About the Authors

Acknowledgments

Unit I Nursing Basics

Chapter 1 Nursing, Theory, and Professional Practice

Case Study

LO 1.1 Definition of Nursing

LO 1.2 Primary Roles and Functions of the Nurse

LO 1.3 History of Nursing

LO 1.4 Nursing Theories

LO 1.5 Nonnursing Theories With Significant Impact on Nursing

LO 1.6 Criteria for a Profession

LO 1.7 Practice Guidelines

LO 1.8 Socialization and Transformation Into Nursing

LO 1.9 Nursing Practice Licensure and Graduate Specialties

LO 1.10 Certifications and Professional Nursing Organizations

LO 1.11 Future Directions

Summary of Learning Outcomes

Review Questions

References

Chapter 2 Values, Beliefs, and Caring

Case Study

LO 2.1 Beliefs and Values
LO 2.2 Values Conflict
LO 2.3 Beliefs, Health, and Health Care
LO 2.4 Caring and Caring Theories
LO 2.5 Professional Caring
LO 2.6 Caring Behaviors in Nursing
LO2.7 Compassion Fatigue
Summary of Learning Outcomes
Review Questions
References

Chapter 3 Communication

Case Study

LO 3.1 The Communication Process
LO 3.2 Modes of Communication
LO 3.3 Types of Communication
LO 3.4 The Nurse–Patient Helping Relationship
LO 3.5 Factors Affecting the Timing of Patient Communication
LO 3.6 Essential Components of Professional Nursing Communication
LO 3.7 Social, Therapeutic, and Nontherapeutic Communication
LO 3.8 Defense Mechanisms

LO 3.9 Special Communication Considerations

Summary of Learning Outcomes

Review Questions

References

Chapter 4 Critical Thinking in Nursing

Case Study

LO 4.1 Critical Thinking, Clinical Reasoning, and Clinical Judgment

LO 4.2 Theoretical Underpinnings of Critical Thinking

LO 4.3 Intellectual Standards of Critical ThinkingLO 4.2

LO 4.4 Critical-Thinking Components and Attitudes

LO 4.5 The Role of Critical Thinking in Nursing Practice

LO 4.6 Thinking Errors to Avoid

LO 4.7 Methods for Improving Critical-Thinking Skills

Summary of Learning Outcomes

Review Questions

References

Unit II Nursing Process

Chapter 5 Introduction to the Nursing Process

Case Study

LO 5.1 Definition of the Nursing Process

LO 5.2 Historical Development and Significance of the Nursing Process

LO 5.3 Characteristics of the Nursing Process

LO 5.4 Steps of the Nursing Process

LO 5.5 Cyclic and Dynamic Nature of the Nursing Process

Summary of Learning Outcomes

Review Questions

References

Chapter 6 Assessment

Case Study

LO 6.1 Methods of Assessment

LO 6.2 Physical Assessment

LO 6.3 Types of Physical Assessment

LO 6.4 Data Collection

LO 6.5 Validating Data

LO 6.6 Data Organization

Summary of Learning Outcomes

Review Questions

References

Chapter 7 Nursing Diagnosis

Case Study

LO 7.1 Nursing Diagnosis Methodology

LO 7.2 Nursing Taxonomies

LO 7.3 NANDA-I Nursing Diagnostic Statements

LO 7.4 Components of NANDA-I Nursing Diagnostic Statements

LO 7.5 Nursing Diagnosis in the Electronic Medical Record

LO 7.6 Steps for Identification of Accurate Nursing Diagnoses

LO 7.7 Avoiding Problems in the Diagnostic Process

LO 7.8 Application to Patient Care

Summary of Learning Outcomes

Review Questions

References

Chapter 8 Planning

Case Study

LO 8.1 The Planning Process

LO 8.2 Prioritizing Care

LO 8.3 Goal Development

LO 8.4 Outcome Identification and Goal Attainment

LO 8.5 Care Plan Development

LO 8.6 Types of Interventions

LO 8.7 Planning Throughout Patient Care

Summary of Learning Outcomes

Review Questions

References

Chapter 9 Implementation and Evaluation

Case Study

LO 9.1 Implementation and Evaluation of Nursing Care

LO 9.2 Direct Care

LO 9.3 Indirect Care

LO 9.4 Independent Nursing Interventions

LO 9.5 Dependent Nursing Interventions

LO 9.6 Collaborative Interventions

LO 9.7 Documentation of Interventions

LO 9.8 Evaluation of the Nursing Care Plan

LO 9.9 Care Plan Modification

Summary of Learning Outcomes

Review Questions

References

Unit III Nursing Process

Chapter 10 Documentation, Electronic Health Records, and Reporting

Case Study

LO 10.1 Documentation Standards and Principles

LO 10.2 The Medical Record
LO 10.3 Nursing Documentation
LO 10.4 Confidentiality and Privacy
LO 10.5 Hand-Off Reports
LO 10.6 Verbal and Telephone Orders
LO 10.7 Incident Reports
Summary of Learning Outcomes
Review Questions
References

Chapter 11 Ethical and Legal Considerations

Case Study

LO 11.1 Ethics and Ethical Theories
LO 11.2 Essential Principles of Ethics in Nursing
LO 11.3 Codes of Ethics
LO 11.4 Bioethics Challenges in Health Care
LO 11.5 Moral Distress
LO 11.6 Sources of Law Impacting Professional Nursing
LO 11.7 Types of Statutory Law
LO 11.8 Professional Liability Issues
LO 11.9 Legal Issues Guiding Patient Care
LO 11.10 Laws Impacting Professional Practice

LO 11.11 Initiatives to Facilitate Safer Practice

Summary of Learning Outcomes

Review Questions

References

Chapter 12 Leadership and Management

Case Study

LO 12.1 Definitions of Leadership and Management

LO 12.2 Leadership

LO 12.3 Management

LO 12.4 Nursing Leadership Roles

LO 12.5 Delegation

Summary of Learning Outcomes

Review Questions

References

Chapter 13 Evidence-Based Practice and Nursing Research

Case Study

LO 13.1 Nursing Research

LO 13.2 Methods of Research

LO 13.3 Components of Research

LO 13.4 Evidence-Based Practice

LO 13.5 Conducting Evidence-Based Research

LO 13.6 Implementing Research in Nursing Practice

LO 13.7 Magnet Hospital Status and the Role of Nursing Research in Practice

Summary of Learning Outcomes

Review Questions

References

Chapter 14 Health Literacy and Patient Education

Case Study

LO 14.1 Health Literacy

LO 14.2 Role of Health Literacy in Nursing and Patient Education

LO 14.3 Types of Patient Education

LO 14.4 Domains of Learning

LO 14.5 Learning Styles

LO 14.6 Factors Affecting Health Literacy and Patient Teaching

LO 14.7 Assessment

LO 14.8 Nursing Diagnosis

LO 14.9 Planning

LO 14.10 Implementation and Evaluation

LO 14.11 Recognizing the Role of Technology

Summary of Learning Outcomes

Review Questions

References

Chapter 15 Nursing Informatics

Case Study

LO 15.1 Definition of Informatics

LO 15.2 Technology in the Information Age

LO 15.3 Benefits of Informatics

LO 15.4 Nursing Informatics Skills and Roles

LO 15.5 Standardized Terminologies

LO 15.6 Information and Education

LO 15.7 Ethical, Legal, and Professional Practice Concerns

LO 15.8 The Future of Nursing Informatics

Summary of Learning Outcomes

Review Questions

References

Chapter 16 Health and Wellness

Case Study

LO 16.1 The Concept of Health

LO 16.2 Health Models

LO 16.3 Health Promotion and Wellness

LO 16.4 Levels of Prevention

LO 16.5 Illness

Lo 16.6 Factors Influencing Health and the Impact of Illness

Summary of Learning Outcomes

Review Questions

References

Unit IV Nursing Assessment

Chapter 17 Human Development

Case Study

LO 17.1 Theories of Human Development

LO 17.2 Development From Conception to Birth

LO 17.3 Development During the Newborn Period

LO 17.4 Infant Development

LO 17.5 Physical, Psychosocial, and Cognitive Development of the Toddler

LO 17.6 Growth and Development During the Preschool Years

LO 17.7 Development During the School-Age Years

LO 17.8 Physical, Psychosocial, and Cognitive Development in Adolescents

Summary of Learning Outcomes

Review Questions

References

Chapter 18 Human Development

Case Study

Lo 18.1 Theories on Aging and Adult Development

Lo 18.2 Physical Changes Due to Aging

Lo 18.3 Young Adulthood: Ages 18 to 34

Lo 18.4 Health Risks and Concerns During Young Adulthood

Lo 18.5 Middle Adulthood: Ages 35 to 65

Lo 18.6 Health Risks and Concerns During Middle Adulthood

Lo 18.7 Older Adulthood: Age 65 and Older

Lo 18.8 Health Risks and Concerns in Older Adulthood

Summary of Learning Outcomes

Review Questions

References

Chapter 19 Vital Signs

Case Study

LO 19.1 Vital Sign Measurement

LO 19.2 Temperature

LO 19.3 Pulse

LO 19.4 Respirations

LO 19.5 Blood Pressure

SKILL 19.1 Measuring Body Temperature

SKILL 19.2 Assessing Pulses

SKILL 19.3 Assessing Respirations

SKILL 19.4 Assessing Pulse Oximetry

SKILL 19.5 Measuring Blood Pressure: Manual and Electronic

Summary of Learning Outcomes

Review Questions

References

Chapter 20 Health History and Physical Assessment

Case Study

LO 20.1 Patient Interview

LO 20.2 Preparation for Physical Assessment

LO 20.3 Assessment Techniques

LO 20.4 General Survey

LO 20.5 Physical Examination

LO 20.6 Completion of the Physical Assessment

Summary of Learning Outcomes

Review Questions

References

Chapter 21 Ethnicity and Culture

Case Study

LO 21.1 Culture and Ethnicity

LO 21.2 Cultural Concepts

LO 21.3 Acquisition of Cultural Identity

LO 21.4 Transcultural Nursing

LO 21.5 Cultural Competence

LO 21.6 Cultural Competence and the Nursing Process

Summary of Learning Outcomes

References

Chapter 22 Spiritual Health

Case Study

Lo 22.1 Spirituality

Lo 22.2 Religion

Lo 22.3 Spiritual Care

Lo 22.4 Assessment

Lo 22.5 Nursing Diagnosis

Lo 22.6 Planning

Lo 22.7 Implementation and Evaluation

Summary of Learning Outcomes

Review Questions

References

Chapter 23 Community Health, Public Health, and Home Health Care

Case Study

LO 23.1 Community Health

LO 23.2 Levels of Health Care

LO 23.3 Factors Affecting Community Health

LO 23.4 Targeted Populations In Community Health

LO 23.5 Assessment

LO 23.6 Nursing Diagnosis

LO 23.7 Planning

LO 23.8 Implementation and Evaluation

Summary of Learning Outcomes

Review Questions

References

Chapter 24 Human Sexuality

Case Study

LO 24.1 Sexual Development

LO 24.2 Normal Structure and Function of the Male and Female Reproductive Systems

LO 24.3 Sex, Sexuality, and Gender Identity

LO 24.4 Sexual Response

LO 24.5 Contraception Options

LO 24.6 Sexually Transmitted Diseases and Infections

LO 24.7 Factors Affecting Sexuality

LO 24.8 Factors Affecting Sexual Function

LO 24.9 Family Dynamics

LO 24.10 Assessment

LO 24.11 Nursing Diagnosis

LO 24.12 Planning

LO 24.13 Implementation and Evaluation

Summary of Learning Outcomes

Review Questions

Unit V Nursing Principles

Chapter 25 Safety

Case Study

LO 25.1 Safety in the Home, Community, and Health Care Settings

LO 25.2 Factors Affecting Safety

LO 25.3 Altered Safety

LO 25.4 Assessment

LO 25.5 Nursing Diagnosis

LO 25.6 Planning

LO 25.7 Implementation and Evaluation

SKILL 25.1 Applying Physical Restraints

Summary of Learning Outcomes

Review Questions

References

Chapter 26 Asepsis and Infection Control

Case Study

LO 26.1 Normal Structure and Function of the Body's Defense System

LO 26.2 Altered Structure and Function of the Body's Defense System

LO 26.3 Assessment

LO 26.4 Nursing Diagnosis

LO 26.5 Planning

LO 26.6 Implementation and Evaluation

SKILL 26.1 Hand Hygiene

SKILL 26.2 Sterile Gloving

SKILL 26.3 Personal Protective Equipment

SKILL 26.4 Sterile Fields

Summary of Learning Outcomes

Review Questions

References

Chapter 27 Hygiene and Personal Care

Case Study

LO 27.1 Structure and Function of Skin, Hair, and Nails

LO 27.2 Alterations in Structure and Function Affecting Hygiene Care

LO 27.3 Assessment

LO 27.4 Nursing Diagnosis

LO 27.5 Planning

LO 27.6 Implementation and Evaluation

Skill 27.1 Bathing a Patient in Bed

Skill 27.2 Perineal Care

Skill 27.3 Foot and Hand Care

Skill 27.4 Therapeutic Massage

Skill 27.5 Hair Care

Skill 27.6 Oral Hygiene

Skill 27.7 Shaving a Male Patient

Skill 27.8 Making an Occupied or Unoccupied Bed

Summary of Learning Outcomes

Review Questions

References

Chapter 28 Activity, Immobility, and Safe Movement

Case Study

LO 28.1 Normal Structure and Function of Movement

LO 28.2 Altered Structure and Function of Movement

LO 28.3 Assessment

LO 28.4 Nursing Diagnosis

LO 28.5 Planning

LO 28.6 Implementation and Evaluation

SKILL 28.1 Manual Logrolling

SKILL 28.2 Ambulation With Assistive Devices

SKILL 28.3 Walking With Crutches

SKILL 28.4 Antiembolism Hose

SKILL 28.5 Sequential Compression Devices

Summary of Learning Outcomes

Review Questions

References

Chapter 29 Skin Integrity and Wound Care

Case Study

LO 29.1 Normal Structure and Function of Skin

LO 29.2 Altered Structure and Function of the Skin

LO 29.3 Assessment

LO 29.4 Nursing Diagnosis

LO 29.5 Planning

LO 29.6 Implementation and Evaluation

SKILL 29.1 Irrigating a Wound

SKILL 29.2 Changing a Sterile Dressing: Dry, Wet/Damp-to-Dry

SKILL 29.3 Obtaining a Wound Culture Specimen

SKILL 29.4 Negative-Pressure Wound Therapy, or Vacuum-Assisted Closure

SKILL 29.5 Applying Wraps and Bandages

Summary of Learning Outcomes

Review Questions

Dedication

I dedicate this book to my husband, Charlie, who has supported my dreams throughout my adult life and nursing career and affably accepts my sometimes-challenging work, continuing education, and speaking schedule.

To our sons and “daughters,” Tim, Jennie, Steve, and Mary, the greatest “kids” anyone could ever ask for, who generously share their encouragement and professional expertise whenever needed.

To our six beautiful and handsome grandchildren, Vivian, Simon, Gwyneth, Thatcher, Oscar, and Elliot, whose middle names or pictures can be found in the book.

To my closest and dearest nursing colleague and friend of many years, Lynne, who is dedicated to preparing 21st-century nursing students with strong clinical judgment skills, resilience, and a commitment to compassionate and safe, patient-centered care.

And to my nursing colleagues at Notre Dame College, Kent State University, North Central State College, Ohio Northern University, and throughout the United

States and around the world for their tireless commitment to educating safe, ethical future nurses to care deeply about their patients and make a positive difference in the world.

Barbara L. Yoost

I dedicate this book to my loving and supportive husband, David. Thank you for your understanding during the past 10 years of writing and editing. Your patience and encouragement mean so much to me.

To our children and their spouses, Brian & Vicki Crawford, and Deanna & Jake Henkle, your support and interest in nursing education inspires me.

To our grandsons Jacob & Alex Crawford, and Jackson & Deacon Henkle, four wonderful boys who are the light of my life.

To my coauthor and colleague in this and many other endeavors, Barbara, who is also my long-time friend.

There is no one else with whom I could have tackled such huge projects. Your expertise and complimentary talents are invaluable to me.

To my mother, Virginia, you continue to inspire me with your knowledge of the written word, even as you celebrate your 95th birthday.

To my extended family and friends, thanks for believing in me and supporting me in my writing process.

To my colleagues across the country who have adopted this textbook, thank you for your positive feedback, critiques, and words of encouragement. You are making a difference in each student's life

Lynne R. Crawford

In Memoriam

We wish to honor two colleagues and contributors to this 2nd edition, who passed away recently. Both Julie McAfoes, RN-BC, MS, CNE, ANEF, FAAN and Pamela Rutar, RN, BSN, MSN, EdD, CNE left us way too early. We are incredibly grateful for their willingness to share their knowledge and time while they were with us. We hope that wonderful memories and the support of others will bring comfort to their families in the months and years ahead. May the contributions of Julie and Pamela to the nursing profession be appreciated and celebrated for years to come.

Assistant Professor, Nursing
West Chester University
West Chester, Pennsylvania

Preface

Fundamentals of Nursing offers a concise and contemporary approach to teaching nursing practice for today's students. It responds to the challenges faced in the nursing profession, including how to apply knowledge-based care and how to adapt to changes in innovations and technology. It guides student nurses through the professional and clinical concepts they will need to master to lead and educate in various settings and to treat and maintain an individual's most healthy and safe state.

Information is presented in a practical and easy-to-understand format that is desirable for achieving optimal patient care.

Fundamentals of Nursing is an ideal textbook for traditional and concept-based curricula. It begins with a basic understanding of the nursing profession and progresses students through the nursing process and into the safe and systematic methods of applying care. The nursing process is introduced in [Chapters 5 to 9](#) and is then integrated and used throughout the text and clinical skills chapters.

Fundamentals of Nursing has three important criteria that will help students develop essential clinical judgment skills and succeed as care providers in the 21st century.

Relevancy: Concise and Contemporary Approach

The Yoost/Crawford team has introduced an approach to nursing practice that focuses on the essential “need to know” concepts. Nursing students have a lot of information they need to digest in a short amount of time, and *Fundamentals of Nursing* presents that information in a clear and concise manner that prepares students to understand the role of the nurse, how to critically think and analyze, and how to confidently and accurately perform the nursing care skills and procedures that will make them successful. To reinforce this approach, every Learning Objective in *Fundamentals of Nursing* is directly tied to the content that elaborates that objective.

Organization: Building-Block Approach to Teaching Nursing

Most nursing faculty agree that students get easily overwhelmed and confused trying to understand the art and science of nursing if the information is not presented in the appropriate way. And yet other nursing books introduce difficult concepts early in their texts, thus bombarding students early in the course with an overload of concepts and terms. The Yoost/Crawford team believes that by slowing down the pace of the information and giving students time to practice and gain mastery, this building-block approach leads to greater student success.

Fundamentals of Nursing is organized in 6 units and 42 chapters. It is shorter than other nursing textbooks but still covers all essential fundamental concepts and skills—just in a clearer, more easy-to-understand manner. Students are not frustrated with repetitive discussions and unnecessary information.

Technology: Powerful Tools for Teaching and Study

Students have different learning styles and conflicting time commitments, so they want technology tools that help them study more efficiently and effectively. A rich amount of resources will help them maximize their study time and make their learning experience more enjoyable. *Fundamentals of Nursing* is accompanied by the interactive Conceptual Care Map creator, additional online-only Case Studies, a Fluid & Electrolytes tutorial, Body Spectrum (a program designed to help students understand or review anatomy and physiology), a Calculations tutorial, animations, skills videos clips, and other resources for the instructor and student. Adaptive Quizzing and Sherpath online products are also available for purchase or bundling to enhance student progress.

Pedagogical Features

A **Case Study** opens every chapter of *Fundamentals of Nursing*, and is designed to help students develop their analytical, critical thinking, and clinical reasoning skills. These case studies represent situations similar to those the nurse may encounter in daily practice. Students are encouraged to consider the case study as they read through the chapter and to check their understanding by answering the **Critical Thinking Exercises**. These exercises appear throughout each chapter and tie directly to the case study scenario introduced at the beginning of the chapter. Students are required to use the case study content and what they have learned from the chapter materials to apply critical thinking and sound clinical judgment when answering the questions.

Copyright [Thinkstock.com](https://www.thinkstock.com) for [Chapters 13, 20, 21, 22, 24, 25, 31, 37, and 41.](#)

Copyright [Shutterstock.com](https://www.shutterstock.com) for [Chapters 14, 16, 23, 28, 30, 38, and 42.](#)

The **Conceptual Care Map** is a *unique*, interactive learning tool developed to assist students in their ability to make clinical judgments and synthesize knowledge about the whole patient. Although the first part employs some principles of a traditional concept map, the Conceptual Care Map requires the student to develop a plan of care after analyzing and clustering related patient assessment data. This tool assists students in recognizing the importance of each type of assessment data that provides the foundation for individualized, patient-centered care plan development.

Boxed Features

- **Interprofessional Collaboration and Delegation** boxes stress the importance of effective and accurate communication among the health care team about a patient's condition and treatment, as well as the importance of assigning tasks appropriately.
- **Ethical, Legal, and Professional Practice** boxes address ethical and legal dilemmas commonly faced in nursing to prepare students to act in a professional and nonjudgmental manner while protecting patient rights.
- **Patient Education and Health Literacy** boxes stress the importance of patient education and how to deliver information in an understandable manner based on the patient's level of health literacy.
- **Health Assessment Question** boxes help students learn how to properly ask and use assessment questions when interviewing patients.
- **Diversity Considerations** boxes prepare students to care for and communicate with patients of diverse ages, cultural, ethnic, and religious backgrounds, as well as various morphological characteristics.
- **Evidence-Based Practice and Informatics** boxes provide students with current research and resources that, combined with clinical

expertise, will contribute to improved patient care outcomes.

- **Home Care Considerations** boxes highlight issues that pertain specifically to transitional nursing practice from the acute care setting to home.

- *Safe Practice Alert!* boxes underscore significant patient safety concerns and provide information to ensure the safety of both the patient and the nurse.

- *QSEN Focus!* boxes illustrate application of the six Quality and Safety Education for Nurses (QSEN) competencies for prelicensure nursing students: (1) patient-centered care, (2) teamwork and collaboration, (3) evidence-based practice, (4) quality improvement, (5) safety, and (6) informatics.

Nursing Skills

Skills are written in a clear and concise manner, with the nursing care actions and rationale presented in a straightforward, step-by-step format and supported by evidence-based practice notations, photographs, and illustrations.

Nursing Care Guidelines provide guidelines and resources to reduce risk and ensure safety for the patient and nurse.

End-of-Chapter Features

The **Summary of Learning Outcomes** reinforces key concepts integral to achieving a basic understanding of chapter content and applying theory to nursing practice.

Every chapter ends with **10 review questions**. An **additional five review questions** are available on the accompanying Evolve site. These questions help students review what they have learned and evaluate their understanding by providing complete answers and rationales.

About the Authors

Barbara L. Yoost, MSN, RN, CNE, ANEF

Barbara Yoost received her BSN and MSN with a concentration in Adult Medical Surgical Education from Kent State University. She is a Certified Nurse Educator and Fellow in the National League for Nurses Academy of Nursing Education. She practiced as an intensive care nurse while beginning her teaching career at the request of Kent State University's founding Dean Linnea Henderson. Barbara has held full-time faculty appointments at North Central State College in the ADN program; at Huron School of Nursing, part of the Cleveland Clinic Health System, in the Diploma program; and at her alma mater and Notre Dame College in their BSN programs, giving her a unique perspective on the needs of prelicensure students in all types of programs. She is currently an Adjunct Professor of Nursing at Notre Dame College and emerita faculty at Kent State University. Her passion for innovative teaching and active learning strategies has defined her nursing education career. She is committed to engaging students in the educational process and providing faculty with practical methods to evaluate student outcomes. Barbara is the coauthor of *Conceptual Care Mapping: Case Studies for Improving Communication, Collaboration, and Care* and the *Clinical Companion*

for this 2nd edition textbook. She speaks and presents faculty workshops across the United States and internationally. She serves on the Ohio Northern University Nursing Program Advisory Board and the EOCUMC Board of Benefits. Barbara is a member of the American Nurses Association, National League for Nurses, Sigma Theta Tau International, and Phi Beta Delta, the Honors Society of International Scholars. She is a recipient of the Kent State University Distinguished Honors Faculty Award, KSU College of Nursing Distinguished Alumni Recognition, and the STTI Delta Xi Excellence in Nursing Education Award. She has been a Certified Nurse Educator since 2006, a Fellow in the Academy of Nursing Education since 2011, and was a Clinical Nurse Specialist from 1994-2018. An avid sailor and kayaker, Barbara and her husband, Charles, enjoy traveling and spending time with family.

Lynne R. Crawford, MSN, MBA, RN, CNE

Lynne Crawford's interest in nursing began with a desire to work with children. She graduated from Kent State University with her BSN and began her nursing career working in pediatric neurology. While still working at Akron Children's Hospital she earned her MSN in Pediatric Nursing Education from Frances Payne Bolton School of Nursing at Case Western Reserve University and received the Cushing Robb Prize for academic achievement in the graduate program upon graduation. Her career in nursing education began at Kent State University

College of Nursing, where she taught pediatric nursing. After receiving her MBA, she worked as an RN supervisor in long-term care facilities. She returned to Kent State University to teach fundamentals of nursing. Her passion for fundamentals grew as she witnessed the students' transformation during their fundamentals rotation. Mentoring students and clinical faculty have been the most rewarding aspects of her nursing education career. She is emerita faculty at Kent State University. Lynne has presented at national conferences in the areas of student-centered learning activities, handheld technology, and conceptual care mapping. She is a coauthor of *Conceptual Care Mapping: Case Studies for Improving Communication, Collaboration, and Care*, and was a subject matter expert in the development of online simulations for nursing students. A charter member of the Delta Xi chapter of Sigma Theta Tau International, Lynne is also a member of the National League for Nursing and Beta Gamma Sigma Honor Society for Collegiate Schools of Business. Since 2010 she has been a Certified Nurse Educator, and in 2011 she was recognized as a Distinguished Alumna Honoree at KSU College of Nursing. Lynne and her husband, David, enjoy many hobbies including sailing on Lake Erie, flying in their single-engine aircraft, motorcycling, traveling, and spending time with family.

Acknowledgments

Rapidly changing nursing and medical research outcomes and practice guidelines require significant modifications to how we educate future nurses. This second edition of *Fundamentals of Nursing: Active Learning for Collaborative Practice* is the result of overwhelming acceptance of our innovative, succinct approach to contemporary nursing education.

We want to give a shout-out to the entire Elsevier team with whom we work. Their professionalism, expertise, and tireless efforts to help us prepare nursing students for safe and evidence-based patient care is inspiring. We want to especially thank these special people:

- Tamara Myers, Director, Traditional Markets in Education, whose knowledge, energy, creative vision, and teamwork are unmatched. The book, software, ancillary products, and online resources are a reality due to her hard work and leadership. It is difficult to imagine this project ever becoming a reality without the encouragement and support of Tamara.
- Laura Selkirk, Senior Content Developmental Specialist, for her exhaustive work on a thousand details including: editing, finding photos, securing permissions, accessing video clips, and turning our manuscript into a textbook and ebook. We are incredibly grateful to be working with Laura.

- Rachel McMullen, Senior Project Manager, for her coordination of the final steps. We appreciate her patience as we continued to update research findings throughout the month before publication.
- Our contributors and reviewers who shared their knowledge and time to write and thoughtfully consider the needs of fundamentals students, making sure the textbook presented essential up-to-date information in a user-friendly, accessible manner.
- The nursing faculty from traditional and concept-based programs who have adopted the book and shared how the textbook has supported student learning and positive outcomes. We applaud your dedication to strong, foundational nursing education.
- The literal thousands of current and former students in the United States and around the world, who have read and reviewed chapters, and utilized many of our innovative learning strategies during their nursing education. We are grateful for your feedback and commitment to excellence. It is wonderful to watch you progress in your nursing careers.

It is our hope that *Fundamentals of Nursing: Active Learning for Collaborative Practice*, Second Edition will continue to help both students and faculty make a positive difference in the rapidly changing health care environment of the 21st century and beyond.

Barbara L. Yoost

Lynne R. Crawford

UNIT I

Nursing Basics

OUTLINE

Chapter 1 Nursing, Theory, and Professional Practice

Chapter 2 Values, Beliefs, and Caring

Chapter 3 Communication

Chapter 4 Critical Thinking in Nursing

CHAPTER 1

Nursing, Theory, and Professional Practice

LEARNING OUTCOMES

Comprehension of this chapter's content will provide students with the ability to:

- LO 1.1 Characterize nursing.
- LO 1.2 Differentiate among the functions and roles of nurses.
- LO 1.3 Analyze historical events in the evolution of nursing.
- LO 1.4 Summarize nursing theories.
- LO 1.5 Examine nonnursing theories that influence nursing practice.
- LO 1.6 Articulate the criteria of a profession as applied to nursing.
- LO 1.7 Consider standards of practice and nurse practice acts.
- LO 1.8 Analyze the socialization and transformation process of a nurse.
- LO 1.9 Explore the levels of educational preparation in nursing and differentiate among the nurse's roles depending on education.
- LO 1.10 Investigate possible certifications in various arenas of nursing and professional organizations in nursing.
- LO 1.11 Probe the future directions in nursing.

profession, p. 3
socialization, p. 13
standards, p. 2

Case Study

John, a registered nurse (RN), arrives for work on the day shift on an acute care medical unit and receives a patient assignment for the shift. The assignment includes care of five medical patients. After receiving the night shift report, John makes rounds on the five patients, assesses each patient, lists patient problems, sets patient goals, and plans care for all five patients for the day. During the shift, John administers intravenous (IV) medications, ensures that oral medications are administered by the licensed practical nurse (LPN), instructs the unlicensed assistive personnel (UAP) to bathe two of the patients who need assistance, assists a patient with ambulation, provides discharge education on a new medication, evaluates and updates the plan of care for each patient, and notifies the primary care providers (PCPs) of critically abnormal blood work results for two patients.

One patient's friend comes to visit and stops John in the hallway to ask detailed questions about the patient's condition. John states that patient information is protected and cannot be shared without the consent of the patient.

At a recent continuing education conference, John learned about new research concerning administering intramuscular (IM) medication in the deltoid. Current evidence shows that aspirating the syringe after the needle is inserted into the muscle before administering the medication is no longer recommended. He remembers this new information while preparing to give a patient an IM immunization before discharge.

John believes that self-care maintains wholeness. He meets patients' self-care needs by helping, guiding, teaching, supporting, or providing the environment to promote self-care abilities.

Refer back to this case study to answer the critical-thinking questions throughout the chapter.

Registered nurses (RNs) constitute the nation's largest health care profession. Nurses provide care to patients throughout the life span, from babies (and their parents) at the joyful occasion of birth to people who are at the end of life's journey. The privilege of caring for patients is the hallmark of this rewarding career. Those who follow this career path often are inspired by other nurses who have touched their lives, by stories they have read or heard about specific nurses, or by the concept of a helping profession that allows the nurse to make a difference in someone's daily life. The study of nursing requires a broad base of knowledge from the physical and behavioral sciences, humanities, nursing theories, and related nonnursing theories.

Within the field of nursing, various roles are performed in numerous arenas. Each of these roles is governed by nursing **standards** (minimum set of criteria) of practice to deliver quality care and by state nurse practice acts that provide legal criteria for adequate patient care. Nurses work in various areas within a hospital by focusing on a specific population (such as children or the elderly) or a specific department (such as critical care or surgery). They may concentrate on areas outside the hospital patient care environment, serving in positions such as nursing faculty member, school nurse, or legal nurse consultant, or be involved with computers in the field of nursing.

Nursing has continued to evolve throughout history to meet the needs of the patient and the changing health care environment. With a growing need for nurses, the future of nursing provides an incredible avenue for committed, caring practitioners to be involved in a profession that continues to progress to meet health care demands, utilizing innovative solutions related to the delivery of nursing care services. This complex profession that serves society by providing quality nursing care in a variety of settings is a career that combines the art of caring with scientific knowledge and skills.

LO 1.1 Definition of Nursing

In 1860, Florence Nightingale (Fig. 1.1) in her *Notes on Nursing* stated that nursing's role was "to put the patient in the best condition for nature to act upon him" (p. 133). As nursing has progressed to the 21st century, specific nursing definitions have been developed by professional organizations. Part of the [American Nurses Association \(ANA\) \(2018\)](#) definition of **nursing** illustrates how nursing has evolved:

FIGURE 1.1 Florence Nightingale. (Courtesy Library of Congress, Washington, DC.)

... nurses work tirelessly to identify and protect the needs of the individual. Beyond the time-honored reputation for compassion and dedication lies a highly specialized profession, which is constantly evolving to address the needs of society. From ensuring the most accurate diagnoses to the ongoing education of the public about critical health issues; nurses are indispensable in safeguarding public health.

The [International Council of Nurses \(ICN\) \(2018\)](#) definition of nursing further illuminates the autonomous role of nurses and their part in not only patient care but also health policy:

Nursing encompasses autonomous and collaborative care of individuals of all ages, families, groups and communities, sick or well and in all settings. Nursing includes the promotion of health, prevention of illness, and the care of ill, disabled and dying people. Advocacy, promotion of a safe environment, research,

participation in shaping health policy and in patient and health systems management, and education are also key nursing roles.

Virginia [Henderson \(1966\)](#) is known for her specific definition of nursing:

The unique function of the nurse is to assist the individual, sick or well, in the performance of those activities contributing to health or its recovery (or to peaceful death) that he would perform unaided if he had the necessary strength, will or knowledge. And to do this in such a way as to help him gain independence as rapidly as possible (p. 15).

Nursing is seen as a **holistic** (physical, mental, emotional, spiritual, and social) profession that addresses many dimensions necessary to fully care for a patient. A **profession** is an occupation that requires a specialized body of knowledge and training. The all-encompassing nature of the nursing profession sets it apart from the medical profession, which treats an illness with a specific medical diagnosis. Nurses build on their broad education and understanding of illness to promote wellness and health maintenance. Nurses include the patient and family in their care while collaborating with all members of the health care team. Caring, which often is considered to be synonymous with nursing, is a fundamental value for nurses in both their personal and professional lives.

LO 1.2 Primary Roles and Functions of the Nurse

Nurses function in many roles each day to care for their patients. Nurses have various responsibilities within each role that relate to promotion of health, prevention of illness, and alleviation of suffering. Nurses assist patients with restoration of their health and help them cope with illness, disability, and issues related to the end of their lives (ICN, 2012). The roles include care provider, educator, advocate, leader, change agent, manager, researcher, collaborator, and delegator.

Care Provider

“The nurse's primary professional responsibility is to people requiring nursing care” (ICN, 2012, p. 2). Through education, the nurse acquires critical-thinking skills to determine the necessary course of action, psychomotor skills to perform the necessary interventions, interpersonal skills to communicate effectively with the patient and family, and ethical and legal skills to function within the scope of practice and in accordance with the profession's code of ethics.

The scientific process that nurses use to care for their patients is a multistep approach called the **nursing process**. As a care provider, the nurse follows this process to assess patient data, prioritize nursing diagnoses, plan the care of the patient, implement the appropriate interventions, and evaluate care in an ongoing cycle. [Chapter 5](#) provides a detailed description of the nursing process.

Educator

The nurse ensures that patients receive sufficient information on which to base consent for care and related treatment. The nurse assesses learning needs, plans to meet those needs through specific teaching strategies, and evaluates the effectiveness of patient teaching. Patients need to be informed about their medications, procedures, diagnostics, and health promotion measures. Education becomes a major focus of discharge planning so that patients will be prepared to handle their own needs at home. The nurse must understand literacy standards and regulatory guidelines related to patient rights, informed consent, educating patients, improving quality care, and meeting patient needs. The Joint Commission, an accrediting organization for health care facilities, publishes standards for patient and family education to improve health care outcomes. [Box 1.1](#) provides a definition of health literacy.

Box 1.1

Patient Education and Health Literacy

Definition of Health Literacy

Health literacy is defined in *Healthy People 2020* as follows: “The degree to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions” (U.S. Department of Health and Human Services, 2010).

Low health literacy is associated with increased hospitalization, greater emergency care use, lower use of mammography, and lower receipt of influenza vaccine (Agency for Healthcare Research and Quality, 2011).

A goal of patient education by the nurse is to inform patients and deliver information that is understandable by assessing their level of health literacy. The more understandable health information is for patients, the closer the care is coordinated with need.

Advocate

As the patient's advocate, the nurse interprets information and provides necessary education. The nurse then accepts and respects the patient's decisions even if they are different from the nurse's own beliefs. The nurse supports the patient's wishes and communicates them to other health care providers. It is up to the nurse to be an advocate for patients, especially in situations in which they cannot speak for themselves, such as during a severe illness or under general anesthesia.

Leader

A leader provides direction and purpose to others, builds a sense of commitment toward common goals, communicates effectively, and assists with addressing challenges that arise in caring for patients in a health care setting. Other characteristics of a leader are integrity, creativity, interpersonal skills, and the ability to think critically and problem-solve. The nurse leader motivates others toward common goals. See [Chapter 12](#) for more information about the nurse as a leader.

Change Agent

The nurse can be a change agent in a leadership role. This role requires knowledge of change theory, which encourages change and provides strategies for effecting change. In this role, the nurse works with patients to address their health concerns and with staff members to address change in an organization or within a community. This role can be extended to bringing about change in the legislation on health policy issues.

Manager

A nurse manages all of the activities and treatments for patients. Promoting, restoring, and maintaining the patient's health requires coordinating all of the health care providers' services. This is accomplished efficiently and effectively within a reasonable time period for the welfare of the patient. In addition to managing a team of patients, the nurse may be the manager of a unit in a hospital. A nurse manager in a hospital oversees the staff on a patient care unit

while managing the budget and resources required for necessary functions. See [Chapter 12](#) for more information on nurses as managers.

Researcher

Although not all nurses may have had research methodology in their coursework, nurses are often involved in research. Nurses critique research studies and apply research to practice. Nurses determine care concerns and ask questions about nursing practices. Nursing problems that are identified become the basis of research. By incorporating research into their practice, nurses are involved in evidence-based practice (EBP). [Box 1.2](#) defines EBP and the components of the process. [Chapter 13](#) expands on these topics.

Box 1.2

Evidence-Based Practice and Informatics

Definition of Evidence-Based Practice

Evidence-based practice (EBP) is the integration of best research evidence with clinical expertise and patient values to facilitate decision making. Clinical problems are discovered during patient care, and nurses gather information and research in the literature coupled with patient input to determine the EBP.

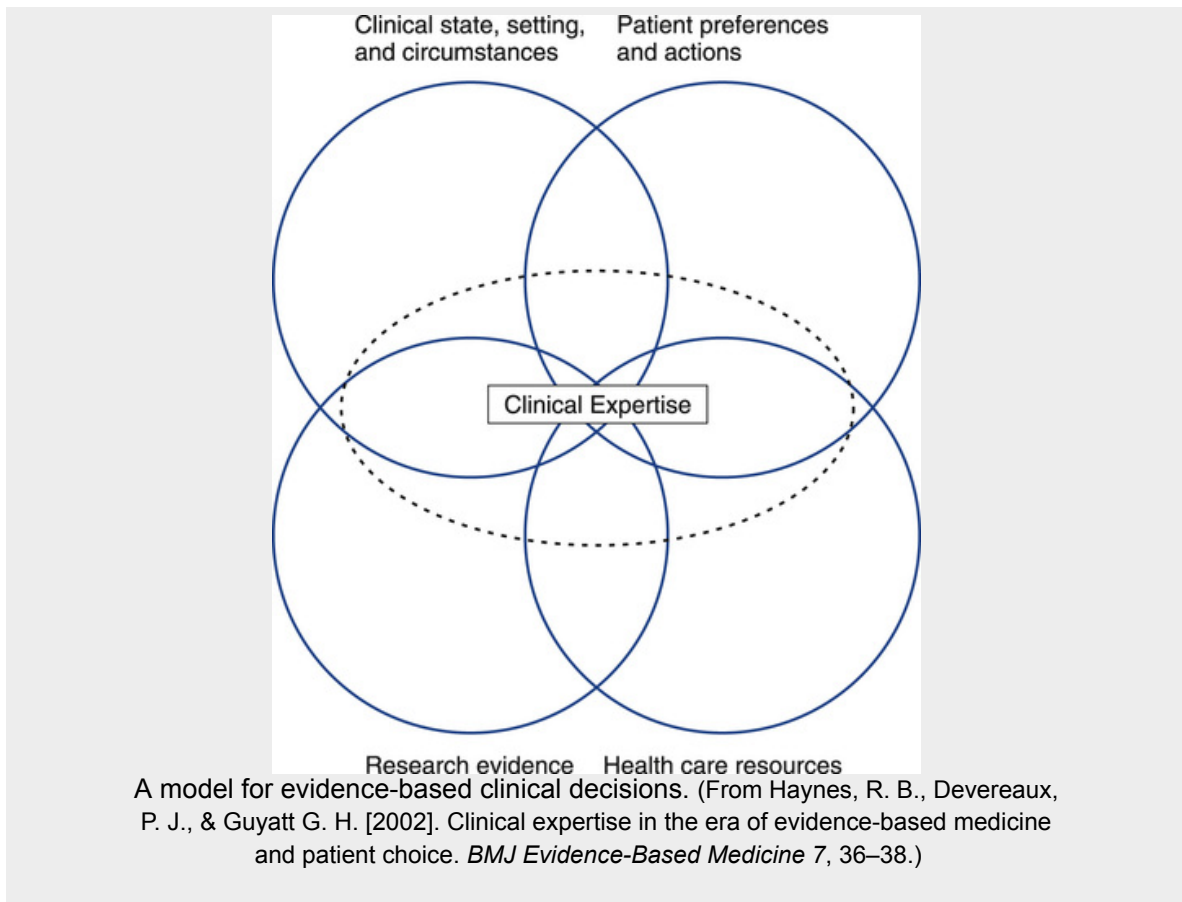

Evidence-based practice (EBP) is an integration of the best-available research evidence with clinical judgment about a specific patient situation that takes into consideration patient preferences and values.

There are five components:

1. Clinical state, setting, and circumstances
2. Patient preferences and actions
3. Research evidence
4. Health care resources
5. Clinical expertise

The first four components intersect with the clinical expertise of the nurse as seen in the figure below.

The key element of evidenced-based clinical decision making is personalizing the evidence to fit a specific patient's circumstances. The clinical expertise is overlaid as the means to integrate the four components, thus constituting a fifth element of the model.

Collaborator

Collaboration is the process by which two or more people work together toward a common goal. In nursing, interprofessional collaboration occurs when RNs, unlicensed assistive personnel (UAP), licensed practical nurses (LPNs), primary care providers (PCPs), social workers, clergy, and therapists all interact productively to provide high-quality patient care. **Box 1.3** describes the characteristics necessary for effective teamwork. All health care team members are responsible for patient care. The nurse plays an important role in the coordination of this care to make sure that all goals are met. The nurse is responsible for ensuring that all patient care orders are carried out and for communicating with the entire team.

Box 1.3

Interprofessional Collaboration and Delegation

Characteristics of Teamwork

- Clinical competence and accountability
- Common purpose
- Interpersonal competence and effective communication

- Trust and mutual respect
- Recognition and valuation of diverse complementary knowledge and skills
- Humor

To prepare students for their interactions during their profession, the National League for Nursing (NLN) promotes engagement of students in interprofessional education (IPE) and interprofessional practice (IPP) to improve health outcomes by delivering team-based care ([NLN Board of Governors, 2015](#)). The competency to work in teams is meant to provide safer, quality care ([Thibault, 2013](#)). The practice of working in teams in some educational programs should emphasize utilization of team work skills to deliver patient-centered care to prepare the nurse for entry level practice ([IPEC, 2011](#); [Speakman & Arenson, 2015](#)).

Delegator

In the process of collaboration, the nurse delegates certain activities to other health care personnel. **Delegation** is the process of entrusting or transferring the responsibility for certain tasks to other personnel, including UAP, licensed vocational nurses (LVNs), and LPNs. The RN needs to know the scope of practice or capabilities of each health care team member. For example, UAP are capable of performing basic care that includes providing hygienic care, taking vital signs, helping the patient ambulate, and assisting with eating. The RN retains ultimate responsibility for patient care, which requires supervision of those to whom patient care is delegated. The *Five Rights of Delegation*, as well as additional guidelines for consideration, are discussed in [Chapter 12](#). Additional information on delegation can be found in the article “National Guidelines for Nursing Delegation” on the [National Council of State Boards of Nursing \(NCSBN, 2016\)](#) website.

All of these roles are interrelated as the nurse cares for patients on a daily basis ([Fig. 1.2](#)). As a provider of care, the nurse assesses, leads, manages, and educates. The nurse is the patient advocate, researching appropriate care and collaborating with and delegating to other health care providers.

FIGURE 1.2 Roles of the nurse.

1. Which roles of the nurse are exhibited by John, and when are they displayed?

LO 1.3 History of Nursing

Nursing had its beginnings in religious and military services in the Middle Ages, particularly during the Crusades. In 1860, Florence Nightingale's *Notes on Nursing* raised the profile of nursing with critical thinking and respect for patient needs and rights. Nightingale is considered the founder of modern nursing and is known for her care of the sick in the Crimean War. Her contributions influenced developments in the field of epidemiology by connecting poor sanitation with cholera and dysentery. Her role in nursing included establishing nursing as a respected profession for women that was distinct from the medical profession. She founded a nursing school and stressed the need for university-based and continuing education for nurses.

During the Civil War, two nurses emerged to further nursing. Dorothea Dix was the head of the U.S. Sanitary Commission, which was a forerunner of the Army Nurse Corps. Clara Barton (Fig. 1.3) practiced nursing in the Civil War and established the American Red Cross. History continues to reveal other nurse leaders. Linda Richards was America's first trained nurse, graduating from Boston's Women's Hospital in 1873, and Lenah Higbee (Fig. 1.4), superintendent of the U.S. Navy Nurse Corps, was awarded the Navy Cross in 1918.

FIGURE 1.3 Clara Barton. (Courtesy National Park Service, U.S. Department of the Interior.)

FIGURE 1.4 Lenah Higbee. (Courtesy U.S. Navy and the National Archives.)

After World War II, scientific and technologic advances brought changes to both principles and practices in health care delivery. This new approach required critical care specialty units and more experienced and skilled nurses. Health promotion became a greater focus, leading to a need for nurse practitioners (NPs). The timeline in Fig. 1.5 provides a brief overview of modern nursing up to the present day.

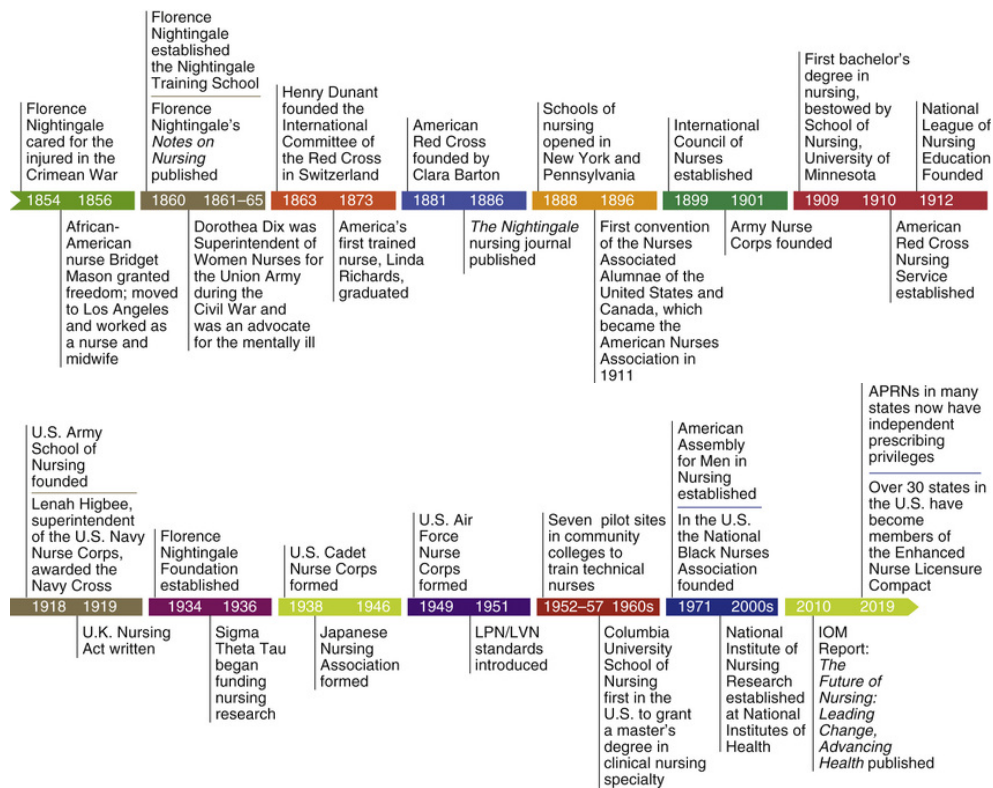

FIGURE 1.5 Timeline of nursing.

LO 1.4 Nursing Theories

To enhance nursing as a profession, nursing works to establish itself as a scientific discipline. A **discipline** is a specific field of study or branch of instruction or learning. Nursing leaders believe nursing needs a theoretical base that reflects its practice. With this belief, nursing theories have emerged from the time of Nightingale to the present to give substance to the body of knowledge of nursing.

Definitions

A **metaparadigm**, the most abstract level of knowledge, is defined as a global set of concepts that identify and describe the central phenomena of the discipline and explain the relationship between those concepts (Fawcett and DeSanto-Madeya, 2013). For example, the metaparadigm for nursing focuses on the concepts of person, environment, health, and nursing. The next level of knowledge is a **philosophy**, which is a statement about the beliefs and values of nursing in relation to a specific phenomenon such as health. A philosophy provides guidance in practice.

The third level of knowledge is a nursing **conceptual framework** or **model**, which is a collection of interrelated concepts that provides direction for nursing practice, research, and education. A conceptual model addresses the four concepts of the nursing metaparadigm: (1) optimal functioning of the person or patient, (2) how people interact with the environment, (3) illness and health promotion, and (4) nursing's role (Alligood, 2018). Each is defined and described by the theorist in the model. In nursing practice, nursing models approach the nursing process in a logical, systematic way. The model influences the data the nurse collects and the care of the patient. Conceptual models often are based on other nonnursing theories, such as system or stress theory. The fourth level of nursing knowledge is a **nursing theory**, which represents a group of concepts that can be tested in practice and can be derived from a conceptual model.

Theories include both grand theories and middle-range theories, which are derived from conceptual models. A **grand theory** consists of a global conceptual framework that defines broad perspectives for nursing practice and provides ways of looking at nursing phenomena from a distinct nursing viewpoint. Although grand theories are derived from conceptual frameworks, they remain almost as broad as the framework itself. A grand theory defines key concepts and principles of the discipline in an abstract way (Alligood, 2018).

A **middle-range theory** is moderately abstract and has a limited number of variables. Therefore middle-range theories are more concrete and narrowly focused on a specific condition or population than are grand theories (Fawcett and DeSanto-Madeya, 2013). They can be tested directly through application to practice situations and are useful in nursing research and practice. These theories provide a map of how patients are assessed and how care is planned and delivered (McKenna and Slevin, 2008).

Overview of Key Nursing Theories

Florence Nightingale

Florence [Nightingale's \(1860\)](#) concept of the environment emphasized illness prevention, clean air, water, and housing. Her nursing theoretical work discussed environmental adaptation with appropriate noise levels, hygiene, light, comfort, socialization, hope, nutrition, and conservation of patient energy. This theory states that the imbalance between the patient and the environment decreases the capacity for health and does not allow for conservation of energy.

Hildegard Peplau

Hildegard [Peplau \(1952\)](#) focused on the roles played by the nurse and the interpersonal process between a nurse and a patient. The interpersonal process occurs in overlapping phases: (1) *orientation*; (2) *working*, consisting of two subphases—identification and exploitation; and (3) *resolution*. This theory has been used widely in psychiatric nursing and enhances the understanding of changing aspects regarding the goals and roles in the nurse–patient relationship.

Virginia Henderson

Virginia [Henderson \(1966\)](#) defined nursing as “assisting individuals to gain independence in relation to the performance of activities contributing to health or its recovery” (p. 15). Her 14 components were based on Maslow's hierarchy of human needs from the physiologic, psychological, sociocultural, spiritual, and developmental domains. She described the nurse's role as *substitutive* (doing for the person), *supplementary* (helping the person), or *complementary* (working with the person), with the ultimate goal of independence for the patient.

Martha Rogers

Martha [Rogers \(1970\)](#) developed the Science of Unitary Human Beings. She stated that human beings and their environments are interacting in continuous motion as infinite energy fields. The model includes four dimensions: (1) energy fields, (2) openness, (3) patterns and organizations, and (4) dimensionality. The dimensions are used in developing the three principles of *resonancy* (continuous change from lower to higher frequency), *helicy* (increasing diversity), and *integrality* (continuous process of the human and environmental fields). Well-being of the patient is illustrated by pattern and organization. Nurses assist the patient with repatterning to develop well-being. The resultant well-being of pattern and organization includes a symphonic interaction between the patient and the environment.

Sister Callista Roy

Sister Callista [Roy's \(1970\)](#) Adaptation Model is based on the human being as an adaptive open system. The person adapts by meeting physiological-physical needs, developing a positive self-concept–group identity, performing social role functions, and balancing dependence and independence. Stressors result in illness by disrupting the equilibrium. Nursing care is directed at altering stimuli that are stressors to the patient. The nurse helps patients strengthen their abilities to adapt to their illnesses or helps them develop adaptive behaviors.

Dorothea Orem

Three interrelated theories of self-care, self-care deficit, and nursing systems constitute Dorothea Orem's (1971) Self-Care Deficit Theory of Nursing. A self-care deficit exists when patients are unable to meet their self-care needs. Nursing systems care for patients who require assistance in one of three categories: (1) *wholly compensatory*, (2) *partly compensatory*, or (3) *supportive-educative*. The goal of nursing care is to help patients perform self-care by increasing their independence.

Imogene King

Imogene M. King (1971) developed a general systems framework that incorporates three levels of systems: (1) *individual or personal*, (2) *group or interpersonal*, and (3) *society or social*. The theory of goal attainment discusses the importance of interaction, perception, communication, transaction, self, role, stress, growth and development, time, and personal space. In this theory, the nurse and the patient work together to achieve the goals in the continuous adjustment to stressors.

Betty Neuman

Betty Neuman's (1972) Systems Model includes a holistic concept and an open-system approach. The model identifies energy resources that provide for basic survival, with lines of resistance that are activated when a stressor invades the system. The person has a normal response to stress, known as *normal lines of defense*, whereas a flexible line defends against unusual stress. Stressors may be intrapersonal, interpersonal, or extrapersonal. Three environments—*internal*, *external*, and *created*—are defined, and nursing actions involve three levels of prevention—primary, secondary, and tertiary (discussed in more detail in Chapter 16). The nurse's goal is to assist with attaining and maintaining maximum wellness, focusing on patients' responses to stressors, and strengthening their lines of defense. Two theories were produced from this model: optimal patient stability and prevention as intervention.

Rosemarie Rizzo Parse

In 1981 Rosemarie Rizzo Parse formulated the Theory of Human Becoming by combining concepts from Martha Rogers' Science of Unitary Human Beings with existential-phenomenological thought. This theory looks at the person as a constantly changing being and at nursing as a human science. Today, Parse's theory is called the *Human Becoming School of Thought*.

Jean Watson

Jean Watson's (1988) theory is based on caring, with nurses dedicated to health and healing. The nurse functions to preserve the dignity and wholeness of humans in health or while peacefully dying. The caring process in a nurse-patient relationship is known as *transpersonal caring* and includes carative factors that satisfy human needs. Additional concepts include the caring moment or occasion, caring or healing consciousness, and clinical caring processes, such as sensitivity

and mindfulness. The practice of nursing focuses on the goals of growth, meaning, and self-healing. [Table 1.1](#) compares the various nursing theories and models.

TABLE 1.1
Nursing Model and Theory Comparison

THEORIST AND THEORY OR CONCEPTUAL FRAMEWORK (YEAR)	GENERAL CONCEPT	METAPARADIGM			
		NURSING	PERSON	HEALTH	ENVIRONMENT
<i>Nightingale</i> Environmental Theory (1860)	Environment	Providing fresh air, warmth, quiet, cleanliness, and proper nutrition to facilitate reparative process.	Patient who is acted on by nurse and affected by environment has reparative powers.	Maintaining well-being by using a person's powers and control of environment.	Foundation of theory; included physical, psychological, and social.
<i>Peplau</i> Theory of Interpersonal Relations (1952)	Interpersonal	A therapeutic, interpersonal process that functions cooperatively with others to make health possible; involves problem solving.	An individual; a developing organism who tries to reduce anxiety caused by needs and lives in unstable equilibrium.	Implies forward movement of the personality toward creative, constructive, productive, personal, and community living.	Acknowledgment of the environment and influence of culture and other factors.
<i>Henderson</i> Humane and holistic care for patients (1966)	Helping the patient become as independent as possible	Temporarily assisting an individual who lacks the necessary will, strength, and knowledge to satisfy one or more of 14 basic needs.	The patient as a sum of parts with biopsychosocial needs, and the patient is neither client nor consumer.	Being as independent as possible with the 14 basic needs. Affected by age, culture, and physical, intellectual, and emotional factors.	All external conditions and influences that affect life and development.
<i>Rogers</i> Science of Unitary Human Beings Model (1970)	Integrality, resonancy, and helicy; characterized by nonrepeating rhythmicities	Both an art and a humanistic science supported by an organized body of knowledge arrived at by scientific research and logical analysis.	A unitary human being is an "irreducible, indivisible, four-dimensional energy field."	Rogers defined health as an expression of the life process. Health and illness are part of the same continuum.	The environment is an "irreducible, four-dimensional energy field identified by pattern and integral with the human field."

THEORIST AND THEORY OR CONCEPTUAL FRAMEWORK (YEAR)	GENERAL CONCEPT	METAPARADIGM			
		NURSING	PERSON	HEALTH	ENVIRONMENT
<i>Roy</i> Adaptation Model (1970)	Adaptation	The science and practice that expands adaptive abilities and enhances person and environment transformation.	A biopsychosocial being with a unified system; an adaptive system in the four modes: physiological-physical, self-concept-group identity, role function, and interdependence.	Equilibrium resulting from effective coping and a state of becoming integrated and whole that reflects person-environment mutuality.	Environment seen as all conditions that shape an individual's behavior.
<i>Orem</i> Self-Care Deficit Theory (1971)	Self-care maintains wholeness: theory of self-care, self-care deficit, and nursing systems	Meets self-care needs by acting or doing for, guiding, teaching, supporting, or providing the environment to promote patient's ability.	Patients require assistance either wholly or partially compensatory or supportive-educative.	Structurally and functionally whole or sound; self-care deficit occurs when the person cannot carry out self-care.	Components are internal and external; include environmental factors.
<i>King</i> General systems framework (1971)	Importance of the interaction between nurses and patients	The nurse and patient mutually communicate, establish goals, and take action to attain goals.	Human beings bring a different set of values, ideas, attitudes, and perceptions to exchange.	Dynamic state in the life cycle; continuous adaptation to stress to achieve maximum potential for daily living.	Constant interaction with a variety of environmental factors.
<i>Neuman</i> Systems Model (1972)	Holistic concepts and open systems	Interventions are activated to strengthen lines of defense and resistance to stressors and maintain adaptation.	The person is a complete system: physiologic, psychological, sociocultural, developmental, and spiritual aspects.	Primarily concerned with effects of stress on health; wellness is equilibrium.	Balance between internal and external by adjusting to stress and defending against tension-producing stimuli.
<i>Parse</i> Human Becoming Theory (1981)	Man's reality is given meaning through lived experiences	A human science and art that uses an abstract body of knowledge to serve people.	Being who is more than the sum of the parts: reaching beyond the limits that a person sets and constantly transforms.	Open process of being and becoming; involves synthesis of values.	Energy is exchanged with the environment.
<i>Watson</i> Human Caring Theory (1988)	Humanitarian and science orientation to human caring processes	Human being to be valued, cared for, respected, nurtured, understood, and assisted.	Complete physical, mental, and social well-being and functioning.	Healing consciousness and self-healing.	Caring and society affect health.

LO 1.5 Nonnursing Theories With Significant Impact on Nursing

Nursing requires a strong scientific knowledge base in the natural, social, and behavioral sciences. Accordingly, nursing theories often are influenced by interdisciplinary theories. Nurses use these theories in their practice.

2. Which nursing theorist do John's beliefs parallel?

Maslow's Hierarchy of Needs

Maslow's hierarchy of needs specifies the psychological and physiologic factors that affect each person's physical and mental health (Fig. 1.6). The nurse's understanding of these factors helps with identifying nursing diagnoses that address the patient's needs and values. Needs at the lower levels of the pyramid-shaped hierarchy must be met before needs at higher levels are addressed. At the base of the pyramid are physiologic needs including oxygen, food, elimination, temperature control, sex, movement, rest, and comfort. These are followed by safety and security, love and belonging, self-esteem, and self-actualization. This hierarchy allows nurses to plan the care of patients by addressing their needs on the basis of priorities.

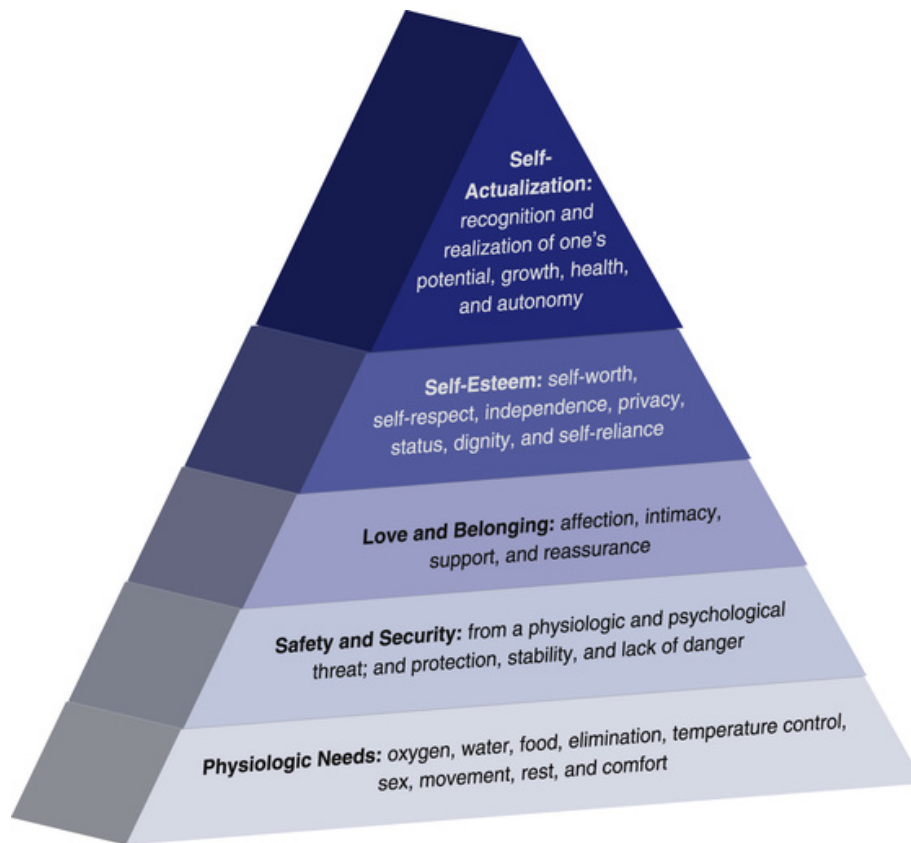

FIGURE 1.6 Maslow's hierarchy of needs.

Erikson's Psychosocial Theory

[Erikson's \(1968\)](#) Psychosocial Theory of Development and Socialization is based on individuals' interacting and learning about their world. Nurses use concepts of developmental theory to care for their patients at various stages in life. Because nurses strive to meet the holistic needs of patients, they must address the developmental issues. See [Chapter 17](#) for a detailed discussion of Erikson's theory.

Lewin's Change Theory

Nurses function as change agents in their leadership role and therefore need to understand change theory. According to [Lewin's \(1951\)](#) Change theory, change is a three-step process. *Unfreezing*, the first step, is overcoming inertia and changing the mind-set, which involves bypassing the defenses. During unfreezing, the right environment is created for change. The second step, *moving or change*, is the time of transition and confusion when change takes place. Change is supported and implementation of the change occurs. The third step is *refreezing*, during which the change is completed, reinforced, and accepted. Change theory recognizes the dynamic nature of change and the need to constantly evaluate nursing practice. First, the nurse needs to recognize when change is needed. Next, the nurse analyzes the situation to determine what is maintaining the situation and what is working to change it. Then the nurse identifies methods to use in the change process and analyzes the influence of those involved in the change.

Paul's Critical-Thinking Theory

Critical thinking, according to Paul (1993), is an “intellectually disciplined process of actively and skillfully conceptualizing, applying, analyzing, synthesizing, and/or evaluating information gathered from, or generated by, observation, experience, reflection, reasoning, or communication, as a guide to belief and action” (p. 110). In applying Paul's definition, nurses analyze data, develop a patient care plan, implement a plan of action for the patient, and evaluate the plan of care. Certain intellectual values are recognized as pertinent to any subject matter, such as clarity, accuracy, precision, consistency, relevance, sound evidence, good reasons, depth, and fairness (Paul, 1993). Nursing expands upon this process of critical thinking and adapts it to the care of the patient.

Each of these critical-thinking skills is learned in the context of nursing and in the application to patient care. Chapter 4 explores more fully the concept of critical thinking in nursing.

Rosenstock's Health Belief Model

Rosenstock (1974) developed the psychological Health Belief Model. Originally, the model was designed to predict responses of patients to treatment, but recently the model has been used to predict more general health behaviors. The model addresses possible reasons for why a patient may not comply with recommended health promotion behaviors. This model is especially useful to nurses as they educate patients. Rosenstock's Health Belief Model (Fig. 1.7) is based on four core beliefs of people's perceptions by their own assessment:

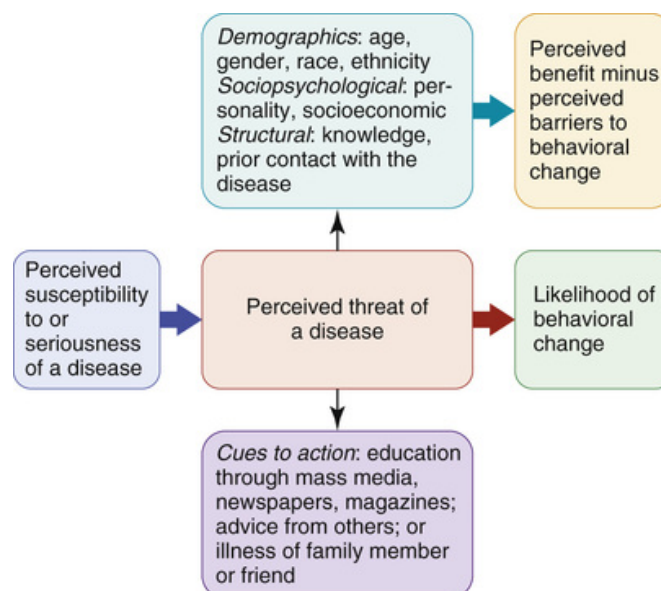

FIGURE 1.7 Rosenstock's Health Belief Model.

- Perceived susceptibility of the risk of getting the condition

- Perceived severity of the seriousness of the condition and its potential consequences
- Perceived barriers of the influences that facilitate or discourage adoption of the promoted behavior
- Perceived benefits of the positive consequences of adopting the behavior

LO 1.6 Criteria for a Profession

As stated earlier, a profession is an occupation that requires at a minimum specialized training and a specialized body of knowledge. Nursing meets these requirements. Thus nursing is considered to be a profession. Specific criteria or characteristics are used to further define status as a profession. The sociologist, [Flexner \(2001\)](#), first published a list of such criteria in 1915 that often is used as a benchmark for determining the status of an occupation as a profession.

Altruism

A profession provides services needed by society. Additionally, practitioners' motivation is public service over personal gain (altruism). Nurses recognize nursing as their life's work, being an important component of their lives and clearly defining who they are. Nurses focus on service to their patients and the community.

Body of Knowledge and Research

There is a well-defined, specific, and unique body of theoretical knowledge in nursing, leading to defined skills, abilities, and norms, that is enlarged by research. A profession is distinguished by a specific culture with norms and values common to its members. To advance knowledge in their field, professionals publish and communicate their knowledge. A profession develops, evaluates, and uses theory as a basis for practice. Nursing has been based on theory since the days of Nightingale. Numerous models for nursing practice have been developed. Nursing's reliance on research for practice is considered EBP.

Accountability

Nursing requires accountability, which involves accepting responsibility for actions and omissions. Accountability has legal, ethical, and professional implications. It is essential for developing trusting relationships with patients and co-workers.

Higher Education

Professionals are educated in institutions of higher learning. A profession requires that its members have an extended education, as well as a basic liberal foundation. Higher education provides the basis for practice and allows for lifelong educational opportunities, such as earning a master's or doctoral degree with its associated advantages of professional development. Greater professional opportunities for nurses and the training necessary to extend nursing science through advanced practice and research are possible through higher education. A profession has a clear standard of educational preparation for entry into practice. Graduates with diplomas or associate's and bachelor's degrees in nursing are eligible to take the NCLEX-RN examination.

Autonomy

Members of a profession have autonomy in decision making and practice and are self-regulating in that they develop their own policies in collaboration with one another. Nursing professionals make independent decisions within their scope of practice and are responsible for the results and consequences of those decisions.

Code of Ethics

Professions have codes of ethics to guide decisions for practice and conduct.

Ethics is the standards of right and wrong behavior. The ICN and the ANA each have developed a code of ethics for nurses. Public opinion polls show that nurses are admired for their nursing ethics and honesty by rating them the highest of all professionals. [Chapter 11](#) provides more information on the *ANA Code of Ethics for Nurses*.

Professional Organization

Numerous organizations have evolved to support and encourage high standards in nursing. Members participate in these organizations, which aim to support and advance nursing. Each organization participates in determining responsibilities and standards of conduct for individual members and the group and in regulating its members' adherence to its own professional standards. The ANA is an example of a professional organization that provides standards of professional nursing practice.

Licensure

A profession is committed to competence and has a legally recognized license. Members are accountable for continuing their education. An RN is committed to professional development and is required to continue to learn and maintain competency. All licensed nurses keep their knowledge base current by formal and informal continuing education and can demonstrate competency when required. Although there is more than one educational method of becoming a nurse, attainment of the legal right to practice as a RN in the United States is contingent on passing a standardized licensing examination.

Diversity

“Inherent in nursing is respect for human rights, including cultural rights, the right to life and choice, to dignity and to be treated with respect. Nursing care is respectful of and unrestricted by considerations of age, colour, creed, culture, disability or illness, gender, sexual orientation, nationality, politics, race or social status” (ICN, 2012, p. 1). Diversity includes developmental aspects, morphologic aspects (body frame size/obesity), culture, religion, and ethnicity. In providing care, the nurse promotes an environment in which the human rights, values, customs, and spiritual beliefs of the individual, family, and community are respected. To respect the diversity of patients, nurses practice culturally competent care as defined in [Box 1.4](#). [Chapter 21](#) discusses ethnic and cultural diversity in greater detail.

Box 1.4

Diversity Considerations

Culture

- *Cultural and linguistic competence* is a set of behaviors, attitudes, and policies that come together among health care professionals and allow for effective work in cross-cultural situations.
- *Culture* is the integrated patterns of human behavior that include the language, thoughts, communications, actions, customs, beliefs, values, and institutions of racial, ethnic, religious, or social groups.
- *Competence* implies having the ability to function effectively within the context of the cultural beliefs, behaviors, and needs presented by patients.
- **Cultural competence** is a method of bringing interprofessional health care providers together to discuss health concerns whereby cultural differences enhance, rather than hinder, the conversation through a respectful atmosphere responsive to the health beliefs, practices, and cultural and linguistic needs of diverse patients.

LO 1.7 Practice Guidelines

The profession of nursing is guided by standards of practice and nurse practice acts. The Standards of Professional Nursing Practice published by the ANA help ensure quality care and serve as legal criteria for adequate patient care. ANA standards have two parts. The first part, the standards of practice, includes six responsibilities for the nursing process: assessment, diagnosis, outcomes identification, planning, implementation, and evaluation (ANA, 2015). Nurses providing direct patient care continuously follow these standards as they utilize the nursing process. Further discussion of the nursing process can be found in [Chapter 5](#).

The second part of Standards of Professional Nursing Practice focuses on standards of professional performance, which includes ethics, culturally congruent practice, communication, collaboration, leadership, education, EBP and research, quality of practice, professional practice evaluation, resource utilization, and environmental health (ANA, 2015). Nurses who attend continuing education conferences or further their education, use evidence to guide their nursing practice, or communicate and collaborate with patients and other professionals are practicing within the standards.

3. Which of the ANA Standards of Professional Nursing Practice is John exhibiting during the shift?

Nurse practice acts provide the scope of practice defined by each state or jurisdiction and set forth the legal limits of nursing practice. These acts are laws that the nurse must be familiar with to function in practice. Nurse practice acts are worded in broad legal terms that need to be interpreted by nurses to be clearly understood within the context of their profession. A *scope of practice* defines the boundaries of the practice of nursing and clarifies how it may intersect with other professions or disciplines. The ANA, NLN, American Association of Colleges of Nursing (AACN), and American Organization of Nurse Executives (AONE), along with the NCSBN, devised a decision-making tool for nurses to help determine interventions and activities that can safely be performed (Ballard, Haagenson, Christiansen, et al., 2016). A nurse who is unsure about performing an intervention can use this tool to decide if he or she can complete the intervention safely within the scope of nursing practice. In addition to adhering to nurse practice acts, nurses must function within the policies and procedures of the facility in which they are employed.

Guiding the nurse's professional practice are ethical behaviors. It is essential that nurses understand and incorporate basic concepts of ethics into their

practice. The main concepts in nursing ethics are accountability, advocacy, autonomy (be independent and self-motivated), beneficence (act in the best interest of the patient), confidentiality, fidelity (keep promises), justice (relate to others with fairness and equality), nonmaleficence (do no harm), responsibility, and veracity (be truthful). As an example, the nurse holds in confidence personal information and uses judgment in sharing this information about a patient. Ethical guidelines direct the nurse's decision making in routine situations and in ethical dilemmas. *ANA's Principles for Social Networking and the Nurse* ([ANA, 2011](#)) outlines six principles that nurses must follow to protect patient privacy and maintain professional boundaries. The *ANA Code of Ethics for Nurses* is discussed in [Chapter 11](#).

LO 1.8 Socialization and Transformation Into Nursing

Socialization to professional nursing is a process that involves learning the theory and skills necessary for the role of nurse. Internalizing this specific role allows the nurse to participate as a member of the profession. During this process of socialization to nursing, the student's knowledge base, attitudes, and values are affected regarding nursing practice. This process allows the person to grow both professionally and personally as the student internalizes a full understanding of the profession. This initial transformation continues after the student graduates and acquires experience while working and pursuing further education. Transformation to being a nurse requires students to become response-based practitioners with the ability to recognize the complexity of a situation and prioritize concerns (Benner, Sutphen, Leonard, et al., 2010).

Benner (2001) used Dreyfus's (1980) model of skill acquisition in her description of novice to expert (Fig. 1.8). Benner's model identifies five levels of proficiency: novice, advanced beginner, competent, proficient, and expert. The student nurse progresses from novice to advanced beginner during nursing school and attains the competent level after approximately 2 to 3 years of work experience after graduation.

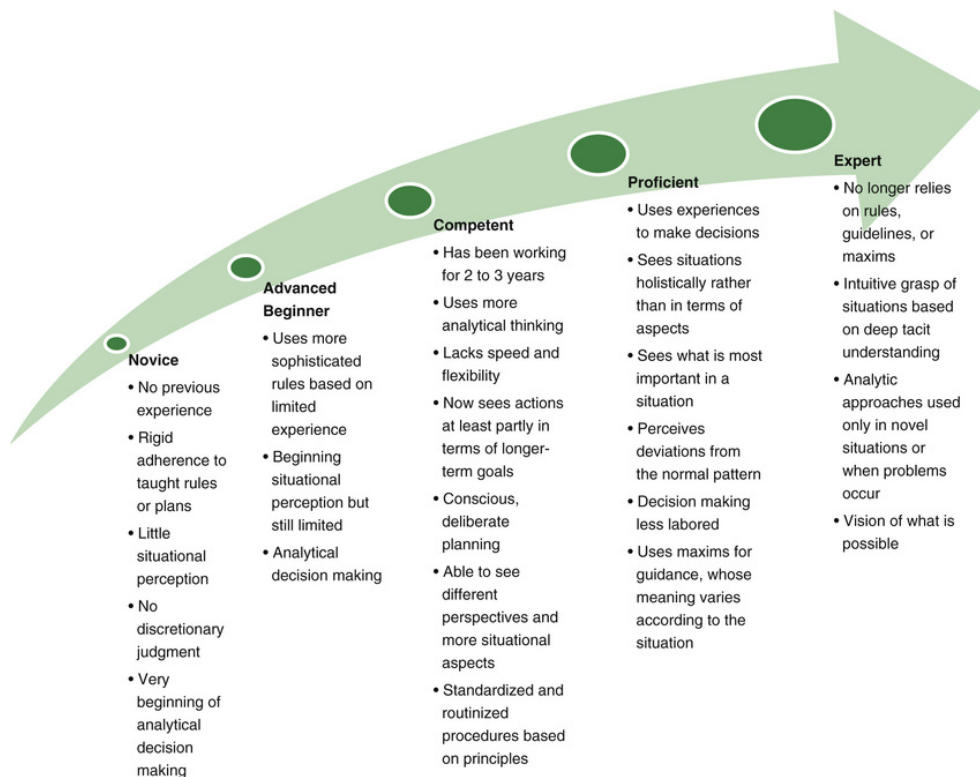

FIGURE 1.8 Benner's Novice to Expert Model. (From Benner, P. [2001]. *From novice to expert: Excellence and power in clinical nursing practice*. Reprinted by permission of Pearson Education, Inc., New York, New York.)

The Essentials of Baccalaureate Education for Professional Nursing Practice are provided and updated by the AACN (2008). The document offers a framework for the education of professional nurses with outcomes for students to meet. If students meet these outcomes, their socialization into the role of a professional nurse will have begun. The first eight essentials describe the knowledge, skills, and attitudes required of the nursing student to meet the desired outcome. The ninth essential describes the practice of the nurse upon graduation from a baccalaureate program. In addition, other AACN documents outline competencies for nurses at the graduate education level.

The National League for Nursing (NLN) outlines and updates competencies for practical, associate, baccalaureate, and graduate nursing education programs. The titles of the competencies for each type of education program are "Human Flourishing," "Nursing Judgment," "Professional Identity," and "Spirit of Inquiry." The outcomes for each competency are progressively more complex at each educational level (NLN, 2010).

The NCSBN provides resources and tools on its website for nurses at all levels of practice. The video "New Nurses: Your License to Practice" is available for viewing at <https://www.ncsbn.org/8243.htm> and contains helpful re-information for student nurses and new graduate nurses.

LO 1.9 Nursing Practice Licensure and Graduate Specialties

Nursing provides various educational paths to practice. The two types of licensed nurses, the LVN/LPN and the RN, have different scopes of practice, but both must obtain a license to practice by passing a specific licensure examination. **Licensure** is the granting of a license that provides legal permission to practice. There are three accrediting bodies for schools and colleges of nursing: the AACN's Commission on Collegiate Nursing Education (CCNE), the Accrediting Commission for Education in Nursing (ACEN), and the NLN Commission for Nursing Education Accreditation (CNEA). The CCNE accredits baccalaureate and graduate nursing programs; the CNEA and the ACEN accredit a variety of different nursing programs, including practical, diploma, associate, baccalaureate, and graduate programs.

Licensed Practical Nurse or Licensed Vocational Nurse

LPNs (or LVNs as they are called in California and Texas) are not RNs. They complete an educational program consisting of 12 to 18 months of training, and then they must pass the National Council Licensure Examination for Practical Nurses (NCLEX-PN) to practice as an LPN/LVN. They are under the supervision of an RN in most institutions and are able to collect data but cannot perform an assessment requiring decision making, cannot formulate a nursing diagnosis, and cannot initiate a care plan. They may update care plans and administer medications with the exception of certain intravenous (IV) medications. Later they may choose to complete an LPN/LVN-to-RN program to become an RN.

Registered Nurse

To obtain the RN credential, a person must graduate from an accredited school of nursing and pass a state licensing examination—the National Council Licensure Examination for Registered Nurses (NCLEX-RN). The student may attend a 2- or 4-year degree program or a 3-year diploma program. Entry-level pay for graduates from all types of programs who have passed their NCLEX examinations is similar. In many facilities, nurses must have a bachelor's degree to advance into management or to hold specialized positions.

Associate Degree in Nursing

Associate Degree in Nursing (ADN) programs usually are conducted in a community college setting. Most programs require that students complete courses in psychology, human growth and development, biology, microbiology, and anatomy and physiology as a basis before they begin their nursing coursework. The nursing curriculum focuses on adult acute and chronic disease, maternal/child health, pediatrics, and psychiatric/mental health nursing. ADN RNs may return to school to earn a bachelor's degree or higher in an RN-to-BSN or RN-to-MSN program.

Diploma Programs

Generally associated with a hospital, the Diploma in Nursing program combines classroom and clinical instruction, usually over a period of 3 years. The number of such programs has decreased as nursing education has shifted to academic institutions.

Bachelor of Science in Nursing

The university-based Bachelor of Science in Nursing (BSN) degree provides the nursing theory, sciences, humanities, and behavioral science preparation necessary for professional nursing responsibilities and the knowledge base in research necessary for advanced education. Bachelor's degree programs include community health and management courses beyond those traditionally provided in an associate degree program. Nursing theory, bioethics, management, research and statistics, health assessment, pharmacology, pathophysiology, and electives in complex nursing processes are covered. The Institute of Medicine (IOM; now called *National Academy of Medicine*) report *The Future of Nursing: Leading Change, Advancing Health* recommends that 80% of nurses in the United States be at least baccalaureate-educated by 2020, while encouraging health care organizations to support nurses with associate degrees or diplomas to enter baccalaureate programs within 5 years of graduation (IOM, 2011).

Master of Science in Nursing

When obtaining a master's degree in nursing, called a Master of Science in Nursing (MSN) degree, the nurse may focus on a specific area of advanced practice. There are four specialties in which nurses provide direct patient care in advanced practice roles: certified nurse midwife (CNM), nurse practitioner (NP), clinical nurse specialist (CNS), and certified registered nurse anesthetist (CRNA). Four additional advanced practice roles that do not always involve direct patient care are clinical nurse leader (CNL), nurse educator, nurse researcher, and nurse administrator.

Advanced Practice Nurses

Advanced practice registered nurse (APRN) is a designation for an RN who has met advanced educational and clinical practice requirements at a minimum of a master's degree level and provides at least some level of direct care to patient populations. APRNs have acquired theoretical research-based and practical knowledge as part of the graduate education and are either certified or approved to practice in their expanded, specialized roles. In many states APRNs have independent prescribing privileges giving APRNs the ability to prescribe medications without collaborating with a physician (Stokowski, 2018). Advanced practice nurses have a set of core competencies (Hamric & Tracy, 2019):

- Direct clinical practice
- Collaboration
- Expert coaching and guidance

- Research
- Ethical decision making
- Consultation
- Leadership

CNMs provide well-gynecologic and low-risk obstetric care and attend births in hospitals, birth centers, and homes. NPs work in clinics, nursing homes, hospitals, or private offices and are qualified to provide a wide range of primary and preventive health care services, prescribe medication, and diagnose and treat illnesses and injuries. NPs may focus on a specific population, working in fields such as pediatrics or gerontology, or may have a more general family practice. NPs or physicians may be the patient's PCP. CNSs work in hospitals, clinics, nursing homes, private offices, and community-based settings and manage a wide range of physical and mental health problems. They may work in consultation, research, or education. CRNAs, whose role is the oldest of the advanced nursing specialties, administer much of the anesthetics given to patients in the United States.

Other Advanced Roles

A new role is that of the CNL, who oversees the integration of care for a distinct group of patients and may actively provide direct patient care in complex situations utilizing EBP. This clinician functions as part of an interprofessional team and is not in an administration or management role. The CNL is a leader in the health care delivery system in all settings in which health care is delivered, not just the acute care setting. Implementation of this role varies across settings.

A master's degree can lead to one of the advanced practice roles that may not have a direct patient care component. The nurse educator option prepares nurses to practice as faculty in academic settings, such as colleges, universities, hospital-based schools of nursing, and technical schools, or as staff development educators in health care facilities. Nurse educators combine their clinical abilities with responsibilities related to designing curricula, teaching and guiding learners, evaluating learning and program outcomes, advising students, and engaging in scholarly work.

Two other options for nurses with master's degrees are researcher and administrator. Nurse researchers use statistical methodologies to discover or establish facts, principles, or relationships. They may be involved in clinical trials with patients or other clinical research regarding patient care. Nurse administrators coordinate the use of human, financial, and technological resources to provide patient care services. Positions include facilitator, manager, director, chief nurse executive, and vice president of nursing.

Doctor of Philosophy and Doctor of Nursing Practice

Doctoral nursing education can result in a doctor of philosophy (PhD) degree. This degree prepares nurses for leadership roles in research, teaching, and administration that are essential to advancing nursing as a profession. A newer, practice-focused doctoral degree is the doctor of nursing practice (DNP), which

concentrates on the clinical aspects of nursing. DNP specialties include the four advanced practice roles of NP, CNS, CNM, and CRNA. In addition, some DNPs focus on the CNL option.

LO 1.10 Certifications and Professional Nursing Organizations

Nurses may pursue certifications in specialty areas after they have practiced for several years. Nurses may choose membership in professional nursing organizations to network, remain current in their practice, and have access to current research.

Certifications

Nurses may become certified in a specialty. Each nursing certification has minimum work experience and education requirements. After meeting required criteria, nurses must pass an examination and maintain specific continuing education and work requirements. There are certifications for RNs, as well as nurses with master's degrees and other advanced practice nurses.

The [American Nurses Credentialing Center \(ANCC\) \(2018\)](#) awards Magnet Recognition to hospitals that have shown excellence and innovation in nursing. Individual nurses in a variety of practice roles can seek certification through ANCC. For a complete list of specialties available, visit <https://www.nursingworld.org/certification/>.

Professional Organizations

Belonging to a professional organization is an important aspect of one's profession. Nursing organizations enable the nurse to have access to current information and resources, as well as a voice in the profession. Nursing organizations include the ANA, the NLN, the ICN, Sigma Theta Tau International Honor Society of Nursing, and the National Student Nurses Association (NSNA). Participating in NSNA while in nursing school is an important beginning to a nurse's professional career. There are also more than 80 specialty organizations, such as the American Association of Critical-Care Nurses, the Emergency Nurses Association, the National Association of School Nurses, and the Oncology Nurses Society.

LO 1.11 Future Directions

People worldwide are living longer and healthier lives (Fig. 1.9). This increase in lifespan has led to a rapidly increasing population of those 65 years of age and older. Projections indicate that by 2030, this group will total 1 billion: One person of every eight in the world will be 65 or older (National Institute on Aging, 2011). The greatest increases are seen in developing countries. Life expectancy is increasing, placing a greater burden on health care systems worldwide.

FIGURE 1.9 The growing population of older adults will require more nurses to care for them. (© istock.com)

Larger portions of the population are in retirement, with a consequent strain on both health and pension systems. As the Baby Boomers enter retirement, providing health care to this large portion of the population in the United States and other nations becomes a concern. This aging population will require more nurses to care for them. This need is one factor related to the current nursing shortage.

As the 21st century began, many organizations worked to make safety in health care a priority. The AACN's Quality and Safety Education for Nurses (QSEN) program, the IOM's report *The Future of Nursing: Leading Change, Advancing Health*, and The Joint Commission's National Patient Safety Goals will guide nurses into the future as safe and caring practitioners.

Nursing Shortage

According to the World Health Organization (WHO), there is a shortage of health care workers worldwide leaving over four million people without quality health care. An additional 4.3 million health workers are needed, but not enough people are being trained to meet the demand (WHO, 2018). The WHO (2016) outlines specific strategies for strengthening nursing and midwifery services worldwide in the third of a series of reports, *Nursing and Midwifery-WHO Global Strategic Directions for Strengthening Nursing and Midwifery 2016-2020*. This report calls for educated competent professionals working in intraprofessional and interprofessional collaborative partnerships.

With the changing demographics of an increasing elderly population and the aging nursing workforce, the total number of new nurses needed continues to grow. The U.S. Department of Labor's Bureau of Labor Statistics' Employment Projections 2016-2026 shows that healthcare support occupations and healthcare practitioners and are projected to be among the fastest growing occupational groups (2018). This does not include replacement nurses needed to fill vacancies left by retirement and attrition. Nursing schools are struggling to expand capacity. The AACN is working with colleges, policy makers, other nursing organizations and the media to bring attention to this problem (AACN, 2017). The lack of faculty is an impediment to increasing nursing school enrollment, and many faculty members are nearing retirement age. In some areas, clinical sites are full. Creative, collaborative educational strategies are needed to meet the increased demand for health care education.

With an insufficient number of nurses to care for patients, nurses face an increased level of stress, which can be expected to have an adverse impact on job satisfaction. This work situation can cause nurses to leave the profession, which further contributes to the nursing shortage and affects overall access to health care. Therefore nursing is a profession that will continue to be in demand. The Enhanced Nurse Licensure Compact (eNLC) was enacted in 2018. Under eNLC nurses in over 30 states can now apply for a multistate license (NCSBN, 2018). This will make it easier for nurses to relocate to areas where there are shortages, and practice telehealth across state lines.

Quality and Safety Education for Nurses

The QSEN initiative, funded by the Robert Wood Johnson Foundation, adapted the IOM competencies for nursing. The IOM report *Health Professions Education: A Bridge to Quality* (IOM, 2003) outlined five core areas of proficiency for students and professionals: delivering patient-centered care, working as part of an interdisciplinary team, practicing evidence-based medicine, focusing on quality improvement, and using information technology. QSEN adds safety as a competency. The six QSEN competencies are: patient-centered care, teamwork and collaboration, EBP, quality improvement, safety, and informatics. Knowledge, skills, and attitudes for each competency were developed for use in pre-licensure nursing education (Cronenwett, Sherwood, Barnsteiner, et al., 2007) and graduate education.

Institute of Medicine (Now National Academy of Medicine) Report

The Future of Nursing: Leading Change, Advancing Health (IOM, 2011) identified several goals for nursing in the United States:

- Nurses should practice to the full extent of their education and training.
- Nurses should achieve higher levels of education and training through an improved education system that promotes seamless academic progression.

- Nurses should be full partners with physicians and other health care professionals in redesigning health care in the United States.
- Effective workforce planning and policy making require better data collection and an improved information infrastructure.

The report outlined recommendations and specific actions to achieve these goals.

National Patient Safety Goals

The Joint Commission is the accrediting organization for health care facilities in the United States. In 2003, The Joint Commission established the first set of National Patient Safety Goals to improve patient safety for a variety of accredited health care facilities, including hospitals. The hospital goals for 2019 include the following:

- Improve the accuracy of patient identification.
- Improve the effectiveness of communication among caregivers.
- Improve the safety of using medications.
- Reduce the harm associated with clinical alarm systems.
- Reduce the risk of health care-associated infections.
- The hospital identifies safety risks inherent in its patient population.

Each category has specific elements of performance that are required for the health care worker to meet the goals ([The Joint Commission, 2019](#)). As new problems in patient care emerge, the safety goals are reassessed and revised.

Independent Nursing Practice

As previously mentioned, one characteristic of a profession is autonomy. Nurses have attained increased autonomy over time. Nursing has control over its education, practice, and legal recognition through licensure. State nurse practice acts regulate scope of practice, and state board examinations are required to practice. Nursing has a code of ethics that reflects current issues. This autonomy leads to functioning independently of any other profession or external entity. As employees of organizations, nurses do not always have full freedom in deciding on patient care within the defined scope of nursing practice. Striving toward this independence is a goal of nursing. Advanced practice nurses in some states work in collaboration with a physician, but NPs are increasing independence in their practice. APRNs in many states now have independent prescribing privileges. The introduction of the DNP as the practice doctoral degree for advanced practice

nurses is intended to place them on the same level as those with other professional degrees. Thus nursing continues to establish itself as a full-fledged profession.

Summary of Learning Outcomes

LO 1.1 *Characterize nursing*: Nursing is a holistic profession that addresses the many dimensions necessary to fully care for a patient.

LO 1.2 *Differentiate among the functions and roles of nurses*: Nurses provide care to patients while functioning in multiple roles as care provider, educator, advocate, leader, change agent, manager, researcher, collaborator, and delegator.

LO 1.3 *Analyze historical events in the evolution of nursing*: Historically, the nursing profession has evolved from a religious and military background to meet the nursing needs of society.

LO 1.4 *Summarize nursing theories*: Nurses use nursing theories to guide their practice. Nursing theories began with Florence [Nightingale's work in 1860](#) and continue to the present. Each theory discusses the four concepts of nursing, person, health, and environment.

LO 1.5 *Examine nonnursing theories that influence nursing practice*: Nonnursing theories that influence nursing practice include systems theory, developmental theory, change theory, theory of human needs, and leadership theories.

LO 1.6 *Articulate the criteria of a profession as applied to nursing*: Nursing is evaluated against the criteria of a profession, which include altruism, body of knowledge, accountability, higher education, autonomy, code of ethics, professional organization, and licensure.

LO 1.7 *Consider standards of practice and nurse practice acts*: ANA standards of professional nursing practice guide and direct the practice of nursing; state nurse practice acts define nurses' scope of practice.

LO 1.8 *Analyze the socialization and transformation process of a nurse*: Socialization into the nursing profession follows a process from novice to advanced beginner during nursing

school. The nurse reaches the competent level after several years of practice. Transformation takes place when the student gains the ability to perceive and prioritize the situational needs of complex care.

LO 1.9 *Explore the levels of educational preparation in nursing and differentiate among the nurse's roles depending on education:* Numerous levels of education (diploma, associate, baccalaureate, master's, and doctoral degrees) and career opportunities in nursing can be pursued.

LO 1.10 *Investigate possible certifications in various arenas of nursing and professional organizations in nursing:* Many different certifications are available to nurses who meet specific requirements and pass qualifying examinations. Nursing organizations represent all nurses and nursing specialties.

LO 1.11 *Probe the future directions in nursing:* Future directions in nursing include dealing with the nursing shortage, implementing new patient safety programs, and exploring the role of the independent nurse.

Review Questions

1. In comparing the American Nurses Association (ANA) and the International Council of Nurses (ICN) definitions of nursing, what component does the ICN mention that is not included in ANA's definition and is indicative of a more global focus?
 - a. Advocacy
 - b. Health promotion
 - c. Shaping health policy
 - d. Prevention of illness
2. A profession has specific characteristics. In regard to how nursing meets these characteristics, which criteria are consistent and standardized processes? (*Select all that apply.*)
 - a. Code of ethics
 - b. Licensing
 - c. Body of knowledge
 - d. Educational preparation
 - e. Altruism
3. What specific aspect of a profession does the development of theories provide?
 - a. Altruism
 - b. Body of knowledge
 - c. Autonomy
 - d. Accountability
4. Health care workers are discussing a diverse group of patients respectfully and are being responsive to the health beliefs and practices of these patients. What important aspect of nursing professional practice are they exhibiting?
 - a. Autonomy
 - b. Accountability
 - c. Cultural competence
 - d. Autocratic leadership

5. A nurse makes a medication error, immediately assesses the patient, and reports the error to the nurse manager and the primary care provider (PCP). Which characteristic of a professional is the nurse demonstrating?
- Autonomy
 - Collaboration
 - Accountability
 - Altruism
6. Which are included in the ANA standards? (*Select all that apply.*)
- Standards of professional performance
 - Code of ethics
 - Standards of practice
 - Legal scope of practice
 - Licensure requirements
7. Which core competency of advanced practice nursing is the Master of Science in Nursing (MSN) nurse educator exhibiting when counseling a student in therapeutic communication techniques?
- Leadership
 - Ethical decision making
 - Direct clinical practice
 - Expert coaching
8. Which statements describe a component discussed in nursing theories? (*Select all that apply.*)
- Optimal functioning of the patient
 - Interaction with components of the environment
 - The conceptual makeup of the administration of the hospital
 - The illness and health concept
 - Safety aspect of medication administration

9. Which factors affect the nursing shortage? (*Select all that apply.*)
- a. Aging faculty
 - b. Increasing elderly population
 - c. Job satisfaction due to adequate number of nurses
 - d. Aging nursing workforce
 - e. Greater autonomy for nurses
10. A nurse has performed a physical examination of the patient and reviewed the laboratory results and diagnostics on the patient's chart. The nurse is performing which specific nursing function?
- a. Diagnosis
 - b. Assessment
 - c. Education
 - d. Advocacy

CHAPTER 2

Values, Beliefs, and Caring

LEARNING OUTCOMES

Comprehension of this chapter's content will provide students with the ability to:

- LO 2.1 Describe the differences between beliefs and values and how they develop.
- LO 2.2 Explain the use of the values clarification process in dealing with a values conflict.
- LO 2.3 Summarize how the beliefs of nurses and patients influence health care.
- LO 2.4 Discuss caring and four nursing theories with the concept of caring as their primary focus.
- LO 2.5 Articulate ways in which nurses develop into caring professionals.
- LO 2.6 Identify essential behaviors that demonstrate caring.
- LO 2.7 Define compassion fatigue and identify prevention strategies.

KEY TERMS

active listening, p. 31

belief, p. 22

caring, p. 26

compassion, p. 29

compassion fatigue, p. 31

first-order beliefs, p. 22

generalizations, p. 22

higher-order beliefs, p. 22

nursing presence, p. 30

paradigms, p. 26

patient-centered care, p. 26

prejudice, p. 23

stereotype, p. 22

values, p. 22

values clarification, p. 23

values conflict, p. 23

values system, p. 23

Case Study

Hwa Yeon Lee (H. L.) calls herself “Clara” for the benefit of her American friends who cannot pronounce her Korean name. She is a 20-year-old college student who arrives in the emergency department accompanied by an older Korean man, who is a longtime friend of her family. Her major complaint is a throbbing headache, which she reports “has not let up for the past 3 days and nights.” She rates the pain as an 8 or 9 on a scale of 0 to 10. H. L. expresses concern that “it might be something serious,” because she has never experienced anything like this before. In fact, she states, “I can't remember ever having a headache that lasted longer than a half hour.”

While awaiting diagnostic test results, H. L. tells the nurse that her parents still live in a small village in Korea and sacrificed a great deal to send her to the United States to attend college. She traveled to this country alone at the age of 16 and lived with her parents' friends until she graduated from high school. She now lives in a one-room apartment near the small private college that she attends.

When diagnostic test results show no abnormalities, the physician writes a prescription for a mild narcotic analgesic (pain medication) without asking H. L. what type of treatment she typically prefers for pain relief. He attributes the pain to stress, a migraine headache, or possibly hormones, because her menstrual period began the day before. When the nurse tries to administer the medication to H. L., she respectfully refuses it, saying, “No, thank you.” H. L. explains that she came to the emergency department only to find out if the cause was something serious, but now that she knows it is not, she prefers alternative therapy, such as meditation or acupuncture for pain relief. After H. L. leaves, the nurse is bewildered and somewhat angry over her refusal to take the medication. The nurse turns to a colleague and asks, “Why did she come here if she didn't want our help?”

Refer back to this case study to answer the critical-thinking questions throughout the chapter.

