines, sleep aids, and sleep arrangements are components of cultural practices related to the use of space and interaction distances (Giger, 2018). Traditionally experts recommend

having infants and children sleep in their own beds. Co-sleeping or bed-sharing, in which infants and children sleep with their parents, is a culturally preferred habit that varies among cultures (Mileva-Seitz et al., 2016). In the United States, bed-sharing is more common in younger, less-educated, minority/ethnic mothers (Bombard et al., 2018). Reasons for bed-sharing practices relate to breastfeeding, comfort, tradition, better or more sleep, and protection for an infant (i.e., to protect against the cold) (Mileva-Seitz et al., 2016). Health care providers in the United States discourage it because of safety issues. One belief is that co-sleeping does not promote independence (Mileva-Seitz et al., 2016). Research results indicate that co-sleeping or bed-sharing is a risk factor for sudden infant death syndrome (SIDS) (Carlin and Moon, 2017). Research does not show that using a device to make bed-sharing safe reduces infant suffocation or SIDS (AAP, 2016). Bed-sharing is not recommended for infants who were born prematurely or with parents who use alcohol or drugs or smoke because of the increased risk for SIDS (Mitchell et al., 2010; Carlin and Moon, 2017). Bed-sharing is often related to infant sleep problems such as frequent awakenings, nighttime crying, increased time spent awake at night and less nighttime sleep (Mileva-Seitz et al., 2016; Mindell et al., 2017). As a nurse, be culturally sensitive when discussing co-sleeping practices with parents and developing sleeping plans for children.

Implications for Patient-Centered Care

- Complete a thorough sleep assessment of the child and family.
- Discuss the risks of co-sleeping with parents. During the discussion remain culturally sensitive and respectful of the parents' views (Mileva-Seitz et al., 2016).
- Instruct parents who practice co-sleeping to avoid using alcohol or drugs that impair arousal. Decreased arousal prevents the parents from waking if the child is having problems (Mitchell et al., 2017).
- Recommend to parents that they share a room but not the bed with their infant (Bombard et al., 2018).
- Encourage parents to use light sleeping clothes, to keep room temperature comfortable, and to avoid bundling the child tightly or in too many clothes.
- Remove pillows and blankets from the infant's bed (Gaw et al., 2017).

Bedtime Snacks

Some people enjoy bedtime snacks, whereas others cannot sleep after eating. A dairy product such as warm milk or cocoa that contains L-tryptophan is often helpful in promoting sleep. A full meal before bedtime often causes gastrointestinal upset or reflux and interferes with the ability to fall asleep.

Warn patients against drinking or eating foods high in sugar or with caffeine before bedtime. Coffee, tea, colas, and chocolate act as stimulants, causing a person to stay awake or to awaken throughout the night. Caffeinated foods and liquids and alcohol act as diuretics and cause a person to awaken in the night to void.

Infants require special measures to minimize nighttime awakenings for feeding. It is common for children to need middle-of-the-night bottle-feeding or breastfeeding. [Hockenberry and Wilson \(2019\)](#) recommend offering the last feeding as late as possible. Tell parents not to give infants bottles in bed.

Building Competency in Evidence-Based Practice

At her annual checkup, Julie Arnold tells you that she continues to have trouble falling asleep, so she drinks 1 to 2 glasses of wine before bedtime to make her sleepy. Based on the current evidence, what is your best response?

Pharmacological Approaches

Melatonin is a neurohormone produced in the brain that helps control circadian rhythms and promote sleep ([Kryger et al., 2017](#)). It is a popular nutritional supplement that is found to be helpful in improving sleep efficiency and decreasing nighttime awakenings. The recommended dose is 0.3 to 3 mg taken 2 hours before bedtime. Older adults who have decreased levels of melatonin find it beneficial as a sleep aid ([Kryger et al., 2017](#)). Short-term use of melatonin has been found to be safe, with mild side effects of nausea, headache, and dizziness being infrequent. A melatonin receptor agonist, such as ramelteon or tasimelteon, is well tolerated and appears to be effective in improving sleep by improving the circadian rhythm and shortening the time needed for sleep onset ([Avidan and Neubauer, 2017](#); [Patel et al., 2018](#)). It is safe for long- and short-term

use, particularly in older adults. Common side effects include diarrhea, drowsiness, tiredness and dizziness.

Several other herbal products help in sleep. Valerian is effective in mild insomnia and RLS. It affects the release of neurotransmitters and produces very mild sedation (WebMD, 2017). Lavender essential oil may improve sleep quality (O'Malley, 2017). Passionflower (maypop) has mild sedative effects and is used as a natural sleep aid (WebMD, 2017). Chamomile, an herbal tea, has a mild sedative effect that may be beneficial in promoting sleep (MacMillan, 2017). Caution patients about the dosage and use of herbal compounds because the US Food and Drug Administration (FDA) does not regulate them. Herbal compounds may interact with prescribed medications, and patients need to avoid using these together (Meiner and Yeager, 2019).