Nurses are called on to provide care for patients with beliefs and values that may be vastly different from their own. In fact, the beliefs of many patients and their families may seem strange or, at times, perplexing to the nurse. In a multicultural practice environment, gaining an understanding of what beliefs and values are, how they develop, and in what ways they shape the behaviors of both patients and nurses will help nurses assist patients toward better health outcomes.

LO 2.1 Beliefs and Values

Patients and their families look to nurses to support and guide them through some of the most difficult and vulnerable periods of their lives. They need to know that the nurse will be sensitive to their beliefs and values and will strive to understand how they want to be treated. It is important for nurses to have strong professional values to guide their practice that are consistent with society's expectations of a trusted professional. It is essential that nursing students develop and continue to adhere to critical professional nursing values throughout their careers. Understanding the importance and the relatedness of beliefs and values is a vital first step.

A **belief** is a mental representation of reality or a person's perceptions about what is right (correct), true, or real, or what the person expects to happen in a given situation. In a religious or spiritual sense, to have a belief means to place trust or have faith in a deity (such as God) or in something (such as a religious ritual, tradition, or philosophy) (Sartori, 2010). Three types of beliefs are recognized: *zero-order beliefs*, most of which are unconscious, such as object permanence; *first-order beliefs*, which are conscious, typically based on direct experiences; and *higher-order beliefs*, which are generalizations or ideas that are derived from first-order beliefs and reasoning (Bem, 2002).

Values are enduring ideas about what a person considers is the good, the best, and the “right” thing to do and their opposites—the bad, worst, and wrong things to do—and about what is desirable or has worth in life (Rassin, 2010). Values determine the importance and worth of an idea, a belief, an object, or a behavior. Personal values include the life principles that are most important to people and shape their thoughts, feelings, and, ultimately, actions. Values play a large part in how individuals view and evaluate themselves (self-concept) and others. Values, such as caring, strongly influence a person's selection of friends, professional decisions, organizational membership, and support of social causes.

First-Order Beliefs

First-order beliefs serve as the foundation of an individual's belief system (Bem, 2002) (Table 2.1). People begin developing first-order beliefs about what is correct, real, and true in early childhood directly through experiences (e.g., most nurses are female) and indirectly from information shared by authority figures, such as parents or teachers (e.g., anyone, regardless of gender, can become a nurse). People continue to develop first-order beliefs into adulthood through both direct experiences and the acquisition of knowledge from a vast number of sources with various degrees of expertise and levels of influence. People seldom question their

first-order beliefs and rarely replace one, because to do so would require a great deal of rethinking about both that belief (which has been perceived as real or true) and similar or closely associated beliefs. Nurses need to keep in mind that presenting information to patients that challenges their first-order beliefs may cause a great deal of emotional or cognitive upset (Rassin, 2010).

TABLE 2.1
Overview of Beliefs and Values Formation

FIRST-ORDER BELIEFS	HIGHER-ORDER BELIEFS	VALUES
Purposes		
<ul style="list-style-type: none"> • Provide basic information about what is real or true • Indicate what a person expects on the basis of information shared or obtained from others • Are the foundation for the formation of all other beliefs 	Categorize or bring order to a multitude of ideas	Establish the foundation of self-concept Indicate a person's judgments of ideas, objects, or behavior Provide a framework for decision making Guide life decisions on the basis of what a person views as most important
Derived From		
<ul style="list-style-type: none"> • Life experiences • Respected authorities • Parents or caregivers • Culture • Ethnicity • Education • Religion • Spirituality 	Assumptions based on first-order beliefs Inductive reasoning Deductive reasoning	Personal experiences Family of origin Spirituality Religious beliefs Cultural/ethnic background Education Professional development
Examples		
<ul style="list-style-type: none"> • Most nurses are female. • Anyone, regardless of gender, can become a nurse. 	<i>Generalization:</i> All nurses wear white uniforms. <i>Stereotype:</i> Nurses are more caring than other adults. <i>Prejudice:</i> Women are better nurses than men.	Professional nursing values include advocacy, altruism, collaboration, compassion, confidentiality, integrity, fidelity, responsibility, social justice, courage, autonomy (ANA, 2015). Others include respect for human dignity, professionalism, caring, equality, freedom, justice, safety, and accuracy (Kaya, Işik, Senyuva, & Kaya, 2017; Elliott, 2017).

Higher-Order Beliefs

Higher-order beliefs are ideas derived from a person's first-order beliefs, using either inductive or deductive reasoning (Bem, 2002). In the process

of learning, people form **generalizations** (general statements or ideas about people or things) to relate new information to what is already known and to categorize the new information, making it easier to remember or understand. Generalizations may arise at an unconscious level. People may remain unaware of how they came to believe certain ideas in the first place, and even though generalizations are mental abstractions, they may be considered as real and true as first-order beliefs. One of the major problems with generalizations is that they are not true in all instances. When generalizations are treated as if they are always true, they are called *stereotypes*.

A **stereotype** is a conceptualized depiction of a person, a group, or an event that is thought to be typical of all others in that category. One problem with stereotypes is that sometimes people use stereotypes to rationalize personal biases or prejudices. A **prejudice** is a preformed opinion, usually an unfavorable one, about an entire group of people that is based on insufficient knowledge, irrational feelings, or inaccurate stereotypes. Most generalizations and even stereotypes seldom arise out of unkind or pathologic intent but are used by people to remember new information and to categorize their ideas and beliefs. Many stereotypes are of a harmless variety and are replaced as a person's knowledge or personal experiences broaden.

Values System

A **values system** is a set of somewhat consistent values and measures that are organized hierarchically into a belief system on a continuum of relative importance (Harris, 2010). Anthropologists and social scientists have noted that in every culture, a particular value system prevails and consists of culturally defined moral and ethical principles and rules that are learned in childhood. Each individual possesses a relatively small number of values and may share the same values with others, but to different degrees. A values system helps the person choose between alternatives, resolve values conflicts, and make decisions. Within every culture, however, values vary widely among subcultural groups and even between individuals on the basis of the person's gender, personal experiences, personality, education, and many other variables (Box 2.1).

Box 2.1

Diversity Considerations

Life Span

- Families and cultures have attitudes about what and how to eat that they transmit in the form of values.
- Parents and grandparents use many strategies to transmit their values about healthy eating to their children and grandchildren. Some of the strategies include limiting the purchase of unhealthy foods, involving children in shopping and meal preparation, and engaging children in ongoing conversations about healthful eating and the value of weight control.

Culture, Ethnicity, and Religion

- In some cultures, parents may arrange marriages for their children. Arranged marriages where the bride and groom first meet on their wedding day sometimes limit the ability of the future spouses to discuss potential values conflicts prior to matrimony (Singh, et al., 2016).
- Pharmaceutical treatment may be rejected by individuals from some cultures based on traditional beliefs and values. Exploring the implementation of alternative or complementary therapies may help to meet patient needs while demonstrating respect.

Disability

- People with disabilities note that the real problem with being disabled often is not the physical or mental condition that places limits on what they can do, but rather the situation of being excluded from society and not permitted to contribute that makes them feel devalued and isolated.
- Nurses demonstrate respect for patients with disabilities by including them in their care as much as possible and seeking to understand what works best for each person, rather than generalizing treatment modalities (Fig. 2.1).

FIGURE 2.1 People with disabilities often can assist nurses in identifying care strategies that work best for them. (© Thinkstock.com.)

Morphology

- Obesity is threatening to overtake malnutrition as the most serious global health problem in both developed and developing countries. The three major contributors to obesity are genetics, food marketing practices, and reduced physical activity. Food corporations have historically exerted a major impact on the values of young people through advertising focused on fast- and processed-food consumption ([World Health Organization, 2017](#)).
- Increasing the value that people place on exercise and the consumption of fresh fruits and vegetables is the focus of worldwide strategies to reduce the incidence of obesity.

QSEN Focus

Collecting information on patient values during the interview and assessment process is essential to providing patient-centered care.

LO 2.2 Values Conflict

A **values conflict** occurs when there is an actual or perceived difference between two or more belief systems. Patients may experience a values conflict if evidence-based practice supports interventions that are inconsistent with their preferred, traditional treatment modalities. Providing care for a convicted murderer may elicit troubling feelings for a nurse, resulting in a values conflict between the nurse's commitment to care for all people and a personal repugnance for the act of murder. When people experience values conflicts or exhibit incongruent stated values and actions, values clarification may be helpful.

Values Clarification

Values clarification is a therapeutic process that allows individuals to consider, clarify, and prioritize their personal values. Clearly identifying core values increases a person's self-awareness and eases decision making. Nurses can use values clarification to help patients identify the nature of a conflict and reach a decision based on their values. Possibly the most helpful application of the values clarification process occurs when it is used by the nurse to assist a patient or family faced with making a health care decision or decisions concerning end-of-life care. Nurses may use the values clarification process to better identify their own personal values in challenging care situations.

While helping patients with values clarification and care decisions, nurses must be aware of the potential influence of their professional nursing role on patient decision making. Nurses should be careful to assist patients to clarify their own values in reaching informed decisions. This strategy will help avoid the risk of unintended persuasion on the part of the nurse. Providing information to patients so that they can make informed decisions is a critical nursing role. Giving advice or telling patients what to do in difficult circumstances is both unethical and ill-advised (Box 2.2). Fig. 2.2 is an example of a values clarification tool that nurses can use with patients.

Box 2.2

Patient Education and Health Literacy

Teaching Pregnant Women Dealing With Substance Abuse or Addiction

Ackley, et al (2017) note that the most effective approach for dealing with a values conflict in which substance abuse or an addiction is involved is to begin with an assessment interview, during which the nurse should:

- Listen for the subtle signs of denial, such as an unrealistic display of optimism or downplaying or minimizing the significance of the danger to the fetus.
- Avoid direct confrontation, such as, “I hear you say you want a healthy baby, but I see that you are still smoking.”
- Use a matter-of-fact approach to inform the patient of the reality of the consequences of the harmful behavior to the unborn child.
- Provide straightforward information about the effects of the substance abuse on the fetus to better equip the patient to understand the problem—an understanding that is integral to motivating change.

Your values are your ideas about what is most important to you—what you want to live for and the values you want to live by. Values are the silent forces behind many of your actions and decisions. The goal of “values clarification” is to become fully conscious of their influence, and to explore and honestly acknowledge what you truly value. You can be more self-directed and effective when you know which values you choose to keep and live by as an adult, and which ones will get priority over others. Identify your values by designating them as a **1** (important), a **2** (somewhat important), or a **3** (not important), and then rank in order your top three **1**s. When done, reflect on any lifestyle changes you might need to make so your lifestyle is more in line with what you value most.

<input type="checkbox"/> Achieving highly	<input type="checkbox"/> Being treated fairly	<input type="checkbox"/> Having prized possessions
<input type="checkbox"/> Avoiding boredom	<input type="checkbox"/> Being well-organized	<input type="checkbox"/> Having self-acceptance
<input type="checkbox"/> Being a creative person	<input type="checkbox"/> Being with people	<input type="checkbox"/> Having self-control
<input type="checkbox"/> Being a good parent (or child)	<input type="checkbox"/> Enjoying sensual pleasures	<input type="checkbox"/> Having someone’s help
<input type="checkbox"/> Being a spiritual person	<input type="checkbox"/> Fighting injustice	<input type="checkbox"/> Having things in control

FIGURE 2.2 Values clarification tool. (Adapted from material at www.smartrecovery.org. Credited to Joyce Sichel, from Barnard, M. E., & Wolf, J. L. (Eds.). (2000). *The RET book for practitioners*, New York: Albert Ellis Institute.)

1. List five concerns related to beliefs and values that nurses should consider immediately when caring for a patient with a cultural background different from their own.

2. Identify two assessment questions regarding treatments that H. L. has used in the past to treat headaches that would have been helpful for the nurse to ask. What follow-up question should the nurse have asked after H. L. stated that she had never had a headache lasting longer than a half-hour?

LO 2.3 Beliefs, Health, and Health Care

Although personal beliefs are one of the most important factors in determining how a person responds to a health problem and its treatment, the beliefs of nurses and other health care workers are equally important factors in determining how patients are treated. Patients listen to or do not listen to, trust or mistrust, and act upon or ignore information provided by members of the health care team on the basis of their previous experiences and, sometimes, stereotypes or prejudices.

This phenomenon is seen in research conducted to identify treatment disparities due to ethnic or racial differences. In a study of patients with sickle cell disease and the wait time they experienced in the emergency department, researchers found that African American race and a diagnosis of sickle cell disease contributed to longer wait times for care—between 25% and 50% longer than for patients without those characteristics ([Haywood, Tanabe, Naik, Beach, & Lanzkron, 2013](#)). In another study of 34,203 patients hospitalized for hip fractures who were 65 years old and older, on Medicare, and predominantly female, the Hispanic patients were almost three times more likely than the white patients, and the blacks were twice as likely as the whites, to be discharged to home self-care rather than to a rehabilitation facility. The researchers explained that the differences were due to the fact that the nonwhite families tended to have less favorable perceptions of rehabilitation facilities than the family members of white patients ([Jaffe & Jimenez, 2015](#)). The disturbing part of the findings is that those who went home to self-care seldom walked again.

Another example of how patients' beliefs may affect their health behaviors is found in a study that linked patients' feelings of hopelessness to poor participation in cardiac rehabilitation exercise ([Dunn, Olamijulo, Fuglseth, et al., 2014](#)). When patients did not believe that rehabilitation would make a difference, they did not participate. A large number of health care disparities may be traced to the health beliefs of either patients or health care providers.

Safe Practice Alert

Nurses must collaborate effectively with patients to find treatment methods that are congruent with the patients' belief systems and that promote healthy outcomes. This approach requires excellent assessment skills and a willingness to listen carefully to determine how patients' personal beliefs impact their health beliefs. Failure to consider the

patient's belief systems may result in ineffective implementation of the plan of care.

Equally revealing are studies indicating the presence of a gap, in many cases, between what nurses believe to be true and real and what patients believe to be so (Mendes, 2015; Holroyd, Dahlke, Fehr, Jung, & Hunter, 2009). This gap widens when nurses are formally educated in scientific causes of diseases and evidence-based practice. As nurses learn about their discipline, their **paradigm** (or worldview) gradually changes to one based on a body of knowledge that focuses on scientific principles and may dismiss other explanations for the presence of disease or illness. This scientific or modern paradigm has been nursing's predominant paradigm since the early 1900s, which was when nurses began conducting research using the scientific method. Patients, however, may hold a worldview very different from the scientific paradigm.

To determine a patient's values and beliefs, nurses must listen and ask relevant questions. Incorporating patient values and beliefs into a plan of care requires that patients and their families or primary caregivers be actively involved in establishing goals and outcome criteria (Box 2.3). Patients should be included in determining what interventions will be implemented to assist them in achieving their goals.

Box 2.3

Interprofessional Collaboration and Delegation

Patient-Centered Care

The Institute of Medicine (now the National Academy of Medicine) recommends the provision of health care be patient centered. **Patient-centered care** is defined as “providing care that is respectful of, and responsive to, individual patient preferences, needs and values, and ensuring that patient values guide all clinical decisions” (IOM, 2001, p. 40). Patient-centered care is best provided through therapeutic relationships that reflect the value of care and compassion. Lown, McIntosh, Gaines, McGuinn, and Hatem (2016) developed a model for interprofessional education of health care professionals that incorporates compassion, collaboration, and caring. These researchers believe empathy and compassion, when practiced among all members of the health care team, including the patient, provide the foundation for effective collaboration that leads to greater patient and professional satisfaction, human connectedness, support, and resilience. Additionally, Bilodeau, Dubois, and Pepin (2015) identified four integral facets of interprofessional patient-centered care:

- Patient needs to be a member of the team
- Provision of support needs to be consistent with the patient's experience and level of involvement
- Respectful care reflects patient's values and goals not those imposed by the health care professional
- Collaboration among all members of the team needs to occur consistently and regularly

Reflection on the definition of patient-centered care and facets believed to be necessary for patient-centered care to be delivered in today's complex health care environment reveals patient-centered care cannot truly occur without interprofessional collaboration reflective of care, concern, and compassion.

LO 2.4 Caring and Caring Theories

The value of caring is considered by many as the essence of nursing (Smith, 2013). **Caring** is defined as having concern or regard for another and is conceptualized as a human trait, a moral imperative, an affect, the nurse–patient interpersonal relationship, and a therapeutic intervention (Morse, Solberg, Neander, Bottorff, & Johnson, 1990). As a profession, nursing can trace its earliest beginnings to the types of nurturing activities that demonstrate care, such as taking time to be with a suffering person, actively listening, advocating for the vulnerable, valuing and respecting all individuals, attempting to relieve pain, and making the healing process an act of the body, mind, and spirit. A substantive body of evidence is emerging demonstrating the significance of caring and the importance of caring nurse–patient interactions. Today, there are professional organizations, nursing program curricula, journals, and a multitude of research studies advancing the science of caring in nursing.

Many nursing theories exist that identify the concept of caring as the primary focus. Four of the most significant theories are presented in this chapter. These theories complement one another but approach the idea of caring and nursing from very different paradigms. A nurse's paradigm, or the way the nurse views the world, significantly affects how the nurse provides care. Therefore understanding theories of caring can positively influence nursing practice.

Madeline Leininger: Theory of Cultural Care Diversity and Universality

Madeline Leininger is widely recognized for identifying the role culture plays in health and health care. She is considered the founder of transcultural nursing and developed an ethnonursing method of research used by many nurse scientists. As a nurse and anthropologist, Leininger found that human caring was a universal phenomenon. Leininger's Theory of Cultural Care Diversity and Universality is based on several beliefs including but not limited to the following assumptions: (1) care is a central unifying focus of nursing; (2) a cure cannot occur without caring; (3) culture is embedded in all aspects of one's being; and (4) culturally congruent care promotes health and well-being (McFarland & Wehbe-Alamah, 2018).

Nursing, according to Leininger, is both an art and a science that provides culture-specific care to individual patients and groups to promote or maintain health behaviors or recovery from illness. Within the model, three nursing actions focus on finding ways to provide culturally congruent care. These three nursing actions include: (1) preserving or

maintaining the patient's cultural health practices; (2) accommodating, adapting, or adjusting health care practices for culturally congruent care; and (3) culture care repatterning or restructuring of professional actions and health care decisions as mutually established by the patient and nurse (Leininger & McFarland, 2006). The Theory of Culture Care Diversity and Universality has been used to promote understanding of care needs among diverse populations. For example, Schumacher (2010) used the theory, as well as the ethnonursing method, to identify beliefs, practices, and meanings associated with health among Dominican people residing in rural villages. The Sunrise Enabler model, a conceptual guide for application of the theory (see Chapter 21, Fig. 21.4), was used by Christensen (2014) to promote knowledge and understanding essential to providing effective nursing care to incarcerated women.

Jean Watson: Theory of Human Caring

One of the best-known and most popular caring theories is Watson's Theory of Human Caring. The Theory of Human Caring, although shaped by a variety of influences, such as Carl Rogers, Yalom, and Hildegard Peplau, was derived through Jean Watson's exploration of her own beliefs, values, and experiences regarding personhood, nursing, medicine, health, and healing (Watson, 1997). Watson found nursing to be distinct from medicine with a greater holistic focus on care versus cure. The theory was first developed in the mid-late 1970s and identified 10 carative factors that described the components of the transpersonal nurse–patient relationship (Watson, 2015). Continued development of the theory throughout the late 1990s to the present day includes the transformation of these caring factors to what is termed *caritas processes*, which is reflective of Watson's emerging thoughts within the unitary-transformative perspective (Box 2.4).

Box 2.4

Watson's Ten Caritas Processes

- Practicing loving-kindness and equanimity within context of caring consciousness.
- Being authentically present and enabling, and sustaining the deep belief system and subjective life world of self and one-being cared for.
- Cultivating one's own spiritual practices and transpersonal self, going beyond ego self.

- Developing and sustaining a helping-trusting, authentic caring relationship.
- Being present to and supportive of the expression of positive and negative feelings.
- Creatively using self and all ways of knowing as part of the caring process; engaging in artistry of caring-healing practices.
- Engaging in genuine teaching-learning experience that attends to wholeness and meaning, attempting to stay within other's frame of reference.
- Creating healing environment at all levels, whereby wholeness, beauty, comfort, dignity, and peace are potentiated.
- Assisting with basic needs, with an intentional caring consciousness, administering "human care essentials," which potentiate alignment of mind-body-spirit, wholeness in all aspects of care.
- Opening and attending to mysterious dimensions of one's life-death; soul care for self and the one-being-cared for; "allowing and being open to miracles."

Copyright from [Watson, J. \(2010\)](#). *Core Concepts of Jean Watson's Theory of Human Caring/Caring Science*.

The Theory of Human Caring has been used in education, practice, and research throughout the world. [Becker et al. \(2008\)](#) demonstrated improvement in caring behaviors among student nurses after a teacher intervention based on the Theory of Human Caring. [Arslan-Ozkan, et al. \(2014\)](#) demonstrated nursing care consistent with Watson's theory of increased self-efficacy and adjustment among Turkish women experiencing infertility. Interested students are referred to [Nelson and Watson's \(2012\)](#) collection of international research on caritas for additional examples.

Kristen Swanson: Theory of Caring

Kristen Swanson studied under Jean Watson and as such her work is informed by The Theory of Human Caring. However, her middle-range theory is not viewed as an application of Watson's model ([Swanson, 2015](#)). The theory was developed upon completion of three studies that explored the experiences of women who suffered a miscarriage. In the model, caring is defined as a "nurturing way of relating to a valued 'other' toward whom one feels a personal sense of commitment and responsibility" (p. 162), and is characterized by five processes: knowing, being with, doing for, enabling, and maintaining belief ([Table 2.2](#)).

TABLE 2.2**Swanson's Five Caring Processes With Subdimensions**

KNOWING	BEING WITH	DOING FOR	ENABLING	MAINTAINING BELIEF
Avoiding assumptions Centering on the one cared for Assessing thoroughly Seeking cues Engaging the self of both	Being there Conveying ability Sharing feelings Not burdening	Comforting Anticipating Performing competently/skillfully Protecting Preserving dignity	Informing/explaining Supporting/allowing Focusing Generating alternatives/thinking it through Validating/giving feedback	Believing in/holding in esteem Maintaining a hope-filled attitude Offering realistic optimism "Going the distance"

From Swanson, K. (1991). Empirical development of a middle range theory of caring. *Nurs Res*, 40(3), 161-166.

Through a study funded by the National Institute of Nursing Research (NINR), Swanson demonstrated that caring as described earlier and experienced by patients who suffered a miscarriage contributed to positive outcomes specifically decreased anger, depression, and negative mood states (Swanson, 1999). In 2009, Swanson investigated the effects of caring-based interventions for couples (both men and women) extending applicability of the model. Most recently, Swanson has proposed connections between the five caring processes with corresponding healing outcomes: being understood (knowing), feeling valued (being with), feeling hopeful (maintaining belief), feeling capable (enabling), and feeling safe and comforted (doing for) (Swanson, 2015) (Fig. 2.3).

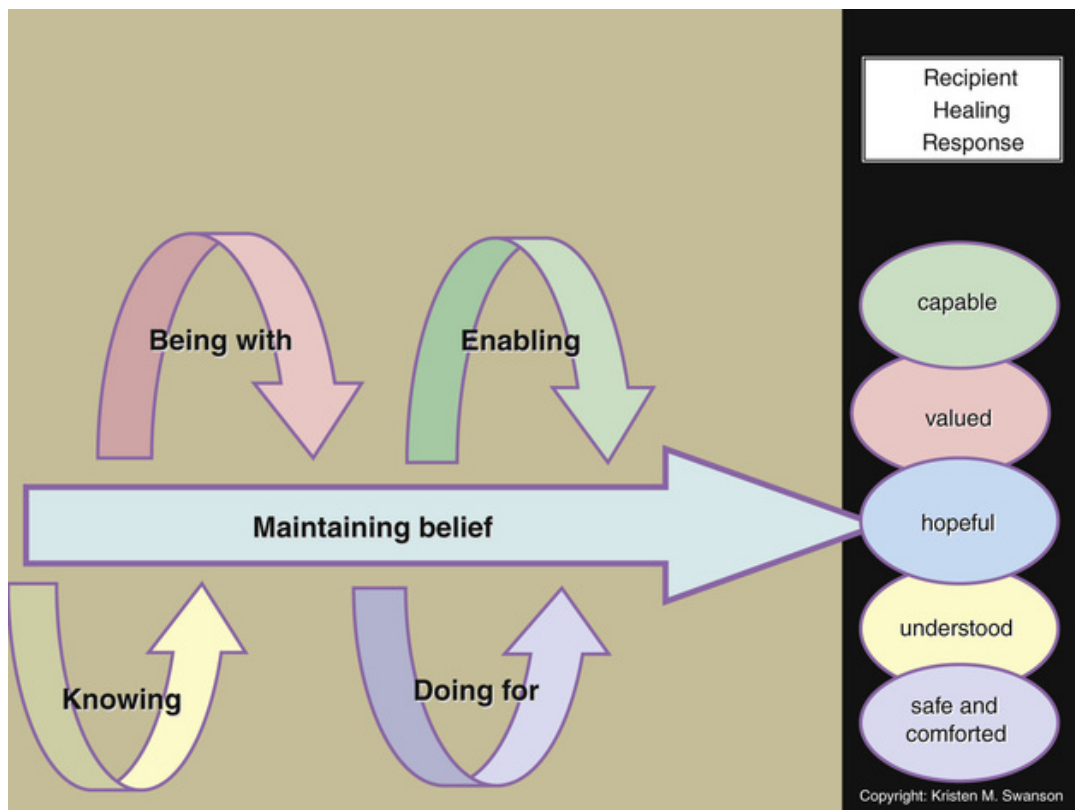

FIGURE 2.3 Swanson theory of caring and healing. (Copyright Kristen M. Swanson)

Anne Boykin and Savina Schoenhofer: Theory of Nursing as Caring

Sr. Simone Roach, a pioneer in nursing ethics, believed caring to be the human mode of existence and described six attributes of caring: compassion, competence, conscience, confidence, commitment, and comportment (behavior). In his philosophical work, *On Caring*, Mayeroff (1971) defined eight caring ingredients: alternating rhythms, courage, honesty, hope, humility, knowing, patience, and trusting. The work of Sr. Simone Roach and the thoughts of philosopher, Milton Mayeroff, influenced the creation of the Theory of Nursing as Caring (Boykin & Schoenhofer, 2015). Additionally, Paterson and Zderad's notion of awareness of self and others as necessary for the nurturing response can be seen in definitions of caring and nursing described in the Theory of Nursing as Caring (Boykin & Schoenhofer, 2015).

In the theory, caring is defined as “the intentional and authentic presence of the nurse with another who is recognized as person living caring and growing in caring” (Boykin & Schoenhofer, 2001, p. 13), and “the general intention of nursing as a practiced discipline is nurturing persons living caring and growing in caring” (Boykin & Schoenhofer, 2015, p. 343). One of the major concepts of the theory is the nursing

situation in which the nurse and patient share the lived experience of caring. It is in this nursing situation that nursing is created and can best be understood. The model has been used in a variety of settings to guide practice, education, and research ([Boykin, Schoenhofer & Valentine, 2014](#); [Dunn, 2012](#); [Dyess, Boykin, & Bulfin, 2013](#)).

LO 2.5 Professional Caring

Christiansen (2009) defined *caring* as the way nurses express themselves to patients or their family members in a sensitive and empathetic manner that communicates “authentic concern.” Nursing students, in Christiansen's view, must take moral responsibility to develop and demonstrate competency in caring skills just as they display other nursing skills. Developing the ability to demonstrate caring is an essential part of becoming a professional nurse, which can be measured and evaluated by instructors in the clinical setting. The objective behaviors that constitute authentic concern typically are expressed by the nurse through eye contact, tone of voice and pace of speech, body language, and attention directed toward the patient.

Although there has been disagreement in the past about whether or not it is possible to teach values, specifically caring, recent research suggests that care, compassion, and empathy can be taught. Emersion of students in authentic experiences using simulation, vignettes, reflective thought, and faculty role modeling can increase levels of caring in student nurses (Nadelson, Zigmond, Nadelson, Scadden, & Collins, 2016; Richardson, Percy, & Hughes, 2015). Thoughtful discussion of caring and uncaring behaviors as observed during practice with faculty may further facilitate the development of caring behaviors.

Patient perceptions of nurse caring have been shown to impact outcomes (Box 2.5). The caring theories presented, although uniquely different, share commonalities in regard to characteristics, traits, and actions that convey caring to patients. In the paragraphs that follow, six common concepts are presented that reflect caring when exemplified or employed by nurses. The American Nurses Association (ANA, 2015) Code of Ethics speaks to each of these ideas (Box 2.6). Students are encouraged to reflect on how these characteristics, traits, and behaviors are emulated in their own developing nursing practice.

Box 2.5

Evidence-Based Practice and Informatics

Studies That Demonstrate Outcomes Associated With Caring in Nursing Practice

- Patient perceptions of caring nurse behaviors, specifically those associated with connectedness, assurance, and respect, were found to

be associated with higher levels of patient satisfaction among surgical patients across multiple European countries (Palese, Tomietto, Suhonen, et al., 2011).

- The importance and significance of caring behaviors as perceived by patients varies by gender and ethnicity (Merrill, Hayes, Clukey, & Curtis, 2012).
- Establishment of the interpersonal nursing–patient relationship was found to be essential to perceptions of nurse caring among trauma patients' families. Caring behaviors most often perceived by family members were those associated with taking time to get to know the patient and allowing patient and family to have input and some control over when activities occurred (Nantz & Hines, 2015).
- Patient experiences of caring nurse behaviors and patient-centeredness were found to be associated with patient perceptions of quality of care with the following behaviors most significant: knowledgeable, effective therapeutic communication skills, timely assistance and support, and environmental support for care needs (Edvardsson, Watt, & Pearce, 2016).
- The following caring behaviors were found to be most important among critically ill intubated patients and their families and thought to contribute to recovery: provision of information and reassurance, proficiency with skills, being present, offering guidance and use of soothing tone of voice (Weyant, Clukey, Roberts, & Henderson, 2017).

Box 2.6

Ethical, Legal, and Professional Practice

Values in Nursing Code of Ethics

The [American Nurses Association \(2015\)](#) *Code of Ethics for Nurses* incorporates and addresses the values of care, compassion, and collaboration. Specifically the following provisions address the topics of discussion in this chapter:

- Provision 1: The nurse practices with compassion and respect for the inherent dignity, worth, and unique attributes of every patient.
 - Compassion is defined in the *Code* as: “an awareness of suffering, tempered with reason, coupled with a desire to relieve the suffering; a virtue combining sympathy, empathy, benevolence, caring and mercy. Used with cognitive and psychomotor skills of healing to meet the patient's needs” (p. 57).

- Provision 5: The nurse owes the same duties to self as to others, including the responsibility to promote health and safety, preserve wholeness of character and integrity, maintain competence, and continue personal and professional growth.
- Provision 6: The nurse through individual and collective efforts establishes, maintains, and improves the ethical environment of the work setting and conditions of employment that are conducive to safe, quality health care.
- Provision 8: The nurse collaborates with other health professionals and the public to protect human rights, promote health diplomacy, and reduce health disparities.

LO 2.6 Caring Behaviors in Nursing

Many authors, theorists, and professional groups have identified qualities and behaviors that demonstrate caring in nursing practice. Some of the most essential behaviors include compassion, presence, touch, and active listening in the nurse–patient relationship.

Compassion

Compassion is the force that impels and empowers one to recognize, acknowledge, and act to alleviate human suffering (Schantz, 2007). The terms *sympathy* and *empathy* are often used interchangeably with *compassion*. However, there are differences among these terms. *Sympathy* means to have pity for another's situation, whereas *empathy* refers to the ability to understand or share the feelings of another. To be compassionate is to act upon one's sympathetic and empathetic response to another's situation. One needs to be empathetic in order to be compassionate.

Compassion is both an outcome and a process conveyed through a caring nurse–patient relationship. Factors associated with compassion include: attentiveness, listening, confronting, involvement, helping, presence, and understanding. A genuine sense of caring, willingness to provide support, and engaging the patient as a person with individual needs are necessary for the patient to experience the nurse as compassionate (Sinclair, Norris, McConnell, et al., 2016). The nurse's ability to develop and display compassion may be influenced by such things like the nurse's knowledge and expertise; nurse, patient, and organizational cultures; as well as prior experiences regarding compassion (Jones, Winch, Strube, Mitchell, & Henderson, 2016). Compassionate care has been found to be associated with increased patient trust and hope, improved adherence, and greater patient disclosure regarding health behaviors.

Lack of compassion may ultimately influence patient satisfaction, as well as other health related outcomes, as patients feel devalued, unsupported, and misunderstood. Although health care providers and patients alike feel compassion is of significant importance to health care, many patients feel compassion is lacking (Lown, Rosen, & Marttila, 2011). In response to a growing concern of lack of compassion in health care, the Schwartz Center for Compassionate Healthcare, located within Massachusetts General Hospital, was established in 1995 to support and advance compassionate health care.

Presence

Nurses are the only health care providers who are typically with patients 24 hours a day, 7 days a week. By simply being present in a patient's room, nurses have the potential to calm the fears of a patient and family and demonstrate caring. In the discipline of nursing, the notion of nursing presence extends beyond one's physical presence and availability to patients. **Nursing presence** is defined as the shared perception of human connectedness between a nurse and a patient (Kostovich, 2012). Such an intentional relational engagement with the patient leads to greater knowing and awareness of the patient and thus a more meaningful connection (Penque & Kearney, 2015). McMahan and Christopher's (2011) Theory of Nurse Presence identifies five components to nurse presence: individual nurse characteristics, individual patient characteristics, shared characteristics within the nurse–patient pair, environmental characteristics reflective of relational work, and the nurse's intentional decision to engage in practice. Nurses can enhance presence through mindful meditation exercises and centering activities prior to engaging with patients.

Nurse presence has been associated with patient satisfaction specifically those satisfaction indices related to listening, courtesy, and respect with longer time frames of nurse presence correlating with demonstration of courtesy and respect (Penque & Kearney, 2015). Other outcomes thought to be associated with nurse presence include enhanced physical and emotional comfort, greater quality of life, feelings of empowerment, peacefulness, and healing (Kostovich, 2012).

Touch

Touch is the intentional contact between two or more people. It occurs so often in patient care situations that it has been deemed to be an essential and universal component of nursing care. Task-oriented touch and caring touch are common forms of physical contact used in nursing care. Touch can also be viewed as an intervention, such as the use of healing touch (HT) or therapeutic touch (TT). Regardless of the type of touch used, all forms of touch should be used carefully with patients while maintaining professional boundaries and ethical standards of care.

Task-Oriented Touch

Task-oriented touch includes performing nursing interventions, such as giving a bath, changing dressings, suctioning an endotracheal tube, giving an injection, starting an intravenous (IV) line, or inserting an nasogastric (NG) tube. Task-oriented touch should be done gently, skillfully, and in a way that conveys competence. Patients become alarmed when they detect that their nurse is unfamiliar with a procedure. It is best to seek assistance with any procedure or skill that the nurse cannot safely accomplish alone.

Every task-oriented procedure should be explained to a patient, followed by feedback indicating patient understanding, before care is initiated.

Caring Touch

Caring touch is considered by most people to be a valuable means of nonverbal communication. In today's highly technical world of nursing, caring touch is an essential aspect of patient-centered care. Caring touch can be used to soothe, comfort, establish rapport, and create a bond between the nurse and the patient. Care may be conveyed by holding the hand of a patient during a painful or frightening procedure or when delivering bad news. This is an important way that nurses let patients know they are not alone and that another human being cares (Fig. 2.4).

FIGURE 2.4 Touch can be used to communicate caring in difficult situations. (© Thinkstock.com.)

Even when the nurse's intentions are to provide comfort, however, touch can be perceived as being intrusive or, at times, hostile by some patients, such as those who are confused or suspicious, those who have been abused, or those who are aggressive or under the influence of drugs or alcohol. In the case of a patient who has been abused, it is especially important to ask permission before touching the patient. Nurses need to be culturally sensitive to how caring touch may be perceived by patients

from a culture different from their own. Gender differences must be respected and may necessitate permission before initiation of care.

Touch as an Intervention

There are certain types of touch that are used as nursing interventions. Healing touch (HT) is the use of intentional light touch to promote relaxation (Foley, Anderson, Mallea, Morrison, & Downey, 2016). HT has been found to aid in pain management, reduce anxiety, lower blood pressure, and positively impact patient satisfaction. As a result of its potential therapeutic effects, HT may help decrease overall length of stay for hospitalized patients.

Therapeutic touch (TT) is a process of energy exchange performed by certified practitioners. In employing TT, the practitioner directs his/her hands on the patient's body without actually touching the skin. The focus of both the practitioner and the patient during the session is on healing. TT has been associated with decreased anxiety, decreased incidence of cardiac dysrhythmias, and improved vital signs (Zolfaghari, Eybpoosh, & Hazrati, 2012). Research on TT continues to more fully understand and document its effectiveness. Additional information on TT as a nursing intervention is presented in [Chapter 36](#) in the context of pain management.

Active Listening

A vital aspect of providing effective and appropriate nursing care is being able to actively listen to a patient in a way that conveys understanding, sensitivity, and compassion. Caring involves interpersonal relationships and communication skills that require paying more attention to the details of communication than would be necessary in a social conversation.

Active listening is a specific communication technique in which one fully concentrates on what the other is saying in a conscious effort to fully understand the other. This type of listening is a highly developed skill that takes time and experience to acquire. It can be learned with practice and enhanced with sensitivity and attention to the feedback that is received during each interaction.

In a caring nurse–patient relationship, the nurse takes responsibility for establishing trust, making sure that the lines of communication are open, and that the nurse accurately understands not only what the patient is saying but also that the nurse is clearly understood. Active listening means paying careful attention and using all of the senses to listen rather than just passively listening with the ears. It requires energy and concentration and involves hearing the entire message—what the patient means, as well as what the patient says. This type of listening focuses solely on the patient and conveys respect and interest. For more

information on active listening and other therapeutic communication techniques, refer to [Chapter 3](#).

3. What actions by the nurse would have communicated caring and attention to H. L.'s beliefs when she was first admitted to the emergency department? What action should the nurse have taken to exhibit concern when H. L. refused the prescribed medication?

LO2.7 Compassion Fatigue

Those who provide care to others are at risk for developing compassion fatigue. **Compassion fatigue** is an extreme state of distress experienced as the progressive and cumulative result of exposure to stress in the therapeutic use of self in caring for others (Coetzee & Klopper, 2010).

Compassion fatigue involves the nurse experiencing a feeling of being unable to meet the needs of patients arising from the inability to alleviate suffering (Ledoux, 2015). Compassion fatigue may result in feelings of vulnerability, anxiety, depression, and anger. Left unrecognized, compassion fatigue can produce physical and mental exhaustion manifested by difficulty sleeping, poor concentration, and low morale; and it can lead to compulsive behaviors, such as substance abuse.

Nurses experiencing compassion fatigue often detach themselves from patients, have a higher risk of making errors, exercise poor judgment, and experience difficulty in maintaining interprofessional relationships (Ledoux, 2015). Given the increased risk for compassion fatigue and the magnitude of its effects, nurses may benefit from approaches to develop resiliency and prevent compassion fatigue (Box 2.7).

Box 2.7

Evidence-Based Practice and Informatics

Compassion Fatigue Prevention Research

Research suggests the following strategies may be helpful in preventing compassion fatigue among health professionals, including nurses:

- Development and maintenance of meaningful recognition programs (Kelly, Runge, & Spencer, 2015)
- Formation of organizational culture that provides ongoing support for the education and prevention of compassion fatigue (Berg, Harshbarger, Ahlers-Schmidt, & Lippoldt, 2016)
- Self-care and personal renewal activities, such as maintenance of good physical and emotional health, yoga, and meditation (Houck, 2014)
- Utilization of mindfulness-based stress reduction activities (Duarte & Pinto-Gouveia, 2016)

Nurses must recognize the beliefs and values that are held by patients and families in order to provide culturally sensitive, relationship-based

care. Incorporating patient concerns and outward displays of caring, such as touch and active listening, into patient treatment is essential to practicing evidence-based nursing. Nurses who have a commitment to respecting the ideas of others, lifelong learning, and caring are trusted by patients to provide safe, competent care.

Summary of Learning Outcomes

LO 2.1 *Describe the differences between beliefs and values and how they develop:* Beliefs are mental representations of reality, or what a person thinks is real or true; values are enduring beliefs that help the person decide what is right and wrong and determine what goals to strive for and what personal qualities to develop. Beliefs and values are developed through personal experiences, family influences, culture, ethnic background, spirituality, religion, and education.

LO 2.2 *Explain the use of the values clarification process in dealing with a values conflict:* The nurse needs to recognize when a values conflict exists and seek ways to identify the underlying factors causing the concern. A values clarification tool can be used to help patients examine past life experiences and consider where they spend their time, energy, and money to provide insight into what they truly value and believe. Values clarification can help nurses become more aware of their own personal values and beliefs that impact professional nursing practice.

LO 2.3 *Summarize how the beliefs of nurses and patients influence health care:* The beliefs of both nurses and patients influence how patients are treated, what patients listen to and act upon, and patient outcomes.

LO 2.4 *Discuss caring and four nursing theories with the concept of caring as their primary focus:* Caring is having concern or regard for another and can be conceptualized as a human trait, a moral imperative, an affect, the nurse–patient interpersonal relationship, and a therapeutic intervention. Leininger's Cultural Care Theory states that culturally based nursing

actions are intended to preserve, accommodate, or reconstruct the patient's meaningful health or life patterns. Watson's Theory of Human Caring is a holistic model of care in which the nurse's focus is on ten carative factors or processes. Swanson's Theory of Caring focuses on five processes of relationship-based caring for the nurse: maintaining belief, knowing, being with, doing for, and enabling the patient. Boykin and Schoenhefer's Theory of Nursing as Caring focuses on persons living caring and growing in caring with the nursing situation.

LO 2.5 *Articulate ways in which nurses develop into caring professionals:* Nurses develop caring skills through life experiences, educational activities, observation of both positive and negative role models, and interaction with strong professional mentors.

LO 2.6 *Identify behaviors that demonstrate caring:* There are a multitude of ways in which nurses demonstrate caring including through compassion, presence, touch, and active listening.

LO 2.7 *Define compassion fatigue and identify prevention strategies:* Compassion fatigue is extreme distress experienced as a result of continued exposure to stress in the therapeutic use of self in caring for others. Self-care including maintenance of good physical and emotional health, yoga, meditation, and mindfulness-based stress reduction activities are shown to help protect nurses from developing compassion fatigue.

Review Questions

1. Nurses need to understand how beliefs and values are different. A nurse begins to offer information to a patient, and the patient says, "I've already heard all of that before, and I don't agree with any of it." How should the nurse proceed?
 - a. Ask the patient to explain his values.
 - b. Ask the patient to explain what he believes.
 - c. Ask the patient about his prejudicial attitude.
 - d. Confront the patient about the apparent values conflict.
2. Which nursing theory of care describes how the nurse's presence in the nurse–patient relationship transcends the physical and material world, facilitating the development of a higher sense of self by the patient?
 - a. Swanson's Theory of Caring Processes
 - b. Madeline Leininger's Cultural Care Theory
 - c. Watson's Theory of Human Caring
 - d. Boykin and Schoenhofer's Theory of Nursing as Caring
3. Which statement best describes for new parents how and when children develop first-order beliefs?
 - a. During infancy, and once developed, such beliefs seldom change
 - b. From life experiences during the toddler and preschool years
 - c. Throughout life from firsthand experiences and information provided by authority figures
 - d. From teen and young-adult peer interaction and mentorship of professional role models

4. As the nurse explained the preoperative instructions to the patient, the patient's older brother suddenly stepped into the doorway and yelled, "People who go under the knife always die. Don't do it! They're going to kill you." What type of higher-order belief is the patient's older brother displaying?
 - a. Distress
 - b. Stereotype
 - c. Prejudice
 - d. Denial

5. After admitting a homeless patient to the floor, the nurse tells a colleague that "homeless people are too dumb to understand instructions." What action should the colleague take first?
 - a. Ignore the nurse's prejudicial comment without responding.
 - b. Offer to trade assignments and care for the homeless patient.
 - c. Ask the nurse about the patient's personal history assessment data.
 - d. Challenge the nurse's thinking, pointing out the ability of all people.

6. The nurse in the emergency department is caring for an 8-year-old who has had a serious asthma attack. When the nurse attempts to explain the problem to the child's mother, she smells cigarette smoke on the mother's breath. The nurse asks the mother if she has been smoking, and the mother responds, "Yes, and I know they've told me before I can't smoke around him." What should the nurse do next?

- a. Ask the patient's mother what she values more, her child or her habit.
 - b. Ask the patient's mother to explain what she believes about smoking and asthma.
 - c. Ask the patient's mother about her prejudicial attitude toward smoking.
 - d. Confront the patient's mother about the values conflict she's experiencing.
7. A nurse is working with a 35-year-old patient who needs to decide whether to donate a kidney to his brother who has been in renal failure for 5 years. The patient shares with the nurse that the decision is especially difficult because he would not be able to continue to work in his current profession and would be unable to support his three small children if he ever needed dialysis. Which interventions would be most appropriate for the nurse to implement in this situation? (*Select all that apply.*)
- a. Explain that it is unlikely that he will ever need dialysis even if he has only one kidney.
 - b. Guide the patient through a values clarification process to help him make a decision based on his values.
 - c. Provide information the patient needs to help him make an informed decision.
 - d. Ask for his permission to contact the kidney donation team to answer any questions he may have.
 - e. Assure him that everything will be alright since he is helping his brother.
8. A 57-year-old male patient who was hospitalized with an admitting blood pressure of 240/120 asked the nurse if his family could bring in some meat and vegetable

dishes from home. He explained that he cannot eat the foods on the hospital menu, because it is summer and the hospital is only offering chicken and fish, which in his culture are “hot” foods that will interfere with his healing. Which response by the nurse would best demonstrate an application of Leininger's theory?

- a. Discourage the family from bringing in food, explaining that the idea of “hot” and “cold” foods is a superstition without scientific basis.
 - b. Negotiate home-prepared food options with the patient and his family to ensure that treatment for the patient's blood pressure is supported.
 - c. Explain that the patient will need to have home-prepared foods evaluated by the dietary staff to ensure that they are acceptable options.
 - d. Tell the family to bring in any foods they want, to help preserve the patient's cultural practices and dietary preferences.
9. In Swanson's Caring Theory, the nurse demonstrates caring using several techniques. Which intervention is appropriate and most important for the nurse to include in a patient's plan of care?
- a. Call patients by their first name to demonstrate a caring attitude.
 - b. Sit at the bedside for at least 5 minutes each hour.
 - c. Use touch based on the nurse's judgment of what is appropriate.
 - d. Ask the patient to identify the most important thing to accomplish during the nurse's shift.
10. A new nurse is about to insert a nasogastric (NG) tube for the first time but is not sure what equipment to gather or how to begin the procedure. The patient is an

80-year-old woman who is frightened and slightly confused. Which actions by the nurse would best demonstrate caring? (*Select all that apply.*)

- a. Offer the patient pain medication to help her calm down.
- b. Hold the patient's hand while inserting the nasogastric tube.
- c. Speak calmly while explaining the procedure to the patient beforehand.
- d. Ask another, more experienced nurse for assistance before initiating care.
- e. Delay inserting the nasogastric tube until the patient's husband comes to visit.

CHAPTER 3

Communication

LEARNING OUTCOMES

Comprehension of this chapter's content will provide students with the ability to:

- LO 3.1 Identify key components of the communication process.
- LO 3.2 List examples of the verbal and nonverbal modes of communication.
- LO 3.3 Explain the primary purpose of the various types of communication.
- LO 3.4 Describe how significant aspects of the nursing process are implemented in the nurse–patient helping relationship.
- LO 3.5 Discuss factors affecting the timing of patient communication.
- LO 3.6 Recognize the roles of respect, assertiveness, collaboration, delegation, and advocacy in professional nursing communication.
- LO 3.7 Identify social, therapeutic, and nontherapeutic communication techniques.
- LO 3.8 List defense mechanisms used by patients while they communicate.
- LO 3.9 Illustrate methods of communicating in special situations.

KEY TERMS

- assertiveness, [p. 44](#)
- channel, [p. 37](#)
- decode, [p. 38](#)
- defense mechanisms, [p. 49](#)
- encode, [p. 37](#)
- feedback, [p. 37](#)
- interpersonal communication, [p. 41](#)
- intrapersonal communication, [p. 41](#)

referent, p. 37
role boundaries, p. 42
sender, p. 37
therapeutic communication, p. 45
verbal communication, p. 38

Case Study

Kirk Beatrice (K.B.), a married, 38-year-old father of two middle school –age children, was diagnosed with advanced melanoma. His doctor suggested an experimental treatment to stop further metastasis of the cancer. K.B. was admitted within the past 24 hours to the oncology unit for treatment of anemia and fatigue. His medical history includes basal cell carcinoma diagnosed 10 years earlier and a concussion that occurred while in college. His surgical history includes repair of a fractured left tibia sustained while playing high school basketball.

K.B.'s vital signs are T 36.8°C (98.2°F), P 82 and regular, R 18 and unlabored, BP 118/54 mm Hg, and a pulse oximetry reading of 99% on room air. He reports lower back and right hip pain at a level of 7/10 before administration of analgesics. He complains of feeling exhausted. His hemoglobin level is 8.2 g/dL. K.B. appears tense and angry when the nurse goes into the room to see if he has ordered his lunch.

Refer back to this case study to answer the critical-thinking questions throughout the chapter.

Effective communication is an essential skill for the professional nurse. Critical nursing roles such as assessment and patient education require excellent and comprehensive communication to meet patients' needs. Patient advocacy, collaboration among health care team members, and safe patient care require the nurse to communicate in a way that clarifies a given situation. Communication is identified by The Joint Commission as a cause of the top five types of sentinel events (i.e., unexpected death, permanent harm, or temporary harm requiring intervention to prevent death) that occurred from 2005 through 2017 (The [Joint Commission, 2018](#)).

To be viewed as competent, the nurse's communication skills must be professional and credible. Understanding the process of communication, the various modes in which individuals communicate,

and the skills of therapeutic communication can greatly enhance the ability of a nurse to effectively care for patients and their families.

LO 3.1 The Communication Process

The dynamic process of communication occurs when six key elements interact (Fig. 3.1). The elements of the communication process include a **referent** (event or thought initiating the communication), a **sender** (person who initiates and encodes the communication), a **receiver** (person who receives and decodes, or interprets, the communication), the **message** (information that is communicated), the **channel** (method of communication), and **feedback** (response of the receiver). For communication to be effective, the process must be interactive and ongoing. Realizing that a variety of factors may initiate the communication process helps the nurse critically analyze the purpose and meaning of interactions.

FIGURE 3.1 Conceptual model of communication.

Referent

The referent, or initiating event or thought that leads one person to interact with another, may be anything, including a sensation. A patient may initiate a conversation due to feeling pain, having thoughts or concerns, recognizing a new lesion or symptom, hearing something unfamiliar or confusing, tasting a strange flavor, or smelling an

unfamiliar scent. Each perceived event has the potential for initiating communication with others.

Sender

Senders may be individuals or groups who have a message to share. Senders **encode** messages by translating their thoughts and feelings into communication with a receiver. The sender decides which mode of communication can most effectively convey the intended meaning of the message.

Message

A message is the content transmitted during communication. Messages are transmitted through all forms of communication, including spoken, written, and nonverbal modalities. Many factors influence whether a message is effectively communicated. The timing of conversations, educational levels of the people involved, modes of communication used, and physical and emotional factors may determine the outcome of interaction among individuals. For example, if a patient is experiencing significant pain, the nurse must address the patient's need for pain relief before attempting to obtain basic demographic data. The nurse must observe the patient's nonverbal messages to avoid missing essential elements of the communication.

Channel

Messages are conveyed and received through a variety of channels. Any of the five senses may be used as channels, or methods, of communication. When a patient calls for help, the channel of communication is auditory. When a nurse observes a patient's gait for stability, communication is achieved through the visual channel. When a patient's wound smells noxious, the channel is olfactory. The accuracy of communication may be affected by the number of channels used to convey information. Typically, the more channels that are used to communicate, the more effectively the message is conveyed. This may not be the case, however, when the use of too many channels of communication overwhelms the receiver with information.

Receiver

There must be a receiver of information for the process of communication to take place. Receivers need to actively listen, observe, and engage in a conversation to **decode**, or sort out the meaning of, what is being communicated. Numerous factors may affect the ability of

the receiver to accurately decode a message, including shared experiences with the sender, timing, educational background, cultural influences, and physical and emotional states. The message may be misinterpreted if clarity is not sought and achieved by the receiver.

Feedback

To avoid misinterpretation of a message, it is essential that the receiver provide feedback to the sender regarding the conveyed meaning. By asking the receiver to restate the message, the sender is able to verify that the message was understood. This is especially important when a nurse and patient are communicating. If a nurse uses medical terminology that is not understood and a patient does not ask for clarification, effective communication cannot take place. Verification in the form of feedback is essential in nurse–patient interactions to ensure successful communication.

LO 3.2 Modes of Communication

Although various methods can be used to convey information, there are only two basic forms of communication: verbal and nonverbal. **Verbal communication** may be spoken, written, or electronic. Most communication is nonverbal and provided in the form of body language such as gestures and eye contact. Nurses are bombarded with verbal and nonverbal communication throughout each workday. Understanding the significance of the two primary modes of communication and the various methods through which they take place is essential. Watching carefully for consistency or inconsistency between a patient's verbal and nonverbal communications (e.g., patient states that he is okay, with tears running down his face) allows the nurse to interpret and validate verbal statements.

Nonverbal Communication

Nonverbal communication is wordless transmission of information. According to seminal research by [Mehrabian \(1971\)](#), 93% of communication is nonverbal. Body language constitutes 55% of all nonverbal communication, and voice inflection accounts for 38%. Nonverbal communication is the more accurate mode of conveying information. Realizing the frequency and value of nonverbal communication helps the nurse observe and assess patients more accurately. Nurses who perceive the potential effect of their own nonverbal behavior will communicate more professionally and consistently when interacting with others.

Body Language

Body language is conveyed in many ways. Posture, stance, gait, facial expressions, eye movements, touch, gestures, and symbolic expressions influencing personal appearance, such as jewelry and make-up, generally communicate a person's thoughts more accurately than simple verbal interactions. The nurse needs to observe the patient and family members for nonverbal cues while interviewing or completing assessments. Cultural and ethnic differences, mental health issues, and physical and emotional states affect the way people communicate.

Posture, Stance, and Gait

The way a person stands, sits, or ambulates can convey volumes to those observing. A relaxed body while sitting or standing indicates

openness to what is being shared verbally in the conversation. If a patient sits with crossed legs or arms during an educational interaction with the nurse, the patient may be indicating a lack of openness to or acceptance of the information being shared. The manner in which patients and nurses ambulate communicates clearly without any words being spoken. A person's gait gives multiple cues to the nurse. If assistive devices are being used, the nurse knows that independent ambulation is at least temporarily impaired. A distinctive, intentional gait may communicate self-confidence, the need for immediate action, or a variety of potentially negative cues. A patient who is walking slowly with a bowed head may be feeling hopeless or exhausted or be in deep thought. Those observing a nurse running into a patient's room will certainly get the impression that there is an emergency. If a nurse walks quickly into a room and completes a task without making eye contact with the patient in the bed, the patient will have the impression that the nurse does not have time to address or does not care about the patient's needs and concerns.

Facial Expressions and Eye Movements

Grimacing or rolling the eyes communicates significant information. Some facial expressions may indicate fear or apprehension regarding impending diagnostic testing or surgery. The nurse must be especially perceptive when communicating with the patient and family members to observe the visual cues to their feelings. If there is incongruence between verbal communication and nonverbal facial expressions of patients or family members, the nurse must interview and assess the situation more carefully to identify and validate the most significant needs.

The facial expressions and eye movements of the nurse are of considerable concern. It is imperative to provide professional nursing care. Making inappropriate facial expressions may be offensive and hurtful to patients or their family members. The nurse must control his or her facial expressions to avoid communicating disdain or judgmental attitudes in challenging patient care situations. Maintaining a neutral facial expression establishes an environment of caring and openness in which the patient and family members can feel safe to share their innermost concerns.

Touch, Gestures, and Symbolic Expressions

Making physical contact in patient care situations can communicate caring or can be perceived as restrictive, depending on the type of touch used. Gently touching a blind patient's arm before providing care helps alert the patient to the nurse's presence (Fig. 3.2). Therapeutic touch,

such as holding the patient's hand or touching the patient's shoulder, can provide comfort and may alleviate pain. This is especially true when a patient is undergoing a painful or stressful procedure. In most cases, it is important for the nurse to be aware of or verify a patient's openness to touch before implementing it as a nursing intervention.

FIGURE 3.2 The nurse gently touches the arm of a blind patient to alert him to her presence. (Copyright [istock.com](https://www.istock.com).)

Significant research has been conducted on human interaction. The anthropologist Edward Hall (1966) developed the theory of **proxemics** (i.e., study of the spatial requirements of humans and animals). He identified four specific distances in which people interact: intimate space (0 to 1.5 feet), personal space (1.5 to 4 feet), social space (4 to 12 feet), and public space (12 feet or more). Fig. 3.3 illustrates these four basic distances. Nurses interact with patients within each of these distances, and they must become increasingly comfortable with and sensitive to interacting within the intimate-distance area while providing direct care. Box 3.1 addresses cultural and other diversity factors that affect patients' comfort levels and tolerance with personal space and physical touch). Additional information on cultural differences related to communication and the use of interpreters while caring for patients whose native language is different from that of the nurse is provided in Chapter 21.

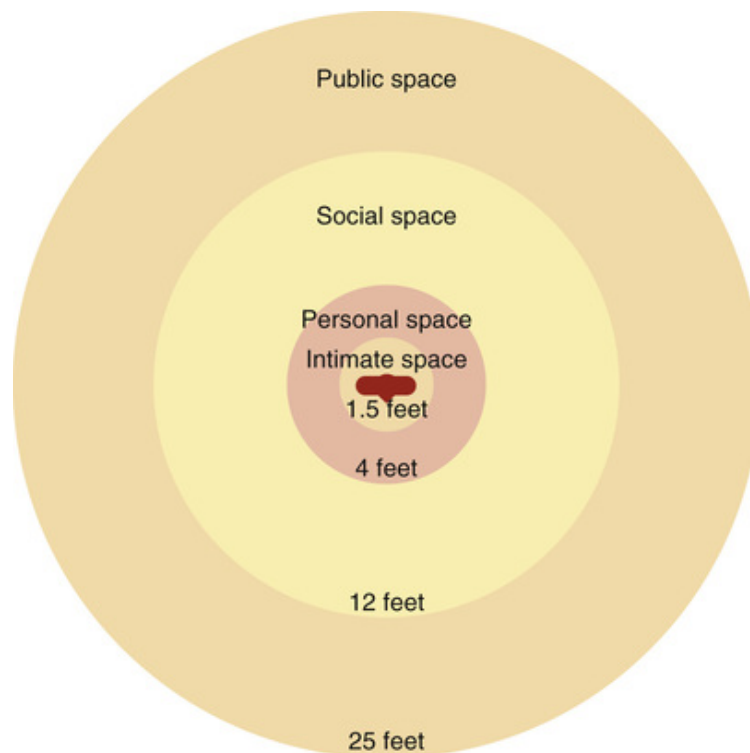

FIGURE 3.3 Hall's zones of interaction significantly affect communication in cross-cultural settings.

Box 3.1

Diversity Considerations

Life Span

- The need for personal space increases with age until early adulthood ([Hutchinson, 2013](#)).
- Older adults of some cultures require personal care from younger, same-gender members of their family ([Yarger & Brauner-Otto, 2014](#)).

Gender

- Women generally prefer more personal distance in social situations ([Sorokowska et al., 2017](#)).
- Making direct eye contact immediately before touching a patient of the opposite sex may help communicate caring and alleviate anxiety in the patient ([Pullen, Barrett, Rowh, et al., 2009](#)).

- In some cultures, nurses of the opposite sex may not be permitted to perform personal care or examine private areas of the patient's body ([Pullen, 2014](#)).
- The use of touch is important to demonstrate respect and provide appropriate care for lesbian, gay, bisexual, transgender (LGBT) people ([National Women's Law Center \[NWLC\], 2014](#)).

Culture and Ethnicity

- People born in more densely populated areas typically require less personal space for comfort.
- English-speaking people typically prefer at least 18 inches of distance between themselves and others when conversing. In contrast, people of various cultural backgrounds may be comfortable standing very close while communicating ([Purnell, 2013](#)) (see [Fig. 3.4](#)).
- Direct eye contact may be perceived as aggressive or impolite by individuals from Arab, Indo-Chinese, or American Indian cultures ([Pullen, 2014](#)).
- Special communication challenges exist between migrants and nurses that must be addressed to avoid health inequities ([Henly, 2016](#)).

FIGURE 3.4 Nurses need to respect the amount of personal space preferred by patients and families during conversation. (© [istock.com](https://www.istock.com).)

The use of gestures may be challenging to nurses practicing in a multicultural environment. Although they may enhance verbal communication, gestures may be viewed as inappropriate by patients of various cultures. Gestures may be most effective when used with people who have limited hearing. Establishing specific meanings for gestures before placing a patient on a ventilator or before a patient loses the ability to speak because of an advancing neurologic disease can facilitate communication when the patient is unable to speak.

Symbolic expression through the use of make-up, jewelry, or clothing may communicate self-esteem, economic resources, or mental health. Observing the appearance of a patient may provide the nurse with an indication of the patient's wellness or need for attention. Make-up and clothing may be used by a patient to hide inner feelings, or these symbols can indicate that the patient's condition is improving.

Nurses should be aware of their own use of symbolic expressions. Professionalism is best expressed without dramatic make-up, fragrance, or the smell of cigarette smoke and with minimal jewelry while performing patient care. Nurses who take pride in their professional

appearance are more likely to be perceived by patients as competent and caring.

Voice Inflection

The second most significant form of nonverbal communication is voice inflection. Spoken words may be emphasized through tone, volume, and the rhythm or rate of speech. Nurses must be sensitive to their voice inflections when speaking with patients to avoid a condescending tone that may be perceived as patronizing. Active listening is critical to perceiving the quality of speech used during interactions with others. Voice inflection provides insight into the significance of information being shared.

1. Describe nonverbal behaviors that may indicate tension and anger.

2. Identify at least two possible causes of K.B.'s nonverbal indications of tension and anger.

Verbal Communication

According to [Mehrabian \(1971\)](#), only 7% of communication about feelings and attitudes is verbal. This research finding underscores the critical need to integrate spoken, written, and electronic information with nonverbal cues garnered through observation and physical assessment.

Setting, Context, and Content

Spoken words may be communicated face to face, in a group setting, or through devices such as phones or intercoms. The setting of communication greatly influences what is or what can be shared. Depending on the confidentiality or privacy of the interaction, conversations may be overheard or taken out of context. Although it is important to get feedback when sharing patient information verbally to verify that the information is accurate, verbalizing potentially harmful or confidential information in a public setting may have legal ramifications for health care professionals. The context and content of verbal communication must be closely monitored by the nurse to avoid misinterpretation or errors in patient care.

Written Communication

Written communication, although effective in providing details and legal documentation, lacks the nuances that voice inflection and interactive conversation can provide. For example, it may be difficult to perceive urgency when reading progress notes. The meaning of written communication is often enhanced through discussion. Oral reports or grand rounds typically highlight the urgency of patient needs more than written documentation.

Electronic Communication

Special care must be taken to maintain confidentiality while communicating electronically. Electronic communication in the form of information referencing, e-mail, social networking, and blogging can quickly contribute to a person's knowledge, providing patients and health care professionals with vital information. However, the potential for miscommunication exists, in part because nonverbal cues are not apparent. When communicating verbally by electronic media, patients and nurses must take time to validate and verify shared information, because misunderstandings can occur if feedback is inadequate.

[Chapter 10](#) provides additional information on the requirements of electronic documentation.

LO 3.3 Types of Communication

Nurses engage in four basic types of professional communication: intrapersonal, interpersonal, small-group, and public communication. Each has a different focus and potential outcome.

Intrapersonal Communication

Intrapersonal communication (i.e., occurring internally) focuses on personal needs and can influence a person's well-being. **Positive self-talk** is internal conversation that provides motivation and encouragement; it may be used to build self-esteem and self-confidence. By encouraging positive self-talk, nurses empower patients to fight their diseases and persevere through difficult situations. For example, a patient may choose to repeat a phrase of encouragement silently while undergoing a painful diagnostic procedure; likewise, internally verbalizing that an invasive procedure is of a time-limited nature may make the experience more tolerable. Nurses and student nurses may use positive self-talk to overcome anxiety or discomfort while taking examinations or performing new or painful procedures, such as starting an intravenous infusion.

Negative self-talk (i.e., harmful or destructive internal conversation) may damage the ability of an individual to achieve his or her greatest potential or to overcome adversity. Negative self-talk may increase a patient's perception of pain, anxiety, or inability to meet the challenges of a poor prognosis.

Meditation (i.e., mindful reflection or contemplation) is another form of intrapersonal communication. Some people use it regularly as a means of self-encouragement and reassurance. Different from **prayer** (i.e., form of meditation traditionally directed to a deity), meditation is a continuous thought process that centers on one idea with the goal of achieving inner peace and relaxation.

Interpersonal Communication

Interpersonal communication takes place between two or more people. It may be formal or informal and conversational, and it may or may not have a stated goal or purpose. In the context of an interview, it may vary from the strictly formal to very casual. Health history interviews and patient–nurse interactions have a specific focus and intention and require confidentiality and setting of role boundaries. Effective interpersonal communication among health care professionals is

essential to ensure patient safety. Research indicates that 80% of preventable medical errors involve issues of interpersonal communication (Neese, 2015).

QSEN Focus!

Open communication among interdisciplinary teams of health care professionals creates a culture of safety, which is necessary to protect patients from harm and meet patient safety standards.

Interprofessional Communication

Effective collaborative communication among various members of the interdisciplinary health care team is essential for patient safety. This is especially true when patient care is being transferred to new care providers. Deficient hand-off communication is a major factor in adverse patient outcomes and many types of sentinel events (Scott et al., 2017). One method of interpersonal communication that has been adopted to increase interprofessional and hand-off communication is the SBAR model: situation, background, assessment, and recommendation (Box 3.2).

Box 3.2

Ethical, Legal, and Professional Practice

Hand-Off Communication

SBAR (situation, background, assessment, and recommendation) is a widely accepted method of hand-off communication that involves interpersonal communication designed to enhance patient safety and outcomes.

- SBAR is a standardized communication tool that supports accurate transfer of information between care providers. It is best used in a quiet, face-to-face environment that allows the receiving caregiver to ask questions and clarify a patient's plan of care (Barry, 2014).
- SBAR is often used by nursing as a hand-off tool and as a structured method for all communications between providers.
- SBAR communication requires the sharing of clear information focused on the four topical areas:

- **Situation:** What is happening right now?
- **Background:** What led to the current situation?
- **Assessment:** What is the identified problem, concern, or need?
- **Recommendation:** What actions or interventions should be initiated to alleviate the problem?
- Using SBAR format when documenting patient progress notes increases the clarity of shared information for legal purposes.

[Chapter 10](#) provides additional information on SBAR methodology.

Ethical Implications

Information shared during informal and formal nurse–patient interaction is considered confidential. The nurse must maintain the patient's right to privacy to ensure that the Health Insurance Portability and Accountability Act (HIPAA) regulations are met. The American Nurses Association's *Principles for Social Networking and the Nurse* (2011) provides guidance to nurses on how to use social networking ethically while providing for the privacy and confidentiality required for professional nursing practice. Nurses (and nursing students) must not post or transmit identifiable patient information on social media, and they are required to report social media content that may compromise a patient's right to privacy or cause harm (ANA, 2011). The video *Social Media Guidelines for Nurses* available on the National Council of State Boards of Nursing (NCSBN) website at <https://www.ncsbn.org/347.htm> provides information for students and nurses on how to use social media responsibly and avoid legal ramifications of its misuse. [Chapter 11](#) provides more information about ethical and legal interpersonal communication.

Professional **role boundaries** define the limits and responsibilities of individuals in a given setting. When undertaken by nurses, actions such as sharing personal phone numbers with patients, agreeing to meet patients outside the health care setting, and inappropriate touching violate these boundaries. Ethical or legal action may be taken against nurses who ignore professional role boundaries. The NCSBN video on professional boundaries in nursing available at <https://www.ncsbn.org/464.htm> is an excellent online resource.

Small-Group Communication

Communication in small groups focuses on meeting established goals or the needs of group participants. Focus groups, support groups, and task forces are examples of groups in which patients or nurses may be

involved. Leaders of small groups may emerge from the group or be appointed before a first meeting. Nurses may be asked to lead small groups in their professional roles.

Safe Practice Alert

It is the nurse's responsibility to establish and maintain professional role boundaries when interacting with patients.

Small-Group Dynamics

When asked to lead small groups, nurses need to be aware of the phases of group development and group dynamics that may facilitate or hinder communication. In 1965, psychologist Bruce Tuckman identified four phases of group development: forming, storming, norming, and performing. He later added a fifth—adjourning—to denote the stage of closure in the small-group setting (Tuckman & Jensen, 1977). Aspects of these phases parallel those of the nurse–patient helping relationship. Although Tuckman's phases appear to be linear, leaders should remember that group dynamics include individual personalities and that the arrival or departure of members may cause fluctuation among the various stages of group development.

During the forming phase, group members rely heavily on the leader to identify the mission and goals of the group. Ground rules are identified, and trust is established through the development of interpersonal relationships.

The storming phase of small-group development may involve some personality conflicts among the group participants. Group members with control issues may emerge. During the storming phase, the group leader needs to work with members to resolve conflicts and build cohesion. It is the group leader's responsibility to ensure that all members feel safe to share their thoughts and ideas freely without fear of ridicule.

Increased trust and openness emerge during the norming phase, resulting in productivity and meaningful sharing of information. During this phase, it is essential that the group leader encourage participation of all group members. The leader must redirect interaction if one member of the group tends to dominate the discussion. It is also important for group leaders to avoid sharing too many of their own thoughts or feelings. Sharing affirmations of what the group has accomplished and identifying future work constitute a vital role of an effective small-group leader.

Interdependence emerges during the performing phase of group development. During this phase, problem solving takes place within the group. Group members are typically highly committed during this time. Collaboration is effective in groups that perform at a high level.

The adjourning phase takes place as the small group disperses, having achieved the group's goals. By recognizing the various phases of group development and using strategies to encourage communication among all group members, nurses can be very effective small-group facilitators.

Public Communication

Nurses communicate in a public forum through patient and community education on health care issues, including wellness. Public communication requires education, preparation, openness to diverse opinions, and communication skills that encourage acceptance and dialogue. Nurses may be asked to serve as professional experts on health care issues for the media. Training in public speaking may be beneficial for nurses who anticipate extensive public communication in their professional roles.

LO 3.4 The Nurse–Patient Helping Relationship

A helping relationship develops through ongoing, purposeful interaction between a nurse and a patient. Each helping relationship evolves as a result of systematic, intentional activities of the nurse. The focal point of the nurse–patient helping relationship is the patient and the patient's needs and concerns. Nurse–patient relationships focus on five areas: (1) building trust, (2) demonstrating empathy, (3) establishing boundaries, (4) recognizing and respecting cultural influences, and (5) developing a comprehensive plan of care.

Phases of the Helping Relationship

The nurse–patient helping relationship consists of three phases: orientation or introductory, working, and termination (Table 3.1). Preinteraction activities, such as gathering assessment and diagnostic data, organizing the data, identifying areas of concern, and planning the interaction, prepare the nurse for the initial contact with the patient.

TABLE 3.1
Phases of the Nurse–Patient Helping Relationship

PHASE	FOCUS
Orientation or introductory	<ul style="list-style-type: none">• Making introductions, establishing professional role boundaries (formally or informally) and expectations, and clarifying the role of the nurse• Observing, interviewing, and assessing the patient, followed by validation of perceptions• Identifying the needs and resources of the patient
Working	<ul style="list-style-type: none">• Development of a contract or plan of care to achieve identified patient goals• Implementation of the care plan or contract• Collaborative work among the nurse, patient, and other health care providers, as needed• Enhancement of trust and rapport between the nurse and the patient• Reflection by the patient on emotional aspects of illness• Use of therapeutic communication by the nurse to keep interactions focused on the patient
Termination	<ul style="list-style-type: none">• Alerting the patient to impending closure of the relationship• Evaluating the outcomes achieved during the interaction• Concluding the relationship and transitioning patient care to another caregiver, as needed

Nursing Process in the Helping Relationship

The five steps of the nursing process are used in each phase of the helping relationship. During preinteraction and the orientation phase, the nurse gathers assessment data and formulates nursing diagnoses that are appropriate for the patient. Objective data are collected during preinteraction and the orientation phase, whereas subjective data are obtained almost exclusively while interacting with the patient during the orientation or introductory phase.

Nursing diagnoses for individual patients are identified during the orientation phase after assessment data are gathered and clustered. International Classification for Nursing Practice (ICNP) nursing diagnoses commonly related to communication concerns include the following:

- *Impaired Verbal Communication*
- *Powerlessness*
- *Risk for Powerlessness*
- *Social Isolation*
- *Situational Low Self Esteem*
- *Anxiety*
- *Fear*

During the working phase of the helping relationship, goals or outcome statements and nursing interventions are developed in collaboration with patients and their families. It is important for the nurse to discuss assessment findings and concerns with the patient to establish realistic short-term and long-term goals. Communication with patients before initiating nursing interventions helps alleviate anxiety and promotes goal attainment.

The evaluation step of the nursing process is completed during the termination phase of the helping relationship. During this phase, the nurse and patient determine the level of patient goal fulfillment and the possible need for further intervention. Outcomes of the nurse–patient helping relationship are greatly affected by the nurse's use of therapeutic communication and by the patient's receptivity.

LO 3.5 Factors Affecting the Timing of Patient Communication

Many factors influence when communication with patients is best initiated, including the patient's pain or anxiety level and the physical location of the patient. Distractions in the patient's environment, including the presence of visitors, also may interfere with communication.

Pain or Anxiety

Patients experiencing a moderate to high level of pain comprehend direct, empathetic communication most effectively. Short questions or specific instructions are the best methods for exchanging information with patients when they are suffering from acute or severe chronic pain. A similar approach is most effective with patients who are experiencing intense anxiety. If the nurse must provide an anxious patient with instructions for a diagnostic test or surgical procedure, short sentences that include only essential information should be used. Extensive patient education or preoperative teaching should be provided at an earlier or different time, when the patient is more relaxed or when the pain level is more tolerable.

Location and Distractions

Several factors affect the location appropriate for communication with patients. Privacy and confidentiality are critical during the interviewing and assessment process. Patients should not be asked to share their health histories while visitors or non-health care providers are present. Simply pulling a cubicle curtain around a patient's bed does not prevent the transmission of sound beyond the curtain. If it is impossible to provide a private area in which to gather vital information, ask for the patient's permission to conduct the interview in the current setting before initiating the health history interview. Make every effort to talk with patients in an environment with as few interruptions and distractions as possible.

Effective communication can be challenging if technology and other people distract the patient and nurse. Although technology, such as MP3 players, televisions, and cardiac monitors, may provide entertainment or valuable patient information, communication is enhanced when the people involved are attentive to the interaction. Ask the patient to turn off competing technology and to focus on the nurse–

patient interaction as needed. Turn down the volume of audible monitor alerts during an extensive patient interaction. Remember to return the monitor alerts to their original levels before leaving the patient's bedside.

It is appropriate for the nurse to ask visitors to leave a patient's room for a few minutes to obtain critical, private information directly from the patient. The best source of information for an alert, oriented adult patient is the patient, not a spouse, another relative, or a visitor who happens to be present when the health history is taken. By focusing directly on the patient, the nurse communicates concern and is more attuned to subtle information communicated verbally and nonverbally.

With the patient's permission, relatives and friends may be considered secondary sources of subjective information. Data gathered from these persons may be helpful in validating or clarifying the information provided first by the patient. Relatives or friends of the patient may become sources of information after required permission has been secured, especially if the patient is disoriented, comatose, absent, or a minor.

Safe Practice Alert

Make sure the patient is alert and oriented before obtaining a health history or asking the patient to make significant health care decisions.

LO 3.6 Essential Components of Professional Nursing Communication

Respect, assertiveness, collaboration, delegation, and advocacy are critical components of professional nursing communication that facilitate positive patient outcomes. Respecting patients and advocating on their behalf builds trust and conveys caring. Collaborating and delegating assertively with health care team members creates a positive work environment focused on patient needs.

Respect

Respect for patients and their families is conveyed by nurses verbally and nonverbally. Asking a patient's name preference during initial contact demonstrates respect and establishes the foundation for a trusting nurse–patient relationship. Ensuring privacy, providing necessary health care information, and fostering autonomy in decision making are nursing actions that further strengthen the relationship. Controlling facial expressions and body language during challenging interactions with patients and health care team members is essential to consistently demonstrate respect.

Assertiveness

Assertiveness is the ability to express ideas and concerns clearly while respecting the thoughts of others. Assertive nurses communicate with patients, families, and other members of the health care team regularly and without hesitation. Assertive communication by nurses demonstrates confidence and elicits respect from patients and colleagues. Overly assertive nurses may be perceived as aggressive if they do not respect the rights and opinions of others. Nurses who communicate aggressively tend to receive negative or defensive responses from patients, family members, and health care team members.

Collaboration

Collaboration with other health care professionals is a key factor in communicating necessary health care information and providing comprehensive patient care. Most patients require the collaboration of many different health care professionals during hospitalization or outpatient treatment, and the nurse is often the coordinator of this team.

Physicians, nurse practitioners, laboratory technicians, social workers, and respiratory, physical, occupational, and speech therapists, along with unlicensed assistive personnel, may share responsibility for patient care. The nurse must contact key health care professionals in an expedient manner and with respect and recognition of time and resource limitations. Ongoing communication with the patient about the status of the health care team collaboration is essential to allay unnecessary anxiety associated with not knowing what is happening.

QSEN Focus!

Requesting input from other members of the interdisciplinary health care team enhances a nurse's ability to meet the patient's needs. Each professional brings a different perspective and unique expertise that should be valued.

Delegation

Delegation is a multifaceted responsibility of the registered nurse. When communicating during delegation, nurses must show collegiality and respect for all members of the health care team. It is important to call other health care team members by their preferred names. Accuracy while communicating helps ensure positive patient outcomes. Receiving feedback from the person to whom care is delegated is required by law and provides an opportunity for clarity, which ensures greater accuracy. [Chapter 11](#) provides further information on the legal requirements of delegation.

Communicating therapeutically with colleagues during the delegation process shows respect and recognizes the many stressors with which all members of the health care team cope while providing patient care. Offers of support and encouragement help convey empathy and promote teamwork. [Chapter 12](#) focuses on the strengths of nursing leaders.

Advocacy

Patient advocacy is a hallmark of professional nursing. Advocacy involves defending the rights of others, especially those who are vulnerable or unable to make decisions independently ([Box 3.3](#)). To be an effective advocate for patients, the nurse must be knowledgeable, organized, and able to communicate in a caring manner. Nurses who communicate therapeutically and assertively are better able to advocate for their patients.

Box 3.3

Evidence-Based Practice and Informatics

Perioperative Patient Advocacy

- Patient advocacy is especially important in the perioperative setting when patients are sedated or under general anesthesia.
- Roles of the nurse in advocacy for the perioperative patient include:
 - Protection
 - Preserving patient values
 - Support
 - Informing
- Perioperative nurses are the anesthetized patient's representatives to ensure the patient's needs are being met and values are being honored.
- Although perioperative nurses sometimes perceive their ability to advocate for patients as difficult due to a hierarchical surgical environment or potential repercussions, they actively communicate their concerns to protect patients from harm.

From Sundqvist, A., Holmefur, M., Nilsson, U., & Anderzen-Carlsson, A. (2016). Perioperative patient advocacy: An integrative review. *Journal of PeriAnesthesia Nursing*, 31(5), 422-433.

LO 3.7 Social, Therapeutic, and Nontherapeutic Communication

Significant differences exist between social and **therapeutic communication** (i.e., beneficial, positive interaction). Nurses who understand this difference are effective in gathering information from patients and identifying their needs. Patients perceive nurses who develop strong therapeutic communication skills as caring, professional, and compassionate. Nurses who understand the impact of effective communication on patient care are less likely to engage in social conversation with patients and coworkers when it is not appropriate.

Social Communication

Social communication most often occurs among individuals who know each other or who are getting to know each other informally. It typically involves mutual sharing of ideas, with a balanced focus on all parties engaged in the conversation. Friends may compare experiences, give advice, verbalize opinions, or make judgments on the behavior of others; anger and humor—appropriate or inappropriate—may be expressed. Most social conversations are multifaceted and change focus as topics of conversation evolve.

Therapeutic Communication

The primary focus of therapeutic communication between a patient and nurse is the patient. Nurses engaged in therapeutic conversations set their own opinions and judgments aside to listen more fully to their patients. Through various techniques, such as active listening, open posture, and reflection, nurses encourage patients to explore personal concerns (Fig. 3.5). Patients often respond with open, honest sharing to nurses who are accepting of alternative ideas and empathetic to the circumstances of others. Nurses need to value the important role of therapeutic and open dialogue in the healing process.

FIGURE 3.5 Talking with patients at eye level enhances communication. (© [istock.com](https://www.istock.com).)

The use of therapeutic communication techniques enhances nurse–patient relationships and helps achieve positive outcomes. Consistent use demonstrates empathy and concern for patients. Various techniques greatly assist the nurse in gathering, verifying, and validating assessment data.

[Table 3.2](#) provides examples and rationales for verbal therapeutic communication techniques that nurses should practice while providing care within all settings. [Table 3.3](#) highlights examples and rationales for some essential nonverbal therapeutic techniques that nurses should implement when communicating with patients.

TABLE 3.2**Verbal Techniques for Initiating and Encouraging Communication**

TECHNIQUE	EXAMPLES	RATIONALE
Offering self	"I'll sit with you for a while." "I'll stay with you until your family member arrives."	<ul style="list-style-type: none"> • Demonstrates compassion and concern for the patient • Establishes a caring relationship
Calling the patient by name	"Good morning, Mr. Trimble." "Hi, Ms. Martin. How are you feeling this evening?"	<ul style="list-style-type: none"> • Conveys that the nurse sees the patient as an individual • Shows respect and helps establish a caring relationship
Sharing observations	"You look tense." "You seem frustrated." "You are smiling."	<ul style="list-style-type: none"> • Raises the patient's awareness of his or her nonverbal behavior • Allows the patient to validate the nurse's perceptions • Provides an opening for the patient to share possible joys or concerns
Giving information	"It is time for your bath." "My name is Pam, and I will be the RN taking care of you until 7 p.m." "Your surgery is scheduled for 10:30 a.m. tomorrow."	<ul style="list-style-type: none"> • Informs the patient of facts needed in a specific situation • Provides a means to build trust and develop a knowledge base on which patients can make decisions
Using open-ended questions or comments	"What are some of your biggest concerns?" "Tell me more about your general health status." "Share some of the feelings you experienced after your heart attack."	<ul style="list-style-type: none"> • Gives the patient the opportunity to share freely on a subject • Avoids interjection of feelings or assumptions by the nurse • Provides for patient elaboration on important topics when the nurse wants to collect a breadth of information
Using focused questions or comments	"Point to exactly where your pain is radiating." "When did you start experiencing shortness of breath?" "How has your family responded to your being hospitalized?" "What is your greatest fear?" "Where were you when the symptoms started?" "Tell me where you live."	<ul style="list-style-type: none"> • Encourages the patient to share specific data necessary for completing a thorough assessment • Asks the patient to provide details regarding various concerns • Focuses on the immediate needs of the patient
Providing general leads	"And then?" "Go on." "Tell me more."	<ul style="list-style-type: none"> • Encourages the patient to keep talking • Demonstrates the nurse's interest in the patient's concerns
Conveying acceptance	"Yes." Nodding. "I follow what you are saying." "Uh huh."	<ul style="list-style-type: none"> • Acknowledges the importance of the patient's thoughts, feelings, and concerns

TECHNIQUE	EXAMPLES	RATIONALE
Using humor	"You are really walking well this morning. I'm going to have to run to catch up!"	<ul style="list-style-type: none"> • Provides encouragement • May lighten heavy moments of discussion • Used properly, allows a patient to focus on positive progress or better times and does not change the subject of a conversation
Verbalizing the implied	<i>Patient:</i> "I can't talk to anyone about this." <i>Nurse:</i> "Do you think others won't understand?"	<ul style="list-style-type: none"> • Encourages a patient to elaborate on a topic of concern • Provides an opportunity for the patient to articulate more clearly a complicated topic or feeling that could be easily misunderstood
Paraphrasing or restating communication content	<i>Patient:</i> "I couldn't sleep last night." <i>Nurse:</i> "You had trouble sleeping last night?"	<ul style="list-style-type: none"> • Encourages patients to describe situations more fully • Demonstrates that the nurse is listening
Reflecting feelings or emotions	"You were angry when your surgery was delayed?" "You seem excited about going home today."	<ul style="list-style-type: none"> • Focuses on the patient's identified feelings based on verbal or nonverbal cues
Seeking clarification	"I don't quite follow what you are saying." "What do you mean by your last statement?"	<ul style="list-style-type: none"> • Encourages the patient to expand on a topic that may be confusing or that seems contradictory
Summarizing	"There are three things you are upset about: your family being too busy, your diet, and being in the hospital too long."	<ul style="list-style-type: none"> • Reduces the interaction to three or four points identified by the nurse as being significant • Allows the patient to agree or add additional concerns
Validating	"Did I understand you correctly that. ...?"	<ul style="list-style-type: none"> • Allows clarification of ideas that the nurse may have interpreted differently than intended by the patient

TABLE 3.3**Nonverbal Techniques for Facilitating Communication**

TECHNIQUE	EXAMPLES	RATIONALE
Active listening	<ul style="list-style-type: none">• Maintaining intermittent eye contact• Matching eye levels• Attentive posturing• Facing the patient• Leaning toward the person who is speaking• Avoiding distracting body movement	<ul style="list-style-type: none">• Conveys interest in the patient's needs, concerns, or problems• Provides the patient with undivided attention• Sends a clear message of concern and interest
Silence	<ul style="list-style-type: none">• Being present with a person without verbal communication	<ul style="list-style-type: none">• Provides the patient time to think or reflect• Communicates concern when there is really nothing adequate to say in difficult or challenging situations
Therapeutic touch	<ul style="list-style-type: none">• Holding the hand of a patient• Providing a backrub• Touching a patient's arm lightly• Shaking hands with a patient in isolation	<ul style="list-style-type: none">• Conveys empathy• Provides emotional support, encouragement, and personal attention• Relaxes the patient

A helpful reference for remembering the various aspects of active listening is the acronym SOLER (Egan, 2014). **S** encourages the listener to *sit* (if possible) facing the patient. **O** reminds the nurse to maintain an *open* stance or posture while listening. **L** suggests that the listener *lean* toward the speaker, positioning the body in an open stance. **E** refers to maintaining *eye* contact without staring. **R** reminds the nurse to *relax*. Demonstrating relaxation during a conversation encourages the person sharing to continue. It also conveys a sense of attention, interest, and comfort with the subject being shared. Refer to [Chapter 2](#) for further information on active listening.

Phrasing requests in a positive manner is a very effective communication technique that helps promote patient cooperation and affirmation. Instead of saying, “Don't forget to use your incentive spirometer,” reword the request with a positive focus by saying, “Remember to use your incentive spirometer every hour to help prevent pneumonia.” Positive language tends to motivate individuals to comply with important activities. Practice on friends and family by rewording requests in a positive manner that supports cooperation.

3. Write two opening statements or questions that may be used by the nurse to approach K.B. and identify the underlying cause of his concern.

4. Name three therapeutic communication techniques that may be used by the nurse to encourage K.B. to share his thoughts and concerns.

Nontherapeutic Communication

Nontherapeutic communication can be hurtful and potentially damaging to interaction. Changing the subject (e.g., in response to a patient who expresses a desire to talk about a concern that makes the nurse uncomfortable) or sharing personal opinions limits conversation between the nurse and the patient and discourages open conversation on sensitive topics. Many aspects of social conversation should be avoided when interacting with patients. Most are considered nontherapeutic and tend to shift the conversational focus away from the patient's concerns. Nurses engaging in nontherapeutic social conversation tend to be labeled by patients as uncaring and self-absorbed. [Table 3.4](#) provides examples of nontherapeutic communication that should be avoided.

TABLE 3.4**Nontherapeutic Communication**

ACTION	EXAMPLES	RATIONALE
Asking "why" questions	<p>"Why did you do that?"</p> <p>"Why are you feeling that way?"</p> <p>"Why do you continue to smoke when you know it is unhealthy?"</p>	<ul style="list-style-type: none"> • Implies criticism • May make the patient defensive • Tends to limit conversation • Requires justification of actions • Focuses on a problem rather than a possible solution
Using closed-ended questions or comments	<p>"Do you feel better today?"</p> <p>"Did you sleep well last night?"</p> <p>"Have you made a decision about radiation yet?"</p> <p>"Are you ready to take your bath?"</p> <p>"Will you let me give you your medicine now?"</p>	<ul style="list-style-type: none"> • Results in short, one-word, yes or no responses • Limits elaboration or discussion of a topic • Allows patient to refuse important care • Differs from focused questions that direct an interview
Changing the subject	<p><i>Patient:</i> "I'm having a difficult time talking with my daughter."</p> <p><i>Nurse:</i> "Do you have grandchildren?"</p> <p><i>Patient:</i> "I just want to die."</p> <p><i>Nurse:</i> "Did you sleep well last night?"</p>	<ul style="list-style-type: none"> • Avoids exploration of the topic raised by the patient • Demonstrates the nurse's discomfort with the topic introduced by the patient
Giving false reassurance	<p>"Everything will be okay."</p> <p>"Surgery is nothing to be concerned about."</p> <p>"Don't worry; everything will be fine."</p>	<ul style="list-style-type: none"> • Discounts the patient's feelings • Cuts off conversation about legitimate concerns of the patient • Demonstrates a need by the nurse to "fix" something that the patient just wants to discuss
Giving advice	<p>"If it were me, I would. ..."</p> <p>"You should really exercise more."</p> <p>"You should absolutely have chemotherapy to treat your breast cancer if you expect to live."</p> <p>"Of course you should tell your co-workers that you've been diagnosed with cancer."</p>	<ul style="list-style-type: none"> • Discourages the patient from finding an appropriate solution to a personal problem • Tends to limit the patient's ability to explore alternative solutions to issues that need to be faced • Implies a lack of confidence in the patient to make a healthy decision • Removes the decision-making authority from the patient
Giving stereotypical or generalized responses	<p>"It's for your own good."</p> <p>"Keep your chin up."</p> <p>"Don't cry over spilt milk."</p> <p>"You will be home before long."</p>	<ul style="list-style-type: none"> • Discounts patient feelings or opinions • Limits further conversation on a topic • May be perceived as judgmental

ACTION	EXAMPLES	RATIONALE
Showing approval or disapproval	"That's good." "You have no reason to be crying."	<ul style="list-style-type: none"> • Limits reflection by patients • Stops further discussion on patient decisions or actions • Implies a need for patients to have the nurse's support and approval
Showing agreement or disagreement	"That's right." "I disagree with what you just said."	<ul style="list-style-type: none"> • Discontinues patient reflection on an introduced topic • Implies a lack of value for the thoughts, feelings, or concerns of patients
Engaging in excessive self-disclosure or comparing the experiences of others	"I had the same type of cancer 2 years ago." "I have several family members who drink too much, too." "I go to that restaurant every Friday for fish."	<ul style="list-style-type: none"> • Implies that experiences related to a disease process are similar for all patients • Takes the focus away from the patient • Limits further reflection or problem solving by the patient
Comparing patient experiences	"The lady in room 250 just had this surgery last week and did just fine." "My uncle had this type of inflammatory bowel disease and ended up having to have a colostomy."	<ul style="list-style-type: none"> • Removes the focus of conversation from the patient • Invalidates each individual patient experience as being unique and important • Breaches confidentiality
Using personal terms of endearment	"Honey." "Sweetie, it is time to take your medicine." "Sport, how about if you show me how well you can walk across the room?"	<ul style="list-style-type: none"> • Demonstrates disrespect for the individual • Diminishes the dignity of a unique patient • May indicate that the nurse did not take the time or care enough to learn or remember the patient's name
Being defensive	"The nurses here work very hard." "Your doctor is extremely busy." "This is the best hospital in the area." "You won't get any better care anywhere else."	<ul style="list-style-type: none"> • Moves the focus from the patient • Discounts the patient's feelings and thoughts on a subject • Limits further conversation on a topic of patient concern

Avoiding nontherapeutic communication requires practice and experience. Intentionally incorporating as many therapeutic communication strategies as possible into conversations helps a nurse better meet patients' needs.

LO 3.8 Defense Mechanisms

When individuals are under extreme stress or unable to comprehend and cope with the reality of a situation, they may use defense mechanisms to protect themselves and their psyches. **Defense mechanisms** are unconscious strategies that allow an individual to decrease or avoid unpleasant circumstances. Some defense mechanisms are protective when employed for short or long periods; others are consistently harmful. When used indefinitely, some defense mechanisms, such as denial, prevent an individual effectively addressing critical issues. Others, such as compensation, may positively influence the productivity of an individual's life.

Patients faced with a situation perceived as hopeless may exhibit anger toward a nurse. When this happens, it is important for the nurse to recognize displacement and address the real concerns of the patient rather than taking the patient's expressions of anger personally. [Table 3.5](#) defines common defense mechanisms that are important for the nurse to recognize when used by patients overwhelmed with the stress or realities of unpleasant situations in which they find themselves. [Chapter 32](#) provides additional information on reactions to stress and defense mechanisms.

TABLE 3.5

Defense Mechanisms

DEFENSE MECHANISM	DEFINITION
Compensation	Using personal strengths or abilities to overcome feelings of inadequacy
Denial	Refusing to admit the reality of a situation or feeling
Displacement	Transferring emotional energy away from an actual source of stress to an unrelated person or object
Introjection	Taking on certain characteristics of another individual's personality
Projection	Attributing undesirable feelings to another person
Rationalization	Denying true motives for an action by identifying a more socially acceptable explanation
Regression	Reverting to behaviors consistent with earlier stages of development
Repression	Storing painful or hostile feelings in the unconscious, causing them to be temporarily forgotten
Sublimation	Rechanneling unacceptable impulses into socially acceptable activities
Suppression	Choosing not to think consciously about unpleasant feelings

Nurses should document the use of defense mechanisms by patients. Use of unhealthy defense mechanisms over an extended period may require referral to a professional counselor.

Safe Practice Alert

Discuss possible referral for professional counseling with the primary care provider if patients exhibit detrimental use of defense mechanisms while trying to cope with stressful situations.

LO 3.9 Special Communication Considerations

Many patients have sensory impairment, making nonverbal or verbal communication, or both, impossible. Communication with sensory-impaired patients requires patience, creativity, and adaptation to ensure that patient needs are met. The nurse's ability to modify the method of communication greatly affects the quality of care delivered. Feelings of isolation, frustration, and depression by individuals with sensory impairment may be prevented if their caregivers use specific strategies to enhance communication. By assessing family dynamics and gathering community services information, nurses can better identify potential strengths and obstacles in patient support systems that affect effective communication.

Hearing-Impaired Patients

Various approaches may be effective in providing patient care for those with impaired hearing. Patients who normally wear hearing aids should be encouraged to place them in their ears during morning care. Checking or replacing hearing aid batteries regularly helps avoid most associated mechanical difficulties.

When communicating with a hearing-impaired patient, the nurse should make sure the area is well lit with as little background noise as possible. Hearing aids amplify all sounds, making noisy environments confusing and frustrating. Raising the voice level slightly, speaking clearly, and making sure the patient can see the nurse's face helps facilitate communication. Adequate lighting enhances the patient's ability to see the speaker's mouth and face and interpret nonverbal communication. Stay within 3 to 6 feet of patients with hearing problems when conversing and avoid turning or walking away while talking. Consistent affirmative answers to the nurse's questions may be an indication that the patient is not hearing or understanding the information being shared. Care should be taken to verify that patients truly comprehend the content of verbal interaction. Extra patience may be required by the nurse to demonstrate caring while communicating with hearing-impaired patients.

Many of the strategies used when communicating with hearing-impaired patients are important when interacting with people who are deaf. Adequate lighting, avoiding overenunciation, and speaking slowly while in direct proximity to deaf patients can help their ability to read lips and perceive the meaning of gestures and facial expressions. If deaf

patients use sign language as their primary means of conversing, an interpreter should be contacted to help with communication of critical information (Box 3.4). Gestures and the use of pictures can facilitate informal communication when an interpreter is unavailable.

Box 3.4

Interprofessional Collaboration and Delegation

Use of Interpreters

- Collaboration with the institutional department responsible for obtaining interpreters for deaf patients or those with limited English proficiency (LEP) should be initiated by the nurse as soon as the need is identified.
- Interpretation may be provided by a professional interpreter face-to-face with patients and families or by phone or video medical interpretation.
- Family members should not be used as interpreters of specific medical information to maintain the patient's right to privacy and avoid possible misinterpretation of medical terminology.
- Nurses need to be aware of interpreter laws in their area of employment and follow hospital policy and procedures regarding interpreter use in patient care.
- Access to interpretation or translation for deaf and LEP patients is required by Title VI of the Civil Rights Act of 1964, which mandates equal rights for people regardless of race, color, or national origin.

From U.S. Department of Health and Human Services: Guidance to Federal Financial Assistance Recipients Regarding Title VI Prohibition against National Origin Discrimination Affecting Limited English Proficient Persons: Summary, 2017. Retrieved from <https://www.hhs.gov/civil-rights/for-providers/laws-regulations-guidance/guidance-federal-financial-assistance-title-VI/index.html>; http://onlineresources.wnylc.net/pb/orcdocs/LARC_Resources/LEPTopics/HC/hhsrevisedlepguidance.pdf

Written communication is especially helpful when the nurse is providing detailed information to literate hearing-impaired or deaf

patients and family members. A whiteboard and erasable marker or computer tablet kept at the bedside of a deaf patient may facilitate more effective communication. Institutional policies detailing the accommodations necessary to provide safe care to deaf patients should be followed.

Visually Impaired Patients

An important factor to remember when caring for visually impaired or blind patients is that they are rarely hearing impaired. Typically, blind patients have heightened auditory and olfactory senses.

Communication with blind patients can be characterized as anticipatory, meaning the nurse should alert visually impaired patients of potential hazards or object locations to provide necessary information and safe care. The position of numbers on an analog clock is often used as a reference when communicating the location of food on the plate of a blind patient. For example, the nurse may inform the visually impaired patient that the meat entrée is in the 6 o'clock position and the coffee cup is at 2 o'clock on the tray. This system may be helpful in orienting blind patients to their hospital rooms. For example, from the vantage point of lying in bed, the bathroom may be at the 10 o'clock position and the phone at 5 o'clock on the bedside cabinet.

Large-print, Braille, audio, or e-books may be helpful in communicating effectively with visually impaired or blind patients. Many library materials and online resources are available to assist with patient education.

Gentle physical contact, such as a light touch on the arm, alerts the blind patient that someone is present. This is especially important if the patient has been sleeping, is in a noisy environment, or is hearing-impaired.

Physically or Cognitively Impaired Patients

Communicating in ways that best meet the needs of physically or cognitively impaired individuals requires ongoing creativity and adaptation. Patients with severe respiratory difficulties requiring endotracheal intubation or a tracheostomy need special accommodations to communicate. Some of these patients may be able to use nonverbal cues such as head nodding or hand squeezing to communicate their needs. A whiteboard with erasable markers or a computer tablet can be particularly helpful. Patients with expressive aphasia may benefit from these communication aids if their cognitive capacity and physical ability to write are intact. If a patient is weak, the caregiver should hold the board and help the patient write.

Communication with a semicomatose or postoperative patient still partially anesthetized may be realized through physical touch and hand squeezing and by observing for nonverbal signs. If the patient grimaces when touched or moved or responds when asked to squeeze the nurse's hand, communication is established. The nurse must talk to the patient before initiating care and throughout procedures, even if the patient is seemingly unaware of the surroundings. Individuals can hear even when they are physically unable to move or speak. This fact is important for nurses to remember when caring for patients who are temporarily noncommunicative or comatose.

Quadriplegic patients who have a tracheostomy or who are on a ventilator may use electronic devices and a variety of gestures or eye movements to communicate. Assistive devices that use eye movement technology help paralyzed patients who are mentally alert and have neuromuscular control of the head and neck communicate. These devices include electronic transducers that connect remotely to computers. In addition to becoming familiar with assistive electronic equipment, nurses must pay close attention to the meaning of specific nods or shoulder shrugs to fully communicate with quadriplegic patients.

Patients diagnosed with intellectual disabilities or dementia require special attention by caregivers. Consulting with the family members of these patients often provides helpful hints and insights into what is most effective in gaining their cooperation with necessary nursing interventions. Avoiding confrontation is important. It is better to accept a demented patient's thought process than argue or try to correct an erroneous line of thinking.

Families and Communities

Providing support for the families of hospitalized patients involves ongoing communication. Because the discipline of nursing addresses the effects of illness on patients rather than simply the illness itself, establishing and maintaining viable lines of communication among patients and their family members or friends is critical. Particularly helpful are therapeutic communication techniques, which may provide insight into the existence and strength of available support systems. Family dynamics are often revealed by listening and observing, providing a clearer picture of the impact of illness and the associated circumstances on patients and their families. Assessment data about patients' families and the communities in which they live are a significant resource for formulating patient-centered plans of care.

Nurses should become familiar with community services to provide for the ongoing needs of discharged patients and their families. Nurses

should engage community leaders in dialogue related to health care access and home care services. By taking seriously their role as public communicators, nurses can influence the wellness and quality of life in the communities in which they work and live.

Summary of Learning Outcomes

LO 3.1 *Identify key components of the communication process:* A referent initiates communication between a sender and a receiver during which a message is sent through a channel and followed by feedback to ensure accuracy.

LO 3.2 *List examples of the verbal and nonverbal modes of communication:* The most common and accurate mode of communication is nonverbal, which uses various forms of body language and voice inflection. Verbal communication may be spoken, written, or electronic.

LO 3.3 *Explain the primary purpose of the various types of communication:* Effective intrapersonal, interpersonal (including interprofessional), small-group, and public communication skills are used by nurses to adequately provide for patient safety and meet the needs of patients, families, and the communities in which they practice.

LO 3.4 *Describe how significant aspects of the nursing process are implemented in the nurse–patient helping relationship:* The relationship focuses on addressing identified patient needs. The nurse must use all steps of the nursing process to build a trusting relationship focused on positive patient outcomes.

LO 3.5 *Discuss factors affecting the timing of patient communication:* Several factors influence the ability of patients to respond to nurse-initiated communication. They include pain level, anxiety, and environmental factors such as distractions or level of privacy.

LO 3.6 *Recognize the roles of respect, assertiveness, collaboration, delegation, and advocacy in professional nursing communication:* Nurses communicate professionally by showing respect, advocating for patients, and assertively conveying patient needs during collaboration and delegation.

LO 3.7 *Identify social, therapeutic, and nontherapeutic communication techniques:* Nurses must practice using a variety of therapeutic communication techniques to address the needs of patients.

Nontherapeutic communication may be considered social and shifts conversational focus away from the concerns of patients.

LO 3.8 *List defense mechanisms used by patients while communicating:* Individuals under extreme stress may use defense mechanisms to protect themselves and their psyches to better cope with the reality of life experiences.

LO 3.9 *Illustrate methods of communicating in special situations:* Nurses may use a variety of methods such as whiteboards, computer tablets, physical touch, and online resources to communicate effectively with sensory-impaired or nonverbal patients. Assessing family and community dynamics facilitates enhanced communication and patient safety.

Review Questions

1. A hospitalized patient experiences a sharp, stabbing pain while visiting with his spouse. Both the patient and his wife become very concerned, and the patient's call light is activated. What referent initiated communication between the patient and the nurse?
 - a. Interaction between the patient and his wife
 - b. Concern on the part of the patient's spouse
 - c. Pain experienced by the patient
 - d. Activation of the call light
2. Which factors influence whether a message is effectively communicated? (*Select all that apply.*)
 - a. Timing of the conversation
 - b. Educational level of participants
 - c. Mode of communication used
 - d. Physical environment of discussion
3. If a patient is grimacing, what assessment statement or question would be most beneficial in identifying the underlying cause of the nonverbal communication?
 - a. "Did you lose something?"
 - b. "You appear to be having pain."
 - c. "I will turn off the lights and let you rest."
 - d. "May I get you something to relieve your tension?"
4. What action by the nurse would most ensure accurate interpretation of patient communication?
 - a. Providing feedback regarding the conveyed message

- b. Writing down the patient's conversational highlights
 - c. Assuming significant cultural differences exist
 - d. Verifying the patient's emotional state
5. If a patient's verbal and nonverbal communications are inconsistent, which form of communication is most likely to convey the true feelings of the patient?
- a. Written notes
 - b. Facial expressions
 - c. Implied inferences
 - d. Spoken words
6. What strategy would be most effective in communicating with a highly anxious adult immediately before surgery?
- a. Providing specific, concise instructions
 - b. Detailing likely causes of their anxiety
 - c. Focusing on postoperative details
 - d. Using instructional multimedia DVDs
7. What action should the nurse take if an alert and oriented patient asks the nurse for personal contact information?
- a. Ask the patient why the personal information is needed.
 - b. Report the interaction to the nursing supervisor immediately.
 - c. State that it would not be appropriate to share that information.
 - d. Change the subject, and hope that the patient does not ask again.

8. What would be the best therapeutic response to a patient who expresses indecision about recommended chemotherapy treatments?
 - a. "Can you tell me why you are undecided?"
 - b. "It's always a good idea to have chemotherapy."
 - c. "What are you thinking about the treatments at this point?"
 - d. "You should follow whatever your health care provider recommends."

9. Which statement is most accurate regarding symbolic expression?
 - a. Skills confidence can be shared most effectively by nurses through wearing distinctive clothing.
 - b. Clothing choices by a hospitalized patient rarely reflects his or her economic resources.
 - c. Make-up use by a patient is unnecessary for any reason during hospitalization.
 - d. Nondramatic make-up use and minimal accessorizing by nurses demonstrates professionalism.

10. Which defense mechanism is being exhibited when a 27-year-old patient insists on having a parent present during routine care?
 - a. Denial
 - b. Regression
 - c. Repression
 - d. Displacement

CHAPTER 4

Critical Thinking in Nursing

LEARNING OUTCOMES

Comprehension of this chapter's content will provide students with the ability to:

- LO 4.1 Identify the relationship among critical thinking, clinical reasoning, and clinical judgment.
- LO 4.2 Summarize how theories of critical thinking apply to professional nursing practice.
- LO 4.3 Describe the intellectual standards of critical thinking.
- LO 4.4 Discuss critical-thinking components and attitudes.
- LO 4.5 Apply principles of critical thinking in nursing practice.
- LO 4.6 Explain errors to avoid in providing safe and competent patient care.
- LO 4.7 Describe methods for improving critical thinking in nursing.

KEY TERMS

accuracy, [p. 57](#)

bias, [p. 60](#)

breadth, [p. 57](#)

validation, p. 58

Case Study

Jason is completing his first year as a nurse and works with a team of nurse practitioners and oncology surgeons in a private practice. He reviews each patient's chart at least 1 week before admission for surgery and develops a preliminary, individualized preoperative plan of care that best supports a positive patient outcome. The next chart Jason reads is that of Fran Larchmere (F.L.), who is a 24-year-old, intellectually disabled woman from a local group home. She has been referred to the oncology practice for ovarian cancer surgery. A note on the chart states that F.L. has a history of a congenital heart defect and seizures. She has limited verbal skills and physically lashes out or withdraws in unfamiliar situations.

Refer back to this case study to answer the critical-thinking questions throughout the chapter.

Survival and success in our complex society depends on critical thinking, which is an essential competency for registered nurses (RNs) (Chaffee, 2012; Paul, 1993). The practice environment of nursing requires higher-order thinking so that the nurse can accurately assess and analyze clinical issues and make clinical judgments and decisions. **Critical thinking** is “the ability to apply higher-order cognitive skills (conceptualization, analysis, evaluation) and the disposition to be deliberate about thinking (being open-minded or intellectually honest) that lead to action that is logical and appropriate” (Papp et al., 2014, p. 716). For the nurse, critical thinking provides a framework for reflection on judgments and actions that result in positive outcomes, increasing the accuracy of clinical decisions.

LO 4.1 Critical Thinking, Clinical Reasoning, and Clinical Judgment

Critical thinking has become a buzzword for all types of thinking, but it must be differentiated from casual or haphazard thinking, such as trial and error. Nurses make life-and-death decisions on the basis of critical thinking influenced by scientific research and best practices. “Critical thinking involves the application of knowledge and experience to identify patient problems and to direct clinical judgments and actions that result in positive patient outcomes” (Benner, Hughes, & Sutphen, 2010, p. 104). **Clinical reasoning** is the ability to focus and filter clinical data to recognize what is most and least important, so the nurse can identify if an actual problem is present (Benner, Hooper-Kyriakidis, & Stannard, 2011). Nurses use clinical reasoning skills when taking into consideration the context and concerns of a patient or family while observing changes in a clinical situation. **Clinical judgment** combines the critical thinking, critical reasoning, and repetitive decision-making skills of a nurse. Sound clinical judgment requires knowledge to assess and observe situations, identify priority patient concerns, and implement evidence-based interventions to provide safe patient care (Woo, 2016). A nurse's critical thinking, clinical reasoning, and clinical judgment skills develop over time with increased knowledge and expertise.

Many definitions for critical thinking can be found in social science, education, and health science literature. In nursing education and practice, the term *critical thinking* is often used synonymously with *problem solving*, *decision making*, *reasoning*, or *judgment*. Definitions of these related terms are given in Table 4.1. Although many of these terms are used interchangeably, for the purposes of this chapter, critical thinking is considered the foundation for the other processes.

TABLE 4.1

Processes That Depend on Critical Thinking

Process	Definition
Problem solving	Systematic, analytic approach to finding a solution to a problem
Decision making	Choosing a solution or answer from among different options; often considered a step in the problem-solving process
Reasoning	Logical thinking that links thoughts, ideas, and facts together in a meaningful way; used in scientific inquiry and problem solving
Judgment	The result or decision related to the processes of thinking and reasoning

In 1990 the [American Philosophical Association](#) published a Delphi report that focused on the conceptualization of critical thinking by a consensus of 46 experts, including theorists, educators, and specialists in critical-thinking assessment, over a 22-month time frame. The report describes “the ideal critical thinker as habitually inquisitive, well-informed, trustful of reason, open-minded, flexible, fair-minded in evaluation, honest in facing personal biases, prudent in making judgments, willing to reconsider, clear about issues, orderly in complex matters, diligent in seeking relevant information, reasonable in the selection of criteria, focused in inquiry, and persistent in seeking results that are as precise as the subjects and the circumstances of inquiry require” (p. 3). Other themes from the Delphi report include honesty, trust, persistence, and precision. In the current health care delivery system, it is imperative that nurses maintain their professional practice and competency through seeking new knowledge, asking questions, making sound decisions, and remaining vigilant and open to changes and new developments.

LO 4.2 Theoretical Underpinnings of Critical Thinking

The seminal works of Paul (1985, 1988, 1993; Paul & Elder, 2001, 2002), A (1991, 2011), Schön (1983), and the later works of Alfaro-LeFevre (2017) have been used to understand critical thinking and its application to nursing practice, education, and research. Critical thinking about any topic is a way to improve the quality of thought processes through analysis, assessment, and reconstruction. The interaction of these concepts is central to the development of critical thinking. Consistent theoretical underpinnings in these works include the following:

- *Reflection*: Thinking that examines actions and beliefs, identifies new perspectives and knowledge, and can result in creative problem solving and enhanced practice. Benner (2001) and others assert that the ability to engage in reflection about and during practice and to make changes in practice based on the reflections is the hallmark of an experienced practitioner. Reflection is an effective tool that enables students and nurses to think about how best to improve their future caregiving in similar situations.
- *Evidence*: Identification and use of evidence are necessary to guide analysis of situations and decision making. Nursing practice must be based on evidence gained through research and review of findings.
- *Standards*: Critical thinking needs to be assessed and evaluated according to standards to ensure the quality of thinking. Nursing practice is based on standards established by the American Nurses Association in areas such as the nursing process,

ethics, education, research, communication, leadership, and collaboration.

- *Attributes or traits:* Some personal characteristics are associated with critical thinking. Fairness, responsibility, and empathy are examples of traits that contribute to a nurse's ability to think critically while providing safe patient care.

The critical-thinking model of [Alfaro-LeFevre \(2017\)](#) has been specifically applied to nursing practice and includes four overlapping and integrated concepts: critical-thinking characteristics, theoretical and experiential knowledge, interpersonal skills, and technical competencies. To develop critical thinking, the nurse needs to develop a critical-thinking character, which includes maintaining high standards and developing critical-thinking qualities such as honesty, fair-mindedness, creativity, patience, persistence, and confidence.

The next step in the development of critical thinking includes taking responsibility for personal learning and seeking needed experiences that can provide the necessary knowledge on which to base the thinking. Fostering interpersonal skills, such as teamwork, conflict management, and advocacy, is important in the development of critical thinking. Self-evaluation and having thinking evaluated by others require the ability to accept and use constructive criticism.

The last step in Alfaro-LeFevre's critical-thinking model is technical competency. Until proficiency is achieved with technical skills, mental energy focused on psychomotor skills competes with other conceptual or knowledge gaps. This is often seen in clinical practice when a new skill or procedure is performed by the nurse. Being overly focused on the task may interfere with the nurse's ability to attend to the patient's questions and anxiety about the procedure.

LO 4.3 Intellectual Standards of Critical Thinking

LO 4.2

According to [Paul and Elder \(2001\)](#), intellectual standards are foundational to thinking critically: “Critical thinkers routinely ask questions that apply intellectual standards to thinking. The ultimate goal is for these questions to become so spontaneous in thinking that they form a natural part of our inner voice, guiding us to better and better reasoning” (p. 84). The following intellectual standards are essential to critical thinking: clarity, accuracy, precision, relevance, depth, breadth, logic, significance, and fairness. [Table 4.2](#) defines these intellectual standards and lists questions that facilitate the application of each standard. As with any skill, critical thinking can be enhanced through practice. The routine use of these questions should promote critical thought.

TABLE 4.2**Intellectual Standards for Critical Thinking**

Definitions	Assessment Questions
<i>Clarity:</i> Being easily understood or precise in thought and style; considered a gateway standard because a statement cannot be evaluated for accuracy or precision if it is ambiguous	• How can you elaborate on that point?
	• How could you express that point differently?
	• What is an illustration?
	• What is an example?
	• This is what I heard you say; am I correct about your meaning?
<i>Accuracy:</i> Representing something in a true and correct way	• Is that true?
	• How can I determine whether this information is correct?
	• How can this information be verified?
<i>Precision:</i> Providing sufficient detail to understand exactly what was meant	What are additional details?
	• Can you be more specific?
<i>Relevance:</i> Focusing on facts and ideas directly related and pertinent to a topic	How is this related to the question?
	• How does that relate to the issue?
	• What is the relationship to other ideas?
<i>Depth:</i> Getting beneath the surface of the topic or problem to identify and manage related complexities	• How does this address the complexities of the issue?
	• How does this take into account the problems associated with the question?
	• What are the most significant factors in the problem?
<i>Breadth:</i> Considering a topic, problem, or issue from every relevant viewpoint	• Are there other points of view for consideration?
	• How would this issue look from a different viewpoint?
	• Is there another way to approach this problem?
<i>Logic:</i> Using a mutually supportive and sensible combination of thoughts and facts to form a conclusion	• Does this fit together logically?
	• Does this make sense?
	• How does the evidence lead to this solution or answer?

Definitions	Assessment Questions
	<ul style="list-style-type: none"> • How do the conclusions support the evidence?
<p><i>Significance:</i> Concentrating on the most important information (e.g., concepts, facts) when considering an issue</p>	<ul style="list-style-type: none"> • What is the most significant information needed to address the issue? • How is that fact important in this context? • Which question or concept is most important to the issue?
<p><i>Fairness:</i> Thinking or acting in accord with reason and without bias</p>	<ul style="list-style-type: none"> • How is the conclusion justified in relation to the evidence? • Are the assumptions justified? • Am I considering other points of view?

Modified from Paul R, Elder L. (2001). *Critical thinking: Tools for taking charge of your learning and your life*. Upper Saddle River, NJ: Prentice-Hall.

LO 4.4 Critical-Thinking Components and Attitudes

Critical thinking is not random or casual thinking. It is thinking characterized by accuracy, self-reflection, clarity, and soundness (Paul & Elder, 2001). Effective critical thinking depends on specific components such as a knowledge base, reasoning, inference, validation, and attitudes that promote learning.

Knowledge Review

Because critical thinking is disciplined, this form of thinking is contextual and requires knowledge of the subject that is the focus of the thinking. It is not possible for a person to think critically about something if the person knows nothing about the subject matter.

Baseline Knowledge

In nursing, baseline knowledge includes content learned in prerequisite courses, such as human growth and development, nutrition, genetics, anatomy, physiology, biochemistry, and psychology; nursing-specific courses, such as fundamentals of nursing, pathophysiology, and pharmacology; and specialty information about specific patient populations, such as pediatrics, adult health, maternal-child health, and critical care. These courses provide foundational knowledge that prepares the nurse to deal with practice and clinical issues.

Information Gathering

Data collection is an important concept for professional nursing practice and is integral to assessment, the first step in the nursing process. The focus of data collection often is based on knowledge gaps. The application of critical-thinking skills to information gathering assists the nurse in collecting relevant, precise, and accurate data. Because clinical decisions are often based on such data collection, it is important that the nurse use critical-thinking skills during these assessments.

When a patient is initially interviewed and assessed, the nurse must complete a thorough analysis of the patient's physical, emotional, spiritual, and psychomotor status. Several tools are available to guide the nurse in conducting detailed, complete assessments, including Gordon's Functional Health Patterns. The nurse often works with unlicensed assistive personnel (UAP) to collect relevant data on height

and weight, intake and output, and vital signs. Nurses collaborate with other health care professionals to coordinate care ([Box 4.1](#)).

Interdisciplinary clinical rounds, which include physicians, nurses, physical therapists, occupational therapists, and dietitians, are often undertaken to identify priorities of care, discuss overlapping areas of treatment, and ensure coordination of care.

Box 4.1

Interprofessional Collaboration and Delegation

Critical Thinking and Safe Patient Care

- Optimal patient management requires critical thinking and collaboration with all disciplines involved in the patient's care. Interdisciplinary clinical rounds are an effective approach to management of complex patient problems related to discharge planning, end-of-life decisions, and other ethical issues.
- The registered nurse uses critical thinking to guide decisions related to delegation of assignments and tasks. Before delegation of a task, the nurse must be knowledgeable about the role, scope of practice, and competency of the recipient of the delegated task.
- When developing preoperative plans of care, nurses use critical thinking, collaboration, and communication. Critical thinking helps the nurse identify missing data. Collaboration and communication promote team-oriented decision making that supports positive patient outcomes ([Mulcahy & Pierce, 2011](#)).

Patient safety is compromised when nurses have underdeveloped critical-thinking skills, knowledge, and awareness. All nurses need to develop critical-thinking skills for their own job satisfaction and improved patient outcomes ([Turkel et al., 2016](#)).

Nurses must be equipped with a large knowledge base in addition to data collection and information-gathering skills to help them find answers when faced with new problems, questions, and situations. When the nurse is able to formulate a question when faced with a new problem or situation, possible solutions can be pursued.

Reasoning

Paul and Elder (2006) explain that the terms *thinking* and *reasoning* are often used synonymously, although reasoning is more formal because it usually is aimed at finding answers, providing explanations, and forming conclusions. Wilkinson (2011) states, "Reasoning is logical thinking that links thoughts in meaningful ways. Reasoning is used in scientific inquiry, in examining controversial issues, and in problem solving (i.e., nursing process)" (p. 58). Nurses use clinical reasoning to monitor patients through ongoing assessment and evaluation and to guide decision making. Nurses use inductive reasoning and deductive reasoning in their practice.

Inductive Reasoning

Inductive reasoning uses specific facts or details to make conclusions and generalizations; it proceeds from specific to general. The nurse observes that a patient who recently had an indwelling urinary catheter removed complains of burning on urination and that the urine is cloudy and foul smelling. On the basis of this assessment, the nurse may reason that the patient has a urinary tract infection (UTI), because the findings are consistent with those seen in other patients with documented UTIs; this inductive argument is probably correct. The strength of inductive reasoning is closely related to the number of previous observations and the quality of the reasons (Wilkinson, 2011). However, because the conclusions are based on observations and assumptions, not valid proof, further actions may be required to substantiate the conclusion. In the example of the patient with burning on urination, a urine sample may be ordered for analysis to investigate the possibility of a UTI, a complication that can result from an indwelling urinary catheter.

Deductive Reasoning

Deductive reasoning involves generating facts or details from a major theory, generalization, or premise (i.e., from general to specific). In providing care for a patient with a suspected infection, the nurse observes for signs such as an elevated temperature and sources of infection to validate this deductive argument. These assessment findings may be consistent with an infection. However, as with inductive reasoning, other factors that may cause an elevated temperature need to be addressed to support this reasoning. For example, a patient who is dehydrated also may have an elevated temperature. It is generally accepted that if the premises or facts are true, the conclusions in deductive reasoning are also correct.

Inferences

Paul and Elder (2001) describe inferences as intellectual acts that involve a conclusion being made based on something. The accuracy of an inference is directly related to the accuracy of the basis of the inference. Inferences are frequently based on assumptions, which are beliefs taken for granted and assumed to be true. Assumptions may be used to guide decision making even when they are based on something that was previously learned and not questioned.

It is important that nurses examine their assumptions and inferences about patients and their health care. When assessing an obese patient, the nurse may assume the person eats too much and never exercises. On the basis of this assumption, the nurse may make the inference that the patient does not care about personal health. On further assessment, the nurse finds that the patient has severe hypothyroidism that is contributing greatly to the patient's obesity. This example reinforces the importance of the accuracy of assumptions and illustrates that inferences may be logical or illogical, accurate or inaccurate, or justified or unjustified.

Intuition

Intuition is the feeling that you know something without specific evidence. Wilkinson (2011) describes intuition as a problem-solving approach that relies on an inner sense. Intuition is gaining favor as a valid characteristic of expert clinical judgment acquired through knowledge, practice, and experience. Alfaro-LeFevre (2017) explains that expert nurses use intuition to facilitate problem solving because their hunches (most likely intuition) are based on experiential knowledge. Less experienced nurses rely more on logic and a step-by-step approach when encountering the same issue (Fig. 4.1). In either situation, intuition based on critical thinking requires analysis and evidence to support actions.

FIGURE 4.1 The intuition and knowledge of experienced nurses can help direct the practice of newer colleagues in emergency situations. (© Shutterstock.com.)

Interpretation

Examining how information is organized and given meaning guides the interpretation of the information. Interpretations must be differentiated from facts and evidence because they are based on personal conceptions, experiences, and perspective. Paul and Elder (2006) describe critical thinkers as being able to recognize their interpretations, differentiate the interpretations from the evidence, consider alternative interpretations, and reconsider their interpretations in light of new data.

Interpretation of data is an important aspect of professional nursing practice. Some data are objective (e.g., laboratory values, diagnostic examination results, clinical manifestations), and other data are subjective (e.g., facial expressions, mood, body language). However, in both situations, nurses are expected to interpret data and use it to guide their decisions and actions.

1. The critical-thinking skill of interpretation needs to be employed first to begin developing F.L.'s plan of care. Consider all that Jason knows about the patient and identify a minimum of three

people or resources Jason needs to consult to gather essential patient data. Provide a rationale for each of your answers.

Validation

Along with the specific components of critical thinking—knowledge, reasoning, and inferences—validation of information is required before taking action. [Alfaro-LeFevre \(2017\)](#) defines **validation** as verifying that the information or data collected are “factual, accurate, and complete” (p. 152).

One aspect of validation is to find support for the findings or data. Subjective data are often validated with objective data; for instance, a patient complains of severe itching, and the nurse validates this subjective finding when observing scratch marks and a rash.

Validation is also pertinent to ensuring the competency of nurses in the clinical setting. When an experienced nurse begins employment at a new facility, competency assessments (i.e., validations) are frequently completed as part of the orientation process. For example, although a nurse might have been responsible for inserting intravenous (IV) catheters at a previous place of employment, demonstration of skill competency based on facility-specific expectations and standards is required before the nurse inserts IV catheters in patients at a new workplace.

Attitudes Necessary for Critical Thinking

Critical-thinking attitudes promote learning, reasoning, and discipline. Particularly relevant to nursing, these attitudes foster critical thinking that focuses on clarity, precision, clarification, validation, and recognition of bias. [Table 4.3](#) defines 11 intellectual traits identified by [Paul \(1993\)](#) as essential for competence in critical thinking.

TABLE 4.3**Essential Critical-Thinking Traits**

Intellectual Trait	Definition
Confidence	Feeling certain about one's ability to accomplish a goal
Thinking independently	Considering a wide range of ideas before coming to a conclusion
Fairness	Avoiding bias or prejudice and dealing with a situation in a just manner
Responsibility and accountability	Acting on sound knowledge and acknowledging actions as one's own
Risk taking	Being willing to try new ideas
Discipline	Following orderly thinking to do what is best
Perseverance	Staying determined to work until the goal is achieved
Creativity	Formulating new ideas and alternative approaches
Curiosity	Being motivated to achieve and asking why
Integrity	Being honest and willing to adhere to principles in the face of adversity
Humility	Admitting one's limitations

Modified from Paul R. (1993) *Critical thinking: How to prepare students for a rapidly changing world*. Santa Rosa, CA: Foundation for Critical Thinking.

LO 4.5 The Role of Critical Thinking in Nursing Practice

The rapid rate of change and increasing complexity of health care and information technology make critical thinking essential in nursing. No longer is rote memorization and recall of content sufficient for the complex decisions and judgment required in professional nursing practice. Because knowledge and technology continue to expand for nursing professionals, the content learned in nursing school is not sufficient to maintain competence in nursing practice.

Professional nursing requires a commitment to lifelong learning. Nurses must possess critical-thinking skills to maintain pace with ever-changing treatment modalities and technological advances. Outdated learning strategies that focus on remembering content must be replaced by a focus on understanding the rationales and outcomes. It is an expectation of professional practice that nurses update and maintain their competency and knowledge base. Maintaining competency through professional development and reviewing research is facilitated by having critical-thinking abilities (Box 4.2).

Box 4.2

Evidence-Based Practice and Informatics

Critical Thinking and Technology

- Technology-enhanced learning improves nursing education, helps in the development of critical thinking, and improves patient safety.
- Research indicates that students feel more confident and safer when they are permitted to use referencing software during clinical experiences.
- Using technology allows students to connect related information, perceive its meaning, and guide nursing intervention planning and implementation.
- Handheld technology supports clinical competency and helps students in the development of clinical decision-making skills.

From [Swart R. \(2017\)](#). Critical thinking instruction and technology enhanced learning from the student perspective: A mixed methods research study. *Nurse Education in Practice*, 23, 30–39; [McNally G, Frey R, Crossan M. \(2017\)](#). Nurse manager and student nurse perceptions of the use of personal smartphones or tablets and the adjunct applications, as an educational tool in clinical settings. *Nurse Education in Practice*, 23, 1–7.

Because nursing requires the application of knowledge to make clinical decisions and guide care, it involves active participation by the nurse. The application of knowledge requires development of a questioning attitude. This process is sometimes referred to as *thinking like a nurse*.

Critical Thinking in the Nursing Process

Nurses use critical-thinking skills to guide decision making and solve problems. The scientific method, one approach to problem resolution, is systematic, logical, and based on data collection and hypothesis testing.

The steps include (1) identification of the problem, (2) definition or clarification of the problem, (3) statement of the problem, (4) determination of criteria for evaluation, (5) data collection, (6) generation of solutions, and (7) hypothesis testing ([Wilkinson, 2011](#)). The scientific method is an established system of critical thinking that has been well studied.

Because nursing care is not always a problem, the scientific method is not always applicable to nursing practice. The nursing process, which consistently requires critical thinking, is based on assessment, diagnosis, planning, implementation, and evaluation, and it can be applied without a definitive problem. [Lipe and Beasley \(2004\)](#) apply essential critical-thinking skills to the nursing process in the following manner:

- *Interpretation*: Nurses use this skill to understand and explain the meaning of data. Drawing on knowledge of theory and application, the nurse uses interpretative skills to consider possible causes and implications of observed data, events, and actions. Using knowledge of the action of a medication, the nurse interprets the effects of the medication.
- *Analysis*: Investigating plans of action on the basis of examination of subjective and objective data is an

example of nursing analysis. Considering the advantages, disadvantages, and consequences of all possibilities, the nurse determines appropriate explanations or actions. The nurse analyzes the clinical presentation of a patient in relation to admitting diagnoses and ordered treatments to ensure they have an appropriate rationale.

- *Evaluation*: Information, including the reliability, credibility, and bias of the source, is assessed.

Relevance, one of Paul's intellectual standards, is important in the evaluation of new information.

Nurses also evaluate when determining whether the desired outcome for an intervention was achieved.

- *Inference*: [Alfaro-LeFevre \(2017\)](#) identifies inference as one of the skills of critical thinking and defines making inferences as drawing valid conclusions. Alfaro-LeFevre goes on to define inference as making deductions or forming opinions that follow logically, based on patient cues (subjective and objective data). Nurses gather relevant baseline data and compare them with other information, such as admitting diagnoses, medical history, and knowledge of disease processes, to make inferences.

- *Explanation*: The ability to explain conclusions is an important critical-thinking skill. Paul's intellectual standards of clarity, accuracy, and precision are important in this skill, as well as the ability to provide a sound rationale for thoughts and actions. In the acute care setting, the nurse should have sound rationales regarding which patient to assess first, which findings to report to the

primary care provider, and what actions to delegate to UAP.

- *Self-regulation*: Similar to reflection, self-regulation requires monitoring of thinking, with specific emphasis on reflecting on the rationale for the conclusion drawn and action taken. The nurse ponders, “Did I collect all relevant data? Are my assumptions accurate?” As these statements demonstrate, the focus is on assessing personal thinking, decision making, and actions. With effective self-reflection, the nurse recognizes errors and makes changes to correct them.

- *Clinical decision making*: For nurses, the consistent use of the essential skills of critical thinking guides clinical decision making. Nurses make many decisions throughout a typical day, and data collection and interpretation guided by critical thinking are more likely to result in sound clinical decisions.

LO 4.6 Thinking Errors to Avoid

Critical thinking, reasoning, and decision making can be negatively influenced by errors in thinking. Factors that can influence thinking may be based on past experiences, cultural beliefs, emotions, states of mind, and other interpersonal and intrapersonal causes. Consider the following possible reasons for flawed thinking.

Bias

Decisions may be unduly influenced by **bias**, which is an inclination or tendency to favoritism or partiality. Bias may be related to a preconceived notion or prejudice. For example, a nurse may consistently postpone care of elderly patients on the assumption that their care will take more time than caring for younger patients, without considering the actual acuity of the individual patients. It is important for nurses to examine personal biases because they can negatively affect care.

Safe Practice Alert

It is essential to thoroughly assess and validate the underlying reasons for patient concerns or problems. This can avoid unnecessary bias that may interfere with the nurse's ability to provide appropriate patient-centered care.

Illogical Thinking

Illogical thinking is characterized by a failure to follow rational, systematic processes when approaching an issue or problem. Often making hasty generalizations and assumptions that do not consider the evidence, the illogical thinker may jump to conclusions. Another trait associated with this type of thinking is an appeal to tradition (Lipe & Beasley, 2004): “We have always done it this way.” Alfaro-LeFevre (2017) identifies this appeal to tradition as resistance to change. Too often change is considered “guilty until proved innocent.” Overcoming this barrier does not mean embracing every new change uncritically. It means being willing to suspend judgment long enough to make an informed decision on whether the change is worthwhile.

When illogical thinking is used, creativity in thinking can be limited and new ideas and approaches do not evolve. If nurses do not stay current, illogical thinking can occur, causing care to be compromised.

Lack of Information

People cannot think critically about something without having knowledge about it. Knowledge deficit can cause errors in thinking. Nurses in practice must continue to build their knowledge base to provide safe and appropriate care. This is particularly relevant to the increased numbers of medications that nurses administer and the possible interactions with other medications and foods. The nurse can make a medication error if new or unfamiliar medications are not researched before administering them to patients.

Safe Practice Alert

It is the nurse's responsibility before administering medications to understand the reason that a medication is prescribed, the expected patient response, potential adverse reactions, and drug interactions. References are available on point-of-care, handheld devices and in the health care facility electronic health record. If a new medication is not referenced in either of these places, requesting information from the pharmacist is recommended.

Closed-Mindedness

Errors in thinking and decision making can result from intentionally overlooking alternatives suggested by others. When relevant information from patients or experts is ignored because of closed-mindedness, nursing care can be compromised. Closed-minded individuals often believe their way is the best and preferred way. For example, a nurse may think it is best for all patients to be bathed in the morning and is resistant to the idea of patients bathing in the evening. However, there is a patient who prefers evening baths because he has a colostomy that he cares for in the evening and prefers to bathe after this is completed. The closed-minded nurse may ignore the individual needs and values of the patient.

QSEN Focus!

Open-mindedness is essential to ensure the development of therapeutic nurse–patient relationships and collaborative interdisciplinary practice that promotes patient safety and patient-centered care.

Erroneous Assumptions

Assumptions are beliefs that are taken for granted and assumed to be true. According to [Paul and Elder \(2001\)](#), assumptions can be unjustified or justified, depending on whether there are good reasons for them. Erroneous assumptions can lead to safety issues in the clinical setting. For example, the nurse observes that the breakfast tray of a diabetic patient has been removed from the patient's room and assumes that the patient ate. On the basis of this assumption, the ordered hypoglycemic agent to lower blood glucose levels is administered. However, the food might have been discarded by the patient or removed at the patient's request without having been eaten. In this scenario, the nurse should question the patient about food intake and check the amount of food left on the tray, if possible, before administering the medication.

QSEN Focus!

Asking questions for clarification before implementing patient care is essential to ensuring patient safety and providing patient-centered care. Actively listening to patients enhances a nurse's ability to communicate patient needs, values, and preferences to other members of the interdisciplinary health care team.

2. After consulting several resources and individuals, Jason decides that F.L. can be assigned to a multibed preoperative area before surgery, even though it is often crowded and noisy. What critical-thinking skill should Jason employ regarding this decision? What change to the plan of care would you, as the nurse, recommend and why?

LO 4.7 Methods for Improving Critical-Thinking Skills

Critical thinking is a skill that can be improved with practice. Reflection on one's thinking is an important exercise to facilitate critical-thinking skills. According to [Wilkinson \(2011\)](#), “Critical thinking requires reflection. Reflection means to ponder, contemplate, or deliberate on something. Reflective thinking integrates past experiences into the present and explores potential alternatives ([Box 4.3](#)). In reflection, one considers an array of possibilities and reflects on the merits of each” (p. 40). Along with an attitude of reflection, the following strategies are intended to improve critical thinking.

Box 4.3

Ethical, Legal, and Professional Practice

Caring and Competence

- Reflection and critical thinking are essential for providing competent and caring nursing care.
- Combined competence and caring lead to more positive patient outcomes ([Rhodes, Morris, & Lazenby, 2011](#)).
- Research conducted with nursing students as they progressed through their academic program revealed enhanced perceptions of caring and an understanding of the need for competence. Student perceptions of the importance of caring and competence reflected nursing values, especially altruism, and coincided with the students' beliefs of self-efficacy and goal attainment ([Morris et al., 2012](#)).
- Continuing education, certification, and mandatory Joint Commission annual competency reviews are methods used to enhance critical thinking and ensure the competence of licensed nurses.

Discussion With Colleagues

Whether in an academic setting or in the clinical area, discussion of a problem, issue, or situation with colleagues may improve critical thinking. Through dialogue with others who have expertise or

experience with the issue being faced, knowledge gaps can be filled, erroneous assumptions exposed, and unconscious biases addressed. Nurses can verify their assessments and diagnoses through discussion with colleagues to enhance clarity, precision, and accuracy.

Emotional Intelligence

Emotional intelligence (EI) is described as the ability of individuals to monitor their own and others' feelings and emotions, discriminate among them, and use the information to guide both their thinking and actions. Cognitive abilities are necessary to gain knowledge and skill, but they are not the only determining factor. A review of the literature identifies preparation for professional nursing practice depends not only on the student's cognitive intelligence but also on the control of emotions (Fernandez, Salamonson, Griffiths, et al., 2012). Although the literature relating to qualified nurses in the clinical setting is extensive, there is limited research on the EI of student nurses. In one small study of student nurses in the United States, it was found that there was a statistically significant positive relationship between EI and nursing performance (Beauvais, Brady, O'Shea, et al., 2011).

Audible Verbalization of Thoughts

Nurses may use a type of “think aloud” as an inner dialogue to examine their thinking (Paul & Elder, 2001). In a process closely related to discussion with colleagues, the nurse verbally talks through data, assumptions, and plans for accuracy and relevance. This exercise incorporates elements of reflective thinking, which focuses on examining personal thinking. Nurses who apply previously learned knowledge through verbalization may discover knowledge gaps, identify illogical thinking, or validate their reasoning (Lee, Bae, et al., 2016). The nurse who can recognize and verbalize what is unknown is better equipped to seek what is often a more creative answer or solution.

Literature Review

Because critical thinking cannot occur about subjects that are unknown, a review of literature may foster this type of thinking by addressing knowledge deficits. The process of literature review can be facilitated through the application of the intellectual standards described earlier. The more accurate, clear, and precise the reviewer can be in approaching the literature, the greater is the likelihood that the information discovered addresses the original issue, question, or

problem. Refer to [Chapter 13](#) for additional information on literature review.

Intentional Application of Knowledge

Applying knowledge using a case-based approach promotes and facilitates active learning, improves clinical problem solving ability, and encourages the development of critical thinking skills ([Popil, 2011](#)). Case studies require the use of information to solve real-world problems. Nursing practice is based on the application of knowledge to address patient, family, or community needs or requests. Case studies are useful in complex situations requiring problem solving ([Popil, 2011](#)).

Critical thinking can be improved by intentionally applying new concepts in the clinical setting. For example, when learning about acid-base and electrolyte balance, the student may review patients' laboratory values, analyze the results, and correlate the laboratory results with the patient's symptoms and diagnoses.

Concept Maps

Concept mapping is a teaching-learning strategy that improves the critical thinking skills of students ([Atay & Karabacak, 2012](#)). Concept maps take meaningful knowledge of a subject and present it in a schematic format. They are useful instructional tools for both students and faculty. Constructing concept maps requires reflection, creativity, and insight, all of which are key skills associated with critical thinking ([Harrison & Gibbons, 2013](#)). Concept maps can be used for note taking, mapping nursing care plans, and preparing for examinations. Through visual representations, a student can make correlations between related concepts ([Alfaro-LeFevre, 2017](#)). For example, when a student is studying or reviewing the pathophysiology and management of a patient with a brain tumor, the pathophysiology of the disease process can be the central theme. Main themes related to this disease process include representations of the clinical manifestations, treatment modalities, and nursing care. With a focus on correlating the main themes with the central theme, the pathophysiologic basis of the clinical manifestations is represented along with the rationales for the medical and nursing interventions.

Throughout this textbook, conceptual care maps are used to assist students in organizing assessment data and applying critical-thinking skills to the development of nursing care plans. Conceptual care maps require students to organize, cluster, analyze, and synthesize data while identifying relationships among findings. This learning and organizational tool assists in the development of patient-centered goals,

the recognition of evidence-based research interventions, and the evaluation of patient outcomes. Conceptual care mapping is especially helpful for identifying relationships. Mapping relationships among patient data helps students formulate a picture of how factors contribute to one another ([Alfaro-LeFevre, 2017](#)). The conceptual care map is a visual representation of a student's critical-thinking process and patient care plan ([Fig. 4.2](#)).

FIGURE 4.2 Use of the conceptual care map to organize and analyze information allows students to understand the relationship among patient data

Simulation

Critical thinking is described as the ability of the nurse to think in action and reason as a situation changes over time by capturing and understanding the significance of clinical trajectories (Benner et al., 2010). Because this process develops over time and focuses on interactions in the discipline of nursing practice, it is important that learning environments be as realistic as possible. With the growing use of human patient simulators in nursing curricula, students are provided with realistic situations that foster increased confidence and competence. Research indicates that high-fidelity patient simulation benefits nursing students in terms of knowledge, value, and realism (Weaver, 2011). Simulated experiences enable the student to apply previously learned content in a safe and realistic environment that allows time for questioning, clarifying, and feedback. The opportunity to experience and act in a range of complex clinical situations through simulation enables health care students to rehearse and refine the skills and holistic practices of their discipline. Simulation promotes an understanding of clinical situations requiring specific responses and professional interactions, while fostering the growth of professional identity (Kelly et al., 2016).

Students need to analyze their performance and examine their understanding of simulated learning experiences. Debriefing enhances student learning and increases personal awareness and self-efficacy (International Nursing Association for Clinical Simulation and Learning [INACSL], 2016). If the simulation involves a patient experiencing respiratory distress from an exacerbation of asthma, in the debriefing, the student should be able to correlate the breath sounds with the pathophysiologic changes due to asthma and provide rationales for supplemental oxygen and any other nursing interventions played out in the scenario. Simulation exercises require that students explore their thinking and reflect on the assumptions, inferences, and decisions made — all elements of critical thinking.

Role Playing

Many approaches to role playing can facilitate critical thinking. Role playing may involve assigning some students or facilitators to different roles within a clinical scenario, while others observe. At the conclusion of the role play, everyone participates in the debriefing or discussion of the scenario. As with simulation, this approach allows learners to interact in a safe, controlled environment. Research shows that teaching innovations, including role play, can positively influence students' awareness of the necessity for creativity and critical thinking in nursing care (Chan, 2013).

Written Work

In a review of the literature, [Kennison \(2012\)](#) noted that reflective writing can be an effective strategy for facilitating students' thinking skills. Strategies that focus on improving critical thinking through written work include reviewing and rewriting study or lecture notes, noting key facts while reading, identifying knowledge gaps while reading, and journaling. [Alfaro-LeFevre \(2017\)](#) explains that writing that is clear, organized, relevant, and focused requires the writer to apply critical-thinking principles.

Critical thinking is essential to safe, effective, professional nursing practice. It facilitates the collection of accurate patient data and the planning of patient-centered, evidence-based nursing care. Critical thinking is a skill that can be improved and facilitated through intentional and consistent application. Integrated into the nursing process, critical thinking is the method through which nurses think like a nurse.

3. Jason is unfamiliar with all of the special needs of intellectually disabled individuals. What critical-thinking methods should he undertake to improve his clinical decision-making skills and develop an individualized patient-centered plan of care for F.L.?

Summary of Learning Outcomes

LO 4.1 *Identify the relationship among critical thinking, clinical reasoning, and clinical judgment:* Critical thinking is a required competency of professional nurses and is defined as a deliberate, reflective process that guides decision making and problem solving. Clinical reasoning requires critical thinking, knowledge, and expertise for decision making in clinical situations. Clinical judgment combines the critical thinking, critical reasoning, and repetitive decision-making skills of a nurse.

LO 4.2 *Summarize how theories of critical thinking apply to professional nursing practice:* The interaction of reflection, evidence, standards, and theoretical underpinnings fosters critical thinking. Critical thinking is used by nurses for decision making, clinical judgment, reasoning, problem solving, and organizing and prioritizing care.

LO 4.3 *Describe the intellectual standards of critical thinking:* Thinking critically requires competence in fundamental intellectual standards. These standards include clarity, accuracy, precision, relevance, depth, breadth, logic, significance, and fairness of the thinking process.

LO 4.4 *Discuss critical-thinking components and attitudes:* Effective critical thinking depends on specific components such as having an adequate knowledge base, reasoning, making inferences, and validating. Possessing the attributes of responsibility, accountability, creativity, perseverance, integrity, and humility assists nurses

in the application of critical thinking to nursing practice.

LO 4.5 *Apply principles of critical thinking in nursing practice:* Critical thinking is essential at each step of the nursing process for clinical decision making. It is an expectation of professional practice that nurses update and maintain their competency and knowledge base. Maintaining competency through professional development and research reviews is facilitated by the nurse using critical-thinking skills. Decisions related to delegation, collaboration, and teamwork largely depend on the use of critical-thinking standards.

LO 4.6 *Explain errors to avoid in providing safe and competent patient care:* Patient safety is potentially threatened by errors in critical thinking that include bias, lack of knowledge, illogical thinking, closed-mindedness, and erroneous assumptions.

LO 4.7 *Describe methods for improving critical thinking in nursing:* Nurses can improve clinical decision making through discussions with colleagues, think aloud activities, literature review, intentional application of knowledge, concept mapping, simulation exercises, role playing, and written work.

Review Questions

1. The nurse receives change-of-shift report on the five assigned patients and reviews prescriptions, treatments, and medications scheduled for the shift. Based on analysis of this information, the nurse chooses which patient to assess first. Which process of critical thinking best describes the nurse's action?
 - a. Problem solving
 - b. Decision making
 - c. Inference
 - d. Reasoning
2. In approaching a new clinical situation, the nurse uses which question to facilitate precision in critical thinking?
 - a. "What do I know about this situation?"
 - b. "What additional details do I need to gather?"
 - c. "Does the clinical presentation correlate with the diagnosis?"
 - d. "Are the treatments appropriate for the diagnosis?"
3. Which question would be most appropriate for the nurse to ask while evaluating the relevance of patient data?
 - a. Do these findings make sense?
 - b. How can this information be verified?
 - c. What are the most significant factors in the problem?
 - d. What is the relationship of this information to other data?

4. The nurse is assigned to develop a plan of care for a patient with a medical diagnosis that is unknown to the nurse. Guided by critical thinking, which action should the nurse take first?
 - a. Ask the patient to describe the chief complaint
 - b. Request that another nurse be assigned to this patient
 - c. Review information about the medical diagnosis and routine management
 - d. Complete a physical assessment of the patient
5. The nurse obtains a lower-than-normal (88% on room air) pulse oximetry reading on a patient. Which actions by the nurse result from accurately employing the critical-thinking skill of analysis in the nursing process? (*Select all that apply.*)
 - a. Assessing the patient for symptoms of hypoxia
 - b. Providing oxygen according to standing orders
 - c. Elevating the head of the bed, if not contraindicated
 - d. Allowing the patient to be alone to rest more comfortably
 - e. Discussing adaptations needed for daily activities with the patient
6. Which of the following actions reflects inductive reasoning?
 - a. Using subjective and objective data to confirm a diagnosis
 - b. Assessing for specific clinical presentations based on a disease process
 - c. Correlating elevated blood pressure to pathophysiology

- d. Validating an automatic blood pressure cuff reading with a manual measurement
7. The nurse is completing an assessment on a patient with sudden onset of abdominal pain. During the assessment, the nurse considers similar presentations and the underlying pathophysiology related to the patient's clinical manifestations. Which critical-thinking skill should the nurse use first to determine the cause of the patient's abdominal pain?
- a. Evaluation
 - b. Interpretation
 - c. Reflection
 - d. Inference
8. The nurse can facilitate critical thinking through the use of which interpersonal skills? (*Select all that apply.*)
- a. Teamwork
 - b. Intuition
 - c. Judgment
 - d. Conflict management
 - e. Advocacy
 - f. Reasoning
9. In providing care to a patient admitted to rule out human immunodeficiency virus (HIV) infection, wearing gloves during which activity may be an indication of bias?
- a. Collecting the patient's medical history
 - b. Initiating intravenous access
 - c. Performing oral care

- d. Completing a bed bath
10. During the assessment of a patient admitted for a total hip replacement, the nurse asks the patient to explain prior hospital experiences and, more specifically, any operative experiences. These questions reflect the nurse's use of which intellectual standard of critical thinking?
- a. Clarity
 - b. Logic
 - c. Precision
 - d. Significance

UNIT II

Nursing Process

OUTLINE

Chapter 5 Introduction to the Nursing Process

Chapter 6 Assessment

Chapter 7 Nursing Diagnosis

Chapter 8 Planning

Chapter 9 Implementation and Evaluation

CHAPTER 5

Introduction to the Nursing Process

LEARNING OUTCOMES

Comprehension of this chapter's content will provide students with the ability to:

- LO 5.1 Define the nursing process.
- LO 5.2 Describe the historical development and significance of the nursing process.
- LO 5.3 Articulate the characteristics of the nursing process.
- LO 5.4 Describe the steps in the nursing process.
- LO 5.5 Explain the significance of the cyclic and dynamic nature of the nursing process.

KEY TERMS

assessment, [p. 71](#)

Clinical Care Classification (CCC), [p. 73](#)

evaluation, [p. 75](#)

implementation, [p. 74](#)

International Classification for Nursing Practice (ICNP), [p. 73](#)

nursing diagnosis, [p. 73](#)

nursing process, [p. 68](#)

outcome identification, [p. 74](#)

planning, [p. 73](#)

Case Study

Emilia Perez (E. P.), a 48-year-old woman, is admitted to the nursing unit 2 hours after undergoing a right mastectomy (i.e., surgical removal of the breast). The floor nurse receives a report from the postanesthesia care unit (PACU) nurse that includes the patient's admitting diagnosis of breast cancer, latest vital signs, focused assessment, medication and intravenous (IV) orders, pain level and the time she was last medicated for pain, and the status of her surgical dressing. Initially, E. P. appears to be comfortable, dozing occasionally between short conversations with her husband, who is at her side. When E. P. fully awakens 3 hours after arriving on the nursing unit, she complains of sharp, constant pain on the right side of her chest. She rates her pain at 8 of 10 on the pain scale. She is grimacing and appears tense.

Refer back to this case study to answer the critical-thinking questions throughout the chapter.

Contemporary nursing practice is based on the **nursing process**, which is the systematic method of critical thinking used by professional nurses to develop individualized plans of care and provide care for patients. Similar to the scientific process, the nursing process is organized and methodical, with five primary steps: assessment, diagnosis, planning, implementation, and evaluation. Effective use of the nursing process depends on a nurse's knowledge, familiarity with standardized nursing diagnosis terminology, evidence-based practice (EBP), and ability to evaluate patient responses to interventions.

LO 5.1 Definition of the Nursing Process

The nursing process is the foundation of professional nursing practice. It is the framework within which nurses provide care to patients in an organized and effective manner. [Paul \(1988\)](#) describes critical thinking as a complex process during which individuals think about their thinking to provide clarity and increase precision and relevance in a specific situation while attempting to be fair and consistent. Critical thinking using the nursing process allows nurses to collect essential patient data, articulate the specific needs of individual patients, and effectively communicate those needs, realistic goals, and customized interventions with members of the health care team. [Chapter 4](#) provides additional information on its importance in nursing.

Thinking like a nurse is facilitated by nurses using the nursing process in the development of individualized patient plans of care. The Joint Commission requires a written plan of care that summarizes the treatment for every patient. Care plans can be handwritten or be part of the electronic medical record (EMR). Some standardized care plans may be available to nurses as basic templates for individual care plan development; however, all patients are required to have unique, patient-centered plans of care designed to meet their specific needs. Nursing care plans often incorporate aspects of multidisciplinary clinical pathways. Following the steps of the nursing process helps nurses to provide patient care that meets standards required by state boards of nursing and guided by the [American Nurses Association's \(ANA's\) *Nursing: Scope and Standards of Practice* \(2015\)](#).

LO 5.2 Historical Development and Significance of the Nursing Process

The term *nursing process* was first used by Lydia Hall in 1955 (de la Cuesta, 1983). In the late 1950s and early 1960s, other nurses (Johnson, 1959; Orlando, 1961; Wiedenbach, 1963) began using the term to define the steps used for decision making while initiating and providing patient care. In 1973, the ANA identified five specific steps of the nursing process in its *Standards of Clinical Practice* (1991). These five steps—assessment, diagnosis, planning, implementation, and evaluation—define how professional nursing practice is conducted. Outcome identification was added as an essential aspect of the nursing process by the ANA in 1991. Most nursing professionals and educators recognize outcome identification as part of the planning step within the traditional five-step nursing process.

Professional nursing practice in all types of settings is based on the nursing process. It is used to assess individuals, families, and communities; diagnose needs; plan attainable goals; identify outcome criteria; implement specific interventions; and evaluate degrees of goal attainment. Critical thinking, using the various steps of the nursing process, facilitates the development of safe, individualized, patient-centered care. It takes into consideration a patient's personal preferences, cultural traditions, values, and lifestyle. Professional nurses address the responses of people, families, and communities to health-related problems and promote healthy lifestyles through application of the nursing process.

LO 5.3 Characteristics of the Nursing Process

The nursing process has several essential characteristics that must be recognized and understood by nurses to be effectively applied to the practice of nursing. The nursing process requires that nurses think critically. It is dynamic, organized, and collaborative, and it is universally adaptable to various types of health care settings.

Analytical

The nursing process requires nurses to think analytically using many aspects of critical thinking. Nurses must be able to assess patients accurately and then organize and analyze their findings to provide safe care. At each step of the process nurses must address concerns:

- Is the data collection thorough and accurate?
- Are outcomes specific and realistic for the individual patient or group?
- Have all the underlying factors contributing to the patient's response to illness or group concerns been adequately addressed in the plan of care?
- Could any of the nursing interventions have a negative impact on the patient or group?
- Does each intervention provide for patient-centered care and the safety of the patient?
- Are there new data that necessitate modification of the existing plan of care?

The nursing process is dynamic and has overlapping steps (Fig. 5.1). At any given time, nurses are required to think simultaneously about several steps of the nursing process to make sure all critical data are considered and to provide evidence-based, patient-specific care.

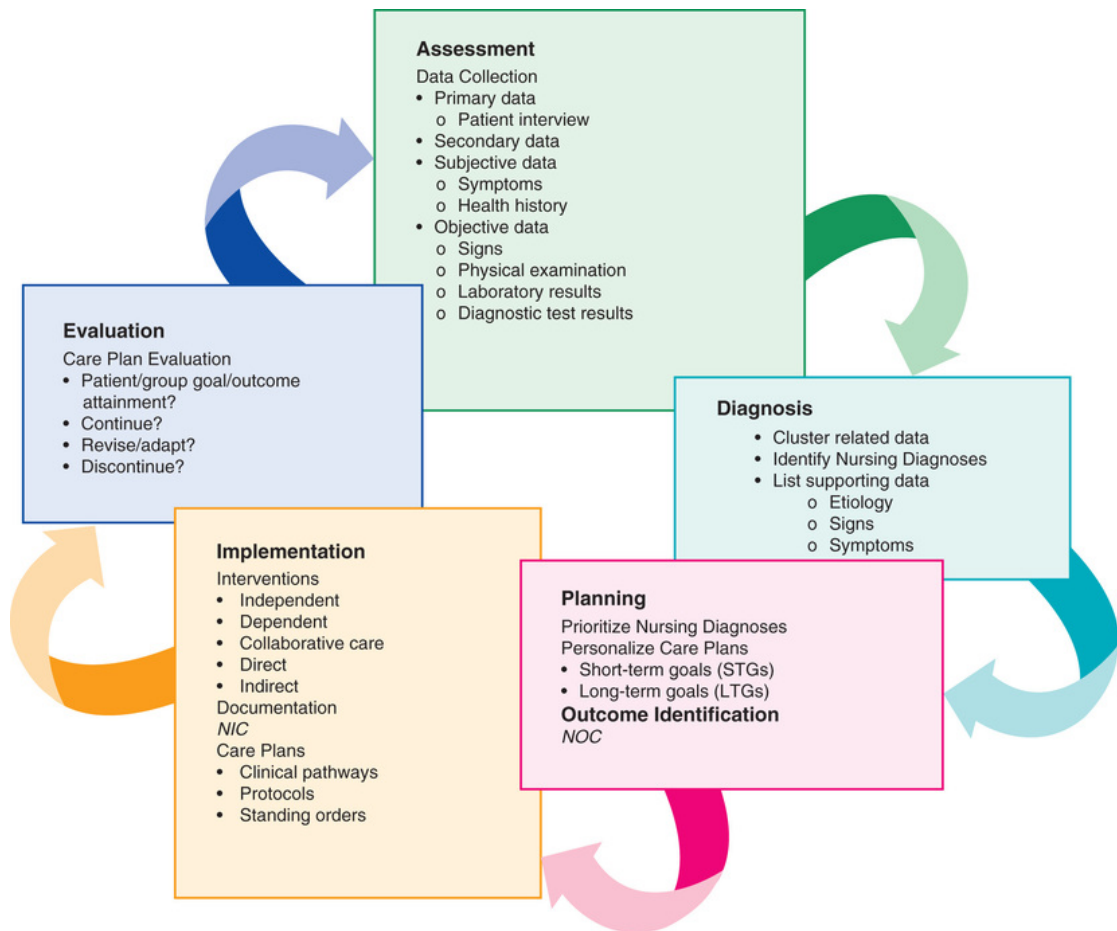

FIGURE 5.1 The dynamic nursing process includes five steps, with outcome identification as a subcategory of planning. *NIC*, Nursing Interventions Classification; *NOC*, Nursing Outcomes Classification.

The nursing process is cyclic rather than linear. As an individual patient's condition changes, so does the way a professional nurse thinks about that patient's needs, forcing modification of earlier plans of care. At each step of the nursing process, nurses must consider the accuracy and effectiveness of their thought process. This form of reflective thought is an essential aspect of critical thinking. The evolutionary nature of the nursing process allows nurses to adjust to changing patient needs. Plans of care must evolve as patients' needs change.

Dynamic

The nursing process is dynamic, changing over time in response to patients' needs. The dynamic, responsive nature of the nursing process allows it to be used effectively with patients in any setting and at every level of care, from the intensive care unit to outpatient wellness clinics and with groups of any size or configuration. Keeping the five steps of the nursing process in mind, a nurse conducts ongoing assessment as a

patient's condition changes and modifies the plan of care on the basis of those findings.

Table 5.1 briefly describes the dynamic nature of the nursing process in caring for a patient recovering from surgery. Notice that the nursing diagnosis is *Acute Pain* (ICNP) in both situations; however, the plan of care is individualized for the patient on the basis of assessment findings, changing needs, setting, and timing of interaction. The dynamic nature of the nursing process makes this possible.

TABLE 5.1**Abbreviated Nursing Process for a Surgical Patient**

2 HOURS AFTER SURGERY	3 DAYS AFTER SURGERY
Assessment	
Patient reports pain level of 8 of 10. Patient grimacing and clutching abdomen. Apical pulse: 104 beats/min and regular	Patient reports pain level of 5 of 10 during AM care. Patient states, "I don't have too much pain now except when I move around." Apical pulse: 68 beats/min and regular
ICNP Nursing Diagnosis With Supporting Data	
<i>Acute Pain</i>	<i>Acute Pain</i>
Tissue trauma Reports pain level of 8 of 10	Postoperative tissue inflammation Increased pain with movement
Planning	
Short-term goal: Patient verbalizes a pain level of 4 or 5 of 10 within $\frac{1}{2}$ hour of receiving prescribed pain medication. Outcome identification: Verbal affirmation of 4 or 5 pain level Relaxed arms at sides and decreased guarding of abdomen Apical pulse rate between 60 and 100 beats/min NOC example: Pain Level Reported Pain	Short-term goal: Patient reports a pain level of 2 or 3 of 10 during AM care within 24 hours. Outcome identification: Verbal affirmation of 2 or 3 pain level Patient acknowledges tolerable level of discomfort with movement. Apical pulse remains between 60 and 100 beats/min NOC example: Pain Level Reported Pain
Implementation	
Medicate patient with morphine sulfate (4 mg IVP q 2 hr PRN) for severe pain. Position patient for comfort. Encourage use of a pillow for splinting areas of pain. Initiate relaxation techniques as appropriate. NIC example: Pain Management Provide the person optimal pain relief with prescribed analgesics.	Medicate patient with acetaminophen (650 mg PO q 4-6 hr) for moderate pain. Encourage patient to request pain medication before physical activity. Monitor patient's pain level before and after AM care. NIC example: Pain Management Evaluate the effectiveness of the pain control measures used through ongoing assessment of the pain experience.
Evaluation	
Goal met. Patient fell asleep on left side within 20 minutes of receiving morphine. Arms relaxed at sides. Continue plan of care during immediate postoperative period.	Goal not met. Patient continues to report a pain level of 5 or 6 with AM care. Discuss alternative pain relief medication and strategies with patient and primary care provider. Revise plan of care.

Organized

Following the steps of the nursing process ensures that care is well organized and thorough. The nursing process provides a standardized method of addressing patient needs that is understood by nurses worldwide. Due to its systematic nature, nurses use the nursing process as a framework for the development of individualized plans of care.

Outcome Oriented

The nursing process is designed to achieve specific, well-defined outcomes. Care plans are developed to meet each patient's goals, not the goals of standardized patients or members of the health care team, including the nurse. Decisions regarding which nursing interventions and medical treatments to implement are made based on safety and their effectiveness in meeting a patient's identified needs and desired outcomes. By referring to an individualized care plan developed within the nursing process context, nurses and other health care team members can treat a patient or group consistently and identify care that is effective while modifying efforts that are not helping meet established goals and achieve desired outcomes.

Care plans developed using the nursing process as a standardized framework hold nurses and other health care team members accountable for their actions. If the nurse's priority goals and the patient's goals are being met, the plan of care is effective. If not, the nurse needs to use critical-thinking skills, knowledge, and the nursing process to modify the plan to better address identified concerns.

QSEN Focus!

Nurses must ascertain the expectations of patients and their families to develop patient-centered plans of care. Acknowledging patient preferences empowers patients and their families to actively participate in the health care process.

Collaborative

Collaboration among several members of the health care team is often required to adequately address patient needs. In many cases, nurses incorporate orders from a primary care provider, nursing interventions, and input from others (such as physical therapists, social workers, or respiratory therapists) into a patient's plan of care to help alleviate patient problems and achieve established patient-centered goals and outcomes. For example, if a patient is experiencing shortness of breath,

the nurse may place a nasal cannula for oxygen administration according to the physician's order, elevate the head of the patient's bed to reduce respiratory effort, and call the respiratory therapist to administer a breathing treatment to expand the patient's airways. Each of these interventions is part of the implementation step of the nursing process. In other cases, the nurse may incorporate actions by the patient or patient's family to address patient goals. This is especially true when the patient is not acutely ill or requires home care.

1. Identify two types of health care team members with whom the nurse would expect to collaborate while caring for E. P.

Adaptable

The nursing process is adaptable for developing plans of care for individuals who are hospitalized or are receiving care in an outpatient, long-term care, or home setting. It is an equally useful method for addressing the needs of a specific group or population.

Consider the problem of childhood obesity in a specific community. By using the nursing process, assessment data can be gathered regarding who is affected and what the underlying causes are. Analyzing these data allows nurse researchers to identify the problems and establish short- and long-term goals for improvement. After establishment of goals for alleviating childhood obesity in a community, area professionals from a variety of disciplines may collaborate on the implementation of programs designed to address the individualized needs of that specific population. After implementation of programs, evaluation is conducted to determine whether the goals were achieved.

The nursing process is adaptable in the community setting (Fig. 5.2). At each step, revisions of the plan may need to take place. Care plan changes can depend on a variety of concerns, including cost and availability of professionals to implement interventions. However, the universal nature of the nursing process enables this adaptability. Engaging the help of others in collaboration about how best to achieve patient or community goals can dramatically improve outcomes in all settings.

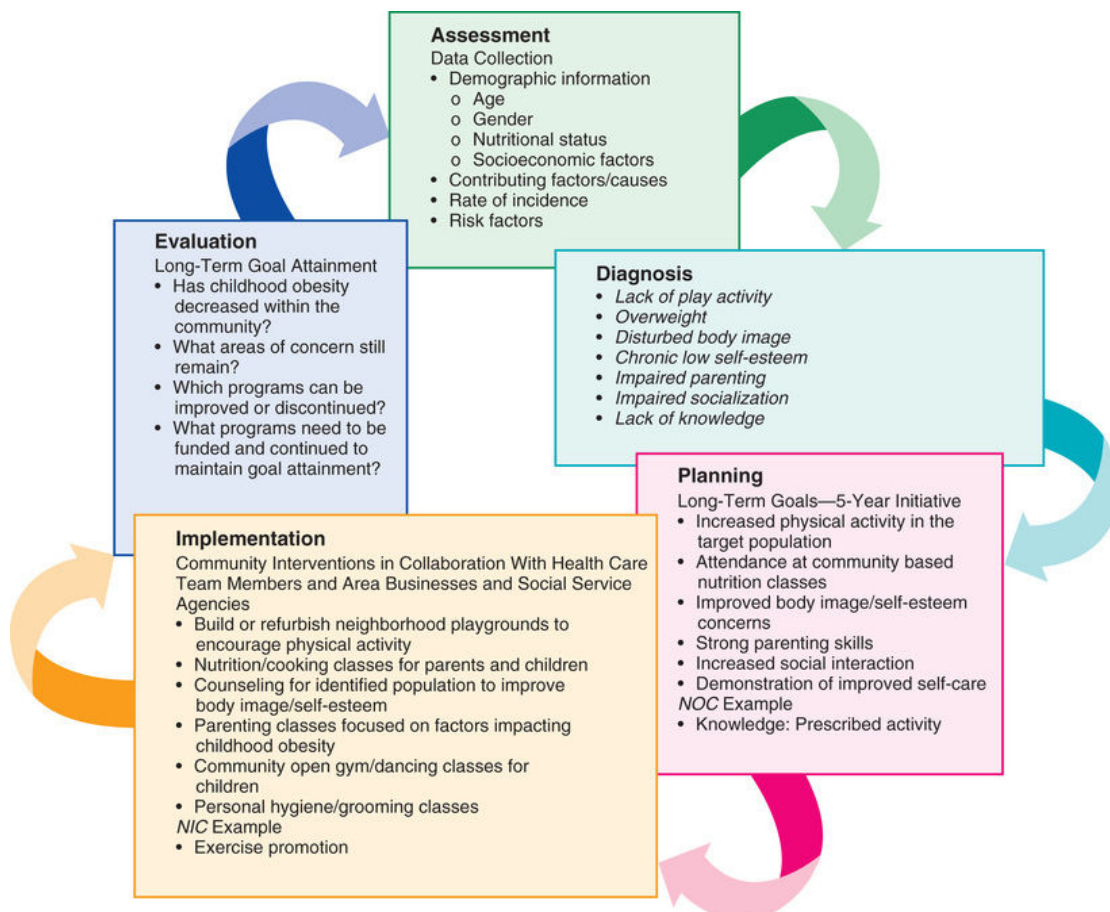

FIGURE 5.2 The nursing process can be adapted to the community setting to address childhood obesity. *NIC*, Nursing Interventions Classification; *NOC*, Nursing Outcomes Classification.

LO 5.4 Steps of the Nursing Process

Each step of the nursing process—assessment, diagnosis, planning, implementation, and evaluation (ADPIE)—has a unique purpose.

1. During the assessment step, data are gathered through observation, interviews, and physical assessment.
2. In the diagnosis step, data are analyzed, validated, and clustered with related assessment findings to identify problems. Each problem is then stated in standardized language as a specific nursing diagnosis to provide greater clarity and universal understanding by all care providers.
3. During the planning step of the nursing process, the nurse prioritizes the nursing diagnoses and identifies short- and long-term goals that are realistic, measurable, and patient or group focused, with specific outcome identification for evaluation purposes.
4. The implementation step includes initiating specific nursing interventions and treatments designed to help achieve established goals or outcomes.
5. In the evaluation step, the nurse determines whether the goals are met, examines the effectiveness of interventions, and decides whether the plan of care should be discontinued, continued, or revised.

Although each step of the nursing process has a clearly identified purpose, all of the steps are interdependent. Each requires information from the others for adequate development and revisions of an effective plan of care. The steps overlap and require thoughtful consideration by the nurse at each transition for the maintenance of accuracy and effectiveness.

Assessment

Assessment is the organized and ongoing appraisal of a patient's well-being (Fig. 5.3). Assessment involves collecting data from a variety of sources that is needed to care for patients. Data collection begins at the first direct or indirect encounter with a patient. Specific data are collected during the patient interview, health history, and physical assessment. Nurses assess the state of a patient's physical, psychological, emotional, environmental, cultural, and spiritual health

to gain a better understanding of his or her overall condition. This is known as a *holistic approach* to patient care.

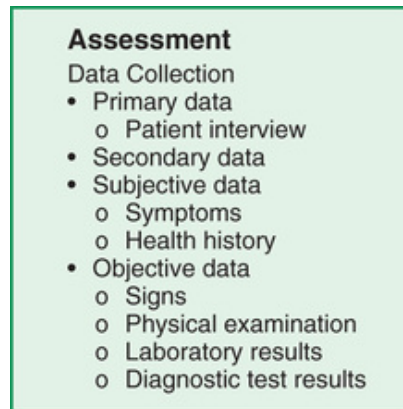

FIGURE 5.3 Assessment in the nursing process.

Assessment data can be collected from a variety of sources, including patients, family members, friends, communities, health care professionals, medical records, and laboratory and diagnostic test results. Data may be categorized as primary or secondary and as subjective or objective, depending on the source and form of the information. Primary data consist of information obtained directly from a patient. Secondary data are collected from family members, friends, other health care professionals, or written sources such as medical records and test results. Some nurses may subdivide secondary data to identify information as indirect if it is obtained from medical charts or a hand-off communication.

Subjective data (i.e., symptoms) are spoken. Patients' feelings about a situation or comments about how they are feeling are examples of subjective data. Data shared by a source verbally are considered subjective. Subjective data may be difficult to validate because they cannot be independently and objectively measured. Subjective data are most often gathered during a patient interview or health history. Use of an interpreter may be necessary when the patient or family members speak a language unfamiliar to the nurse. Subjective data are typically documented in the patient's medical record as direct quotations; for example, "I didn't get much sleep last night" or "I've had diabetes since I was 10 years old."

Data collected from medical records, laboratory, and diagnostic test results, or physical assessments are objective. Objective data (i.e., signs) consist of observable information that the nurse gathers based on what can be seen, measured, or tested. Most objective data are collected by the nurse during physical assessment, which includes inspection, palpation, percussion, and auscultation, or during direct patient care.

Collecting an extensive health history and completing a thorough head-to-toe physical assessment are typically required when a patient is admitted to a hospital or seeking health care from a primary care provider for the first time. This information provides a baseline for future reference. Shorter, focused assessments are conducted by the nurse routinely throughout hospitalization or during repeated clinic visits to assess a patient's change of status. Collecting accurate information and documenting the findings in the patient's medical record are imperative for later comparison. The documentation process helps the nurse organize patient information so that it can be analyzed, validated, and clustered before the identification of accurate nursing diagnoses (see [Chapters 6 and 10](#)). For additional information on the assessment of a community, refer to [Chapter 23](#).

2. List five additional pieces of data that the nurse who admits E. P. to the nursing unit would want to know before initiating care. Next to each item, identify whether it is subjective or objective. Write examples of the five data that would be appropriate for a postoperative mastectomy patient.

3. Write four questions that the nurse could ask to obtain primary data on E. P. From what sources could the nurse obtain secondary data?

Diagnosis

The second step of the nursing process is the nursing diagnosis ([Fig. 5.4](#)). The **nursing diagnosis** is a description of what a nurse observes or discovers while assessing a patient or group, for example, *Sleep*

Deprivation, Risk for Infection, or Health-Seeking Behavior. All three of these nursing diagnoses are from the ICNP. Groups may include, without being limited to, families or entire communities. A nursing diagnosis identifies a problem, potential problem, or opportunity for improvement. According to the ANA, “nursing diagnosis is the nurse's clinical judgment about a client's response to actual or potential health conditions or needs” (ANA, 2017). Accurate identification of nursing diagnoses for patients or groups results from carefully analyzing, validating, and clustering related subjective (symptoms) and objective (signs) data. If data collection includes inaccurate or inadequate information or if data are not validated or clustered with related information, a patient may be misdiagnosed.

FIGURE 5.4 Diagnosis in the nursing process.

Several organizations, including the International Council of Nurses (ICN), **NANDA International, Inc. (NANDA-I)**, and Sabacare, Inc., provide standardized languages or taxonomies to identify specific problems or vulnerabilities and plan customized care. Both NANDA-I and the ICN update their taxonomies every 2 to 3 years based on research findings. The **ICNP** taxonomy developed in collaboration with the ICN is available in over 20 languages online at <https://www.icn.ch/icnp-browser>. The complete NANDA-I taxonomy, including new nursing diagnoses, is published in *Nursing Diagnoses: Definitions and Classification*. Medical diagnoses are labels for diseases whereas nursing diagnoses consider a patient's response to medical diagnoses and life situations in addition to making clinical judgments based on a patient's actual medical diagnoses and conditions.

The nursing taxonomy and structure of writing nursing diagnosis statements developed by NANDA-I is frequently taught in United States colleges and universities. However, with the integration of EMRs into health care, identification of nursing diagnoses for patients and the documentation of supporting patient data is streamlined using checklists and dropdown options. The NANDA-I taxonomy is not integrated into EMRs, although some nursing diagnoses are identical among several standardized languages, such as *Acute Pain, Activity*

Intolerance, and *Risk for Infection*. EMRs do contain nursing diagnosis taxonomies from several other organizations including the International Classification for Nursing Practice (ICNP) and the **Clinical Care Classification (CCC)** System. **Chapter 7** provides extensive information on how to identify and formulate personalized nursing diagnoses for specific patients. It explains how to write NANDA-I style nursing diagnosis statements and how to discern and document nursing diagnoses with supporting data specific to a patient within an EMR.

Using well-defined nursing diagnoses, such as *Activity Intolerance* or *Risk for Spiritual Distress*, all nurses can clearly understand a patient's problems. It is the nurse's responsibility to accurately identify and use nursing diagnoses for every patient to develop patient-centered goals and realistic outcome criteria in individualized plans of care. Patients may have multiple problems, requiring a variety of nursing diagnoses. Regardless of how many nursing diagnoses a patient has, each must be considered in the planning process.

QSEN Focus!

It is essential that nurses work with various members of the interdisciplinary health care team to plan holistic patient care. Respecting the unique skills and contributions of others on the health care team facilitates better communication and achievement of patient health goals.

Planning

Planning is the third step of the nursing process (**Fig. 5.5**). During **planning**, the nurse prioritizes identified patient or group nursing diagnoses, establishes short- and long-term goals, chooses outcome indicators, and identifies interventions to address specific goals. Deciding the order in which nursing diagnoses are addressed depends on several factors, including the severity of symptoms and the patient's preference. A patient's ability to breathe is of greater concern than the need to complete activities of daily living independently. After emergent needs are dealt with, less critical problems take priority. This aspect of the nursing process is another indication of its dynamic nature and interrelatedness.

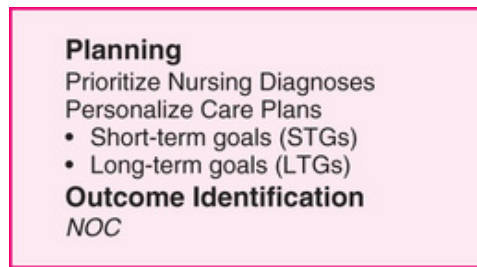

FIGURE 5.5 Planning in the nursing process. NOC, Nursing Outcomes Classification.

Establishing short- and long-term goals to address nursing diagnoses involves discussion with the patient and often requires collaboration with family members and other members of the health care team (Box 5.1). Coordinated, team-based patient care is called *collaborative care*. The patient's health care team members may include several nurses: the primary care provider; medical or surgical specialists; respiratory therapists; a dietician; a physical therapist; occupational, music, or art therapists; a spiritual adviser; and social workers. The patient's primary nurse is often the central figure in coordinating collaborative care.

Box 5.1

Interprofessional Collaboration and Delegation

Team-Based Patient Care

- Collaboration and delegation of care are integral to the implementation step of the nursing process. Nurses do not have the time or expertise to address all of the needs of patients.
- Effective collaboration with and delegation to various members of the health care team require the nurse to become familiar with the scope of practice and abilities of each member.
- After the nurse has established the scope of practice and abilities of the health care team members, their unique skills and abilities can be coordinated to benefit patient care and achieve positive patient outcomes.
- Planning comprehensive care that addresses the multiple needs of patients often facilitates shorter recovery or rehabilitation periods, leading to reduced length of hospitalization and greater patient satisfaction.

Short- and long-term goals are designed to meet the patient's immediate needs and future needs, which may extend over weeks or months. Some sources establish time parameters for short-term or long-term goals, but others do not. According to [Carpenito \(2016\)](#), goals that are achievable within an immediate time frame of less than approximately 1 week are short-term goals, whereas goals that will take more time to achieve—weeks to months—are long-term goals. All short- and long-term goals must be (1) patient or group focused, (2) realistic, and (3) measurable. For example, a patient-focused, realistic, and measurable short-term goal may be written for a patient with the nursing diagnosis of *Activity Intolerance*: The patient walks to the bathroom without experiencing shortness of breath within 48 hours after surgery.

Goal setting creates a structure, or framework, within which nursing care takes place. Goals help direct the patient's health care team and ensure that all members of the team work to achieve the same outcomes. Whenever possible, it is important to include patients in identifying their short- and long-term goals.

Outcome identification, added by the [ANA in 1991](#) as a specific aspect of the nursing process, involves listing behaviors or observable items that indicate attainment of a goal. The Nursing Outcomes Classification (NOC) is one resource for outcome identification. Outcome classification for a patient with the nursing diagnosis of *Activity Intolerance* could be Endurance with an outcome indicator of uncompromised to severely compromised activity ([Moorhead, Swanson, Johnson, & Maas, 2018](#)). Nursing interventions, including collaborative care interventions, are identified by the nurse during the planning stage to help patients or groups meet goals, outcome classifications, and outcome indicators (i.e., criteria that can be observed or measured).

One method of determining interventions to meet outcome goals is use of Nursing Interventions Classification (NIC). NIC provides nurses with multidisciplinary interventions linked to specific nursing diagnoses and the NOC. For a patient with the nursing diagnosis of *Activity Intolerance*, the desired outcome of Endurance, and a goal of being able to walk to the bathroom without experiencing shortness of breath within 48 hours after surgery, the nurse may select interventions from NIC related to Exercise Therapy: Ambulation ([Butcher, Bulechek, Dochterman, & Wagner, 2018](#)). Using NIC as a reference, the nurse remains responsible for customizing and implementing appropriate interventions for each specific patient.

Developing a patient- or group-centered plan to address identified short- and long-term goals requires that a nurse use critical thinking,

creativity, expertise, and communication skills. The plan of care needs to be relevant to the patient's or group's health status and goals, and the plan must be based on the latest evidence-based nursing practices. By identifying specific desired-outcome indicators for improvement, the nurse can more easily implement research-based nursing interventions to address the unique needs in every situation. [Chapter 8](#) provides additional information on goal setting and outcome identification resources.

4. Write a patient-focused, measurable, and realistic short-term goal for E. P., whose priority nursing diagnosis is *Acute Pain*.

Implementation

The **implementation** step of the nursing process focuses on initiation of appropriate interventions designed to meet the unique needs of each patient or group ([Fig. 5.6](#)). Interventions may be independent, dependent, or collaborative nursing actions requiring direct or indirect nursing care. All should be derived from EBP standards that have evolved from research conducted to elicit the best outcomes possible.

FIGURE 5.6 Implementation in the nursing process. *NIC*, Nursing Interventions Classification.

QSEN Focus!

Nurses should read original research articles and systematic reviews of literature related to their specialties to stay current and implement new evidence into practice.

Clinical Pathways, Protocols, and Standing Orders

Clinical pathways, protocols, and standing orders often impact interventions carried out in the implementation phase of the nursing process. Clinical pathways, sometimes referred to as care pathways, care maps, or critical pathways, are multidisciplinary resources designed to guide patient care. Clinical pathways emerged in the 1980s in an effort to provide better-quality, standardized care for patients, and they were developed through EBP research (Gebreiter, 2017). Nurses contribute to the formation of clinical pathways by using the nursing process to identify unique nursing interventions that assist patients in achieving desired outcomes. A clinical pathway for the care of a postmastectomy breast cancer patient is shown in Fig. 5.7. Independent, dependent, direct, and indirect interventions are listed in the critical pathway.

Actual or Potential Problem	Activity/Treatments	Postoperative Day 1 Outcome Date	Initials	Postoperative Day 2 Outcome Date	Initials	Discharge Outcome Date	Initials
Comfort	Medications	IV fluids		IV fluid DC'd			
		Parenteral/oral analgesia		Oral analgesia		Oral analgesia provides pain relief	
		Antiemetic prn					
	Positioning	Assist with pillows for support Performs active ROM		Independent		Independent regular ambulation	
	Complementary therapy	Identify type: music, distraction, lighting, relaxation therapy, other		Identify type: music, distraction, lighting, relaxation therapy, other			
Mobility	Activity	Sits up in chair		Ambulates without assistance		Demonstrates physical therapy exercises	
		Ambulates q3hr with assistance		Physical therapy consult			
Respiratory	Respiratory therapy	Deep breathing and coughing		Deep breathing and coughing		Incentive spirometry and deep breathing, as needed	
		Incentive spirometry, as ordered		Incentive spirometry, as ordered			
Skin Integrity	Dressing	Assess dressing and drains		Remove incisional dressing; assess incision for redness		Oral temperature <102°F; incision without redness or pus	
		Empty and measure drain output		Maintain drain assessment		Understands drain care, as applicable	
		Bathes while keeping dressings and drains dry		Bathes, keeping drain sites dry		Maintains care around incision and drain sites	
Nutrition	Diet	DC IV fluids, as ordered		Tolerates regular diet without nausea		Tolerates regular diet	
		Clear liquids, advance as tolerated					
Self-Care	Activities of daily living	Completes self-care with minimal assistance		Performs drain care with minimal assistance		Completes self-care and drain care without assistance	
	Patient education	Discusses signs and symptoms (s/s) of infection and hematomas					
Psychosocial	Coping strategies	Spiritual, psychological, and/or social work consult, as needed		Visit from support group representatives		Verify follow-up appointments	
		Provide reconstructive surgery information, as requested		Provide breast prosthesis information, if requested			
Document initials when outcome is met. Record reason if not met in patient's electronic medical record or narrative note.							

FIGURE 5.7 Clinical pathway for treating a breast cancer patient after mastectomy. DC, Discontinue; IV, intravenous; ROM, range of motion.

Protocols are written plans that can be generalized to groups of patients with the same or similar clinical needs that do not require a physician's order. Health care agencies have established protocols outlining procedures for admitting patients or handling routine care situations. Because protocols are generalized to patient populations, they are often included in critical pathways.

Standing orders are written by physicians and list specific actions to be taken by a nurse or other health care provider when access to a physician is not possible or when care is common to a certain type of situation, such as what to do if a patient experiences chest pain or what actions to take after a colonoscopy. Standing orders are most commonly used in situations in which care is somewhat standardized, but the implementation of standing orders still requires extensive clinical judgment by the nurse. Community health nurses may practice with

standing orders that identify how to treat emergency situations in a patient's home. However, all nurses must be able to recognize and act on changes in a patient's condition that are not covered by the standing orders.

Safe Practice Alert

Following protocols or implementing standing orders requires critical thinking and use of the nursing process to determine the applicability of interventions in specific patient care circumstances. Blindly following critical pathways, protocols, or standing orders is contraindicated in all nursing care situations.

All nursing interventions that are implemented for patients must be documented or charted. In some cases this may involve checking off an intervention in the patient's EMR, or it may require completion of an additional form or area on the EMR designed to track the effectiveness of specific interventions. Most health care agencies have special requirements for documenting interventions, such as the use of physical restraints or pain protocols. Proper documentation of interventions facilitates communication with all members of the health care team and provides an essential legal record (Box 5.2). Accurate charting helps alleviate omissions and repetition of care. Documentation also allows nurses to evaluate the effectiveness of nursing interventions in meeting patient goals and outcomes, which is the final step in the nursing process.

Box 5.2

Ethical, Legal, and Professional Practice

Documentation

- All health care professionals are required to document patient interventions they implement in a traditional or an electronic medical record (EMR).
- Nurses must document the physical treatment and patient education that is provided.
- Follow-up evaluation of interventions must be documented to help the health care team determine the effectiveness of treatments, activities, and prescribed medications.

- Ethical and legal standards mandate that nurses chart or document only the interventions that they themselves implement.

5. List three interventions that the nurse would want to implement to help E. P. achieve the identified short-term goal.

Evaluation

Evaluation focuses on the patient or group and the patient's or group's response to nursing interventions and goal or outcome attainment (Fig. 5.8). Evaluation is not a record of the care that was implemented. Evaluation must clearly identify the effectiveness of implemented interventions with the patient or group as its focus. During the evaluation step of the nursing process, nurses use critical thinking to determine whether short- and long-term goals were met and desired outcomes were achieved. Monitoring whether the goals were attained is a collaborative process involving the patient or group.

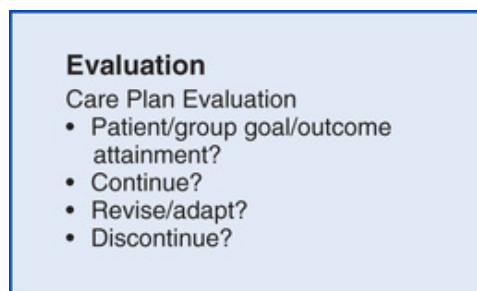

FIGURE 5.8 Evaluation in the nursing process.

Nurses need to ask some questions when evaluating the effectiveness of provided nursing interventions:

- Did the patient or group meet the goals and outcome criteria established during the planning phase?

- Since care began, have new assessment data been identified that should be taken into consideration?
- Does the care plan need to be modified in response to patient or group changes?
- Based on the patient's or group's response to the implemented interventions, should the plan of care be continued, revised, or discontinued?

The answers to these and other questions determine how best to proceed with individualized care.

LO 5.5 Cyclic and Dynamic Nature of the Nursing Process

The steps of the nursing process are cyclic and dynamic; one aspect of care leads into and informs the next. It is crucial that the professional nurse continuously reassess the patient or group, revise care as needed, and evaluate whether the goals are being met. As the short-term goals are met, that section of the nursing plan can be eliminated or discontinued. Sometimes, nursing care needs to be modified to meet other needs that were not previously identified.

The ongoing process of evaluating and adjusting intervention strategies requires nursing care to be based on current evidence. This evaluation process is also based on the nurse's ability to critically think about what care was given and what care may be needed in the future. The nursing process is a professional nurse's best tool for application of the scientific method to patient care. It is the essential critical-thinking method used by nurses to provide safe, competent nursing care to patients, families, and communities.

Summary of Learning Outcomes

LO 5.1 *Define the nursing process:* The nursing process is the scientific method through which professional nurses systematically identify and address actual or potential patient problems. Critical thinking, using the nursing process, allows nurses to collect essential patient data, articulate the specific needs of individual patients, and effectively communicate those needs, establish realistic goals, and customize interventions with members of the health care team.

LO 5.2 *Describe the historical development and significance of the nursing process:* The five primary steps of the nursing process were clearly identified by the early 1960s and have remained virtually unchanged since then, with only the addition of a subcategory to planning, outcome identification, in the early 1990s. Professional nursing practice in all types of settings is based on the nursing process. It is used to assess individuals, families, and communities; diagnose needs; plan attainable goals; implement specific interventions; and evaluate degrees of goal attainment.

LO 5.3 *Articulate the characteristics of the nursing process:* The nursing process requires nurses to think critically. It is dynamic, organized, and collaborative, and it is universally adaptable to various types of health care settings.

LO 5.4 *Describe the steps in the nursing process:* During the assessment step of the nursing process, patient or group data are gathered. In the diagnosis

step, data are analyzed and clustered with related assessment information to identify problems and then are stated as specific nursing diagnoses. During the third step of the nursing process, planning, the nurse prioritizes the nursing diagnoses and identifies goals with specific outcome identification. The implementation step includes initiating specific nursing interventions designed to help achieve established goals. During the evaluation step, the nurse determines goal attainment, the effectiveness of interventions, and whether the plan of care should be discontinued, continued, or revised.

LO 5.5 *Explain the significance of the cyclic and dynamic nature of the nursing process:* Use of the nursing process requires the professional nurse to continuously reassess patients or groups, revise care as needed, and evaluate whether goals are being met. As goals are met, portions of the nursing plan can be eliminated or discontinued. Nursing care sometimes needs to be modified to meet previously unidentified needs. The ongoing process of evaluating and adjusting intervention strategies requires nursing care that is based on current evidence-based practice (EBP).

Review Questions

1. What is the purpose of the nursing process?
 - a. Providing patient-centered care
 - b. Identifying members of the health care team
 - c. Organizing the way nurses think about patient care
 - d. Facilitating communication among members of the health care team
2. A patient comes to the emergency department complaining of nausea and vomiting. What should the nurse ask the patient about first?
 - a. Family history of diabetes
 - b. Medications the patient is taking
 - c. Operations the patient has had in the past
 - d. Severity and duration of the nausea and vomiting
3. An alert, oriented patient is admitted to the hospital with chest pain. From whom should the nurse collect primary data on this patient?
 - a. Family member
 - b. Physician
 - c. Another nurse
 - d. Patient
4. What is the primary purpose of the nursing diagnosis?
 - a. Resolving patient confusion
 - b. Communicating patient needs
 - c. Meeting accreditation requirements
 - d. Articulating the nursing scope of practice

5. On what premise is a nursing diagnosis identified for a patient?
 - a. First impressions
 - b. Nursing intuition
 - c. Clustered data
 - d. Medical diagnoses
6. Which statement is an appropriately written short-term goal?
 - a. Patient will walk to the bathroom independently without falling within 2 days after surgery.
 - b. Nurse will watch patient demonstrate proper insulin injection technique each morning.
 - c. Patient's spouse will express satisfaction with patient's progress before discharge.
 - d. Patient's incision will be well approximated each time it is assessed by the nurse.
7. What should be the primary focus for nursing interventions?
 - a. Patient needs
 - b. Nurse concerns
 - c. Physician priorities
 - d. Patient's family requests
8. Which nursing action is critical before delegating interventions to another member of the health care team?
 - a. Locate all members of the health care team.
 - b. Notify the physician of potential complications.
 - c. Know the scope of practice and competency of the other team member.

- d. Call a meeting of the health care team to determine the needs of the patient.
9. A patient reports feeling tired and complains of not sleeping at night. What action should the nurse perform first?
- a. Identify reasons the patient is unable to sleep.
 - b. Request medication to help the patient sleep.
 - c. Tell the patient that sleep will come with relaxation.
 - d. Notify the physician that the patient is restless and anxious.
10. What action should the nurse take regarding a patient's plan of care if the patient appears to have met the short-term goal of urinating within 1 hour after surgery?
- a. Consult the surgeon to see if the clinical pathway is being followed.
 - b. Discontinue the plan of care, because the patient has met the established goal.
 - c. Monitor patient urine output to evaluate the need for the current plan of care.
 - d. Notify the patient that the goal has been attained and no further intervention is needed.

CHAPTER 6

Assessment

LEARNING OUTCOMES

Comprehension of this chapter's content will provide students with the ability to:

- LO 6.1 Identify methods used during the assessment phase of the nursing process.
- LO 6.2 Describe techniques used during physical assessment.
- LO 6.3 Differentiate among the three types of physical assessment.
- LO 6.4 Categorize types of data collected during the assessment process.
- LO 6.5 Use strategies to validate patient assessment data.
- LO 6.6 Organize data according to established theoretical frameworks.

Case Study

Judith Kline (J. K.), a 55-year-old woman, arrived at an urgent care center complaining of generalized malaise, an overwhelming feeling of exhaustion that was not relieved with rest, and difficulty walking more than 10 ft. She has thinning scalp hair, scaly skin, and puffiness around her eyes. She appears to be anxious. She is married and responsible for raising three grandchildren (2, 4, and 8 years old). She is employed full time as a college professor and is worried that she may have a serious condition that will compromise her ability to work and care for her grandchildren. She enjoys gardening and reading books. Her vital signs are: T 36° C (36.8° F), BP 102/68, P 68 and regular, and R 12 and unlabored.

Refer back to this case study to answer the critical-thinking questions throughout the chapter.

Assessment is the first step in the nursing process (Fig. 6.1). Assessment establishes the baseline on which each phase of the nursing process builds. As soon as the patient's records are accessed, or a patient is first observed, the process of assessment begins. Valuable information about a patient is collected during the interview, health history, and physical examination. The assessment phase of the nursing process includes much more than collection of physical data. Physical, emotional, spiritual, socioeconomic, and cultural attributes unique to the individual are considered. After data are collected, they must be analyzed, validated, organized, and documented to provide the foundation for an individual patient-focused plan of care.

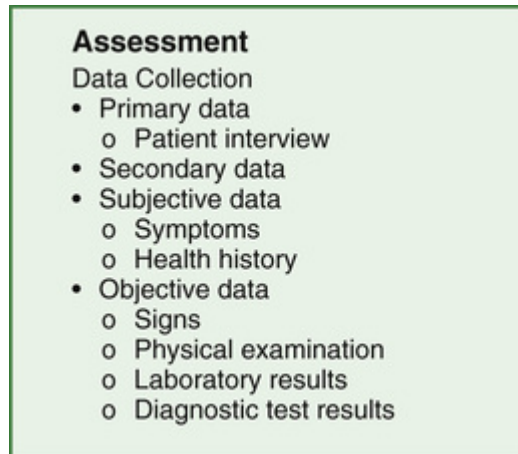

FIGURE 6.1 Assessment in the nursing process.

LO 6.1 Methods of Assessment

Methods through which assessment is conducted include observation; the patient interview, including the completion of a health history and review of systems; and a physical examination. Assessment proceeds in a logical and organized fashion to various degrees of depth during each patient–nurse interaction.

Observation

A nurse can gather significant information about a patient's emotional condition and health status by observing the patient's affect, clothing, personal hygiene, and obvious physical conditions, such as a limp or an open wound. Using the senses of sight, hearing, and smell during the observation phase helps the nurse gather important patient information, which can guide later aspects of the assessment process.

Before initiating the patient interview, the nurse should review data collected previously by other health care professionals to avoid repetition. The nurse should be prepared with required forms and assessment tools to prevent disruption during the dialogue. All significant observations should be documented and verified for accuracy during the interview phase of assessment.

Patient Interview

The **patient interview** is a formal, structured discussion in which the nurse questions the patient to obtain demographic information, data about current health concerns, and medical and surgical histories. During the assessment phase of the nursing process, it is essential for the nurse to gather information regarding developmental, cultural, ethnic, and spiritual factors that may affect the patient. These factors can significantly influence patient outcomes and must be considered when developing a patient-centered plan of care.

Patients who feel accepted and relaxed in the health care environment are more likely to disclose vital information to the nurse during the interview and physical examination. [Box 6.1](#) lists

some of the many factors that may affect patient cooperation and response to the assessment process.

Box 6.1

Diversity Considerations

Life Span

- Establishing rapport is essential for gaining the trust of a patient. The nurse should consider the patient's generational cohort, which may influence behavior and willingness to share personal information during the interview process.
 - Generational factors may influence behavior ([Cannon & Boswell, 2016](#); [Smith-Trudeau, 2016](#)).
 - Veterans (born before 1945) respect authority; are detail oriented; communicate in a discrete, formal, respectful way; may be slow to warm up; value family and community; and accept physical touch as an effective form of therapeutic communication.
 - Baby Boomers (born 1946–1964) are optimistic; are relationship oriented; communicate by using open or direct speech, using body language, and answering questions thoroughly; expect detailed information; question everything; and value success.
 - Generation X members (born 1965–1976) are informal; are technology immigrants; multitask; communicate in a blunt or direct, factual, and informal style; may talk in short sound bites; share information frequently; and value time.
 - Millennials, also known as Generation Y (born 1977–1994) are flexible; are technologically literate or are technology natives; multitask; communicate by using action verbs and humor; may be brief in the form of texting or e-mail exchanges; like personal attention; and value individuality.
 - Generation Z (born 1995–2012) value group work; digitally connected; want immediate feedback;

accepting of others; value honesty; close to family; entrepreneurial.

Culture, Ethnicity, and Religion

- Cultural and ethnic norms affect the willingness of patients to speak openly about health concerns.
- Nurses should explain the need for information that may be considered intimate in nature.
- Privacy must be provided before interviewing patients regarding sensitive information, such as the use of recreational drugs or sexual activity.
- Traditional treatment modalities common in a patient's culture or religion should be explored and documented during the interview process. It is important that this information be collected and recorded in a nonjudgmental manner.
- Electronic or live interpretation should be secured for patients who speak a language different from that of the health care providers.

Gender

- Personal space, communication patterns, and gender considerations unique to a patient's cultural background should be incorporated into the interview process to provide culturally competent care.
- Requests of patients for caregivers of the same gender should be honored whenever possible.

Morphology

- Physical assessment requires patient cooperation and positioning that may be difficult or impossible for individuals who are morbidly obese or physically disabled.
- Adjust the location in which the examination takes place based on patient needs. For example, if a patient is unable to

lie comfortably on a narrow examination table, arrange for a bed that can accommodate the patient.

Disability

- If a patient is paralyzed and unable to move independently from a wheelchair to a flat examination surface, seek help to safely transfer the patient so that a complete physical assessment can be done.
- Ask the trusted care providers of mentally challenged individuals to assist with the physical examination to ensure greater patient comfort and promote a feeling of safety and familiarity.
- Make any required adaptations during the physical assessment that are necessary to perform a thorough examination. The ability to provide safe patient care is challenged if the quality of the examination is compromised due to disability.

The patient interview consists of three phases: orientation (or introductory), working, and termination. Each phase contributes to the development of trust and engagement between the nurse and the patient.

Orientation Phase

During the orientation phase of the interview, the nurse should establish the name by which the patient prefers to be addressed. Some individuals prefer formal titles of respect (e.g., Dr., Mr., Ms., Professor) and the use of surnames, whereas others are comfortable with less formality. How a patient is addressed is the patient's choice.

The nurse should provide a personal introduction and state the purpose for the interview. This introductory phase is essential for establishing trust between the nurse and the patient, which affects all future interactions. Demographic data should be collected by asking focused or closed-ended questions. More general information can be gathered by open-ended communication techniques. Identifying patient needs and determining the extent

to which patients want to be involved in care planning are important aspects of the introductory phase.

The environment and timing of the interview are very important. Health Insurance Portability and Accountability Act (HIPAA) guidelines should be followed and privacy provided during patient interviews. The environment should be as private as possible. Privacy from other individuals and freedom from stressors that may affect the patient should be considered when determining when, where, and how to conduct the interview. The interview should be conducted in an area that is free from as many distractions as possible. Ensuring that the patient is comfortable and relaxed often takes prior thought and planning by the nurse. The patient should feel safe, because the questions raised may cause stress and anxiety.

When feasible, the nurse and the patient should be seated at eye level with each other (Fig. 6.2). In this way, the interaction between the nurse and the patient is horizontal instead of vertical. Standing over someone implies control, power, and authority. The implication of power can result in less-than-optimal data collection and a potential conflict as the patient strives to regain control over the situation.