The use of nonprescription sleeping medications is inadvisable. Patients need to learn the risks of such drugs. Over the long term these drugs lead to further sleep disruption, even when they initially seemed effective. Caution older adults about using over-the-counter antihistamines because of their long duration of action, which can cause confusion, constipation, urinary retention, and an increased risk of falls (Avidan and Neubauer, 2017). Help patients use behavioral and proper sleep-hygiene measures to establish sleep patterns that do not require the use of drugs.

Acute Care

Patients in acute care settings have their normal rest and sleep routine disrupted, which generally leads to sleep problems. In this setting nursing interventions focus on controlling factors in the environment that disrupt sleep, relieving physiological or psychological disruptions to sleep, and providing for uninterrupted rest and sleep periods for patients. "Excessive Sleepiness" in the *Evidence-based Geriatric Nursing Protocols for Best Practice* is based on the principle that nurses need to individualize an effective strategy based on patient needs and that sleep medications are a last-resort intervention (Chasens and Umlauf, 2012).

Environmental Controls

In a hospital you control the environment in several ways (Box 43.11). Close the curtains between patients in semiprivate rooms. Dim lights on a hospital nursing unit at night. One of the biggest problems for patients in the hospital is noise. Important ways to reduce noise are to conduct conversations and reports in a private area away from patient rooms and

to keep necessary conversations to a minimum, especially at night (Flynn Makic et al., 2014). Provide patients with ear plugs or eye masks to decrease noise and light stimulation (Caple and March, 2016; Litton et al., 2016). Additional ways to control noise in the hospital are listed in Box 43.12.

Box 43.11 Evidence-Based Practice Sleep Hygiene in Hospitalized Patients

PICOT Question: Does the use of a sleep-hygiene protocol versus routine care in patients in the intensive care unit decrease delirium related to decreased sleep?

Evidence Summary

Sleep disruption commonly occurs in patients in the intensive care unit because of disruption of normal routines, anxiety and stress, noise, pain, medical treatments, and environmental factors (Martinez et al., 2017; Owens et al., 2017). Sleep deprivation impacts physical and psychological healing and often causes delirium (Flannery et al., 2016). Implementation of nurse-driven sleep-hygiene protocols has been shown to be effective in improving sleep in patients in the intensive care unit (Martinez et al., 2017; Smithburger et al., 2017). Effective strategies in the protocols focused on education of staff nurses on protocol and interventions to decrease environmental stimuli and limit patient disruptions, pain management, avoidance of the use of restraints, early mobility, and family involvement (Martinez et al., 2017; Smithburger et al., 2017). Implementing these strategies improved patient sleep and decreased delirium (Flannery et al., 2016; Martinez et al., 2017).

Application to Nursing Practice

- Work with nurses on the unit to develop a sleep-hygiene protocol.
- Cluster nursing activities to provide uninterrupted periods of sleep (Martinez et al., 2017).
- Provide early physical therapy and mobility for patients (Hayhurst et al., 2016; Martinez et al., 2017).
- Reduce lighting, telephone volumes, and staff conversations in the halls during quiet time and nighttime (Martinez et al., 2017).

- Use sleep-hygiene measures with patients such as personal hygiene, adjusting room temperature, and relaxation methods.
- Educate and involve family in implementing strategies (Smithburger et al., 2017).

Box 43.12 Control of Noise in the Hospital

- Close doors to patients' room when possible.
- Keep doors to work areas on unit closed when in use.
- Reduce volume of nearby telephone and paging equipment.
- Wear rubber-soled shoes. Avoid clogs.
- Turn off bedside oxygen and other equipment that is not in use.
- Turn down alarms and beeps on bedside monitoring equipment.
- Turn off room television and radio unless patient prefers soft music.
- Avoid abrupt loud noise such as flushing a toilet or moving a bed.
- Keep necessary conversations at low levels, particularly at night.
- Designate a time period during the day for "quiet time" for patients.

Promoting Comfort

Make the patient more comfortable by providing personal hygiene before bedtime. A warm bath or shower is very relaxing. Offer patients restricted to bed the opportunity to wash their face and hands. Tooth brushing and care of dentures also help to prepare the patient for sleep. Have patients void before going to bed so that they are not kept awake by a full bladder. While a patient prepares for bed, help to position him or her off any potential pressure sites (Fig. 43.5). Offering a back rub or massage helps relax the patient.

FIG. 43.5 Positioning patient for sleep.

Removal of irritating stimuli is another way to improve the patient's comfort for a restful sleep. Changing or removing moist dressings, repositioning drainage tubing, reapplying wrinkled thromboembolic hose, and changing tape on nasogastric tubes eliminate constant irritants to the patient's skin. Cleanse the perineal or anal area thoroughly for patients

who are incontinent. Patients who are diaphoretic benefit from a cool bath and dry clothes or linens.

Establishing Periods of Rest and Sleep