FIGURE 6.2 Sitting at eye level with a patient during the interview communicates caring and acceptance. (© [istock.com.](https://www.istock.com))

Nonverbal behaviors of the nurse can influence the information obtained from the patient. Negative nonverbal cues, such as distracting gestures (e.g., tapping a pen, swinging a foot, looking at a watch), inappropriate facial expressions, and lack of eye contact, communicate disinterest. Strategies to establish a trusting relationship with the patient before the physical examination is conducted include: 1) communicating professionally, 2) sitting close and leaning in slightly toward the patient, 3) listening attentively while demonstrating appropriate eye contact, 4) smiling or maintaining a neutral facial expression, and 5) using a moderate rate of speech and tone of voice.

Working Phase

During the working phase of the interview, the nurse must stay focused on the purpose of the interaction. The nurse needs to individualize the process on the basis of the health of the patient and concerns that emerge during the course of the interview. Active, engaged listening is imperative during this process. The nurse must stay alert to what the patient says and how information is presented. Sometimes how the patient shares information is more important than what the patient says. The nurse should watch for emotional cues indicating fear or painful experiences and the appropriateness of verbal and nonverbal cues.

Educational needs are assessed during the patient interview (Box 6.2). The nurse should document gaps in patient knowledge and areas in which clarification of disease processes or treatment would be beneficial. Opportunities for health promotion are identified. Knowing a patient's level of education and professional background is often helpful in designing appropriate patient teaching.

Box 6.2

Patient Education and Health Literacy

The Role of Assessment in Patient Education

- The opportunity for teaching begins with a patient's entry into the health care environment, whether it is in an acute or community setting.
- Prior to initiating patient education, the nurse needs to assess a patient's cognitive ability, reading level, and potential language barriers.
- Assessment should include collecting information about what the patient already knows about her or his current condition and what additional knowledge is needed.
- Assessment information about the patient's educational needs should be documented and should guide aspects of the patient's individualized plan of care.
- Thorough assessment of the patient's knowledge should be used to determine the need for referrals and educational interventions.

A variety of communication techniques can be incorporated into the interview process. Open-ended questions encourage narrative responses from patients. Closed-ended, focused, and direct questions elicit specific information, such as the exact location of a patient's pain. It is appropriate to use direct questions to gather data about a patient's health history or during the review of body systems, when a yes or no answer is adequate. Direct questions can be expanded on with open-ended questions if more extensive information is needed. [Chapter 3](#) provides in-depth discussion on therapeutic communication techniques that are helpful during the patient interview.

During an admission interview, a thorough health history and review of systems should be conducted. If a patient being admitted to the hospital is too ill to interact for an extended period, the interview can be broken into smaller segments. Interviews with patients already hospitalized or established in the health care system are less extensive and more focused on newly identified patient concerns or problems.

Health History

An in-depth **health history** includes all pertinent information that can guide the development of a patient-centered plan of care. The health history includes demographic data, which is collected

during the orientation phase of the interview; a patient's chief complaint or reason for seeking health care; history of current illness; allergies; medications; adverse reactions to medications; medical history; family and social history; and health promotion practices (Table 6.1). Because a patient's health history is continuously evolving, the data collection is ongoing, progressive, and methodical.

TABLE 6.1**Framework for Collecting Health History Data**

TYPE OF DATA	SPECIFIC INFORMATION
Demographic data	Name Address Telephone numbers Age Birth date Birthplace Gender Marital status Race Cultural background or ethnic origin Spiritual or religious preference Educational level Occupation
Chief complaint or current illness	Reason for seeking care Onset of symptoms
Allergies and sensitivities	Medication Food (e.g., peanuts, eggs) Environmental agents (e.g., latex, tape, detergents) Reaction to reported allergens (e.g., rash, breathing difficulty, nausea, vomiting) Contrast dye
Medications, vitamins, and herbal supplements	Prescriptions Over-the-counter medications and herbal remedies Dosage, frequency, and reason for use
Immunizations	Childhood and adult immunizations Date of last tuberculin skin test Date of last vaccines (e.g., flu, pneumonia, shingles)
Medical history	Childhood illnesses, accidents, and injuries Serious or chronic illnesses Hospitalizations, including obstetric history for female patients Date of occurrence and current treatment
Surgical history	Type of surgery Date Problems with anesthesia Any complications

TYPE OF DATA	SPECIFIC INFORMATION
Family history	Age and health status of living parents, grandparents, siblings, and children Age at death and cause of death of deceased immediate family members Genetic diseases or traits, familial diseases (e.g., cardiovascular disease, high blood pressure, stroke, blood disorders, cancer, diabetes, kidney disease, seizure disorders, drug or alcohol dependencies, mental illness)
Social history	Use of tobacco, alcohol, or recreational drugs Environmental exposures Animal exposures and pets Living arrangement Safety concerns (e.g., intimate-partner violence, emotional or physical abuse) Recent domestic or foreign travel
Cultural and spiritual or religious traditions	Primary language Dietary restrictions Religion Values and beliefs related to health care
Activities of daily living (ADLs)	Nutrition (e.g., meal preparation, shopping, typical 24-hour dietary intake); recent changes in appetite Caffeine intake Self-care activities (e.g., bathing, dressing, grooming, ambulation) Physical living environment (e.g., steps, access to toileting or sleeping areas, indoor plumbing, carpet or rugs) Use of prosthetics or mobility devices Leisure and exercise activities Sleep patterns (e.g., hours per night, naps, sleep aids)
Cognitive or emotional status	Cognitive functioning Personal strengths Self-esteem Support system (e.g., family, friend, support groups, professional counseling)

Thorough documentation of health history findings in the format required by the health care facility contributes to better communication among health care team members and a more individualized plan of care. Ongoing efforts should be made to add missing data as they are obtained and to clarify any erroneous or confusing information.

Review of Systems

A review of systems, which is conducted by asking the patient questions pertaining to each body system, completes the health history. During the review of systems, the nurse collects subjective, patient-reported data. Questions asked during the

review of systems usually are brief and inquire about the normal function of each area, such as “Are you experiencing any difficulty breathing?” or “Do you ever experience diarrhea or constipation?” Any deviation from normal triggers more directive questions and affects the physical assessment. Health assessment questions related to each body system can be found in [Chapter 20](#).

After the collection of data, goals for care are established during the working phase in collaboration with the patient. Family members and other members of the health care team may be included in the goal-setting process. Information gathered during the interview and data gathered during the physical examination combine to form the foundation of a unique, patient-centered plan of care.

Health Promotion

While conducting a health history and review of systems, the nurse may identify health promotion activities, such as exercise classes or screening activities (i.e., colonoscopy, mammography, or monthly blood pressure checks), in which the patient participates. Risk factors may also become apparent during both wellness and sick visits. Information may be shared by a patient, family member, or caregiver that raises a current or potential concern unrelated to the patient's chief complaint. Some risk factors relate to age, developmental level, gender, or cultural background. Accident or falls prevention, bicycle safety, age-appropriate immunizations, strategies for disease prevention, exercise regimen, and nutritional guidelines customized to the specific person are some of the health promotion topics for discussion that may be relevant based on assessment findings.

Termination Phase

As the end of the interview approaches, care is taken to review key findings and prepare the patient for the conclusion of the discussion. This can be done effectively by summarizing and validating the information covered with the patient. By reviewing the information with the patient, a consensus is established. As the interview concludes, the patient should be allowed an opportunity to interject additional pertinent information. The session is concluded with the nurse acknowledging the patient's

participation and describing the next steps that the patient should expect.

LO 6.2 Physical Assessment

On completion of the patient interview, health history, and review of systems, the nurse begins the physical assessment. During the physical assessment the nurse collects objective data. If diagnostic tests, such as blood tests or x-rays, were ordered before the patient was seen, the nurse reviews the results. Privacy for the patient is ensured, good lighting is established, and the equipment and instruments needed (such as a stethoscope, sphygmomanometer, and pulse oximeter) are gathered before the physical examination is started. A penlight, otoscope, and ophthalmoscope may be required, depending on the type of physical assessment being conducted. Hand hygiene is performed, and clean gloves are worn if contact with body fluids is anticipated. Vital signs are taken and recorded at the beginning of the physical examination.

The assessment techniques of inspection, palpation, percussion, and auscultation are performed one at a time in this order for each body system except during assessment of the abdomen. During abdominal assessment, auscultation precedes palpation and percussion. The altered sequence of abdominal assessment avoids stimulation of the bowel before auscultation of bowel sounds.

Inspection

Inspection involves the use of vision, hearing, and smell to closely scrutinize physical characteristics of a whole person and individual body systems. Distinguishing between normal and abnormal findings for patients of different age groups begins the moment the nurse first observes and meets the individual, and it continues throughout the examination. Symmetry should be assessed by comparing the right and left sides of the body. Because the human body is usually anatomically symmetric, observing for abnormalities on both sides is important for detecting anatomic deviations. After inspection, further examination is performed using palpation and percussion.

Palpation

Palpation uses touch to assess body organs and skin texture, temperature, moisture, turgor, tenderness, and thickness. Palpation can determine organ location and size against the expected anatomic norm, any distention or masses, and vibration or pulsation associated with movement. Palpation is used to affirm details observed during inspection. Only light palpation should be applied to areas described by patients as sensitive or painful. Physicians or advanced practice nurses perform deep palpation to determine organ size and variation.

Percussion

Percussion involves tapping the patient's skin with short, sharp strokes that cause a vibration to travel through the skin and to the upper layers of the underlying structures. Vibration is reflected by the tissues, and the character of the sound heard depends on the density of the structures that reflect the sound. Knowing how the various densities reflect or absorb sound helps to determine the approximate size, shape, and borders of organs, masses, and fluid. An abnormal sound implies that an organ or area is possibly compromised with another substance, such as air, blood, or other bodily fluids. An advanced practice nurse or physician typically performs percussion.

Auscultation

Auscultation is a technique of listening with the assistance of a stethoscope to sounds made by organs or systems such as the heart, blood vessels, lungs, and abdominal cavity. The characteristics of auscultated sounds depend on the body tissue or organ being assessed. Breath sounds, heart sounds, and bowel sounds are routinely assessed through auscultation. Practice is required to be able to differentiate normal from abnormal findings.

LO 6.3 Types of Physical Assessment

Three primary types of physical assessment are conducted by nurses in a variety of practice settings. Determining which is indicated depends on the situation and timing of the nurse–patient interaction. An initial comprehensive or complete physical examination should be performed by a nurse when a patient is admitted to the hospital. It can be followed by clinical or focused assessments at the beginning of each shift or more often, depending on the patient's condition and the health care facility's policies and guidelines. Emergency assessments, including triage, are conducted in emergent situations to quickly assess the extent of patient injuries and determine care priorities.

It is the responsibility of the professional nurse to determine if a patient's condition warrants more frequent or extensive assessment in any given situation. Although some aspects of assessment can be delegated to other members of the health care team or unlicensed assistive personnel (UAP), the nurse must know what can be legally and safely delegated and what requires the nurse's coordination of care and personal attention ([Box 6.3](#)). A patient's plan of care is evaluated and modified on the basis of the assessment findings collected during every type of assessment.

Box 6.3

Interprofessional Collaboration and Delegation

The Registered Nurse's Critical Role in Assessment

- Initial and ongoing assessment of patients requiring critical care cannot be delegated to unlicensed assistive personnel (UAP).

- Initial patient assessment of unstable patients cannot be delegated to a licensed practical or licensed vocational nurse (LPN/LVN). An LPN/LVN may contribute to the ongoing assessment of patients and document their observations and care.
- Routine assessment of vital signs of a patient in stable condition may be delegated to an LPN/LVN or qualified UAP.
- Nurses delegating assessment of vital signs must:
 - Determine the stability of the patient and complexity of the problem before delegation.
 - Verify that the UAP are trained and capable of accurately performing the skills.
 - Collaborate with the UAP to confirm completion of vital sign measurement and proper documentation.
- Specific patient assessment may require the assistance of other health team members, such as in these examples:
 - Determination of a patient's ability to swallow is commonly delegated to a speech therapist.
 - Establishing a patient's level of stability while using crutches is typically done by a physical therapist.

Comprehensive Assessment

A comprehensive or complete assessment includes a thorough interview, health history, review of systems, and extensive physical head-to-toe assessment, including evaluation of cranial nerves and sensory organs, such as with sight and hearing testing. A complete physical examination may be conducted on admission to a hospital, during an annual physical at the office of a physician or nurse practitioner, or on initial interaction with a specialist. Comprehensive assessments often include a variety of laboratory and diagnostic tests that are ordered by the primary care provider (PCP).

Focused Assessment

A focused or clinical assessment is a brief individualized physical examination conducted at the beginning of an acute care–setting work shift to establish current patient status, or during ongoing

patient encounters in response to a specific patient concern. A focused assessment may be conducted when signs indicate a change in a patient's condition or the development of a new complication. This type of assessment is the most common type conducted by a nurse. Vital signs are assessed during each focused examination, which includes assessment of the pain level and pulse oximetry readings. The nurse examines the head, eyes, ears, nose, throat, neck, thorax (including lung and heart sounds), abdomen (including bowel sounds), and extremities.

During a focused examination, edema, peripheral pulses, capillary refill, skin turgor, and muscle strength are routinely identified. Wounds, intravenous sites, supplemental oxygen levels and delivery systems, nasogastric (NG) tubes, cardiac monitoring, and urinary catheters are assessed and documented. While assessing extremities, the nurse evaluates edema, pulses, capillary refill, and strength. Intake and output levels are documented, as well as any unique concerns of the patient at the time of the assessment. After completion of the basic head-to-toe assessment, attention turns to any health concerns raised by the patient.

Emergency Assessment

Emergency assessment is a physical examination done when time is a factor, treatment must begin immediately, or priorities for care need to be established in a few seconds or minutes. Patient treatment is based on a quick survey of accident or illness onset, followed by a narrowly focused physical examination of critical injuries or symptoms and signs.

Patient responsiveness is determined in an attempt to establish the potential extent of injury to vital organs. Attention is paid to the patient's airway, breathing, and circulation. Other concerns in the emergent setting are noticeable deformities, such as compound fractures, contusions, abrasions, puncture wounds, burns, tenderness, lacerations, bleeding, and swelling. During an emergency, the nurse may never have time to do a complete assessment and may work to stabilize one body system at a time. In this event, the nurse must remember to continually reassess every 5 to 15 minutes, depending on the stability of the patient.

Triage, a form of emergency assessment, is the classification of patients according to treatment priority. Patients are categorized

by the urgency of their condition. Most emergency departments use a five-tier triage system referred to as the Emergency Severity Index (ESI). The five-tier system classifies patients by levels numbered 1 through 5 (Table 6.2). The triage nurse must remember that symptoms can change, and ongoing reassessments are required.

TABLE 6.2
Emergency Severity Index Triage System

Emergency Severity Index (ESI) DESIGNATION	EXAMPLE CONDITIONS
Level 1 Resuscitation: Critical, life-threatening condition	<ul style="list-style-type: none"> • Severe trauma • Cardiac arrest • Respiratory arrest or severe distress • Seizure
Level 2 Emergent: High risk, imminently life-threatening condition	<ul style="list-style-type: none"> • Chest pain • Possible stroke • Subarachnoid hemorrhage • Suicidal or homicidal
Level 3 Urgent: Moderate risk, potentially life-threatening condition	<ul style="list-style-type: none"> • Abdominal pain (without indication of abdominal aortic aneurysm) • Hip fracture • R/O appendicitis • R/O venous thromboembolism
Level 4 Semi urgent: Low risk, stable health condition	<ul style="list-style-type: none"> • Twisted ankle injury • R/O urinary tract infection
Level 5 Non-urgent, Lower risk	<ul style="list-style-type: none"> • Poison ivy • Cold symptoms • Minor aches and pains

R/O, Rule out.

Adapted with permission from Gilboy, N., Tanabe, P., Travers, D., et al. (2012). Emergency Severity Index (ESI): A triage tool for emergency department care, Version 4: Implementation Handbook, AHRQ.

Triage is usually conducted when a patient enters the emergency department. However, the increasing patient load at emergency departments has engendered a trend toward telephone triage, which can help a patient determine whether urgent care, along with a trip to the emergency department, is necessary or if the patient can wait and make a physician or clinic appointment.

LO 6.4 Data Collection

Throughout the assessment process, various types of data that contribute to the patient record are collected and documented. The combined data are grouped using an established organizing framework and serve as the foundation for a patient-centered plan of care.

Collecting data is a systematic process that must be ongoing throughout the nurse-patient interaction. A nurse must be able to assess a patient's response to treatment, evaluate changes in the patient's evolving health status, and make clinical decisions based on those changes. The nurse must realize that the assessment process is cyclic and should be fluid and dynamic. The two forms of data, subjective and objective, that are elicited during the nurse-patient interaction and physical assessment are categorized as primary and secondary.

Primary and Secondary Data

Primary data come directly from the patient. Patients are the best source of information about their conditions, feelings, and what they have done to address their concerns before seeking professional health care. In most cases, it is best to collect data from the patient before seeking information from secondary sources.

Safe Practice Alert

Remember that patients are most familiar with their bodies and feelings. Nurses must actively listen to patients to better understand their concerns and care preferences. Involving patients in their care enhances patient satisfaction and outcomes.

If an adult patient is cognitively impaired or unconscious or if the patient is an infant or young child, subjective data about how the patient has been acting or feeling needs to be obtained from the patient's family or guardian. Information shared by family members, friends, or other members of the health care team is

secondary data. Likewise, data obtained from reviewing a patient's chart, medical records, results of laboratory and diagnostic tests, and literature reviews are secondary. Verification of primary and secondary data is vitally important to avoid a plan of care based on inaccurate information. Primary caregivers and family members can be extremely helpful in providing valuable assessment data on patients with disabilities.

Subjective Data

Subjective data are spoken information or **symptoms** that are typically difficult to validate. Subjective data usually are gathered during the interview process if patients are well enough to describe their symptoms. Alert and oriented adult patients are the source of primary, subjective data. Family members, friends, and other members of the health care team can contribute valid secondary, subjective data.

Subjective data should be documented as direct quotations (within quotation marks). Statements may include descriptions of feeling dizzy or ill, emotions, concerns, and other types of knowledge that cannot be quantified objectively. For example, if a patient is experiencing chest pain and says, "It feels like an elephant is standing on my chest," the nurse should include the patient's statement in his or her medical record.

Objective Data

Objective data, also referred to as **signs**, can be measured or observed. The nurse's senses of sight, hearing, touch, and smell are used to collect objective data. Objective assessment data are acquired through observation, physical examination, and analysis of laboratory and diagnostic test results. Examples of objective data are blood pressure readings, pulse measurement, and hemoglobin levels—any information that can be compared with established norms.

1. Identify data that the nurse collected by looking at J. K.

2. Classify each piece of J. K.'s data in the case study as subjective or objective.

LO 6.5 Validating Data

Sometimes during assessment of a patient, the nurse observes nonverbal cues that imply possible physical or emotional concerns (Fig. 6.3). A **cue** is a hint or an indication of a potential disease process or disorder. For instance, if a patient winces, it may indicate pain, or if a patient resists being touched, the patient may be a victim of physical abuse. Crying, a disheveled appearance, and lack of eye contact may be cues of depression. However, conclusions about the underlying cause of the patient's actions cannot be assumed. All cues need to be interpreted and validated to verify the data's accuracy.

FIGURE 6.3 Nonverbal cues often alert the nurse to potential physical or emotional concerns of the patient. (© [istock.com.](https://www.istock.com/))

Validating data is making sure that the data are accurate. As patient information is collected, consistency between subjective and objective data must be confirmed. Confirming the validity of collected data often requires verbally checking with the patient to see whether assumptions or conclusions at which the nurse arrived are correct. Sometimes, the nurse can use laboratory and diagnostic test results to validate the subjective data. For example, objective data can validate patient subjective data when the patient's hemoglobin level is low, indicating anemia, and the patient complains of feeling fatigued and dizzy. In the day-to-day process of caring for the patient and family, pertinent information becomes available to corroborate initial assessment data. Although data validation should be done on a continual basis, care should be taken to avoid repetition.

Data Interpretation

Careful observation and attention to detail help the nurse notice subtle cues and recognize how best to validate and interpret patient data. While interpreting data, the nurse must be careful to avoid inaccurate **inferences** (i.e., conclusions) based on the nurse's personal preferences, past experiences, generalizations, or outdated and inaccurate health care information. Interpreting data and making inferences that determine patient care must involve ongoing interaction with patients and others, which includes sensitivity to the patient's expectations, cultural and ethnic traditions, and values.

QSEN Focus!

Patient-centered care requires the nurse to understand patient and family preferences and values. The nurse must recognize patients' expectations for care and provide care with respect for the diversity of human experience.

Accurate interpretation of patient data requires that the nurse have a wide breadth of knowledge, including disease processes, vital sign parameters, and normal values and outcomes for laboratory and diagnostic tests. The nurse must know typical

signs and symptoms of disease processes and which laboratory and diagnostic test results should be monitored on the basis of a patient's condition and medical diagnosis.

3. Write a minimum of five follow-up questions that the nurse should ask J. K. to obtain additional assessment data.

Review of current references and evidence-based practice (EBP) research is essential for implementing safe patient care (Box 6.4). Care must be taken to ensure that materials accessed online are accurate and scholarly. Information from reliable sources is valuable for determining appropriate interventions that should be included in a patient's plan of care.

Box 6.4

Evidence-Based Practice and Informatics

Electronic Resources for Evidence-Based Nursing Practice

Many reliable mobile apps, websites, and research databases that are available to nurses provide information that can guide patient care:

- Reference apps are available for every type of mobile device, making assessment, diagnostic, and medication information accessible at the point of care.
- Information from online websites—including the Centers for Disease Control and Prevention (CDC), the National Institutes of Health (NIH), and Agency for Healthcare

Research and Quality (AHRQ)—contain evidence-based practice (EBP) research and can be used to help interpret assessment information.

- Research databases, such as the Joanna Briggs Institute EBP Database, Cumulative Index of Nursing and Allied Health Literature (CINAHL), and the Cochrane Review, provide nurses with current EBP research and applications.

LO 6.6 Data Organization

After the patient's data are collected, validated, and interpreted, the nurse organizes the information in a framework (format) that facilitates access by all members of the health care team. In some cases, health care facilities have their own organizing formats, but most use formats based on one of the three traditional organizing frameworks.

Body Systems Model

The body systems model organizes data based on each system of the body: integumentary, respiratory, cardiovascular, nervous, reproductive, musculoskeletal, gastrointestinal, genitourinary, and immune systems. It follows a sequence like the medical model for physical examination. The body systems model for data organization tends to focus on the physical aspects of a patient's condition rather than a more holistic view.

Head-to-Toe Model

Organizing assessment data in a head-to-toe (cephalic–caudal) pattern ensures that all areas of concern are addressed. The nurse documents information regarding the patient's general health status first, including data related to psychosocial concerns, emotional status, cultural and ethnic influences, and living conditions. Vital sign assessment data are then recorded, followed by objective and subjective patient information. Physical assessment data are documented, starting with the head and ending with findings related to the lower extremities.

Gordon's Functional Health Patterns

A third method of organizing health assessment data is based on areas of function. Marjory [Gordon \(2016\)](#) developed functional health patterns to help nurses focus on patient strengths and related but sometimes overlooked data relationships. For instance, one of the functional health patterns is activity and exercise. In this health pattern, the patient data related to cardiac, respiratory,

and musculoskeletal function are recorded because the ability of a patient to initiate and continue activity depends on the condition of the heart, lungs, and muscles and bones.

Table 6.3 illustrates each functional health pattern with an example of patient assessment data that would be recorded in it. This method of organizing patient data is a more holistic approach than the others. Its comprehensive structure is beneficial when organizing vast amounts of patient information and when clustering related patient data before formulating nursing diagnoses, patient goals, and treatment outcomes.

TABLE 6.3**Functional Health Patterns**

FUNCTIONAL HEALTH PATTERN	FOCUS
Health perception/Health management	Patient's perceived level of health Social habits Living conditions Health and safety concerns
Nutritional/Metabolic	Food consumption Fluid intake and balance Tissue integrity
Elimination	Excretory function Bowel Bladder Skin
Activity/Exercise	Activities of daily living (ADLs) Exercise and leisure Cardiac status Respiratory status Musculoskeletal status
Sleep/Rest	Sleep patterns Rest and relaxation activities Fatigue levels
Cognitive/Perceptual	Sensory intactness Cognitive ability Level of consciousness Neurologic function
Self-perception/Self-concept	Identity Body image Self-worth Self-esteem
Role/Relationship	Role satisfaction Role strain Relationship function or dysfunction
Sexuality/Reproductive	Perceived satisfaction with sexuality Reproductive stage
Coping/Stress Tolerance	Coping abilities, stress tolerance Support system evaluation
Value/Belief	Values Spiritual beliefs Cultural patterns Influences on decision making

From Gordon, M. (2016). *Manual of nursing diagnosis* (13th ed.). Sudbury, MA: Jones & Bartlett.

Regardless of which organizing framework is used to document patient information, it is imperative that the data be recorded accurately and in a format that is accessible to all members of the

health care team. Factual and complete documentation facilitates comprehensive care that is responsive to patient needs.

Accurate assessment is essential to the overall effectiveness of every patient-centered plan of care. Nurses must develop excellent assessment skills to accurately aid in appropriate diagnosis and treatment of their patients.

4. Organize the assessment findings from J. K. into functional health patterns.

Summary of Learning Outcomes

LO 6.1 *Identify methods used during the assessment phase of the nursing process:* Assessment requires observation; a patient interview, including collection of demographic data; a health history; a review of systems; and a physical examination.

LO 6.2 *Describe techniques used during physical assessment:* The assessment techniques of inspection, palpation, percussion, and auscultation are performed one at a time in this order for each body system except during assessment of the abdomen. During abdominal assessment, auscultation precedes palpation and percussion.

LO 6.3 *Differentiate among the three types of physical assessment:* A complete physical examination is typically performed on admission to the hospital, at an initial visit to a specialist, or during an annual physical. Focused assessments are most often done at the beginning of each shift but can be done more often, depending on the patient's condition, evolving complications, and health care facility policies and guidelines. Emergency assessments, including triage, are conducted in emergent situations to quickly assess the extent of patient injuries and determine care priorities.

LO 6.4 *Categorize the types of data collected during the assessment process:* Primary data are obtained directly from a patient, whereas secondary data consist of information collected from family members, other members of the health care team, and medical records. Subjective data are symptoms or spoken information. Objective data are signs or information that is observed.

LO 6.5 *Use strategies to validate patient assessment data:* Sometimes, the nurse can use laboratory and diagnostic test results to validate subjective data. In some cases, cues validate symptoms reported by patients. In other cases, confirming the validity of collected data requires verbally checking with the patient to see whether the nurse's assumptions or conclusions are correct.

LO 6.6 *Organize data according to established theoretical frameworks:* Three commonly used methods of organizing patient data are by body system, in head-to-toe format, and by functional health patterns. The first two methods focus on the medical model and illness, whereas the functional health pattern approach is more holistic.

Review Questions

1. Which action by a patient marks the beginning of the physical assessment process?
 - a. Redressing after a physical examination
 - b. Breathing normally during auscultation
 - c. Greeting the nurse in the examination room
 - d. Sharing work environment information

2. Which factors should be taken into consideration by the nurse before and during a patient interview? (*Select all that apply.*)
 - a. Distance between the chairs in which the nurse and patient are sitting
 - b. Traditional treatments typically used by the patient to treat disease
 - c. Gender preference for primary care providers (PCPs)
 - d. Physical condition of the patient
 - e. Music preference of the patient

3. Which action by the nurse is most appropriate during the orientation phase of the patient interview?
 - a. Always position patients in a comfortable reclined position to ensure their comfort during questioning.
 - b. Ask which name a patient prefers to be called during care to show respect and build trust.

- c. Quickly conduct a review of systems to determine the need for a complete or focused assessment.
 - d. Begin with questions about intimacy and sexuality to address sensitive issues first.
4. Which activity by the nurse best demonstrates part of the working phase of a patient interview?
- a. Summarizing previously discussed key topics
 - b. Including selected family members in care planning
 - c. Transferring care responsibilities to the home health nurse
 - d. Verifying the name by which a patient prefers to be addressed
5. Which entry in a patient's electronic health record best indicates the need for a nurse to gather secondary rather than primary subjective data?
- a. Complaining of chest pain
 - b. Apical pulse 110
 - c. Comatose
 - d. Difficulty swallowing
6. Which line of questioning by the nurse best represents an appropriate approach to the review of systems aspect of the assessment process?

- a. "What do you do for a living? Can you describe your work environment?"
 - b. "Is there a family history of heart disease, cancer, high blood pressure, or stroke?"
 - c. "When was your last annual physical? What immunizations did you receive at that time?"
 - d. "Do you have any chest tightness, shortness of breath, or difficulty breathing while exercising?"
7. Which cue by a patient can be validated by laboratory and diagnostic test results?
- a. Deeply sighing with fatigue
 - b. Bilateral crackles in the lungs
 - c. Oxygen saturation of 98% on room air
 - d. 2+ pitting edema of the ankles and feet
8. A patient discusses his job stress and family relationships with the nurse during his health history interview. In which organizational framework is this type of data likely to be recorded most extensively?
- a. Body systems model
 - b. Physical assessment model
 - c. Head-to-toe assessment model
 - d. Functional health patterns model
9. When initiating a physical examination, which action should the nurse take first?
- a. Review of the patient's prior medical records

- b. Gather admission health history forms
 - c. Assess the patient's vital signs
 - d. Perform light and deep palpation for fluid
10. If the nurse discovers that a patient's right elbow is swollen and painful during a physical examination, which action should the nurse take next?
- a. Apply ice to decrease swelling and reduce pain
 - b. Percuss the area to determine the presence of fluid
 - c. Perform passive range of motion to promote flexibility
 - d. Inspect the patient's left elbow to compare its appearance

CHAPTER 7

Nursing Diagnosis

LEARNING OUTCOMES

Comprehension of this chapter's content will provide students with the ability to:

- LO 7.1 Explain basic nursing diagnosis methodology.
- LO 7.2 Describe the historical development of nursing taxonomies.
- LO 7.3 Differentiate among the three types of NANDA-I nursing diagnostic statements.
- LO 7.4 Recognize NANDA-I nursing diagnostic statement configuration with applicable components.
- LO 7.5 Identify appropriate nursing diagnoses and associated supporting data within an electronic medical record system.
- LO 7.6 Implement the steps for accurately identifying nursing diagnoses.
- LO 7.7 Discuss how to avoid common problems associated with the diagnostic process.
- LO 7.8 Articulate the contribution of nursing diagnosis to the individualized care of patients.

Case Study

Charlotte Hayes (C. H.) is a 34-year-old woman admitted to the emergency room yesterday complaining of nausea, vomiting, and right upper quadrant pain. An upper right quadrant sonogram revealed several large stones in the gallbladder and possibly smaller stones in the common bile duct, requiring an open cholecystectomy.

On the first postoperative day, C. H.'s vital signs are: BP 170/98, P 92 and regular, R 28 and unlabored, and T 38.1° C (100.6° F). She reports a pain level of 7 of 10, and her pulse oximetry reading is 92% on room air. Her incision is 5 inches long, running parallel to the right upper quadrant ribs; it is secured with retention sutures. Because of her obesity, the incision is taut in certain sections. There is no swelling and only slight redness along the incision. The sterile gauze dressing has a minimal amount of dried blood. She has an intravenous (IV) line of 5% dextrose running at 125 mL/hr.

C. H. has been medicated for pain three times during the 12-hour night shift and is currently requesting more pain medicine. Crackles are audible during lung auscultation. She does not want to turn, cough, and breathe deeply because “it hurts.” She has gotten up once to urinate 750 mL of concentrated urine and has not had a bowel movement. She denies having nausea and vomiting. She is asking when she can eat but remains on a clear liquid diet. She states that she is not comfortable in her bed. She appears anxious, expresses concern about her job, and wants to know when she can leave.

Refer back to this case study to answer the critical-thinking questions throughout the chapter.

Nursing diagnosis is the second step of the nursing process. Formulation of nursing diagnoses follows patient data collection and involves the analysis and clustering of related assessment information. The use of nursing diagnoses facilitates clear communication of patient

needs and promotes professional accountability and autonomy by defining and describing the independent area of nursing practice (ANA, 2015). Nursing diagnoses clearly communicate to legislators, consumers, and insurance providers the unique care nurses deliver and the specific nature of the health conditions they treat (Box 7.1). Use of a unified language classification system, or **taxonomy**, is an effective vehicle for communication among nurses and other health care professionals. The integration of various taxonomies into electronic medical records (EMRs) has facilitated opportunities for research and increased global collaboration with the goal of improving patient safety and clinical decision making. The nursing taxonomy and structure of writing nursing diagnosis statements developed by North American Nursing Diagnosis Association International (NANDA-I) is frequently taught in United States colleges and universities. However, with the integration of EMRs into health care, identification of nursing diagnoses for patients and the documentation of supporting patient data are streamlined by the use of checklists and drop-down options. EMRs contain nursing diagnoses from several organizations including the International Classification for Nursing Practice (ICNP) developed by the International Council of Nurses (ICN) and the Clinical Care Classification (CCC) System from Sabacare, Inc.

Box 7.1

Ethical, Legal, and Professional Practice

Responsibilities of the Professional Nurse

Accurate identification of nursing diagnoses for patients is critical to professional nursing practice, as delineated in the [American Nurses Association's \(ANA\) *Nursing: Scope and Standards of Practice* \(2015\)](#).

Professional nurses are required to:

- Identify accurate, applicable nursing diagnoses to guide quality, individualized nursing care of patients.
- Consider ethical and legal consequences for failure to identify areas of concern requiring treatment.
- Understand the implications of delayed recovery, further negative health issues, and, if it occurs, the death of the patient.
- Realize the ultimate risk for litigation involving the nurse if accurate nursing diagnoses are not identified.

- Formulate individualized nursing diagnostic statements at all levels of professional practice, and assign medical diagnoses within the scope of the nurse practice acts governing advanced practice nursing.

This textbook presents nursing diagnosis labels from the ICNP. This chapter shows students how to formulate NANDA-I nursing diagnosis statements for instructional purposes only. Students will be introduced to the EMR format for selecting nursing diagnoses and documenting supporting data to prepare them for their clinical experiences and professional nursing practice. The EMR format of (1) identifying a patient-appropriate nursing diagnosis and (2) listing clustered, supporting data, including the **etiology** (underlying cause), will be used throughout the textbook when discussing the diagnosis step of the nursing process.

QSEN Focus!

The use of standardized nursing diagnosis language to communicate patient data enhances the accurate transfer of information among nurses and other health care team members, which is essential for patient safety. Because a nursing diagnosis consolidates a great volume of information in a concise format, it provides an effective shorthand means of communicating the patient's status.

LO 7.1 Nursing Diagnosis Methodology

Nursing diagnosis “is the nurse’s clinical judgment about a client’s response to actual or potential health conditions or needs” (ANA, 2018). Nursing diagnosis follows assessment in the nursing process. In this step, the nurse makes clinical decisions about a patient’s experiences and responses to problems or life events identified during the data collection process. Identification of correct nursing diagnoses depends on accurate collection, validation, analysis, and clustering of data (Box 7.2). Careful consideration of the patient’s subjective (symptoms) and objective (signs) assessment data identifies if a patient has an existing or potential problem or is seeking help to improve his or her lifestyle or situation. Patient assessment data is clustered, a nursing diagnosis is identified, and supporting data is listed as part of the diagnosis step in the nursing process (Fig. 7.1).

Box 7.2

Evidence-Based Practice and Informatics

Applying the Nursing Process to Practice

- Professional nursing practice demands that nurses continually develop their knowledge and critical-thinking skills to apply them to patient care using the nursing process. Use of the nursing process maintains focus on the patient: the patient’s needs, potential concerns, and/or response to situations.
- Proper identification and articulation of nursing diagnoses guide the dynamic nursing process.
- Changes in patient status and life experiences require the addition, modification, and discontinuation of nursing diagnoses on the basis of nursing judgment and evidence-based research findings.
- Evidence-based practice (EBP) enhances a nurse’s ability to use the nursing process for clinical judgment and inquiry during patient care.
- Clinical research, documenting the study findings of nurses who practice using the nursing process, is required to support the addition of new nursing diagnoses to standard language classification systems (taxonomies), such as International

Classification for Nursing Practice (ICNP) or North American Nursing Diagnosis Association International (NANDA-I).

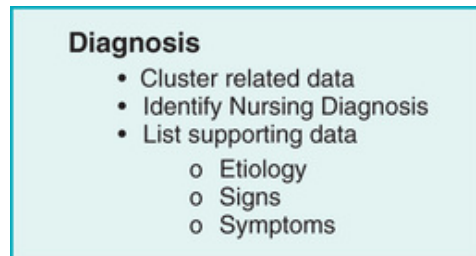

FIGURE 7.1 Diagnosis in the nursing process.

Differentiating Between Medical and Nursing Diagnoses

Whereas medical diagnoses identify and label medical (physical and psychological) illnesses, nursing diagnoses are much broader in focus. Nursing diagnoses consider a patient's situation more holistically, including how the patient is responding to current circumstances. Nursing diagnoses take into consideration a patient's attitudes, strengths, and resources—not just the medical problems identified—which are critical for planning holistic, individualized care. Nursing diagnoses are clinical judgments or decisions made by nurses based on patient assessment data.

LO 7.2 Nursing Taxonomies

Before the 1970s, there was no uniform, systematic method used by nurses to identify patients' health concerns. Assessments were completed and data collected, leading to identification of patient problems without a standardized method of communicating the findings. Nursing care was primarily guided by physicians' orders and directed at treating the signs and symptoms specific to medical diagnoses. Now several organizations have developed taxonomies to guide nursing care throughout the world.

Evolution

The first unofficial nursing diagnosis conference, with 100 nurses in attendance, was held in 1973 to develop a nursing taxonomy (Gebbie, 1976). The nurses continued to meet every 2 years until 1982, when the group officially became the North American Nursing Diagnosis Association, or NANDA (NANDA-I, 2018). NANDA pioneered work in nursing language and classification with its identification of nursing diagnoses.

The organization is composed of nurses from all areas of nursing, including practice, research, education, administration, and specialty areas. In 2002, NANDA became NANDA International (NANDA-I) to acknowledge the increased interest in nursing taxonomy worldwide (NANDA-I, 2018). The initial goals were to generate, name, and implement nursing diagnostic categories. These goals exist today in addition to the goals of revising the taxonomy, promoting research to validate diagnostic labels, and encouraging nurses to use the taxonomy in practice.

In the early 1990s, the American Nurses Association (ANA) supported the collaboration of multiple classification systems utilized for acute, home, and community care to develop the ICNP taxonomy by the ICN (Warren & Coenen, 1998). The ICNP incorporates nursing diagnoses (similar to and in some cases identical to NANDA-I labels), outcomes that are dependent on nursing actions, and nursing interventions. ICNP nursing diagnoses are incorporated into EMRs and are recognized by the World Health Organization (WHO) for use by nurses internationally.

Cycle of Revision

The NANDA-I and ICNP taxonomies are dynamic. Every 2 to 3 years, both taxonomies are evaluated and revised based on nursing research conducted to validate current and evolving nursing practice. Diagnoses are accepted based on how well research supports them. Nursing students and nurses for whom English is not their native language may find it helpful to refer to one of approximately 20 ICNP translations available at <https://www.icn.ch/icnp-browser>. The complete NANDA-I taxonomy, including new nursing diagnoses, is published in *Nursing Diagnoses: Definitions and Classification*.

LO 7.3 NANDA-I Nursing Diagnostic Statements

Three types of nursing diagnostic statements—problem-focused, risk, and health promotion—may be written in NANDA-I format. Determining which type is needed for each patient can be challenging. Fig. 7.2 is an algorithm to help nurses with the decision-making process. Nurses may identify one or more of each type of nursing diagnosis for a patient, depending on the patient's current health status or situation. It is important that all applicable nursing diagnoses are recognized to guide patient care. Determining the priority in which to address each nursing diagnosis takes place during the planning phase of the nursing process.

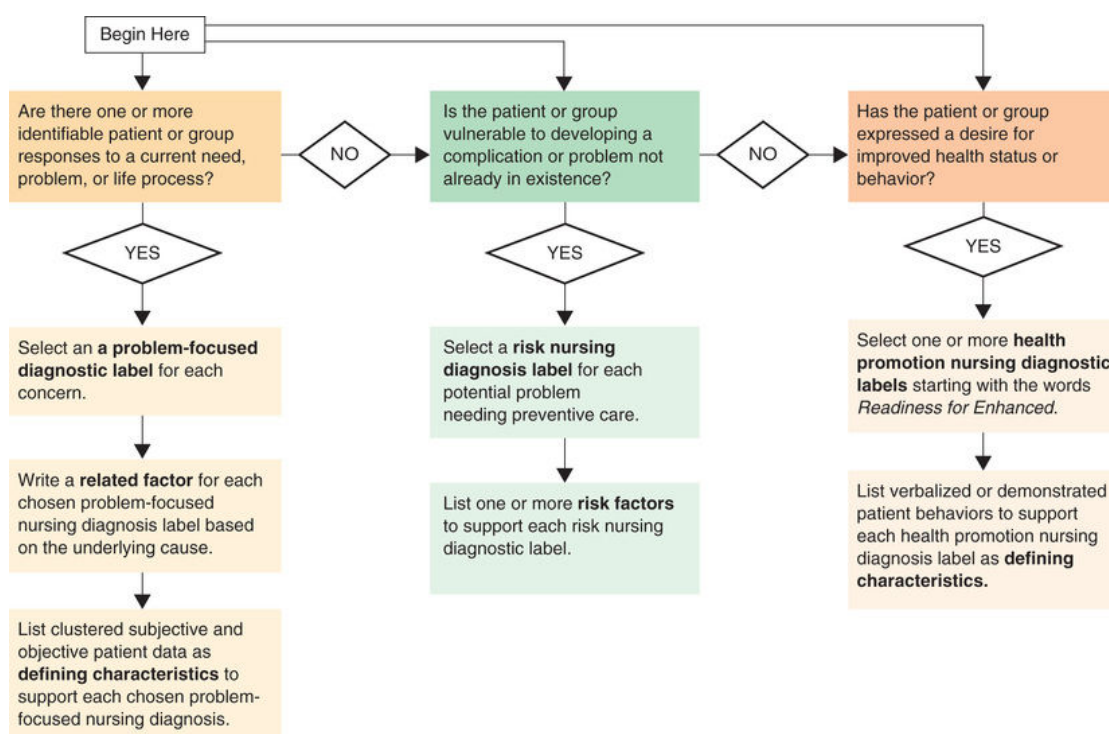

FIGURE 7.2 Algorithm for writing the three types of NANDA-I nursing diagnosis statements.

Problem-focused nursing diagnoses are clinical judgments about undesirable human responses to health conditions or life processes that occur in an individual, family, group, or community (NANDA-I, 2018). **Risk nursing diagnoses** identify risk factors that are vulnerabilities of an individual, family, group, or community for developing negative human responses to health conditions or life processes (NANDA-I,

2018). **Health promotion nursing diagnoses** are clinical judgments concerning the motivation and desire of an individual, family, group, or community to increase well-being and to actualize human health potential (NANDA-I, 2018). When writing health promotion nursing diagnoses, the clustered supporting data (i.e., defining characteristics) should reflect a verbalized desire to address positive lifestyle changes and increase healthy behaviors.

After nursing diagnoses have been established and goals and interventions are planned, patient care is provided, often in collaboration with a variety of health care professionals or agencies (Box 7.3). Patient education needs to be included as a part of patient care in most cases. Each of the three types of nursing diagnoses requires the nurse's clinical judgment, which is based on patient assessment data, knowledge, and nursing experience.

Box 7.3

Interprofessional Collaboration and Delegation

Engaging Others in Patient Care

The provision of excellent care to patients requires a team approach to achieve success. The nurse plays an important role, but many other individuals and disciplines are involved in the provision of excellent care:

- Social workers
- Pharmacists
- Dietitians
- Occupational and physical therapists
- Chaplains
- Physicians
- Unlicensed assistive personnel
- Environmental services
- Maintenance department staff

The successful implementation of a plan of care requires the nurse to delegate at certain times and collaborate at other times:

- Nurses are well trained in providing patient education, but the primary care nurse may delegate patient teaching regarding glucometer use to test blood sugar levels for a newly diagnosed diabetic patient to the clinical nurse specialist whose practice focus is diabetic teaching.
- Collaboration may occur among the chaplain, physician, and nurse to meet the various spiritual needs of a patient.
- The rooms must be clean and the equipment working correctly for patients to recover well. The environmental and maintenance staffs are crucial for excellence in patient care.
- Even though collaboration and delegation may occur, the nurse is ultimately responsible for the continued assessment of patient needs and progress. Detection of additional problems or lack of progress with the patient should prompt the nurse to reconsider the nursing process steps.

LO 7.4 Components of NANDA-I Nursing Diagnostic Statements

Each type of nursing diagnostic statement contains sections or parts to comply with NANDA-I guidelines. Problem-focused nursing diagnostic statements are written with three parts: (1) a diagnosis label, (2) related factors, and (3) defining characteristics. Risk nursing diagnoses have two segments: (1) a diagnosis label and (2) risk factors preceded by the phrase *as evidenced by* (NANDA-I, 2018). Health promotion nursing diagnoses also are written with only two sections: (1) the diagnosis label and (2) defining characteristics.

Diagnosis Label

The NANDA-I **diagnosis label** is a concise term or phrase that represents a pattern of related, clustered data (NANDA-I, 2018). The diagnosis label is the first section of every NANDA-I nursing diagnosis statement. It describes the diagnostic focus and requires nursing judgment before its assignment to a patient. A nurse must be familiar with the patient's signs and symptoms and the etiology of any problems, potential problems, or needs before determining an appropriate nursing diagnosis label. To accurately identify diagnosis labels for a patient, the nurse must (1) understand the meaning of a diagnostic label, (2) cluster and analyze related assessment findings, and (3) make a clinical judgment based on the patient's condition. All risk NANDA-I nursing diagnoses begin with the words: *Risk for*. All health promotion NANDA-I nursing diagnosis labels begin with the words: *Readiness for Enhanced* (NANDA-I, 2018). Nursing diagnoses from NANDA-I or other taxonomies, such as the ICNP or CCC, may be used within the NANDA-I structure.

Related Factors

According to the NANDA-I guidelines, the second part of a problem-focused nursing diagnosis consists of related factors. **Related factors** are the underlying cause or etiology of a patient's problem. Reviewing a patient's history can help the nurse determine accurate related factors. Nursing interventions are planned and implemented in the next two steps of the nursing process to treat the related factors identified as the cause of the patient's problem.

Defining Characteristics

Defining characteristics are traditionally written as the third section of a problem-focused NANDA-I nursing diagnostic statement. In the case of a risk or health promotion nursing diagnosis, risk factors or defining characteristics are the second, rather than the third, component of the nursing diagnostic statement. **Risk factors** that are identified in a risk nursing diagnosis are environmental, physical, psychological, or situational concerns that increase a patient's vulnerability to a potential problem or concern. **Defining characteristics** are cues or clusters of related assessment data that are signs, symptoms, or indications of a problem-focused, or health promotion nursing diagnosis.

1. Identify three pieces of supporting data that the nurse could use to corroborate the nursing diagnosis of *Acute Pain* for C. H.

LO 7.5 Nursing Diagnosis in the Electronic Medical Record

Within the EMR, nurses have the responsibility to identify and document nursing diagnoses for each patient based on sound clinical judgment following assessment. Nursing diagnoses in an EMR are typically chosen from a drop-down list that originates from taxonomies, such as the ICNP or CCC. Once the nurse chooses an appropriate nursing diagnosis based on clustered patient data, the nurse selects, or manually enters, patient-specific supporting data including an etiology, and signs and symptoms related specifically to the diagnosis. Although the process of documenting specific nursing diagnoses and their supporting data is simplified within EMRs, the nurse retains the responsibility to identify relevant patient data to avoid errors in individualized care planning.

LO 7.6 Steps for Identification of Accurate Nursing Diagnoses

Accurate identification of nursing diagnoses requires analysis of assessment data and clustering of related cues and information. All patient information should be considered as potentially contributing to the identification of diagnostic labels. This information includes subjective and objective data collected through physical assessment of the patient, interview of the patient and family members, and laboratory and diagnostic test results including x-rays, physicians' orders, and documentation from health care providers. Verifying specific nursing diagnoses for a particular patient or situation follows accurate analysis and clustering of data.

Data Clustering

After collecting and reviewing all of the assessment data, the nurse looks for patterns and related data to support specific nursing diagnoses. This process is referred to as *clustering data*. **Clustering** involves organizing patient assessment data into groupings with similar underlying causes. The nurse looks for cues among the data that support the diagnosis of a problem. For example, objective and subjective data related to mobility can be clustered. Data related to nutritional status, such as weight, height, and dietary intake, can be clustered.

One patient may have several problems simultaneously, requiring the nurse to understand the potential relatedness of signs and symptoms from various body systems. The nurse combines an understanding of pathophysiology, normal structure and function, disease processes, and symptomatology to accurately cluster data. For example, a patient with congestive heart failure may have the following seemingly diverse but related assessment findings:

- Subjective data:
 - Patient reports weight gain of 10 lbs in 48 hours.
 - Patient complains of “shortness of breath.”
 - Patient complains of “feeling tired all the time.”

- Objective data:
 - Bilateral basilar crackles in the lungs on auscultation
 - Bilateral 2+ pitting edema of the ankles and feet

Although these individual assessment findings may seem unrelated at first glance, they are all signs and symptoms of heart failure that should be clustered to support the nursing diagnosis of *Hypervolemia* (ICNP). In other circumstances, clustered data relate to only one body system in support of a nursing diagnosis. The following data would be clustered to support the nursing diagnosis of *Impaired Gas Exchange* (ICNP):

- Subjective data:
 - Patient states, “I am having difficulty breathing.”
 - Patient complains of “getting winded” with activity.
- Objective data:
 - Dyspnea on exertion
 - Pulse oximetry reading of 88% on room air

The nurse finds that some data or cues may support more than one type of nursing diagnosis. For example, difficulty with mobility or ambulation observed by the nurse and verbalized by the patient can be a defining characteristic for a NANDA-I problem-focused nursing diagnosis or supporting data in an EMR documented as *Impaired Mobility* (ICNP) with supporting data of limited range of motion, slow, unsteady gait, and patient states, “I am having a very difficult time walking.”

The patient's difficulty with mobility may also make the patient vulnerable to developing constipation or decreased peripheral blood circulation. In this case, the patient's plan of care may include the risk nursing diagnoses of *Risk for Constipation* (ICNP) with supporting data of decreased peristalsis and limited ambulation, and *Risk for Impaired Peripheral Tissue Perfusion* (ICNP) with supporting data of limited mobility, increased potential for deep vein thrombosis, and patient states, “I am having a very difficult time walking.”

Analysis of patient assessment data may yield several clusters of related data or cues. It is common to apply several nursing diagnoses to one patient. This is especially true for acutely ill patients with multiple problems related to complex physical or psychological needs. For example, one patient may have ICNP nursing diagnoses, such as *Acute Pain*, *Risk for Fall-Related Injury*, *Powerlessness*, and *Impaired Sleep*.

2. List a minimum of three nursing diagnosis labels (not including *Acute Pain*) applicable to C. H.'s current condition.

Diagnostic Validity

Before selecting nursing diagnoses, the nurse reviews available options from either the taxonomy in the EMR or the NANDA-I list to ensure accurate use of the diagnosis. The nurse chooses nursing diagnoses within the EMR or writes nursing diagnostic statements as needed to address the highest-priority needs of the patient. These diagnoses are uniquely based on the assessment data of each patient (Box 7.4). Accurate nursing diagnoses are foundational to the development of an effective, personalized plan of care.

Box 7.4

Diversity Considerations

Life Span

- Assessment that is specific for each individual, regardless of age, is important to establish accurate, applicable nursing diagnoses.
- Making assumptions based solely on a patient's chronologic age without thorough assessment may lead to impersonal, generalized diagnostic statements that do not reflect a patient's true condition or circumstances.

Culture, Ethnicity, and Religion

- Although some medical diagnoses are more common for specific ethnic groups, how patients respond to illnesses varies dramatically, requiring individualized identification of nursing diagnoses.
- Consider the impact of cultural food practices and their influence on patient health when identifying nursing diagnoses.
- Some care plan interventions may conflict with the religious practices of patients. A thorough assessment of each individual is crucial for accuracy in selecting nursing diagnoses and subsequent interventions.

Disability

- The incidence of chronic diseases and conditions, especially high blood pressure, diabetes, and cancer, varies widely by race and ethnicity. The primary focus of nursing diagnosis in the acute care setting is current illness or exacerbation of chronic illness rather than long-term, permanent disabilities.
- When patients with disabilities are being treated for acute or chronic illness, the nurse needs to understand their capabilities and limitations. This enables the nurse to identify appropriate nursing diagnoses that address current patient needs and provide individualized, patient-centered care.

Morphology

- There has been an increase in the number of morbidly obese patients admitted to hospital care and subsequently to home health care services. Nursing diagnoses for these patients should include a focus on long-term needs to support their personal goals and improve their health status.

LO 7.7 Avoiding Problems in the Diagnostic Process

A variety of errors in identification and NANDA-I statement structure or statement content may occur when determining nursing diagnoses. These include clustering unrelated data, accepting erroneous data, missing the true underlying etiology of a problem, using medical diagnoses as related factors in a NANDA-I nursing diagnostic statement, and identifying multiple nursing diagnosis labels in one NANDA-I nursing diagnostic statement.

Data Clustering

Clustering unrelated data most often occurs when the nurse has not completed a thorough review of the patient's assessment information or is missing important data. For example, at first glance, a patient's inability to urinate and minimal oral fluid intake may seem related. However, after further review of the data, the nurse should realize that they are not related; the patient has an intravenous (IV) infusion running at 150 mL/hr that provides adequate hydration, as well as the patient's postoperative status after abdominal surgery. In this case, the patient's inability to urinate most likely results from having had abdominal surgery and may be expected, depending on when the operation was performed. Clustering unrelated data can be avoided with more information.

3. Identify two risk nursing diagnoses for C. H., and provide supporting data for each one.

Accurate Data Collection

Errors in data collection (e.g., omitting key information) or an incomplete understanding or knowledge of assessment techniques or a patient's condition may lead to the inclusion of erroneous data in a NANDA-I nursing diagnostic statement or supporting data list. It is the

nurse's responsibility to collect accurate, extensive assessment data and analyze them on the basis of accurate scientific knowledge. Poor assessment skills or misinterpretation of assessment findings may lead to improper treatment and poor-quality patient care. It is the nurse's responsibility to stay current in nursing research to provide the best care possible.

Safe Practice Alert

Research is being conducted on a continuous basis in the discipline of nursing. Evidence-based nursing practice should always be the realm within which the nurse practices. To ensure safe nursing practice founded on empirical research results, the professional nurse must commit to reading about, discussing, and disseminating the most current and best practices for nursing care.

Inaccurate documentation of data may lead to errors in diagnosis. Accurate documentation is essential to ensure patient safety and to facilitate communication among health care professionals. For example, misinterpretation of a critical laboratory value or recording the absence of dependent edema, although it exists, prevents the accurate diagnosis of patient needs and may endanger a patient's life.

QSEN Focus!

Effectively collecting and documenting patient data contribute to evidence-based practice research and support the accurate diagnosis of patient problems and implementation of best nursing practice.

Formulating Related Factors

The underlying etiology, or cause of a patient's concern or situation, rather than a medical diagnosis, should be used as a related factor when writing a NANDA-I nursing diagnosis statement and can be included in the list of supporting data in the EMR. By doing so, the nurse articulates an understanding of the pathophysiology or situation with which the patient is faced. For instance, for a patient who has the medical diagnosis of pneumonia and has an oxygen saturation of 88% on room air, the first two sections of a proper NANDA-I nursing diagnostic statement may be *Impaired Gas Exchange* (ICNP) related to poor alveolar perfusion. The medical diagnosis of pneumonia, restlessness, change in mental status, and dyspnea can be clustered with the other data as

defining characteristics in a NANDA-I statement or identified as supporting data along with the etiology, poor alveolar perfusion, in the EMR.

Identifying the Correct Cause

The related factor in a NANDA-I problem-focused nursing diagnosis needs to address the underlying etiology of the patient's problem expressed by the nursing diagnostic label rather than listing data that are defining characteristics. This can be achieved by thinking of the related factor as a broad statement of causality rather than specific data or cues that support the diagnosis.

The related factor in a problem-focused NANDA-I nursing diagnosis statement needs to be significantly comprehensive in nature to direct the focus of future nursing interventions. For instance, this is a properly stated problem-focused NANDA-I nursing diagnosis statement:

Impaired Swallowing (ICNP) related to neuromuscular impairment as evidenced by aspiration with liquids noted during swallowing study, observed choking when trying to take liquids, and patient verbalization, "I can't swallow without choking!" Remember that the *related to* section in a NANDA-I diagnostic statement needs to identify the underlying cause of the nursing diagnosis, which is supported by the data listed as defining characteristics. In the EMR, the supporting data for *Impaired Swallowing* (ICNP) would be neuromuscular impairment, aspiration with liquids noted during swallowing study, observed choking when trying to take liquids, and patient verbalization, "I can't swallow without choking!"

Focusing on One Problem at a Time

When writing NANDA-I nursing diagnosis statements, the nurse should avoid inclusion of more than one label in the statement.

Regardless of the type of NANDA-I nursing diagnosis statement being written, only one label should be used in each statement. For example, a preoperative patient who is anxious about surgery and has diarrhea due to the surgical preparation should have these two problems addressed as separate nursing diagnoses. The nurse would not start off by stating "*Anxiety and Diarrhea* related to ..." To address the separate concerns of this patient accurately, the nurse would write two NANDA-I nursing diagnostic statements. One would begin "*Anxiety* related to"; the other would begin "*Diarrhea* related to." Both are approved nursing diagnoses in the ICNP and NANDA-I taxonomies. Including more than one nursing diagnosis label in a NANDA-I diagnostic statement causes

confusion and may prevent the identification and treatment of critical patient concerns due to lack of organization and focus.

4. On discharge, C. H. expresses a desire to improve her health status. Identify two nursing diagnoses focused on health promotion that may apply to her situation and provide a rationale for each.

LO 7.8 Application to Patient Care

By identifying appropriate nursing diagnoses, the nurse enables accurate development of individualized patient plans of care. The nursing diagnosis step of the nursing process leads the nurse to the planning phase, which begins with prioritizing the identified nursing diagnoses. Nursing diagnoses and patient outcomes, which are established during the planning step, help the nurse determine appropriate interventions for patient care. [Chapters 8](#) and [9](#) provide more information on nursing interventions and individualized plans of care based on nursing diagnoses and identified patient outcomes.

Ultimately, nurses are accountable for formulating accurate nursing diagnoses and intervening appropriately. By collecting accurate and complete assessment data and identifying specific nursing diagnoses for each patient, the professional nurse has a significant impact on patient care outcomes, the quality of patient care, and patient satisfaction.

Summary of Learning Outcomes

LO 7.1 *Explain basic nursing diagnosis methodology:* Nursing diagnosis is the second step of the nursing process. When deciding on an accurate nursing diagnosis for a patient or group, the nurse makes clinical judgments about a patient's or group's experiences and responses to identified problems or life events expressed during the data collection process.

LO 7.2 *Describe the historical development of nursing taxonomies:* The original NANDA-I nursing taxonomy was developed in 1973. The ICNP released its first nursing taxonomy in 1996. Both organizations update nursing diagnoses regularly based on the strength of research support.

LO 7.3 *Differentiate among the three types of NANDA-I nursing diagnostic statements:* Problem-focused nursing diagnoses describe the response of a patient, family, group, or community to a current need, problem, or life process. Risk nursing diagnoses identify specific potential problems in individuals or groups vulnerable to developing complications due to their current disease state or life experience. Health promotion nursing diagnoses are clinical judgments based on the expressed desire of patients, families, or groups for change (NANDA-I, 2018).

LO 7.4 *Recognize NANDA-I nursing diagnostic statement configuration with applicable components:* Problem-focused nursing diagnostic statements are written with three parts: (1) a diagnosis label, (2)

related factors, and (3) defining characteristics. Risk nursing diagnoses have two segments: (1) a diagnosis label and (2) risk factors. Health promotion nursing diagnoses are also written with only two sections: (1) a diagnosis label and (2) defining characteristics that indicate an expressed desire for improvement ([NANDA-I, 2018](#)).

LO 7.5 Identify appropriate nursing diagnoses and associated supporting data within an electronic medical record system: Nursing diagnoses in an EMR are typically chosen from a drop-down list that originate from taxonomies, such as the ICNP or CCC. Once the nurse chooses an appropriate nursing diagnosis based on clustered patient data, the nurse selects, or manually enters, patient-specific supporting data, including an etiology (underlying cause), and signs and symptoms related specifically to the diagnosis.

LO 7.6 Implement the steps for accurately identifying nursing diagnoses: Accurate identification of nursing diagnoses for patients is achieved through careful analysis and clustering of patient data, followed by verification of the specific nursing diagnoses for use with each individual patient.

LO 7.7 Discuss how to avoid common problems associated with the diagnostic process: To identify appropriate nursing diagnoses for patients, the nurse must avoid clustering unrelated data, accepting erroneous data, using medical diagnoses as related factors in NANDA-I nursing diagnostic statements, missing the true underlying etiology of a problem, and identifying multiple nursing

diagnoses labels in one NANDA-I nursing diagnostic statement.

LO 7.8 *Articulate the contribution of nursing diagnoses to the individualized care of patients:* As the second step of the nursing process, the nursing diagnosis provides a framework on which nurses provide care to patients in an organized and effective manner. An accurate nursing diagnosis promotes positive patient outcomes, quality patient care, and patient satisfaction.

Review Questions

1. What is the most important reason for nurses to use a standardized taxonomy, such as the ICNP, CCC, or NANDA-I?
 - a. Insurance documentation
 - b. Professional autonomy
 - c. EMR data analysis
 - d. Patient safety
2. Which nursing diagnosis statements are appropriately written according to 2018-2020 NANDA-I format? (*Select all that apply.*)
 - a. *Risk for Infection* (ICNP) related to elevated temperature and white blood count
 - b. Readiness for *Effective Family Process* (ICNP) as evidenced by an expressed desire for improved communication and mutual respect verbalized by family members
 - c. *Impaired health maintenance* (ICNP) related to inability to access care as evidenced by failure to keep appointments, homebound status
 - d. *Risk for Hemorrhaging* (ICNP) as evidenced by prolonged clotting time
 - e. *Chronic Pain* (ICNP) related to osteoarthritis as manifested by verbalized postoperative discomfort
3. Which phrase best represents a related factor in a problem-focused nursing diagnosis?
 - a. Unsteady gait requiring the assistance of two people
 - b. Redness and swelling around the incision site

- c. Ineffective adaptation to recent loss
 - d. Patient complaint of restlessness
4. Which actions does the nurse need to take before determining the types of nursing diagnoses that are applicable to a patient? (*Select all that apply.*)
- a. Review the patient's past and present medical history.
 - b. Analyze the nursing assessment data to determine whether information is complete.
 - c. Outline an individualized plan of care to address each concern.
 - d. Consider potential complications to which the patient is susceptible.
 - e. Evaluate how the patient has responded to treatment.
5. What is the primary difference between a NANDA-I risk nursing diagnosis and a problem-focused nursing diagnosis?
- a. Related factors are not part of a risk diagnosis.
 - b. There is no cause and effect relationship established.
 - c. Defining characteristics are subjective in a risk diagnosis.
 - d. There are no nursing interventions prescribed with a risk diagnosis.
6. What is the most important action for a nurse to take to have a new nursing diagnosis considered for inclusion in the ICNP or NANDA-I taxonomies?
- a. Share concerns with the nurse manager on the nursing unit.

- b. Offer alternative care for a patient and family members.
 - c. Discuss how to address patient needs with physicians.
 - d. Provide evidence-based research to support nursing care.
7. What is the most significant problem that may result from improperly written NANDA-I nursing diagnostic statements?
- a. Lack of direction for formulating patient plans of care
 - b. Omission of physician or primary care provider orders
 - c. Combining of two unrelated patient concerns
 - d. Increased team collaboration needs
8. Which statement best describes the relationship of medical diagnoses and nursing diagnoses?
- a. Medical diagnoses are imbedded in nursing diagnoses.
 - b. Nursing diagnoses are derived from medical diagnoses.
 - c. Medical diagnoses are not relevant to nursing diagnoses.
 - d. Medical diagnoses may be interrelated to nursing diagnoses.
9. A patient has just experienced a cardiac arrest on the unit. The nurse has implemented the acute care plan for management of code situations. What is the next step the nurse should take?

- a. Resume all interventions for previously identified nursing diagnoses.
 - b. Perform the steps of the nursing process related to the patient's current condition.
 - c. Seek physician input related to updating the nursing diagnosis statements.
 - d. Evaluate the success of the acute care plan for management of the cardiac arrest.
10. What signs and symptoms would the nurse appropriately cluster as supporting data for a patient with extreme anxiety? (*Select all that apply.*)
- a. Denies any difficulty falling asleep
 - b. Elevated pulse rate auscultated at 140 bpm
 - c. Continuous foot tapping throughout intake interview
 - d. Demonstrates how to give insulin self-injection without hesitation
 - e. Patient states, "I feel nervous all the time, especially when I am alone."

CHAPTER 8

Planning

LEARNING OUTCOMES

Comprehension of this chapter's content will provide students with the ability to:

- LO 8.1 Articulate nursing actions that take place during the planning process.
- LO 8.2 Describe various measures used in prioritizing patient care.
- LO 8.3 Illustrate an understanding of goal development.
- LO 8.4 Describe the relationship between outcome identification and goal attainment.
- LO 8.5 Identify formats in which patient-centered plans of care can be developed.
- LO 8.6 Distinguish among the types of interventions.
- LO 8.7 Discuss the importance of planning throughout patient care.

KEY TERMS

long-term goals, p. 102

Nursing Interventions Classification, p. 104

Nursing Outcomes Classification, p. 103

outcome indicators, p. 103

short-term goals, p. 102

Case Study

Viola Rizzi (V.R.) is a 64-year-old woman who was diagnosed 1 year earlier with end-stage renal disease. On Monday, she is admitted to the hospital with a 15-lb weight gain over the past 4 days, blood pressure of 210/120 mm Hg, pulse of 104 beats/min and regular, and respirations at 32 breaths/min with shortness of breath and crackles heard bilaterally on auscultation. Her pulse oximetry reading is 92% on 2 L of oxygen. She states, “I am so short of breath!” Her ankles are swollen with 3+ pitting edema, and she verbalizes that she is tired. V.R. typically has hemodialysis treatments through an arteriovenous (AV) graft three times each week on Tuesday, Thursday, and Saturday. She reports that she had transportation problems on Saturday and has not had dialysis since last Thursday. Her AV graft, located on the right forearm, is functional, with a strong thrill and bruit and without redness, swelling, or drainage. Her laboratory work reveals elevated potassium, low calcium, low hematocrit and hemoglobin, low serum albumin, and elevated blood urea nitrogen (BUN) and creatinine levels. V.R. is placed on telemetry to monitor her cardiac function until her fluid volume overload and hyperkalemia are resolved.

Treatment includes vital signs taken every 4 hours, fluid restriction to 1000 mL/day, intake and output measurements, daily weight measurement, complete blood count (CBC) and chemistry evaluations every morning, urinalysis when urine is available, hemodialysis initially and daily for 2 days, monitoring with a telemetry unit, a bone density x-ray, a chest x-ray, and an electrocardiogram. The patient was maintained on a 1500-calorie renal diet and bed rest with bathroom privileges.

The nurse on the previous shift admitted V.R. and identified the following [International Classification for Nursing Practice \(ICNP\)](#) nursing diagnoses:

Hypervolemia

- *Supporting Data:* Compromised renal function, a 15-lb weight gain, compromised lung function, crackles, swollen ankles, elevated blood pressure and heart rate

Impaired Breathing

- *Supporting Data:* Increased fluid in lungs, increased respiratory rate, crackles on auscultation, shortness of breath observed and stated by the patient

Risk for Injury

- *Supporting Data:* Hypocalcemia, possible phosphorous retention, bone reabsorption of calcium, increased parathyroid hormone level, inadequate calcium absorption

Risk for Infection

- *Supporting Data:* Hemodialysis access, AV graft cannulation

Impaired Health Maintenance

- *Supporting Data:* Limited transportation options, stated inability to get to dialysis appointment on Saturday, fluid retention due to missing dialysis, electrolyte imbalance

Refer back to this case study to answer the critical-thinking questions throughout the chapter.

Planning is the third step of the nursing process. During the planning phase, the professional nurse prioritizes the patient's nursing diagnoses, determines short- and long-term goals, identifies outcome indicators, and lists nursing interventions for patient-centered care. Each of these actions requires careful consideration of assessment data and a thorough understanding of the relationship among nursing diagnoses, goals, and evidence-based interventions.

LO 8.1 The Planning Process

Critical decisions regarding the patient are made during the planning step of the nursing process (Fig. 8.1). To begin planning, the nurse prioritizes each nursing diagnosis that is identified and establishes goals in collaboration with the patient. The nurse identifies the most urgent goals to be addressed, considers the patient's capabilities, and then selects interventions to include in the patient's individualized plan of care. The order in which nursing diagnoses are addressed depends on factors such as the severity of symptoms and the patient's preference. For example, a patient's ability to breathe is of greater concern than the ability to complete activities of daily living independently. After emergent needs are met, less critical needs are addressed. The nurse's ability to prioritize patient needs expressed through nursing diagnoses is essential for establishing realistic outcome criteria and interventions to help meet them. Goals are set for short- and long-term attainment.

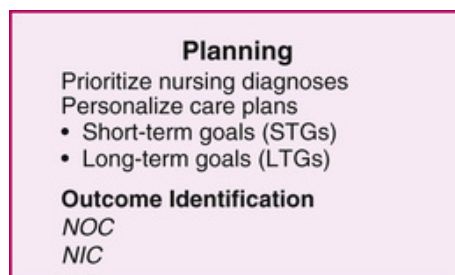

FIGURE 8.1 Planning in the nursing process. *NOC*, Nursing Outcomes Classification; *NIC*, Nursing Interventions Classification.

Patients should be included in the planning process. Involving patients in planning their care helps them (1) be aware of identified needs, (2) accept realistic and measurable goals, and (3) embrace interventions to best achieve the mutually agreed-on goals. Inclusion of patients in the planning process tends to improve goal attainment and patient cooperation with interventions. By accepting guidance and input from patients during the planning process the nurse provides them with a greater sense of empowerment and control. A large portion of the success in or progress toward achieving the goals remains within the patient's power!

QSEN Focus!

Nursing care should consistently acknowledge the worth of the individual, recognizing that each person views life and makes treatment choices based on unique life experiences.

Depending on the patient's condition or circumstances, it may be advantageous to include members of the patient's support system (i.e., family, friends, and caregivers) in the planning phase. Including patients and their families enhances their understanding of identified needs and increases their sense of ownership in working toward the established goals. The professional nurse is instrumental in communicating and teaching the steps necessary for patient improvement. It is imperative for the patient to understand the plan of care and be an active participant in the nursing interventions.

LO 8.2 Prioritizing Care

Setting priorities among identified nursing diagnoses is the first step in the planning process. The nurse is responsible for monitoring patient responses, making decisions culminating in a plan of care, and implementing interventions, including interdisciplinary collaboration and referral, as needed (Box 8.1). The nurse is significantly accountable for patient achievement of desired outcomes. Providing safe and effective care to all patients is a national priority. Nurses are constantly challenged by increasing patient comorbidities (two or more medical conditions or disease processes occurring at the same time) and greater complexity of patient needs.

Box 8.1

Ethical, Legal, and Professional Practice

Standards of Care Guide Practice

- Professional nurses have more accountability now than at any other time in the history of nursing.
- Standards of care are met through the prudent performance of the nursing process.
- The planning step is critical for guiding patient care to acceptable patient outcomes.
- Standards of care for nursing practice are legal requirements of nursing knowledge and competency.
- Laws such as state nurse practice acts and regulatory requirements of programs and private institutions determine minimum standards of care. Oversight of nurses' adherence to standards of care is the legal responsibility of members of state boards of nursing or other governmental agencies (Zerwekh & Garneau, 2018).
- The planning step provides concrete evidence to support the accuracy and pertinence of the patient care plan.
- Conscientious practice of the nursing process in development of the patient care plan ensures that professional standards of care are being met.

Maslow's Hierarchy of Needs

Use of Maslow's (1987) hierarchy of needs helps organize the most urgent to less urgent needs. This framework organizes patient data according to

basic human needs common to all individuals. Maslow's theory suggests that basic needs, such as physiologic needs, must be met before higher needs, such as self-esteem (Table 8.1). Applying this theory to the prioritization of nursing diagnoses means that a patient's nursing diagnosis of *Nausea* (ICNP) is of more immediate concern than the patient's *Impaired Socialization* (ICNP). Even in this case, the needs of the patient may be related. A patient experiencing nausea (because of chemotherapy treatment or as a reaction to medication) may increase interactions with others after the nausea is relieved. This example underscores the interrelatedness of patient responses to illness and life situations.

TABLE 8.1

Maslow's Hierarchy of Needs Applied to Patient Data

LEVEL OF NEEDS	EXAMPLES OF DATA
Physiologic: Basic survival needs	Airway patency, breathing, circulation, oxygen level, nutrition, fluid intake, body temperature regulation, warmth, elimination, shelter, sexuality, infection, pain level
Safety and security: Need to be safe and comfortable	Physical safety (falls and drug side effects), psychological security (knowledge of routines and procedures, bedtime rituals, fear of isolation and dependence needs)
Love and belonging: Need for love and affection	Compassion of care provider, information from family and significant others, strength of support system
Self-esteem: Need to feel good about oneself	Changes in body image (injury, surgery, puberty), changes in self-concept (ability to perform usual role functions), pride in abilities
Self-actualization: Need to fulfill maximum potential; need for growth and change	Goal attainment, autonomy, motivation, problem-solving abilities, ability to provide and accept help, feeling of accomplishment, desired roles

Modified from Maslow, A.H. (1987). *Motivation and personality* (3rd ed.). New York: Harper & Row.

Life-Threatening Concerns Versus Routine Care

It is essential that the nurse identify life-threatening concerns and patient situations that need to be addressed most quickly. The ABCs of life support in the health care setting (airway, breathing, and circulation) are a valuable tool for directing the nurse's thought process. Depending on the severity of a problem, the steps of the nursing process may be performed in a matter of seconds. For instance, if a patient is in respiratory arrest, the most critical goal is for the patient to begin breathing.

In critical situations, the steps of the nursing process are performed through instant clinical reasoning by the nurse and do not involve patient input. The necessity for this type of rapid clinical judgment requires the nurse to have the ability to recognize the existence of crises, have extensive knowledge of current best practice, and have excellent professional skills. Optimal patient safety requires nurses to acquire and continually improve their assessment and critical-thinking skills. After a patient is stabilized, the

nurse continues assessment to evaluate the patient's updated status, determine possible causes of complications, and identify less urgent goals and interventions for care.

Some situations fall between life-threatening and routine, and the patient's needs require a proportional response. For example, a patient's need for medication to relieve pain rated 3/10 is not as urgent as a patient's need for relief of pain rated 10/10. Likewise, a pain level of 10 that does not appear to affect the patient's ability to breathe is severe, but it is not as life-threatening as an ABC problem. The patient's feelings about which concerns are most important influence the ranking of nursing diagnoses in addition to clinical judgment. For situations in which no life-threatening concern exists, goal setting for a patient-centered plan of care must take patient preferences into consideration.

Conflicting Priorities

Occasionally, the nurse and patient have conflicting priorities. The nurse and patient may have different beliefs and values regarding health practices. Based on prior experiences, each may reach conclusions before fully understanding the other's perspective. Patients may have difficulty accepting and making necessary lifestyle changes. Finding time to exercise when a patient typically works 12 hours each day or giving up traditional cultural foods due to medication interactions can be challenging. Identifying realistic goals that are acceptable to patients and include adherence to sound health care regimens requires time and cooperation by everyone involved in the goal-setting process. Nurse–patient collaboration in the goal-setting process can help alleviate the incidence of conflicting priorities.

Planning that includes patient teaching to support goal attainment and explain the importance and implementation of interventions is a core nursing responsibility. If patients do not understand what has been taught, the potential for goal achievement is diminished. The nurse must account for individual differences in goal planning to facilitate effective teaching and positive patient outcomes (Box 8.2).

Box 8.2

Diversity Considerations

Life Span

- Research assessing the health literacy of over 25,000 patients indicated inadequate health literacy in a majority of patients 66 years and older (Sand-Jecklin, Daniels, & Lucke-Wold, 2017).

- Face-to-face communication is the most effective method of providing patient education for older adults (Brooks, Ballinger, Nutbeam, & Adams, 2016).
- The ability of a patient to grasp the importance of goals is directly related to the patient's comprehension of the purpose for recommended treatments and interventions. Patient education by nurses facilitates greater understanding of all aspects of the planning process.

Gender

- Research indicates that women have higher health literacy than do men (Sand-Jecklin, Daniels, & Lucke-Wold, 2017).
- Sixteen percent of men and 12% of women had below basic health literacy in the most recent National Assessment of Adult Literacy (NAAL) in the United States (Kutner, Greenberg, Jin, & Paulsen, 2006).
- Time taken to educate all patients during the goal-setting process is valuable for achieving positive outcomes.

Culture, Ethnicity, and Religion

- Minority patients globally and those with low English proficiency in the United States are especially vulnerable to low health literacy (Nguyen, Park, Han, et al., 2015).
- The *Agency for Healthcare Research and Quality (AHRQ) Health Literacy Universal Precautions Toolkit, 2nd edition* can assist nurses in meeting the health literacy needs of patients and families. The toolkit is available at <https://www.ahrq.gov/professionals/quality-patient-safety/quality-resources/tools/literacy-toolkit/healthlittoolkit2.html>.
- Interpretation should be made available to all patients whose primary language is different from that of the care provider.
- Nurses need to ask about cultural norms and religious traditions and preferences while formulating patient care goals for all individuals.

Disability

- Before implementing teaching strategies to support goal attainment, the nurse must explore a patient's disabilities and the effects they may have on achieving specific goals. Successful accommodation of a patient's disabilities should yield attainable goals that lead to positive outcomes.

Morphology

- For the morbidly obese patient, success in addressing healthy interventions and moving toward a healthier body mass index can depend on realistic goal setting and patient teaching. These patients require keen assessment by the nurse and accommodation considerations for goal achievement.

1. Prioritize the nursing diagnoses identified for V.R. from most important to address first to the least urgent.

LO 8.3 Goal Development

Goals are broad statements of purpose that describe the aim of nursing care. Goals represent short- or long-term objectives that are determined during the planning step. Some sources establish time parameters for short- and long-term goals, whereas others do not. According to [Carpenito \(2016\)](#), goals that are achievable in less than a week are **short-term goals**, and goals that take weeks or months to achieve are **long-term goals**. A short-term goal for a morbidly obese patient might be “Patient will lose 1 lb during 1 week's hospitalization.” A long-term goal for this patient might be “Patient will lose 50 lb in 1 year.”

Useful and effective goals have certain characteristics. They are mutually acceptable to the nurse, patient, and family. They are appropriate in terms of nursing and medical diagnoses and therapy. The goals are realistic in terms of the patient's capabilities, time, energy, and resources, and they are specific enough to be understood clearly by the patient and other nurses. They can be measured to facilitate evaluation.

The nurse creates goals with the patient and possibly with the family by discussing the patient's current condition, the condition to which the patient wants to progress, and the actions the patient and nurse undertake to accomplish the goal. The nurse's input into this process is critical to developing reasonable goals and interventions. Without the nurse's guidance during this step, the goals and interventions may be too weak to promote the patient's success or too aggressive for the patient to achieve. The nurse works with the patient to develop a plan of care that is reasonable, is appropriately challenging, and promotes patient success for goal attainment.

Goal Characteristics

Goals are statements designed in collaboration with patients to provide guidance and ultimately a measure of progress when addressing nursing diagnoses (i.e., patient problems). The goals should be realistic, patient centered, and measurable.

Realistic Goals

Realistic goals consider the patient's physical, mental, and spiritual condition in relation to the ability to attain goals. The nurse must consider the effects of conditions, such as severe pain related to recent surgery or clinical depression or hopelessness, on the ability of the patient to reach goals in a timely manner. Other barriers to goal attainment may be related to economic issues or available resources. Some goals may be too ambitious to attain and need to be reevaluated and revised.

Patient-Centered Goals

Patient-centered goals are written specifically for the patient. The goal should specify the activity the patient is to exhibit or demonstrate to indicate goal attainment. The activity may be the patient ambulating, eating, turning, coughing and deep breathing, or any number of other activities. These goals are written to reflect patient, not nursing, activities.

Measurable Goals

Measurable goals are specific, with numeric parameters or other concrete methods of judging whether the goal was met. When writing a goal statement with a patient, the nurse needs to clearly identify how achievement of the goal will be evaluated. When terms such as *acceptable* or *normal* are used in a goal statement, goal attainment is difficult to judge because they are not measurable terms, unless they refer to laboratory values or diagnostic test findings. For example, although there is a normal range for blood pressure, the goal “The patient's morning blood pressure will be between 120 and 140 mm Hg systolic and 70 and 90 mm Hg diastolic” is preferable to “Blood pressure will be within the normal range.” Physiologic norms vary somewhat from person to person and sometimes depend on age and ability. The use of measurable verbs when writing goals and outcomes is essential for establishing criteria with which attainment can be evaluated (Box 8.3).

Box 8.3

Measurable Verbs for Writing Goals and Outcomes

- Administer
- Ambulate
- Articulate
- Attend
- Call
- Cough
- Create
- Decide
- Demonstrate
- Describe
- Design
- Discuss
- Exercise

- Express
- Identify
- Inject
- List
- Perform
- Report
- Schedule
- Select
- Share
- Sit
- Stand
- State
- Touch
- Verbalize
- Walk
- Watch
- Weigh

Time-Limited Goals

In most cases, goal statements need to include a time for evaluation. The time depends on the intervention and the patient's condition. Some goals may need to be evaluated daily or weekly, and others may be evaluated monthly. The health care setting affects the time of evaluation. If the goal is set during hospitalization, the goal may need to be evaluated within days, whereas a goal set for home care may be evaluated weekly or monthly. At the time of evaluation, the goal is assessed for goal attainment, and new goals are set or a new evaluation date for the same goal may be chosen if the goal is still applicable for the patient care plan.

LO 8.4 Outcome Identification and Goal Attainment

Outcome identification, which was added by the American Nurses Association (ANA) in 1991 as a specific aspect of the nursing process, involves listing observable behaviors or items that indicate attainment of a goal. Similar to standard language taxonomies for nursing diagnoses, there are taxonomies for nursing outcomes including the International Classification for Nursing Practice (ICNP), the Clinical Care Classification System (CCC), and *Nursing Outcomes Classification (NOC)*. NOC is a standardized vocabulary used for describing patient outcomes. In this system, an outcome is “an individual, family, or community state, behavior, or perception that is measured along a continuum in response to nursing interventions” (Moorhead, Swanson, Johnson, & Maas, 2018). **Outcome indicators** are criteria by which goal attainment is observed or measured.

Moorhead and colleagues (2018) think that for the nursing profession to become a full participant in clinical evaluation research, policy development, and interdisciplinary work, patient outcomes influenced by nursing care must be identified and measured. Nurses play a critical role in achievement of positive outcomes and in outcome identification. An example of a measurable goal statement and a NOC and indicator is provided in Table 8.2.

TABLE 8.2
Goal Statement and Nursing Outcome Classification and Indicator

ICNP NURSING DIAGNOSIS WITH SUPPORTING DATA	MEASURABLE GOAL	NURSING OUTCOME CLASSIFICATION (NOC) AND INDICATOR
<i>Hyperthermia</i> Illness Temperature elevation of 102.4°F Skin warm to touch	Patient's temperature will return to between 98.2° and 98.6°F within 48 h.	<i>Vital signs</i> Body temperature

2. Write one short-term goal or desired outcome for each of V.R.'s identified nursing diagnoses.

LO 8.5 Care Plan Development

There are multiple formats in which to develop individualized care plans for patients, families, and communities. Each health care agency has its own form, including electronic formats, to facilitate the documentation of patient goals and formulate individualized, patient-centered plans of care. All formats contain areas in which the nurse identifies key assessment data, nursing diagnoses, goals, interventions for care, and evaluation of outcomes. In most agencies and specialty units, standardized care plans that must be individualized for each patient are available to guide nurses in the planning process. These types of plans, including clinical pathways, are addressed in [Chapter 9](#).

In formulating patient care plans, students can use the conceptual care map (CCM). This tool facilitates the organization of assessment data, nursing orders, and physician orders (i.e., treatments); analysis of medication orders and laboratory and diagnostic testing results; and development of a plan of care based on the patient's total picture. [Fig. 8.2](#) shows a partially completed CCM. It is a combination of a concept map and a care plan. This format for care plan development enhances the nursing student's ability to accurately collect, analyze, and synthesize patient data for identifying appropriate nursing diagnoses, goals, and interventions. It can be used to organize patient data and develop a plan of care. The patient data in the assessment area of the CCM can be organized in a variety of ways, including by a head-to-toe approach, body systems, or Gordon's functional health patterns.

The conceptual care map provided in [Fig. 8.2](#) is partially completed to indicate how to use the map as a learning tool. Using it as an example, complete Nursing Diagnoses 2 and 3.

LO 8.6 Types of Interventions

During the planning phase of the nursing process, the nurse works with the patient, family, and other caregivers to design activities that can assist the patient in improving health and attaining goals. These activities are called *interventions*. The three types of interventions—independent, dependent, and collaborative—take into consideration five key elements:

- Patient assessment findings indicating signs and symptoms that have resulted from or occurred in response to an illness or life experience
- The underlying etiology or related factor identified in each nursing diagnosis
- Realistic patient outcomes considering the patient's health status and resources for improvement
- Evidence-based interventions aligned with patient acceptance and practicality
- Expertise of the nurses and other health care professionals and agencies involved in the patient's care

The nurse is primarily responsible for making decisions about which interventions are best suited to meet a patient's individual needs. There is no substitute for an extensive understanding of the nursing process, excellent skill set, knowledge of best nursing practices, and compassion for a patient's situation. Professional nursing practice guides each aspect of decision making in the planning process ([Box 8.4](#)).

Box 8.4

Evidence-Based Practice and Informatics

Engaging Nurses in Point-of-Care Research Increases Evidence-Based Practice

Nurses are accountable for the quality and systematic improvement of nursing practice ([ANA, 2015](#)).

- Nurses often choose interventions based on tradition rather than research findings.
- Research indicates that patient outcomes improve when evidence-based practice is incorporated into patient plans of care.
- Individual barriers to research utilization by nurses include a lack of knowledge of the research process and perceived lack of authority to change practice.
- Institutional barriers to implementation of evidence-based practice are identified as insufficient time to implement research findings and lack of access to research.
- Empowering nurses to identify clinical concerns and participate in point-of-care research themselves increases their confidence and excitement about their nursing practice.
- Nurses must take responsibility for researching and incorporating evidence-supported nursing interventions into patient care plans.
- Excellent websites for EBP point-of-care resources from which nurses can obtain information are Nursing Reference Center, Mosby's Nursing Consult, and JBI COnNECT+.

From Black, A., Balneaves, L., Garossino, C., Puyat, J., & Qian, H. (2015). Promoting evidence-based practice through a research training program for point-of-care clinicians. *The Journal of Nursing Administration* 45(1), 14-20; Campbell, J., Umaphathysivam, K., Xue, Y., & Lockwood, C. (2015). Evidence-based practice point-of-care resources: A quantitative evaluation of quality, rigor, and content. *Worldviews on Evidence-Based Nursing*, 12(6), 313-327.

Independent Nursing Interventions

The ability of nurses to enact independent interventions has expanded in recent years, allowing nurses to initiate care that they recognize as essential in meeting patient needs or preventing complications. Ordering heel protectors for patients susceptible to skin breakdown and initiating preventive measures (e.g., activity regimens, consultations with social workers, preadmission teaching) are often independent, nurse-initiated interventions.

Methods of determining interventions to meet patient outcome goals is to use intervention taxonomies such as ICNP, CCC, or *Nursing Interventions Classification (NIC)*. NIC is a comprehensive, research-based, standardized collection of interventions and associated activities. NIC provides nurses with multidisciplinary interventions linked to a nursing diagnosis and a corresponding NOC. It is useful for clinical documentation, communication of care across settings, integration of data across systems and situations, effectiveness research, productivity measurement, competency evaluation, reimbursement, and curricular design. Each NIC includes associated

activities that nurses do on behalf of patients, independent and collaborative interventions, and direct and indirect care (Butcher, Bulechek, Dochterman, & Wagner, 2018). An example of a NIC with associated activities is provided in Table 8.3.

TABLE 8.3
Nursing Intervention Classification and Associated Activities

ICNP NURSING DIAGNOSIS WITH SUPPORTING DATA	NURSING INTERVENTION CLASSIFICATION (NIC)	ASSOCIATED ACTIVITIES
<i>Hyperthermia</i> Illness Temperature elevation of 102.4°F Skin warm to touch	<i>Temperature regulation</i>	1. Monitor temperature at least q 2 h, as appropriate. 2. Monitor skin color and temperature. 3. Administer antipyretic medication, as appropriate.

From Butcher, H.K., Bulechek, G.M., Dochterman, J.M., & Wagner, C. (2018). *Nursing interventions classification (NIC)* (7th ed.). St. Louis: Mosby; Moorhead, S., Swanson, E., Johnson, M., & Maas, M. (Eds.) (2018). *Nursing outcomes classification (NOC)* (6th ed.). St. Louis: Mosby. ICNP is owned and copyrighted by the International Council of Nurses (ICN). Reproduced with permission of the copyright holder.

Dependent Nursing Interventions

Some interventions originate from health care provider orders. The nurse incorporates these orders into the patient's overall care plan by associating each with the appropriate nursing diagnosis. Dependent nursing interventions include orders for oxygen administration, dietary requirements, medications, and diagnostic tests. Dependent interventions complement independent nursing interventions to address patient needs more fully. As the role of the advanced practice nurse expands, nurse practitioners are becoming increasingly responsible for what were traditionally considered only physician-initiated interventions. The associated activities shown in Table 8.4 are both independent and dependent nursing interventions. Monitoring the patient's temperature and skin color are independent nursing interventions, whereas administering antipyretics is a dependent action.

TABLE 8.4**Care Plan With Independent and Dependent Nursing Interventions**

ICNP NURSING DIAGNOSIS WITH SUPPORTING DATA	MEASURABLE GOAL	NURSING OUTCOME CLASSIFICATION (NOC) AND INDICATOR	NURSING INTERVENTION CLASSIFICATION (NIC)	ASSOCIATED ACTIVITIES
<i>Hyperthermia</i> Illness Temperature elevation of 102.4°F Skin warm to touch	Patient's temperature will return to between 98.2° and 98.6°F within 48 h.	<i>Vital signs</i> Body temperature	<i>Temperature regulation</i>	1. Monitor temperature at least q 2 h, as appropriate. 2. Monitor skin color and temperature. 3. Administer antipyretic medication, as appropriate.

From Butcher, H.K., Bulechek, G.M., Dochterman, J.M., & Wagner, C. (2018). *Nursing interventions classification (NIC)* (7th ed.). St. Louis: Mosby; Moorhead, S., Swanson, E., Johnson, M., & Maas, M. (Eds.) (2018). *Nursing outcomes classification (NOC)* (6th ed.). St. Louis: Mosby. ICNP is owned and copyrighted by the International Council of Nurses (ICN). Reproduced with permission of the copyright holder.

Collaborative Interventions

Collaborative interventions require cooperation among health care professionals and unlicensed assistive personnel (UAP). Collaborative interventions include activities such as physical therapy, home health care, personal care, spiritual counseling, medication reconciliation, and palliative or hospice care (Box 8.5). These types of interventions require consultation with other health care professionals or referrals to specialists or agencies for assistance.

Box 8.5

Interprofessional Collaboration and Delegation

Transitional Care from Hospital to Home

- Coordination between hospital personnel and health care professionals after a patient is discharged is critical to patient safety.
- Accurate communication among members of the interdisciplinary health care team is essential to ensure that patients receive treatments

and medications that are ordered.

- Depending on the individual patient's needs, nurses may collaborate with multiple members of the health care team, including pharmacists, respiratory therapists, physical and occupational therapists, social workers, primary care providers, rehabilitation facility personnel, and home care providers.
- According to research findings, transitional care interventions (TCI) to reduce hospital readmission rates include:
 - nurse-led coordination of care
 - telephone follow-up
 - medication reconciliation
 - multidisciplinary clinics
 - inpatient education
 - engagement of patients and caregivers
 - home care

Implementation of a transitional care intervention (TCI) bundle significantly reduces 30-day hospital readmission rates underscoring the critical need for a collaborative approach to patient discharge and follow-up.

From Lee, J. (2017). Transitional care intervention: A readmission solution. *Nursing Management* 48(3), 32-39.

Collaborative interventions may involve the expertise of a few or many members of the health care team. In the case of home or hospice care, the nurse is most often the care planner and coordinator of care among many health care team members before, during, and after acute care. Care planning cannot be delegated to UAP.

3. Considering each identified short-term goal or desired outcome, identify at least one intervention per goal or outcome that should be included in V.R.'s care plan.

4. Provide a list of interdisciplinary team members that V.R.'s physician or nurse may need to consult with during her hospitalization.

LO 8.7 Planning Throughout Patient Care

Planning patient care is an ongoing process that takes place at a variety of times and in many settings. Care planning begins when a patient and nurse first interact, and it continues until the patient no longer requires care. The process of planning is similar in all circumstances, even if the setting or timing varies. Seamless communication throughout a patient's care ensures continuity of treatment and improved patient outcomes.

Preadmission teaching is a significant role for the outpatient surgery or office nurse who contacts patients before testing or surgery to educate them on preadmission procedures and facilitate their cooperation. Through early intervention, patients learn what will happen, and they are better prepared for health care experiences. This increased understanding aids patients as they approach diagnostic testing or surgery (Box 8.6).

Box 8.6

Patient Education and Health Literacy

Preoperative Patient Teaching

Effective preoperative teaching has a significant impact on patient satisfaction and outcomes.

Sharing information focused on patient safety is essential. Effective preoperative teaching has been shown to:

- reduce postoperative complications, fear, anxiety, and stress
- increase postoperative pain control
- decrease patient length of stay
- decrease recovery time after discharge.

Providing written materials for patient or caregiver reference reinforces preoperative teaching and is an excellent resource after discharge.

From Lewis, S., Bucher, L., Heitkemper, M., & Harding, M. (2017). *Medical-surgical nursing: Assessment and management of clinical problems* (10th ed.). St. Louis: Elsevier; Ping, G. (2014). Preoperative education interventions to reduce anxiety and improve recovery among cardiac surgery patients: A review of randomized controlled trials. *Journal of Clinical Nursing*, 24, 34.

Acute care, community, and home care nurses continually review patient data to determine the need for revised goal setting and care plans.

Discharge planning plays an important role in the success of a patient's transition to the home setting after hospitalization (Box 8.7). Because most patients are in the hospital for only a short time, nurses must begin discharge planning on admission and continue until a patient is dismissed. Research shows that comprehensive discharge planning reduces medication errors and readmissions (Sexson, Lindauer, & Harvath, 2017). Home care planning adapts to the situation as the patient's condition improves or deteriorates due to advancing disease.

Box 8.7

Home Care Considerations

Discharge Planning

- Early, structured discharge planning ensures a smoother transition of patients from hospital to home.
- To better ensure medication administration safety after discharge, it is important to identify the person who will oversee medication administration in the home.
- Goals of care need to be discussed with both the patient and caregivers.
- Providing both verbal and written care instructions and medication administration instructions is important to patient safety.
- Stress the importance of patient and caregiver communication with the primary care provider before adjusting medication dosage or frequency of administration.
- Verification of access to food and medication as well as other required services is an important aspect of discharge planning.

Adapted from Sexson, K., Lindauer, A., & Harvath, T. (2017). Discharge planning and teaching. *The American Journal of Nursing*, 117(5), 58-60.

The significance of developing organized plans of care for patients cannot be stressed enough. The nurse must take seriously the responsibility of prioritizing patient needs, developing mutually agreed-on goals, determining outcome criteria, and identifying interventions that can help patients achieve positive outcomes. After these actions are completed in the planning phase of the nursing process, it is time for implementation of the patient's plan of care.

Summary of Learning Outcomes

LO 8.1 *Articulate nursing actions that take place during the planning process:* During planning, the professional nurse prioritizes the patient's nursing diagnoses, determines short- and long-term goals, identifies outcome indicators, and lists nursing interventions for patient-centered care.

LO 8.2 *Describe various measures used in prioritizing patient care:* Maslow's hierarchy of needs and the ABCs of life support in the health care setting are helpful resources in prioritizing care. Collaboration with patients while developing goals can decrease the incidence of conflicting priorities.

LO 8.3 *Illustrate an understanding of goal development:* Goals need to be patient centered, realistic, and measurable. Using measurable verbs and time limits when writing goals assists the nurse in evaluation of patient goal attainment.

LO 8.4 *Describe the relationship between outcome identification and goal attainment:* Outcome identification, added by ANA in 1991 as a specific aspect of the nursing process, involves listing observable behaviors or items that indicate attainment of a goal.

LO 8.5 *Identify formats in which patient-centered plans of care can be developed:* Each health care facility or agency has its own electronic health record or form on which patient care plans are formulated and documented. In some agencies and specialty units, standardized care plans, which must be individualized for each patient, are available to guide nurses in the planning process. The conceptual care map (CCM) is a format for nursing students to use when developing patient care plans. It helps students accurately collect, analyze, and

synthesize patient data that are used to identify appropriate nursing diagnoses, goals, and interventions.

LO 8.6 *Distinguish among the types of interventions:*

Independent interventions are nurse initiated, and dependent nursing interventions require an order from a patient's health care provider. Collaborative interventions require cooperation among a few or many members of the interdisciplinary health care team.

LO 8.7 *Discuss the importance of planning throughout patient care:* Care planning begins when a patient and nurse first interact and continues until the patient no longer requires care. It takes place at a variety of times and places. It can include preadmission, acute care, home care, and discharge planning. Seamless communication throughout a patient's care ensures continuity of treatment and improved patient outcomes.

Review Questions

1. Which action would the nurse undertake first when beginning to formulate a patient's plan of care?
 - a. List possible treatment options
 - b. Identify realistic outcome indicators
 - c. Consult with health care team members
 - d. Rank patient concerns from assessment data
2. Which resource is most helpful when prioritizing identified nursing diagnoses?
 - a. *Nursing Interventions Classification (NIC)*
 - b. Gordon's functional health patterns
 - c. Maslow's hierarchy of needs
 - d. *Nursing Outcomes Classification (NOC)*
3. If a patient is exhibiting signs and symptoms of each of these nursing diagnoses, which should the nurse address first while planning care?
 - a. *Fatigue*
 - b. *Acute Pain*
 - c. *Lack of Knowledge*
 - d. *Disturbed Body Image*
4. Which statement illustrates a characteristic of goals within the care planning process?
 - a. Goals are vague objectives communicating expectations for improvement.
 - b. Short-term goals need not be measurable, unlike long-term goals.
 - c. Goal attainment can be measured by identifying nursing interventions.

- d. Long-term goals are helpful in judging a patient's progress.
5. Which nursing goal is written correctly for a patient with the nursing diagnosis of *Risk for Infection* after abdominal surgery?
- a. Nurse will encourage use of sterile technique during each dressing change.
 - b. Patient's white blood count will remain within normal range throughout hospitalization.
 - c. Patient's visitors will be instructed in proper handwashing before direct interaction with patient.
 - d. Patient will understand the importance of cleaning around the incision with a clean cloth during bathing.
6. If the nurse chooses the *Nursing Outcome Classification (NOC)*, Appetite for a chemotherapy patient, which outcome indicators would be acceptable for evaluation of goal attainment? (*Select all that apply.*)
- a. Expressed desire to eat
 - b. Report that food smells good
 - c. Use of relaxation techniques before meals
 - d. Preparation of home-cooked meals for self and family
 - e. Uses nutritional information on labels to guide selections
7. Which action by the nurse would be most important in developing a patient-centered plan of care for an alert, oriented adult?
- a. Providing a written copy of care options to the patient and family
 - b. Collaborating with the patient's social worker to determine resources

- c. Listening to the patient's concerns and beliefs about proposed treatment
 - d. Engaging the patient's family, friends, or care providers in conversation
8. Which interventions can the nurse initiate independently while providing patient care? (*Select all that apply.*)
- a. Ordering a blood transfusion
 - b. Auscultating lung sounds
 - c. Monitoring skin integrity
 - d. Applying heel protectors
 - e. Adjusting antibiotic dosages
9. The nurse notices that a patient is becoming short of breath and anxious. Which intervention is a dependent nursing action, requiring the order of a primary care provider?
- a. Elevating the head of the patient's bed
 - b. Administering oxygen by nasal cannula
 - c. Assessing the patient's oxygen saturation
 - d. Evaluating the patient's peripheral circulation
10. Which situation indicates the greatest need for collaborative interventions provided by several health care team members?
- a. Hospice referral
 - b. Physical assessment
 - c. Activities of daily living
 - d. Health history interview

CHAPTER 9

Implementation and Evaluation

LEARNING OUTCOMES

Comprehension of this chapter's content will provide students with the ability to:

- LO 9.1 Explain the significance of implementation and evaluation in the nursing process.
- LO 9.2 Describe different types of direct-care interventions.
- LO 9.3 Differentiate among various forms of indirect-care interventions.
- LO 9.4 Identify examples of independent nursing interventions.
- LO 9.5 Recognize dependent nursing interventions.
- LO 9.6 Discuss collaborative nursing interventions.
- LO 9.7 Identify the significance of documentation in the implementation step.
- LO 9.8 Apply evaluation principles used in the nursing process.
- LO 9.9 Describe the relevance of care plan modification.

Case Study

Antonio Giordano (A.G.) is a 65-year-old man with a 20-year history of smoking who came to the emergency department complaining of shortness of breath and anxiety. He is allergic to penicillin and has a medical history of hypertension and a high cholesterol level. His vital signs are T 101.6°F (38.6°C), P 96 and regular, R 24, BP 132/74, O₂ saturation 89% on room air, and pain level of 3/10. A.G.'s respiratory assessment reveals slightly labored respirations with diminished breath sounds in both upper lobes and rhonchi in the left base, orthopnea, pain in his chest, and a productive cough of thick, yellow sputum. He states that he has been unable to shower without becoming dizzy and sleeps only about 4 hours each night in a recliner. A.G. expresses concern that he has not been able to go to work for a week and may lose his job. After being diagnosed with pneumonia, A.G. is transferred to a telemetry unit.

Treatment included vital signs taken every 4 hours, intake and output measurements, oxygen at 2 to 4 L per nasal cannula to maintain O₂ saturation above 92%, intravenous (IV) administration of 0.9 NaCl at 75 mL/hr, and incentive spirometry every hour while awake. The patient was maintained on a 4-g sodium, low-fat, low-cholesterol, no-caffeine diet and on bed rest with bathroom privileges. Medication orders included the following:

- Ciprofloxacin: 400 mg IV q 12 h
- Methylprednisolone: 40 mg IVP q 8 h
- Albuterol breathing treatments: q 4 h and PRN for shortness of breath
- Lorazepam: 1 mg PO q 8 h and PRN for anxiety

Refer back to this case study to answer the critical-thinking questions throughout the chapter.

After the first three phases of the nursing process (i.e., assessment, diagnosis, and planning) are completed, the nurse proceeds to implementation and evaluation. In these steps, the plan of care is carried out, and patient outcomes are evaluated. Based on evaluation findings, the nurse revises, continues, or discontinues the plan of care.

LO 9.1 Implementation and Evaluation of Nursing Care

Nurses and other members of the interdisciplinary health care team provide care through interventions designed to promote, maintain, or restore a patient's health during the implementation phase of the nursing process. Interventions may be direct or indirect activities, and they may be independent, dependent, or collaborative nursing actions. Each intervention is included in the patient-centered plan of care to support patient goals identified during the planning process.

Implementation consists of performing a task (e.g., repositioning a patient, assessing vital signs, administering medications, teaching patients and families, calling chaplains) and documentation of each intervention (Fig. 9.1). Many factors are taken into consideration by the nurse before initiating patient care. Some factors that influence care plan implementation are provided in Box 9.1.

FIGURE 9.1 Implementation in the nursing process.

Box 9.1

Factors to Consider Before Care Plan Implementation

Implementation of a patient's plan of care requires consideration of many factors, including:

- Patient education and health literacy level
- Relevant cultural, religious, or ethic factors and limitations
- Potential communication or language barriers
- Patient abilities and condition status
- Patient resources
 - Support system accessibility
 - Insurance coverage or ability to pay for treatment
- Patient treatment preferences
- Nurse and health care provider experience and competency
- Best practice research findings
- Scope and standards of nursing practice
- Institutional resources

Evaluation focuses on the patient and the patient's response to nursing interventions and outcome or goal attainment. Effective evaluation of patient progress or condition changes dictates the need to continue, modify, or discontinue aspects of the plan of care. Care plan modification is done to improve patient outcomes.

LO 9.2 Direct Care

Direct care refers to interventions that are carried out by having personal contact with patients. For example, direct-care interventions include cleaning an incision, administering an injection, ambulating with a patient, and completing patient teaching at the bedside. Some direct-care interventions must be carried out by the registered nurse (RN), but others may be delegated to another care provider, such as unlicensed assistive personnel (UAP), with proper training and supervision by the nurse.

Safe Practice Alert

Before implementing all interventions, the nurse must check the patient's identity using a minimum of two methods. Asking a patient to state his or her name and birth date while cross-checking what the patient says with the patient's armband information are the two most common ways to verify patient identity. This critical safety step prevents interventions from being performed on the wrong person.

Reassessment

One form of direct care that is ongoing throughout all stages of the nursing process is reassessment. After the nurse completes a patient's initial assessment and develops a plan of care, continual reassessment of the patient detects noticeable changes in the patient's condition, requiring adjustments to interventions outlined in the plan of care. For example, a patient may initially be unresponsive and unable to breathe independently, requiring the aid of a ventilator. As the patient's condition improves and he or she is able to breathe without the ventilator, this intervention can be deleted from the plan of care, and oxygen administered by nasal cannula may take its place. The need for continual patient reassessment underscores the dynamic nature of the nursing process and is crucial to providing essential care.

Activities of Daily Living

Activities of daily living (ADLs) include tasks that are undertaken on a regular basis: eating, dressing, bathing, toileting, and ambulation. Because patients perform ADLs at different levels, it is important for the nurse to assess where deficits exist and to determine whether patients require short- or long-term interventions to address their needs. For

example, patients who have limited mobility after knee surgery need short-term interventions for ambulation assistance. Patients who have debilitating strokes (i.e., cerebrovascular accidents) or amputations require long-term interventions, which may or may not change as the severity of disability changes or the duration since the initiating event lengthens.

Physical Care

Many interventions focus on physical care that is performed when treating patients. These interventions may include invasive procedures, such as starting an intravenous line or inserting a catheter, or they may be noninvasive, such as administering oral medications and repositioning. The nurse must perform the procedures competently and safely, taking into consideration any special needs of the patient (Box 9.2). Some procedures may be unfamiliar to the nurse, and some techniques vary among health care facilities. The state boards of nursing provide some procedural guidance; however, each institution adheres to internal policies and procedures. Nurses must take responsibility for learning and adapting procedures to ensure proper technique and practice within regulatory guidelines.

Box 9.2

Diversity Considerations

Life Span

- Interventions must always be age- or developmental-level appropriate.
- Older individuals with cognitive deficits may require care that would typically be provided only for children or adults with physical disabilities.
- Encouraging patients of all ages to actively participate in their care provides them with a sense of control, even in the most serious circumstances.

Gender

- Identify gender roles that may affect care delivery.

- Some patients may prefer care from nurses of the same gender. This preference may stem from generational norms, personal comfort, or cultural considerations.

Culture, Ethnicity, and Religion

- Culture plays an important role in communicating with patients. Professional interpretation services should be implemented when detailed care information needs to be shared.
- It is important to know whether eye contact or physical contact should be avoided due to cultural norms.
- Proper explanation of all procedures is essential for individuals of all cultures.
- Asking patients to share their understanding of a procedure that has just been explained is a valuable way to verify that communication has been successful.
- Some interventions may be declined because of religious affiliation (e.g., blood transfusion for a Jehovah's Witness, pork-based insulin for a Muslim patient).

Disability

- Interventions must be individualized for each patient and adapted for any limitations (e.g., amputation, learning disability, blindness, deafness).

Morphology

- The nurse must ensure safe practice in relation to patient body size and should seek additional support or equipment when necessary (e.g., mechanical lift equipment, sliding boards).
- Some institutions have units that are dedicated to the care of morbidly obese patients.

Skills manuals and software are excellent references for nurses seeking information on approved nursing care procedures. Point-of-care references in the form of hand-held technology provide bedside nurses with evidence-based interventions to implement during patient care. In 2000, the Institute of Medicine (IOM [now the National Academy of Medicine]) endorsed point-of-care reference use by all health care

professionals in its landmark report, *To Err Is Human: Building a Safer Health System* (Kohn, Corrigan, & Donaldson, 2000).

Informal Counseling

In some cases, nurses provide support and intervene with patients through informal counseling. Counseling is the process through which individuals use professional guidance to address personal conflicts or emotional problems. Nurses counsel patients by providing a “listening ear” or stimulating a patient's thought process or decision-making process. Informal counseling may occur when the patient is faced with a new diagnosis (e.g., breast cancer), a chronic condition (e.g., diabetes), a loss (e.g., death of a parent), or acute illness (e.g., pneumonia). Informal counseling encourages patients to express their concerns and emotions and to ask questions.

The nurse uses counseling techniques to identify the need for indirect interventions (e.g., consultations for other services) that should be implemented. When the need for in-depth or formal counseling is perceived, the nurse can recommend that a patient be referred for psychotherapy, which is outside the scope of practice of a nurse without advance practice training.

Teaching

Teaching is an essential professional nursing intervention. Each interaction with a patient is an opportunity to teach. While administering medications at the bedside, the nurse assesses the patient's knowledge of the prescribed medications and provides supplemental information, reinforcement, and clarification as needed. During ambulation, a nurse may teach a patient about safe ambulation or the correct way to use a walker. At other times, teaching is more formalized, such as discharge teaching after open heart surgery.

Each teaching method and patient interaction involving teaching requires the nurse to individualize the teaching plan for the patient. The nurse must keep in mind the best way that the patient learns, the patient's educational and knowledge level, cultural considerations, and potential communication barriers. Readiness to learn is also an important consideration. For example, when a patient returns from surgery, it is essential that some information be reviewed (e.g., how to use the patient-controlled analgesia pump and incentive spirometer), but completing all discharge teaching at this time would not be effective. Choosing opportunities in which the environment and the patient's condition are most conducive to learning is recommended.

Another teaching plan consideration is whether to involve family and care providers in the teaching process. Spouses, children, and friends often are involved in the care of a patient after discharge. With the patient's permission, the nurse should share instructions with the people who may assist with care. Nurses empower patients and their support systems through effective teaching. When nurses provide patients and their families with opportunities to ask questions and comprehend health care information, they become an integral part of the health care process.

1. What teaching interventions focused on health promotion would be most appropriate for A.G. before he leaves the hospital?

LO 9.3 Indirect Care

Indirect care includes nursing interventions that are performed to benefit patients but do not involve face-to-face contact with patients. Examples of indirect care include giving change-of-shift report, communicating and collaborating with members of the interdisciplinary health care team, and ensuring availability of needed equipment. These activities assist in providing comprehensive care to patients, although their impact may not be obvious to or known by patients.

Communication and Collaboration

Effective communication and collaboration regarding patient care are essential for patient safety and positive patient outcomes. Change-of-shift-reports, ongoing communication with primary care providers (PCPs) and specialists, and accurate documentation of assessment findings provide continuity of care. The use of electronic medical records (EMRs) allows patients' records to be accessed in an efficient manner and by multiple organizations, increasing communication while decreasing the time necessary to transfer information. Their use connects pieces of the patient care puzzle and reduces the potential for transcription errors. Patient status reports may lead to the addition of PCP orders, such as consultations with specialists or services (e.g., physical therapy, social services, mental health services) that can be added to the plan of care and substantially benefit the patient. Effective communication and collaboration between the nurse and all members of the health care team, including patients, is essential for providing patient-centered, comprehensive care.

Referrals

Referrals in health care involve sending a patient to another member of the interdisciplinary health care team or agency for a consultation or other services. In some cases, a PCP may refer a patient to a medical or surgical specialist for further assessment, testing, or treatment. Referral information provided by a specialist can provide the nurse and PCP with ideas for a more structured plan of care to address specific patient concerns.

Referrals for specialized services can support and protect patients. Nurses are often instrumental in initiating these types of referrals. For instance, if a patient is experiencing extreme anxiety during chemotherapy treatments, the nurse may set up a referral with the

music therapist to assist the patient with relaxation. Nurses initiate referrals for specific dietary requests and adaptive care devices, such as bedside commodes or specialized beds, depending on the patient's unique circumstances. In collaboration with social services, a nurse may refer discharged patients to community agencies that provide in-home assistive services. Some referrals may require the order of a physician or an advanced practice nurse.

Research

Implementation of evidence-based care is not unique to nursing; it involves interventions provided by all members of the interdisciplinary health care team. The best methods for treating patients with a variety of signs and symptoms are researched by nurses with input from the research findings of other disciplines. Nursing care continues to evolve as nursing research provides new knowledge and recognizes best practices to improve patient care and outcomes. Evidence-based practice guidelines and updated information must be included in plans of care. To implement research-based interventions, nurses must read recent literature and remain current in practice. Accurate communication of care plans among health care team members and the use of informatics to locate relevant research and treatment options support the implementation of best practices (Box 9.3).

Box 9.3

Evidence-Based Practice and Informatics

The Role and Impact of Technology on Patient Care

Electronic resources have enhanced the ability of nurses to communicate patient needs and explore new treatment modalities available for patient care:

- Electronic medical records (EMRs) often include care plan formats that enhance nurses' ability to formulate individualized plans of care and facilitate coordination of care. Documentation of evaluative criteria and data in a patient's EMR allows nurses and other health care providers to collaborate electronically while responding to changes in the patient's health status.
- Data documented in EMRs is beneficial for improving patient safety, increasing nurse efficiency, and evaluating the quality of

care ([Lavin, Harper, & Barr, 2015](#))

- Hand-held computers are effective for patient documentation, patient care, and evidence-based research access. Evidence indicates that hand-held computers can facilitate accurate and thorough documentation ([Mickan, Tilson, Atherton, Roberts, & Heneghan, 2013](#)).
- Research comparing patient follow-up using a mobile app instead of in-person outpatient clinic follow-up visits after ambulatory surgery identified a reduction in follow-up visits without a reduction in patient satisfaction or an increase in postoperative complications. Future studies need to be completed to further investigate the effectiveness of patient's using mobile apps for postoperative follow-up in various situations ([Sammour & Hill, 2017](#)).

Advocacy

Nurses advocate by supporting and working on behalf of patients or people for whom they have concern. Advocacy can be easy or challenging, depending on the situation. Nurses advocate for patients by coordinating care and supporting the changes necessary to improve conditions and outcomes. Excellent negotiation techniques are required for nurses who advocate on behalf of patients' rights with insurance companies or legislative leaders. As resources for patient care become increasingly limited, nurse advocacy is critical for ensuring patient access to needed services.

Delegation

Delegation is the transfer of responsibility for performing a task to another person while the nurse who delegated the task remains accountable ([ANA, 2015](#)). Delegation is an indirect intervention based on assessment findings and established care priorities. Nurses must be familiar with the nurse practice act in their practice jurisdiction to ensure legal delegation. The nursing process cannot be delegated. In most jurisdictions, licensed practical nurses (LPNs) function in a dependent role and may not delegate ([Knecht, 2017](#)). The RN is most responsible for incorporating delegation into practice.

Delegation principles focus on the appropriate intervention being performed under the correct circumstances, by the correct personnel, and with the correct direction and supervision ([Box 9.4](#)). In the United States, the [National Council of State Boards of Nursing \(2016\)](#) published National Guidelines for Nursing Delegation to stress the importance of all individuals accepting responsibility in the delegation process to

ensure patient safety (Fig. 9.2). These more detailed guidelines incorporate many aspects of the original [Delegation Decision Making Tree \(1997\)](#) adapted from an original Ohio Board of Nursing tool available at <http://www.health.ri.gov/publications/guides/DelegationDecisionMakingTree.pdf>.

Box 9.4

Interprofessional Collaboration and Delegation

The Five Rights of Delegation

Collaboration among health care team members sometimes results in the nurse delegating some aspects of patient care to unlicensed assistive personnel. The National Council of State Boards of Nursing has provided the Five Rights of Delegation to support safe delegation of patient care:

- *Right task*: Is this a task that can and should be delegated?
- *Right circumstance*: Is this appropriate given the patient's current condition or situation?
- *Right person*: Does this person have the skills, scope of practice, understanding, and expertise to perform this task?
- *Right direction and communication*: Has proper information about what tasks need to be completed been shared so that what needs to be done is clear?
- *Right supervision and evaluation*: Has the nurse followed up to ensure that care was adequate to meet the needs of the patient?

Modified from [National Council of State Boards of Nursing. \(2016\). National Guidelines from Nursing Delegation](#). Retrieved from https://www.ncsbn.org/NCSBN_Delegation_Guidelines.pdf

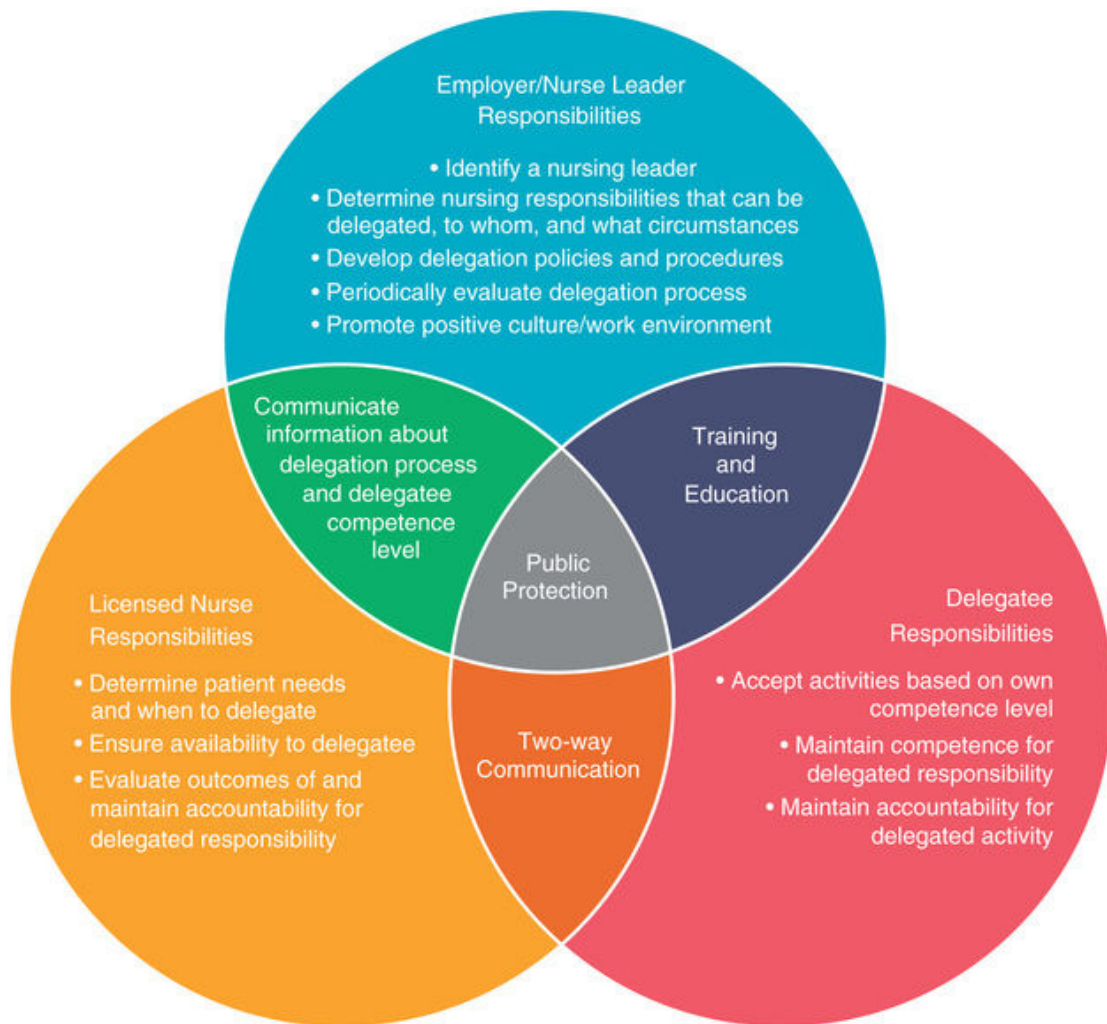

FIGURE 9.2 National Council of State Boards of Nursing Delegation Model. (From National Council of State Boards of Nursing. (2016). National guidelines for nursing delegation, *Journal of Nursing Regulation*, 7(1), 5-14.)

Prevention-Oriented Interventions

Some interventions prevent illness or complications and promote healthy activities or lifestyles. Interventions such as patient education and immunization programs are prevention oriented (Box 9.5). These interventions influence patient outcomes and may be as important as intervening in crisis situations. Cleansing an incision is a nursing intervention that can help prevent infection. Educating a patient about risk-factor modification for cardiovascular disease may prevent a future myocardial infarction. Placing infants on their backs to sleep on a firm surface without bed sharing reduces the risk for sudden infant death syndrome (American Academy of Pediatrics, 2016). Being current in evidence-based practice enhances a nurse's ability to include preventive interventions in patient plans of care.

Box 9.5

Patient Education and Health Literacy

Human Papillomavirus Vaccination (HPV) Compliance and Recommendations

- HPV vaccine has been available since 2006 to reduce the rates of cervical cancer and anogenital warts.
- As of 2014, HPV vaccination rates in girls and boys (ages 13 to 17) in the United States was only 60% and 41.7%, respectively.
- A lack of both patient education and strong recommendations by primary care providers has hindered higher participation in HPV vaccination programs.
- School entry requirements can increase greater coverage of adolescents and reduce racial and ethnic disparities.
- Community education campaigns by nurses and public health departments are proven effective in improving attitudes and acceptance of HPV vaccine.

Adapted from North, A., & Niccolai, L. (2016). Human papillomavirus vaccination requirements in US schools: Recommendations for moving forward. *American Journal of Public Health, 106*(10), 1765-1770.

LO 9.4 Independent Nursing Interventions

Independent nursing interventions are tasks within the nursing scope of practice that the nurse may undertake without a physician or PCP order. Determining what nursing interventions to include in a patient's plan of care and prioritizing that care are independent nursing interventions based on nursing knowledge. Repositioning a patient in bed, performing oral hygiene, and providing emotional support through active listening are examples of other independent nursing interventions.

The extent to which nurses can implement independent nursing interventions is often determined by the area in which care is taking place. For instance, community nurses or those working in international field hospitals may have the authority to initiate interventions traditionally reserved for other health care professionals in a formal inpatient setting. Safe nursing practice requires nurses to know (1) how to perform interventions before their independent implementation and (2) whether the initiation of independently chosen interventions is permitted in their practice setting.

LO 9.5 Dependent Nursing Interventions

Dependent nursing interventions are tasks the nurse undertakes that are within the nursing scope of practice but require the order of a primary care provider to be implemented. They require nurses to pay strict attention to the details of what is ordered and to recognize when implementing a dependent nursing intervention is appropriate or should be withheld. Administering patient medications or administering oxygen to a patient are examples of common dependent nursing interventions that require clinical judgment before implementation. These interventions are based on a collaborative effort of the nurse and the PCP to provide care to patients.

Clinical Pathways, Protocols, and Standing Orders

Clinical pathways, protocols, and standing orders often affect interventions carried out in the implementation phase of the nursing process. **Clinical pathways**, sometimes referred to as care pathways, care maps, or critical pathways, are multidisciplinary resources designed to guide patient care. Clinical pathways emerged in the 1980s in an effort to provide better-quality, standardized care for patients, and they were developed through evidence-based practice research (Gebreiter, 2017). Nurses contribute to the formation of clinical pathways by using the nursing process to identify unique nursing interventions that assist patients in achieving desired outcomes. Refer to Chapter 5, Fig. 5.7 for an example of a clinical pathway. Independent, dependent, direct, and indirect interventions are included in the critical pathway.

Protocols are written plans that can be generalized to groups of patients with the same or similar clinical needs that do not require a physician's order. Health care agencies have established protocols outlining procedures for admitting patients or handling routine care situations. Because protocols are generalized to patient populations, they are often included in critical pathways.

Some physician orders are received through a preapproved standardized order set known as **standing orders**. For example, when patients return to their rooms after cardiac catheterization, standing orders may indicate that the patients are to remain on bed rest for a specified period. To follow the standing orders, the nurse maintains patients on bed rest for the indicated amount of time. When the specified time period ends, and a patient's condition remains unstable, the nurse contacts the physician for further orders rather than

continuing to follow the standing orders. Regardless of the existence of standing orders, it is the nurse's responsibility to continually reassess individual patients and not blindly follow orders. [Box 9.6](#) provides an example of standing orders for patients with chest pain.

Box 9.6

Standing Orders for Patients With Chest Pain

Standing orders for patients experiencing chest pain include independent and dependent nursing interventions:

- Assess vital signs.
- Obtain an electrocardiogram (ECG).
- Initiate or maintain telemetry.
- Initiate oxygen therapy beginning at 2 L per nasal cannula; monitor pulse oximetry levels.
- Administer sublingual nitroglycerin (0.4 mg SL); repeat up to three times, as needed.
- Initiate intravenous access if not already available.
- Notify laboratory to assess cardiac enzymes.
- Notify physician for further orders.

Safe Practice Alert

Following critical pathways and protocols or implementing standing orders requires critical thinking and use of the nursing process to determine the applicability of interventions in specific patient care circumstances. Blindly following critical pathways, protocols, or standing orders is contraindicated in all nursing care situations.

Medication Administration

Medication administration is within the scope of nursing practice and is performed as a dependent nursing intervention. Nurses must complete three checks and follow the six rights of medication administration to safely carry out this type of dependent action. Nurses check the primary care provider's orders, the patient's allergies, and the expiration date of the medication to be administered, and then address the six rights. They include administering the right medication and dosage, by the correct route, to the right patient, at the right time, and documenting correctly

(see [Chapter 35](#)). All forms of prescription medication (i.e., oral, topical, and parenteral) require an order before administration, as does providing oxygen to a patient.

Medical Treatments

Medical treatments are dependent nursing interventions. Examples of medical treatments requiring a physician order include urinary catheterization, 24-hour urine collection, dressing changes, incision irrigation, intubation, and placement of a nasogastric tube. The nurse collects data and gathers supplies and necessary information to carry out these interventions. Nurses must use sound clinical judgment to perform interventions and should seek clarification as needed. For example, if a patient has been ordered to ambulate four times daily, but a recent ultrasound confirms the presence of a deep vein thrombosis in the patient's left leg, the nurse would contact the physician about the ultrasound results to obtain updated orders before ambulating the patient.

2. The admitting nurse identified five initial nursing diagnoses for A.G.: *Impaired Gas Exchange*, *Fatigue*, *Impaired Airway Clearance*, *Risk for Fall-Related Injury*, and *Anxiety*. List a minimum of two nursing interventions to implement for each of these nursing diagnoses.

3. Highlight all of the independent nursing actions listed as interventions for A.G.'s care.

LO 9.6 Collaborative Interventions

Collaborative nursing interventions require consultation and coordination of patient care with a variety of members of the health care team. The complexity of a patient's condition determines the number and specialty of health care professionals required for care implementation. Collaborative interventions include activities such as medication reconciliation; physical, occupational, and respiratory therapy; personal care; home and hospice services; and spiritual care. In many cases, the nurse coordinates patient care and is responsible for ensuring that each need of the patient is met. Clear communication among health care team members and frequent interdisciplinary meetings help facilitate effective collaborative interventions.

LO 9.7 Documentation of Interventions

All interventions that are performed by nurses or other health care personnel need to be documented. A common adage states, “If it's not documented, it's not done.” Nurses must document to accurately convey information to other care providers. If a nurse does not document that a medication was administered, for example, the patient may receive an additional dose. If completion of patient orders is not documented—such as if laboratory results were not reported and the patient needs to have another blood draw—the patient may be adversely affected medically and financially (e.g., a repeated blood draw is painful and costly).

Documentation most often is charted in the patient's electronic health record and standardized flow sheets according to agency policy. Patient health records are legal documents. Within the Health Insurance Portability and Accountability Act (HIPAA) guidelines, patient documentation is provided to insurance companies and others for billing and reimbursement. All documentation entries should be completed in a timely, accurate, and professional manner. More information on documentation is provided in [Chapter 10](#).

LO 9.8 Evaluation of the Nursing Care Plan

Evaluation is the final step in the nursing process (Fig. 9.3). **Evaluation** focuses on the patient and the patient's response to nursing interventions and outcome attainment. Evaluation is not a record of care that was implemented. Patient outcomes serve as the criteria against which the success of a nursing intervention is judged (Butcher, Bulechek, Dochterman, & Wagner, 2018). Information on the effectiveness of nursing interventions is a by-product of the evaluation process. During the evaluation phase, nurses use critical thinking to determine whether a patient's short- and long-term goals were met and whether desired outcomes were achieved. Monitoring whether the patient's goals were attained is collaborative, involving the patient in the decision-making process.

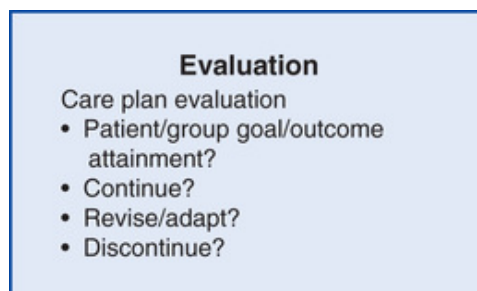

FIGURE 9.3 Evaluation in the nursing process.

Goal Attainment in the Plan of Care

The evaluation process begins with determining whether patient goals have been met. Although interventions may or may not be performed, evaluation examines the extent to which interventions affected patient outcomes. Did the patient achieve the goal that was set?

Each nursing care plan is tailored to meet the specific needs of a patient. Ideally, when patient outcomes are evaluated, they will be positive, indicating improved patient status. Unfortunately, this is not always the case. For instance, a patient may have a nursing diagnosis of *Acute Pain* after a motor vehicle accident. The goal is for the patient to report a pain level of less than 6 of 10 during the nurse's shift. Nursing interventions include assessing pain, administering analgesic medication, repositioning the patient, distracting the patient, providing

a quiet environment, and giving the patient an opportunity to share concerns. The patient consistently rates his pain level at 8 of 10 for the entire shift. In this case, evaluation reveals that the patient's goal was unmet, and that revision of the patient-centered care plan is required to more effectively address his needs.

Continuation, Adaptation, or Revision of the Plan of Care

When a patient goal is unmet or only partially met, the plan of care may need to be revised or adapted to support goal attainment. A lack of goal achievement requires reassessment of the patient to determine the underlying cause. Patients may develop complications (e.g., deep vein thrombosis) that limit the ability to ambulate four times each day, making a goal of increased ambulation unattainable. When complications arise, or patient goals are only partially met, the nurse revises the plan of care in response to the evaluation findings. It is common for plans of care to change to meet evolving needs. Reassessment occurs with each patient–nurse interaction. As changes in a patient's condition occur, the plan of care should be revised.

Evaluation of a patient goal or outcome may be positive when the patient's goal is met and the problem resolved. When this happens, the nurse needs to determine whether the patient's plan of care should be continued to support sustained or greater improvement or should be discontinued. Decisions such as this are made by the nurse on the basis of patient preference and the nurse's clinical judgment.

Discontinuing the Plan of Care

Goal attainment is one reason that plans of care are discontinued. Another is changing circumstances. If the goal was for the patient to demonstrate proper injection of enoxaparin before discharge and the patient did so safely and accurately for three consecutive injections, the outcome has been met, and this aspect of the plan of care can be discontinued.

However, if a goal was for a patient to ambulate three times daily without assistance, but the patient became unresponsive due to a cerebrovascular accident (CVA), the ambulation goal is no longer realistic or appropriate, and this aspect of the plan of care needs to be discontinued. [Table 9.1](#) illustrates goal and evaluation statements in the context of the nursing process. [Table 9.2](#) shows examples of how to formulate evaluation statements in various situations.

TABLE 9.1**Goal and Evaluation Statements**

ICNP NURSING DIAGNOSIS WITH SUPPORTING DATA	NURSING OUTCOME CLASSIFICATION (NOC) AND INDICATOR	NURSING INTERVENTION CLASSIFICATION (NIC) AND ASSOCIATED ACTIVITIES
<i>Impaired Mobility</i> Recent surgical intervention Limited range of motion Pain with movement Difficulty moving	<i>Ambulation</i> Walks moderate distance	<i>Activity therapy</i> 1. Determine patient's commitment to increasing range of activity. 2. Assist with choosing activities consistent with physical capabilities.
Goal: Patient will increase walking to a minimum of 100 yards four times per day before discharge.		
Evaluation statement: Goal met. Patient ambulating 200 yards four or five times each day. Continue plan of care until discharge.		

From Butcher, H.K., Bulechek, G.M., Dochterman, J.M., & Wagner, C. (2018). Nursing interventions classification (NIC) (7th ed.). St. Louis, MO: Mosby; Moorhead, S., Swanson, E., Johnson, M., & Maas, M. (Eds.) (2018). Nursing outcomes classification (NOC) (6th ed.). St. Louis, MO: Mosby. ICNP is owned and copyrighted by the International Council of Nurses (ICN). Reproduced with permission of the copyright holder.

TABLE 9.2**Types of Evaluation Statements**

Goal: Patient will ask for assistance by using the call light and waiting for help before toileting every time ambulation to the bathroom is required.	
Evaluation statement <i>when goal is met</i>	Goal met. Patient consistently requests assistance before toileting. Continue plan of care to ensure patient safety or discontinue plan of care because patient no longer requires assistance for safe use of the toilet.
Evaluation statement <i>when goal is partially met</i>	Goal partially met. Patient forgetting to ask for assistance with toileting during the day. Revise plan of care to include use of bed alarm.
Evaluation statement <i>when goal is unmet</i>	Goal is unmet. Discontinue plan of care. Patient is no longer able to call for assistance due to diminished level of consciousness.

Reflection on Unmet Goals

If patient goals are not achieved, the nurse reflects on questions such as these: What barriers did the patient have in meeting these goals? Were the goals realistic? What happened that was not anticipated? What can be done differently? These questions assist the nurse in revising the plan of care.

Reassessment should occur every time the nurse interacts with a patient or reviews updated diagnostic laboratory or test results. The nurse must continually monitor for changes in a patient's condition that affect the plan of care. Higher-priority goals sometimes emerge through the reflection process.

4. A goal for A.G. was "Patient's oxygen saturation will remain above 96% on 2 L of O₂ per nasal cannula throughout the first 24 hours of hospitalization." When evaluating whether or not the goal was met, the nurse notices that since he was admitted 25 hours earlier, the only time his oxygen saturation fell to 93% on 2 L of O₂ was right after dinner, and then it returned to 95% within 30 minutes. Write an evaluative statement for this goal to be documented in A.G.'s patient-centered plan of care.

LO 9.9 Care Plan Modification

Care plans should be updated regularly after patient evaluations. The nursing process is ongoing in an attempt to meet patient needs. The nursing process is not linear but is dynamic and cyclic, constantly adapting to a patient's health status. Care plan modifications may be necessitated due to deterioration or improvement of a patient's condition.

The Joint Commission requires patient care plans to be evaluated on a continual basis. In many agencies, nurses are required to evaluate patient outcomes at least once during every shift. Making modifications to plans of care as a patient's status changes is a necessary component of providing safe patient care.

As a patient-centered plan of care changes, new goals are developed. After new goals are formulated, additional interventions are developed and implemented to assist the patient in achieving them. The patient care plan remains the cornerstone of nursing care. Evaluation is how nurses determine a care plan's effectiveness in meeting the patient's needs.

Although implementation and evaluation are considered the last two steps of the nursing process, they are as integral to helping patients achieve positive outcomes as are the other steps. Providing individualized, patient-centered care and evaluating whether that care has helped achieve positive patient outcomes are essential to safe, professional nursing practice.

Summary of Learning Outcomes

LO 9.1 *Explain the significance of implementation and evaluation in the nursing process:* Nurses and other members of the interdisciplinary health care team provide care through interventions designed to promote, maintain, or restore a patient's health during the implementation phase of the nursing process. Implementation consists of performing a task and documenting each intervention. Evaluation focuses on the patient and the patient's response to nursing interventions and outcome attainment. The nurse uses evaluation data to adapt a plan of care on the basis of the patient's changing health status.

LO 9.2 *Describe different types of direct-care interventions:* Direct care refers to interventions that are carried out by having personal contact with patients. Direct nursing interventions include reassessing patients, assisting with ADLs, giving physical care, counseling, and teaching.

LO 9.3 *Differentiate among various forms of indirect-care interventions:* Indirect care includes nursing interventions performed to benefit patients without face-to-face contact. Indirect nursing interventions include communicating and collaborating with other health care team members, making referrals, doing research, advocating, delegating, and engaging in preventive actions such as patient education and health promotion.

LO 9.4 *Identify examples of independent nursing interventions:* Independent nursing interventions are tasks within the nursing scope of practice that the nurse may undertake without a physician or PCP

order. The extent to which nurses can implement independent nursing interventions is often determined by the area in which care is taking place.

LO 9.5 Recognize dependent nursing interventions:

Dependent nursing interventions are tasks the nurse undertakes that are within the nursing scope of practice but require the order of a physician or PCP to implement. They require nurses to pay strict attention to the details of what was ordered and to recognize when implementing a dependent nursing intervention is appropriate or should be withheld in consultation with the PCP.

LO 9.6 Discuss collaborative nursing interventions:

Collaborative interventions include activities such as medication reconciliation, physical, occupational, and respiratory therapy, personal care, home and hospice services, and spiritual care. In many cases, the nurse coordinates collaborative patient care and is responsible for ensuring that each need of the patient is met.

LO 9.7 Identify the significance of documentation in the implementation step: Nurses must document effectively to convey information accurately to other care providers. Within the HIPAA guidelines, patient documentation is provided to insurance companies and others for billing and reimbursement.

LO 9.8 Apply evaluation principles used in the nursing process: Evaluation focuses on the patient and the patient's response to nursing interventions and outcome attainment. Evaluation is not a record of the care that was implemented. Information on the

effectiveness of nursing interventions is a by-product of the evaluation process. During the evaluation phase, nurses use critical thinking to determine whether a patient's short- and long-term goals were met and the desired outcomes were achieved.

LO 9.9 *Describe the relevance of care plan modification:* Care plan modification is based on the effectiveness of interventions to meet and improve desired patient outcomes. Monitoring changes in a patient's condition is essential for determining the extent to which a plan of care is continued, modified, or discontinued.

Review Questions

1. What should the nurse consider before implementation of all nursing interventions? (*Select all that apply.*)
 - a. Potential communication barriers
 - b. Diverse cultural practices
 - c. Scope of nursing practice
 - d. Functional status of the patient
 - e. Time of most recent shift change
2. Which intervention would be most important for the nurse to include in a patient's care plan if the patient is unable to complete activities of daily living without becoming fatigued?
 - a. Instruct the patient to shower and shave simultaneously
 - b. Discourage the patient from bathing while hospitalized
 - c. Encourage the patient to rest between bathing activities
 - d. Ask the patient's spouse to assist with all bathing
3. Which nursing intervention is most important to complete before giving medication to a patient?
 - a. Provide water to aid in the patient's ability to swallow the medication.
 - b. Double-check the patient's allergies before giving the drug.
 - c. Ask the patient to verify having taken the medication before.

- d. Place the patient in a side-lying position to prevent aspiration.
4. Which direct-care intervention would be most effective in helping a patient cope emotionally with a new diagnosis of cancer?
- a. Reassessing for changes in the patient's physical condition
 - b. Teaching the patient various methods of stress reduction
 - c. Referring the patient for music and massage therapy
 - d. Encouraging the patient to explore options for care
5. What should be taken into consideration by the nurse when deciding on interventions to include in a patient's plan of care? (*Select all that apply.*)
- a. Patient's treatment preferences
 - b. Cultural and ethnic influences
 - c. Nurse's professional expertise
 - d. Current evidence-based research
 - e. Convenience to the nursing staff
6. Which task may the registered nurse safely delegate to unlicensed assistive personnel without prior intervention?
- a. Ambulating a patient with ataxia and new right-sided paresthesia
 - b. Feeding a patient with cerebral palsy who recently aspirated
 - c. Transporting a patient to the hospital entrance for discharge

- d. Administering prescribed programmed medications
7. Which actions are part of the evaluation step in the nursing process? (*Select all that apply.*)
- a. Recognizing the need for modifications to the care plan
 - b. Documenting performed nursing interventions
 - c. Determining if nursing interventions were completed
 - d. Reviewing whether a patient met their short-term goal
 - e. Identifying realistic outcomes with patient input
8. Which action by the day-shift nurse provides objective data that enables the night-shift nurse to complete an evaluation of a patient's short-term goals?
- a. Encouraging the patient to share observations from the day
 - b. Leaving a message with the charge nurse before shift change
 - c. Documenting patient assessment findings in the patient's chart
 - d. Checking with the pharmacist regarding possible drug interactions
9. Which notation is most appropriate for the nurse to include in a patient's chart regarding evaluation of the goal, "Patient will ambulate three times daily in the hallway before discharge without shortness of breath (SOB)"?
- a. Goal not met; patient states he is tired.

- b. Goal not met; patient ambulated three times in room.
 - c. Goal met; patient ambulated three times in the hallway.
 - d. Goal met; patient ambulated three times in the hallway without SOB.
10. What situations would necessitate modification of a patient's plan of care? (*Select all that apply.*)
- a. Decrease in patient's level of orientation
 - b. Discharge of patient to rehabilitation facility
 - c. Patient adherence to established plan of care
 - d. Sudden onset of shortness of breath in patient receiving oxygen

UNIT III

Nursing Process

OUTLINE

Chapter 10 Documentation, Electronic Health Records, and Reporting

Chapter 11 Ethical and Legal Considerations

Chapter 12 Leadership and Management

Chapter 13 Evidence-Based Practice and Nursing Research

Chapter 14 Health Literacy and Patient Education

Chapter 15 Nursing Informatics

Chapter 16 Health and Wellness

CHAPTER 10

Documentation, Electronic Health Records, and Reporting

LEARNING OUTCOMES

Comprehension of this chapter's content will provide students with the ability to:

- LO 10.1 Identify the standards for effective documentation by nurses.
- LO 10.2 Discuss the functions of the medical record, including the electronic health record.
- LO 10.3 List the important attributes of nursing documentation in the medical record.
- LO 10.4 Define *privacy* and *confidentiality* as they relate to information in a medical record.
- LO 10.5 Describe standardized formats for use in hand-off reports and change-of-shift reports.
- LO 10.6 Explain the process of accepting verbal and telephone orders.
- LO 10.7 Discuss the proper use of incident reports.

Case Study

Marcella Schmidt (M.S.) is a 73-year-old, widowed female admitted to the hospital after a right hip fracture sustained when she tripped and fell in a parking lot. She had open reduction and internal fixation of her right hip 24 hours earlier. Her medical history indicates that she is in good health, with no other medical diagnoses. She is employed part time at the community library. She is allergic to penicillin and states she got hives all over her body when she took it for strep throat several years ago.

M.S.'s vital signs are T 36.6° C (97.9°F), P 80 and regular, R 18 and unlabored with an SpO₂ of 97% on 2 L oxygen via nasal cannula, and BP 140/80. She ambulated to the bathroom twice with assistance but grimaced while walking. She transferred from bed to chair with assistance to eat lunch. The physical therapist worked with her on ambulation during the afternoon. She indicates that she is anxious to get moving so she can go home.

Her right hip incision is well approximated, without swelling or excessive redness, and there is no drainage on the dressing. She rates her pain at 7/10 and states that she has “sharp pain that shoots from my hip to mid-calf when I move.” She received oral hydrocodone 5 mg/acetaminophen 500 mg at 0800, 1200, and 1600. At 45 minutes after being medicated she reported pain of 3/10. The nurse responsible for her care on the 12-hour day shift needs to document care according to facility policy, which mandates the SOAPIE format.

Refer back to this case study to answer the critical-thinking questions throughout the chapter.

Health care documentation is any written or electronically generated information about a patient that describes the patient, the patient's health, and the care and services provided, including the dates of care. These records may be paper or electronic documents, such as electronic medical records, faxes, e-mails, audiotapes, videotapes, and images. The

primary purpose of health care documentation and record-keeping systems is facilitation of information flow that supports the continuity, quality, and safety of care. The goal in documenting care is to describe the facts clearly and concisely to improve interdisciplinary communication.

Nurses are responsible for coordinating patient care and implementing the nursing process. They collect reliable data to document baseline patient information and the patient's response to nursing interventions including patient education. Documentation using the nursing process is usually embedded into workflow documents within the electronic health record. Thorough, accurate documentation reflects the patient experience and is crucial for goal-directed patient care and evaluation of outcomes ([Burlingame et al., 2018](#)).

LO 10.1 Documentation Standards and Principles

Standards for documentation are established by each health care organization's policies and procedures. They should be in agreement with The Joint Commission's (TJC's) standards and elements of performance, including having a medical record for each patient that is accessed only by authorized personnel. General principles of medical record documentation from the [Centers for Medicare and Medicaid Services \(2017\)](#) include the need for completeness and legibility; the reasons for each patient encounter, including assessments and diagnosis; and the plan of care, the patient's progress, any changes in diagnosis and treatment, the date, and the identity of the observer.

The [American Nurses Association \(ANA, 2010\)](#) has identified principles of nursing documentation related to the characteristics of documentation, education and training, policies and procedures, protection systems, entries, and standardized terminologies. The ANA's model for high-quality nursing documentation reflects the nursing process and includes accessibility, accuracy, relevance, auditability, thoughtfulness, timeliness, and retrievability.

Accurate documentation is necessary for hospitals to be reimbursed according to diagnostic-related groups (DRGs). DRGs are a system used to classify hospital admissions. Each DRG is reimbursed at a specific rate, and payment is often based on the documentation supporting the hospital stay.

LO 10.2 The Medical Record

The **medical record** is a document with comprehensive information about a patient's health care encounter, as well as demographic, administrative, and clinical data. The record serves as the major communication tool between staff members and as a single data access point for everyone involved in the care of the patient. It is a legal document that must meet guidelines for completeness, accuracy, timeliness, accessibility, and authenticity.

The medical record promotes continuity of care and ensures that patients receive appropriate health care services. The record can be used to assess quality-of-care measures, determine the medical necessity of health care services, support reimbursement claims, and protect health care providers, patients, and others in legal matters. It is a clinical data archive. The medical record serves as a tool for biomedical research and provider education, collection of statistical data for government and other agencies, maintenance of compliance with external regulatory bodies, and establishment of policies and regulations for standards of care (Box 10.1).

Box 10.1

Ethical, Legal, and Professional Practice

The Medical Record

- The medical record is the legal documentation of care provided to a patient.
- In the event of litigation, the medical record is often the only available evidence of the event in question.
- Medical record documentation should be based on fact, not opinions.
- Every entry in a medical record must include a date, time, and signature with credentials.
- Ethical practice dictates that nurses document only interventions that are performed.
- Medical record entries cannot be altered or obliterated.

Written Medical Records

The use of paper medical records requires no special technical training. The paper-based medical record has served clinical practice for many years, but the formal structure of the information within the record has changed significantly over time, moving from an unstructured or semistructured chronologic record of events to a problem- or task-oriented structure. Paper medical records are now rarely used except in cases of electronic system downtime due to power outages or mass disasters. When using paper charting nurses are responsible for knowing how to correctly spell and document events.

Historically, paper records had several potential problems. The paper chart was available to only one person at a time. Paper is fragile, susceptible to damage, and can degrade over time. Handwriting was sometimes illegible. Storage and control of paper records was a major problem.

Entries into paper medical records were traditionally made with black ink to enable copying or scanning, unless a facility required or allowed a different color. The date, time, and signature, with credentials of the person writing the entry, were included in the entry. No blank spaces were left between entries because this could allow someone to add a note out of sequence.

Safe Practice Alert

Paper records must be available only to people with an appropriate need for access. When not in use, paper charts must be secured in a location accessible to staff members but not accessible to patients, families, and visitors.

Electronic Health Records

The term *electronic medical record* is often used interchangeably with *electronic health record* or *computerized patient record*. The **electronic medical record (EMR)** is a record of one episode of care, such as an inpatient stay or an outpatient appointment. The **electronic health record (EHR)** is a longitudinal record of health that includes the information from inpatient and outpatient episodes of health care from one or more care settings (**Box 10.2**). In the American Recovery and Reinvestment Act (ARRA) of 2009, the government mandates the use of a certified EHR for each person in the United States by 2014 (**US House of Representatives, 2009**).

Box 10.2

Interprofessional Collaboration and Delegation

Use of the Electronic Health Record

- The electronic health record (EHR) includes documentation over time from inpatient and outpatient sources.
- Physicians, nurse practitioners, nurses, medical assistants, physician assistants, unlicensed assistive personnel (UAP), social workers, and therapists may contribute to the EHR. Check the facility policy for documentation guidelines.
- Laboratory data and other test results are available in multiple care settings to facilitate making decisions regarding patient care.
- In some circumstances, documentation of care including obtaining vital signs on stable patients and assisting with activities of daily living may be delegated to the UAP.
- Registered nurses are responsible for reviewing documentation by UAP for all patients under their care.

Although the EHR varies among health facilities, the major components are health information, diagnostic test results, an order-entry system, and decision support. Health information comprises patient data such as demographics, assessment findings, flow sheets that include point-of-care results, diagnoses, nursing treatments, and a medication profile listing historical and currently active medication orders. The nursing process is integrated in the EHR through documentation related to each of the five steps (i.e., assessment, diagnosis, planning, implementation, and evaluation). Diagnostic findings include current and historical results from procedures, laboratory tests, and x-rays.

Computerized provider order entry (CPOE) allows clinicians to enter orders in a computer that are sent directly to the appropriate department. Decision support in the electronic record may include medication interaction screening and reminders for preventive health actions such as vaccinations. More sophisticated decision support systems assist the diagnostic process and include recommendations for treatment. The electronic record provides connectivity to enhance communication between all members of the health care team, who can access and update the record simultaneously. The EHR supports

administrative processes with more efficient and timely data abstraction for scheduling, billing, and claims management.

The goal as health care switched to EHR implementation was to use cutting-edge technology that had safety and security built in so that it conformed with the Health Insurance Portability and Accountability Act (HIPAA) (Dente, 2011). EHR technology enables the sharing of data throughout an institution or hospital system, improves continuity of care, enables research, and expedites reporting of required statistics. Use of EHRs can reduce storage space, allow simultaneous access by multiple users, facilitate easy duplication for sharing or backup, decrease medication errors, and increase portability in environments using wireless systems and hand-held devices. Although data are often entered by keyboard, they also can be entered by means of dictated voice recordings, light pens, or handwriting and pattern recognition systems. Computer programs can convert these types of data entry to text.

Electronic Health Record Documentation

As more health care facilities implement EHRs and EMRs, the quality of nursing documentation improves, enhancing patient safety and communication with other providers. However, implementation of electronic records does involve a learning curve as staff become accustomed to the new system. Consideration must be given to how the new system fits into the existing workflow. All health care personnel must have a basic level of computer competency in addition to an understanding of documentation principles. Disadvantages of use of computers for documentation include computer and software failure and problems if there is a power outage. Therefore any facility using an EHR system must have computer support and maintenance available at all times and have a backup plan in place in the event of a power outage.

QSEN Focus!

Effective use of technology and standardized best practice facilitated by the EHR enable the nurse to provide safer patient care.

Access to an EHR is controlled through assignment of individual passwords and verification codes that identify people who have the right to enter the record. Passwords should never be shared with anyone. Health care information systems have the ability to track who

uses the system and which records are accessed. These organizational tools contribute to the protection of personal health information.

Computer Availability

The move to electronic documentation requires computers to be readily available to health care staff. Originally, computers were located in the nurses' stations for use by all. Many facilities now support point-of-care documentation, with computers in each patient's room and mobile devices such as computer tablets (Fig. 10.1) or workstations on wheels (WOWs) that can be rolled to a patient's bedside (see Chapter 15). The ability to document at the point of care supports the goals of timeliness and accuracy of documentation.

FIGURE 10.1 A nurse documents on a tablet at a patient's bedside. (Copyright [istock.com.](https://www.istock.com/))

Safe Practice Alert

When reviewing patient information, ensure that computer screens are not visible to others in the area. Always log off when finished documenting in an EHR.

LO 10.3 Nursing Documentation

The delivery of safe, evidence-based, high-quality nursing practice requires nursing documentation to be “clear, accurate, and accessible” (ANA, 2010). Nursing documentation is an important part of effective communication among nurses and with other health care providers. Nursing documentation is part of a permanent medical record. It is a record of the nursing care that identifies the nurses providing care and the contribution of that care to patient outcomes. Documentation is a way of demonstrating that professional and legal standards of care are met and is sometimes used to determine reimbursement for care.

Documentation guidelines require accessible, accurate, timely nursing documentation that is clear, concise, complete, and objective (ANA, 2010). Documentation should be factual, accurate, and nonjudgmental, with proper spelling and grammar. Events should be reported in the order they happened, and documentation should occur as soon as possible after assessment, interventions, condition changes, or evaluation. Each entry includes the date, time, and signature with credentials of the person documenting. Double documentation of data should be avoided because legal issues can arise due to conflicting data.

The documentation format used should reflect the care needs of patients and the practice setting. Specific documentation formats, including narrative, charting by exception, and flow charts, are discussed later in this chapter. Nursing documentation should clearly describe the patient's health status and include a care plan that reflects the needs and goals of the patient, the nursing interventions, and the impact of the interventions on the patient outcomes. Interactions with physicians and other health care providers are included (ANA, 2010).

Critical Aspects of Documentation

Some health care facilities combine different methods of charting to improve the effectiveness of documentation. Nursing documentation is guided by the five steps of the nursing process: assessment, diagnosis, planning, implementation, and evaluation. Expected nursing documentation includes a nursing assessment, the care plan, interventions, the patient's outcomes or response to care, and assessment of the patient's ability to manage after discharge. Care plans provide treatment guidelines for individual patients and are part of the permanent health record. The care plan should clearly identify patient preferences, with goals mutually developed by the patient and nurse.

The use of standardized nursing language has many advantages for direct patient care. Standardized nursing terminologies such as the *International Classification for Nursing Practice (ICNP)*, *NANDA International, Inc. (NANDA-I) nursing diagnoses*, *Nursing Interventions Classification (NIC)*, and *Nursing Outcomes Classification (NOC)* may be used in the documentation process. According to the International Council of Nursing (ICN), ICNP facilitates the description and comparison of nursing practice in every setting across the globe. ICNP terminology allows ICN to represent nursing practice worldwide to promote evidenced-based quality care. ICNP can be used with EHRs as a standardized language (ICN, 2018).

Do-Not-Use Abbreviations

Nurses must be aware of the danger of using abbreviations that may be misunderstood and compromise patient safety. TJC (2018) has compiled a list of do-not-use abbreviations, acronyms, and symbols to avoid the possibility of errors that may be life-threatening (Table 10.1). TJC supplies a toolkit to help facilities reach conformity in this area, and it recommends that each facility implement a “spell it out” campaign rather than using risky abbreviations. The Error-Prone Abbreviations, Symbols, and Dose Designations chart is available from the Institute for Safe Medication Practices (Fig. 10.2).

TABLE 10.1
Do-Not-Use Abbreviations

Do Not Use	Potential Problem	Use Instead
U, u (unit)	Mistaken for the number 0 or 4 or for cc	Write <i>unit</i>
IU (international unit)	Mistaken for IV (intravenous) or the number 10	Write <i>international unit</i>
QD, Q.D., qd, q.d. (daily)	Mistaken for each other	Write <i>daily</i>
QOD, Q.O.D., qod, q.o.d (every other day)	Period after Q mistaken for I, and the O mistaken for I	Write <i>every other day</i>
MS, MSO ₄ , and MgSO ₄	Confused with one another	Write <i>morphine sulfate</i>
	Can mean morphine sulfate or magnesium sulfate	Write <i>magnesium sulfate</i>
Trailing zero (X.0 mg)	Decimal point is confusing	Write as X mg
Lack of leading zero (.X mg)		Write as 0.X mg

From The Joint Commission. Facts about the official “Do Not Use” list of abbreviations, 2018. Retrieved from https://www.jointcommission.org/facts_about_do_not_use_list/.

ISMP's List of *Error-Prone Abbreviations, Symbols, and Dose Designations*

The abbreviations, symbols, and dose designations found in this table have been reported to ISMP through the ISMP National Medication Errors Reporting Program (ISMP MERP) as being frequently misinterpreted and involved in harmful medication errors. They should **NEVER** be used when commu-

nicating medical information. This includes internal communications, telephone/verbal prescriptions, computer-generated labels, labels for drug storage bins, medication administration records, as well as pharmacy and prescriber computer order entry screens.

Abbreviations	Intended Meaning	Misinterpretation	Correction
µg	Microgram	Mistaken as "mg"	Use "mcg"
AD, AS, AU	Right ear, left ear, each ear	Mistaken as OD, OS, OU (right eye, left eye, each eye)	Use "right ear," "left ear," or "each ear"
OD, OS, OU	Right eye, left eye, each eye	Mistaken as AD, AS, AU (right ear, left ear, each ear)	Use "right eye," "left eye," or "each eye"
BT	Bedtime	Mistaken as "BID" (twice daily)	Use "bedtime"
cc	Cubic centimeters	Mistaken as "u" (units)	Use "mL"
D/C	Discharge or discontinue	Premature discontinuation of medications if D/C (intended to mean "discharge") has been misinterpreted as "discontinued" when followed by a list of discharge medications	Use "discharge" and "discontinue"
IJ	Injection	Mistaken as "IV" or "intraocular"	Use "injection"
IN	Intranasal	Mistaken as "IM" or "IV"	Use "intranasal" or "NAS"
HS	Half-strength	Mistaken as bedtime	Use "half-strength" or "bedtime"
hs	At bedtime, hours of sleep	Mistaken as half-strength	
IU**	International unit	Mistaken as IV (intravenous) or 10 (ten)	Use "units"
o.d. or OD	Once daily	Mistaken as "right eye" (OD-oculus dexter), leading to oral liquid medications administered in the eye	Use "daily"
OJ	Orange juice	Mistaken as OD or OS (right or left eye); drugs meant to be diluted in orange juice may be given in the eye	Use "orange juice"
Per os	By mouth, orally	The "os" can be mistaken as "left eye" (OS-oculus sinister)	Use "PO," "by mouth," or "orally"
q.d. or QD**	Every day	Mistaken as q.i.d., especially if the period after the "q" or the tail of the "q" is misunderstood as an "i"	Use "daily"
qhs	Nightly at bedtime	Mistaken as "qhr" or every hour	Use "nightly"
qn	Nightly or at bedtime	Mistaken as "qh" (every hour)	Use "nightly" or "at bedtime"
q.o.d. or QOD**	Every other day	Mistaken as "q.d." (daily) or "q.i.d." (four times daily) if the "o" is poorly written	Use "every other day"
q1d	Daily	Mistaken as q.i.d. (four times daily)	Use "daily"
q6PM, etc.	Every evening at 6 PM	Mistaken as every 6 hours	Use "daily at 6 PM" or "6 PM daily"
SC, SQ, sub q	Subcutaneous	SC mistaken as SL (sublingual); SQ mistaken as "5 every;" the "q" in "sub q" has been mistaken as "every" (e.g., a heparin dose ordered "sub q 2 hours before surgery" misunderstood as every 2 hours before surgery)	Use "subcut" or "subcutaneously"
ss	Sliding scale (insulin) or ½ (apothecary)	Mistaken as "55"	Spell out "sliding scale;" use "one-half" or "½"
SSRI	Sliding scale regular insulin	Mistaken as selective-serotonin reuptake inhibitor	Spell out "sliding scale (insulin)"
SSI	Sliding scale insulin	Mistaken as Strong Solution of Iodine (Lugol's)	
i/d	One daily	Mistaken as "tid"	Use "1 daily"
TIW or tiw	3 times a week	Mistaken as "3 times a day" or "twice in a week"	Use "3 times weekly"
U or u**	Unit	Mistaken as the number 0 or 4, causing a 10-fold overdose or greater (e.g., 4U seen as "40" or 4u seen as "44"); mistaken as "cc" so dose given in volume instead of units (e.g., 4u seen as 4cc)	Use "unit"
UD	As directed ("ut dictum")	Mistaken as unit dose (e.g., diltiazem 125 mg IV infusion "UD" misinterpreted as meaning to give the entire infusion as a unit [bolus] dose)	Use "as directed"
Dose Designations and Other Information	Intended Meaning	Misinterpretation	Correction
Trailing zero after decimal point (e.g., 1.0 mg)**	1 mg	Mistaken as 10 mg if the decimal point is not seen	Do not use trailing zeros for doses expressed in whole numbers
"Naked" decimal point (e.g., .5 mg)**	0.5 mg	Mistaken as 5 mg if the decimal point is not seen	Use zero before a decimal point when the dose is less than a whole unit
Abbreviations such as mg, or mL, with a period following the abbreviation	mg mL	The period is unnecessary and could be mistaken as the number 1 if written poorly	Use mg, mL, etc. without a terminal period
Dose Designations and Other Information	Intended Meaning	Misinterpretation	Correction
Drug name and dose run together (especially problematic for drug names that end in "l" such as Inderal40 mg; Tegretol300 mg)	Inderal 40 mg Tegretol 300 mg	Mistaken as Inderal 140 mg Mistaken as Tegretol 1300 mg	Place adequate space between the drug name, dose, and unit of measure
Numerical dose and unit of measure run together (e.g., 10mg, 100mL)	10 mg 100 mL	The "m" is sometimes mistaken as a zero or two zeros, risking a 10- to 100-fold overdose	Place adequate space between the dose and unit of measure
Large doses without properly placed commas (e.g., 100000 units; 1000000 units)	100,000 units 1,000,000 units	100000 has been mistaken as 10,000 or 1,000,000; 1000000 has been mistaken as 100,000	Use commas for dosing units at or above 1,000, or use words such as 100 "thousand" or 1 "million" to improve readability
Drug Name Abbreviations	Intended Meaning	Misinterpretation	Correction
To avoid confusion, do not abbreviate drug names when communicating medical information. Examples of drug name abbreviations involved in medication errors include:			

APAP	acetaminophen	Not recognized as acetaminophen	Use complete drug name
ARA A	vidarabine	Mistaken as cytarabine (ARA C)	Use complete drug name
AZT	zidovudine (Retrovir)	Mistaken as azathioprine or aztreonam	Use complete drug name
CPZ	Compazine (prochlorperazine)	Mistaken as chlorpromazine	Use complete drug name
DPT	Demersal-Phenergan-Thorazine	Mistaken as diphtheria-pertussis-tetanus (vaccine)	Use complete drug name
DTO	Diluted tincture of opium, or deodorized tincture of opium (Paregoric)	Mistaken as tincture of opium	Use complete drug name
HCl	hydrochloric acid or hydrochloride	Mistaken as potassium chloride (The "H" is misinterpreted as "K")	Use complete drug name unless expressed as a salt of a drug
HCT	hydrocortisone	Mistaken as hydrochlorothiazide	Use complete drug name
HCTZ	hydrochlorothiazide	Mistaken as hydrocortisone (seen as HCT250 mg)	Use complete drug name
MgSO4**	magnesium sulfate	Mistaken as morphine sulfate	Use complete drug name
MS, MSO4**	morphine sulfate	Mistaken as magnesium sulfate	Use complete drug name
MTX	methotrexate	Mistaken as mitoxantrone	Use complete drug name
NoAC	novel/new oral anticoagulant	No anticoagulant	Use complete drug name
PCA	procainamide	Mistaken as patient controlled analgesia	Use complete drug name
PTU	propylthiouracil	Mistaken as mercaptopurine	Use complete drug name
T3	Tylenol with codeine No. 3	Mistaken as liothyronine	Use complete drug name
TAC	triamcinolone	Mistaken as tetracaine, Adrenalin, cocaine	Use complete drug name
TNK	TNKase	Mistaken as "TPA"	Use complete drug name
TPA or tPA	tissue plasminogen activator, Activase (alteplase)	Mistaken as TNKase (tenecteplase), or less often as another tissue plasminogen activator, Retavase (reteplase)	Use complete drug names
ZnSO4	zinc sulfate	Mistaken as morphine sulfate	Use complete drug name
Stemmed Drug Names	Intended Meaning	Misinterpretation	Correction
"Nitro" drip	nitroglycerin infusion	Mistaken as sodium nitroprusside infusion	Use complete drug name
"Norflex"	norflexacin	Mistaken as Norflex	Use complete drug name
"IV Vanc"	intravenous vancomycin	Mistaken as Invanz	Use complete drug name
Symbols	Intended Meaning	Misinterpretation	Correction
℥	Dram	Symbol for dram mistaken as "3"	Use the metric system
℥	Minim	Symbol for minim mistaken as "ml"	
x3d	For three days	Mistaken as "3 doses"	Use "for three days"
> and <	More than and less than	Mistaken as opposite of intended; mistakenly use incorrect symbol; "< 10" mistaken as "40"	Use "more than" or "less than"
/ (slash mark)	Separates two doses or indicates "per"	Mistaken as the number 1 (e.g., "25 units/10 units" misread as "25 units and 10" units)	Use "per" rather than a slash mark to separate doses
@	At	Mistaken as "2"	Use "at"
&	And	Mistaken as "2"	Use "and"
+	Plus or and	Mistaken as "4"	Use "and"
°	Hour	Mistaken as a zero (e.g., q2° seen as q 20)	Use "hr," "h," or "hour"
∅ or ∅	zero, null sign	Mistaken as numerals 4, 6, 8, and 9	Use 0 or zero, or describe intent using whole words

**These abbreviations are included on The Joint Commission's "minimum list" of dangerous abbreviations, acronyms, and symbols that must be included on an organization's "Do Not Use" list, effective January 1, 2004. Visit www.jointcommission.org for more information about this Joint Commission requirement.

Safe Practice Alert

Document using only accepted abbreviations and acronyms to facilitate effective communication among care providers that supports safe patient care.

Documentation Formats

Nurses use a variety of documentation formats, usually based on facility policy. Source-oriented charting gives each profession a separate section of the record in which to do narrative charting. The **problem-oriented medical record (POMR)** integrates charting from the entire care team in the same section of the record. The POMR format provides a framework for documentation. The nurse's notes may be in a narrative format or in a problem-oriented structure such as the PIE, APIE, SOAP, SOAPIE, SOAPIER, DAR, or CBE format. The elements in each of these types of charting are listed in [Table 10.2](#).

TABLE 10.2

Problem-Oriented Medical Records Formats

Format	Elements
PIE	Problem, intervention, evaluation
APIE	Assessment, problem, intervention, evaluation
SOAP	Subjective data, objective data, assessment, plan
SOAPIE	Subjective data, objective data, assessment, plan, intervention, evaluation
SOAPIER	Subjective data, objective data, assessment, plan, intervention, evaluation, revisions to plan
DAR	Data, action, response
CBE	Charting by exception

Narrative Charting

Narrative charting is chronologic, with a baseline recorded on a shift-by-shift basis. Data are recorded in the progress notes, often without an organizing framework. Narrative charting may stand alone, or it may be complemented by other tools such as flow charts, flow sheets, and checklists. This charting format may be time-consuming and contain lengthy notes that may not add to the care process.

Formatted Charting

Problem-oriented documentation can be completed in a variety of formats and follows a selected structure.

PIE Notes

A **PIE note** is used to document problem (*P*), intervention (*I*), and evaluation (*E*). For example, a PIE note may read as follows:

P: Acute pain in lower right quadrant of abdomen rated by postsurgical patient as 8/10.

- I:** Morphine sulfate (5 mg IV) given at 0930 per order for LRQ abdominal pain relief.
- E:** Patient reported a 3/10 pain level 20 minutes after an analgesic was administered.

APIE Notes

An **APIE note** adds assessment (*A*), combining subjective and objective data with the PIE format. For example, the *A* in an APIE note may read as follows:

- A:** Patient holding hand over surgical site and grimacing while reporting pain at a level of 8/10 on the pain scale.

SOAP Notes

A **SOAP note** is used to chart the subjective data (*S*), objective data (*O*), assessment (*A*), and plan (*P*). The format is sometimes expanded to a **SOAPIE note**, which includes the actual interventions (*I*) and an evaluation (*E*) of intervention outcomes. Another form of the SOAP note is the **SOAPIER note**, which adds revision (*R*) of the plan of care as necessary to meet the follow-up needs of the patient. Documentation is usually organized in the following way:

- S:** What do the patient and others tell you?
- O:** What are the results of the physical examination, relevant vital signs, or other tests?
- A:** What is the patient's current status?
- P:** What interventions are necessary?
- I:** What treatments did the nurse provide?
- E:** What are the patient outcomes after each intervention?
- R:** Does the plan stay the same? What changes are needed to the care plan?

DAR Notes

A **DAR note** is used to chart the data (*D*) collected about the patient problems, the action (*A*) initiated, and the patient's response (*R*) to the actions. A DAR note may read as follows:

- D:** Patient grimacing. Holding hand at abdominal surgical site. Pulse 98. States pain at a level of 8/10.
- A:** Given morphine sulfate 5 mg IV per order and repositioned for comfort.

R: 20 minutes after morphine is given, patient states relief with a pain level at 2/10.

1. Develop a SOAPIE note for M. S.

Charting by Exception

Charting by exception (CBE) is documentation that records only abnormal or significant data. It reduces charting time by assuming certain norms. For this type of charting, each facility must define what is normal. Any assessment finding outside normal is charted as an exception.

Case Management Documentation

The case management process of documentation is focused on providing and documenting high-quality, cost-effective delivery of patient care. This documentation uses standards of care to monitor patient outcomes on a regular basis, often using a predetermined care path format. The goal of case management is to achieve realistic and desired patient and family outcomes within appropriate lengths of stay and with appropriate use of resources. Clinical pathways based on nursing assessments provide standardized, evidence-based patient care that leads to achievement of outcomes. These ideas are discussed in greater detail in [Chapter 5](#).

Flow Sheets

Flow sheets and checklists may be used to document routine care and observations that are recorded on a regular basis, such as vital signs, medications, and intake and output measurements ([Fig. 10.3](#)). Data collected on flow sheets may be converted to a graph, which pictorially reflects patient data and is helpful when identifying trends or making comparisons. Flow sheets and checklists are part of the permanent medical record.

FIGURE 10.3 Flow sheet. (Courtesy Epic Systems Corporation, Verona, WI, 2012.)

A **medication administration record (MAR)** is a list of ordered medications, along with dosages, routes, and times of administration, on which the nurse initials medications given or not given. If a medication is not given, the nurse notes the reason on the MAR. A paper MAR usually includes a signature section in which the nurse is identified by linking the initials used with a full signature. The EHR includes an electronic medication administration record (eMAR).

Safe Practice Alert

Medications administered must be documented immediately to avoid confusion about what has been given and the possibility of double dosing.

Bar-Coded Medication Administration

Many facilities using electronic records have incorporated **bar-coded medication administration (BCMA)** into the process of medication administration. Using a portable scanner, the nurse scans the patient's wristband and the medication to be given. In some facilities, the nurse's bar-coded identification is also scanned. If the eMAR and the scanned medication do not agree, the nurse receives an alert about a potential problem. The use of BCMA and eMAR allows the nurse to obtain a report of medications given, held, or due. [Chapter 35](#) provides more information on medication administration.

Kardex

Originally, the Kardex was a nonpermanent filing system for nursing records, orders, and patient information that was held centrally on the unit. The Kardex contained patient orders and demographic information. Although computerization of records may mean that the Kardex system is no longer active, the term *kardex* continues to be used generically for certain patient information held at the nurses' station.

Admission and Discharge Summaries

An admission summary includes the patient's history, a medication reconciliation, and an initial assessment that addresses the patient's problems, including identification of needs pertinent to discharge planning and formulation of a plan of care based on those needs. The discharge summary addresses the patient's hospital course and plans for follow-up, and it documents the patient's status at discharge. It includes information on medication and treatment, discharge placement, patient education, follow-up appointments, and referrals.

Legal Issues of Documentation

Nurses' notes are legal documents. The medical record is seen as the most reliable source of information in any legal action related to care. When legal counsel is sought because of a negative outcome of care, the first action taken by an attorney is to acquire a copy of the medical record. Documentation that meets specific guidelines can prevent a case from going to court or can provide protection if a case does go to trial.

Every entry into the medical record should include a date, time, and signature. Notes should never be altered or obliterated. Documentation mistakes must be acknowledged. If an error is made in paper documentation, a line is drawn through the error and the word *error* is placed above or after the entry, along with the nurse's initials (Fig. 10.4) and followed by the correct entry. If an error is made in electronic documentation, it can be corrected on the screen view, but the error and correction process will remain in the permanent electronic record. Log-on access to the electronic record identifies the person making the change. Any correction in documentation that indicates a significant change in patient status should include notification of the primary care provider (PCP).

Date	Time	Discipline	Problem intervention evaluation	Patient progress notes
4/22/19	0800	Nursing	Problem	Patient states that pain in sheet rates 4/10 ^{error no} in left wrist rates 8 out of 10. pain does not radiate, and is sharp. Pain started four hours ago' after patient fell off of his bike. It is worse with movements. Vital signs: T: 36.6°C, P : 92 and regular, R: 24 & regular, BP: 153/84. _____ Norma Carr, RN
			Intervention	Administered 2 mg morphine I V per order. _____ Norma Carr, RN
4/22/19	0830	Nursing	Evaluation	Patient states pain is 3/10. Resting at this time. _____ Norma Carr, RN

FIGURE 10.4 Correcting an error in written documentation.

Documentation should be completed as soon as possible after care is given. Timeliness of documentation depends on the patient's condition. When the patient's acuity and complexity of care are high, documentation occurs more frequently. Waiting until the end of shift to document creates the potential for errors and compromises patient safety. Keep in mind that in most health care settings a 24-hour clock is used for documentation.

The principles of documentation remain the same regardless of whether it is completed on paper or in an EHR. However, electronic recording, transmitting, and receiving of patient information poses significant challenges for nurses in regard to confidentiality and security of patient information.

LO 10.4 Confidentiality and Privacy

The **confidentiality** of patient information must be safeguarded and the information shared only with individuals who have a need and a right to know. Nurses have a professional and legal obligation to protect patient information. In health care, confidentiality addresses the ethical principle that assumes a health professional will hold secure all information relating to a patient unless the patient gives consent for disclosure (ANA, 2010).

The right to **privacy** is the right to be free from intrusion or disturbance in a person's private life (ANA, 2010). In the context of recorded information, it refers to the expectation of controlling or, in some cases, the legal right of a person to control access to personal information.

The **Health Insurance Portability and Accountability Act (HIPAA)**, originally passed in 1996, created standards for the protection of personal health information, whether conveyed orally or recorded in any form or medium. The act clearly mandates that protected health information may be used only for treatment, payment, or health care operations. Nurses share the responsibility for preventing a breach of this information. **Chapter 11** provides more information on HIPAA.

HIPAA privacy standards should be applied during phone, fax, e-mail, or Internet transmission of protected patient information. Patient information should be shared and the EHR accessed only in private work areas or at the individual patient's bedside. EHR access is password protected. **Box 11.7** lists procedural and documentation concerns associated with HIPAA.

Patients' rights include obtaining, viewing, or updating a copy of their own medical records. Methods for implementation vary by facility and type of medical record. The ARRA of 2009 updated some aspects of HIPAA. A fee can be charged for copying and mailing records; however, facilities cannot charge for retrieval of a patient's medical records (US Department of Health and Human Services [DHHS], 2017).

LO 10.5 Hand-Off Reports

The real-time process of passing patient-specific information from one caregiver to another or among interdisciplinary team members to ensure continuity of care and patient safety is often called a **hand-off**. Hand-offs can be oral, as in a face-to-face meeting or telephone communication, or they can be written or recorded. The information exchange can take place between providers, between shifts, and at the time of unit transfer or discharge referral.

Transitioning patients from one type of care to another (e.g., acute care to long-term care, inpatient to outpatient care) involves risks due to a lack of uniformity in the hand-off process and inadequate training on how to communicate during the transfer of care. Hand-off reporting should provide accurate, timely, important information to the next caregiver to ensure patient safety. This is vital because communication breakdown accounts for a high number of medical errors (Wagner, 2015). When complete and accurate information is not shared during a hand-off report, patients may not get needed care, proper medications, or recommended therapies.

The process of making a change-of-shift report serves several functions. Hand-offs provide accurate and timely information about the care, treatment, and services rendered to a patient, addressing the patient's current condition and anticipated changes. Patient information that supports care delivery and clinical decision making must be shared to facilitate continuity of care. The hand-off process can be an opportunity for collaborative problem solving. Improvement in the hand-off process can increase patient safety and promote positive patient outcomes. During an average hospital stay of approximately 4 days, as many as 24 hand-offs can occur for just one patient, because shifts change every 8 to 12 hours and many individuals are responsible for care. An ineffective hand-off may lead to wrong treatments, wrong medications, or other life-threatening events, increasing the length of stay and causing patient injury or death.

2. What information is important to share with the nurse who will be responsible for M. S.'s care on the next shift?

Unfortunately, wide variations exist in the quality and quantity of information shared in the shift report. Several of the top 10 reported sentinel events such as medication errors, falls, and delay in treatment could occur due to incomplete hand-off reporting (TJC, 2017a). A **sentinel event** is a safety occurrence that affects a patient and causes death, serious permanent or temporary injury, or requires interventions to sustain life (TJC, 2017b). These events are called *sentinel* because they signal the need for an immediate investigation and response. In 2005, 70% of sentinel events were caused by communication breakdowns and 50% of those occurred during patient hand-off. To improve the effectiveness of communication among caregivers, TJC (2019) introduced a national patient safety goal in 2006, which became a standard in 2009, requiring implementation of a standardized approach to hand-off communications (Box 10.3).

Box 10.3

Evidence-Based Practice and Informatics

Hand-Off Reports

One multihospital system piloted a new intershift hand-off process on a unit in seven hospitals to test improvements in patient and nurse satisfaction. The goal of the pilot program was to use evidence-based practice to implement a new hand-off process to improve patient safety and satisfaction and promote patient-centered care.

Pilot Hand-Off Program

- The hospital system implemented an evidence-based hand-off process.
- A standardized tool was used for nurses to exchange information in the hand-off report to ensure that pertinent information was passed on to the next shift.
- Patients and their families were invited in writing to participate in the intershift hand-off, which occurred at the bedside.
- Patients and their families were at the center of the hand-off, and nurses deliberately sought input from them.

Results of the Program

- Nurses had increased knowledge about patient priorities.
- New nursing graduates reported feeling empowered.
- Nurses were able to jointly teach at the bedside and collaboratively assess patients.
- Nurses perceived that appropriate information was being exchanged and that relationships between shifts improved.
- Patient satisfaction scores improved significantly in all three categories measured:
 - Nurses kept patients informed
 - Friendliness and courtesy of the staff
 - Likelihood to recommend the hospital

Adapted from Thomas, L., Donohue-Porter, P. (2012). Blending evidence and innovation: Improving intershift handoffs in a multihospital setting. *Journal of Nursing Care Quality*, 27(2), 116-124.

Wagner (2015) thinks that implementing a standardized process for hand-offs helps nurses deliver safe, effective care. In many sites, the move to standardized shift reports consists of bedside reports that include incoming staff, outgoing staff, and the patient (Fig. 10.5). A consistent method of face-to-face hand-off reporting enhances quality and safe patient care. Interprofessional patient care conferences and rounds are a major source of communication between health care professionals and patients (Box 10.4).

FIGURE 10.5 Hand-off report includes the patient's input.

Box 10.4

Patient Education and Health Literacy

“Patient Participation in Hand-Off Reports”

Hand-off reports are enhanced with patient participation. Nurses should:

- Teach patients to actively participate with staff during the bedside rounds.
- Ask patients to validate the information shared during the rounding process.
- Encourage patients to ask questions during the rounding process.

Current hand-off mechanisms vary from hospital to hospital and even from unit to unit. A communication format specifically suggested for use in nurse–physician interactions is **SBAR** (i.e., situation, background, assessment, and recommendation), a situation-briefing tool used by the U.S. Navy (Table 10.3). SBAR was adapted for health care at Kaiser Permanente of Colorado and has become widely used in the United States and in the British National Health Service. SBAR is often used by nursing as a hand-off tool and as a structured method for all communications between providers.

TABLE 10.3

SBAR Communication Tool

Element	Description
Situation	What is happening at the current time?
Background	What are the circumstances leading up to this situation?
Assessment	What does the nurse think the problem is?
Recommendation	What should we do to correct the problem?

From [Institute for Healthcare Improvement. SBAR toolkit, 2018](http://www.ih.org/knowledge/pages/tools/sbartoolkit.aspx). Retrieved from <http://www.ih.org/knowledge/pages/tools/sbartoolkit.aspx>.

The SBAR model, not unlike the nursing process, begins with the active situation, the related background, the assessment of the problem, and a recommendation for a solution. “SBAR offers a simple way to help standardize communication and allows parties to have common expectations related to what is to be communicated and how the communication is structured” ([Institute for Healthcare Improvement, 2018](#)). Research is being conducted to identify the most effective methods for patient hand-offs, but use of a consistent process or tool is key to positive patient outcomes.

An ISBAR is being implemented in some settings. The “I” in this mnemonic stands for Identify. It is recommended that the hand-off communication start with identification of the health care providers involved in the hand-off and of the patient ([SA Health, 2018](#)). [TJC \(2017c\)](#) discusses ISBAR as one of the tools that can improve patient safety if used consistently as a standardized format for hand-offs by trained health care personnel.

3. The nurse needs to call the PCP to renew M.S.'s pain medication. Develop an SBAR report for this call.

Use of EHRs supports development of a standardized and integrated shift report to facilitate better communication of significant information. When documentation is completed electronically at the point of care, the potential for errors and omitted information is decreased. A hand-off report can be printed that is specifically designed to address all pertinent information for a patient assignment. Even with computerized

systems, nurses should continue to ask questions and seek additional information for hand-off reports.

QSEN Focus!

Teamwork and collaboration are demonstrated when the nurse appreciates the risks associated with hand-offs among providers and across transitions of care and follows communication practices that minimize those risks.

Patient safety issues are heightened when information is transferred during intrahospital transport. Some facilities have developed a structured “ticket-to-ride” communication tool that includes important information to ensure adequate care during transport and at the destination within the hospital. This process decreases the risk for adverse events while increasing patient satisfaction ([Pesanka, Greenhouse, Rack et al., 2009](#)).

LO 10.6 Verbal and Telephone Orders

With the advent of EMRs, CPOEs, and widespread access to information technology, many facilities limit verbal or telephone orders to emergency situations. The PCP can access the EMR from a smartphone, hand-held device, or personal computer and enter or send orders directly to the appropriate department. This removes the nurse or unit secretary from the ordering process and decreases the possibility of error.

If a verbal or phone order is necessary in an emergency, the order must be taken by a registered nurse (RN), who repeats the order verbatim to confirm accuracy and then enters the order into the paper or electronic system, documenting it as a verbal or phone order and including the date, time, physician's name, and RN's signature. Most facility policies require the physician to cosign a verbal or telephone order within a defined period.

LO 10.7 Incident Reports

When an unusual and unexpected event involving a patient, visitor, or staff member occurs, an incident report is completed. An incident may be the occurrence of a fall, a medication error, or an equipment malfunction. The purpose of this report is to document the details of the incident immediately to ensure accuracy. Incident reports are objective, nonjudgmental, factual reports of the occurrence and its consequences. The incident report is not part of a medical record but is considered a risk management or quality improvement document. The fact that an incident report was completed is not recorded in the patient's medical record; however, the details of a patient incident are documented.

Safe Practice Alert

Incident reports, which are used in the risk management process, must include only facts, not suppositions or opinions.

Summary of Learning Outcomes

LO 10.1 *Identify the standards for effective documentation by nurses:* Standards for documentation should be in agreement with TJC's standards, the general principles of medical record documentation from the Centers for Medicare and Medicaid Services, and the ANA principles.

LO 10.2 *Discuss the functions of the medical record, including the electronic health record:* The medical record may be written or electronic. It is an accurate, comprehensive record of a patient's health care encounter and a major communication tool between health care providers.

LO 10.3 *List the important attributes of nursing documentation in the medical record:* Nursing documentation demonstrates nursing contributions to patient care and must be accurate, timely, comprehensive, and relevant.

LO 10.4 *Define privacy and confidentiality as they relate to information in a medical record:* Nurses must maintain the confidentiality and privacy of patients' personal health information.

LO 10.5 *Describe standardized formats for use in hand-off reports and change-of-shift reports:* Nurses must be able to determine the critical information necessary to ensure patient safety when communicating with other nurses and other health care professionals. Use of standardized formats for hand-offs and shift reports helps ensure the accurate exchange of pertinent information.

LO 10.6 *Explain the process of accepting verbal and telephone orders:* Only RNs can accept a verbal or telephone order, and they must immediately enter the order into the paper or electronic record.

LO 10.7 *Discuss the proper use of incident reports:* Incident reports are factual accounts of an incident involving a patient, visitor, or staff member that are not part of the medical record.

Review Questions

1. A hospital has just implemented the use of electronic health records (EHRs). While learning to use this new system, the nurse realizes that EHRs may do which of the following?
 - a. Limit access to the patient record to one person at a time
 - b. Improve access to patient information at the point of care
 - c. Negate the use of nursing documentation
 - d. Increase the potential for medication errors
2. Which statement best contributes to the nurse's documentation of assessment of patient status in the patient's medical chart?
 - a. "Patient had a good day with minimal complaints. Patient was pleasant and cooperative during morning care."
 - b. "Patient complained that the nurse didn't come quickly enough when she pressed the call button."
 - c. "Patient rated pain 7/10 at 7:45 a.m. Received pain medication at 8 a.m. reporting pain 3/10 at 8:30 a.m."
 - d. "Patient was grumpy today, even after administration of pain medication, a back massage, and a nap."
3. A patient requests a copy of his medical record. What is the correct response by the nurse?
 - a. Inform him that his record is the property of the facility and cannot be accessed by anyone but staff.

- b. Tell him that the Code for Nurses does not allow you to give him access to his records.
 - c. Acknowledge that he has the right to have a copy of his records, and make arrangements per facility policy.
 - d. Refer his request to the hospital administrator because all such requests need to go through proper channels.
4. A patient's sister comes to visit and asks to read the patient's medical records. What is the best response by the nurse?
- a. Settle her in a chair at the nurses' station and give her access.
 - b. Respond that the contents of a patient's medical records are private and confidential.
 - c. Tell her she can read the medical records only if the patient sits with her.
 - d. Distract the sister by changing the subject and then walking away.
5. Which are reasons that accurate documentation in the medical record is important? (*Select all that apply.*)
- a. Reimbursement for care
 - b. Evidence of care provided
 - c. Communication between health care providers
 - d. Nonlegal documentation of a nurse's actions
 - e. Promotion of continuity of care
6. Which note is an example of the S in SBAR?
- a. Patient resting; pain was rated 3/10 1 hour after receiving narcotic analgesic.

- b. Patient was admitted on evening shift with a fractured right femur after a fall at home.
 - c. Patient's pain was rated 8/10 before administration of narcotic pain medication.
 - d. Assess pain every 2 hours, continue pain medication as prescribed, and provide backrub.
7. Which attributes are important in nursing documentation? (*Select all that apply.*)
- a. Inconsequentiality
 - b. Timeliness
 - c. Relevancy
 - d. Accuracy
 - e. Factual basis
8. When should administered medications be documented?
- a. At the end of a shift when all medications have been given
 - b. As given to avoid the possibility of double dosing
 - c. After every meal to document at least three times daily
 - d. When the nurse has time before going on break
9. What is an advantage of the use of paper medical records?
- a. Charts with paper records are always available to all health care team members.
 - b. Paper records do not need much storage space in the health care facility.
 - c. Writing implements are always available on nursing units and patient rooms.

- d. Recording on paper does not require any special computer knowledge.
10. What is a purpose of a hand-off report?
- a. Ensures continuity of care and patient safety
 - b. Keeps the doctor informed
 - c. Completed when a patient is discharged to home
 - d. Determines patient assignments

CHAPTER 11

Ethical and Legal Considerations

LEARNING OUTCOMES

Comprehension of this chapter's content will provide students with the ability to:

- LO 11.1 Identify key ethical theories that affect nursing practice.
- LO 11.2 Apply ethical principles to professional nursing practice.
- LO 11.3 Describe how the American Nurses Association (ANA) Code of Ethics for Nurses applies to nursing education and practice.
- LO 11.4 Discuss the role of ethics in genetic, biomedical, and end-of-life health care decision making.
- LO 11.5 Examine the potential impact and interventions to address moral distress.
- LO 11.6 Differentiate among constitutional, statutory, regulatory, and case laws as they relate to professional nursing practice.
- LO 11.7 Identify various types of statutory law, including intentional and unintentional torts, and their potential effect on nurses providing patient care.
- LO 11.8 Explain liability issues (such as professional boundaries, delegation, and documentation) that are pertinent to nursing practice.
- LO 11.9 Summarize the legal issues that guide patient care.
- LO 11.10 Discuss how laws impact nursing practice.
- LO 11.11 Describe initiatives designed to facilitate safer nursing practice.

Case Study

Cameron Augustine (C. A.) is a single, 27-year-old, paraplegic veteran. He was injured 8 months earlier while riding in a jeep that hit a roadside bomb. On returning home from his military service, he began rehabilitation and has been learning to adapt to life confined to a wheelchair. C. A. uses a straight catheter to empty his bladder three or four times each day. He was admitted to the hospital yesterday for treatment of a persistent urinary tract infection. When asked, C. A. states that he “prefers to be called Cameron.” He answers questions abruptly with one-word responses and expresses a lack of trust in his physicians and nurses.

C. A. has a high school sweetheart to whom he is engaged, and she visits him each evening after work. During the day, C. A. makes an occasional sexually suggestive remark to his 24-year-old female nurse. C. A. asks the nurse for her personal contact information and permission to call her for help with his care after he is discharged from the hospital.

Refer back to this case study to answer the critical-thinking questions throughout the chapter.

High ethical and legal standards must be maintained within professional nursing practice to ensure safe and comprehensive patient care. It is the responsibility of every nurse to be familiar with the rights of patients and with the ethical and legal requirements of professional nursing. To provide safe and compassionate patient care, nurses must base their decisions and actions on the ethical and legal standards of care, current clinical facility policies, and evidence-based practice guidelines.

Nurses are consistently considered to be honest and ethical professionals by most respondents in an annual Gallup poll ([Gallup, 2018](#)). This designation carries with it significant responsibility. Nurses are required to advocate for patients and their families and build trusting relationships. Professional nurses are encouraged to model healthy lifestyle choices and work for equal health care access for all individuals in their communities. By focusing on the needs of others and maintaining a commitment to excellence, nurses maintain high ethical and legal standards of care.

LO 11.1 Ethics and Ethical Theories

The study of **ethics** considers the standards of moral conduct in a society. Personal ethics are influenced by values, societal norms, and practices (Burkhardt & Nathaniel, 2014). Family, friends, beliefs, education, culture, and socioeconomic status influence the development of ethical behavior. Behaviors that are judged as ethical or unethical, right or wrong, reflect a person's character.

Ethical Theories

Decision making in health care is influenced by theories that view ethical behavior from a variety of philosophical perspectives. Personal ethical dilemmas arise when values conflict and individuals are required to make choices among equally undesirable alternatives. For instance, when a middle-aged patient who does not believe in organ transplantation is diagnosed with chronic renal failure, the patient may need to (1) decide to begin hemodialysis treatments three times per week indefinitely, which will significantly limit the patient's ability to work full time and travel; (2) accept impending death without treatment; or (3) undergo kidney transplantation. None of these three options is without significant consequences, and at least one of them is in direct opposition to the patient's values. A nurse's ability to empathize with patients and families who are faced with challenging health care decisions is enhanced by the nurse's knowledge of ethical theories and their potential impact on behavior.

Deontology

Deontology is an ethical theory that stresses the rightness or wrongness of individual behaviors, duties, and obligations without concern for the consequences of specific actions (Aiken, 2015). Immanuel Kant, an 18th-century German philosopher, developed many aspects of deontologic theory. With its focus on duty, deontology is the foundation of most professional codes of ethics, including the Code of Ethics for Nurses (Burkhardt & Nathaniel, 2014). Meeting the needs of patients while maintaining

their right to privacy, confidentiality, autonomy, and dignity is consistent with the tenets of deontology.

Kant believed that the ethical rules of deontology were consistent and could be understood by all rational individuals (Burkhardt & Nathaniel, 2014). However, Kant's assertion that moral rules were applicable to all people, all of the time, and in every situation, is particularly challenging in a modern, multicultural society. His rigid, universal conceptualization of deontologic theory is difficult to apply in complex situations. For instance, when a patient is sedated and decisions need to be made regarding care, should the nurse act on what the nurse knows to be the desire of the patient, or is the nurse obligated to listen to a spouse whose wishes conflict with those of the patient?

Utilitarianism

Compared with deontology, utilitarianism is on the opposite end of the ethical theory continuum. Utilitarianism maintains that behaviors are determined to be right or wrong solely on the basis of their consequences (Aiken, 2015). The father of modern utilitarianism is Jeremy Bentham, a political philosopher of the late 18th century. Bentham's work was further developed by John Stuart Mill, a 19th-century British moral philosopher who posited the principle of *greatest happiness*. The utilitarian concept of greatest happiness maintains that the right action is one that brings the greatest happiness to the most people (Mill, 1910). "The end justifies the means" is a phrase that expresses the essence of pure utilitarianism. Unlike the rigidity of deontology, utilitarianism views actions as neither right nor wrong without knowing how they benefit the greater good or society. Advocates of utilitarian thought tend to be highly concerned with social justice while exhibiting resistance to rules and regulations (Aiken, 2015).

Decision making in health care based on pure utilitarianism becomes challenging when the individual rights of patients are inconsistent with the needs of society. For example, a cancer patient may be asked to participate in the trial of a new chemotherapy regimen. Although society may benefit from information gained during the drug trial, the patient undergoing treatment may react violently to the medication and become more

ill. In this case, which action is best? Should the nurse support the patient's participation in the drug trial so that many people may benefit from the findings of the study, or should the nurse support the patient's right to refuse treatment because it may cause him additional suffering?

Although many additional ethical theories exist, most are variations of deontology or utilitarian thought. Although theoretical approaches to ethical dilemmas vary widely, the essential ethical principles on which each theory is based are fundamentally the same.

LO 11.2 Essential Principles of Ethics in Nursing

Nursing practice requires ethical decision making on a consistent basis. Nurses make judgments about patients' rights and benefits in many situations. Becoming familiar with essential ethical principles can help nurses understand how values and morals impact patient care.

Beneficence

In its simplest form, **beneficence** can be defined as doing good. Nurses demonstrate beneficence by acting on behalf of others and placing a priority on the needs of others rather than on personal thoughts and feelings. Nursing practice is motivated by the principle of beneficence. Nurses are socialized to focus on patient needs and concerns, even if they differ significantly from those of the nurse. One of the most challenging situations in which beneficence must take precedence over a nurse's personal feelings occurs when a nurse is assigned to care for an incarcerated murderer or rapist. The ethical concept of beneficence necessitates providing care for the prisoner without reproach. Nurses are required by beneficence to provide compassionate care for all people in all circumstances.

Nonmaleficence

First, do no harm is the colloquial definition of **nonmaleficence**. Unlike beneficence, which requires actively doing good, nonmaleficence requires only the avoidance of harm. It is a fundamental ethical mandate for all health care professionals. The phrase, "do no harm," appears in the original Hippocratic oath describing the ethical practice of medicine. Nonmaleficence requires nurses to provide compassionate care for all patients, especially those who are undergoing painful medical interventions developed to cure debilitating diseases. Nurses are often required to weigh the benefits of medical treatments with their risks and potential harm to patients.

The ethical principle of nonmaleficence is challenged most when health care professionals are involved in end-of-life decisions. Some health care professionals may contend that **euthanasia** (act of painlessly ending the life of another) is murder. Others believe that patients should have the autonomy to make their own decisions regarding end-of-life care, including the option of a painless death facilitated by a health care professional. This issue has ethical and legal implications for nursing practice. Does hospice care, which is endorsed by physicians and nurses as an appropriate and holistic approach to end-of-life care, border on euthanasia because it includes withholding extreme medical treatment? Alternatively, is hospice the most compassionate method of caring for individuals whose death, rather than life, would be extended if extreme medical interventions were implemented? [Chapter 42](#) provides additional information on hospice care.

Respect for Autonomy

A patient who makes independent health care decisions is demonstrating autonomy. **Autonomy**, or self-determination, is the freedom to make decisions supported by knowledge and self-confidence. Nurses promote autonomy when they include patients in the process of developing care plans with realistic goals and interventions.

Nurses demonstrate personal autonomy in many different situations. When nurses stand up for their beliefs in critical situations or pursue continuing education without being required to do so, they are acting autonomously. Autonomy is a defining characteristic of a well-adjusted, independent adult.

Veracity

Truthfulness defines the ethical principle of **veracity**. Honesty promotes unrestricted communication among individuals, demonstrates respect for others, and builds trust. Veracity is considered a virtue by deontologic and utilitarian philosophers. Challenges to this ethical ideal arise when nurses are faced with situations in which individuals perceive the truth as potentially harmful. For example, some family members of a seriously ill patient may prefer that the patient not be told about a poor

prognosis. Keeping secrets from patients is in direct conflict with the ethical principles of autonomy and veracity. Withholding information violates a patient's rights, and it may permanently damage the nurse–patient relationship if the patient discovers the truth. Opposing the wishes of well-intentioned family members can be extremely difficult. However, as with all ethical decisions, nurses must carefully weigh the potential benefits and risks of their actions.

Justice

To do **justice** is to act fairly and equitably. Although justice may seem easy to achieve, the concept is often challenging to apply in health care. Human, material, and financial resources are limited. Many patients may deserve the attention of a nurse simultaneously, which requires the nurse to prioritize. While a nurse is caring for one patient, others may feel that their needs are being ignored.

Justice mandates that all people be treated impartially. Fairness implies that all individuals should have ready access to health care regardless of their ability to pay. However, how are the costs of health care to be covered? Is it fair for some to bear the burden of care for all?

Organ donation is another challenging issue in health care justice. Many potential recipients are in need of transplants, but a limited number of organs are available for transplantation. How can fair decisions be made regarding who will receive the limited number of donor organs? As with many ethical principles, justice is important but difficult to apply universally.

Accountability

Accountability is the willingness to accept responsibility for one's actions. Accountability is required to provide safe patient care and address potential problems. Accountability is a personal attribute that does not require the encouragement of others to be expressed. A nurse who is accountable readily admits to actions without having to be questioned by others.

An important aspect of accountability is tested when a nurse inadvertently makes a mistake. A nurse who is being accountable reports the error and takes responsibility to ensure patient safety,

regardless of the personal consequences. Nurses who exhibit accountability are honest, accept the consequences of their actions, and initiate best nursing practices based on current evidence-based research.

Advocacy

Supporting or promoting the interests of others or of a cause greater than ourselves defines **advocacy**. Patient advocacy is an essential aspect of nursing. A nurse is ethically required to advocate for the rights of all patients, including those who are unable to express themselves and those with whom the nurse disagrees philosophically. Advocacy is an important aspect of collaboration and coordination of patient care. Frequently, nurses must contact various referral agencies and network with several health care professionals to meet patient needs. The process of advocacy requires nurses to focus on patients' needs and benefits.

Confidentiality

Confidentiality is the ethical concept that limits sharing private patient information. Maintaining the confidentiality of patient information means that its disclosure is limited to authorized individuals and agencies. Confidentiality is the cornerstone of a nurse–patient relationship in which trusting, unguarded communication takes place.

All health care professionals are required by law to maintain the confidentiality of patient information. This protects patients from being ridiculed or judged inappropriately on the basis of personal information. Confidentiality also protects patients from being denied jobs or benefits because of their health care history.

Due to the critical nature of confidentiality and patient care, this concept is discussed throughout the textbook in relation to various aspects of patient care. The Health Insurance Portability and Accountability Act (HIPAA) is explored in detail later in this chapter.

Fidelity

Keeping promises or agreements made with others constitutes **fidelity**. In nursing, fidelity is essential for building trusting

relationships with patients and their families. Fidelity in relationships with colleagues is necessary to ensure comprehensive care. When a nurse acknowledges a patient's request for pain medication, assesses the patient's pain level and quality, and returns within a few minutes with the analgesic medication, the nurse is demonstrating the ethical concept of fidelity. Following through on promises is a critical factor in establishing strong professional relationships with patients and their families.

Responsibility

Responsibility is the concept of being dependable and reliable. A nurse who is responsible adheres to professional standards of care, complies with institutional policies, meets requirements of continuing education, and follows the orders of physicians and nurse practitioners (NPs). The nature of responsibility depends on the specific role in which an individual is functioning. For example, the responsibilities of nurses caring for older adults are very different from those practicing in the delivery room. Each nurse has specific responsibilities to fulfill to adequately meet the requirements of individual patient care.

1. Name four ethical principles that, when implemented by the nurse, will help C. A. establish trust in his health care providers.

LO 11.3 Codes of Ethics

A [code of ethics](#) is a formalized statement that defines the values, morals, and standards guiding practice in a specific discipline or profession. These principles should be reflected in the actions of professionals in a particular group. Codes of ethics delineate group expectations and identify specific behaviors that are required by members. Ethical codes promote behavior that is of a higher standard than is required by law.

Historical Background

The foundation of ethical codes of professional conduct for nurses is the original Nightingale Pledge, which was written in 1893 by Lystra Gretter, a nurse educator, to be recited by nursing graduates at their commencement. The Nightingale Pledge was an adaptation of the Hippocratic oath for physicians.

The first official Nursing Code of Ethics was adopted in 1950 by the American Nurses Association (ANA). The ANA evolved from The Nurses' Associated Alumnae of the United States and Canada in 1896. Periodic revisions are made to the Nursing Code of Ethics in response to societal changes and evolution of the professional role of nurses.

Code of Ethics for Nurses

The current nursing code, the Code of Ethics for Nurses with Interpretive Statements, was published in 2015. It includes a glossary of terms and links to support documents that provide a foundation for the Code. The Code of Ethics for Nurses is “a succinct statement of the ethical values, obligations, duties, and professional ideals of nurses individually and collectively,” the profession's “nonnegotiable ethical standard,” and “an expression of nursing's own understanding of its commitment to society” (ANA, 2015, p. viii). The nursing code identifies nine basic provisions under which nursing practice is to take place. In the complete Code of Ethics for Nurses, specific professional expectations (such as respect for others, advocacy, and a

commitment to the rights of patients, families, and groups) are described under each of the basic provisions.

Provision 1.5 states, “Respect for persons extends to all individuals with whom the nurse interacts. Nurses maintain professional, respectful, and caring relationships with colleagues, and are committed to fair treatment, transparency, integrity-preserving compromise, and the best resolution of conflicts” (ANA, 2015, p. 4). The provision continues by saying, “This standard of conduct includes an affirmative duty to act to prevent harm. Disregard for the effects of one's actions on others, bullying, harassment, intimidation, manipulation, threats, or violence are always morally unacceptable behaviors” (p. 4). It is expected that nurses (including student nurses) will not engage in behaviors that show “disregard for the effect of one's actions on others.” This is a powerful mandate for all nurses to communicate and act professionally to prevent inflicting physical or emotional pain on others while pursuing nursing education and engaging in nursing practice.

Responsibility of Nurse Educators

The responsibilities of nursing faculty are addressed specifically in the Code of Ethics for Nurses. Nurse educators are required to advise and supervise their students. Faculty members are expected to collaborate with students to identify individual learning needs in the clinical setting and facilitate the educational process. According to the Code of Ethics for Nurses, faculty members share responsibility and accountability for the patient care provided by their students (Fig. 11.1).

FIGURE 11.1 Nursing faculty members advise and support student learning in the clinical setting. (From Bob Christy, Kent State University, Kent, OH.)

Nurse educators are required to instill in students the values and professional standards of nursing. Faculty members are expected to enhance student commitment to all ethical principles and to socialize nursing students in the fundamental requirements of the profession. Expecting nursing students to meet professional standards while pursuing their education is a primary responsibility of nursing faculty.

Provision 3.3 of the Code of Ethics for Nurses states that, “professional nursing is a process of education and formation ... that involves the ongoing acquisition and development of the knowledge, skills, dispositions, practice experiences, commitment, relational maturity, and personal integrity essential for professional practice. Nurse educators, whether in academics or direct care settings, must ensure that basic competence and commitment to professional standards exist prior to entry into practice” (ANA, 2015, p. 11).

Responsibility of Student Nurses

Student nurses are held to the same ethical standards as professional nurses. This requires that students pursuing nursing education behave responsibly and respectfully toward all people, be accountable for their actions, develop professionally, and strive to learn all that is necessary to safely care for patients and their

families. In 2001, the National Student Nurses Association (NSNA) adopted the Code of Academic and Clinical Conduct, in which students agree to “promote the highest level of moral and ethical principles” and “promote an environment that respects human rights, values, and choice of cultural and spiritual beliefs” (NSNA, 2018).

Nursing is a difficult discipline requiring that students be committed to excellence, compassion, and integrity. Preparing to be responsible for the lives of others requires nursing students to be disciplined in their studies and practice communication and clinical skills with which students in other academic majors are not focused. Students can successfully meet the professional standards expected by the Code of Ethics for Nurses by attending class, laboratories, and clinical experiences regularly; studying and practicing skills; and actively seeking to apply ethical principles to patient care.

Professional Ethical Standards in the Academic Setting

Adhering to the ethical principles of nursing is a lifestyle commitment that may require significant or minimal personal behavior modification. Student nurses and faculty members are expected to demonstrate high ethical standards at all times—in the classroom, the laboratory, and clinical areas and during all electronic and interpersonal communication. If a peer is acting inappropriately, it is every student's responsibility to call the behavior to that student's attention and solicit the help of a faculty member if the student does not respond to peer intervention. Any form of cheating cannot be tolerated, because a student who engages in cheating may be unable to acquire the knowledge necessary to safely care for patients and their families. Faculty should be addressed with respect consistently, and students should expect to be treated with dignity and respect while being held to a high level of accountability by nurse educators.

Civility (being polite and respectful) is essential in all interactions among faculty and nursing students. Courteous interaction between students and faculty members establishes professional communication patterns and affects the way in which students interact with patients. Nurse educators and students

report instances of incivility in the education setting. Faculty members report student behaviors, such as tardiness, inattentiveness (e.g., texting during class), disrespectful remarks, and more aggressive offenses. Students report being belittled or treated with disrespect by clinical staff, instructors, or classmates (Luparell, 2013). If nurses are to maintain high standards of ethical practice, adherence to those standards must begin in the academic setting and be applied in all professional, personal, and clinical encounters.

LO 11.4 Bioethics Challenges in Health Care

Bioethics is the study of ethical and philosophical issues in biology and medicine. Bioethical dilemmas arise on a consistent basis in health care, and nurses are faced with such decisions throughout their practice. Patients often seek information regarding bioethical concerns from nurses. Changing mores within society and cultural differences among people require nurses and other health care professionals to consider alternatives that were previously unknown. Advances in scientific research, innovative treatments, and advanced technology have increased the bioethical issues in our society.

Genetic Testing

The ability to test individuals for potentially debilitating or fatal genetic diseases has increased significantly in the past decade. Genetic testing can assist in determining the likelihood of disorders, such as cystic fibrosis, Huntington disease, and breast cancer. On the basis of the outcome of genetic testing, individuals may decide to abort an abnormally developing fetus, choose not to have children to avoid passing on a serious genetic disorder, or have preventive surgery (such as a prophylactic mastectomy) to prevent breast cancer. None of these decisions is easily made. All have an ethical component and require the support of a professional counselor, loved ones, and friends to decide what is best in each unique circumstance.

The results of genetic testing may indicate the existence or future development of a severely debilitating or fatal disorder, or genetic testing may identify only the potential for development of a serious disease. Both circumstances make decisions based solely on genetic test results difficult. How does a person decide whether to have a bilateral prophylactic mastectomy on the basis of genetic testing when medical research does not clearly identify best practice? As is evident, such types of decisions require time and counseling from professionals and health care team members who are familiar with possible options for care.

Cloning and Embryonic Stem Cell Research

Cloning of organs and embryonic stem cell research are extremely controversial ethical issues faced by nurses practicing in various specialty areas. The ability to grow cloned organs and tissues that can be transplanted into humans in acute need of surgery is a major scientific accomplishment. Embryonic stem cell research has the potential to save lives through the development of effective treatment or cures for disorders, such as severe spinal cord injury, Alzheimer disease, cystic fibrosis, and multiple sclerosis.

However, ethical dilemmas exist worldwide among health care professionals, scientists, theologians, politicians, and others about what types of cells can be cloned or used for research, for what purposes, and by whom.

There are no clear solutions to these dilemmas. Responsible individuals who have studied all aspects of these issues differ greatly on how research should proceed. While research endeavors in cloning and embryonic stem cells offer great potential for reducing human suffering, ethical dilemmas and research requirements in these areas continue to evolve. Studying research issues in depth and completing values clarification (see [Chapter 2](#)) can help nurses identify their feelings about controversial ethical topics.

End-of-Life Care

One of the greatest challenges in nursing is helping patients and families cope with end-of-life decisions that focus on quality-of-life issues. Due to cultural, spiritual, educational, and philosophical differences among people, these decisions are often emotionally charged and rarely based solely on intellectual knowledge. Two major roles of a nurse caring for a dying patient are: (1) providing accurate information regarding the disease process and treatment options and (2) offering support for the patient and family without interjecting personal opinions. An essential ethical concept is autonomy, which underscores the importance of allowing patients to make their own health care decisions.

Ethical dilemmas in end-of-life care exist regarding the establishment of do-not-resuscitate (DNR) orders, adherence to advance directives, including living will and organ donation

requests, removal of extraordinary measures already initiated, and continuance of **futile care** (i.e., care that is useless and prolongs the time until death rather than restoring life). End-of-life institutional policies and DNR order requirements guide individual nursing practice in these ethically challenging situations. **Chapter 42** provides further discussion of issues related to the dying patient.

Resource Access and Allocation

The allocation of human and material resources and provision of access to those resources are concerns for nurses. These bioethical challenges are evident when staffing levels for safe patient care are sought, when few organs are available for transplantation but many patients are awaiting life-saving transplants, and when lack of social support and services or financial limitations prevents individuals from obtaining adequate health care.

Studies published in the *New England Journal of Medicine* and *Journal of the American Medical Association (JAMA)* indicate that increased staffing of registered nurses (RNs) correlates with better patient care outcomes and fewer preventable postoperative patient deaths (Aiken, Clarke, Cheung, Sloane, & Silber, 2003; Needleman, Buerhaus, Mattke, Stewart, & Zelevinsky, 2002). The ANA supports the Registered Nurse Safe Staffing Act, which attempts to address the issues of patient safety and responsible, professional nursing practice. The economic limitations of hospitals and other health care facilities make providing safe staffing levels a challenge for nurse managers and hospital administrators. The need to decide between two equally undesirable situations underscores the ethical nature of adequate staffing.

Organ transplantation and the extensive number of decisions surrounding it raise endless ethical questions. If a patient who is a strong organ transplant candidate decides that the postoperative care is too extensive, is the patient allowed to die without undergoing the recommended transplantation? Who should undergo organ transplantation and based on what priorities? Should a person who has a history of alcoholism receive a liver transplant? Are there enough donor livers available for transplantation in a person who has been previously diagnosed

with pancreatic cancer? Does a child with Down syndrome deserve to receive a much-needed heart transplant? Allocation of organs and decisions on when and how donor organs are to be assigned involve endless ethical decision making of multidisciplinary teams of health care professionals, including bioethicists.

Whether all clinical facilities should have expensive diagnostic equipment and where such resources should be located are ethical dilemmas. Should state-of-the-art diagnostic equipment be available only to patients who can pay for its use? With limited numbers of nurses and other health care professionals available to provide care, how many should be assigned to clinics for the uninsured? There are no easy answers to these concerns.

Although some nurses might argue that no preference should be given to patients with greater financial resources, who will pay for new technologies and research if the patients with the greatest philanthropic potential are denied care while the uninsured receive extensive services? These types of ethical dilemmas and financial challenges have motivated great change in the health care system in recent years, requiring nurses to provide more care with fewer material resources.

Ethical Decision Makers

All nurses are faced with ethical decisions each day in practice, and some choose to obtain further education and experience in the field of bioethics and participate on institutional ethics committees along with physicians, ethicists, attorneys, and academicians (Fig. 11.2). Ethics committees are required by The Joint Commission (TJC) to respond to ethical challenges related to patient care requiring consultation. The work of the ethics committees in health care institutions helps prevent unnecessary legal intervention in patient care matters. Box 11.1 identifies the roles of ethics committees in clarifying health care dilemmas. If acceptable resolutions are not achieved through consultation with the ethics committee, patients, families, and health care providers, the legal system may become involved.

FIGURE 11.2 Multidisciplinary ethics committees work diligently to resolve bioethics dilemmas. (Copyright [istock.com.](https://www.istock.com/))

Box 11.1

Ethical, Legal, and Professional Practice

Multidisciplinary Ethics Committees

Multidisciplinary ethics committees in health care facilities are essential for providing equitable and legal patient care. They often include physicians, nurses, attorneys, hospital administrators, social workers, risk management representatives, and specific subject matter experts (as needed). Committee work typically focuses on challenging patient care situations involving potential legal and ethical concerns. Ethics committees

- Provide educational resources on ethical issues to committee members and institutional staff.
- Establish policies that govern health care decision making.
- Review cases in which clarity is needed.
- Identify sets of values relevant to cases requiring consultation.
- Determine any values conflicts that may exist.

- Interview key individuals impacting the case being reviewed.
- Provide unbiased input that is not possible from a patient, family members, or close caregivers.
- Clarify potential legal implications of the medical or nursing interventions.

LO 11.5 Moral Distress

Ethical dilemmas may lead to moral distress for nurses. **Moral distress** is the anguish that health care professionals experience when their basic beliefs of what is right and wrong or ethical principles are challenged. Nurses may suffer moral distress when they are unable to act according to their personal core values or obligations, or when their professional actions do not result in the preferred patient or situational outcome (Wallis, 2015). Moral distress is most often experienced around end-of-life issues. This is especially true when family members insist on care or treatment that is considered futile or unnecessary for a dying patient. Other sources of moral distress for nurses include technology that interrupts personal interaction or continuity of care, poor communication among health care team members, patients, or families, lack of adequate staff, incompetent staff, and cost reductions that compromise patient care (Wallis, 2015).

Guilt, frustration, or anger caused by moral distress may result in burnout, poor patient care, decreased job satisfaction, and increased job attrition (Lamiani, Setti, Barlascini, Vegni, & Argentero, 2017; Musto, Rodney, & Vanderheide, 2015; Oh & Gastmans, 2015; Wallis, 2015). Research is being conducted on moral resilience as a method for responding effectively to moral distress or ethical challenges. **Moral resilience** is “the capacity of an individual to sustain or restore [his or her] integrity in response to moral complexity, confusion, distress, or setbacks” (Rushton, 2016, p.112). Evidence-based moral distress interventions include without being limited to “The 4A's to Rise Above Moral Distress” developed by the American Association of Critical-Care Nurses (Box 11.2), The Moral Distress Education Project available at <http://www.ccentral.com/node/1106>, and clinical ethics residency programs for nurses. These interventions and coping strategies help nurses become empowered and increasingly resilient (Rushton, Caldwell, & Kurtz, 2016).

Box 11.2

AACN's 4A's to Rise Above Moral Distress

Ask: Am I or other team members feeling distressed or suffering?

Affirm: Validate your feelings with others and commit to taking care of yourself

Assess: Identify the specific sources of your distress, determine its severity, and determine your readiness to make an action plan

Act: Create and implement a plan of action, manage setbacks, preserve your integrity, and move toward resolving the concern

From Hurst, D. (2017). Mitigating moral distress in nursing. *Nursing Made Incredibly Easy!*, 15(6):11-12.

LO 11.6 Sources of Law Impacting Professional Nursing

There are four major sources of law: constitutional, statutory, regulatory, and case law (Judson & Harrison, 2016). Aspects of each type of law help govern the practice of nursing.

Constitutional Law

Constitutional law is derived from a formal, written constitution that defines the powers of government and the responsibilities of its elected or appointed officials. Constitutional law in the United States is based on the U. S. Constitution. Each state has a constitution that must be consistent with the U. S. Constitution. In the United States, constitutional law impacts nursing indirectly, because the legislative bodies that enact statutory law are established and governed by the Constitution. The Bill of Rights and other amendments to the U. S. Constitution further identify the rights of individuals, such as freedom of speech and religion, that affect the ethical practice of nursing.

Statutory Law

Statutory law is created by legislative bodies such as the U.S. Congress and state legislatures. Statutory laws are often referred to as *statutes*. State statutes should be consistent with all federal laws. Statutes governing health care, such as provisions for care of the uninsured and the actions that constitute child abuse, originally became law after they were introduced and passed as bills in a legislative body. Legislators introduce bills in Congress or state legislatures in response to the rapidly changing health care environment, nursing and medical research, and constituents' concerns.

Each state's legislature passes laws referred to collectively as a **nurse practice act (NPA)**. The NPA defines the scope of nursing practice in the state. Matters pertaining to licensure, accreditation of schools and colleges of nursing, and professional roles are outlined in a state's NPA. It is the responsibility of all nurses to

become familiar with the NPA in the state of their employment and to adhere to the laws that govern practice.

Regulatory Law

State legislatures give authority to administrative bodies, such as state boards of nursing, to establish **regulatory law**, which outlines how the requirements of statutory law will be met. Nursing rules and regulations are categorized as regulatory law. Rules and regulations, written by members of boards of nursing, articulate how nurses practice within the laws of the state NPA. The rules and regulations set the standards for safe practice.

Because of the evolving nature of medical and nursing knowledge, emerging technologies, and economic factors that impact health care, nurses must actively seek to keep current to avoid practicing illegally. Some of the nursing rules and regulations identify who is permitted to administer medications in various institutions, the procedure for reporting unsafe or unethical nursing practice, and the number of continuing education hours required for licensure.

Safe Practice Alert

Rules and regulations governing nursing practice are reviewed and revised on a regular basis. To stay current, nurses must read updates from their boards of nursing and seek continuing education in the legal aspects of nursing practice.

Case Law

Judicial decisions from individual court cases determine **case law**. Case law was historically referred to as *common law* because it originally was determined by customs or social mores that were common at the time. The decisions of cases used to be shared only orally by judges with one another (Judson & Harrison, 2016). In contemporary society, case law is established by judicial decisions based on the outcome of specific court cases. These court decisions are documented and published. They set legal precedents on which similar cases are decided in the future. The rights of patients to informed consent were established through case law.

LO 11.7 Types of Statutory Law

Statutory laws may be criminal or civil in nature. **Criminal law** is the body of state and federal laws written to prevent harm to the country, state, and individual citizens. Criminal laws define the nature of specific crimes and the required punishment. Federal criminal law violations include treason and kidnapping or serious offenses that occur across state borders. State criminal laws address crimes such as murder, rape, theft, and practicing nursing without a license (Judson & Harrison, 2016).

Depending on the nature of the committed crime, it may be designated as a misdemeanor or a felony. A **misdemeanor** is a crime of lesser consequence that is punishable by a fine or incarceration in a local or county jail for up to 1 year. A **felony** is a more serious crime that results in the perpetrator's being imprisoned in a state or federal facility for more than 1 year. Practicing nursing without a license, child abuse, and illegal drug dealing are examples of felonies. Felonies are classified by levels of seriousness. Class A felonies may result in punishment by death or life imprisonment.

Civil law governs unjust acts against individuals, rather than federal or state crimes. In civil law, court judgments require the payment of restitution in the form of services or money to the victim or family members. Lawsuits are filed under civil law for offenses, such as defamation of character, slander, libel, invasion of privacy, negligence, or malpractice. Civil law includes a category of law known as **torts**, which are wrongs committed against another person that do not involve a contract. Torts against another person may cause injury, damage property, or infringe on an individual's personal rights. Torts can be classified as intentional or unintentional.

Intentional Torts

Intentional torts are wrongs committed by individuals who deliberately seek to injure or hurt another person. It is imperative that nurses be familiar with intentional tort law to avoid acting irresponsibly while providing nursing care. Intentional torts may be committed by nurses and other individuals, including

students, if they act in an unprofessional manner. Nurses should be particularly aware of intentional torts such as assault, battery, defamation of character, false imprisonment, and invasion of privacy.

Assault

Assault is a threat of bodily harm or violence caused by a demonstration of force by the perpetrator. A feeling of imminent harm or feeling of immediate danger must exist for assault to be claimed.

Battery

Actual physical harm caused to another person is **battery**. The threat to hurt someone is carried out. Battery may involve angry, forceful touching of people, their clothes, or anything attached to them (Guido, 2013). Performing a surgical procedure without informed consent is an example of battery. Actions much more subtle, such as inserting an intravenous (IV) catheter or urinary catheter against the will of a patient, also may be classified as battery.

Safe Practice Alert

Inform patients of procedures before initiating care. If there is any doubt about a patient's comprehension of a procedure, asking the patient to explain what is to be done will alert the nurse to any areas of ambiguity that need clarification and ensure patient understanding.

Defamation of Character

Defamation of character occurs when a public statement is made that is false and injurious to another person. Written forms of defamation of character are considered **libel**. Broadcasting or reading statements aloud that have the potential to hurt the reputation of another person is considered libel.

Oral defamation of character is **slander**. Slander is spoken information that is untrue, causing prejudice against someone or

jeopardizing that person's reputation. For instance, if a nursing student says that a classmate cheated on an examination despite this being untrue, the student has committed slander. A nurse who falsely judges a patient as uncooperative or drug seeking and shares that information during a shift report may be charged with slander if the patient perceives that the nurse's accusations negatively influenced the patient's care.

False Imprisonment

Unauthorized restraint or detention of a person is considered **false imprisonment**. Preventing patients from leaving a health care facility at their request may be considered false imprisonment (Judson & Harrison, 2016). To prevent health care providers and institutions from being held liable if a patient chooses to leave a facility when physicians and nurses think that it is in the patient's best interest to remain hospitalized, the patient is asked to sign an against medical advice (AMA) form. A signed AMA form documents that the patient has chosen to leave the facility when leaving could jeopardize the patient's condition.

Safe Practice Alert

Nurses must be careful when discussing information about patients and colleagues. As professionals, nurses are required to share only accurate information in writing and conversation. Nurses should avoid making judgmental statements while documenting or orally communicating information.

Depending on the situation, physically restraining a patient may be considered false imprisonment and battery. Health care institutions are required to have procedures in place to document and allow temporary restraint of individuals who are mentally unstable or disoriented or who suffer from a contagious disease. Sometimes, the legal system must become involved to deem a patient incompetent, allowing the appointment of a temporary guardian.

Invasion of Privacy

Public disclosure of private information, use of a person's name or likeness without permission, intrusion into a person's place of solitude, and meddling into another's personal affairs are examples of **invasion of privacy**. Accessing the medical record of a patient for whom a nurse does not have the responsibility of providing care is an example of invasion of privacy. Other examples include making confidential information about anyone public without permission and asking patients specific information regarding their wills or personal affairs that do not directly affect nursing care.

Safe Practice Alert

Even sharing with others that a friend or colleague is hospitalized is an invasion of privacy if authorization to share that information publicly has not been secured from the patient.

Unintentional Torts

Unintentional torts are omissions or acts by individuals that cause unintended harm. The unintentional torts of negligence and malpractice are charged when individuals, health care providers, or institutions fail to act responsibly, causing injury to others.

Negligence

Creating a risk of harm to others by failing to do something that a reasonable person would ordinarily do or doing something that a reasonable person would ordinarily not do constitutes **negligence**. For instance, if water is spilled on a hospital corridor floor, a reasonable person would recognize it as a potential fall hazard, seek to alert others to its presence, and have it cleaned up as quickly as possible. Nurses are held to the same standards as the public to avoid charges of simple negligence. Nurses, physicians, and other health care providers also are held to a higher standard due to the professional nature of their education and work.

Malpractice

Malpractice is negligence committed by a person functioning in a professional role. Malpractice may occur when a professional (such as a nurse) acts unethically, demonstrates deficient skills, or fails to meet standards of care required for safe practice. Examples of these types of malpractice include engaging in sexual activity with a patient; calculating medication dosages inaccurately, resulting in a patient's drug overdose; and administering penicillin to a patient with a documented penicillin allergy, resulting in the patient's death from a severe allergic (anaphylactic) reaction. Even if a physician or NP inadvertently orders a medication to which the patient is allergic, it is the nurse's responsibility to check the patient's allergies before administering all medications to meet standards of care for safe practice. To avoid a charge of malpractice, a nurse must provide care commensurate with care provided by other nurses with similar levels of education and experience (Burkhardt & Nathaniel, 2014).

Judson and Harrison (2016) stress the four Ds of negligence, which are four components that must exist to prove professional negligence or malpractice:

- *Duty*: It must be proved that the nurse or other health care provider owed a duty of care to the accusing patient.
- *Dereliction*: There must be evidence that the nurse's actions did not meet the standard of care required or that care was totally omitted.
- *Damages*: Actual injury to the accusing patient must be evident.
- *Direct cause*: A causal relationship must be established between harm to the accusing patient and the actions or omitted acts of the nurse.

Burden of proof (i.e., responsibility for establishing that the four Ds of negligence exist) lies with accusing patients and their

attorneys. All health care professionals, including nurses, must remember that the intent to harm someone is not a requirement for malpractice. Good intentions are not a defense against malpractice.

Actions especially helpful in avoiding charges of malpractice include maintaining (1) current professional practice knowledge, (2) competent practice skills, and (3) professional relationships with patients and their families. The National Council of State Boards of Nursing (NCSBN) video, *Professional Boundaries in Nursing*, is a helpful resource for nursing students and is available at: <https://www.ncsbn.org/464.htm>. Additional measures for practicing within the law are listed in [Box 11.3](#).

Box 11.3

Guidelines for Professional Nursing Practice Within Legal Boundaries

In addition to maintaining current professional practice knowledge, competent practice skills, and professional relationships with patients and their families, nurses should follow guidelines to practice legally and avoid charges of malpractice:

- Maintain confidentiality.
- Follow legal and ethical guidelines when sharing information.
- Document promptly and accurately.
- Adhere to established institutional policies governing safety and procedures.
- Comply with legal requirements for handling and disposing of controlled substances.
- Meet licensure and continuing education requirements.
- Practice responsibly within the scope of personal capabilities, professional experience, and education.

All nurses should be covered by professional malpractice insurance to provide legal support in the event that legal action is

brought against them for any type of perceived professional misconduct. Nursing students and faculty may be covered by the school's malpractice insurance during clinical experiences. However, practice outside an assigned clinical experience is typically not covered by an educational or health care institution's insurance policy. Nurses and nursing students should seriously consider purchasing an individual malpractice insurance policy to cover their nursing activities outside of their place of employment or clinical experience (e.g., when volunteering).

LO 11.8 Professional Liability Issues

Three professional liability issues are of particular concern for nurses: (1) professional practice conduct, (2) adherence to the Principles for Delegation established by the ANA and legally binding within each state's nurse practice act, and (3) accurate and timely documentation.

Professional Practice Conduct

Building and maintaining trusting relationships with patients and colleagues requires professional communication and competent practice. Focusing on the needs of patients and their families helps nurses avoid crossing professional boundaries that breach patients' rights. Nurses are in a position of power due to their professional role and access to private patient information. In all patient care situations, it is imperative that nurses recognize their authority and take intentional steps to avoid misconduct.

The [NCSBN \(2018\)](#) recognizes specific nurse behaviors that indicate a potential for professional boundary violations, including the following:

- Engaging in excessive self-disclosure of personal information to a patient
- Keeping secrets with a patient; limiting others from conversation and patient information
- Spending excessive amounts of time with one patient
- Acting as if a patient is a family member or close personal friend
- Failing to protect the patient from inappropriate sexual involvement with the nurse

Examples of professional boundary violations are listed in [Box 11.4](#).

Box 11.4

Boundary Issues That Violate Ethical and Legal Standards in Nursing

- Stealing a patient's property
- Personally gaining at a patient's expense
- Intervening in a patient's personal relationships
- Making seductive or sexually disparaging statements
- Engaging in sexual conduct with a patient or patient's family member

Social Networking

Use of the Internet and social networking sites to exchange knowledge and share information has increased exponentially in recent years. Nursing students and nurses must understand their professional obligations associated with sharing online information. The ANA's *Principles for Social Networking and the Nurse* (2011) and the NSNA's *Recommendations for Social Media Usage and Maintaining Privacy, Confidentiality and Professionalism* (n.d.) provide guidelines for online nursing practice and assist nurses and nursing students in understanding the limitations and consequences associated with violating online social media boundary issues. The NCSBN video, *Social Media Guidelines for Nurses*, which is available at <https://www.ncsbn.org/347.htm>, is another helpful resource.

In addition to professional boundary violations, nursing practice misconduct may include illegally obtaining patient medication (including narcotics), engaging in drug abuse, or practicing incompetently. All of these are serious offenses punishable by law.

Nurses must be alert to the potential for violating professional conduct standards in all patient care situations and act intentionally to avoid breaking the law or the Code of Ethics for

Nursing. Nurses who engage in professional misconduct are subject to legal and disciplinary action in their state or jurisdiction. In addition to being charged with a misdemeanor or felony, depending on the seriousness of the action, nurses may have their nursing licenses permanently or temporarily taken away or restricted to allow only specific employment.

Substance Use Disorder

Substance use disorder (SUD) “encompasses a pattern of behaviors that range from misuse to dependency or addiction, whether it is alcohol, legal drugs, or illegal drugs” (NCSBN, 2018). SUD is another challenging issue for the nursing profession. Nurses have an ethical and legal responsibility to report colleagues suspected of alcohol or drug abuse as described in the NCSBN video, *Substance Use Disorder in Nursing*, which is available at <https://www.ncsbn.org/333.htm>. Box 11.5 provides a list of changes or activities that may be observed in situations where drug use or drug diversion exists. It is imperative that nurses report suspected use to supervisors or nurse managers, and in some states or jurisdictions to the board of nursing so that the public can be protected and the nurse can receive help as quickly as possible.

Box 11.5

Evidence-Based Practice and Informatics

Possible Behavioral Changes and Indications of Drug Diversion in Nurses With Substance Abuse Disorder

- Increased isolation from friends and colleagues
- Diminished job performance
- Increased number of mistakes, including medication administration errors
- Memory lapses, confusion, decreased level of alertness

- Absence from the nursing unit for extended periods of time
- Inaccurate narcotic counts that vary depending on the day and shift
- Repeated medication administration record corrections
- Volunteering to medicate the patients of colleagues for pain

From National Council of State Boards of Nursing (NCSBN). (2014). What you need to know about substance abuse disorder in nursing. Retrieved from https://www.ncsbn.org/SUD_Brochure_2014.pdf

2. Identify a charge that could be made against the nurse if she engages in a social relationship with C. A. that violates nursing standards of care.

Adherence to Principles of Delegation

Appropriate delegation by RNs seeks to ensure patient safety and meet nursing standards of care. The [ANA \(2013a\)](#) *Principles for Delegation by Registered Nurses to Unlicensed Assistive Personnel (UAP)* and *Scope of Nursing Practice Decision-Making Framework* ([Ballard, et al., 2016](#)) clearly delineate the basic nursing responsibilities related to delegation. The document is supplemental to each state's NPA. Additional information on delegation is found in [Chapter 12](#). All nurses must become familiar with and adhere to their specific state or jurisdictional requirements for delegation to prevent patient injury and legal action.

Accurate and Timely Documentation

Nurses are required to document patient information in written or electronic format. This documentation becomes the legal record of

care provided by the nurse. Falsification of patient records is unethical and illegal.

Documentation must be accurate to provide a realistic view of a patient's condition. Serious documentation errors include (1) omitting documentation from patient records, (2) recording assessment findings obtained by another nurse or unlicensed assistive personnel (UAP), and (3) recording care not yet provided. Nurses sometimes document that a patient has received medication before its administration. This is a serious violation of the law and becomes a medication error of omission if the nurse is distracted before administering the patient's medication.

A second major legal concern related to documentation is the issue of timeliness. For patient care to proceed smoothly, nurses must record assessment findings and concerns as soon after their discovery as possible. Documentation of assessment data in a timely manner allows other health care professionals to accurately address a patient's concerns or change in status. For instance, if a nurse finds patient A's blood pressure and apical pulse elevated during the morning assessment but fails to document those findings before proceeding to another patient's room, the physician responsible for patient A's care may make rounds while the nurse is in the other patient's room and fail to realize patient A's change in condition. Nurses must always record patient findings as quickly and as accurately as possible to ensure safety and provide appropriate care. The use of an incident report for documenting unusual patient circumstances is discussed in [Chapter 10](#), which also provides extensive guidelines that must be followed to meet the legal and ethical requirements for documentation.

3. Write four interventions that the nurse should initiate to avoid crossing professional boundaries with C. A.

LO 11.9 Legal Issues Guiding Patient Care

Some issues affect nursing practice regardless of the setting in which care is provided. To ensure safe and legal patient care, nurses need to be aware of their responsibilities in regard to informed consent, patients' rights, organ donation, advance directives, and DNR orders.

Informed Consent

Giving permission or consent for treatment is implied when a patient makes an appointment to see a physician or NP. General consent forms giving permission for treatment in a hospital are signed by a patient before being admitted. Patients undergoing surgery and invasive diagnostic procedures are required to provide informed consent.

Informed consent is permission granted by a patient after discussing each of the following topics with the physician, surgeon, or advanced practice nurse who will perform the surgery or procedure: (1) exact details of the treatment, (2) necessity of the treatment, (3) all known benefits and risks involved, (4) available alternatives, and (5) risks of treatment refusal. Legal regulations mandating the content of an informed consent document and the procedure for obtaining informed consent are typically outlined in a state's medical practice act ([Judson & Harrison, 2016](#)).

Ultimately, it is the responsibility of the physician (or advanced practice nurse in some states) who is performing the surgery or procedure to explain the content of the informed consent form and acquire the patient's signature. Nurses are usually asked to witness the patient's signing of the form. By witnessing a patient's signing of an informed consent the nurse verifies that the patient is mentally competent and that the signature is that of the patient.

Informed consent for minors, except in the case of emancipated or married minors, must be obtained from their parents or legal guardians. Patients who are mentally incompetent or are under the influence of alcohol or drugs are not legally permitted to give informed consent due to their inability to comprehend the

required information. Informed consent for these patients must be obtained from a legal guardian, power of attorney, or health care proxy. Securing informed consent from competent adults who have already received preoperative medications that may impair their ability to comprehend and make sound decisions is not permissible.

Acting as a patient advocate, the nurse is responsible for ensuring that the patient has received adequate information regarding the proposed procedure, understands the content of the informed consent form, and was not coerced into giving informed consent. Discussing the surgery or procedure with a patient and allowing the patient to ask questions and receive answers to any questions is an excellent method of ensuring that a patient's autonomy in decision making has been respected. Although physicians and nurses are allowed to make recommendations to patients regarding the necessity of treatment, coercing or forcing a patient to sign an informed consent form is not permitted (Burkhardt & Nathaniel, 2014).

QSEN Focus!

Intervening on behalf of a patient who needs additional information before giving informed consent is one method of providing safe, patient-centered care. Helping patients locate frequently updated, evidence-based online sources for health care information increases their health literacy and their ability to make informed health care decisions.

When obtaining informed consent, nurses must be concerned with the legal implications of a patient's ability to read the informed consent document and the patient's cultural beliefs regarding decision making. If a patient is illiterate or requires an interpreter, the method of obtaining informed consent must be adapted appropriately. Use of a professional interpreter rather than a family member is essential to provide detailed medical information accurately.

A patient whose culture prefers to allow other family members to make final health care decisions is inconsistent with nursing's ethical belief in autonomy. However, in this situation, the method

of obtaining informed consent may need to be adapted to meet the patient's beliefs within the scope of the law. The solution may be as simple as providing information regarding the surgery or procedure to the patient and family members involved in the decision-making process and then verifying that adequate opportunity for asking questions and receiving clarification has been given.

Patient's Bill of Rights

In 1992, the American Hospital Association (AHA) adopted the Patient's Bill of Rights to inform consumers of health care about specific privileges of which they should be aware. The original list of 12 rights has been revised and formatted as a brochure entitled *The Patient Care Partnership: Understanding Expectations, Rights and Responsibilities* (AHA, 2006). The brochure informs patients that they should expect (1) high-quality hospital care, (2) a clean and safe environment, (3) involvement in their care, (4) protection of their privacy, (5) help when leaving the hospital, and (6) help with their billing claims.

QSEN Focus!

To provide patient-centered care, nurses need to discuss with patients the level to which they want to be involved in planning their care. Factors such as culture, age, level of education, cognitive ability, physical health, and energy affect a patient's ability and desire to actively participate in the process.

Organ Donation

Organ donation is encouraged to address the tremendous need of individuals who are suffering from life-threatening illnesses and could benefit from organ transplantation. According to the United Network for Organ Sharing (UNOS), over 114,000 people in the United States were waiting for organ transplants in December 2018. Only 34,771 organ transplantations of all types took place in 2017. Organs for those procedures were received from 16,478 donors (UNOS, 2018). These statistics underscore the critical need for organ donation. The UNOS establishes the policies and

procedures for obtaining and allocating donated organs to waiting recipients. The National Organ Transplant Act of 1984 made the sale or purchase of organs illegal in the United States.

In 1968, the Uniform Anatomical Gift Act was approved to allow people over the age of 18 to donate their bodies or body parts after death for transplantation, deposit in tissue banks, or research. Consent for organ donation must be given in writing. In many states, licensed drivers are permitted to sign organ donation forms on the back of their licenses. Adults who do not have a driver's license can obtain a separate organ donation card to carry in their wallets. However, having a signed form indicating the desire to be an organ donor is not enough in most states. Individuals must make their desire to donate organs known to family members before their death to ensure that their wishes are fulfilled. In some states, regardless of the existence of signed organ donation forms, final permission for organ and tissue donation must be received from family members of the deceased.

All nurses need to be aware of institutional policies and procedures for organ donation. Often, hospitals contact designated personnel who are specially trained in talking with family members about organ donation. These organ procurement professionals help in relaying vital information and facilitating the process of donation.

Advance Directives

In 1990, the federal government passed the Patient Self-Determination Act, which requires health care providers to supply all patients with written information regarding their rights to make medical decisions and implement advance directives (Judson & Harrison, 2016). Advance directives consist of three documents: (1) living will, (2) durable power of attorney, and (3) health care proxy, commonly referred to as a *durable power of attorney for health care*. It is the responsibility of nurses and other health care providers to document the existence of advance directives in patient's medical records. If a patient has signed and notarized advance directives, a copy of each document should be placed in the patient's medical record on admission to a health care facility.

Living Will

A [living will](#) specifies the treatment a person wants to receive when he or she is unconscious or no longer capable of making decisions independently. Specifications in a living will may address end-of-life care and the circumstances under which treatment should be withheld or stopped. A living will may indicate when a person wants to have extraordinary measures, such as cardiopulmonary resuscitation (CPR) or ventilator treatment, terminated. Preferences regarding organ donation, performance of an autopsy, and a designated spokesperson also may be specified in a living will.

All states recognize the legitimacy of living wills, although individuals need to communicate their wishes with family members and provide copies of their living wills to health care providers and family members as documentation of their preferences. The existence of a signed living will alleviates confusion and may help avoid legal disputes regarding the care of loved ones.

Durable Power of Attorney

A [durable power of attorney](#) is a legal document that allows a designated person to make legal decisions on behalf of an individual unable or not permitted to make legal decisions independently. It sets limits on the powers of the person designated as having power of attorney and is not limited to matters related to medical care. Spouses, domestic partners, and attorneys are the most common people to be granted power of attorney.

Health Care Proxy

The specific durable power of attorney for medical care is called a [health care proxy](#). This document specifies the person who can make health care decisions for an individual who is unable to comprehend information or communicate his or her wishes for any reason. The health care proxy limits the scope of power of the designated person or people to medical care and treatment decisions. One or more alternates should be named in the health care proxy document in case the primary designate is unavailable

in an emergency. For U.S. residents, [Box 11.6](#) provides information on the process of completing advance directives and how to obtain advance directive forms.

Box 11.6

Patient Education and Health Literacy

Advance Directives

Completing advance directive forms is a process that involves personal reflection, information gathering, discussion with loved ones, decision making, and documentation of individual choices. State agencies and all health care facilities can provide copies of blank advance directive forms on request. The online U. S. Living Will Registry at <http://liv-will1.uslivingwillregistry.com/forms.html> provides information for individuals, family members, health care professionals, and institutions. Resources on this site include the following:

- Personal-choice options and benefits of advance directives
- Definitions of terms used on all advance directive documents
- Organ donation information and registration
- Printable living will and health care proxy forms for each of the 50 states

Signed and notarized advance directive documents allow an individual's health care choices to be followed when resuscitation or other extraordinary measures are being considered.

Do-Not-Resuscitate Orders

Patients who are faced with life-threatening illness or their designated family members acting as health care proxies may choose to refuse or limit treatment. This designation is documented as a [do-not-resuscitate \(DNR\) order](#). Sometimes, DNR orders are referred to as *no codes*, indicating that no extraordinary measures are to be taken to prolong a patient's life in the case of a natural death. DNR orders are written documents

that indicate the extent of resuscitation efforts preferred by a patient or legally designated family members in the case of cardiac or respiratory arrest.

Each state has laws and every health care institution has policies that must be followed to designate a patient as DNR. In most cases, the written DNR order must be renewed on a regular basis, similar to that of an order for antibiotic therapy or narcotic medication administration. Some states have different levels of designations for DNR orders, such as DNR-CC (i.e., do not resuscitate, comfort care), that identify specific protocols for administering medications and providing treatment in addition to instructions on CPR or endotracheal intubation. Nurses should become familiar with their state's statutes and health care institution's policies to ensure compliance with DNR orders.

LO 11.10 Laws Impacting Professional Practice

Many laws guide the practice of nursing throughout the world. Laws delineate acceptable nursing practice, provide a basis on which many health care decisions are determined, and protect nurses from liability in cases in which safe practice is maintained. The discussion of laws in this chapter is limited to those pertaining specifically to the practice of nursing in the United States. These laws impact professional practice within and outside hospitals, extended care facilities, mental health institutions, public health clinics, private practice offices, and many other institutions. Each state has a nurse practice act (NPA) that establishes the standards of care required for legal nursing practice. Licensure, laws, rules, and regulations governing nursing practice are enforced to protect the public from harm. Errors in health care occur too frequently. In many cases, the nurse is the last line of defense to prevent an error in medication administration or other types of patient care. Keeping current with changing laws related to nursing practice and technology can ensure safety for nurses and their patients.

Licensure

Licensure of nurses seeks to ensure professional competence. The laws of each state and Canadian province or territory require graduates of accredited nursing schools and colleges to pass the National Council Licensure Examination (NCLEX) before beginning professional practice (see [Chapter 1](#)). Most states recognize only their own licenses. However, beginning in 2000, the Nurse Licensure Compact (NLC), which is a multistate licensure model, was initiated to allow nurses licensed in one state to practice physically and electronically in other states in the consortium. On January 19, 2018, the Enhanced Nurse Licensure Compact (eNLC) was implemented. More than 30 states are currently participating. There are 11 licensure requirements that nurses must meet to qualify for a multistate license (https://www.ncsbn.org/ULRs_1_19_18.pdf). The eNLC is an

especially significant legal initiative considering technologic advancements that allow electronic transfer of medical information and consultation among medical and nursing professionals across state lines and around the world.

Standards of Care

Standards of care are the minimum requirements for providing safe nursing care. Federal and state laws, rules and regulations, accreditation standards, and institutional policies and procedures are used to formulate nursing standards of care. Institutional policies and procedures must be consistent with state laws, rules, and regulations, which must comply with federal law.

The ANA identifies standards for safe practice and regularly releases policy statements and current practice information to guide and update the standards of care for nurses. Each state's board of nursing establishes accreditation standards for schools and colleges of nursing that must be met. These accreditation standards help ensure that graduates of nursing programs meet standards-of-care requirements in their nursing practice.

Academic accreditation standards established by the Commission for Nursing Education Accreditation (CNEA), the Accrediting Commission for Education in Nursing (ACEN), and the Commission on Collegiate Nursing Education (CCNE), and the accreditation standards for health care institutions required by The Joint Commission (TJC) contribute to a large body of safe-practice requirements.

By adhering to standards of care, nurses can avoid accusations of unsafe, negligent care and malpractice. Standards of care are used as the benchmark against which a nurse's actions are evaluated. These standards are fairly universal for all nurses practicing in similar specialties. For instance, the standards of care for intensive care unit (ICU) nurses practicing in Kentucky are consistent with the expected standards of care for ICU nurses in California. The same is true for advanced practice nurses, including certified registered nurse anesthetists (CRNAs), certified nurse midwives (CNMs), clinical nurse specialists (CNSs), and nurse practitioners (NPs). The conduct of advanced practice nurses is required to meet the standards of care in their specialty areas. General nursing standards of care are defined for

each specialty. Pursuing continuing education, reading professional journals, and actively participating in professional organizations (such as, the ANA, the National League for Nursing [NLN] and state or specialty nursing associations) are the best ways for practicing nurses to remain current on standards of care.

Health Insurance Portability and Accountability Act

The Health Insurance Portability and Accountability Act (HIPAA) was enacted in 1996 to protect the privacy of health care information. HIPAA contains four sets of standards, each with rules that must be implemented by all health care facilities (Judson & Harrison, 2016). The accessibility aspect of HIPAA allows sharing of protected health information (PHI) with those who need it to properly care for individuals seeking treatment, and limits access by individuals and agencies that may use the information prejudicially or for monetary gain. PHI includes physical or mental health data, health care treatment locations and occurrences, and payment information related to all health care treatment (U.S. Department of Health and Human Services, 2013). The HIPAA portability section prevents individuals who have had health care coverage through an employer for a minimum of 12 months from losing their coverage during a job change, even in the case of preexisting health conditions.

Privacy and confidentiality are the two expectations of HIPAA most relevant to nursing practice. By requiring predisclosure authorization, the HIPAA Privacy Rule enables an individual to control the sharing of personal information (Dunn, Rose, & Wieland, 2013). The Privacy Rule limits disclosure of patient health care information to the patient and only those people and health care agencies to which the patient has granted specific permission. Confidential treatment of patient records involves limiting access to documentation of interactions between patients and health care providers.

Electronic transmission of health care information heightened the necessity for HIPAA. Nurses should pay particular attention to the rules of privacy and confidentiality while engaging in phone, fax, e-mail, or Internet transmission of protected patient information. The information should never be shared in public

areas, safeguarded in all areas, and all electronic health record software should be closed by the nurse after documentation to ensure patient privacy and prevent a breach of confidentiality. In some health care institutions, a patient is asked to identify a code word that the patient's family member or friend must share with the nurse before receiving any information on the patient's condition from the nurse. Nurses must refrain from sharing patient information with unauthorized individuals. Many web resources are available that provide helpful information on HIPAA privacy and confidentiality issues for health care professionals. [Box 11.7](#) lists procedural and documentation concerns associated with HIPAA.

Box 11.7

Nursing Care Guideline

Procedures and Documentation Required by HIPAA

Background

- The Health Insurance Portability and Accountability Act (HIPAA) of 1996 was established to protect patients' privacy and personal information. It encompasses accessibility, privacy, security, and confidentiality.
- The act makes provisions for verbal, written, and electronic information.
- Health care providers of all disciplines and at all levels must remain current on the principles of this act through continuing education at their facility or an accredited educational institution.
- Civil and criminal penalties are set forth in the act for violation of any provision of the act.
- Provision 3 of the American Nurses Association Code of Ethics specifically addresses the nurse's responsibility for protecting the patient's right to privacy and confidentiality.

- “Privacy is the right to control access to, and disclosure or nondisclosure of, information pertaining to oneself and to control the circumstances, timing, and extent to which information is disclosed” (ANA, 2015, p. 9).
- “Confidentiality pertains to the nondisclosure of personal information that has been communicated within the nurse-patient relationship” (ANA, 2015, p. 9).
- “The nurse has the duty to maintain confidentiality of all patient information, both personal and clinical in the work setting and off duty in all venues including social media or any other means of communication” (ANA, 2015, p. 9).

Procedural Concerns

- Patients must be offered or have access to a notice of their rights under this act.
- Patient names cannot be posted or released.
- Discussion of patient information cannot be held in public-access areas, and discussions in nursing areas must be held using soft voices.
- Using a camera and/or recorder or not concealing patient information while preparing school assignments is considered a violation of the act, resulting in penalties.
- Paper or electronic charts cannot be visible or left in an open, public-access area.
- Fax transmissions require special consideration.
 - Include a cover sheet with the word *Confidential* (set in a highly visible way) and instructions for destroying or returning the information if it is inadvertently delivered to a wrong number.
 - Call ahead, and ensure that the facility is ready to receive the transmission and that the fax machine is in a confidential area.
 - Require the facility to confirm receipt of the transmission.

- Electronic medical records (EMRs) must be password protected, with access given only to those who need it to provide care or those whom the patient has authorized.
- Personnel must log off computers when finished working with patient records. Computers must have the protection of an automatic log off after a certain period of inactivity.
- Passwords can never be shared.
- Patient information should never be e-mailed or faxed unless special arrangements have been made for receiving the data.
- Firewalls and other Internet technology (IT) protections should be installed to prevent unwarranted intrusions and identity theft.

Documentation Concerns

- Patients' rights include
 - Obtaining, viewing, and/or updating a copy of their own medical records.
 - Obtaining information regarding HIPAA and how the facility will use personal information that is collected and requesting variants on those uses.
 - Choosing how to receive information and education about their health.
- Signatures and consents are usually obtained for accessing personal health information.
- Paper documentation should not be thrown in the trash; it must be shredded. This includes scrap paper and report memorandums.
- The Joint Commission (TJC) requires individual facilities to have written policies and procedures in place for the protection of personal health information that is conveyed by verbal, electronic, or printed means.

American Recovery and Reinvestment Act of 2009

The American Recovery and Reinvestment Act (ARRA) of 2009 refined some aspects of HIPAA and improved standards

governing the privacy and security of health information. This act prevents the sale of protected health information (PHI) without a patient's knowledge of payment and authorization, except in the case of public health records, research, and rare, specified business transactions. It also requires patients to receive requested copies of their electronic health records within 30 days and at a minimal cost ([Center for Democracy and Technology, 2009](#)).

Good Samaritan Acts

All 50 states have enacted Good Samaritan laws offering protection for physicians and other health care professionals who provide emergency care at the scene of a disaster, emergency, or accident ([Fig. 11.3](#)). Good Samaritan laws protect health care professionals from charges of negligence in providing emergency care if (1) the care is within the professional's scope of knowledge and standards of care and (2) no fee is received or charged for services.

FIGURE 11.3 Good Samaritan laws protect nurses who provide assistance to accident victims while maintaining standards of care. (Copyright [Shutterstock.com](#).)

In some states, the Good Samaritan law includes a *duty-to-assist* or *duty-to-rescue* clause, which requires people, including health care professionals, to provide care at the scene of an emergency. In Minnesota, failure to provide reasonable assistance may result

in being charged with a petty misdemeanor ([Minnesota Office of the Revisor of Statutes, 2017](#)). Several other states including Wisconsin, Washington, Vermont, Rhode Island, Massachusetts, Hawaii, and California have *duty-to-assist* clauses that apply in specific situations, such as if witnessing a crime or at the scene of an emergency ([Thomson Reuters Foundation, 2014](#)).

Good Samaritan laws may require health care professionals to ask for and receive permission for treatment before initiating care. If a patient is intentionally injured or gross negligence occurs during emergency care, Good Samaritan laws do not protect nurses or other health care professionals from legal consequences.

Safe Practice Alert

Before leaving the scene of an accident in which a nurse has provided emergency treatment, the nurse should transfer the care of injured individuals to equally competent professionals. They may be paramedics or emergency department personnel.

Uniform Determination of Death

Advancements in life support technology caused the original case law definition of death—absence of spontaneous respiratory and cardiac functions—to become limited in scope ([National Conference of Commissioners on Uniform State Laws, 1980](#)). The Uniform Determination of Death Act of 1981 identified a comprehensive and medically sound basis for declaring a person dead. As a result, most states have enacted laws establishing two criteria for death: (1) all spontaneous respiratory and circulatory function stops or (2) all brain function, including that of the brainstem, ends. If brain death has been established, organ procurement for donation may take place.

Medical Aid in Dying and Euthanasia

Medical aid in dying and euthanasia are related but different actions. Both involve facilitating the death of another person ([Marker & Hamlon, 2013](#)). **Medical aid in dying** is when a person who is mentally competent with a prognosis of 6 months or less to live causes his or her own death by self-administering prescribed

medication. Euthanasia occurs when a person who willingly requests to die is injected with a lethal drug dosage by another individual. Both actions typically occur when the person requesting assistance to die is suffering unbearably; experiencing excruciating, chronic pain; or facing certain death as a result of a terminal illness.

As of early 2017, medical aid in dying is legal in California, Colorado, Montana, Oregon, Vermont, Washington state, and Washington, DC ([Compassion and Choices, 2017](#)), and euthanasia is permitted in the Netherlands, Belgium, and Luxembourg. Nurses must be familiar with state or national laws regarding these issues. The participation of nurses in medical aid in dying or euthanasia is opposed by the [ANA \(2013b\)](#) on the basis of the Code of Ethics for Nurses. Nurses are encouraged to provide comprehensive end-of-life patient care that alleviates pain and minimizes suffering.

Natural Death Acts

Laws known as *natural death acts* exist in some jurisdictions that permit competent patients to make health care decisions that may result in their deaths. This includes nursing actions, such as discharging patients who are likely to die without acute care and withholding or withdrawing life-sustaining treatments under the direction of a physician when requested by a competent patient. The acts prevent civil liability, criminal liability, and professional sanctions against health care providers who explain the medical risks associated with the decisions before their initiation.

Americans With Disabilities Act

The Americans With Disabilities Act (ADA), adopted in 1990 and amended in 2009, provides protection against discrimination for individuals who have a physical or mental impairment that interferes with one or several life activities, have a history of impairment, or are perceived as having a disability. Impairment of life activities is identified by the ADA ([2009](#)) as difficulty performing the activities of daily living (ADLs): “seeing, hearing, eating, sleeping, walking, standing, lifting, bending, speaking, breathing, learning, reading, concentrating, thinking, communicating, and working” [Section 12102, (2) (A)].

The ADA delineates requirements for reasonable physical accommodation and services that allow individuals with disabilities to be employed and live reasonably unobstructed lives. This includes readers for the blind and sign language interpreters for those who are deaf. The ADA law mandates accessibility requirements for public and private institutions.

Employment concerns for individuals with communicable diseases, such as human immunodeficiency virus (HIV) infection, are addressed in the ADA. Health care workers infected with HIV and infected patients are not to be discriminated against under this law. ADA rules specify that alternative gender preference, such as homosexuality or bisexuality, is not considered a disability, nor is the illegal use of drugs. Students who are immigrants to the United States need to be aware that having English as a second language is not a disability requiring accommodation. [Box 11.8](#) highlights some accommodations that can be made for individuals with documented disabilities. Most include collaboration with other professionals and referrals to community agencies.

Box 11.8

Diversity Considerations

Disability

- Assistive devices, including individually sized walkers and wheelchairs, are available to assist children, youths, and adults with ambulation.
- Voice-activated computer programs may be provided for quadriplegic individuals of all ages who are unable to use a keyboard.
- Eyeglasses, special contacts, and hearing aids can be fitted for toddlers, children, and adults in need of sensory assistance.
- Instruction for teachers and support staff in monitoring the status of children or adults with intellectual disability or severe physical conditions can be facilitated by the school nurse to avoid preventable medical emergencies.

Culture, Ethnicity, and Religion

- Foreign-language interpreters are accessible by phone or video link or in person to assist a patient in understanding health care.
- Religious beliefs, education, culture, and socioeconomic status influence health care decisions.

Morphology

- Special lifts, beds, and wheelchairs are available for use with morbidly obese patients to provide for their safety and the safety of care providers.

Physical Restraints

Under the law, nurses are responsible for providing safe patient care, which includes preventing patient injury from physical restraint and unrestrained, accidental falls. Historically, physical restraints were used as a primary nursing intervention to prevent patients from injuring themselves or others and to avoid the removal of medical equipment, such as endotracheal tubes or IV lines. Federal and state laws and guidelines from The Joint Commission have mandated that physical restraints be used only in the event that alternative, less restrictive interventions to prevent patient injury have been unsuccessful, and a written order for restraints is in place. The written order must include dates that indicate the start and stop times for use of physical restraints, and it must be updated frequently according to institutional policies. In an effort to prevent injury from restraints, accredited health care facilities have flow sheets on which nurses routinely document the use of physical restraints and the patient's mental and circulatory status. Using physical restraints without proper orders and documented indications of need may result in charges of abuse. Refer to Skill 25.1 for information on the application of physical restraints.

Innovative equipment such as rapid-lift beds that lower to ground level and rise to waist height in a few seconds is being used to reduce falls from bed in extended care facilities. The

employment of sitters to be present with patients when health care providers are out of a patient's room is another creative solution commonly used in hospitals to avoid the use of restraints while providing for patient safety.

Additional Acts Introduced in Congress

The Registered Nurse Safe Staffing Act and the Nurse and Health Care Worker Protection Act have been introduced in the U.S. Congress for several years in an effort to increase patient safety and prevent the loss of RNs from the workforce because of physical injury. One landmark research study published in *JAMA* found that an increase of one patient in the average nurse's assigned workload contributes to a 7% increase in the rate of patient deaths within 30 days of admission and a 7% increase in "failure to rescue" from a life-threatening emergency ([Aiken, Clarke, Sloane, Sochalski, & Silber, 2002](#)). The same study addressed the effect of high patient–nurse ratios on nurse burnout and employment dissatisfaction.

The primary research supporting the Nurse and Health Care Worker Protection Act was conducted by the ANA in collaboration with the U. S. Department of Veteran Affairs. [Chapter 28](#) provides additional information on the Safe Patient Handling and Movement research and initiative. Both bills and the research supporting their enactment underscore the importance of nurses' being involved politically to inform and educate their local, state, and national legislators on issues related to public safety and nursing.

LO 11.11 Initiatives to Facilitate Safer Practice

Patient safety is the number one priority for nurses, medical professionals, and health care agencies. Continuing education requirements for license renewal and agency accreditation are two ongoing efforts to keep health care personnel and institutions up to date and safe. Specialty certification and advanced education are additional strategies that promote nursing excellence and competence.

Certification

Although not required by law, specialty certification documents a nurse's scope of knowledge, and seeks to ensure safe, competent nursing practice. Certification is available to nurses in a wide variety of specialties, including critical care, gastroenterology, oncology, pediatrics, and nursing education. Becoming certified in a nursing specialty requires years of practice, a recognized level of expertise, and a commitment to excellence. Additional time and financial resources are needed to prepare for, successfully complete the certification examination, and retain certification. Nurses who are certified in their areas of practice display a high level of clinical competence and a commitment to comprehensive, safe patient care. [Chapter 1](#) provides additional information on specialty certification (www.nursingcertification.org).

Educational Recommendations

An Institute of Medicine (IOM, 2001; now the National Academy of Medicine [NAM]) report, *The Future of Nursing: Leading Change, Advancing Health*, recommends that 80% of nurses in the United States be baccalaureate educated by 2020 and that health care organizations encourage registered nurses with associate degrees or diplomas to enter baccalaureate programs within 5 years of graduation. These recommendations complement The Consensus Model for Advanced Practice Registered Nurse Regulation, Licensure, Accreditation, Certification, and Education ([NCSBN](#),

2017). The IOM report recommendations and the Consensus model address the need for all nurses to be licensed, graduate from accredited nursing programs, achieve certification in their chosen specialty, and seek graduate education.

Ultimate Responsibility of Professional Nurses

It is ultimately the responsibility of all professional nurses to practice ethically, competently, and within the laws of the state and nation in which they are employed. Ignorance of the rules and regulations governing nursing practice is not a defense against malpractice or employment dismissal.

To prevent breaches of ethical behavior, nurses must reflect on their personal values, become familiar with the Code of Ethics for Nurses, and implement strategies to protect all patients in their care. To avoid unsafe patient care, nurses must maintain their licensure and competency through continuing education and provide care consistent with their level of expertise and the standards of care for their specialty. Individual nurses must accept the responsibility to act ethically and legally in all situations.

Summary of Learning Outcomes

LO 11.1 *Identify key ethical theories that affect nursing practice:* Deontology and utilitarianism are the two fundamental ethical theories on which other ethical theories and codes of ethics are based.

LO 11.2 *Apply ethical principles to professional nursing practice:* Nurses are expected to demonstrate beneficence, nonmaleficence, respect for autonomy, veracity, justice, accountability, advocacy, confidentiality, and other ethical actions in their professional practice.

LO 11.3 *Describe how the American Nurses Association (ANA) Code of Ethics for Nurses applies to nursing education and practice:* The ANA Code of Ethics for Nurses articulates ethical standards with which all nurses, including nursing students, are expected to comply.

LO 11.4 *Discuss the role of ethics in genetic, biomedical, and end-of-life health care decision making:* Decisions regarding genetic testing, biomedical issues (such as, cloning and stem cell research), and end-of-life care involve intellectual knowledge and ethical evaluation. Specially trained members of ethics committees can help guide institutional policies and

procedures that affect nursing practice in ethically challenging situations.

LO 11.5 *Examine the potential impact and interventions to address moral distress:* Guilt, frustration, or anger caused by moral distress may result in burnout, poor patient care, decreased job satisfaction, and increased job attrition. “The 4A's to Rise Above Moral Distress” is a mnemonic representing an evidence-based intervention to help nurses cope with moral distress.

LO 11.6 *Differentiate among constitutional, statutory, regulatory, and case laws as they relate to professional nursing practice:* Laws are established through various means to address criminal and civil violations that may occur during the practice of nursing.

LO 11.7 *Identify various types of statutory law, including intentional and unintentional torts, and their potential effect on nurses providing patient care:* Intentional torts (such as assault, battery, defamation of character, false imprisonment, and invasion of privacy) may be committed by nurses who are unfamiliar with the law and their facility's policies and procedures intended to ensure safe patient care. Nurses may be charged with malpractice (i.e., professional negligence), an unintentional tort, if their actions do not meet professional standards of care.

LO 11.8 *Explain liability issues (such as, professional boundaries, delegation, and documentation) that are pertinent to nursing practice:* Practicing nursing in a manner consistent with ethical and legal standards requires that nurses set professional practice boundaries, follow the Principles for Delegation, and document care expediently and accurately.

LO 11.9 *Summarize legal issues that guide patient care:* Informed consent, patient rights, organ donation, advance directives, and DNR orders guide members of the interdisciplinary health care team to care for patients in a manner consistent with their requests.

LO 11.10 *Discuss how laws impact nursing practice:* Each state has a nurse practice act that establishes the standards of care required for legal nursing practice. Licensure, laws, rules, and regulations governing nursing practice are enforced to protect the public from harm. The American Disabilities Act and the Uniform Determination of Death Act are examples of federal laws that were enacted to guide professional practice. Good Samaritan laws and laws governing medical aid in dying and organ donation are specific to states. Nurses are responsible for becoming familiar with the laws of their state of employment and practicing within those laws.

LO 11.11 *Describe initiatives designed to facilitate safer nursing practice.* Specialty certification for nurses and further education are strategies intended to demonstrate nursing competency and improve patient safety.

Review Questions

1. On which ethical theory do nurses implement their care when they act on the basis of the needs of one specific patient rather than the potential consequences to other patients?
 - a. Deontology
 - b. Autonomy
 - c. Utilitarianism
 - d. Nonmaleficence
2. Which nursing intervention is the best example of patient advocacy?
 - a. Collecting blood samples according to the physician's order each morning
 - b. Assessing the vital signs of a patient who is receiving a blood transfusion
 - c. Seeking an additional analgesic medication order for a patient who is experiencing severe pain
 - d. Accompanying an ambulating patient who is walking for the first time after undergoing surgery
3. What action should nurses who demonstrate accountability take if they forget to administer a patient's medication at the ordered time?
 - a. Document the medication as refused by the patient.

- b. Administer the medication as soon as the error is discovered.
 - c. Record the medication as given after making sure the patient is okay.
 - d. Follow the administration and documentation procedures for medication errors.
4. Nursing students are held to which standards by the Code of Ethics for Nurses? (*Select all that apply.*)
- a. Clinical skills performance equal to that of an experienced nurse
 - b. Demonstration of respect for all individuals with whom the student interacts
 - c. Avoidance of behavior that shows disregard for the effect of those actions on others
 - d. Accepting responsibility for resolving conflicts in a professional manner
 - e. Incorporating families in patient care regardless of patient preference
5. If a student nurse overhears a peer speaking disrespectfully about a patient, nurse, faculty member, or classmate, what is the most ethical first action for the student nurse to take?
- a. Discuss the peer's actions during group clinical conference
 - b. Ignore the initial occurrence and observe if it happens again

- c. Report the actions of the classmate to the clinical instructor
 - d. Speak to the peer privately to prevent further occurrences
6. What nursing intervention is best when a patient is struggling with the decision to abort an abnormally developing fetus discovered during genetic testing in the first trimester of pregnancy?
- a. Recommend additional testing
 - b. Refer the patient to an abortion clinic
 - c. Listen to the patient's concerns
 - d. Discuss regional adoption agencies
7. Making prejudicial, untrue statements about another person during conversation may expose a nurse to being charged with what offense?
- a. Libel
 - b. Assault
 - c. Slander
 - d. Malpractice
8. What legal consequences may a nurse experience if the nurse is convicted of a crime? (*Select all that apply.*)
- a. Loss of nursing licensure
 - b. Employment affirmation
 - c. Monetary penalty

- d. Unit transfer
 - e. Imprisonment
9. What is the best way for a nurse to avoid crossing professional practice boundaries with patients?
- a. Spend extensive time with a patient without visitors
 - b. Focus on the needs of patients and their families
 - c. Intervene in problematic patient relationships
 - d. Relay personal stories when unsolicited
10. What action should a nurse take if a patient who needs to sign an informed-consent form for nonemergency surgery appears to be under the influence of drugs or alcohol?
- a. Contact the physician to see what should be done.
 - b. Ask the patient's spouse to sign the informed-consent form.
 - c. Request permission to bypass the need for a signed consent form.
 - d. Wait to have the informed-consent form signed when the patient is alert and oriented.

CHAPTER 12

Leadership and Management

LEARNING OUTCOMES

Comprehension of this chapter's content will provide students with the ability to:

- LO 12.1 Compare leadership and management.
- LO 12.2 Describe the styles of leadership, including the qualities of effective leaders.
- LO 12.3 Discuss various management theories, including qualities of effective managers.
- LO 12.4 Characterize nursing leadership roles in health care.
- LO 12.5 Explain the underlying principles of delegation in health care.

KEY TERMS

- accountability, p. 160**
- advocate, p. 164**
- autocratic leader, p. 161**
- behavioral theories, p. 160**
- bureaucratic leader, p. 162**
- creativity, p. 162**
- dedication, p. 162**
- delegation, p. 165**
- democratic leader, p. 161**
- formal leadership, p. 162**

humility, p. 162
informal leadership, p. 162
integrity, p. 162
laissez-faire leader, p. 161
leadership, p. 160
magnanimity, p. 162
management, p. 160
openness, p. 162
situational theories, p. 161
supervision, p. 168
trait theories, p. 160
transactional leaders, p. 161
transformational leaders, p. 161

Case Study

Chris, the registered nurse (RN), is assigned to care for six patients. Working with the nurse is Sabrina, a licensed practical nurse (LPN). Terri and Jon, unlicensed assistive personnel (UAP), make up the rest of the care team for the shift. The nurse reviews the list of patients:

- Archer Solomon (A. S.) is a 76-year-old male with chronic obstructive pulmonary disease (COPD) and Alzheimer dementia who was admitted with increasing shortness of breath. He has been living at home with his wife but recently has been having increasing episodes of confusion and disorientation to self, place, and time. He is unable to communicate his level of pain or discomfort. His vital signs at 0400 were: T 37.2° C (99° F), P 102 and regular, R 24 and labored, BP 134/86, with a pulse oximetry reading of 88% on 2 L of oxygen by nasal cannula.
- Suzanne Jarvis (S. J.) is a 45-year-old female on postoperative day 1 after an abdominal hysterectomy. She has a Foley catheter and an intravenous (IV) line. Overnight, she received morphine twice for pain rated as 8 of 10. She has the original abdominal dressing in place. She was afebrile overnight, and other vital signs were within normal limits.
- Janet Kimball (J. K.) is a 92-year-old female with urosepsis who was admitted from home 3 days earlier. She is on IV antibiotics every 8 hours. She is awaiting placement at a local nursing home. She rates her pain at 0 of 10 consistently and is

alert and oriented. She needs assistance with ambulation and meal setup. She was afebrile overnight, and vital signs were stable.

- Ben Lowe (B. L.) is a 29-year-old male admitted 2 days earlier after a motorcycle accident. He was wearing a helmet. His cervical spine x-rays were normal. He is alert and oriented. He had an open fracture of the radius, which was surgically set and pinned yesterday evening. He is ambulatory but requires assistance of one person when moving from the bed to a standing position. He has a saline lock in place and receives IV antibiotics twice each day. At 0600, he received oral medication one time for pain rated 6 of 10. His vital signs overnight were reported as afebrile and stable.
- Alfred Fox (A. F.) is an 88-year-old nonambulatory male admitted from a nursing home 2 days earlier and diagnosed with stage IV lung cancer. His code status is a do-not-resuscitate (DNR) order. He is on oxygen and is having Cheyne-Stokes respirations. He responds only to painful stimuli. The local hospice organization is working with the family and staff.
- Carrie Tomcik (C. T.) is a 22-year-old female admitted from a group home yesterday with pneumonia. She has a history of Down syndrome but has no history of major medical problems. She is receiving respiratory treatments every 4 hours, continuous IV fluids, and IV antibiotics every 6 hours. She is not complaining of pain, but she needs to be encouraged to use her incentive spirometer often. She has an order for ambulation twice each shift. Night shift reports vitals at 0400 as: T 38.3° C (101° F), P 72 and regular, R 22 and labored with a pulse oximetry reading of 94% on room air.

Refer back to this case study to answer the critical-thinking questions throughout the chapter.

New nurses may not consider themselves to be leaders or managers as they enter the realm of nursing care. However, all RNs use leadership and management skills in their daily work. They manage, plan, and coordinate care for their patients. Many nurses are responsible for directing the work of others in

providing patient care. It is important that the beginner nurse have an understanding of the processes involved in leading and managing others.

LO 12.1 Definitions of Leadership and Management

The terms *leadership* and *management* are often used interchangeably. Although these concepts are related, they are different in definition and in practice. Leadership behaviors and management skills complement each other. However, a manager may not possess leadership traits, and a leader may lack management skills.

Leadership is the ability to influence, guide, or direct others. Leadership focuses on relationships, using interpersonal skills to persuade others to work toward a common goal. Leaders may or may not have the authority that comes with a formal position in an organization; their power lies in their ability to form relationships and alliances with those around them. The leader is able to develop followers by sharing a common vision and values. Traditionally, leaders are visionaries who set the overall direction for a group or organization.

Management is the process of coordinating others and directing them toward a common goal. Management is focused on the task at hand. A manager holds a formal position of authority in an organization; that position includes **accountability** and responsibility for accomplishing the tasks within the work environment. Managers demonstrate accountability when they are answerable for their own actions and the actions of those under their direction.

LO 12.2 Leadership

Leaders have the ability to influence and motivate others while maintaining relationships to accomplish a goal. There are many different ideas and theories about why some people are better leaders than others.

Leadership Theory Overview

Researchers have conducted many studies to determine which traits are associated with good leadership and what styles of leadership are most effective. Despite the research, no one leadership style has proved to be best, because different situations require different styles of leadership.

Trait Theories

Early theories about leadership focused on the traits of leaders. **Trait theories** assumed that leaders were born with the personality traits necessary for leadership, which few people were thought to possess. Bass (1990) classified these traits in three categories: intelligence, personality, and abilities. Specific qualities of good leaders include good interpersonal skills, self-confidence, and a willingness to take risks. One problem with the early research on leadership was that it focused on males, and feminine characteristics were not included in the lists of traits. However, this early research laid the groundwork for further studies of leadership behaviors.

Behavioral Theories

Behavioral theories assume that leaders learn certain behaviors. These theories focus on what leaders do rather than on what characteristics they innately possess. Characteristics that were consistent in leaders included task-oriented behavior and consideration for others. Various models were developed on the basis of behavioral research.

Situational Theories

The next wave of leadership theories appeared in the 1970s and 1980s. Situational theorists proposed that behavioral theories did not account for the effect of the environment, or situation, in which the leadership behaviors occurred. Evidence suggests that although no one leadership style is best, leaders who focus on the person and the task are most effective ([Chatalalsingh and Reeves, 2014](#)).

Situational theories suggest that leaders change their approach depending on the situation. The situation includes a number of factors, such as characteristics of the group, the type of business, and the economic climate ([Zerwekh & Garneau, 2012](#)).

Contemporary Theories

The latter part of the past century saw increasing numbers of women in management and leadership positions. Researchers began to study and identify the different leadership styles of women and their influence on organizations. From this research, a variety of new theories developed.

In the late 1970s, [Burns \(1978\)](#) identified transactional leaders and transformational leaders. **Transactional leaders** use reward and punishment to gain the cooperation of followers. One advantage of transactional leadership is that employees know exactly what is expected. The employees realize that if they do what is expected or more, there will be a reward, usually a salary increase or bonus. If the employees fail, some sort of negative consequence is anticipated, ranging from being reprimanded to losing a position. This type of leadership focuses on getting the job done or making change happen. The nurse who is a transactional leader rewards other health care team members who provide safe and effective care and uses reprimands for those who do not meet performance goals for safe patient care.

Transformational leaders employ methods that inspire people to follow their lead. Transformational leaders work toward transforming an organization with the help of others. These individuals think that the interaction between leaders and followers can raise both to higher levels of morality and motivation ([Burns, 1978](#)).

Transformational leadership is sometimes confused with charismatic leadership. Charismatic leaders use charm and

emotion to form allegiances with others. Although this is not necessarily a negative trait, charismatic leaders can be motivated by many things, including personal gain. Although transformational leaders share some characteristics with charismatic leaders, the main difference is that the aim of a transformational leader is to enact change in an organization. The nurse who is a transformational leader inspires other members of the health care team to achieve goals for the sake of excellent patient care by exhibiting safe and effective care measures. This nurse may use stories of satisfied patients and families to motivate staff.

Styles of Leadership

There are many styles of leadership, including transactional and transformational, which have already been discussed. In the late 1930s, Kurt Lewin (1951) conducted studies of teenage boys to identify patterns of leadership behaviors. He identified three basic styles of leadership: autocratic, democratic, and laissez-faire. In addition to these three types, bureaucratic leadership has been identified. Other leadership styles may be a combination of those discussed in this chapter.

Autocratic Leadership

The authoritarian or **autocratic leader** exercises strong control over subordinates. This type of leader assumes that employees are motivated by external forces, such as the need for approval by the supervisor and the need to avoid punishment. Information flows in a top-down style and is primarily directive in nature. The leader demands respect and obedience from employees. If necessary, the autocratic leader uses coercion to ensure accomplishment of the goal.

Although this is a strict form of leadership, it is useful in crisis situations. A nurse may act as an autocratic leader when taking charge after a patient is found unresponsive. In this situation, it is helpful to have a leader who takes control and directs other members of the health care team.

Democratic Leadership

The participative or **democratic leader** believes that employees are motivated by internal means and want to participate in decision making. The primary function of the leader in this situation is to foster communication and develop relationships with followers. Leaders of this type view themselves as equal to their followers even if they hold formal positions of authority. Followers usually are satisfied with this type of leadership and feel that their ideas are valued. However, decision making can be a lengthy process. This type of leadership is not appropriate in a crisis environment, in which decisions must be made rapidly and without debate.

Nurses who are in charge during a shift may have patient assignments and work with other health care team members to provide care. These nurses may see themselves as equals with other team members and may consult with other nurses, exhibiting a democratic form of leadership. This style of leadership can be utilized in unit council meetings where nurses collaborate together to identify solutions to common problems.

Laissez-Faire Leadership

Like the democratic leader, the permissive or **laissez-faire leader** thinks that employees are motivated by their own desire to do well. The laissez-faire leader provides little or no direction to followers, who develop their own goals and make their own decisions. Few policies and procedures are in place. Although this type of leadership benefits followers by allowing them autonomy over their own work, it usually does not succeed in highly structured organizations such as hospitals. It is most useful in situations in which employees are highly educated, trustworthy, motivated, and experienced. A nurse in a leadership position who uses the laissez-faire style of leadership assigns patient care and expects all team members to set goals for the day and manage their time to complete the assignment. Successful implementation of this leadership style in nursing requires a highly efficient and reliable staff, such as seen in some specialized operating room nursing teams with a history of working together on a set type of cases.

Bureaucratic Leadership

Like the autocratic leader, the **bureaucratic leader** assumes that employees are motivated by external forces. This type of leader relies on policies and procedures to direct goals and work processes. The nurse using bureaucratic leadership tends to relate impersonally to staff and exercises power on the basis of established rules.

Qualities of Effective Leaders

Bennis (2003) identified six qualities of effective leaders. They are integrity, dedication, magnanimity, humility, openness, and creativity.

Integrity is the quality of having clear ethical principles and aligning one's actions with the stated values. This is extremely important for health care professionals. Nurses are expected to follow personal and professional ethics, as outlined in the **American Nurses Association (ANA) Code of Ethics for Nurses (2015)**. To maintain the trust necessary for the provision of safe and effective care, nurses must do everything possible to protect shared information and maintain the dignity of every person.

Dedication is the ability to spend the time necessary to accomplish a task. Effective leaders persist in working toward accomplishment of a goal even when doing so is difficult. They encourage others to continue working toward the goal. Nurses persevere through difficult situations to provide care that helps patients reach their goals.

Magnanimity means giving credit where credit is due. Good leaders reflect the work and success of accomplishing a goal by crediting those who helped reach it. Magnanimous leaders accept personal responsibility for failure to accomplish objectives. The nurse leader who is magnanimous gives credit to other health care team members who were instrumental in reaching goals.

Humility is the ability to recognize that no one is superior to another. Effective leaders recognize their own worth while respecting the worth of those around them. The nurse in a leadership position who is humble recognizes the valuable contributions made by others and thus helps foster community.

Openness refers to the leader's ability to listen to other points of view without prejudging or discouraging them. An effective leader considers others' opinions with an open mind, because a

wider variety of solutions to problems is offered. Openness by the nurse leader encourages creative solutions by providing an environment in which people feel comfortable “thinking outside the box.” A nurse leader who demonstrates openness maintains approachability for others when questions arise.

Creativity is the ability to think differently. A creative leader examines all possible solutions to a problem even if at first glance they appear to be unrealistic or outside the norm. This ability allows the nurse leader to inspire followers to consider broader visions and goals.

Formal and Informal Leadership

Leadership may emerge in many circumstances. **Formal leadership** is practiced in an organization as part of an official position, which may or may not be a management position. For example, a nurse can exercise formal leadership in the role of nurse director or supervisor. However, other nurses in the same organization can exercise formal leadership but not have a management role. Examples are nurse practitioners and clinical nurse specialists.

Informal leadership emerges outside the structure of a formal position. For example, staff nurses on a unit demonstrate informal leadership when they take responsibility for coordinating the staff schedule or act as part of the unit governance committee. Informal leadership is exhibited by individuals with strong interpersonal skills who can build relationships to help guide others.

LO 12.3 Management

The function of a manager is to accomplish the organization's goals by coordinating and directing the work of others. Successful managers rely on a variety of abilities, including strong communication, organizational proficiency, and critical-thinking skills.

Management Theory Overview

Over the years, research has been conducted on the functions of management, management styles and behaviors, and the qualities of effective managers. The resulting theories provide a framework for nurses and nurse managers in understanding how effective managers operate in the health care organization to ensure high-quality patient care.

Fayol's Functions of Management

In the early part of the 20th century, Henri Fayol described the functions of management. They are still applicable today and include planning, organizing, directing, and controlling (Conkright, 2015).

Planning

The planning function of a manager is comparable to the assessment, diagnosis, and planning portions of the nursing process. It includes four stages:

1. Setting goals
2. Assessing the current situation and future trends
3. Setting the plan
4. Converting the plan into an action statement

The nurse assesses the patient during the planning function of management. The patient's medical diagnosis and prognosis are considered. The nurse works with the family to decide on the best course of action in light of the information gathered, and a plan is

formulated, which includes the list of nursing interventions necessary to accomplish the goals (Fig. 12.1).

FIGURE 12.1 The nurse works with the patient and family members to establish a plan of care. (Copyright [istock.com.](https://www.istock.com/))

Organizing

The second function of management is organizing. After the plan has been developed, the manager coordinates the work to be done while avoiding duplication of effort. In a hospital setting, the RN organizes the care to be delivered to the patient. The RN delegates care to other health care team members, including LPNs and UAP, matching the team members' skills to the patient's needs to ensure care in the most expedient and cost-effective manner.

Directing

Directing is the management function that ensures the work of the organization is done. Clear direction is essential for smooth operation of any nursing unit. Examples can be seen on nursing units as the charge nurse or unit manager coordinates admissions, discharges, and patient assignments while the RN often directs the work of LPNs and UAP in the course of patient care. Skills required for efficient and clear direction include good

communication, organization, and delegation. The ability to motivate others toward a common goal is helpful, because the nurse must work with other, more autonomous professional personnel in patient care situations and in hospital committee work.

Controlling

The act of controlling involves comparing expected results of the planned work with the actual results. In the nursing process, evaluation is comparable to controlling. Evaluation is the process by which outcomes are compared with goals. In the situation of patient care, the patient's progress is measured on the basis of goals set forth in the nursing care plan. The nurse manager participates in organization-wide monitoring of quality of care through the hospital's quality management processes. These processes help determine care standards and monitor the quality of care delivered.

Mintzberg's Behavioral Model

Mintzberg (1973) described management in terms of behaviors. Underlying his descriptions were two assumptions: (1) much of a manager's time is spent in human relations, and (2) managers are more reactive than proactive. These assumptions provided the basis for three categories of behaviors: interpersonal roles, informational roles, and decisional roles. Mintzberg described three interpersonal roles: figurehead, leader, and liaison. The three informational roles he described are monitor, disseminator, and spokesperson. The third category of Mintzberg's behavioral roles is composed of the four decisional roles: entrepreneur, disturbance handler, resource allocator, and negotiator.

Mintzberg's Contemporary Model

Mintzberg (1994) later proposed another model of management. The two Mintzberg models are related, but the later version takes into consideration the experience, knowledge, and values of the manager. It describes managerial work as occurring at three different levels, rather than by role. The three levels are information, people, and action.

Information Level

The manager brings to the role a collection of experiences, knowledge, values, and competencies. The manager then develops a framework for what the job is supposed to be and includes the purpose of the job, the work to be done, and the way it should be performed. The information level of work includes communicating and controlling. At this level, the manager gives and receives information and then uses that information to manage the work of others. The nurse manager accomplishes this through staff meetings, message boards, and one-on-one interactions with staff.

People Level

The second level of Mintzberg's contemporary model involves people. At this level, the manager focuses on leading and linking people. Leading entails motivating and encouraging others to take action. Linking occurs when the manager networks with individuals outside the work unit to communicate needs and to develop liaisons. Nurse managers motivate the staff to provide high-quality patient care, and they network through interprofessional meetings in the hospital and in the community.

Action Level

At the action level, the focus is doing. At this third level, the manager directs the work of others and works with other departments to gain the resources necessary to achieve the work unit's objective. A nurse manager is working at the action level when contacting the central supply department to get additional dressing supplies when the unit runs short.

Qualities of Effective Managers

Many articles describe the qualities of a good leader. The lists of qualities necessary to be an effective manager can be confusing and are as varied as the number of articles dealing with the topic. [Anonson et al. \(2014\)](#) describe the personal qualities necessary for effective leadership and management in nursing, including self-belief, self-awareness, self-management, personal integrity, and a drive for improvement. It is important for nurse leaders to be focused on the patients rather than themselves to deliver good

patient-focused care. Nurses must desire to improve the status quo to provide higher levels of quality in the care delivered. These qualities are also discussed in other works concerning effective managers (Delgado & Mitchell, 2016; Feather, Ebright, & Bakas, 2015).

Skills of Effective Managers

A *skill* is a developed aptitude. Skills are the tools by which a manager carries out the work. The American Organization of Nurse Executives (AONE, 2005) has outlined the competencies necessary for nurse leaders and managers:

- Communication and relationship building
- Knowledge of the health care environment
- Leadership
- Professionalism
- Business skills

Communication is the foundation of nursing practice. Communication skills are essential for the work of the nurse manager and every nurse. By developing excellent communication skills, the nurse can obtain information, relay a plan, delegate, and evaluate a plan of care. The nurse develops relationships—with patients, families, co-workers, and other health care professionals and managers—that are necessary for functioning in the work environment.

An effective nurse manager must have knowledge of the health care environment. This environment includes trends in the local market area and state and national trends. The nurse manager must be aware of regulations and patient care standards so that clinical policies and procedures implemented at the unit level are in agreement with regulatory body expectations.

Leadership is often mentioned as a quality, but it is also a skill. Leadership as a skill is the application of personal traits to promote change. It is the willingness to take action and motivate others with words and by example.

Professionalism refers to the ability to hold others and oneself accountable for actions and outcomes. The professional nurse is aware of and holds high standards of ethics. Advocacy for the patient is part of this skill. The nurse manager is responsible for ensuring that the patient is the center of all decisions in the health care organization.

An effective manager must have business skills and a business sense. Part of quality care is ensuring that the care the patient receives is cost-effective. The nurse manager must understand concepts of budgeting, staffing, marketing, and information management. An understanding of human resource management is equally important. The skillful nurse manager understands the way these elements interact and their influence in achieving expected outcomes in an economically responsible manner.

Management Styles

Just as there are different leadership styles, different management styles have been identified. Douglas McGregor (1960) identified managers as having Theory X or Theory Y characteristics.

Theory X–style managers believe that the average person dislikes work and will avoid it if given the opportunity to do so. These managers think subordinates must be closely supervised, directed, and coerced into doing their work. They motivate employees by threatening punishment. They think that most workers value job security and have little ambition beyond it.

Theory Y–style managers think that if employees are satisfied in their work, they will view it as being as acceptable as play. These managers believe that satisfied workers are capable of self-direction, self-control, and initiative. They think that given the proper conditions, employees will accept and seek out responsibility on the job.

LO 12.4 Nursing Leadership Roles

A nurse does not have to be a manager to be a leader. Even at the bedside, nurses use leadership skills, although possibly in different ways than a nurse manager.

Patient Care Provider

The nurse must be able to plan, organize, deliver, and evaluate nursing care for patients. The patient-centered care provided depends on the mode of nursing care delivery. In team nursing care delivery, the registered nurse (RN) is ultimately responsible for patient care but may delegate aspects of care to licensed and unlicensed personnel. In primary nursing care, the RN may assume responsibility for all of the care for a select number of patients. In some specialty units, such as intensive care units (ICUs), the nurse may practice one-on-one care delivery with responsibility for the care of only one patient. The type of nursing care delivery is dependent on the facility, setting, staffing, and many other factors.

Communication skills are essential to effectively convey information about patients to colleagues in other disciplines, such as medicine. An example of a nurse in this role is an RN on a hospital unit who assesses, plans, and provides care for a group of patients. The RN also delegates certain aspects of care to other members of the health care team.

1. Which patients in the case study should the registered nurse (RN) consider as priorities in terms of assessment and care? What are the reasons?

Patient Advocate

An **advocate** is someone who supports and promotes the interests of others. The RN acts as a patient advocate during the course of treatment (ANA, 2015). The nurse's unique knowledge and relationship with the patient imparts the responsibility for speaking on the patient's behalf (Box 12.1). Nurse advocacy roles are discussed in Chapter 1.

Box 12.1

Patient Education and Health Literacy

Patient Advocate

- Educating patients about their conditions and about the purposes and expected outcomes of the planned treatment empowers them to act as their own advocates and can improve their cooperation with the treatment plan.
- After patients have information about their conditions, they can seek further information on their own and discuss treatment options with their health care provider.
- Discussing topics, such as the purposes and side effects of medication, can give patients the awareness that they need to monitor their response to treatment, including untoward effects, which can then be reported in a timely manner.

Case Manager

Although many health care organizations have case managers to aid in moving the patient through the health care system, the bedside nurse also acts as a case manager. One important way a nurse can do this is by beginning discharge planning on admission. The data gathered from the patient and family during the admission assessment contain important information about the patient's prehospitalization condition, functional ability, and knowledge of disease. During the admission process, areas of difficulty or lack of function are identified, and planning for discharge is placed into an electronic care plan.

QSEN Focus!

The nurse exhibits teamwork and collaboration when recognizing the contributions of other team members in helping the patient achieve health goals and when assuming the role of a team member or leader, depending on the situation.

Clinical Nurse Leader

The clinical nurse leader (CNL) has a master's degree and certification from the American Association of Colleges of Nursing (AACN) Commission on Nurse Certification (CNC). In this newer nursing role, the CNL oversees patient care or provides direct patient care using evidence-based practice (EBP), evaluates patient outcomes, and updates care plans. The CNL's role may vary in different care settings ([CNC, 2018](#)).

Nurse Educator

Leadership is a crucial role of the nurse educator. In the clinical setting, the nurse educator oversees patient care provided by the student. They are role models for students, as well as staff. According to [Adelman-Mullally et al. \(2013\)](#), the nurse educator also provides vision, stimulates student learning in the clinical setting, questions current methods, and pursues relational integrity.

Financial Resource Manager

The nurse is in a unique position to help manage financial resources. Wise use of supplies is one way the nurse can contain costs and manage charges for the patient. For example, a nurse who is going to perform a dressing change on a patient in the hospital should gather and take into the patient's room only the supplies needed for that procedure. After supplies have been taken into a patient room, they cannot be returned to the clean utility room and would be wasted if not used. The nurse has a responsibility to the patient to consider the cost of prescribed therapies. To do this responsibly, nurses must have an understanding of Medicare, Medicaid, and insurance provisions.

Collaborative Team Member

Coordination of patient care makes the nurse an integral part of the health care team. As part of this process, the nurse must often delegate care to meet the needs of the patient. To delegate effectively and safely, the nurse must have a thorough understanding of the delegation process, the local state nurse practice act, and the scopes of practice of any delegates ([National Council of State Boards of Nursing \[NCSBN\], 2016](#)).

The nurse works as an interprofessional collaborative team member with physicians and allied health colleagues for the benefit of the patient. In recognition of the importance of the need for interprofessional collaboration among nursing and other health care disciplines, the American Nurses Credentialing Center ([ANCC, 2018](#)) included interdisciplinary relationships as one of the original “forces of magnetism” ([Box 12.2](#)) that determined certification in the Magnet Recognition Program.

Box 12.2

Ethical, Legal, and Professional Practice

Magnet Recognition Program

The Magnet Recognition Program developed by the American Nurses Credentialing Center ([ANCC, 2018](#)) recognizes health care organizations for exemplary practice in the areas of patient care, nursing excellence, and innovation in nursing practice. Health care organizations can apply to become Magnet certified. In 2008, a new model was configured that placed the 14 Forces of Magnetism into Five Model Components:

MODEL COMPONENT	FORCES OF MAGNETISM CONTAINED IN THE MODEL COMPONENT
I. Transformational Leadership	Quality of Nursing Leadership Management Style
II. Structural Empowerment	Organizational Structure Personnel Policies and Programs Community and the Health Care Organization Image of Nursing Professional Development
III. Exemplary Professional Practice	Professional Models of Care Consultation and Resources Autonomy Nurses as Teachers Interdisciplinary Relationships
IV. New Knowledge, Innovation, & Improvements	Quality Improvement
V. Empirical Quality Results	Quality of Care

Magnet recognition is beneficial to the health care organization because it recognizes a professional environment that supports development of the nursing staff. The evaluation for Magnet status is based on quality indicators and standards found in the [ANA \(2016\)](#) publication *Nursing Administration: Scope and Standards of Practice*.

The quality indicators and standards put forth in the Magnet Recognition Program are designed to create a professionally satisfying environment for nurses. By enacting nurse-friendly policies and programs, Magnet hospitals are able to recruit and retain nurses at higher rates than non-Magnet organizations. Other health care team members benefit from the professional values and interprofessional collaboration in Magnet-status organizations. Some hospitals have found it easier to recruit and retain other in-demand professionals, such as pharmacists, because of the increased job satisfaction that comes from true interprofessional collaboration ([Brahm, Kelly-Rehm, & Farmer, 2009](#)). Patients also benefit, because Magnet organizations with more stable staffing patterns are better able to consistently provide safe, competent patient care.

LO 12.5 Delegation

For patient care to be completed in a safe and timely manner, it is sometimes necessary for the nurse to delegate tasks to other health care providers. The National Council of State Boards of Nursing (NCSBN) offers support in this process. In their joint statement (ANA & NCSBN, 2005), the ANA describes **delegation** as the transfer of responsibility, and the NCSBN calls it a transfer of authority. This transfer gives a competent individual the authority to perform a selected nursing task in a selected situation. The nurse retains accountability for the delegation. When a nurse assigns the hygienic care of a group of patients to the UAP, the nurse is ultimately responsible for making sure the care is completed. Any significant findings during the care (such as alterations in skin integrity, shortness of breath, or changes in a patient's condition) should be reported to the nurse. The nurse is then responsible for assessing the alterations and addressing them in the plan of care.

QSEN Focus!

Through quality improvement, the nurse appreciates the value of what each team member can do to improve patient care.

Principles of Delegation

First Principle of Delegation

Nurses must have knowledge of the nurse practice act in the state where they are licensed. Each state's nurse practice act defines the RN scope of practice and discusses appropriate delegation. A second resource in delegation is the employing of organization's policy and procedure manual. Employers must have job descriptions for each job class that outline the responsibilities and limitations of each position. The NCSBN website and journal articles are other resources for understanding delegation.

In considering the delegation of nursing tasks, the nurse must ask the following questions:

- Is this task within the RN scope of practice, knowledge, and skill?
- Is this task within the scope and abilities of the person to whom it is being delegated?
- Is this task something that can be delegated?
- Are there adequate resources available to the delegate to complete the task?
- Does the patient's condition require ongoing or frequent assessment or intervention?
- What are the potential risks to patient safety related to this task?
- Does this task entail assessment, evaluation, or nursing judgment?

Second Principle of Delegation

The RN cannot delegate assessment, planning, evaluation, or accountability for the assigned task. This means that even though the task has been assigned, the RN is still responsible for following up with the delegate to ensure that the task has been completed. If the delegate does not carry out the task in a satisfactory manner, the RN is responsible for seeing that it is completed.

Safe Practice Alert

The registered nurse (RN) is responsible for assessment of patients even if certain tasks are delegated to others.

2. Which tasks cannot be delegated to the unlicensed assistive personnel (UAP)? Why?

Third Principle of Delegation

The person to whom the assignment was delegated cannot delegate that assignment to someone else. If the person cannot carry out the assignment, the individual needs to notify the delegating RN so that the task may be reassigned or completed by the RN (Box 12.3).

Box 12.3

Ethical, Legal, and Professional Practice

Delegation

Before delegation, the nurse should do the following:

- Identify:
 - The task to be performed
 - The specific time frame for the task to be completed
- Assess:
 - The patient
 - The type of nursing care needed
 - The complexity and frequency of needed care
 - Patient stability
 - Assessments of other providers
- Determine that all of the following apply:
 - The task requires no nursing judgment.
 - The outcomes are reasonably predictable.
 - There is no need to alter the procedure for completing the task.
 - The task does not require complex observations or critical decisions.
 - Repeated nursing assessments are not required.
 - The consequences of delegating the task are not a risk to the patient.

From Ohio Board of Nursing. (2016). *Standards and practice relative to registered nurse or licensed practical nurse*, Ohio Revised Code 4723-4-01.

Safe Practice Alert

Remember to follow up with the unlicensed assistive personnel (UAP) to ensure that the delegated task has been completed and properly documented.

Five Rights of Safe Delegation

The NCSBN (2016) identifies Five Rights of Delegation. Applying these rights while working with licensed and unlicensed personnel takes some practice. The new nurse may want to enlist the support of more experienced co-workers when first using these rights of delegation (Box 12.4).

Box 12.4

Interprofessional Collaboration and Delegation

Five Rights of Delegation

1. *Right task*: One that is delegable for a specific patient
2. *Right circumstances*: Appropriate patient setting, available resources, and other relevant factors considered
3. *Right person*: The right person delegating the right task to the right person to be performed on the right patient
4. *Right direction or communication*: Clear, concise description of the task, including its objective, limits, and expectations
5. *Right supervision*: Appropriate monitoring, evaluation, intervention, and feedback

Right Task

Wise use of the skills and knowledge available through support staff frees the RN to perform the aspects of care that only a nurse can do. The RN must remember to delegate tasks that do not require nursing judgment. Only tasks that are routine and do not require variation from a standardized procedure should be delegated.

Right Person

The definition of delegation states that a task must be assigned to a competent person in a selected situation. Most states have a certification process for UAP. LPNs or licensed vocational nurses (LVNs) are licensed. Work settings have job descriptions and approved skills or competency lists as part of the hiring and orientation process. In working with a group of people, the nurse becomes knowledgeable about individual skills, strengths, and weaknesses.

Right Circumstance

Delegation depends on the patient care situation. The nurse evaluates a situation and determines whether it is appropriate for delegation. Depending on the unit type and patient acuity, the nurse may elect to negotiate a modified assignment or a different staffing combination.

Right Communication

The first component of supervision is communication. The [ANA and NCSBN \(2005\)](#) state that communication regarding delegation should be clear, concise, correct, and complete. The information that needs to be communicated includes the specific data to be collected, as well as methods for reporting; the activities to be carried out, along with patient-specific instructions and limitations; and the expected outcomes, possible complications, and specific timelines for reporting the information. Cultural differences should be considered when communicating tasks ([Box 12.5](#)).

Box 12.5

Diversity Considerations

Culture, Ethnicity, and Religion

Consider these transcultural phenomena when delegating tasks. Be sure to address any racial or gender prejudices among the staff. Avoid always delegating tasks to the new person; use the expertise of experienced staff. Be sure not to overextend by delegating exclusively to one person or group of people, even if doing so is viewed as conferring higher status.

Cultural phenomena should be considered when delegating to a diverse staff:

- Culture in the form of ethnic values or religious beliefs affects verbal and nonverbal communication. Factors (such as eye contact, posture, and use of assertive or passive terms) must be considered in communicating with a diverse staff (Xiao, Willis, & Jeffers, 2014).
- Of the four zones of interpersonal space (intimate, personal, social, and public), some cultures prefer a closer interpersonal space, whereas others prefer more distance.
- For most cultural groups, the family is the most important social organization, and family responsibilities may be placed above all else, including work.
- Cultural groups may be past, present, or future oriented. Past- and present-oriented cultural groups tend not to focus on long-range goals.
- Individuals and cultural groups with an internal locus of control need to feel in control of their environment and focus on planning. Those with an external locus of control think that fate or chance plays a role in life events and focus more on the obstacles they face.
- Working in multicultural teams offer challenges and opportunities. Individualized communication skills can help build commitment (Jager & Raich, 2011).

Gender

- Be aware of gender differences in communication. Males and females transmit and interpret messages differently.

Disability and Morphology

- Disease, health, body habitus, and wellness all play a role in alertness and stamina.

From Poole, V. L., Davidhizar, R. E., & Giger, J.N. (1995).
Delegating to a transcultural team. *Nurs Manag*, 26(8), 33-34.

Right Supervision

Supervision means monitoring an activity being carried out by someone else and making sure that it is performed correctly. Supervision and accountability go hand in hand. Supervision does not mean that the nurse has to directly observe the delegate carry out the assigned task. However, the nurse does conduct periodic follow-up inquiries with the individual to ascertain that the task is being completed, that clarification of instructions is provided, and that the assignment is adjusted if necessary.

3. What tasks are appropriate to delegate to the unlicensed assistive personnel (UAP) at the start of the shift? Why?

4. What information should the nurse include for the UAP when delegating the tasks?

5. What tasks are appropriate to delegate to the licensed practical nurse (LPN) or licensed vocational nurse (LVN)? Why?

Summary of Learning Outcomes

LO 12.1 *Compare leadership and management:*

Leadership and management are related but different concepts. Leadership is the ability to influence others. Management is the ability to motivate people to accomplish a goal.

LO 12.2 *Describe the styles of leadership, including the qualities of effective leaders:* There are different styles of leadership based on leadership theories. No one style fits every situation. The six qualities of an effective leader are integrity, dedication, magnanimity, humility, openness, and creativity.

LO 12.3 *Discuss various management theories, including qualities of effective managers:*

Management theories provide a framework for nurse managers in understanding how to effectively operate within the health care organization to ensure high-quality patient care. Successful managers possess qualities of self-belief, self-awareness, self-management, personal integrity, and a drive for improvement. Leadership, professionalism, and communication skills are also desirable. Nurse managers must be able to influence change, communicate clearly, solve problems, and be effective organizers.

LO 12.4 *Characterize nursing leadership roles in health care:* Nurses act as leaders in various roles. All nurses have a responsibility to provide safe patient care, to act as patient advocates, be fiscally responsible in care, and collaborate with other team members to provide high-quality, cost-effective care.

LO 12.5 *Explain the underlying principles of delegation in health care:* Appropriate delegation is the responsibility of the RN. The Five Rights of Delegation are right task, right person, right circumstance, right communication, and right supervision. The nurse cannot delegate assessment, planning, evaluation, or accountability for the assigned task.

Review Questions

1. Processes used in management parallel the nursing process. Which sentence describes a nurse using a management principle paralleled with the nursing process?
 - a. Planning is demonstrated when the nurse motivates others.
 - b. Directing is demonstrated when the nurse plans care for the patient.
 - c. Organizing is demonstrated when the nurse coordinates care for patients.
 - d. Controlling is demonstrated when the nurse tells other staff members what to do.
2. Which statement most closely reflects the differences between nurse leaders and managers?
 - a. Nurse leaders are always in formal positions of authority.
 - b. Nurse managers use transactional principles to accomplish goals.
 - c. Nurse leaders rely primarily on interpersonal skills to accomplish goals.
 - d. Nurse managers rely on supervisors for accountability and responsibility.
3. The nurse manager is monitoring overtime for the unit. She closely monitors staff hours and does not allow staff to come in for extra hours if

they are over their allotted time per week. This is an example of which of Mintzberg's decisional roles of the manager?

- a. Entrepreneur
- b. Disturbance handler
- c. Negotiator
- d. Resource handler

4. A nurse manager is trying to improve patient satisfaction ratings for her area of responsibility. The manager meets with the staff and forms an ad hoc committee to address the issues around the problem. This is an example of what style of leadership?

- a. Bureaucratic
- b. Democratic
- c. Laissez-faire
- d. Autocratic

5. A nurse is volunteering in the community to educate parents to increase the number of children in the school district who are immunized. The nurse oversees the activities of a group of volunteers. Which role best describes the nurse's activity in this situation?

- a. Management
- b. Leadership
- c. Volunteerism
- d. Activism

6. Which statement is an example of the use of situational leadership?
- a. The emergency room manager takes a vote on holiday coverage and then responds to a Code Blue by directing orders at the nursing staff.
 - b. The manager in surgery uses the vacation policy to grant time off and then performs a surgical count in an operating room using a checklist.
 - c. A vice president of nursing allows the department directors to make a decision about a hospital policy on holiday time and then sides with a nurse who does not want to work the required time.
 - d. The Chief Executive Officer (CEO) of the hospital instructs the nursing senate to develop a dress code and then changes the dress code after determining he does not like it.
7. To be effective, nurse managers should focus on which area?
- a. Cost-effective operation of the unit
 - b. Motivation of staff
 - c. Accomplishing organizational goals
 - d. The patients and their needs
8. A nurse states she believes in the dignity of each patient. At break, she is overheard talking about a patient in a persistent vegetative state as a

“lump.” This represents an inconsistency in which quality of an effective leader?

- a. Dedication
- b. Magnanimity
- c. Integrity
- d. Humility

9. A nurse delegates a bed bath to unlicensed assistive personnel (UAP). After lunch, the patient rings for the nurse and complains that he has not yet been cleaned up. He is very upset and angry. What should the nurse's next action be?

- a. Assist the patient in getting cleaned up.
- b. Write up the UAP for not carrying out the assignment.
- c. Report the UAP to the unit manager.
- d. Go find the UAP, and tell her to complete the bath immediately.

10. The registered nurse (RN) on an inpatient medical unit delegates vital signs and morning care to the unlicensed assistive personnel (UAP) for five stable patients. The nurse asks the UAP to document the vital signs and report any abnormal results immediately. Which rights of delegation is the nurse demonstrating? (*Select all that apply.*)

- a. Right person

- b. Right circumstance
- c. Right time
- d. Right supervision
- e. Right patient

CHAPTER 13

Evidence-Based Practice and Nursing Research

LEARNING OUTCOMES

Comprehension of this chapter's content will provide students with the ability to:

- LO 13.1 Differentiate various types of nursing research.
- LO 13.2 Compare quantitative and qualitative research methods.
- LO 13.3 Examine the steps involved in the research process.
- LO 13.4 Compare research and its relationship to evidence-based practice.
- LO 13.5 Consider the steps required in conducting evidence-based research.
- LO 13.6 Analyze considerations for implementing research in nursing practice.
- LO 13.7 Explore the relationship of hospital Magnet status with nursing research and practice.

KEY TERMS

- anonymity, p. 174**

Case Study

Craig Nigolian (C. N.) is a 60-year-old male with a 30-year history of smoking. He asks the nurse at his annual physical about quitting smoking. He wants to know the best method for him to use that will provide long-term abstinence. He inquires about oral medications that he has heard about and nicotine replacement therapy (such as nicotine patches, lozenges, or gum). He cannot remember the name of the medication that he saw advertised on TV and in magazines. The nurse uses research and evidence-based practice (EBP) principles to develop a patient-centered plan of care for C. N.

Refer back to this case study to answer the critical-thinking questions throughout the chapter.

Evidence for the practice of nursing is derived from research in nursing, medicine, health care, and disciplines outside of health care. **Evidence-based practice (EBP)** is the integration of best research evidence with (1) clinical expertise; (2) patient values and needs; and (3) the delivery of quality, cost-effective health care. The ultimate goal is to promote positive outcomes for the patient. Nurses often identify potential research problems while caring for patients, such as how best to treat a pressure injury. Some nurses are involved in collecting data for research, whereas others analyze and disseminate findings that affect practice. All nurses need to be familiar with how to review research findings to guide their EBP. Each research study helps expand the nursing knowledge base, and this further defines nursing as a discipline and profession.

LO 13.1 Nursing Research

Research is defined as “the diligent, systemic inquiry or investigation to validate and refine existing knowledge and generate new knowledge” (Gray, Grove, & Sutherland, 2017, p. 1). Federal regulations define research as “systematic investigation, including research development, testing, and evaluation, designed to develop or contribute to generalizable knowledge” (Office of Human Research Protection [OHRP], 2016, §46.102d). These general descriptions provide a basis for understanding research conducted in nursing.

Nursing Research

Nursing research “provides a significant body of knowledge to advance nursing practice” (American Association of Colleges of Nursing [AACN], 2018). Research in nursing incorporates both the scientific and nursing process to rigorously examine issues and propose and test theories that are critical to nursing practice and the profession. Nursing research shapes health policy, impacts the health of individuals worldwide, and influences nursing education.

Research conducted to generate theories is **basic research**. These theories help provide explanations for phenomena. Testing theories in different situations with different populations is **applied research**. **Clinical research** is conducted to test theories about the effectiveness of interventions. Each type of research contributes to the theoretical base for the practice of nursing.

American Nurses Association Research Standards

The American Nurses Association (ANA) standards of professional performance require nurses to use research findings in practice. Two criteria are measured. The first criterion is that nurses need to use the best available evidence, which includes research findings, to guide their practice decisions (ANA, 2015). The second criterion is that nurses participate in research activities that are appropriate for their position and level of education. Activities may include identifying problems in the clinical setting that may be researched; participating in data collection; participating as a member of a research committee or a research program; sharing research findings the nurse has found with others; conducting research; critiquing research that may be used in practice; using research findings to develop policies, procedures, and standards for patient care at health care facilities; and incorporating

research as part of ongoing learning as a nurse. Nurses may participate in one or more of these activities during their careers. The [ANA \(2018\)](#) Research Toolkit was developed to help nurses provide evidence-based care that improves patient outcomes. In 1981, the ANA Commission on Nursing Research published guidelines for the investigative function of nurses according to their level of education.

In 1985, the ANA created the National Center for Nursing Research. This organization evolved into the National Institute of Nursing Research (NINR) in 1993, affording it equal status with other National Institutes of Health (NIH). “The mission of NINR is to promote and improve the health of individuals, families, communities. NINR supports and conducts clinical and basic research and research training on health and illness across the lifespan” ([NINR, 2018](#)).

LO 13.2 Methods of Research

Three methods of research are used in studies: quantitative, qualitative, and combined qualitative and quantitative. Each method is used to gather data. **Data** are facts collected and analyzed by the researcher from the participants in a study. Data are expressed as numbers or in words, and the form of data expression determines which method of research is used.

Quantitative Research

Quantitative research usually produces data in the form of numbers. Quantitative research is based on a postpositivist philosophy, which assumes that reality is objective, fixed, stable, observable, measurable, and value free (Taylor & Medina, 2013). Positivism assumes that the approach is deductive in nature (Taylor & Medina, 2013), and it seeks to gain knowledge through scientific and experimental research (Gray, Grove, & Sutherland, 2017). **Deductive reasoning** formulates a specific conclusion from a large amount of data. Clinical trials of medications that are used to treat certain diseases, such as high blood pressure, employ quantitative research methodology. A nurse may be involved in quantitative research while investigating, for example, the effectiveness of a specific intervention for the prevention of skin breakdown.

There are several types of quantitative research, including descriptive, correlational, and experimental research. **Descriptive research** identifies data and characteristics about the population or phenomenon. A **phenomenon** is a fact, event, or circumstance that can be observed or experienced. Descriptive research can provide a starting point for future research or generate a hypothesis or theory through observation or documentation of a particular situation.

Correlational research is used to explore a relationship between two variables. A **variable** is a concept or item that has values that can change and that can be measured, manipulated, or controlled in the study. Correlational research examines the relationship between two items, such as weight and age. In correlational research, there is no control over the variables. Research may be done by looking retrospectively at a phenomenon and at the variables that can affect its occurrence. Originally, retrospective lung cancer research looked at patients who had or did not have cancer and at possible correlations with specific behaviors, such as smoking.

Experimental research explores the causal relationships between variables. Experimental research examines whether or not one variable

has a cause-and-effect relationship with another, such as a blood pressure medication having an effect on decreasing blood pressure. Experimental research examines a cause, whereas correlational research determines only whether or not the two variables are related to each other. Correlation cannot prove causation.

Quasi-experimental research examines a causal relationship between variables, but it may not meet the strict guidelines of experimental research. Some research of the effects of nursing interventions on patient outcomes may fall into this category. Outcome research includes studies of patient and family responses to interventions or patient satisfaction related to care in the hospital.

Qualitative Research

Qualitative research is based on a constructivist philosophy, which assumes that reality is composed of multiple socially constructed realities of each person or group (Gray, Grove, & Sutherland, 2017; Yin, 2015) and is therefore value laden, focusing on personal beliefs, thoughts, and feelings. Constructivism assumes an approach that is inductive (Creswell & Creswell, 2018). **Inductive reasoning** generalizes from specific facts. Qualitative research usually results in data expressed in words, often in the form of a narrative.

There are several types of qualitative research, including phenomenology, grounded theory, ethnography, and historical. **Phenomenological research** explores the reactions of a specific group of people who experienced a similar event in their lives.

Grounded theory research derives theories from the data collected in studies. The grounded theory method has been used to study postpartum depression, communication processes, and the way people with human immunodeficiency virus (HIV) infection manage their illness.

Ethnography focuses on the sociology of meaning through close field observation of a sociocultural phenomenon. The term *ethnography* is sometimes applied to the field notes or case studies produced from ethnographic research. **Historical research** studies historical documents to determine an accurate picture of a past event or time period.

LO 13.3 Components of Research

The research process involves many different components. The literature review is conducted after a research problem is identified. Ethical procedures must be addressed before the study begins. Data are then collected and analyzed before discussion of the research results.

Literature Review

After a research problem is identified, the purpose of the study is defined. This purpose states why the problem is important. A review is conducted to determine what is already known on the topic and identify any gaps in the literature. A **literature review** is a critical analysis of current information on the subject that will be studied in the research. The literature is searched for relevant articles on the topic, and the resulting information is then analyzed. A literature review typically appears near the beginning of published research articles.

Literature reviews include scholarly analyses of research. An integrative literature review synthesizes research findings and formulates ideas about future research. A **systematic review** of the literature provides a comprehensive, unbiased analysis through the use of a strict scientific design to select and assess each of the studies. A **meta-analysis** merges statistical results from related studies to discover similarities and differences in their findings.

The literature review process includes an overview of the subject, which involves dividing the literature into categories of articles that support a particular position and those that do not. The review should explain how each of the articles is similar to or different from the other articles. Conclusions are drawn about their contributions on the basis of the persuasiveness of the research findings. When reading each article, the researcher needs to determine the type of evidence that is provided: history, statistics, recent findings, or narrative or case study. The analysis includes the objectivity of the author, the credibility of the findings, and the overall value of the study. The purpose of the review is to describe the relationship of each article to the others, interpret the findings, and identify any gaps in the literature, which may provide a need for further research. The literature review provides a rationale for conducting the research proposed for the study.

Data Collection

After the literature review is conducted, hypotheses or research questions are formulated. A **hypothesis** is a statement about two or more variables and their relationship to each other. The design of the research is then selected to provide a plan for how to collect and analyze the data; the design includes the population to be studied and the specific sample for the study. The **sample** consists of the individuals in the population from whom the data will be collected.

Data can be collected by many different methods. **Instruments** are data collection tools. An example of an instrument is a questionnaire, which may be created in a Likert-scale format, showing the degree of satisfaction with each item, or as open-ended questions. Degree of agreement can be shown with 5 being the most satisfied and 1 being the least satisfied. **Fig. 13.1** is an example of a Likert scale. Interviews and focus groups are other means of obtaining data that may have structured questions or a more unstructured format. The data can also include diagnostic information concerning patients (such as, laboratory values) or information (such as, age, gender, ethnicity, vital signs, height, and weight).

I was satisfied with the care I received during my stay in the hospital.

Strongly Agree	Agree	Neither	Disagree	Strongly Disagree
5	4	3	2	1

FIGURE 13.1 Likert scale.

Dependent and Independent Variables

In experimental research, the independent variable is referred to as an *experimental variable* or *treatment variable*. An **independent variable** is a concept or idea whose value determines the value of other (dependent) variables. In research, the independent variable comprises the experimental treatment or intervention, and it is manipulated by the researcher to yield various outcomes. The **dependent variable** is the outcome that is affected by manipulation of the independent variable. For example, in researching the effectiveness of an antihypertensive medication, the medication is the independent variable and the person's blood pressure is the dependent variable.

In a controlled study, some of the participants are assigned to the treatment group and others are assigned to the control group by a random process. The **control group** does not receive the treatment. In the clinical trial of a medication, the control group receives a placebo.

The purpose of a control group is to prevent bias and ensure that the outcome results from the treatment rather than some other factor.

Institutional Review Board

An **institutional review board (IRB)** is a review committee established to help protect the rights and welfare of human research subjects. Regulations require IRB review and approval for research involving human subjects if it is funded or regulated by the federal government. Most research institutions, professional organizations, and scholarly journals apply the same requirements to all human research. The IRB must approve the research and procedure for data collection from human subjects.

A **human subject** is defined as “a living individual about whom an investigator conducting research obtains (1) data through intervention or interaction with the individual or (2) identifiable private information” (OHRP, 2016, §46.102f). *Interventions* may include procedures, such as gathering diagnostic information or manipulating the subject's environment. *Interaction* refers to any communication or contact during the research. *Private information* includes anything not expected to be made public, such as a medical record.

The IRB addresses three ethical principles that are inherent in research. The beneficence principle reminds researchers to minimize harms and maximize benefits. The principle of justice requires researchers to treat people fairly and design research to select subjects equitably and avoid exploitation of vulnerable populations. Autonomy includes the ability to understand and process information (i.e., mental capacity) and the ability to volunteer (i.e., freedom from the control or influence of others). Elements of autonomy and justice are related to issues concerning vulnerable populations and need to be considered when conducting research (Box 13.1). Vulnerable subjects are those with diminished autonomy. Additional information on these ethical concepts is provided in Chapter 11.

Box 13.1

Diversity Considerations

Human Subjects and Research

Research participation by all human subjects is voluntary. However, nurses need to be sensitive to unique circumstances that may affect the willingness or ability of persons to engage in research. Individuals may

choose not to participate because of cultural or religious reasons. When providing information to participants, the researcher must assess their level of understanding and ensure that the information is provided at the appropriate level.

Situations of Vulnerability

- When participants have limitations in volunteerism or capacity, they are vulnerable.
- Vulnerable subjects are more likely to have their rights abused through:
 - Physical control, as occurred during the Holocaust in the Nazi concentration camps, where research was conducted on the prisoners.
 - Coercion, which exists when subjects are told to participate and have reason to fear they will be harmed or threatened if they refuse.
 - Undue influence of someone in authority.
 - Manipulation of the information provided, such as by lying, withholding information, or exaggerating.

Vulnerable Subjects

- Children
- Embryos or fetuses
- Mentally disabled subjects
- Subjects experiencing emergency situations (e.g., being in an ambulance on the way to the hospital may cause a person to make a hasty decision about participating in research)
- Subjects in hierarchical social structures (e.g., hospitalized patients, nursing home residents, students, prisoners, military personnel), who may feel pressured to volunteer
- Educationally disadvantaged subjects, who may be illiterate or unable to comprehend the materials provided
- Economically disadvantaged subjects, who may be influenced by monetary compensation
- Members of marginalized social groups, who may not have access to the legal system
- Individuals with a fatal or incurable illness, who may accept high risks in the hope of a cure even if there is no direct benefit

Respect for persons requires researchers to treat individuals as autonomous human beings, allowing them to choose for themselves. Rules derived from respect for persons include the requirement to obtain informed consent and the requirement to respect the privacy of research subjects. **Informed consent** begins when the subjects are recruited and continues throughout the research process (Box 13.2).

Box 13.2

Ethical, Legal, and Professional Practice

Patient Rights Regarding Informed Consent

- Research participants require an explanation of the study in which they are subjects. Any information provided needs to be in a language that is understandable to them.
- Procedures and the purpose of the study need to be explained.
- The manner in which subject anonymity and confidentiality will be protected needs to be explained.
- Any potential harm, including physical or mental discomfort, and possible benefits from participation should be explained.
- Questions should be answered so that participants fully understand the research and their part in the process.
- All subjects need to be given time to decide about participation.
- Study participants are voluntary, may withdraw at any time, or may choose not to complete tasks.

Confidentiality and Anonymity

The way in which data will be used and made available to others is part of the agreement researchers make with study participants, and it is described in the informed consent. There are procedural design guidelines for anonymity and confidentiality. **Confidentiality** is the assurance that information can be viewed only by those requiring access. **Anonymity** means that a person's identity or personal information is not known. When collected, this type of data must be kept anonymous. If identifiers are used, they should be identification codes that are kept secure and destroyed on completion of the study. When data are to be reported, the researcher must determine whether to use names or pseudonyms. Participants' permission is needed if the data include quotations or can reveal the subject's identity.

The ultimate goal is to protect the identity of those participating, especially if there is any information that they would not want revealed about themselves. The data must be protected in some way. If the data are on a computer, password-protected access is required. Regulations under the Health Insurance Portability and Accountability Act (HIPAA) and its Privacy Rule, which outlines handling of protected health information, must be followed during research and addressed in the IRB application.

Any videos, photos, or audiotapes require releases if they are to be shown in the dissemination of research findings. The participants have the right to review these tapes before allowing them to be used for research. If subjects are involved in a group, they should be reminded that exchange of information in the group and the identities of participants must remain confidential.

Data Analysis

Data analysis techniques are procedures used to summarize words or numbers and create a meaningful result for interpretation. Quantitative analysis involves statistical analysis. Many types of statistical analyses may be performed on the data, and the appropriate technique needs to be applied. Qualitative analysis involves content analysis. This process requires coding of themes and analysis of the narrative content. The qualitative data may contain quotations and require interpretation. Quotations from study participants support the evidence that is provided by the study.

Dissemination of Outcomes

The next stage of the research process is dissemination of the findings. **Dissemination** is communication and distribution of the information. Dissemination may occur by publication in a journal or through a poster, an oral presentation, or a workshop at a conference. Researchers also may discuss study findings with their colleagues in less formal settings. If study participants want the research progress and findings reported to them, the material should be provided in understandable terms.

Nursing research with practical implications may need to be reported to agencies and health care providers to initiate necessary changes. If the research has a large-scale impact, study results should be disseminated to the community, those who funded the research, and policy makers. Research reports can be published by a university on a website or in printed newsletters to provide more public dissemination.

A dissemination plan should be devised at the beginning of the research.

Application to Practice

When most nursing research is conducted, the goal is to apply the findings to practice. Patient education regarding the latest findings is one method of application (Box 13.3).

Box 13.3

Patient Education and Health Literacy

Research Findings

- Patients require research results to be translated into understandable language.
- Brochures and fact sheets that provide brief but pertinent information about different topics have the greatest impact on patients.
- Short videos can relay information about health practices to patients.
- Websites provided by the health care facility or by state or federal health care agencies can be a source of accurate information.
- Public service announcements (such as antismoking campaigns based on research) are a means of educating the community.

One obstacle to applying research to practice is the difficulty in bedside access to information by nurses. Nurses often lack the time to participate in research-related activities. Not all nurses have the educational preparation for research. However, even a novice nurse can identify problems related to improving patient care. By reading research articles, the nurse may notice discrepancies in what is recommended in current practice and what is found in the literature. Research about nursing practice, nursing administration, and nursing education has an impact on patient care.

Nurses often feel that their bedside nursing care is removed from the research process. However, nurses participate every day in the care of patients, which is based on the nursing process. The nursing process is based on the scientific method used in research. Nurses should use research to improve the quality of patient care and should understand

the research base before initiating nursing interventions. To further apply research to practice, nurses need to implement EBP. Nurses are patient advocates who should consistently provide the best possible care for patients. Patient safety and quality improvement must be the focus of nursing practice. By participating in EBP committees and professional organizations, nurses stay up to date on the latest safe practice guidelines and research protocols. Nurses are accountable for their practice and must prevent errors by using the best evidence. Society expects high-quality health care, and nurses are at the forefront of providing that care.

LO 13.4 Evidence-Based Practice

EBP is integration of the best available research evidence and the nurse's clinical expertise to make patient care decisions. EBP allows a nurse to address questions and problems by reviewing the research, clinical guidelines, and other resources to determine practice. EBP results in better patient outcomes, keeps nursing practice current, and increases the nurse's confidence in professional decision making.

The Centers for Disease Control and Prevention (CDC) published the *Guideline for Hand Hygiene in Health-Care Settings*, which provides a review of data regarding handwashing in health care environments and makes recommendations for improving hand hygiene practices and reducing pathogenic transmissions. Clinical practice guidelines such as this are the result of an emphasis on EBP.

Historical Context

EBP plays a significant role in nursing, medicine, and other health care disciplines by improving clinical decision making, which results in better-quality patient care. Nurses provide holistic care when determining the best treatment for patients. In addition to the best evidence, clinical decision making includes factors such as acceptability to the patient and cost-effectiveness.

Nightingale

Florence Nightingale, in her *Notes on Nursing* in 1859, outlined basic principles of nursing science. Nightingale's method of nursing included rigorous monitoring of the effectiveness of interventions and treatments. This provided the initial basis for EBP (Mackey & Bassendowski, 2017). Her work was based on trial and error, careful observation, discussion with patients, and clinical experience (Bloom, Olinzock, Radjenovic, & Trice, 2013). She used statistical data to improve sanitation, health, nursing education, and health administration. Nightingale applied a statistical approach to the study of public health and mortality data and used a pie chart to display research findings. However, nursing did not publish its first EBP journal, *Evidence-Based Nursing*, until 1998.

Cochrane

During the 1970s, physicians began the EBP movement. This occurred after Archie Cochrane, a British epidemiologist, criticized health

professionals' lack of evaluation of their treatment methods. Cochrane's *Effectiveness and Efficiency: Random Reflections on Health Services* is credited with being the impetus for evidence-based medicine. *JAMA* published an article in 1992 that focused on evidence-based medicine in physician education. Named for Cochrane, the Cochrane Library is a collection of research databases for health care. This collection includes the *Cochrane Reviews*, which are systematic reviews and meta-analyses that interpret the results of medical research.

Research Utilization Versus Evidence-Based Practice

Research utilization is a subset of EBP. **Research utilization** is the application of research findings to improve clinical practice (Curtis, Fry, Shaban, & Considine, 2016). As research is conducted, evidence accumulates over time on a topic. Eventually, the evidence becomes accepted into practice. Often, there is a considerable gap in the amount of time between conducting the research and its acceptance. Research utilization is the direct application of findings from a single study to patient care (e.g., tracheal suctioning techniques).

In contrast, EBP integrates theoretical background, clinical judgment, and patient preferences. This is accomplished while the findings are being critically appraised, a process that requires knowledge of research to evaluate scientific evidence. EBP then applies cost-effective and clinically effective evidence to nursing practice. EBP includes research utilization with a complex skill set and larger knowledge base to provide the nurse with enough information to make decisions about the research evidence. EBP involves comparing interventions and determining the best evidence derived from a review of the literature. EBP includes (1) the best possible evidence, (2) clinical expertise, (3) patient values and needs, and (4) cost-effectiveness.

QSEN Focus!

To adequately integrate evidence-based practice (EBP) into patient care, nurses must critique research to differentiate between opinion and evidence by regularly reading current professional journals, and actively participate in their professional organizations.

Barriers to Evidence-Based Practice

Some barriers are common to research utilization and EBP, including the difficulty of communicating how to conduct EBP and the individual

nurse's skills in determining the quality of research available for review. Another limitation is the reluctance of organizations to fund research and subsequently make potentially costly practice changes based on the best evidence.

The proliferation of research available to health care providers has led to an increase in the quality and quantity of evidence on diagnostic tests, treatments, and models of health care delivery. Due to the copious amount of literature on a specific topic, it is difficult to analyze the literature in an efficient and effective manner. Health care literature with clinically applicable findings is published at a rate that is impossible for individual health care professionals to keep up with. It is estimated that medical knowledge doubled every 3.5 years in 2010. By 2020, it is anticipated to double every 73 days ([Densen, 2011](#)). It is practically impossible to estimate how many articles and how much time would be required today for nurses and physicians to stay current with the proliferation of electronic dissemination of information!

Historically there were delays of approximately 17 years for implementation of clinical research into practice ([Trochim, 2010](#)). For example, the research on sudden infant death syndrome (SIDS) conducted in the 1970s that led to the recommendation of placing infants on their backs was not relayed to parents until the early 1990s ([Gilbert, Salanti, Harden, & See, 2005](#)). Such situations led to a need for better EBP resources and an improved process for conducting evidence-based research (EBR) and disseminating the results.

LO 13.5 Conducting Evidence-Based Research

A specific process is required for EBR. It begins with assessment and has six phases. The steps for conducting EBR parallel Larrabee's (2009) model for EBP change (Fig. 13.2).

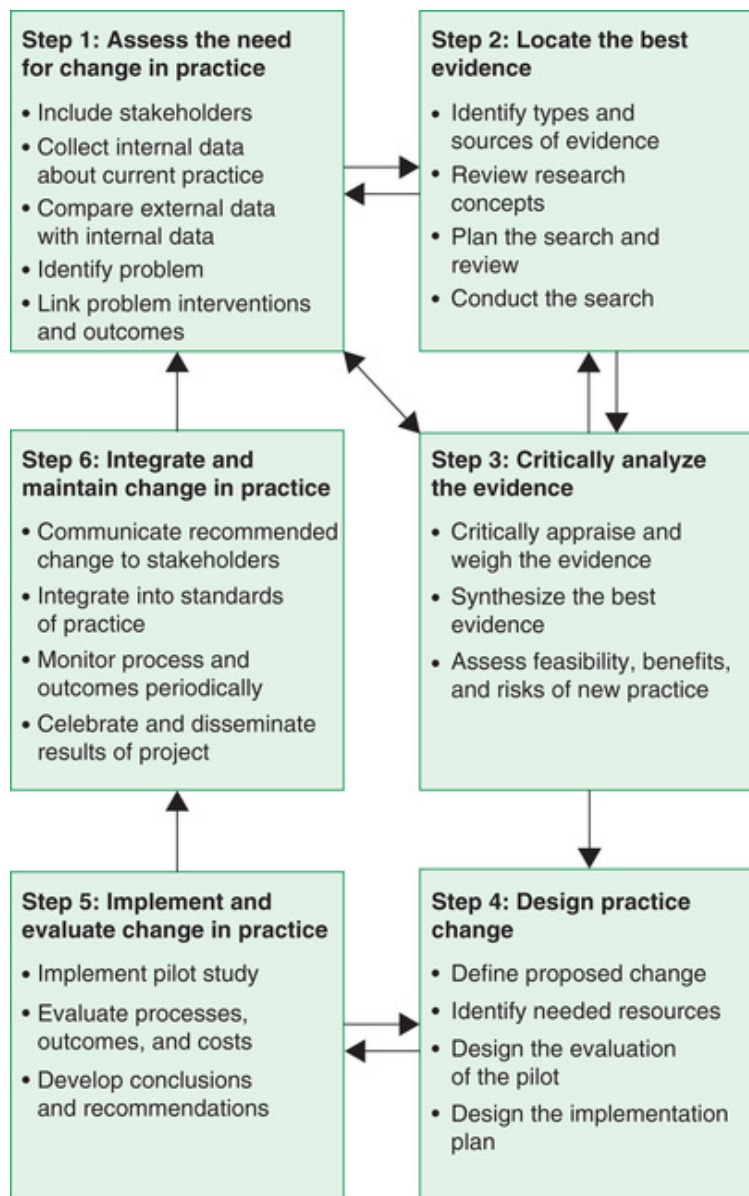

FIGURE 13.2 Larrabee's model for evidence-based practice (EBP) change. (From Rosswurm, M.A., Larrabee, J.H. (1999). Clinical scholarship: A model for change to evidence-based practice, *Image J Nurs Sch* 31(4):317–322.)

Assessing the Problem

The first phase of EBR consists of assessing the need for change in practice by identifying a problem. For a practicing nurse, problems present themselves in the context of caring for patients. This may occur while the nurse is determining the best intervention for a reoccurring problem or addressing a problem specific to a group of patients. The nurse collects data about the current practice to determine what is being done in response to the identified problem. Major stakeholders such as staff nurses, patients, or administrators are involved in this process. A **stakeholder** is someone who is an integral part of the process and may be the end user of the process or anyone who may be affected by the process.

1. If the nurse is not familiar with the medication C. N. is referring to, how will the background information be obtained? What resources are available for this type of information?

Developing a Question

The second phase of EBR consists of formulating a specific research question so that the nurse can effectively search the literature databases. To generate a specific question, a nurse needs to link the problem, interventions, and outcomes. One method of formulating a research question is identified by the acronym **PICO** (i.e., patient, population, or problem; intervention; comparison intervention; and outcomes). The acronym PICOT, which adds the parameter of time, can also be used ([Box 13.4](#)).

Box 13.4

Constructing a Good Research Question

The acronyms PICO and PICOT assist in remembering the steps of research question formulation. The following approach may be used to construct a good research question:

- *P (patient, population, problem)*: Describe the subject of the problem. The nurse determines how best to describe the group of patients participating in the research.
- *I (intervention)*: Define which intervention is being considered for the specific patient or population.
- *C (comparison intervention)*: Describe a second intervention to compare with the first if appropriate. An example is comparison of traditional x-rays with magnetic resonance imaging (MRI).
- *O (outcome)*: Define the type of outcome to assess. An outcome may be the change in a physical sign, the result of a diagnostic test, a patient response to a treatment or intervention, or the cost-effectiveness of a treatment.
- *T (time)*: Identify the time frame in which the research will take place.

A clinical question that can be researched includes a minimum of these four specific components:

- The patient's disorder or disease
- The intervention or finding that is being reviewed
- A comparison intervention (if applicable, not always used)
- The outcome

2. After determining which medication C. N. is referring to, write a clinical question using the PICO model as a guide.

Searching for and Evaluating Evidence

The third phase of EBR involves searching various databases for relevant evidence. This phase also includes evaluating and critically appraising the information that has been identified (Fig. 13.3).

FIGURE 13.3 Multiple databases can be searched for evidence before research findings are evaluated for relevance and implementation into practice.

Searching

Searching databases for evidence begins the third phase. The nurse may need to consult three categories of information resources, which are reviewed in sequential order, depending on need and applicability. The categories are general information (background) resources, filtered resources, and unfiltered resources.

Nurses may encounter conditions outside their specialty area and need an overview. Background resources provide detailed information. If the nurse is looking for a presentation of information or types of therapies, the best source is a background resource. Background resources include UpToDate, STAT!Ref, and MD Consult, which are web-based databases. Another source of background information is a current nursing textbook.

When trying to determine the best treatment or course of action and incorporate the most reliable evidence into the decision, the nurse should use a filtered resource, such as the *Cochrane Reviews* or the *Joanna Briggs Institute Library of Systematic Reviews*. Filtered resources provide the best available evidence. In filtered resources, clinical and subject experts have asked a question and then synthesized evidence to establish conclusions based on the research. This pre-evaluation process is already completed for nurses and allows the resources to be used while caring for patients. The conclusions from filtered resources still

need to be evaluated by clinicians in terms of a specific patient. Filtered resources produce systematic reviews of the literature.

Systematic reviews, such as those of the Cochrane Collaboration, are a mechanism of assisting health care providers in EBP. These reviews are typically conducted by an expert or group of experts in a particular field. The purpose of critiquing a series of studies is to provide health care professionals with recommendations to guide their practice. Some of the groups that systematically review scientific evidence are described in [Box 13.5](#).

Box 13.5

Evidence-Based Practice and Informatics

Research Resources

Systematic Reviews

- *Cochrane Collaboration*: This international collaboration facilitates the creation, maintenance, and dissemination of systematic reviews that are published as *Cochrane Reviews* in the Cochrane Library. These reviews usually are medically oriented, and they are considered the gold standard of reviews.
- *Database of Abstracts of Reviews of Effects (DARE)*: This database contains systematic reviews produced and maintained by the National Health System's Centre for Reviews and Dissemination in the United Kingdom.

Clinical Practice Guidelines

- *Agency for Healthcare Research and Quality (AHRQ)*: In the United States, AHRQ launched its initiative to promote evidence-based practice (EBP) in everyday care through establishment of evidence-based practice centers (EPCs). The EPCs develop evidence reports and technology assessments on topics relevant to clinical, social science or behavioral, economic, and other health care organization and delivery issues by reviewing all relevant scientific literature on clinical, behavioral, organizational, and financing topics. These scientific syntheses may include meta-analyses and cost analyses.

If a resource is not found in a filtered resource that addresses the question, an unfiltered resource may be used. Unfiltered resources

include MEDLINE/PubMed, PsychINFO, and the Cumulative Index to Nursing and Allied Health Literature (CINAHL). The nurse can also check journals for original research studies. The nurse may consult an unfiltered resource to determine whether any new studies have been conducted since the systematic review in the filtered resource was written.

3. On the basis of the clinical question developed for C. N., determine the best clinical resources that address the question, and provide the necessary information to guide the patient care decision.

Critically Appraising Information

After identifying an article or systematic review resource that seems appropriate to the question, the nurse must critically appraise the information. Nurses should not accept research without carefully reviewing the study. **Critical appraisal** is a balanced evaluation of the strengths, benefits, weaknesses, and flaws of the research. Critical appraisal requires a systematic assessment of the evidence to assess validity, results, and relevance before using the research in a clinical situation. This process requires the use of critical-thinking skills. Articles in peer-reviewed journals provide a measure of quality control, but even they may vary in their quality.

If the study is from a primary source that provides original data on a topic with no commentary, the nurse needs to check its validity. Interpreting the data depends on skill and experience, and the nurse may also consult with a peer. To determine validity, the nurse must address a number of issues in the appraisal. **Validity** generally refers to the strength or the degree to which a concept, conclusion, or measurement is justifiable and corresponds accurately to the truth.

Internal Validity

To determine a study's validity, the nurse must first address the internal validity of the research and examine whether the results of the study are reasonable on the basis of how the study was conducted. The study

should address a clearly focused issue. The literature review must be appropriate to the topic. The participants should have been randomly assigned to the experimental and accepted treatment groups, with each group treated equally apart from the experimental treatment itself. By having a control group and random assignment in experimental research, the study has more validity.

All ethical issues related to the research should be addressed. All participants should be accounted for at the end of the study. Measures should be objective and without bias. The subjects and clinicians should be blinded, remaining unaware of which treatment was being received by whom until the end of the study. In all studies, the data collection methods need to be clearly defined, and the analytic methods must be appropriate.

Result Analysis

The nurse must analyze the results of the study. The findings need to be reported in terms of significance. The size and precision of the treatment effect needs to be assessed to determine the significance of the results.

External Validity

External validity and relevance are determined last. External validity is a measure of whether a study can be applied to any other setting. When studies have large numbers of participants, it is easier to generalize the results. Quantitative studies often have large numbers of subjects, whereas qualitative studies frequently have smaller numbers of participants, which may not allow for generalization. A determination needs to be made on whether the outcomes of the study can be applied to a current clinical nursing situation. The treatment needs to be feasible in the current setting. The benefit of the intervention must be weighed against any harm to the individual patient.

Critical appraisal tools have been developed that can assist with this process. For example, a form with check boxes can list individual points to be addressed during the study. In determining questions, some forms give information regarding the sections where the information can be found in the articles about the study. Various critical appraisal tools are available (www.gla.ac.uk/media/media_64037_en.pdf).

If a systematic review is being critically appraised, different criteria are needed to determine whether the results of the review are valid. The review should include appropriate studies and not eliminate any that are pertinent. The quality and results of the studies included in the review should be similar. The review requires a clear presentation of the results of each study and the value of its evidence. Various levels of

evidence should be considered. The systematic review or meta-analysis of randomized controlled trials (RCTs) or evidence-based clinical practice guidelines based on systematic reviews of RCTs are the highest level of evidence. Levels of evidence are listed in descending order in Fig. 13.4. Each level of evidence provides a different level of assurance about the validity of the information provided.

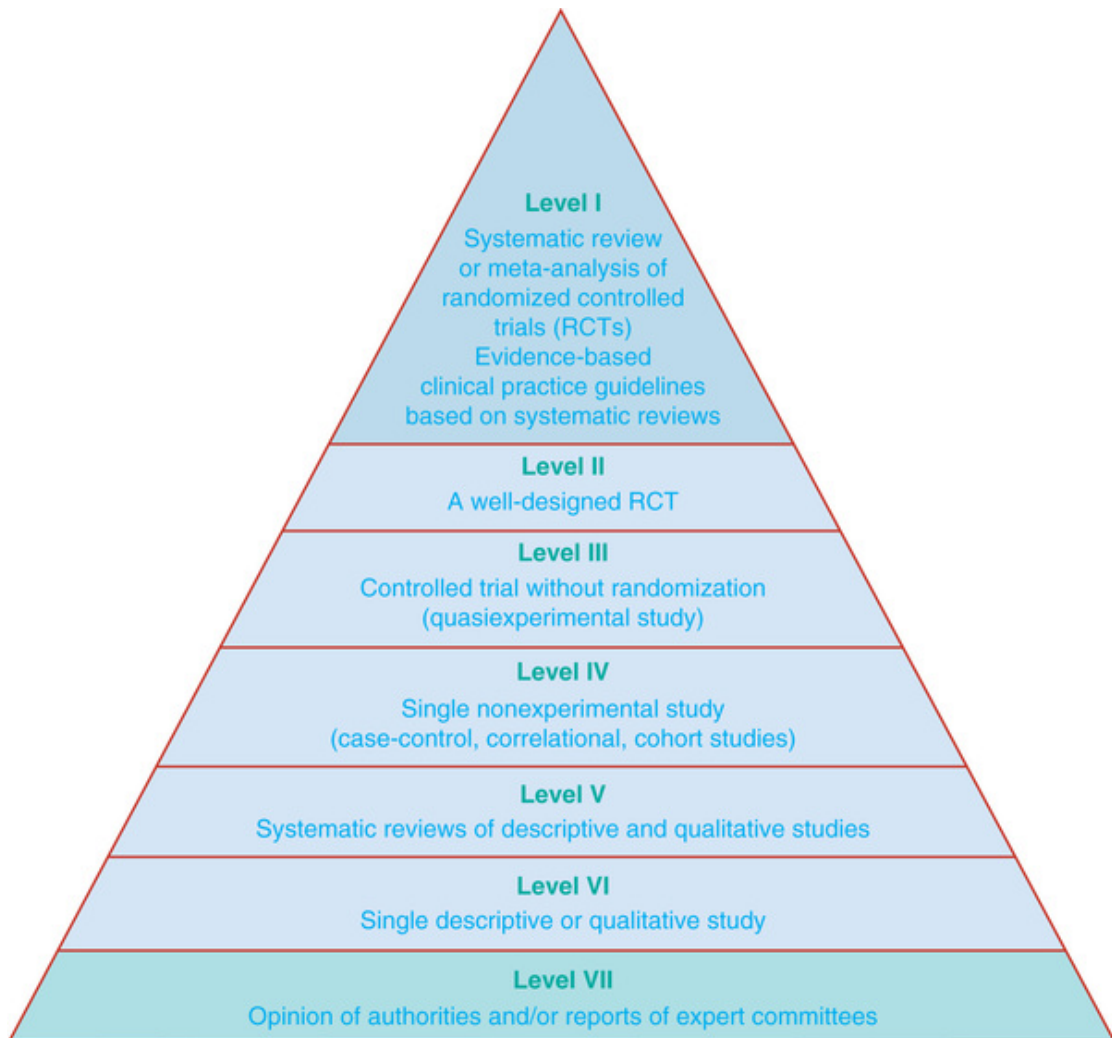

FIGURE 13.4 Levels of evidence: Evidence hierarchy for rating levels of evidence associated with a study's design. Evidence is assessed at a level according to its source. (From LoBiondo-Wood, G., & Haber, J. [2018]. *Nursing research: Methods and critical appraisal for evidence-based practice* (9th ed.). St Louis, Elsevier.)

4. What questions should the nurse ask to critically appraise the identified clinical resources?

Synthesizing the Evidence and Developing a Plan

The fourth phase in the EBR process requires the nurse to design a practice change based on the evidence found in the literature. The plan needs to include how the findings will be conveyed to the nurses who will use the new information. Workshops and in-service or focused training may be necessary if the plan involves a comprehensive change in care or it affects the entire health care agency or community. A bulletin can be provided that lists several safe practice concerns with rationales in the form of a safe practice alert.

Implementing the Plan

The fifth phase in the EBP process requires implementation of the change by applying the evidence. At this point, nurses begin to use the new information in their practice. In the process of implementing EBP, the nurse develops a clinical question, seeks answers to verify and support a clinical decision, and ultimately applies the findings to patients.

Maintaining the Change and Reevaluating

After the change has been integrated and maintained in practice, the final phase in the EBR process consists of evaluating the effectiveness of the decision in terms of the patient's response. The nurse determines whether the diagnosis and treatment were successful, whether there has been any new information in the literature since implementation, and how the clinical decision can be improved or updated. All of these evaluations prompt the nurse to keep up to date with the current literature. [Box 13.6](#) provides an example of EBR.

Box 13.6

Evidence-Based Research Example

Phase 1: Assess the Problem

The nurses questioned the effectiveness of the nasogastric (NG) tube placement verification procedure in their facility and wanted to determine the best practice. Most nurses in the facility were checking placement by aspiration of contents, but other nurses said that a chest x-ray was the preferred method.

Phase 2: Develop a Question

The PICO components of the question for this problem were:

- *Patient*: Patients requiring NG tube placement
- *Intervention*: Verification of NG tube by radiologic (chest x-ray) confirmation
- *Comparison*: Verification of NG tube by another method (aspiration or auscultation)
- *Outcome*: Confirmation of NG tube placement

Phase 3: Search for Evidence and Evaluate

The nurses reviewed multiple research articles and critically appraised the evidence on verification of NG tube placement.

- Multiple, nonradiologic verification methods, including observation for bubbling, auscultation while pushing air into the NG tube, and litmus and pH paper testing, are reported in literature to confirm placement of an NG tube (Fan, Tan, & Ang, 2017).
- Radiologic (chest and/or abdominal x-ray) verification is currently considered the gold standard for ensuring that an NG tube is properly placed into the stomach. Many research studies indicate that it is consistently more accurate in determining NG tube placement than auscultation or aspiration of fluid.
- Some research findings alert physicians and nurses to the limitations of x-ray and encourage continued work to find even more accurate and practical methods to verify NG tube placement (Nejo, Oya, Tsukasa, Yamaguchi, & Matsui, 2016).
- Limitations of chest and abdominal x-ray verification were noted in literature for newborns, because repeated exposure to radiation is potentially dangerous, and displacement of a NG tube may occur within moments following x-ray. Study findings support the use of pH testing, when radiologic exams are not practical or possible (Dias et al., 2017).

- Protocols for verifying placement of a NG tube are still being researched to increase patient safety and ensure positive outcomes.

Phases 4 Through 6: Develop the Plan, Implement the Plan, and Reevaluate

From review of the evidence, a plan was developed to initiate practice change for safer patient care. Staff nurses were educated on the new policy for NG tube verification using radiologic exam. The nurses implemented the change and planned an evaluation of the change in six months.

PICO, Patient (population or problem), intervention, comparison intervention, and outcome.

LO 13.6 Implementing Research in Nursing Practice

EBP has a role to play in improving the care of patients. Nurses should be able to recognize the different types of evidence levels to identify best practices. Any single means to establishing care, even if it is an accepted method, may not meet the complex needs of individual patients. For EBP to be safe and effective, nurses must be able to evaluate the strength and relevance of research findings. Nurses need to understand that there are different types of evidence that should be used to respond appropriately to individual patient preferences (DiCenso, Guyatt, & Ciliska, 2014). Nurses must use critical thinking to implement different care practices that are consistent with patients' values. Collaboration with others provides a mechanism for implementing best practices for patient care (Box 13.7).

Box 13.7

Interprofessional Collaboration and Delegation

Research Participation and Implementation

Interpret and use research in clinical decision making:

- Incorporate evidence-based practice (EBP) into individual practice, and assist colleagues to incorporate research findings into their individual practices.
- Collaborate with colleagues to use research when caring for the same patient on various shifts and days.

Implement EBP beyond personal practice (such as on the nursing unit) at an informational program, for an entire department, or at the organizational level:

- Collaborate with colleagues to use research on the nursing unit to influence the clinical microsystem (i.e., small, functional unit where care is provided).

- Educate unlicensed assistive personnel before delegating care on the importance of EBP for positive patient outcomes.
- Collaborate with administrators to use research to influence the larger practice environment.

Participate in collaborative research:

- Function as a participant or co-researcher in a collaborative, knowledge-generating research project.

LO 13.7 Magnet Hospital Status and the Role of Nursing Research in Practice

Magnet status is recognition given by the American Nurses Credentialing Center (ANCC), an affiliate of the ANA. To receive this recognition, hospitals must satisfy a set of criteria designed to measure the strength and quality of nursing. A Magnet hospital is characterized by excellent patient outcomes due to nursing, a high level of nursing job satisfaction with a low nurse turnover rate, and appropriate resolution of any grievances (Box 13.8). The Magnet Recognition Program supports an evidence-based environment, which includes the nurses' autonomy to improve quality of care through research utilization (ANCC, 2018). Research and EBP must therefore become a part of the nurses' care of the patients.

Box 13.8

Qualities of a Magnet Hospital

Magnet hospitals have the following qualities:

- Nurses are involved in data collection and decision making in the process of delivering patient care.
- The relationship between nursing leaders and staff nurses indicates appreciation and respect and rewards them for advancing nursing practice.
- The administration involves staff nurses in research-based practice through ongoing open communication and collaboration between nurses and other members of the health care team.
- The hospital has an appropriate mix of personnel that allows for the best patient outcomes.

Research and Best Practices

With the increasing emphasis on EBP, nurses must understand research and its application to patient care. A criticism of EBP is that it will become a standard formula. However, a key element of EBP is including the patient in the process to individualize care. There must always be personalization of the evidence to specific patient circumstances. High-quality nursing care is the priority of EBP. Nursing practice must be based on research evidence rather than tradition. As

they begin their practice, new nurses should actively seek opportunities to become involved in EBP immediately, because doing so enables EBP to further evolve and can increase its acceptance in the nursing community.

Summary of Learning Outcomes

LO 13.1 *Differentiate various types of nursing research:* Basic research generates theories, applied research tests the application of research in different situations and populations, and clinical research is used when testing theories about the effectiveness of interventions.

LO 13.2 *Compare quantitative and qualitative research methods:* Quantitative research designs are descriptive, correlational, experimental, and quasi-experimental. Qualitative research designs include phenomenological, grounded theory, ethnographic, and historical.

LO 13.3 *Examine the steps involved in the research process:* Research includes a literature review, data collection, data analysis, dissemination of outcomes, and application to practice. Before conducting research, permission must be sought from an IRB, whose responsibilities include protecting the rights and welfare of the participants.

LO 13.4 *Compare research and its relationship to evidence-based practice:* EBP is integration of the best available research evidence and the nurse's clinical expertise to make patient care decisions. EBP allows a nurse to address questions and problems by reviewing the research, clinical guidelines, and other resources to determine practice. EBP results in better patient outcomes, keeps nursing practice current, and increases the nurse's confidence in professional decision making.

LO 13.5 *Consider the steps required in conducting evidence-based research:* Evidenced-based nursing

research consists of assessing a need for change; developing a question that links the problem, interventions, and outcomes; searching for and synthesizing the best evidence; designing a plan for change; implementing the change; and integrating, maintaining, and evaluating the change.

LO 13.6 *Analyze considerations for implementing research in nursing practice:* Nurses should be able to recognize the different types of evidence levels to identify best practices. Nurses must understand that any single means to establishing care, even if it is an accepted method, may not meet the complex needs of individual patients or be consistent with patients' preferences or values. Collaboration among health care professionals can help with individualizing patient care while incorporating research into practice.

LO 13.7 *Explore the relationship of hospital Magnet status to nursing research and practice:* The Magnet Recognition Program for hospitals supports an evidence-based environment, which includes the nurses' autonomy to improve quality of care by using evidence.

Review Questions

1. A nursing student is taking care of a patient with possible appendicitis and is curious about the best method of diagnosing this disorder. What does the nursing student have to consider in formulating a question using the PICO format (patient, population, or problem; intervention; comparison intervention; outcomes) to determine evidence-based practice (EBP)?
 - a. Problem: Appendicitis; interventions: Ultrasound versus computed tomography (CT) scan; outcome: Diagnosis of appendicitis
 - b. Problem: Pain; interventions: Hydromorphone versus morphine; outcome: Pain free
 - c. Problem: Fever; interventions: Cooling measures versus antipyretics; outcome: Normal temperature
 - d. Problem: Appendicitis; interventions: Complete blood count versus chemistry panel tests; outcome: Painless

2. The nurse decides to access a systematic review database to determine EBP related to the patient's treatment plan for a diagnosis of otitis media (i.e., ear infection). What database can provide that type of resource?
 - a. Cumulative Index of Nursing and Allied Health Literature (CINAHL)
 - b. Cochrane
 - c. PubMed
 - d. MD Consult

3. The nurse researcher provides participants with informed consent so that what ethical principle is upheld?
 - a. Respect for persons
 - b. Beneficence
 - c. Justice
 - d. Ethics
4. The nurse feels that the results of a recent literature search and analysis about handwashing should be implemented in the entire hospital system. With whom would the nurse be required to collaborate?
 - a. Colleagues caring for patients in her unit
 - b. Colleagues in the community
 - c. Administrators at the hospital
 - d. Others in her department
5. Knowledge gained from research in the 1970s about placing infants on their backs to prevent sudden infant death syndrome (SIDS) was not recommended to parents until the 1990s. This is an example of what barrier to EBP?
 - a. Proliferation of research
 - b. Implementation delay
 - c. Information needs not being met
 - d. Lack of readily available resources
6. A patient is on the way to the hospital in an ambulance and is asked to participate in a research protocol for a new treatment for myocardial infarction. What is this an example of? (*Select all that apply.*)

- a. Standard practice
 - b. An ethical dilemma
 - c. A violation of informed consent
 - d. A patient who is in a vulnerable population category
 - e. Compliance with important ethical issues of justice and autonomy
7. Patients are participating in a study to identify genetic disorders. About which potential concerns should the nurse researcher be aware? (*Select all that apply.*)
- a. Violation of confidentiality if a disorder is revealed
 - b. Possible adverse consequences related to employment
 - c. Possible adverse consequences related to reputation
 - d. Possible adverse consequences to insurability
 - e. Inability to prevent the progression of genetic disorders
8. Which entities or documents specifically address the role of the nurse in research? (*Select all that apply.*)
- a. American Nurses Association (ANA) standards of practice
 - b. Institutional review board (IRB)
 - c. Hospital Magnet status
 - d. The Joint Commission (TJC)
 - e. MD Consult
9. Which factors contribute to the nurse having difficulty keeping up with the latest research

findings? (*Select all that apply.*)

- a. Implementation delays
 - b. Proliferation of research
 - c. Volume of health care literature
 - d. Hours spent in direct patient care
 - e. The need to read three articles every day of the week
10. After reading various research articles and reviews on a subject, the nurse designs a practice change based on the literature. What stage of EBP is this?
- a. Maintaining the change
 - b. Implementing the change
 - c. Evaluating and critically appraising
 - d. Synthesizing the evidence and developing a plan

CHAPTER 14

Health Literacy and Patient Education

LEARNING OUTCOMES

Comprehension of this chapter's content will provide students with the ability to:

- LO 14.1 Define health literacy.
- LO 14.2 Explain the role of health literacy in nursing and patient education.
- LO 14.3 Recognize the types of patient education and the settings in which patient education occurs.
- LO 14.4 Differentiate among the three domains of learning.
- LO 14.5 Explain how learning styles affect patient teaching.
- LO 14.6 Describe factors affecting health literacy and patient education.
- LO 14.7 Carry out an assessment of the patient's health literacy and education needs.
- LO 14.8 Identify nursing diagnoses appropriate for use with patient education.
- LO 14.9 Determine goals and outcome criteria for patient education.
- LO 14.10 Implement teaching plans and evaluate their effectiveness.
- LO 14.11 Recognize the role of technology in accessibility of health care information.

KEY TERMS

affective domain, p. 189

cognitive domain, p. 189

health literacy, p. 186

learning, p. 188

multimodal learner, p. 189
psychomotor domain, p. 189
teaching, p. 188

Case Study

Stan Lubic (S.L.), a 53-year-old male patient with a 1-week history of night sweats, shortness of breath, and cough, was seen in the office of the primary care provider (PCP). A chest x-ray and laboratory tests were ordered, and he was diagnosed with bilateral pneumonia and pleural effusions, with a white blood cell (WBC) count of $27,000/\text{mm}^3$. The PCP advises S.L. that he needs to be admitted to the hospital for treatment. S.L. tells the PCP that he does not have insurance and states, "I can't be admitted." The PCP agrees to send him home with prescriptions for an antibiotic, a steroid, and an inhaler. The nurse gives him written instructions to call the office immediately if he feels worse or does not begin to feel better within 48 hours.

Three days later, S. L. is brought to the emergency room by ambulance and is intubated, placed on a ventilator, and transferred to the intensive care unit (ICU). His vital signs are T 38°C (100.4°F), P 92 and regular, R 20 on a ventilator, and BP 153/84. He expressed chest pain as 6 of 10 before being placed on the ventilator. When the PCP speaks with the patient's wife the next day in the waiting room, he asks if her husband seemed to get any better after he started the prescribed medicines. His wife appears confused, and after a few more minutes of conversation, she pulls "the receipt for his office visit" from her purse. However, the papers are not a receipt but the written prescriptions and instructions provided during the visit. The PCP then learns that neither Mr. nor Mrs. L. is able to read.

Refer back to this case study to answer the critical-thinking questions throughout the chapter.

Not all patients in need of health care information can easily grasp the concepts provided during patient teaching. Nurses have a responsibility to present health-related information to patients and their families and to do everything possible to ensure their ability to comprehend and

integrate the information. To teach effectively, nurses must recognize that patients of all ages come from diverse cultural, educational, and socioeconomic backgrounds. Each has a different ability to comprehend health care information. The unique ability of a patient to understand and integrate health-related knowledge is known as **health literacy**.

Health literacy is about patients understanding medical information from the health care team or other sources and using that information to make informed decisions about their care and course of treatment (Schardt, 2011). The Health Literate Care Model (Fig. 14.1) is a model developed to assist health care organizations integrate health literacy as an outcome measure integrating the concept as an organizational policy (Koh, Brach, Harris, et al., 2013). Before the proposal of this model, the most recent comprehensive data exploring health literacy in the United States was from a research project called Assessing the Nation's Health Literacy: Key Concepts and Findings of the National Assessment of Adult Literacy (NAAL), which was conducted in 2003 (White, 2008). The NAAL was the first assessment of the nation's progress in adult literacy since the National Center for Education (NCES) adult literacy assessment performed a decade earlier, the 1992 National Adult Literacy Survey (NALS) (White, 2008).

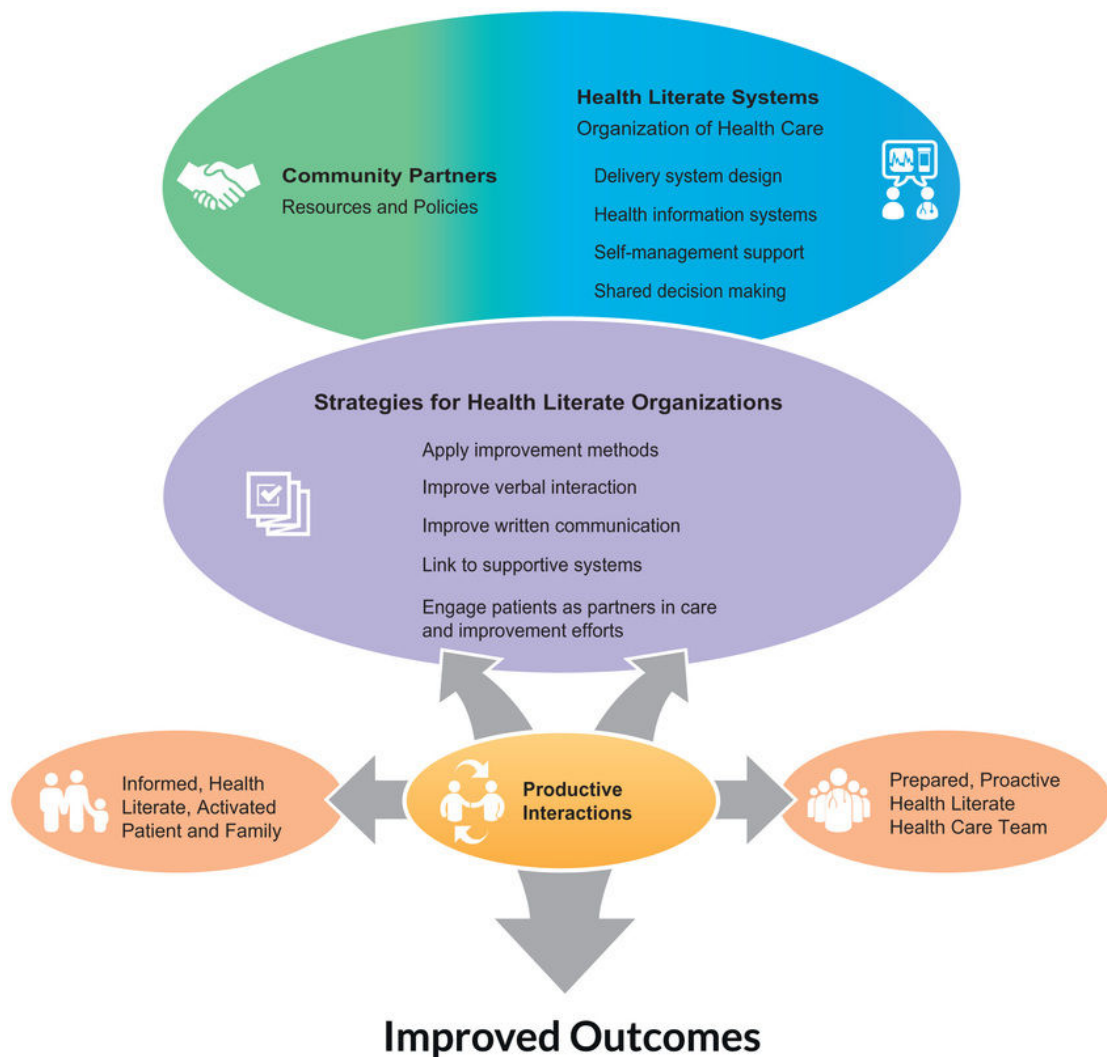

FIGURE 14.1 Health literate care model (From the Office of Disease Prevention and Health Promotion, <https://health.gov/communication/interactiveHLCM/index.html>, 2018.)

Results of the NAAL research indicate that among American adults, 30 million (14%) had below basic health literacy in English and 47 million (22%) had basic health literacy. This means that 77 million (36%) American adults possessed very rudimentary literacy skills that allowed them to read only short, simple printed and written materials (White, 2008).

LO 14.1 Health Literacy

Nurses have been providing educational information to patients since the late 1800s, but health literacy is a recent concept. Florence Nightingale's efforts incorporated the importance of patient education into the nursing profession. [Chapter 1](#) provides additional information on Nightingale.

Although discussion of Nightingale's work often focuses on her efforts to distinguish nursing as a profession and address the impact of sanitation on health, she advocated exploring all aspects of the patient. She thought that patients needed care that is “delicate and decent” and demonstrates “the power of giving real interests to the patient” ([Quixley, 1974](#)). Exploring patients' interests and abilities was an early acknowledgment that nurses must be aware of patients' ability to comprehend the health care information provided.

The realization that consumers need to be able to understand the medical information delivered by health care providers has gained recognition at many governmental levels. The *Healthy People 2020* publication describes a national movement that addresses the priorities of prevention and public health in the United States. Health literacy with its impact on this initiative is being recognized and has become a key component of the project ([Riegelman & Garr, 2011](#)).

As the health care community explores the concept of health literacy, many organizations recognize that before improvements can be made, operational definitions are needed. A global definition of health literacy is “the degree to which individuals have the capacity to obtain, process, and understand basic health information needed to make appropriate health decisions” ([Health Resources and Services Administration, 2017](#)).

In exploring communication patterns and techniques between health care providers and patients with low health literacy, Schwartzberget et al. (2007) defined health literacy as “an individual's ability to read and understand health information and use it to make appropriate health decisions. Low health literacy refers to the condition in which individuals are unable to comprehend health-related information or instructions and may fail to make appropriate decisions regarding their care” (p. 96). The results obtained in their study further explain that although low literacy and low health literacy are related terms, they are not interchangeable. Low health literacy is content-specific, meaning that the individual may not have difficulty reading and writing outside the health care arena. These patients may struggle to comprehend the complicated, unfamiliar terms and ideas found in health-related materials or instructions ([Schwartzberg, Cowett, VanGeest, et al., 2007](#)).

Interest in effective patient education is not a phenomenon unique to the United States. The Institute of Medicine (now National Academy of Medicine) Roundtable on Health Literacy held a workshop in 2012 focused on international health literacy. The workshop combined the strengths of the United States' research, Europe's multilingual and multinational experience, and developing countries' community-based programs ([Institute of Medicine, 2013](#)). Nurses should recognize that there are several definitions of the term *health literacy*.

LO 14.2 Role of Health Literacy in Nursing and Patient Education

Understanding that effective patient education is key to health promotion and wellness, nurses must be aware of the concept of health literacy and determine how it affects the care of every patient. Nurses take primary responsibility for patient education (Scheckel, Emery, & Nosek, 2010). Often, health care professionals assume that the explanations and instructions given to patients and families are readily understood. In reality, research has shown that these instructions are frequently misunderstood, sometimes resulting in serious errors (Cornett, 2009).

As part of the health care team, nurses have direct contact with patients and their families throughout the life span. Teaching that is not effective can have negative implications, as Squellati (2010) describes:

Health literacy is a significant concern for Americans. Understanding health information is vital in addressing issues of access, quality, and affordability. If nurses are not able to teach patients effectively about their conditions and treatments, outcomes will be adversely affected. Providing information in ways that are appropriate for the patient's health literacy level is a step toward decreasing health disparities and increasing patient compliance (p. 110).

Preventing disease, promoting health, providing treatment instructions, clarifying information, and teaching patients to cope with limitations are all components of patient education. In exploring disease prevention, consider the complexity of immunization information given to parents regarding their child. The volume of materials, including the rationale for giving vaccines and the potential side effects and risks, can be overwhelming even for parents with no literacy challenges (Fig. 14.2). Imagine the difficulty parents may have if they are unable to read or write or unable to understand the language or reading level in which the instructions are given.

FIGURE 14.2 Nurses teach parents about immunizations.
(Copyright [istock.com](https://www.istock.com).)

Health promotion activities such as smoking cessation and weight management and management of conditions such as diabetes, chronic renal failure, and heart failure are examples of areas affected by a gap between health care teaching and the patient's health literacy. For example, the new diabetic patient may be given extensive teaching regarding care but may not understand all of the information. If the patient is sent home with reading materials but has difficulty reading or seeing, a gap may exist.

Treatment instructions are another area in which nurses teach patients about some component of their health. Examples include preoperative instructions, those before a procedure, and those given on discharge from the hospital, urgent care, or emergency department. Misunderstanding instructions in any of these settings can be detrimental to the patient.

An example of a gap between the health care information provided and the health literacy of the caregiver is seen in this scenario:

A toddler was diagnosed with an inner-ear infection and prescribed an antibiotic. Her mother understands that her daughter should take the prescribed medication twice each day. After carefully studying the label on the bottle and deciding that it does not tell how to take the medicine, she fills a teaspoon and pours the antibiotic into her daughter's painful ear (Parker, Ratzan, & Lurie, 2003).

Although the child's mother was able to read, she did not understand that the medication was to be taken orally. If the health care provider

caring for this patient had written out the words *by mouth* rather than using the medical abbreviation *PO*, the situation could have been avoided. Most likely, the nurse, physician, and pharmacy staff had opportunities to review the prescription details, including the route of administration, with the toddler's mother. Having the mother verbally repeat instructions is another method of ensuring accurate comprehension. All health care providers have a responsibility to provide instructions that are consistent with the patient's health literacy.

Safe Practice Alert

Do not use abbreviations or medical terminology when providing patients with instructions.

According to the *Healthy People 2020* initiative, health information and the associated access issues have become more complicated. There are many considerations when determining whether an individual has proficient health literacy. The patient should be able to exhibit certain competencies ([DHHS, 2010a](#)):

- read and identify credible health information
- understand numbers in the context of the patient's health care
- make appointments
- fill out forms
- gather health records and ask appropriate questions of physicians
- advocate for appropriate care
- navigate complex insurance programs, Medicare or Medicaid, and other financial assistance programs
- use technology to access information and services

LO 14.3 Types of Patient Education

Patient education occurs in a wide array of settings, which can be categorized as formal and informal. Formal patient education may be delivered in a variety of settings, such as throughout the community in the form of media, in educational and group settings, or in a planned, goal-directed, one-on-one session with a patient in an outpatient or acute care setting. Formal education usually has goals set by the educator or, in the case of patient education, the nurse.

Informal education is usually learner or patient directed. This type of education may occur when a patient asks a question about a medication, treatment, or procedure. The health care information is considered informal because it is situation and patient specific. Some patient education sessions have formal and informal elements, because the nurse and patient may set goals together before the nurse formulates and implements the plan of care, and the patient is free to ask questions that may direct the session.

Patients are inundated with information from the Internet, television, radio, newspapers, and community programs. Nurses can help patients recognize reliable sources and accurate information. More information on helping patients evaluate sources of information is found in [Chapter 15](#).

QSEN Focus!

Nurses are responsible for evaluating sources of health care information and using high-quality electronic sources for patient education.

Many health care consumers begin receiving information as children through their primary education. Handwashing, proper dental care, and nutrition are examples of early instructions. The dangers and risks associated with smoking, drug or alcohol abuse, and drunk driving are taught throughout their secondary education. College students are provided with education intended to promote health and well-being. Health care education continues in adulthood in the form of medication commercials, nutritional food labels, and information obtained from Internet sites.

Teaching is imparting knowledge or giving instruction, whereas **learning** is acquiring knowledge or skills through instruction or experience. Teaching may be delivered in acute care, long-term care,

and outpatient settings. Examples are instructions given regarding a new prescription at a doctor's appointment, information about the need for dietary supplements in a long-term care setting, or postoperative or discharge instructions for the patient in a hospital or other acute care facility. An example of patient education provided for patients with diabetes is outlined in [Box 14.1](#).

Box 14.1

Patient Education and Health Literacy

Living With Diabetes: Sick Days

In one part of diabetic teaching, the nurse instructs the patient about what to do if flulike illness occurs:

- Continue taking diabetes pills or insulin.
- Make a plan with your physician ahead of time that might include:
 - Test blood glucose levels more often than normal and keep track of the results.
 - Drink extra (calorie-free) liquids, and try to eat normally. If unable to eat normally, eat an equivalent amount of carbohydrates.
 - Track weight daily. Losing weight without trying may be a sign of high blood glucose levels or be from other causes. Further evaluation is needed.
 - Check temperature every morning and evening. A fever may be a sign of infection.
- Call the health care provider or go to an emergency room if you:
 - Are too sick to eat normally or are unable to keep down food for more than 6 hours.
 - Are having vomiting or diarrhea for more than 6 hours.
 - Lose 5 pounds or more.
 - Have a temperature higher than 38.3°C (101°F) for 24 hours.
 - Have blood glucose levels lower than 60 mg/dL or that remain higher than 300 mg/dL.
 - Are having trouble breathing.
 - Feel sleepy or cannot think clearly.

Modified from the Centers for Disease Control and Prevention. (2015). Living with diabetes: Sick days. Retrieved from

<https://www.cdc.gov/diabetes/managing/sickdays.html>.

Consideration must be given to the patient's background, readiness to learn, and current condition before education can occur. A patient's ability to read, write, and comprehend healthcare materials enhances health literacy.

LO 14.4 Domains of Learning

To provide effective patient teaching, the nurse must be aware of the three domains, or types, of learning: cognitive, psychomotor, and affective (Bloom, 1956). Effective patient teaching requires knowledge about how the individual learns. **Cognitive domain** learning comprises knowledge and material that is remembered. Memorization and recall of information is needed for the learner to remember, understand, apply, analyze, evaluate, and create the new material.

Learners in the cognitive domain integrate new knowledge through first learning and then recalling the information. They then categorize and evaluate, making comparisons with previous knowledge that result in conclusions related to the new content (Bloom, 1956). Some examples of teaching methods in the cognitive domain include literature written at the appropriate reading level, demonstration, and use of examples. A patient who remembers the information taught during an education session, repeats that information, and is able to ask questions to further enhance knowledge gained is functioning in the cognitive domain.

The **psychomotor domain** incorporates physical movement and the use of motor skills in learning. Teaching the newly diagnosed patient with diabetes how to check blood glucose is an example of a psychomotor skill. Having the patient observe the nurse demonstrating the skill and then demonstrate it and receive feedback is an effective method of teaching learners in the psychomotor domain. When the patient has successfully demonstrated how to perform the task, psychomotor learning has occurred.

Bloom's (1956) third style of learning is the affective domain. **Affective domain** learning recognizes the emotional component of integrating new knowledge. Successful education in this domain takes into account the patient's feelings, values, motivations, and attitudes. Exploring these patient-specific attributes enhances the value of the learned information. A patient who readily receives the information taught, responds to the nurse with active participation, and values the importance of the teaching session is operating in the affective domain.

LO 14.5 Learning Styles

Understanding how individuals learn is important for nurses when considering the written or verbal information they are teaching. Although research has shown that most adults read at an eighth-grade level, 20% of the U.S. population reads at or below a fifth-grade level. Nurses can supplement materials that are written at a high reading level with photos, drawings, and explanations of terms that are difficult to understand.

In addition to being aware of learning domains and the materials used to teach patients, nurses must give consideration to the learning styles, strengths, and abilities of the individual. Tools have been developed to help health care workers evaluate the health literacy of their patients. One such tool is the VARK (*verbal, aural, read/write, kinesthetic*) assessment of learning styles of people who are having difficulty learning (VARK, 2018). The VARK areas are evaluated to educate individuals on the basis of their learning preferences.

The VARK developers have written other assessment aids that are available online. Some are designed to assess learning styles on the basis of language, age, and purpose of the evaluation. Some versions are directed at business, and others are specific to education and may provide valuable learner-specific information to assist the provider of health care information and the patient (VARK, 2018).

Individuals typically learn through more than one method. For example, a patient's VARK assessment may indicate learning through VAR or ARK. When the use of more than one style facilitates learning, the individual is considered a **multimodal learner**, meaning that the person does best when more than one teaching strategy is used or that the person is able to adapt to a variety of teaching strategies (Fig. 14.3) on the basis of what is being presented (VARK, 2018). Understanding how patients learn best makes collaborative learning plans most effective. It is good practice to provide multiple means of learning, because most individuals learn through more than one style and repetition enhances learning.

FIGURE 14.3 A nurse uses a variety of teaching strategies during diabetic teaching. (Copyright [istock.com](https://www.istock.com/).)

LO 14.6 Factors Affecting Health Literacy and Patient Teaching

Many factors affect patients' health literacy. The educational level of the learner and the instructional materials were discussed previously. Factors such as age, culture, language, environment, nature of the content, and current situation, including level of pain, medications, timing of instruction, and economic resources, also must be considered. [Box 14.2](#) addresses some diversity issues that should be considered in planning patient education. Adjustments to factors that are within the nurse's control, such as timing of instruction, are often necessary to achieve the maximum benefit of the nurse–patient interaction.

Box 14.2

Diversity Considerations

Life Span

- Patient education provided for children should be age-specific.
- Use pictures and simple words for young children.
- Use clear, simple explanations for school-age children.
- Before health care teaching sessions for adults, assess reading level, learning styles, and readiness to learn.

Culture and Religion

- Patient education may not be understood because of language, beliefs, and values.
- For patients who do not speak or understand the language of the nurse:
 - Use a professional nonfamily member as an interpreter. Family members should not be used as interpreters of specific medical information to maintain the patient's right to privacy and avoid possible misinterpretation of medical terminology.
 - Use photos, drawings, or video to enhance understanding.
- Different cultural and religious practices, beliefs, and values may interfere with certain medical treatments:

- Nurses who are culturally sensitive tailor education to align with cultural beliefs.
- A patient whose cultural beliefs and values are considered is more likely to accept and follow healthcare provider instructions.

Disability

- Patients with physical impairments may not be able to perform skills requiring psychomotor learning.
- Provide visual and auditory materials as needed.
- A caregiver or significant other may need to be involved in the patient education session.
- Patients with learning disabilities or cognitive alterations need individualized instruction geared to their special needs.
- Patients with vision loss may not be able to read regular printed material. Use other methods:
 - Verbal instructions
 - Demonstration
 - Large-print material
 - Braille or audio materials
- Patients with hearing loss may not be able to hear and understand verbal instructions. Use other methods:
 - Printed material
 - Demonstration
 - Recorded materials amplified through headsets
 - Interpretation:
 - Interpretation for the hearing impaired may be provided by a professional interpreter face-to-face with patients and families or by phone or video medical interpretation (VMI).
 - Access to interpretation or translation for deaf and limited English proficiency (LEP) patients is required by Title VI of the Civil Rights Act of 1964, which mandates equal rights for people regardless of race, color, or national origin.
 - Simulations, photos, drawings, or video to enhance understanding.

Age and Developmental Stage

The patient's age directly affects the instructional methods and materials used. Effective patient education involving a child requires the presence of a parent or caregiver, who is likely the target of teaching. Children should not be excluded from the learning session unless exclusion is deemed appropriate by the parent or caregiver; a presentation using an age-appropriate strategy may complement the instructions reviewed with the adult. The stages of development (see [Chapter 17](#)) should be explored as the foundation for the choice of educational materials. Learning theories as they relate to developmental stages are also discussed in [Chapter 17](#).

Adult learners tend to be self-motivated and able to participate in planning their health education. During a visit to an outpatient facility or inpatient hospital, an adult learner may learn independently, may have learning facilitated by the nurse, or may need a spouse or significant other for support, depending on the diagnosis and current condition of the patient. The pace of adult education sessions depends on the patient, the situation, and the difficulty of the content.

Teaching should be tailored when elderly patients are being educated. Older adults are one segment of the population vulnerable to low health literacy due to educational level or cognitive decline ([National Network of Libraries of Medicine, 2018](#)). Although each patient must be assessed individually, cognitive and sensory alterations often occur with aging, and the teaching materials should be adjusted accordingly.

Role

Exploration of the patient's roles is an important task that must be done before development of a patient education plan. For example, a 32-year-old single mother of five young children who has just undergone a hysterectomy may require a different perspective in her discharge instructions than that in the instructions for a 67-year-old woman living with her husband who recently retired after 35 years as a family practice physician. The first patient may have less support and less flexibility regarding rest, lifting limitations, and cost of prescriptions than the second. It is important not to stereotype and assign roles, but rather to develop a plan in collaboration with the individual. The patient's support system should be taken into consideration when the nurse plans patient education.

Environment

The location of patient education influences the outcome. The setting should be quiet, and the session should have minimal interruptions. Providing privacy is difficult in settings such as emergency

departments, outpatient surgery centers, and semiprivate inpatient rooms, but the nurse should make every effort to ensure confidentiality. Environmental considerations such as good lighting and the availability of resources should be explored to enhance the outcome of patient education.

Timing

The nurse should examine the patient's situation and comfort level before beginning teaching. For example, a postoperative patient who is rating pain at 7 of 10 will be much more receptive to learning after being medicated for pain. A patient who just received a diagnosis of metastatic cancer will learn and assimilate more information later in the day or perhaps the next day. Asking whether a patient would like a family member or caregiver to sit in on the session may affect the timing. The nurse should end the session if the patient shows signs of fatigue. Prioritizing the key points of patient education ensures that the most important aspects are taught at the beginning of a session.

Availability of Resources

Learning objectives should be determined collaboratively between the nurse and the patient to ensure that the availability of resources is congruent with the plan. For example, a patient with limited health care insurance and no prescription plan may not be able to obtain necessary medications or dressing supplies after discharge from the hospital. If a need for support services is identified, the nurse should contact the social services department, discharge planning personnel, or community agencies about assistance for the patient and family.

Evidence-Based Practice

Nurses play a key role in providing patients with accurate, unbiased, scientifically sound information. Individuals may not be able to judge the validity of advertisements or medical treatment claims they see in the media. One of the major sources of medication information obtained by patients in this age of technology is the Internet ([Karch, 2017](#)). Nurses need to be cognizant of this resource and ensure that patients are eliciting information from reliable sites and that they are able to understand and relate the information to their situation. Evidence-based practice (EBP) is used in patient education to help patients analyze evidence used to validate medical claims and information ([Schardt, 2011](#)).

EBP is important, along with attention to the patient's values and preferences when planning treatments that are required by expertise and practical wisdom. Patients may choose to have, or not to have, a recommended treatment (Montori, Britto, & Murad, 2013). Health literacy is woven into treatment plans because nurses must ensure that patients comprehend health care information before determining their preferences in making decisions. Patients trust nurses to share with them valid and legitimate information and resources (Box 14.3).

Box 14.3

Evidence-Based Practice and Informatics

Patient Involvement in Education

- Many patient safety advocates—including The [Joint Commission in National Patient Safety Goals \(2019\)](#) and [Cronenwett and colleagues in Quality and Safety Education for Nurses \(2007\)](#)—encourage the active involvement of patients and their families in patient-centered care.
- To promote involvement, nurses must ensure that patients understand the information relevant to their care.
- Nurses need to provide patients with easy-to-understand information and speak in a clear, distinct voice, using short sentences and understandable terminology.
- Multiple teaching methods should be used to meet the needs of all types of learners.
- Patient education sessions should be reassessed after two to three key points to ensure the patient is still engaged in learning and ready to assimilate more information.
- Information taught at previous sessions can be reviewed before proceeding with new key points.
- Nurses should access facility or organizational patient education materials if they exist; some health care systems use intranet-based resources for use in teaching sessions.
- Consideration should be given to the availability and accessibility of Internet resources to ensure patients are accessing reliable sources and are able to understand content; refer to section “Recognizing the Role of Technology” in this chapter.

QSEN Focus!

Nurses read original research, explore Internet resources and clinical practice guidelines to prepare patient education. By using evidence-based practice, nurses provide patients with the most up-to-date information available.

When exploring the concepts of health literacy and patient education, nurses must recognize the need to work collaboratively with health care professionals in other disciplines, such as physicians, social workers, dietitians, and occupational, speech, and physical therapists. [Riegelman and Garr \(2011\)](#) suggest a framework is needed to connect different health care professionals when planning and developing patient education. Engaging in interprofessional discussions and planning with the patient facilitate the most effective results.

LO 14.7 ♦ Assessment

Assessment of health literacy occurs with each patient encounter. Nurses observe patient behavior during interactions to determine if further assessment is needed. Certain patient behaviors may indicate inadequate health literacy, which has the potential to affect patient education. These behaviors are exhibited in the following examples:

- Information on forms is incomplete or inaccurate.
- Patient wants to take written documents home to discuss with family or asks health care provider to read information aloud, stating, “I left my glasses at home.”
- Patient misses appointments or comes to appointments at an unscheduled time.
- Patient does not follow through with laboratory tests, imaging tests, or referrals to specialists.
- Patient is noncompliant with medication and treatment regimens.
- Patient claims to be taking medication or following a treatment regimen, but laboratory or imaging tests do not show expected results.

1. What cues could have helped the primary care provider and nurse realize that S.L. and his wife were unable to read?

Knowledge or discovery of literacy limits in the assessment stage can aid the nurse in developing the education plan and decrease the potential for life-threatening outcomes. The [Agency for Healthcare Research and Quality \(2016\)](#) has several tools available for health literacy assessment. These tools can be used in different settings depending on the needs of the patient. [Box 14.4](#) provides examples of

questions to ask the patient. Limited literacy skills may result from a lack of educational opportunity (high school level or less education), learning disabilities, or cognitive declines in older adults. Patients' reading abilities may be below standard. Reading abilities are typically three to five grade levels below the last year of school completed. People with a high school diploma typically read at a seventh- or eighth-grade reading level ([National Network of Libraries of Medicine, 2018](#)).

Box 14.4

Health Assessment Questions

Patient Education Focus

- Who will be taking care of you? Who do we need to educate?
- What do you already know about your diagnosis or care of this condition?
- What is your preferred language?
- Do you have access to the Internet?
- What is the highest grade level you completed in school?
- Can you read the local newspaper? Do you like to read books? Magazines?
- What do you hope to learn from our teaching sessions?
- What information do you think is most important?
- Have you ever had instruction on this subject? (If so, ask for details.)
- How do you learn best? (If needed, give examples such as “by watching and doing” and “by reading.”)
- Do you have any difficulty with hearing or vision?
- Are you having pain or discomfort?

2. What could the office nurse have done differently during the initial visit with Mr. Lubic?

The patient's ability to learn or perform health-related care is essential. Low health literacy (i.e., basic or below basic) and cognitive impairments such as memory issues, impaired vision or hearing, or poor hand-eye coordination are factors to be considered in the development of the teaching plan. Special attention should be given to determining patients' learning styles; asking how they learned best or easily retained information in the past elicits valuable information. Determining the patient's physical, emotional, and cognitive readiness to learn is an essential component of the preeducation assessment.

Educational assessment includes designating the learner: patient, family, significant other, or caregiver. Infants, children, and individuals with developmental disabilities need to have an adult as the primary learner. Terminally ill patients and some elderly patients may view themselves as dependent on their caregivers, and they may not want to be involved in learning or may want to have their caregivers present during educational sessions.

In ensuring a comprehensive assessment of patient education and health literacy, the nurse should discuss the motivation and willingness of patients or caregivers to learn and review their previous experiences with health care learning. Helping the patient identify priorities in learning can determine how to proceed with development of the teaching plan. Adults must place value on the need for or purpose of learning ([Gulanick & Myers, 2017](#)).

LO 14.8 ♦ Nursing Diagnosis

On completion of assessment, a nursing diagnosis relevant to the educational needs of the patient or caregiver can be determined. International Classification for Nursing Practice (ICNP) nursing diagnoses specifically related to patient education include:

Lack of Knowledge (i.e., self-administration of insulin)

- **Supporting Data:** New-onset hyperglycemia, patient's verbalized fear of needles, blood glucose levels ranging from 210 to 305 mg/dL.

Ready to Learn (i.e., diabetes management)

- **Supporting Data:** Patient sitting in bed reading diabetes information and literature left on the bedside table yesterday by the nurse; patient asking questions about management of the blood glucose level.

Literacy Problem

- **Supporting Data:** Patient expressing a desire to learn but states the literature about how to obtain blood glucose levels is too hard to read, sets materials aside, and waits for a family member to read them.

LO 14.9 ♦ Planning

After working with the patient or caregiver to determine the appropriate nursing diagnoses, the next step is developing the patient education care plan (Table 14.1). Considering the patient's support system is an integral part of this step, because it may be necessary or helpful to have someone monitor progress. Collaboration with the patient, caregiver, and interprofessional health care team enhances the potential for a positive outcome (Box 14.5). The patient and caregiver, to the extent agreed to by the patient, should be directly involved in determining the goals of teaching. Determining the outcome statements early in this process directs the remainder of the plan.

TABLE 14.1
Care Planning

ICNP NURSING DIAGNOSIS WITH SUPPORTING DATA	NURSING OUTCOME CLASSIFICATION (NOC)	NURSING INTERVENTION CLASSIFICATION (NIC)
<p><i>Lack of Knowledge of Treatment Regimen</i> (i.e., self-administration of insulin)</p> <p>New-onset hyperglycemia</p> <p>Patient's verbalized fear of needles</p> <p>Blood glucose ranging from 210 to 305 mg/dL</p>	<p><i>Knowledge: Diabetes management</i></p> <p>Proper technique to draw up and administer insulin</p>	<p><i>Medication administration: subcutaneous</i></p> <p>Determine the patient's knowledge of medication and understanding of method of administration</p>

Box 14.5

Interprofessional Collaboration and Delegation

Multidisciplinary Patient Education

- Assessment and development of a patient teaching plan may not be delegated to unlicensed assistive personnel.
- Collaboration with the patient, caregiver, dietitian, pharmacist, case manager, and physician is imperative in creating and implementing an effective teaching plan.
- Social workers or discharge planners are able to assist with socioeconomic issues. (For example, the patient may not have insurance coverage for the supplies or medications needed; social workers or discharge planners are familiar with community resources, fee waivers, and other sources of assistance.) These individuals also coordinate and facilitate referrals to home care or other settings that are most appropriate for the patient's situation and educational needs.
- Physical, occupational, and speech therapists can collaborate with nurses to enhance a comprehensive teaching plan.

As health care educators, nurses should allow patients to identify what is most important to them. If a newly diagnosed diabetic patient is interested in learning techniques of care that will allow discharge to home rather than to an extended care facility, the patient is more likely to be receptive to learning about self-monitoring blood glucose levels. After the learning goals related to the issues the patient feels are a priority have been met, the patient may then be able to focus on health promotion and avoiding complications ([Box 14.6](#) and [Fig. 14.4](#)).

Box 14.6

Home Care Considerations

Patient Education in the Home

- The nurse is a guest in the patient's home when providing care or teaching in this setting (see [Fig. 14.4](#)).
- Visits by nurses and other staff in the home setting are less frequent than those in other settings.
- Insurance coverage available for staff visits, supplies, and equipment must be considered when developing the teaching plan in the home.
- To promote continuity, documentation of the teaching plan and progress toward goals must be readily available to all staff visiting the home care patient.

FIGURE 14.4 A nurse teaches a patient how to check pulse and blood pressure before taking medication. (Copyright [istock.com.](https://www.istock.com/))

QSEN Focus!

Patient education is coordinated by the nurse but involves other members of the interprofessional health care team. Teamwork and collaboration are demonstrated when the nurse recognizes and integrates the contributions of the primary care provider, therapists, dietitians, and social workers and respects the unique attributes each brings in helping the patient achieve health education goals.

The following are examples of goals or outcome statements:

- Patient will demonstrate the correct technique for administering insulin within 48 hours.
- Patient will verbalize the need to learn diabetes-related information within 24 hours.
- Patient will demonstrate how to obtain blood glucose levels before discharge.

Before developing the interventions to be used in the patient education plan, the nurse should again consider the health literacy of the patient or caregiver. Strategies of assessment were discussed earlier in this chapter, but it is important to understand that patients with low

health literacy may have difficulty with the following ([Health Resources and Services Administration, 2017](#)):

- filling out complex health forms
- locating providers and services
- sharing their medical history with providers
- seeking preventive health care
- knowing the connection between risky behaviors and health
- managing chronic health conditions
- understanding directions on medicine

LO 14.10 ♦ Implementation and Evaluation

In all patient education situations, having the patient repeat what has been taught, or perform a return demonstration, helps the nurse assess the level of learning that has taken place. *Healthy People 2020* reiterates the three As of health information identified in the National Action Plan to Improve Health Literacy, which states that health information must be accurate, accessible, and actionable (DHHS, 2010b).

Keeping these concepts in mind when implementing the teaching plan can guide the information, the approach, and the evaluation of progress. Accessibility needs to encompass getting the learning content to the learner and planning for the use of alternative methods of instruction for individuals with sensory limitations (e.g., use of Braille boards or magnified fonts for those with visual difficulties and amplified media with headphones for those with auditory issues). [Box 14.2](#) provides guidelines for patients with specific needs.

Nurses often advocate for patients when other members of the health care team have provided information that needs clarification. Making sure that patients understand instructions and terminology and seeking clarification from other providers when needed are part of the nurse's role as patient educator.

Environment

To facilitate learning, care should be taken to ensure physical comfort for the learner, whether in a group or individual session. In setting the stage for effective learning, it is important, for example, to schedule teaching sessions when pain medication has been administered but the patient is not too cognitively affected by the pharmacologic side effects of the medication. Attempting to minimize interruption in a quiet atmosphere of respect and trust is also important. Nurses may have different values or priorities from those of patients, and they must take care to provide a nonjudgmental environment.

Pace

Teaching sessions should focus on one idea at a time and should be kept short. Patients are likely to experience a sense of accomplishment when they are focusing on and mastering one task at a time. Because learners who are ill may be facing fatigue or decreased stamina and attention, lengthy sessions are less beneficial.

Data Integration

Patient education plans require steps to assist the learners with integrating the newly acquired information into their lives. When presenting health care materials, the nurse should use basic terminology that is easily understood by the learner and is consistent with the individual's health literacy level. Instructions should be presented in a clear, concise way at a learner-appropriate level. Information should be presented by starting with familiar concepts and progressing to the less familiar, complex, or abstract ideas.

A variety of teaching methods can be combined to match content with learning style. Examples include verbal instruction, media such as computer-assisted programs and digital media, demonstration and return demonstration, and written instructions. Providing patients with material written in their native language at the end of the session gives them the opportunity to review what they have learned, allowing effective integration of the information.

Repetition and Demonstration

Newly presented information or techniques should be reviewed at the end of the session, with adequate time allowed for questions and demonstration. Having the patient practice a task is extremely beneficial because it enables the nurse to provide immediate feedback, correct errors, and ensure that the patient comprehended the material as it was intended. In some instances, the patient may observe by computer or other format a skill being performed in a simulation scenario until the patient is able to perform the skill. These sessions give the nurse ample opportunity to provide praise and positive feedback to the learner. In all patient education situations, having the patient repeat the information or a return demonstration by the patient helps the nurse assess the level of learning that has taken place.

3. What alternative methods could the nurse and other members of the health care team have used to convey the essential information to the family without relying on written patient discharge instructions?

Evaluation

Ongoing evaluation of patient education occurs by each member of the health care team who provides teaching according to the patient's teaching plan. Having the learner repeat what has been learned can help the nurse evaluate the teaching plan and adjust the plan for future patient education sessions. Future sessions should review what was learned previously and continue to add to what has been taught. Health care team members can view documentation on the electronic health record (EHR) before beginning an education session to determine the patient's progress in meeting educational goals. The teaching care plan is adjusted after each session to enhance future learning.

Ethical, Legal, and Professional Practice

Nurses have an ethical responsibility as a professional to provide patient education at the level of literacy for each individual patient and family. Ensuring that the patient's medical record clearly identifies the patient education conducted is also imperative in today's litigious society.

Documentation

Teaching sessions—including topics and skills reviewed, methods and materials used, and patient progress—must be documented (Fig. 14.5). EHRs document the progress of patient teaching with detailed descriptions of the goals, what was taught, how it was taught, and the patient's reaction to the teaching. In many settings, the learner may be instructed by different individuals in a discipline (e.g., nurses on different shifts) or by interprofessional teams. All members of the teaching team need accurate, up-to-date information regarding the patient's progress toward achieving patient education goals.

Unresolved Education

FIGURE 14.5 An electronic teaching plan shows documentation of unresolved education, learners and their response to the teaching, methods used, and completed instruction. (Courtesy Epic Systems Corporation, Verona, WI, 2012.)

Some agencies have multiple-copy forms that are signed by the nurse and patient to indicate the teaching that has taken place. It is important for the nurse to document what was taught, to whom, by which method, and how the patient responded. Paper or electronic copies of any information necessary for use at home should be made available to the patient.

- Describe what to include in the care plan that would better meet the needs of teaching S.L.

LO 14.11 Recognizing the Role of Technology

The U.S. Census Bureau first began asking citizens about computer ownership and use in 1984, with the most recent report being published in 2011 ([U.S. Census Bureau, 2013](#)). Household ownership of at least one computer increased dramatically from 8.2% in 1984 to 75.6% in 2011 and has likely continued to increase ([U.S. Census Bureau, 2013](#)). Variables such as age, race and ethnicity, gender, household income, region of residence, employment status, and educational attainment in relation to computer ownership and use also have been explored. For example, when the last report was published, persons 18 to 34 years of age stated they lived in a household with a computer and Internet access 82.0% of the time. Individuals over 65 years of age reported living in a household with a computer 61.8% of the time, which is significantly lower than the younger population; however, the use of technology across all age ranges has increased ([U.S. Census Bureau, 2013](#)).

Access to computer resources can be beneficial in that the flexibility and accessibility to health care information has increased. Although there are benefits to this technological advancement, the potential risks for patients obtaining information from unreliable sources and then, for example, altering the medications they take or treatments they try may be harmful. Whether benefit or risk, nurses need to take into consideration that the Internet is an accessible resource for patients so materials should be developed using reliable websites and ensuring the information is provided or revised to meet the literacy needs of the individual.

Summary of Learning Outcomes

LO 14.1 *Define health literacy*: Health literacy refers to a patient's ability to seek and understand information related to health care, disease prevention, and treatment of illness. Patients are unique in their ability to comprehend health care information. Health literacy directly affects the patient's ability to comprehend and integrate knowledge.

LO 14.2 *Explain the role of health literacy in nursing and patient education*: Knowledge of a patient's health literacy level assists nurses in communicating instructions and educational information in an appropriate manner to ensure that the patient understands.

LO 14.3 *Recognize the types of patient education and the settings in which patient education occurs*: Patients are taught in formal settings, in which information is delivered, or in planned one-on-one sessions, and in informal settings, in which information is situation and patient specific.

LO 14.4 *Differentiate among the three domains of learning*: There are three domains of learning: cognitive, psychomotor, and affective. When developing effective teaching plans, the nurse must consider *how* the individual learns.

LO 14.5 *Explain how learning styles affect patient teaching*: Patient education should be conducted in the learning style preferred by the individual (i.e., verbal, aural, read/write, or kinesthetic or a combination of modes) and tailored to the patient's needs.

LO 14.6 *Describe factors affecting health literacy and patient education:* Health literacy and patient education are affected by numerous factors, including cultural background, socioeconomic level, age or developmental stage, role, environment, and timing.

LO 14.7 *Carry out an assessment of the patient's health literacy and education needs:* An assessment must be done before developing a patient teaching plan and should take into consideration the learner and the learning level, educational needs, and previous experiences of the learner.

LO 14.8 *Identify nursing diagnoses appropriate for use with patient education:* Examples of nursing diagnoses appropriate for patients with learning needs are *Lack of Knowledge, Ready to Learn, and Literacy Problem*.

LO 14.9 *Determine goals and outcome criteria for patient education:* Goals are based on particular learning needs and established nursing diagnoses.

LO 14.10 *Implement teaching plans and evaluate their effectiveness:* The nurse maximizes implementation of teaching plans by choosing the best environment, pacing the sessions according to the patient's condition, and providing information that is accurate, accessible, and actionable. The nurse should ask the learner to repeat or perform what has been taught to evaluate what has been learned. The patient education session should be documented in the medical record.

LO 14.11 *Recognize the role of technology in accessibility of health care information:* Technology, including the Internet, is a rapidly expanding and vast resource

for patients regarding most aspects of health care. The nurse should be cognizant of the benefits and risks of patients seeking information online.

Review Questions

1. The nurse is caring for a 6-year-old patient in the emergency department who just had a full left leg cast placed for a fracture. As the nurse is reviewing the discharge instructions with the patient's mother, she states, "You don't have to go over those—I'll read them at home." What should the nurse do?
 - a. Contact the physician immediately.
 - b. Consider the possibility of health literacy limitations and assess further.
 - c. Stop the teaching, because the mother obviously has taken care of casts before.
 - d. Explain to the mother that reading the instructions with her is required.

2. A 58-year-old man is admitted for a small-bowel obstruction late Saturday night. The nurse obtains admitting orders, which include the need to place a nasogastric (NG) tube to low intermittent suction. During the assessment, the nurse determines that the patient does not speak English. Which action(s) should the nurse do before placing the NG tube?
 - a. Take two additional staff members into the room when placing the tube so the patient can be restrained if needed.
 - b. Request an interpreter per facility protocol.
 - c. Do not place the NG tube because the physician would not want to frighten the patient.
 - d. Document the inability to place the NG tube due to lack of ability to communicate.

3. Which nursing diagnoses are used in developing a patient teaching plan? (*Select all that apply.*)
 - a. Moral Distress
 - b. Ready to Learn
 - c. Difficulty Coping
 - d. Literacy Problem
 - e. Anxiety
4. Which nursing diagnosis is appropriate if a patient expresses an interest in learning?
 - a. Ready to Learn
 - b. Lack of Knowledge
 - c. Effective Information Processing
 - d. Health-Seeking Behaviors
5. A 61-year-old man is undergoing an emergency cardiac catheterization when the nurse gives his wife a packet of registration paperwork and asks her to complete the forms. Which observed actions may indicate a health literacy issue? (*Select all that apply.*)
 - a. Putting on glasses before beginning the paperwork.
 - b. Asking someone in the waiting area to read the forms to her “because I need to get new glasses—these just don't work.”
 - c. Waiting until her daughter arrives to begin the paperwork so that her daughter can complete the forms.
 - d. Setting the clipboard aside and staring tearfully out the window.
 - e. Returning the forms only partially filled out, with missing or inaccurate information.

6. Teaching a patient to use an incentive spirometer by demonstration, with a return demonstration by the patient is an example of teaching based on which domain of learning?
 - a. Psychomotor
 - b. Affective
 - c. Psychosocial
 - d. Cognitive

7. The nurse is providing home care to a 62-year-old woman who was recently diagnosed with insulin-dependent diabetes mellitus. What is the most important reason for the nurse to document the teaching session?
 - a. The patient's insurance company requires documentation.
 - b. The nurse's employer requires documentation of home care sessions.
 - c. Other members of the health care team need to know the patient's progress.
 - d. Insulin is a potentially dangerous medication and needs to be documented.

8. Written instructions showing pictures of the steps necessary to test blood glucose, along with demonstration and a return demonstration of the steps, would most benefit which learners?
 - a. Affective
 - b. VARK
 - c. Psychomotor
 - d. Cognitive

9. The nurse is providing care to an 88-year-old male patient who just returned from the recovery room after a right hip replacement. The nurse plans to teach the patient prevention techniques for deep vein thrombosis. What is the best time to provide teaching?
- a. Do it right before the patient's next intravenous pain medication.
 - b. Wait until tomorrow morning because he is in too much pain today.
 - c. Leave written materials on his over-the-bed tray that he can read at his convenience.
 - d. Wait until 10 to 15 minutes after his next intravenous pain medication
10. Which is true about patient teaching sessions?
- a. Present all of the information so the patient can learn all that is needed.
 - b. Present the patient with one idea at a time.
 - c. Ensure the presence of a family member at each session.
 - d. End with a written quiz to ensure understanding of the information.

CHAPTER 15

Nursing Informatics

LEARNING OUTCOMES

Comprehension of this chapter's content will provide students with the ability to:

- LO 15.1 Define nursing informatics.
- LO 15.2 Discuss the uses of technology in health care.
- LO 15.3 Summarize the benefits of informatics.
- LO 15.4 Compare competency levels of nursing informatics.
- LO 15.5 Explain the importance of using standardized terminologies in electronic health records.
- LO 15.6 Implement the use of information technology in obtaining health information for consumers and in educating nurses.
- LO 15.7 Summarize potential ethical issues related to the use of health care information technology.
- LO 15.8 Outline future directions of informatics in nursing.

Case Study

The nurse is caring for Donna Henderson (D. H.), a patient with diabetes on an inpatient medical unit. The nurse enters D. H.'s admission history and nursing assessment into the bedside computer, checks the admission laboratory test results, and reads the patient's current orders entered by the primary care provider. The nurse plans D. H.'s care for the day on the basis of the information in the electronic health record.

D. H. tells the nurse that a friend mentioned a great new product that will allow her to discontinue insulin. The patient looked it up on the Internet and tells the nurse, "I want to stop taking insulin and try the new product."

Refer back to this case study to answer the critical-thinking questions throughout the chapter.

There is growing recognition of the importance of informatics in health care. Nursing represents a large percentage of the workforce in U.S. health care, and is a profession that is critical to successful widespread adoption of health care information technology (IT). If nursing can advocate, adopt, and integrate IT initiatives in practice, the positive impact will be felt beyond the practice of nursing. As the U.S. health care system considers reform, it is important that nurses are able to use the information and communication technologies that address issues of quality, cost-effectiveness, and outcomes of care.

LO 15.1 Definition of Informatics

Informatics is a broad academic field encompassing artificial intelligence, cognitive science, computer science, information science, and social science. *Medical informatics* refers to informatics related to health care and describes a distinct specialty in the discipline of medicine. It deals with the resources, devices, and methods required for the acquisition, storage, retrieval, and use of information in health and biomedicine. In addition to computers, informatics tools in health care include clinical guidelines, formal medical terminologies, and information and communication systems.

Nursing informatics is a specialty area of informatics that addresses the use of health information systems to support nursing practice. The [American Nurses Association \(ANA, 2015\)](#) states that the specialty of nursing informatics integrates nursing computer and information science for the management and communication of data, information, knowledge, and wisdom.

Data Collection

As a nurse assesses a patient, data are collected and organized as a source of information. The computerization of nursing practice data enables capture, storage, retrieval, organization, processing, and analysis of information. The information can be used to make a diagnosis, plan for care, provide nursing decision support, enhance documentation, and identify nursing care trends and costs. Systems that support data collection at the point of care can directly enhance patient care by reducing the potential for errors and supporting improved assessment and data communication. Computers, tablets, or pocket devices used at the bedside for documentation are examples of point-of-care technology. Patient data collected by a nurse and recorded electronically are immediately available to all members of the health care team.

Safe Practice Alert

Nurses must ensure the accuracy of recorded data. Documentation should occur on a timely basis. Bedside and mobile computers enable real-time charting.

Data, Information, Knowledge, and Wisdom

Data are facts, observations, and measurements that can be used as a basis for reasoning, discussion, or calculation, but until they are organized and processed, data are meaningless. *Information* is organized and processed data that can be communicated and are meaningful and useful to the recipient. *Knowledge* is organized and processed information that can be applied to problem solving and decision making. The transformation of patient data to clinical information becomes nursing knowledge. *Wisdom* addresses the use of knowledge and experience to manage and solve problems. Wisdom is the appropriate application of knowledge. At the wisdom level, a nurse uses critical thinking to interpret and evaluate nursing knowledge. At each level of processing, some type of knowledge is produced. Fig. 15.1 shows this progression.

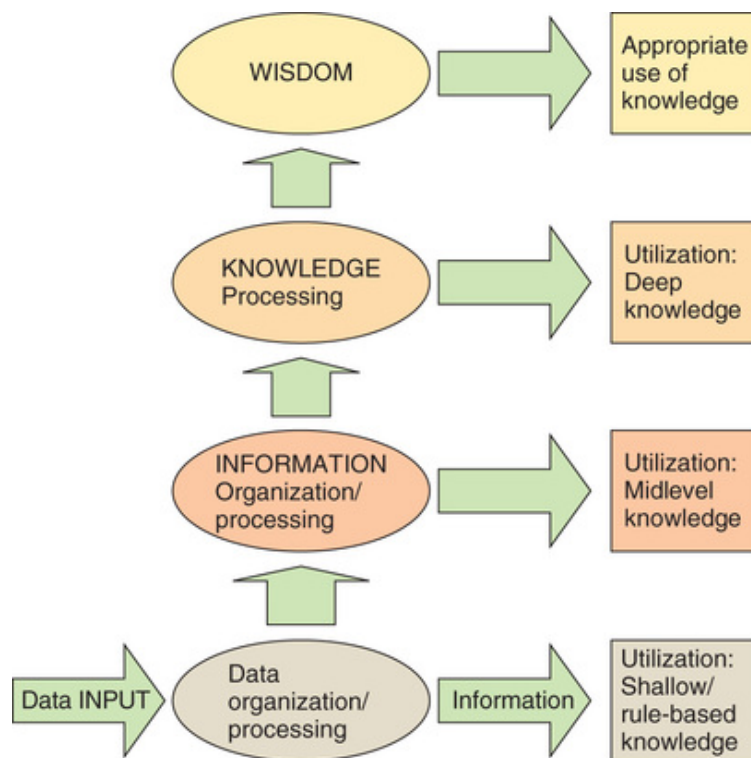

FIGURE 15.1 Data are the foundation of information, knowledge, and wisdom. (Courtesy Margaret Ross Kraft, Maywood, IL.)

1. How is the nurse caring for D.H. using nursing informatics?

LO 15.2 Technology in the Information Age

Nurses working surrounded by computers and mobile IT must develop skills in the use of all available technology. At the same time, it is important to recognize that the rapid advancement of IT means that the technology in use today may be entirely different tomorrow. Some facilities have computer access at every bedside, and others have mobile computers, sometimes called *workstations on wheels* (WOWs), that can be taken to each bedside (Fig. 15.2). Cell phones have cameras, global positioning systems, and Internet connections. Pagers, iPods, fax machines, tablet computers, and personal digital assistants (PDAs) are being used in health care for communication, reference, and documentation. Nurses using technology as part of patient care need to work within facility policy and Health Insurance Portability and Accountability Act (HIPAA) guidelines as outlined in [Chapter 11](#).

FIGURE 15.2 Mobile computer station. (Copyright © Mosby's Clinical Skills: Essentials Collection)

Many mobile devices include handwriting recognition software, some support voice recognition, and some have an internal cell phone and modem to link with other computers or networks. The technology supports bedside charting and remote charting. Nurses may use a portable device such as a smartphone or tablet computer to access reference materials, including medical information and vast amounts of drug information. Some facilities issue these devices to staff ([Box 15.1](#)).

Box 15.1

Evidence-Based Practice and Informatics

Use of Mobile Technology

- The 2010 Institute of Medicine (now National Academy of Medicine) report, *The Future of Nursing: Leading Change, Advancing Health*, emphasizes that nurses use technology resources that “require skills in analysis and synthesis to improve the quality and effectiveness of care” (IOM, 2010).
- Rapid advancements have occurred in the use of mobile technology to assist patients to improve their health. Telehealth is a broad umbrella that includes **connected health** tools that enable remote patient monitoring, patient education, lifestyle management, and biometric monitoring (HIMSS, 2016). Some of these applications involve wearable technology, while others operate on a mobile device. Nurses need to be able to advise their patients on how to best utilize these connected health applications to promote wellness and manage health problems.
- The most obvious advantage of mobile technology is prevention of medication errors. As the final providers in the administration process, nurses are in a position to prevent a medication error. Mobile technology provides nursing students and nurses with instant access to safe dose, compatibility, and pharmacokinetic information that is essential for safe medication administration (Yoost, 2011). The prevalence of mobile devices such as PDAs, tablets, and smartphones has led to the rise in applications, or apps, targeted to health care professionals (Ventola, 2014). Mobile computing has become an integral part of larger health care information systems and allows for monitoring, documenting, referencing, and communicating at the point-of-care.

Robots in operating rooms facilitate less invasive surgical procedures. Robots in pharmacies support safer medication selection.

Information systems have moved from strict alphanumeric data to multimedia information that can include graphics and sound. X-rays are in digital form.

Telehealth, or **telemedicine**, is the use of the Internet to link medical experts with other clinicians, allowing remote consultations with clear video images and high-fidelity links. Telehealth nursing, sometimes known as **telenursing**, is the transmission by a nurse of electronic data,

images, or audio from a patient's bedside or home to other health providers for the purpose of providing care and improving outcomes. Patients may have telehealth hardware in their homes to provide in-home monitoring and direct reporting to their health care providers (Fig. 15.3). The use of telemonitoring offers the opportunity to reduce the cost of health care while improving outcomes and patient satisfaction.

FIGURE 15.3 Telehealth can be used for in-home monitoring of patients. (Copyright [Thinkstock.com](https://www.thinkstock.com/).)

LO 15.3 Benefits of Informatics

In health care, treatment decisions are based on information derived from data. If data are faulty or incomplete, the quality of the derived information may be poor and decisions may be inappropriate and possibly harmful. Health care depends on information. Nursing is an information-intensive profession, and nurses must be able to work in data-rich environments. The actions nurses take depend on the information and knowledge available. The ability to quickly review laboratory results or review a complete medication profile can help the nurse choose appropriate interventions. Long before the development of computers and their widespread use in health care, Florence Nightingale became the first nurse informaticist. She thought that accurate data must be used for nursing decisions (Saba & McCormick, 2015). She used data and statistics to address the health care issues encountered in the Crimean War.

Use of health care IT has improved organization, communication, and decision making; reduced duplicate orders, charting time, and paperwork; made medication administration safer; and enhanced information access and administrative functions. Current initiatives in health care IT are focused on admission systems that capture demographic patient data and bed availability; the electronic health record, which moves the traditional paper patient chart online; computerized provider order entry; bar-code medication administration (BCMA); and e-prescribing, telehealth, personal health records, and radiofrequency identification (RFID).

Safe Practice Alert

Technology at the point of care can provide the right data on the right patient at the right time.

Patient Safety

IT can be used to increase patient safety. Errors are analyzed to develop strategies for prevention. Diagnostic test results are available sooner to support treatment decisions and avoid redundancy in orders. When technology such as a **bar-code medication administration (BCMA)** system is used as part of the process of medication administration, fewer errors are made. After signing into the system or scanning his or her identification (ID) badge, the nurse electronically scans the bar

codes of the patient ID, the electronic medication administration record (eMAR) and the drug to ensure the right patient is getting the right drug and dose at the right time (Fig. 15.4). An alert signals a potential error, and it is the nurse's responsibility to verify all information before administration.

FIGURE 15.4 Bar-code medication administration helps ensure that the right patient receives the right medication and dose at the right time. (Copyright Shutterstock.com.)

Computerized **decision support systems (DSSs)**, sometimes called *clinical decision support systems*, include safe practice alerts and reminders that improve the quality of care. Some DSSs assist in determining a correct diagnosis and choosing an appropriate medication. Access to needed information at the point of care supports evidence-based practice initiatives.

Computerized provider order entry (CPOE) allows orders to be directly communicated to the appropriate department—diet orders to dietary, medication orders to the pharmacy, laboratory orders to the laboratory. Elimination of an intermediary for order transcription decreases the potential for errors related to the ambiguity of handwritten orders and allows quicker responses by appropriate departments. Legibility and availability of computerized documentation improve provider communication. The Agency for Healthcare Research and Quality (AHRQ) recommends CPOE as one of the safe practices for better health care. CPOE systems ensure legible orders and have the potential to reduce ordering and transcribing errors. Disadvantages of CPOE include workflow issues, provider resistance to new technology, and overdependence on technology (AHRQ, 2017).

2. Is it important for the nurse to share the conversation that occurred with D.H. about the new diabetic treatment with the primary care provider? If so, what would be the process for sharing this information?

Safe Practice Alert

Medication administration requires the nurse to perform three checks — patient allergies, the order, and drug expiration — and then check the six rights: right patient, right medication, right dose, right time, right route, and right documentation.

Computerized clinical decision support systems (CDSSs) are usually paired with CPOE. When used with a CPOE system, the CDSS suggests dosages, frequencies, and routes of administration for drugs; cross-checks for drug allergies and drug–drug interactions; and may suggest laboratory tests, depending on the drugs ordered ([AHRQ, 2017](#)).

Record Management

Implementation of computerized or electronic medical records makes patient records readily available through remote access to multiple providers at the same time. This availability of patient information supports efficient delivery of effective care. The **electronic medical record (EMR)**, which is the documentation of a single episode of care (i.e., outpatient visit or inpatient stay), becomes a part of the **electronic health record (EHR)**, which is a longitudinal record of care. EHRs are becoming widely used for individual health care encounters and for maintaining patients' health records over long periods. As EHRs become fully implemented, they include provider order entries, progress notes for all disciplines, computerized medication profiles, access to diagnostic test results on a timely basis, DSSs, and online clinical reminders and alerts. Because nurses have access to drug formularies and the National Library of Medicine, the latest literature on a specific medical problem is readily available.

As care records are aggregated in a data storage system, the patient data can be searched for cases, trends, and outcomes that can be analyzed to determine the best evidence for practice. The ability to quickly review a patient's longitudinal data at the point of care supports the improved management of each patient. Being able to see blood pressure documented over time enables the nurse to assess the effect of an ordered medication. The longitudinal data allow the nurse to see trends in responses to specific interventions and patterns of vital signs and laboratory results. [Chapter 10](#) provides a complete discussion of the EHR.

Another advantage of the EHR is that work lists are created on the basis of the information in the database. Nursing measures can be organized according to the time they are due or the type of task ([Fig. 15.5](#)). Use of work lists helps ensure important patient care and medication administration are carried out at the appropriate times.

Work List Tasks - Last Refresh: 1948

Current Shift: 08/17/19 0701-1501 Start Date: 8/17/2019 Overdue

3. How can the nurse use the information found in D.H.'s EHR to manage her nursing care?

Research Access

The goal of research is knowledge. The computerization and storage of health care data provide a source of information that contributes to the knowledge base of nursing and that of other health care professions. Computer applications are available for quantitative and qualitative research designs. Data management programs can analyze data to identify trends and patterns, allowing meaningful organization of information. Comparisons of nursing care data at the nurse–patient level can initiate comparisons across patient populations, and findings can support evidence-based nursing, evidence-based staffing, and specific billing for nursing services (Welton & Sermeus, 2010). Analysis and comparison of electronically captured health data identifies evidence to support nursing practice. For example, analysis of nursing interventions necessary for care delivery on a particular unit can produce a staffing pattern based on the needs of patients.

Networking

The growth of IT has created many new avenues for connecting with friends, family, and other professionals. The shared global computing network of the **Internet** provides connections with many kinds of resources that can be useful in the delivery of nursing care. Electronic access to libraries is available. E-mail and texting have become common means of communication. A **listserv** is a computer program that automatically sends messages to multiple e-mail addresses on a mailing list. Listservs can be used in health care to connect groups of patients with common problems or to send updated information to large groups.

Social media include online technologies such as Facebook, Twitter, and LinkedIn that allow people to communicate easily via the Internet to share information and resources. These technologies enable a potentially massive community of participants to collaborate, providing a mechanism for tapping into collective power in ways previously unachievable. Nurses should always follow confidentiality and HIPAA guidelines as outlined in **Chapter 11** when using social media. A video, *Social Media Guidelines for Nurses*, is available on the National Council of State Boards of Nursing website at <https://www.ncsbn.org/347.htm>.

A **blog** is a social medium that is usually maintained by an individual and has regular entries of commentary, descriptions of events, or other material such as graphics or videos. Most blogs are interactive, allowing visitors to leave comments and message each other. Many blogs focus on health care issues.

LO 15.4 Nursing Informatics Skills and Roles

According to the [ANA \(2015\)](#), nurses will work in various roles throughout their career. Regardless of the role or specialty, all current and future nurses need competency and skill in informatics.

Descriptions of nursing informatics competencies often focus on levels that include beginner, experienced, specialist, and innovator ([Staggers, Gassert, & Curran, 2002](#)). All levels identify specific knowledge and skills involved in using IT to enter, retrieve, and manipulate data to produce information for nursing practice and contribute to nursing knowledge ([Table 15.1](#)).

TABLE 15.1
Competency Level and Nursing Informatics Skills

COMPETENCY LEVEL	NURSING INFORMATICS SKILLS
Beginner	<ul style="list-style-type: none"> • Demonstrates fundamental skills in information management and computer technology • Identifies and collects relevant data • Possesses keyboarding skills • Documents in the electronic health record (EHR) • Looks up medications and other health information on reputable Internet reference sites
Experienced	<ul style="list-style-type: none"> • Understands data relationships and makes judgments based on trends and patterns in data • Demonstrates skill in information management and the use of computer technology • Suggests areas for Internet technology system improvement. • Relates data posted by others to the nursing assessment, basing the nursing process and clinical decisions on the data, and devising better ways of using data from the EHR
Specialist	<ul style="list-style-type: none"> • Integrates and applies information science, computer science, and nursing science • Applies skills in critical thinking, data management, processing, and system development • Conducts research based on information trends or patient data • Devises applications for computer technology in nursing • Develops new software to enhance nursing care
Innovator	<ul style="list-style-type: none"> • Conducts research and generates theory • Develops solutions and understands the interdependence of systems, disciplines, and outcomes

From Staggers, N., Gassert, C., & Curran, C. (2002). A Delphi study to determine competencies for nurses at four levels of practice. *Nursing Research*, 51(6), 383-390.

4. At what skill level of informatics competency is the nurse functioning? Give examples of the level from the case study.

QSEN Focus!

Nurses need to be proficient in navigating the EHR—documenting and planning patient care in an EHR—and diligent in seeking lifelong learning of information technology skills.

One classification system for nursing informatics competencies uses technical, utility, and leadership categories. Technical competencies pertain to the use of computers and other technological equipment and the use of a variety of software programs for word processing, spreadsheet and database development, presentation, referencing, and e-mail. Utility competencies address critical thinking and evidence-based practice applications. Nurses who have a utility competency recognize the relevance of nursing data for improving practice and can access multiple information sources for gathering evidence for clinical decision making.

Leadership competencies address the ethical and management issues related to using IT in nursing practice, education, research, and administration. Using informatics is a core competency required of all health care professions, but many nurses lack the skills they need as professionals to integrate IT seamlessly into their practice.

Nursing informatics specialists are experts who assume a variety of roles, including training others and supervising the use of information systems, designing systems particularly for use by nurses, and using data for establishing best-practice guidelines. Goals are to improve patient care and safety and establish best-care practices. After meeting the educational and experience requirements, the nurse can receive certification in nursing informatics from the Health Care Information and Management Systems Society (HIMSS) and through the American Nurses Credentialing Center (ANCC).

QSEN Focus!

Nurses must be involved in the design, selection, implementation, and evaluation of information technologies to support patient care.

Basic competencies include computer and information literacy. **Computer literacy** is knowledge of computers and the ability to use them efficiently. Computers are everywhere, and their applications continue to grow at an astounding rate. As health care becomes increasingly dependent on technology, the value of a nurse may be partly measured in terms of technological competency. A computer-literate nurse is able to easily learn and use new computer programs with minimal assistance. **Information literacy** is the ability to recognize when information is needed and how it is produced and the ability to locate, evaluate, and effectively use the needed information to create new knowledge ([American Library Association, 2016](#)). As the amount of available information increases exponentially, individuals must acquire the skills to select, evaluate, and use needed information.

The [Technology Informatics Guiding Education Reform \(TIGER\) initiative \(2018\)](#) identified a set of skills needed by all nurses practicing in the twenty-first century. The TIGER Vision Pillars include management and leadership, education, communication and collaboration, informatics design, and IT policy and culture. This skill set includes informatics competencies that range from basic computer skills to advanced-level IT and literacy competencies and expertise. TIGER's vision for the future of nursing addresses informatics and emerging technologies to provide safer, patient-centered care by using evidence and technology in practice, education, and research.

As nurses progress through levels of competency in the use of IT, many informatics roles are possible. Software capability expands as rapidly as IT hardware, and nurses are very involved in information system implementation. They may function as database managers and data analysts. Nurses are involved in the design and development of systems that offer the ability to document each element of the nursing process—assessment, diagnosis, planning, implementation, and evaluation—in an electronic format. Nurses are often responsible for informatics and health IT education.

LO 15.5 Standardized Terminologies

A **standardized nursing terminology** is a structured vocabulary that provides a common means of communication among nurses. A standardized language ensures that when a nurse talks about a specific patient problem, another nurse fully understands the problem. An example is the choice among *pressure injury*, *pressure ulcer*, *decubitus ulcer*, and *bedsore*. Do all nurses in all settings have a shared understanding of these labels for a patient problem?

Implementation of electronic records increases the necessity for standardized terminologies for documentation, because computers cannot make the association between different expressions meaning the same thing. The use of standardized terminologies promotes consistent documentation and allows the description and comparison of nursing care across a variety of settings, facilitating measurement of the impact of nursing interventions on patient outcomes (Lunney, Delaney, Duffy, et al., 2005).

The **Nursing Minimum Data Set (NMDS)** represents the first attempt to standardize the collection of essential nursing data. These core data, used on a regular basis by most nurses in the delivery of care across settings, provide accurate descriptions of the nursing diagnoses, nursing care, outcomes of care, and nursing resources used. Collected on an ongoing basis, the NMDS enables nurses to compare data across populations, settings, geographic areas, and time (Werley & Lang, 1988).

Implementation of a standardized nursing terminology has made a significant impact on patient outcomes. McCormick, et al. (2015) described how standardized terminology in nursing can be achieved through comparable, sharable, quality data based on evidence. There are specific standardized nursing terminologies and multidisciplinary terminologies such as SNOMED CT: Systematic Nomenclature of Medicine Clinical Terms that support nursing practice. SNOMED CT is a coding system, controlled vocabulary, classification system, and thesaurus, designed to capture information about a patient's history, illnesses, treatment, and outcomes. The use of a standardized nursing terminology provides visibility to the nursing profession and documents the value of professional nursing.

A patient's EHR is based on information in the NMDS. The nursing diagnoses, interventions, and outcomes use standardized nursing terminology. Standardized nursing diagnoses taxonomies are also available from the International Council of Nurses' (ICN) International Classification for Nursing Practice (ICNP) and NANDA International (NANDA-I). More information about these taxonomies is available in

Chapters 5 and 7. The ICNP contains standardized outcomes and interventions. Nursing Outcomes Classifications (NOC) contains measurable patient outcomes. Nursing Interventions Classifications (NIC) provides standardized nursing interventions. See Chapters 5, 8, and 9 for more information about standardized outcomes and interventions. Each nurse reading and documenting in the EHR understands the diagnosis and can provide the interventions and measure the outcomes. Use of multidisciplinary terminologies aids interprofessional health care team members in understanding each other when communicating about a patient.

The **ICNP** is a standard terminology that provides a dictionary to describe and report nursing practice in a systematic way. This information supports care and decision making to inform nursing education, research, and health policy (ICN, 2019). The World Health Organization Family of International Classifications (WHO-FIC) accepted ICNP as a related terminology in 2008.

Other standardized terminologies are available for specialized settings. The Perioperative Nursing Data Set (PNDS) provides terminology standardized for the perioperative nurse. The Nursing Management Minimum Data Set (NMMDS) is used by nurse managers.

LO 15.6 Information and Education

The age of information has expanded the need for health literature. As nurses promote consumer responsibility for health, the Internet is increasingly used to search for information about a specific disease or medical problem. A survey (Fox & Duggan, 2013) found that 72% of Internet users searched for health information online. Of the health seekers, 77% initiated their most recent online health inquiry at a search engine, and 13% began at a health-related website. Positive and negative search results were reported. Unfortunately, only about 20% of health information seekers research online reviews and the rankings of health care service providers and treatments.

As patient advocates, nurses must be prepared to teach consumers how to evaluate the online sources of information and the information provided as they promote health literacy (Box 15.2). “Health literacy is the degree to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions” (Ratzan & Parker, 2000, p. 32). Table 15.2 offers a guide to website evaluation.

Box 15.2

Patient Education and Health Literacy

Health Information Online

- Ask patients where and how they get health-related information.
- Explore with patients their use of computers and how they decide whether information obtained from the Internet is reliable, accurate, and current.
- Teach patients how to evaluate a health-related website.

TABLE 15.2

Website Evaluation Criteria

CRITERION	EVALUATION QUESTIONS
Authority	Who is the sponsor or publisher? Is this a personal page? Where does it come from? Is the author or organization listed? What are the author's credentials?
Purpose	Does the site inform? Explain? Share? Disclose? Sell? What is the intended audience?
Coverage	Are citations correct? Is there a balance of text and images?
Currency	When was the site created? How often is it updated?
Objectivity	What are the goals and objectives of the site? Is there evidence of bias? Is bias explicit or hidden?
Accuracy	Are there footnotes or links to information sources?
Verification	Can the information be found in other sources?

Standards for Internet Health Sites

Ethical standards and guidelines for Internet health sites are being developed and promoted by several organizations. The Health on the Net Foundation (HON) is an international initiative created in 1995 that focuses on the promotion and use of reliable online health information (HON, 2018).

5. What should the nurse say in response to D. H.'s statement about the new product? Refer to the Website Evaluation Criteria in [Table 15.3](#) and identify a strategy the nurse should use to educate her on how to evaluate a health care–related website?

Nursing Informatics and Nursing Education

As nurse educators work with students who have been raised in a “wired” world with widespread information access, IT has become integrated into the curriculum and become part of the educational delivery system. Distance learning opportunities are widely available for formal degree programs and continuing education. Virtual realities and simulations allow the learner to participate in immersion scenarios that help in the development of critical-thinking and decision-making skills. Online discussion boards, classrooms, and support groups, as

well as social media sites, are used for educational activities. An important part of the TIGER vision is the reform of nursing education to provide the twenty-first-century nurse with informatics skills that enable the use of IT to provide the most knowledgeable and safe care possible.

LO 15.7 Ethical, Legal, and Professional Practice Concerns

Key areas of possible ethical conflict related to IT in health care include the creation and retention of documentation, ownership of software, ownership and integrity of data, preservation of privacy and confidentiality, and prevention of computer fraud and misuse. Patients' rights must be protected. It is important that nurses know about applicable laws and regulations, policies, procedures, the ethical codes of their employers, and the ethical codes of their professional organizations.

Data security and confidentiality of patient information are major issues. Access to electronic records requires a user to have system access and verification codes as a measure of security and protection of the patient's privacy. The codes leave an electronic trail of authorized users that can be audited. Only staff caring for a patient should access that patient's records. The HIPAA of 1996 sets the standards on how security and confidentiality of health care information must be maintained. The act also sets the penalties for any breach in security of health care data. HIPAA is discussed in detail in [Chapter 11](#).

Safe Practice Alert

Sign-on and password codes for access to an electronic health record system must never be shared with anyone.

Social Networking

According to a white paper released by the [National Council of State Boards of Nursing \(NCSBN, 2011\)](#), social media and similar electronic communication use has dramatically increased among nurses for both personal and professional purposes. Although social media has many benefits, it can lead to HIPAA violations of privacy and confidentiality when too much information is shared about one's patients and co-workers. Be aware of policies that govern the use of electronic media in the workplace, for example, what websites may be visited using the employer's computer system. Refrain from making comments on social networking sites that could lead to the identification of a specific individual. A nurse who engages in unprofessional conduct or breaches confidentiality may be sanctioned by the state board of nursing and risk

any incurring sanctions including permanent loss of one's nursing license.

Guidelines that help avoid problems using social media include no transmission of any patient's image; no posting of any patient information, including names or other identifiers; no disparaging comments about any patients or staff; and no contact with patients outside of the work setting. Report any breach immediately for quick resolution.

Computer Ethics

The Computer Ethics Institute (CEI) was founded in 1985 to serve as a forum and resource for identifying, assessing, and responding to ethical issues associated with the advancement of information technologies and to facilitate the recognition of ethics in the development and use of computer technologies. CEI developed the Ten Commandments of Computer Ethics (Box 15.3).

Box 15.3

Ethical, Legal, and Professional Practice

Ten Commandments of Computer Ethics

1. Thou shalt not use a computer to harm other people.
2. Thou shalt not interfere with other people's computer work.
3. Thou shalt not snoop around other people's computer files.
4. Thou shalt not use a computer to steal.
5. Thou shalt not use a computer to bear false witness.
6. Thou shalt not copy or use proprietary software for which you have not paid.
7. Thou shalt not use other people's computer resources without authorization or proper compensation.
8. Thou shalt not appropriate other people's intellectual output.
9. Thou shalt think about the social consequences of the program you are writing or the system you are designing.
10. Thou shalt always use a computer in ways that ensure consideration and respect for your fellow humans.

From Computer Ethics Institute. (2011). Ten commandments of computer ethics. Retrieved from <http://cpsr.org/issues/ethics/cei/>.

LO 15.8 The Future of Nursing Informatics

The greatest impact on nursing in the future will be because of advances in technology (Huston, 2013). Improvements in genetics and genomics, diagnostic tools and treatment, robotics, biometrics, and electronic records will mean that the technology in use today will not be the technology of tomorrow. By the time you graduate from nursing school, some of the predictions about the future will already be coming true and others will occur that were not thought of today.

The nursing profession is critical to successful adoption of IT in health care. The focus of nursing informatics is not on direct patient care but on how the process of patient care can be improved and patient safety ensured. There are challenges to advancements in IT, such as increased amount of time spent documenting, cost of equipment, protection of patient privacy, use of different EHRs in different facilities, and resistance by health care providers to new technology. However, the advantages of IT, particularly the EHR, outweigh the challenges. Nurses competent in informatics can help overcome some of the obstacles and advocate for the use of technology in patient care.

As nursing information systems are further refined to completely encompass the work of nurses, the ability to determine the evidence of best practice will be enhanced. Practice models and care delivery systems will integrate more IT. Nurses can expect a wide range of mobile technology tools that permit greater access to information, data processing, and decision support. While adopting new technology that enhances patient care and safety, it is the nurse's responsibility to continue to provide compassionate care.

National strategies for information and communication technologies extend IT investment beyond the hospital setting and physician practices to the home and community. The spread of IT supports consumer empowerment and self-management of wellness and disease. Consumers can electronically access their own health information, communicate with their health care providers, and seek needed education about health care (Weaver, Delaney, Weber, et al., 2010). Nursing must transform itself as a profession to make full use of the capabilities that information and communication technologies provide.

Summary of Learning Outcomes

LO 15.1 *Define nursing informatics:* Nursing informatics is a specialty area of informatics that addresses support of nursing practice in health information systems.

LO 15.2 *Discuss the uses of technology in health care:* Mobile workstations, bedside computers and tablets, cell phones, pagers, iPods, fax machines, and personal digital assistants are used in health care for communication, reference, and documentation. Robots are used in operating rooms and pharmacies, x-rays are in digital form, and telehealth or telemedicine is used to link medical experts with other clinicians and to provide in-home monitoring of patients.

LO 15.3 *Summarize the benefits of informatics:* The benefits include improved organization, communication, and information access; safer medication administration; reduction of duplicate orders and paperwork; better decision making; and improved administrative functions.

LO 15.4 *Compare competency levels of nursing informatics:* Levels of competency in nursing informatics are beginning, experienced, specialists, and innovator, and they determine specific roles for nursing. The nurse's role in the use of informatics intensifies as the competency level increases.

LO 15.5 *Explain the importance of using standardized terminologies in electronic health records:* The use of standardized nursing terminologies using terminology that is understood by all nurses

supports the capture of important data and nursing information.

LO 15.6 *Implement the use of information technology in obtaining health information for consumers and in educating nurses:* As the Internet becomes a widely used source of health information, nurses need to know how to evaluate websites and direct consumers to sites that are reliable.

LO 15.7 *Summarize potential ethical issues related to the use of health care information technology:* Nurses must be aware of potential legal and ethical issues related to computer applications in health care, such as patients' rights and protection of patients' information. Data security and confidentiality of patient information are major issues.

LO 15.8 *Outline future directions of informatics in nursing:* Advancements in nursing informatics will enable nurses to improve patient care and safety, gather evidence of best practice, use point-of-care documentation and references, and advocate for consumer access to health care information.

Review Questions

1. Which descriptions are advantages of health care information technology (IT)? (*Select all that apply.*)
 - a. Increases health care delivery costs
 - b. Improves communication among providers
 - c. Improves administration functions
 - d. Increases the potential for errors
 - e. Decreases the safety of providing care
2. Which description is an example of data?
 - a. A print-out of a patient's history and physical examination
 - b. A patient's blood pressure and pulse rate
 - c. The nurse's knowledge of a disease
 - d. A nurse's interpretation of a change in the patient's condition
3. Which items are supported by point-of-care use of information technology? (*Select all that apply.*)
 - a. More accurate documentation
 - b. Direct access to diagnostic results
 - c. Confidentiality
 - d. Direct access to records by patients
 - e. Access to medication profiles
4. The hospital has implemented a new electronic medication administration record (eMAR). What is true about the use of this new tool?
 - a. Verifies medication dosages
 - b. Reduces medication administration errors

- c. Eliminates the need to count narcotics
 - d. Requires a hard copy of the MAR to be printed
5. A famous rock star has just been admitted to Unit 12A after an automobile accident. A nurse on Unit 12B who is a fan of the musician uses the electronic health record (EHR) to find out how the patient is doing. Which is true regarding the use of a patient's EHR?
- a. Only staff caring for the patient should access this record.
 - b. Permission from a supervisor is needed to read this record.
 - c. The patient's record can be discussed with the nurse's co-worker.
 - d. The nurse can call a friend who works at the local newspaper.
6. Which activity by a unit nurse demonstrates information literacy?
- a. Researching a patient's diagnosis online
 - b. Entering patient data into the electronic health record (EHR)
 - c. Organizing patient data to study trends
 - d. Learning a new electronic health record system
7. The nurse is assigned to administer medications to a patient on a unit that has just implemented bar-code medication administration (BCMA). Which step is proper for the nurse to follow?
- a. Open the medication packages at the nurses' station.
 - b. Ask the patient to verify his or her address.

- c. Scan the nurse's ID, the patient's ID, and the code on the medication package.
 - d. Ask the patient to name two patient identifiers.
8. Which statement is correct concerning the implementation of computerized provider order entry (CPOE)?
- a. The unit secretary transcribes the physician's orders into the computer.
 - b. The nurse must ensure that orders go to the appropriate departments.
 - c. Physician orders go directly to the appropriate department.
 - d. Handwriting legibility is a major problem.
9. Which behaviors are expected of the nurse at the experienced informatics competency level? (*Select all that apply.*)
- a. Collect accurate assessment data.
 - b. Conduct informatics research.
 - c. Group assessment data.
 - d. Document data appropriately on the electronic health record (EHR).
 - e. Integrate information science, computer science, and nursing science.
10. Which description is true about the Nursing Minimum Data Set (NMDS)?
- a. An admission assessment tool
 - b. A discharge summary
 - c. The core nursing data for collection across all sites
 - d. An organization of nursing diagnoses

CHAPTER 16

Health and Wellness

LEARNING OUTCOMES

Comprehension of this chapter's content will provide students with the ability to:

- LO 16.1 Define the concept of *health* in an individual and a corporate context.
- LO 16.2 Compare the theoretical models of health and wellness that provide the basis for nursing practice.
- LO 16.3 Discuss health promotion and its relationship to wellness.
- LO 16.4 Explain the three levels of preventive care and the nursing interventions associated with each.
- LO 16.5 Summarize key aspects of each type of illness and the stages of illness behavior.
- LO 16.6 Identify factors influencing health and their impact on illness.

KEY TERMS

acute illness, [p. 217](#)

Case Study

Melissa Wolford (M. W.) is a 46-year-old female being evaluated at her local walk-in clinic for dyspnea on exertion (DOE). She has noticed a gradual increase in shortness of breath (SOB), fatigue, and daytime sleepiness since “gaining a few pounds” several years ago. She has no known history of illness or disease and does not have a primary care provider. M. W. claims she is rarely ill, except for the occasional cold or seasonal allergies, which she treats using over-the-counter remedies. M. W. is otherwise healthy and appears in no distress. She is currently unemployed, having left her former position as a teacher several years ago to stay home with her only child, who has required around-the-clock care since birth. Her husband is self-employed, and the family currently carries minimal health insurance except for their child, who is a Medicaid recipient.

Vital signs are T 99.5°F (37.5°C), P 92 and regular, R 22 and unlabored at rest, BP 170/94, with SaO₂ of 96% on room air. Her height is 165.1 cm (65 in), and she weighs 90.7 kg (200 lb). She complains of occasional headaches, which are relieved with rest and ibuprofen. M. W. states she has smoked one pack per day of low-tar cigarettes since the age of 17 and has two or three mixed alcoholic drinks per week, drinking almost exclusively on the weekends. She denies the use of recreational drugs but states her husband “smokes weed.” She does not exercise and has a sedentary lifestyle except when assisting her child with activities of daily living. Her diet is mostly fried foods, diet soft drinks, and very few vegetables or fruits. M. W. states she has been “eating more since quitting her job several years back” and has “a sweet tooth for candy and cakes.”

Refer back to this case study to answer the critical-thinking questions throughout the chapter.

At the turn of the nineteenth century, good health and overall wellness were defined as the absence of disease; health and wellness were not viewed as multidimensional concepts. During the latter half of the twentieth century, with the discovery of antiinfective drugs and the rapid growth of the biomedical industry, disease was no longer the primary focus for defining a person's health status.

In the twenty-first century, the concept of health has evolved into a multifaceted model focused on the need to maintain individual health and prevent chronic disease. Current news headlines bombard the general public with topics ranging from the rise in childhood obesity to the increase of smoking among adolescents to the comparable rates in men and women of chronic conditions such as cardiovascular disease, chronic obstructive pulmonary disease (COPD), and stroke. Because noncommunicable diseases claim the lives of three of five people worldwide, the United Nations General Assembly convened a high-level meeting in September 2011 to launch a global campaign for their prevention and control ([United Nations, 2011](#)).

There has never been a more important time to focus on health and wellness in our society. The professional nurse is poised to navigate the challenges of promoting health and wellness among patients by helping them achieve and maintain the highest level of physiologic functioning and mental well-being possible. Likewise, nurses who understand how individuals react to a real or perceived illness in themselves or their loved ones have the advantage of an experiential and scientifically based education to assist in achieving the optimal level of functioning.

LO 16.1 The Concept of Health

Capturing the total meaning of health and wellness for all people in a universal context is a challenging task. However, the World Health Organization (WHO, 1948) offers a definition for **health**: “a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity” (p. 100). The word *health* has several meanings. Individuals define health in terms of their own values, experiences, and ways of living. Organizations and businesses define health in the context of their goals and objectives. Familiar uses of the term *health* in the names of government organizations and businesses include World Health Organization (WHO), Occupational Safety and Health Administration (OSHA), National Institutes of Health (NIH), and health maintenance organization (HMO). *Health* is understood in the context of the name of the organization, but the value each organization, industry, or government office assigns to the meaning of the word varies.

Nurses must balance the requirements of the health care industry and setting in which they are employed with the needs of the individuals for whom they care. Sometimes, this can be extremely challenging. Nurses are responsible for helping patients reach their optimal levels of multidimensional health, but they also must provide health care in a system that requires cost containment and fiscal responsibility. This can place nurses at ethical odds as they seek to meet the perceived health care needs of individuals and remain sensitive to the fiscal limits of their employers. Addressing the fiscal challenges of health care in the twenty-first century while adequately meeting the needs of patients requires creativity and the ability to help individuals identify and achieve their wellness goals.

LO 16.2 Health Models

Health models describe the relationship between health and wellness. These models provide a foundation for defining optimal multidimensional health. Patients' beliefs, values, and attitudes about health and wellness are based on a complex series of experiences that can have positive and negative effects on their health status. Several health models have been developed to guide practice using the nursing process.

Basic Human Needs Model

Maslow's hierarchy of needs describes the relationships between the basic requirements for survival and the desires that drive personal growth and development. The model is most often presented as a pyramid consisting of five levels (see [Chapter 1, Fig. 1.6](#)). The lowest level is related to physiologic needs, and the uppermost level is associated with self-actualization needs, specifically those related to purpose and identity. According to this model, deficiency needs must be met first. This means that until basic physiologic requirements are achieved, attaining the higher levels of the pyramid will not be achievable or a priority. **Self-actualization** is considered the highest level of optimal functioning and involves the integration of cognitive ability, compassion, acceptance of self, and autonomy. In later years, Maslow described a level above self-actualization called *self-transcendence*. He refers to self-transcendence as a peak experience, in which analysis of reality or thought changes a person's view of the world and his or her position in the greater structure of life.

In nursing, the hierarchy of needs model implies that basic physiologic needs are more immediate and therefore of greater importance in terms of survival than higher-level needs. Maslow's hierarchy of needs model supplies a **humanistic** approach (i.e., promotion of human welfare) to health and wellness. Nurses apply this model when developing interventions focused on preventive care and patient education. A humanistic approach to health care focuses on strengths of individuals rather than weaknesses or illness (i.e., physiologic disease or mental disorder) ([Maslow, 1954](#)).

Nurses should also consider that applying a fixed hierarchical order is not always the most accurate method for predicting patient behavior or actions concerning optimal health. Areas of need categorized above basic physiologic function, such as self-esteem and love, often override essential physiologic needs when a patient is confronted with certain

circumstances. For example, nurses encounter a variety of approaches to death and dying when patients are faced with end-of-life issues. Nutrition and fluid needs may not be as much of a priority to the dying as the need for dignity, spiritual guidance, or comfort from loved ones. Nurses regularly witness emotional and self-esteem issues that outweigh physiologic needs. Patients with life-threatening conditions related to anorexia nervosa frequently refuse medical therapies due to issues of self-esteem or lack thereof, which nurses find particularly challenging. A nurse should never assume that one patient's needs are the same as those of another patient with a similar health condition or that a patient's choices follow a hierarchal model of care. Nursing care aimed at the individual's specific level of need during the current health care encounter is the most effective method for prioritizing patient care using Maslow's hierarchy of needs model.

Health Belief Model

The **Health Belief Model (HBM)** was developed by psychologists Hochbaum, Rosenstock, and Kegels ([Rosenstock, 1974](#)). It explores how patients' attitudes and beliefs predict health behavior.

The model has been adapted and reorganized since its original inception. The latest addition to the construct, self-efficacy, was added in 1988. **Self-efficacy** is a person's belief in his or her ability to perform a task successfully. When applied to the nursing process, the HBM is used as a measure for determining the patient's readiness and motivation to act.

There are three primary components to the model that seek to predict how likely individuals are to change their health care behaviors. The first is an individual's perception of susceptibility to illness; for example, a patient with a family history of colon cancer may have several first-degree relatives who have been diagnosed and treated for the disease. The second component is the individual's perception about the seriousness of the illness. If the person does not perceive the need for periodic colonoscopy screenings or does not attempt to lose weight despite warnings that obese people have a higher incidence of colon cancer, the threat of the disease appears to be minimized. The third component is the probability that the individual will act to prevent avoidable health risks. **Preventive action** involves lifestyle change and information gathering about a health topic that leads to a change in behavior.

In the three primary components of the HBM, six main constructs influence an individual's decision to take action about disease prevention, screening, and controlling an illness. The model suggests

that individuals are motivated to take action if they have certain beliefs or experiences such as the following:

- They are susceptible to the condition (i.e., perceived susceptibility).
- The condition has serious consequences (i.e., perceived severity).
- Taking action would reduce the susceptibility or severity of the condition (i.e., perceived benefit).
- The costs of taking action (i.e., perceived barriers) are outweighed by the benefits.
- They are exposed to factors that prompt action, such as media campaigns, postcard reminders, and advice from others (i.e., cues to action).
- They have confidence in their ability to perform an action (i.e., perceived self-efficacy).

Together, the six constructs of the HBM provide a useful framework for implementing the nursing process ([Table 16.1](#)). Nurses can use measures in the model to assess the value of short- and long-term behavioral change strategies designed for optimizing patients' health and wellness status.

TABLE 16.1**Health Belief Model**

Construct	Definition	Change Strategies
Perceived susceptibility	Beliefs about the chances of getting a condition or disease	Define the populations at risk. Tailor risk information to the individual's characteristics or behaviors. Help the individual develop an accurate perception of his or her own risk.
Perceived severity	Beliefs about the seriousness of a condition and its consequences	Specify the consequences of a condition, and recommend action or intervention.
Perceived benefits	Beliefs about the effectiveness of taking action to reduce risk or seriousness	Explain how, where, and when to take action and describe likely positive results.
Perceived barriers	Beliefs about the material and psychological costs of taking action	Offer reassurance, incentives, and assistance; correct misinformation or allegations.
Cues to action	Factors that activate readiness to change	Provide how-to information, promote awareness, and employ reminder systems.
Self-efficacy	Confidence in one's ability to act	Provide training and guidance in performing action. Use progressive goal setting. Give verbal reinforcement. Demonstrate desired behaviors.

Modified from National Cancer Institute. (2012). *Theory at a glance: A guide for health promotion practice*. (2nd ed.). Washington, DC: U.S. Department of Health and Human Services, National Institutes of Health.

1. Which two of the three primary components of the Health Belief Model did M. W. exhibit by coming to the walk-in clinic for evaluation of her dyspnea on exertion?

Health Promotion Model

The **Health Promotion Model (HPM)** developed by Pender and colleagues (Pender, Murdaugh, and Parsons, 2015) defines health as a positive, dynamic state of well-being rather than the absence of disease

in the physiologic state. The model relies on the premise that a multidimensional interaction exists between an individual and the environment, and health promotion consists of behaviors directed at improving the individual's level of well-being.

The model focuses on three areas: (1) individual characteristics and experiences, (2) behavior-specific knowledge and affect, and (3) behavioral outcomes. The concepts that define the model are health promotion and health protection. **Health promotion** is behavior motivated by the desire to increase well-being and optimize health status. **Health protection** includes intentional behaviors aimed at circumventing illness, detecting it early, and maintaining the best possible level of mental and physiologic function within the boundaries of illness (Pender, Murdaugh, and Parsons, 2015). The variables in the HPM promote desired health outcomes as determined by an individual's motivation to achieve a better quality of life and improve functional capacity. Patients may seek nursing care for preventive health maintenance or treatment. Through use of the nursing process, nurses can educate patients about acute, chronic, and preventive health care interventions (Fig. 16.1) (Pender, Murdaugh, & Parsons, 2015).

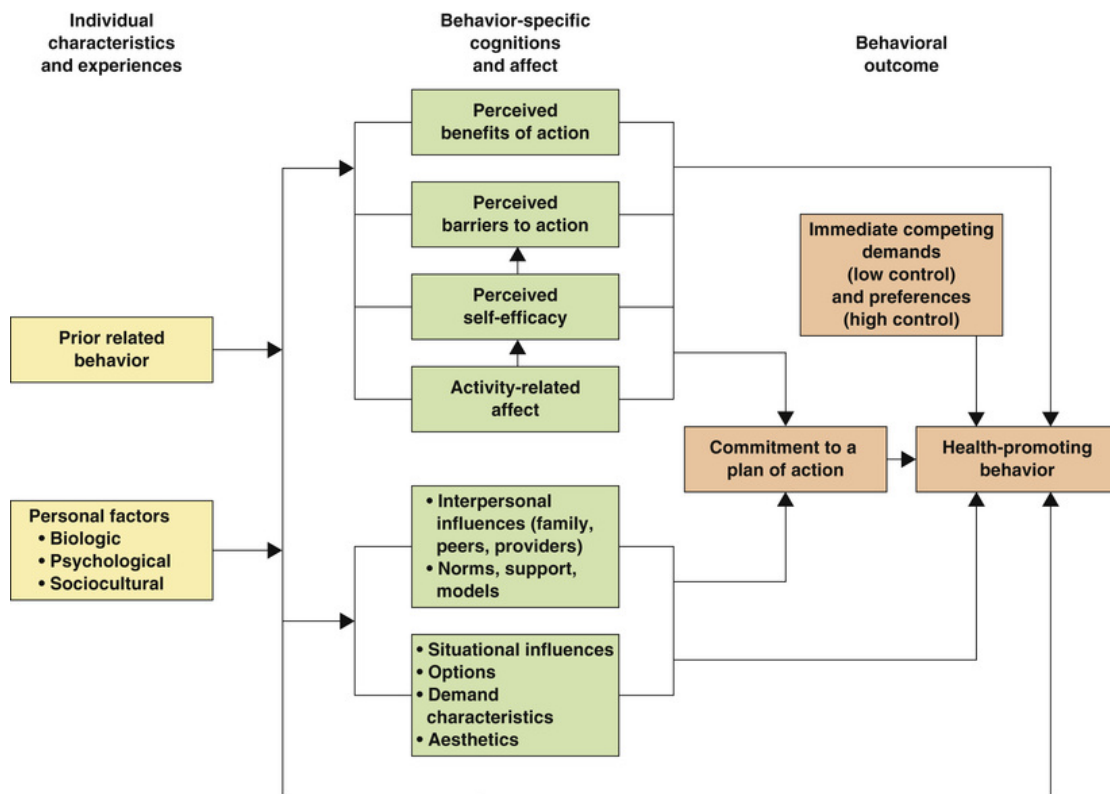

FIGURE 16.1 The Pender Health Promotion Model. (From Pender, N.J., Murdaugh, C.L., Parsons, M.A. *Health promotion in nursing practice* (7th ed.). Copyright 2018. Reprinted by permission of Pearson Education, Inc., New York.)

Holistic Health Models

Holistic health models in nursing care are based on the philosophy that a synergistic relationship exists between the body and the environment. Holistic care is an approach to applying healing therapies. Holistic models focus on the interrelatedness of body and mind. Incorporating features of spirituality, emotional security, and environment into natural, holistic care supports the premise that the body knows how to heal itself if given the proper support. When applied to the nursing process, holistic health models strive to include the patient as an active participant in the healing process rather than a passive receiver of therapeutic interventions.

Nurses participate in holistic care through the use of natural healing remedies and complementary interventions. These include, but are not limited to, the use of art and guided imagery, therapeutic touch, music therapy, relaxation techniques, and reminiscence. Eastern holistic therapists have been using techniques such as acupuncture, yoga, and tai chi for thousands of years as methods of healing and, more recently, in conjunction with modern allopathic medical therapies.

The holistic model provides nurses with strategies to help patients learn how to manage illness and optimal health. Guided imagery, progressive muscle relaxation, and music therapy are effectively used for patients undergoing chemotherapy to help relieve nausea, vomiting, pain, and anxiety (Charalambous, et al, 2016; Karagozoglu, Tekyasar, & Yilmaz, 2012). Relaxation breathing is used for burn patients during dressing changes to manage pain and anxiety (Park, Oh, & Kim, 2013).

Holistic nursing practice has rapidly expanded to meet the growing consumer demand for alternative and complementary interventions. Consumers of health services have become more familiar with alternative care through the Internet, and they have sought alternatives because of increasing health care costs and expectations of management of their own care. Patients should check with their insurer to see if alternative interventions or measures are covered. Holistic nursing interventions are more readily recognized and accepted by patients because mind-body-spirit therapies are sound evidence-based practice.

LO 16.3 Health Promotion and Wellness

Health promotion and wellness are increasingly emphasized in health care visits and outcome planning for chronic disease. Rising health care costs, including the costs of disability, have increased government and consumer demands to minimize the incidence of disease and risk factors that predispose to illness. Concepts of health promotion, wellness, and risk reduction influence individual motivation for setting and achieving health goals.

Health Promotion

The World Health Organization defines health promotion as “the process of enabling people to increase control over, and to improve, their health” (WHO, 2018). Health promotion includes a focus on individual behaviors as well as environmental and social factors. Optimal health implies a balance of physical, occupational, emotional, social, spiritual, intellectual, and environmental well-being (Fig. 16.2).

FIGURE 16.2 Seven optimal health dimensions.

Activities involved in health promotion include routine exercise, meeting nutritional and vitamin requirements, maintaining a body mass index within range for weight and height, good sleep habits, and stress

reduction. Healthy interpersonal relationships, positive self-worth, hope, education, and safe work and living environments all contribute to a person's wellness. Health promotion activities are most effective when an individual is intrinsically motivated and committed to lifestyle changes and personal growth that support positive health behaviors.

Wellness

Wellness is a process of self-care achieved by making choices leading to a healthy life. Wellness knowledge empowers a person to become more aware of bodily needs and how to meet those needs. Individuals seeking wellness need to take environmental, occupational, intellectual, spiritual, emotional, physical, and social lifestyle choices into consideration.

Risk factor reduction is step-by-step improvement of individual health factors. These combined improvements lower the likelihood of developing a disease. For example, an overweight, sedentary middle-aged smoker with a family history of cardiac disease has noticed a steady rise in resting blood pressure over a 3- to 4-year period. The patient is concerned about his slightly elevated blood pressure and begins walking 20 to 30 minutes in the evenings with his wife and reduces his pack-a-day cigarette habit to 10 cigarettes per day. He has taken the first steps in reducing risk factors for cardiac disease, but the threat of disease still exists unless he remains motivated to continue on a more healthful course.

Nurses can support all dimensions of health promotion, wellness, and risk factor reduction by helping patients understand how each dimension depends on the others. Several evidence-based standardized tools are available to help people achieve their goals for a healthy lifestyle. The *Healthy People 2020* initiative is designed to track over 10-year increments the risk factors and personal behaviors related to physical activity, access to health services, tobacco use, substance use, responsible sexual behavior, mental health, immunizations, and injury and violence prevention (DHHS, 2018). *Healthy People 2020* is a data-driven national agenda, used to guide health care professionals to support healthy communities by way of evidence-based public health strategies and increasing public awareness about the different determinants of health. The *Healthy People 2020* initiative can provide nurses with evidence-based resources and tool kits designed to support healthier lifestyles for individuals, families, and communities.

Additional methods nurses can use to identify specific demographic areas for health and wellness promotion activities are found in the U.S. health agency links for state departments of public health. International information is available from the United Nations WHO website. Links

of interest to nurses include hospital mortality rates, disease prevalence, epidemiology statistics, and behavioral risk factor analysis (Box 16.1). Nursing goals for all individuals and their families seeking preventive care are improvement of quality of life through positive lifestyle choices and taking responsibility for health and wellness.

LO 16.4 Levels of Prevention

Illness and disease prevention involves activities and interventions that delay or prevent clinical manifestations, complications, and death.

Leavell and Clark (1965) identified health-related measures as primary, secondary, and tertiary levels of preventive care from a public health perspective. Signs or symptoms to be prevented depend on the stage of health or disease of individuals receiving preventive care.

Primary Prevention

Primary prevention is instituted before disease becomes established by removing the causes or increasing resistance. The goal of intervention during this phase is to modify risk factors to avoid the onset of disease and prevent pathologic processes from occurring (Leavell & Clark, 1965). Health promotion and specific protection strategies are appropriate methods of primary prevention nurses can use for patients. Many health-promoting activities are nonmedical, such as lifestyle changes, nutrition improvement, and environmental alterations. They contribute to the prevention of many diseases and enhance patients' overall vigor and health.

Specific protection strategies are undertaken when health promotion efforts are unsuccessful or inappropriate. The objective is to address a specific disease or potential injury. Examples include the use of seatbelts and airbags in automobiles, helmet use when riding bicycles or motorcycles, and the occupational use of mechanical devices when lifting heavy objects. Immunizations against specific diseases, such as human papillomavirus infection or pneumonia, are also types of primary prevention.

2. List three or four risk factors identified in M. W.'s health history and physical assessment that the nurse should address during this or subsequent clinic visits. Place an asterisk next to preventable lifestyle-related risk factors that M. W. can change with mutually agreed-on interventions.

Secondary Prevention

Secondary prevention is undertaken in cases of latent (hidden) disease. Although the patient may be asymptomatic, medical tests can detect a disease process. Secondary prevention may be directed at individuals who are at risk for complications. The goal for health intervention during this phase is early detection and diagnosis of health problems before patients exhibit symptoms of disease (Leavell & Clark, 1965).

Screening tests may be used to assess for latent disease in vulnerable populations. Although screening examinations do not prevent disease or the cause of disease, they may influence progression to the symptomatic phase. Examples of screening tests used as secondary prevention strategies include the purified protein derivative (PPD) skin test for tuberculosis, fecal occult blood test for colorectal cancer, and mammograms for breast cancer. Nursing care implemented as secondary prevention occurs wherever nurses interact with patients, including in acute care or home care settings and during community health care functions. While implementing secondary prevention measures, nurses can provide preventive health education, which is considered a primary prevention effort.

Tertiary Prevention

Tertiary prevention, also known as the treatment or rehabilitation stage of preventive care, is implemented when a condition or illness is permanent and irreversible. The aim of care is to reduce the number and impact of complications and disabilities resulting from a disease or medical condition. Interventions are intended to reduce suffering caused by poor health and assist the patients in adjusting to chronic conditions.

Qsen Focus!

Patient-centered care plans for addressing tertiary prevention should be developed in collaboration with patients, families, and other health care providers to ensure sensitivity to patient needs and to coordinate care.

Nursing care is focused on rehabilitation efforts in the tertiary stage of prevention. Outcomes are evaluated on the basis of patient responses. The goal is to help patients attain the highest level of physical and mental health achievable within the parameters of impairment caused by disease or disability. The nurse assumes a leadership role in

coordinating all members of the patient's health care team with collaborative efforts to maximize health outcomes (Box 16.2). Collaborative efforts are a necessary function of tertiary prevention because the patient often has health needs encompassing numerous health disciplines that might not have been involved in the initial stage of illness.

Box 16.2

Interprofessional Collaboration and Delegation

Collaboration in Preventive Care

- Prevention is not solely the responsibility of the nurse; it involves active participation by the individual and the combined services of practitioners in a spectrum of health care disciplines as varied as nutrition, physical therapy, exercise physiology, and pharmacy.
- Collaborative health care partnerships are designed to deliver well-balanced care to the patient as a whole, rather than rendering fragmented care involving a single element of a disease process.
- Collaborative preventive care can be mandated in the form of health care legislation, with rates for reimbursement of practitioners determined by the individual provider's ability to collaborate and develop innovative methods for delivering high-quality, cost-effective health care services.
- The role of the nurse is to collaborate and communicate health education to the patient and family, care provider, or surrogate. Patient education responsibilities are not delegated to assistive personnel or other members of the health care team and are considered a cornerstone of nursing care.
- More information about collaborative efforts in preventive health care services that are patient centered and value driven is available at <http://www.icsi.org>.

LO 16.5 Illness

Illness is an abnormal process in which aspects of the social, physical, emotional, or intellectual condition and function of a person are diminished or impaired. People respond to illness in a variety of subjective and objective ways. Response to illness is determined by an individual's emotional and cognitive development and by the physiologic response to stress experienced by the body. For example, pneumonia is an infectious disease that is highly curable when treated promptly and with patient adherence to therapy. One person with pneumonia identifies alterations in health status by the symptoms of illness associated with decreased function (e.g., fever, malaise, cough), seeks treatment, and has a positive physiologic response, maintaining usual daily activities. Another person may ignore or disregard physiologic alterations in health, with the possible result of increasing the duration of the illness, the length of treatment, and the severity of impairment. Perception of illness and the experience of illness go beyond the physical dimension, and the nurse must recognize that a patient's illness is not necessarily synonymous with disease status.

Illness can be categorized as acute or chronic depending on the clinical course and prognosis of disease. Both acute and chronic illnesses can be lethal or cause permanent disability in the host organism.

Acute Illness

Acute illness is typically characterized by an abrupt onset and short duration (<6 months). Clinical manifestations of acute illness appear quickly. They may be severe or lethal, or they may soon resolve because they respond to treatment or are self-limiting. The physiologic and psychological consequences of an acute illness can affect a patient's immediate functional ability. Residual effects of acute illness may last beyond the course of the disease itself.

Chronic Illness

Chronic illness is of greater concern than communicable diseases in many areas of the world, including some developing countries. This focus on chronic illness results from factors such as people living longer; improved health care and medications; high-fat, high-sugar diets and sedentary lifestyles that contribute to obesity; and substance abuse, including tobacco, alcohol, and illegal drugs.

Chronic illness is characterized by a loss or abnormality of body function that lasts longer than 6 months and requires ongoing long-term care. Chronic health conditions may be controlled with lifestyle management or drug therapy, but they are considered to be irreversible. The ability to carry out activities of daily living varies from person to person, depending on progression of the disease process. Chronic illness may be characterized by periods of wellness (**remission**) and **exacerbation** (worsening) of clinical manifestations, which can be life-threatening. Individuals learn to adjust their lifestyles accordingly. The drug regimen, laboratory tests, health care provider visits, and changes in nutritional intake often interfere with the lifestyle the chronically ill individual led before disease onset.

Nurses play a pivotal role in providing care, support, and education for people with chronic illness. Many individuals living with the burden of chronic disease initially find the daily disease management overwhelming. Nurses can help patients establish a daily routine of care by educating them about how to manage their care, available resources, and the symptoms associated with the condition, including emergency or life-threatening situations. Emphasis is on improving quality of life through preventive behaviors. The attitude of being a victim, suffering with, or being afflicted by a chronic illness is viewed by nurses as a counterproductive behavior that needs positive intervention. Nurses can assist patients with strategies that help them cope with their chronic conditions and associated feelings of anger, frustration, and depression. Encouragement and positive support from a professional nurse can help individuals gain control over the alternating periods of health and illness and improve their quality of life.

Illness Behaviors

Social and environmental factors are important components of health and illness. Recognition that the health of an individual is more than just a biologic process related to physiologic function has increased awareness about the sociologic dimension of health that influences illness behaviors.

Several stages of illness behavior have been identified by medical sociologists to describe how people monitor their physical well-being, label and interpret their symptoms, take curative actions, and enter the health care system (**Mechanic, 1995**). People react to illness in a variety of ways based on history, family upbringing, personal values, community constraints, and cultural norms (**Ahmadi & Ahmadi, 2017; Mechanic, 1995**).

For the purpose of providing nursing care, the Suchman **Stages of Illness Model** (1965) best describes illness behavior and how

individuals arrive at the coping mechanisms necessary for the management of disease conditions. According to the model, the process of being ill is composed of five components—or stages—of the illness experience. Each stage is characterized by certain decisions, behaviors, and end points comparable to parts of the nursing process.

During stage I (Symptom experience) of the Suchman model, a clinical manifestation of disease is experienced, and the person acknowledges that something is wrong and seeks a cure. The outcome of stage I is that the person accepts the reality of symptoms and decides to take action in seeking care.

During stage II (Assumption of the sick role), the person decides that the illness is genuine and that care is necessary. This stage gives an individual permission to act sick and to be excused temporarily from typical social and personal obligations. The results of this stage are either acceptance of the sick role or rejection of its necessity.

In stage III (Medical care contact), professional advice from health care providers is sought by the individual. A professional health care provider identifies and validates the illness and legitimizes the sick role. During this stage, the condition still may be denied, or the patient may seek additional medical care or may accept the adverse condition, the medical diagnostic authority, and the plan for treatment.

During stage IV (Dependent patient role), the person, who is designated as a patient, usually undergoes treatment. During this stage, patients often feel dependent on others and may experience ambivalent or fearful thoughts that cause them to reject treatment, the advice of health care providers, and the illness. More often, care is accepted and administered to an ambivalent patient. In this stage, the sick individual has a significant need to be educated and provided with emotional support.

During stage V (Perceived recovery), the patient abandons the sick role and resumes usual tasks and roles to the greatest degree possible. Some people do not willingly give up the sick role; they begin to view themselves as chronically ill, or they malingering in the health care setting, acting sick for secondary gain. Patients with permanent disabilities may require therapy to assist them in making adjustments necessary for performing activities of daily living (ADLs) (Suchman, 1965).

Lo 16.6 Factors Influencing Health and the Impact of Illness

Identifying variables that affect health and wellness is a key component in guiding health promotion activities and preventive behaviors. The variables are often referred to as **social determinants of health**, and they are affected by resource distribution throughout the world. Nonmodifiable influences include the genetic determinants of health. The value a patient assigns to a real or perceived health risk can influence health beliefs, behaviors, and practices that will ultimately determine a positive or negative health outcome. Understanding the effects of these factors affords the nurse an opportunity to initiate the steps of the nursing process to plan, implement, and evaluate individualized care.

Age

The chronologic age of an individual is a strong indicator of susceptibility to disease or disabling conditions. Assessment of the patient begins with risk factors that take into account the person's age and the associated level of immune system function. The very young, especially neonates and infants born prematurely, are more susceptible to infections because of the immaturity of their immune systems. Likewise, older adults have decreased immune system function as a result of the aging process. Older patients are at risk for **opportunistic infections** caused by harmless organisms that become pathogenic and illness from the spread of community-acquired disease. Complications from comorbidities of chronic disease also may increase in the aged population.

Nurses need to educate the parents of newborns, infants, children, and adolescents about the importance of regular, age-appropriate checkups and screening examinations. All adults should be instructed to undergo age-appropriate screening examinations, schedule regular health care provider visits, and receive recommended immunizations to promote wellness and prevent illness (**Box 16.3**). A schedule of immunizations for both children and adults (<http://www.cdc.gov/vaccines/schedules/index.html>) is provided by the Centers for Disease Control and Prevention (CDC) and the U.S. Department of Health and Human Services (DHHS) furnishes links to health screening and disease prevention sites (<https://www.hhs.gov/programs/prevention-and-wellness/health-screenings/index.html>). Nurses should encourage adults of all ages to

act as role models for good health and promote wellness behaviors. Access to peer-reviewed research on age-related preventive services and best-practice guidelines can be found at <https://www.cdc.gov/aging/aginginfo/index.htm>.

Box 16.3

Diversity Considerations

Life Span

- Parents need to have scientific, evidence-based information about immunizations and their consequences before choosing to accept or reject immunizations for their children. The parent's ability to make an informed decision is the primary goal for nurses educating people about childhood immunizations.
- The cost of drug therapy is often a serious financial concern and stressor for older adults on fixed incomes who are living with chronic disease.

Gender

- Although the risk for breast cancer in men is low compared with the risk for women, all men past puberty should be taught and encouraged to perform breast self-examinations for cancer. This is particularly important if there is a family history of malignancies.
- Currently, the [USPSTF \(2017\)](#), is recommending cervical cancer screening by Pap smear alone every three years in women ages 21-29 years, and either Pap alone every 3 years or HPV testing alone every 5 years in women ages 30-65 years. Co-testing was previously recommended. Research is being conducted on the reliability of HPV testing alone versus Pap smear ([JAMA, 2018](#)).

Culture, Ethnicity, and Religion

- A direct relationship exists between race and many factors, including skin color, body structure, susceptibility to disease, nutritional preferences and deficiencies, and psychological characteristics ([Giger, 2017](#)).
- Five-year survival is lower for blacks than whites in the United States for most cancers suggesting the need for a greater focus on

prevention and earlier diagnosis (DeSantis et al., 2016).

- Research indicates a disproportionate relationship among Hispanic families and obesity. High intake of fried foods and sweetened beverages by Hispanic mothers was found to influence their daughters' consumption of fewer than recommended amounts of fruits and vegetables (Range et al., 2015).
- Nursing interventions to encourage wellness activities and change patterns of health-seeking behaviors should be adjusted to meet the personal needs of patients from various cultures. Ethnicity, race, and cultural traditions must be considered, with specific input from patients, to produce positive outcomes (Giger, 2017).

Disability

- Children born with genetic or chromosomal disorders, such as cystic fibrosis, Down syndrome (also called trisomy 21), and sickle cell disease, are at increased risk for opportunistic infections and communicable diseases because of the comorbidities associated with the underlying conditions (Baum, Nash, Foster, et al, 2008).
- Health and wellness guidelines are being expanded to accommodate children and older adults with special needs because they are outliving previous life expectancies as a result of tailored drug therapies and biotechnology advances. Best-practice guidelines can be found at <https://www.cdc.gov/ncbddd/disabilityandhealth/index.html>.

Morphology

- Screening for metabolic syndrome, a precursor of chronic disease, and preventive interventions are aimed at young and middle-aged adults. Components of metabolic syndrome include overweight and obesity (i.e., waist circumference >102 cm [40 inches] in men and >88 cm [35 inches] in women), serum triglyceride levels ≥ 150 mg/dL, serum concentration of high-density lipids <40 mg/dL in men and <50 mg/dL in women, hypertension (i.e., blood pressure $\geq 130/85$ mm Hg), and insulin resistance (i.e., fasting blood glucose ≥ 100 mg/dL) (AHA, 2016).

Gender

Gender-related risk factors for disease are assessed according to the characteristics of each disease. Nurses in primary and acute care settings

are often the first health care providers to approach individuals about gender-specific health and wellness issues. Preventive screening examinations consider reproductive anatomy and follow the current CDC guidelines for age and sexual maturity. For example, a priority assessment task for nurses in a variety of care settings is to ask female and male patients about colorectal cancer screening (Box 16.4). An adolescent male should be assessed for testicular self-examination habits, and older males should have an annual prostate examination. Menstrual history should be obtained from female patients, and annual clinical breast examination is recommended. Pregnancy and childbirth issues, such as gestational diabetes, gestational hypertension, or rectoceles and cystoceles, should be evaluated by the nurse as potential alterations in health status that may need continued monitoring.

Box 16.4

Age-Related Guidelines for Colorectal Cancer Screening

- Colorectal cancer screening should begin at age 45 for people at average risk without a personal or family history of colorectal cancer.
- The fecal immunochemical test (FIT) or guaiac-based fecal occult blood test (gFOBT) may be performed annually.
- Screening by colonoscopy is recommended every 10 years. Screening by virtual colonoscopy or flexible sigmoidoscopy is recommended every 5 years.
- People at high risk may require screening before the age of 45 or more often.
- Decisions about screening tests and their frequency should be discussed during health care provider visits.

Adapted from American Cancer Society (2018). American Cancer Society Guideline for Colorectal Cancer Screening. Retrieved from <https://www.cancer.org/cancer/colon-rectal-cancer/detection-diagnosis-staging/acs-recommendations.html>.

Nurses are knowledgeable resources with whom people can discuss sensitive issues and questions about gender-specific illness and health-promotion activities. Nurses must display sensitivity and comfort in dealing with these issues, which may be awkward or difficult for people

to discuss with friends, family, or other members of the health care team.

Genetics and Inherited Traits

Preventive health care based on principles of human genetics is the next frontier for patient care. The **genetic vulnerability**, or risk for disease expression based on genotype, is involuntarily passed from biologic parents to their offspring. Societal attitudes about testing and management of high-risk populations depend on the potential for expression of genetic disorders possibly triggered by environmental factors. Controlling factors that place stress on physiologic function can reduce pathologic genetic expression and susceptibility to disease. For example, a person with a family history of hyperlipidemia and atherosclerosis is at risk for developing cardiovascular disease later in life. Lifestyle-modifying factors, such as weight reduction, daily exercise, and balanced nutritional intake, can help reduce the likelihood that the genetic risk factor for heart disease will be expressed. Diabetes, cancer, mental illness, and renal disease also have genetic components and are amenable to interventions that reduce risk.

Lifestyle

Health and wellness risk factors are inherent in the choice to engage in and continue particular behaviors. Habitual lifestyle behaviors can produce health benefits or intensify the effects of pathologic risk factors.

Information on lifestyle behaviors that lead to disease is available at disease advocacy and research-sponsored websites that have peer-reviewed material and expert analyses. Website content should be easy to read and understandable for the general population. Most sites that discuss the latest information about health risks, lifestyle behaviors, and outcomes have separate information specifically for health care providers ([Box 16.5](#)). Examples of risky lifestyle behaviors that can lead to poor outcomes include excessive alcohol intake, which can cause liver damage and gastrointestinal distress, and poor dietary choices and lack of exercise, which can lead to overweight or obesity in adults and children.

Box 16.5

Evidence-Based Practice and Informatics

Research Opportunities and Resources Related to Health and Wellness

- Health and wellness topics for each body system offer a broad range of research opportunities.
- Research that evaluates positive and negative lifestyle behavior outcomes is constantly evolving as discoveries are made about the physiologic changes bodies experience with disease and illness.
- Nurses are at the forefront of medical breakthroughs and are expected to be knowledgeable about the latest technology and pharmaceutical interventions.
- Up-to-date information about government-sponsored best-practice guidelines regarding nutrition, physical activity, and healthy living is available at <https://www.hhs.gov/programs/prevention-and-wellness/index.html>.
- For older adults, best-practice guidelines for health and wellness can be found at <http://www.aarp.org/health>, <https://www.cdc.gov/aging/aginginfo/index.htm>, and <https://www.nia.nih.gov/>.

The CDC *Weekly Morbidity and Mortality Report* follows trends in modifiable risk factors in the United States by age, socioeconomic status, and other demographic indicators. Behavioral risk factors such as smoking, poor diet, physical inactivity, and excessive drinking are linked to the leading causes of death in the U.S. population. The **Behavioral Risk Factor Surveillance System (BRFSS)** is an ongoing, state-based, random-digit-dialed telephone survey of the noninstitutionalized U.S. population older than 18 years of age. The BRFSS collects data on health risk behaviors and preventive health services related to the leading causes of death. The results from the BRFSS and other surveys about lifestyle-related risk factors are available online from the National Center for Health Statistics (NCHS) at <http://.cdc.gov/nchs>.

The NCHS (2018) provides the latest data about modifiable risk factors that correlate with disease and illness. These data are available for most areas of the United States and emphasize the need for health promotion and preventive care initiatives tailored to individual, community, and statewide levels of the health care system. The economic impact of modifiable lifestyle-related risk factors that contribute to chronic disease is a serious concern to all communities due to the drain on health care and financial resources needed to

accommodate an ailing population. Nurses are often asked to participate in education efforts to promote health and wellness and reduce disease risk factors as part of their communities' public health agendas.

Nutrition and dietary intake have a direct link to modifiable lifestyle-related risk factors that predispose an individual to obesity, hyperlipidemia, atherosclerosis, heart disease, and cancer. Nurses can assist people with weight loss and maintenance techniques by educating them about the food choices and portion sizes suggested by the CDC's My Plate Food Guide and the USDA's Dietary Guidelines (https://health.gov/dietaryguidelines/2015/resources/2015-2020_Dietary_Guidelines.pdf) for daily caloric requirements. Chapter 30 provides additional information on these requirements.

Exercise is essential for the prevention of illness and promotion of wellness. Physical exercise is any bodily activity or movement that enhances or maintains physical fitness levels and overall health. Exercise strengthens muscles, improves cardiovascular performance, enhances athletic skills and endurance, and reduces or maintains weight, and it is performed for enjoyment (Powers & Howley, 2012). Regular physical exercise boosts the immune system, builds and maintains healthy bone density, increases joint mobility, and helps prevent cardiovascular disease, type 2 diabetes, and obesity. Exercise also improves mental health and helps prevent depression through the release of endorphins and other neurotransmitters that are responsible for exercise-induced euphoria (Powers & Howley, 2012).

There are definitive recommendations for the amount of physical activity adults, children, and the older adult population should include in their weekly routines. Nurses should advise healthy adults to engage in moderate-intensity physical activity for at least 30 minutes 5 or more days per week. As an alternative, adults can participate in vigorous-intensity physical activity for at least 20 minutes 3 or more days per week. Children and adolescents should participate in at least 60 minutes of moderate-intensity physical activity most days of the week. For older adults, the recommendations are 30 minutes of moderate-intensity aerobic activity 3 to 5 days per week, daily stretching, and participation in strength-building activities two or three times per week. These recommendations can be found at <https://www.cdc.gov/physicalactivity/basics/>.

Nurses should warn patients that severe physical pain, shortness of breath, blurred vision, changes in mental status, or any type of symptomatic response to exercise indicates they should immediately stop the exercise and seek help. Any individuals with chronic health

conditions should first speak with their primary care provider before starting a new physical activity routine.

Environment

Where individuals live determines their access to food, water, shelter, and clean air. Indoor and outdoor environmental factors influence 85 of the 102 categories of disease and injury listed in *The World Health Report* (WHO, 2016) and determine the disease-producing organisms and substances to which an individual is exposed.

Indoor environments may harbor toxic household cleaning agents, chemicals (e.g., radon, carbon monoxide, unused drugs), tobacco smoke, and energy sources. Exposure to mold, household pests (e.g., dust mites, spiders), inside cooking fumes, and unsanitary living conditions in an enclosed space increases the likelihood of respiratory illness and skin disorders.

Outdoor environments affect individual health in the areas of sanitation and waste disposal, water quality, air quality, and safety. Children living in areas where there are safety issues related to gang activity, sexual predators, or heavy traffic are less likely to engage in outdoor play activities. Their limited access to safe outdoor play space increases their risk for sedentary behaviors, excessive calorie intake, and obesity.

Nursing assessment is critical in identifying and minimizing modifiable environmental risks that can affect the health status of community members. Nurses familiar with community resources can have a dramatic impact on the health of individuals by making necessary referrals and exploring creative options with community members to minimize negative health factors. The role of the nurse in addressing environmental concerns is often as a change agent and advocate for people with limited financial and educational resources.

3. List nursing interventions to address each of M. W.'s preventable lifestyle-related risk factors that the nurse can discuss with M. W. before including them in an individualized plan of care.

Attitudes and Emotions

Individuals respond differently to illness or the threat of illness. Their attitudes, behaviors, and emotional reactions depend on the severity of the illness and its perceived impact on their health. An individual's unique illness behaviors are influenced by self-concept, opinions of peers and family, and cultural customs.

A short-term, self-limited illness that is not life-threatening does not evoke emotions or actions that cause fundamental changes in daily lifestyle. More often, illnesses such as the flu, ear infections, and sore throats are viewed as minor irritations or inconveniences. They usually require a short-term adjustment in daily routines, and treatment of symptoms is the priority so that the individual can continue with normal activities. The emotional and behavioral changes associated with non-life-threatening illness are usually minimal, and the individual quickly returns to the previous baseline level of emotional functioning.

Chronic, debilitating disease and severe illness can produce a broad range of emotional or behavioral responses in patients and their families. Patients commonly react to the diagnosis of a disease or disorder with a poor prognosis with shock and feelings of numbness or bewilderment. Shock may soon be replaced by anger, denial, anxiety, and withdrawal from others. Emotional responses may be heightened in people who previously had controlled reactions to stressful situations.

After assessment and diagnosis of emotional distress, nurses can plan interventions in collaboration with patients and their families to help identify coping mechanisms and support systems that are appropriate to each situation. Identification and mobilization of patients' support networks help the patients and their families deal with the crisis of severe illness. Interventions that promote stress reduction and encourage positive behaviors are essential to healing. To promote positive patient outcomes, nurses must use their therapeutic communication skills when patients express concerns and wish to discuss their treatment options.

Self-Concept

Self-concept refers to the way in which individuals perceive unchanging aspects of themselves, such as social character, cognitive abilities, physical appearance, and body image. It is a mental image of self in relation to others and the surroundings. If the image is positive, the person will develop strengths, compensate for weaknesses, and experience life in a healthy way. If the image is negative (e.g., frail), the person will find life's challenges devastating and sometimes

insurmountable. The impact of illness on the self-concept of a patient and the patient's support persons depends on how secure the parties' relationships are with one another.

Changed behaviors that may reflect altered self-concept when a person is faced with a severe or terminal illness range from minimally noticeable to extreme. Extreme shifts in behaviors may occur when the individual engages in an activity that was uncharacteristic before the illness, for example, a patient diagnosed with terminal cancer who takes up skydiving despite a long-held fear of heights. Family, friends, and peers may be confused by the deviation from characteristic behaviors, including unmet social obligations, interpersonal tension, and increased interpersonal conflict.

Nurses coordinating care for patients with end-stage disease must learn to recognize subtle and blatant changes in self-concept. The nurse can assist patients and their loved ones in developing effective coping strategies to adapt to differences resulting from alterations in health status.

Developmental Level

Intellect and behavior can be attributed to genetic traits and environmental stimuli. An individual's developmental level, as characterized by mastery of expected milestones and interactions with surroundings, reflects more than chronologic age and physical size. The developmental level depends on a person's ability to reason and learn from life experiences in predictable stages at age-appropriate intervals. When planning care, the nurse must create strategies and integrate activities that conform to the patient's cognitive level of development to achieve a specific outcome.

For many years, sociologists focused primarily on the rapid physical and cognitive growth of children and adolescents during development. Recent research has focused on adult developmental changes because people are living longer and are exposed to illnesses and age-related changes that few individuals in previous centuries lived long enough to experience.

The concept of illness is different at each level of development. Fear and anxiety are common and appropriate traits for children and adults. The impact of disease may be beyond the ability of a child or developmentally delayed adult to comprehend. Painful procedures and fear of the unknown are often part of treatment. Patients may associate the white coat of a health care provider with pain, anxiety, or unwanted physical touch. Knowledge of the individual's developmental level helps the nurse plan care according to the patient's expectations and ability to participate.

Influence of Peers and Family

The value that friends and family place on health status can positively or negatively influence the health of an individual. Typically, the developmental level of the patient determines whether peers or family members have more influence. Children and adults tend to be affected more by family members, whereas adolescents may be influenced more by their friends.

Regardless of the age of the patient, family is the principal collective framework for health promotion and disease prevention. Families weigh health choices and care decisions in each situation of illness according to beliefs, values, and their way of life. Family members typically use health care resources in similar ways, and health practices follow the norms established by parental influence over minors. In some cases, parental figures can send mixed messages about health issues. Consider the parent who drives home intoxicated after telling the children not to drink and drive or the parents who accept the use of recreational drugs in their home because they would rather have their children use drugs where they can monitor them.

Peers and generational norms influence the health behaviors and risk-taking attitudes of adolescent patients. Encouraging open communication and nonjudgmental attitudes among parents or trusted adult authority figures regarding the adolescent patient's health issues is a high-priority educational opportunity for nurses. Peer influence affects adolescent risk behaviors but tends to have less impact on health care matters.

Nurses should stress the importance of parental or adult supervision of adolescent health care. Nurses need to openly discuss family lifestyle and preventive health issues with each family member. Supporting families and assisting parents with coping techniques when dealing with devastating illness or tragedy is a vital aspect of nursing care. It is accomplished by being a good listener and observer and being attentive to emotional cues (Box 16.6). Teaching families to adhere to good health and wellness habits helps members feel positive and productive.

Box 16.6

Child and Adolescent Reactions to Trauma and Loss

- *Preschoolers:* Thumb sucking, clinging to parents, bedwetting, sleep disturbances, fear of the dark, loss of appetite, regression in

behavior, and withdrawal from friends and routines.

- *Elementary school children*: Poor concentration, irritability, aggressiveness, clinging to parents, nightmares, school avoidance, and withdrawal from friends and activities.
- *Adolescents*: Agitation, sleeping and eating disturbances, increased conflicts, physical complaints, delinquent behavior, and poor concentration.

From the [National Association of School Psychologists. \(2016\)](https://www.nasponline.org/resources-and-publications/resources/school-safety-and-crisis/addressing-grief). Helping children deal with tragic events in unsettling times: Tips for parents and teachers. Retrieved from <https://www.nasponline.org/resources-and-publications/resources/school-safety-and-crisis/addressing-grief>.

4. Identify at least three family factors that place M.W. at risk for additional concerns.

Traditions, Beliefs, and Values

Cultural traditions, spiritual beliefs, and the value an individual places on ethnic heritage greatly influence illness behaviors and therapeutic practices. Some people have ethnic practices or religious beliefs that nurses must consider before treatment or diagnostic procedures are performed. For instance, a patient may observe a day of fasting for religious reasons despite the detrimental effects the lack of nutrients has on the disease process.

Religious and cultural practices sometimes are contrary to medical treatment to the point that life-and-death issues become secondary to beliefs. Patients make health care decisions based on cultural background and religious beliefs, and it is the patient's right to accept or refuse medical therapies. To improve adherence with prescribed treatments, nurses should incorporate patients' religious and cultural views into the plans of care.

Health Care Access and Availability

Gaining access to any type of health care can be an intimidating task for healthy and sick individuals. Socioeconomic factors can compound the need for care if it is not affordable. For individuals or families deciding whether to seek treatment, the cost may be a less significant issue than the availability of health care. People living in isolated or less densely populated areas may have little or no access to health care providers or facilities within a reasonable distance. The circumstances affecting access to care may confound nurses' attempts to assist patients to adhere to therapy, including medication, diagnostic test schedules, and follow-up appointments.

The economic stability of individuals or families can determine whether they are willing to seek preventive care or screening examinations. Even if screening is free or low cost, the patient or family members may decline because of the potential for testing positive for a disease. Treatment of a disorder often requires time spent away from work, lost wages, transportation and child care costs, and expensive drug therapies and diagnostic tests. The financial impact can be devastating to families or individuals who have a limited or fixed income and fear that employment stability may be compromised.

Diminished availability of care has a major impact on the health and wellness of the people residing in rural areas and less densely populated regions. The length of time it takes to travel to the nearest health care provider or facility can inhibit patients from seeking care for illness or initiating preventive measures. For example, treatment can be delayed for so long that a minor, non-life-threatening, treatable infection becomes a severe, life-threatening, systemic infection requiring hospitalization and intravenous drug therapy.

Patients who must drive long distances to seek medical care and treatment often bring the entire family for evaluation. During visits, it is not uncommon for the health care provider to address multiple problems with different degrees of severity that have been "saved up" for the long trip. This puts the nurse in an advantageous position to assess the needs of the patient and the family in one visit. The nurse can perform detailed examinations and engage many family members in long-term strategies to address issues of health and wellness.

Urban settings often have more highly specialized health care systems but may lack the availability of primary and preventive care venues. Challenges to meeting personal health needs in urban communities center on poor air quality, crowded living and working conditions, and decreased access to exercise and recreational activities because of availability and safety issues. In these instances, nurses are instrumental in identifying barriers to health maintenance habits and routines. Finding opportunities to maximize health access for patients living in

urban areas can include adding an air-purifying system to an existing air-conditioning unit; reinforcing the necessity and technique of good hand hygiene, especially during seasonal outbreaks of illness; and encouraging exercise routines that accommodate the buddy system or group activities during daytime hours.

The Institute of Medicine ([IOM, 2011](#); now the National Academy of Medicine [NAM]) report, *The Future of Nursing: Leading Change, Advancing Health*, calls for nurses to be full partners in transforming health care in the United States. Nurses have the responsibility and the expertise to help educate, enable, and encourage people of all ages to adopt healthier lifestyles and become proactive about health care practices that can prevent or minimize illness and disease. Day to day, nurses continue the commitment of contributing to the wellness of patients, families, and communities by supporting initiatives, programs, and projects that promote a culture of health and self-care, which improves patients' quality of life.

Summary of Learning Outcomes

LO 16.1 *Define the concept of health in an individual and a corporate context:* Individuals define health in terms of their values, experiences, and ways of living. Organizations and businesses define health in the context of their goals and objectives.

LO 16.2 *Compare the theoretical models of health and wellness that provide the basis for nursing practice:* The Basic Human Needs Model, Health Belief Model, Health Promotion Model, and holistic health models provide a foundation for defining optimal physiologic and mental status while approaching health care delivery from different viewpoints.

LO 16.3 *Discuss health promotion and its relationship to wellness:* The concepts of health promotion, wellness, and risk reduction are interconnected with a person's motivation and goals for achieving a predetermined level of health.

LO 16.4 *Explain the three levels of preventive care and the nursing interventions associated with each:* Health promotion and specific protection strategies are two examples of appropriate ways in which nurses can work with their patients in primary prevention. The goal for health intervention during secondary prevention is early detection and diagnosis of health problems before patients exhibit symptoms of disease. Nursing care is focused on rehabilitation efforts in the tertiary stage of prevention.

LO 16.5 *Summarize key aspects of each type of illness and the stages of illness behavior:* Acute illness is typically characterized by an abrupt onset and short duration (<6 months), with clinical manifestations

that appear quickly, may be severe, and resolve within a short period because they respond to treatment or are self-limited. Chronic illness is any condition in which a loss or abnormality of body function occurs that lasts longer than 6 months and requires ongoing, long-term care. Chronic health conditions may be controlled with lifestyle management or drug therapy, but they are considered to be irreversible. Stages of illness may progress from the acceptance of being ill to the resumption of previously assumed roles and activities.

LO 16.6 *Identify factors influencing health and their impact on illness:* Many factors influence health and illness, including social determinants of health such as age; gender; availability of and access to health care; cultural, spiritual, and ethnic considerations; attitudes; monetary resources; environmental factors; genetics; lifestyle choices; self-concept; and health policies.

Review Questions

1. Which of the listed basic needs identified by Maslow must be addressed first when providing nursing care?
 - a. Self-esteem
 - b. Love and belonging
 - c. Self-actualization
 - d. Nutrition and elimination
2. Which activity best illustrates the use of the Health Promotion Model (HPM) by the nurse to increase the level of well-being for a patient immediately after surgery?
 - a. Holding a pillow across his chest when coughing and deep breathing
 - b. Encouraging the patient to eat his entire evening meal
 - c. Changing his surgical dressing daily as ordered by the physician
 - d. Asking his family to step out of the room during dressing changes
3. A nurse providing preventive care to an overweight patient with a family history of diabetes should engage in which priority care-planning activity for this patient?
 - a. Calculating the patient's body mass index (BMI) and recommending a daily exercise routine
 - b. Instructing the patient to perform blood glucose monitoring once daily

- c. Giving the patient a month's supply of insulin needles and syringes
 - d. Suggesting the patient participate in diabetes education classes offered at a local health facility
4. An active older patient has been frequently evaluated for minor problems at the clinic since the death of her husband 3 months earlier. During one of her visits, she states that she has no energy to get through the day and no desire to keep up with her Tuesday night bridge club. Which type of holistic health model intervention should the nurse employ to help the patient cope with the loss of her husband?
- a. Encouraging prn use of antianxiety medication ordered by her provider
 - b. Sharing the value of music therapy to address anxiety about her loss
 - c. Explaining that she will be over the loss of her husband in a few months
 - d. Encouraging a gradual reentry into social interaction and activities with friends
5. An 8-year-old girl is newly diagnosed with type 1 diabetes. The nurse may expect fear and crying when teaching the child how to self-administer insulin injections due to which influencing factor?
- a. Self-concept
 - b. Self-esteem
 - c. Developmental level
 - d. Hierarchy of needs
6. Three weeks after delivery, a patient started a diet of 800 calories per day and started jogging 2 miles twice

per day. The nurse recognizes the patient's behavior may be most influenced by which motivating factor?

- a. Body image
 - b. Environment
 - c. Illness behavior
 - d. Chronic illness
7. A 65-year-old male patient has been a one-pack-per-day smoker for 40 years. He was recently diagnosed with chronic obstructive pulmonary disease (COPD) and would like to attend a smoking cessation class. The nurse recognizes smoking cessation as which level of prevention for this patient?
- a. Primary prevention
 - b. Secondary prevention
 - c. Statutory prevention
 - d. Tertiary prevention
8. A patient diagnosed with an aggressive cancer is estimated to have 6 months to live. Two months later, the patient's wife calls the nurse's office because she is upset that her husband has taken up motorcycle racing and has already been injured twice. The nurse knows that the patient is experiencing a behavioral change in which factor due to the prognosis of his illness?
- a. Spirituality
 - b. Physical attributes
 - c. Self-concept
 - d. Personal affect

9. The nurse enters a patient's room and notices that the patient has not been out of bed since the previous day. The patient states that his condition has made him bedridden, although the nurse knows that he is capable of independent ambulation. Which type of reaction is the patient exhibiting?
- a. Ambivalence to symptoms
 - b. Illness behavior
 - c. Diminished functional ability
 - d. Overreaction to illness
10. A patient is seeking information about leading indicators that show the importance of health promotion and illness prevention in the United States. To which government-sponsored resource would the nurse refer the patient for the best comprehensive source of information?
- a. The American Cancer Society website
 - b. The *Healthy People 2020* website
 - c. The Centers for Disease Control and Prevention (CDC) *Morbidity and Mortality Weekly Report*
 - d. The American Association of Hospitals home page

UNIT IV

Nursing Assessment

OUTLINE

Chapter 17 Human Development Conception Through Adolescence

Chapter 18 Human Development Young Adult Through Older Adult

Chapter 19 Vital Signs

Chapter 20 Health History and Physical Assessment

Chapter 21 Ethnicity and Culture

Chapter 22 Spiritual Health

Chapter 23 Community Health, Public Health, and Home Health Care

Chapter 24 Human Sexuality

CHAPTER 17

Human Development

Conception Through Adolescence

LEARNING OUTCOMES

Comprehension of this chapter's content will provide students with the ability to:

- LO 17.1 Describe major theories of human development.
- LO 17.2 Explain human development from conception to birth.
- LO 17.3 Identify the primary developmental tasks of the newborn.
- LO 17.4 Outline infant developmental milestones.
- LO 17.5 Describe the physical, psychosocial, and cognitive development of the toddler.
- LO 17.6 Summarize growth and development during the preschool years.
- LO 17.7 Discuss development that occurs during the school-age years.
- LO 17.8 Articulate physical, psychosocial, and cognitive adolescent development.

KEY TERMS

accommodation, p. 231

adaptation, p. 231

assimilation, p. 231

centration, p. 232

conception, p. 234
conservation, p. 232
continuous theories, p. 228
development, p. 228
discontinuous theories, p. 228
ego, p. 228
egocentric, p. 232
embryo, p. 234
equilibration, p. 231
fetus, p. 234
growth, p. 228
id, p. 228
nature versus nurture, p. 228
negative reinforcement, p. 233
object permanence, p. 232
operant conditioning, p. 233
positive reinforcement, p. 233
puberty, p. 242
reversibility, p. 232
seriation, p. 232
superego, p. 228
zygote, p. 234

Case Study

Four-year-old Ella Mendez (E. M.) is admitted to the pediatric unit for dehydration related to diarrhea from gastroenteritis. Vital signs are: T 39.6° C (103.3° F), P 137 and regular, R 28 and unlabored, BP 80/45, and weight 15.5 kg (34 pounds). She had been taking sips of electrolyte solution orally at home but is now lethargic. Her skin and mucous membranes are dry. Her mother is with her, and her father is at home with her siblings. Her mother states that E. M. has had multiple episodes of diarrhea at home today, but she is unsure about urine output. Her mother explains that E. M. is toilet-trained, but the diarrhea has caused her to be incontinent numerous times. Her mother also states that E. M. sleeps in a youth bed at home. Her immunizations are up to date. Her admission history is negative for any major illnesses, and she has met all of her developmental milestones, including walking at 13 months, being toilet-trained at 2 years 3 months, and speaking in full sentences. She attends preschool two times per week.

Refer back to this case study to answer the critical-thinking questions throughout the chapter.

The terms *growth* and *development* are closely related but differ as follows: **Growth** is the process by which an increase in size occurs, measured in humans as height and weight. Growth proceeds in an orderly, predictable pattern, from head to tail (cephalocaudal) and in a proximal to distal (near to far) direction. **Development**, on the other hand, is the increasing maturation of physical ability, thought processes, and behaviors over time. The focus of this chapter is development from conception through the teen years.

LO 17.1 Theories of Human Development

Over the years, many theories have been written about how children develop. From these theories emerged a major debate regarding whether development is predetermined at birth (nature) or whether the child's environment (nurture) controls how development progresses ([nature versus nurture](#)). At present, many developmental experts agree on a middle-of-the-road approach to this debate, believing that a combination of environment and heredity affects the developmental process.

Schools of thought also debate whether development is continuous or discontinuous. [Continuous theories](#) of development subscribe to the belief that development occurs in a smooth and gradual process from infancy to adulthood. [Discontinuous theories](#) describe development as progressing through a series of distinct and predictable stages triggered by inborn factors. As in the nature-versus-nurture debate, most modern theorists acknowledge that both inborn and external factors influence development.

Psychosocial Theories

Certain events in the lives of humans, such as the decision to marry, occur when a person has reached the psychological and social maturity to make such a decision. This maturity is achieved in part as an internal process of maturation and in part is influenced by social and cultural norms. Psychosocial theorists who have attempted to explain this process are Sigmund Freud, Erik Erikson, and Robert Havighurst.

Freud's Theory

[Freud \(1923/1974\)](#) viewed the mind as mostly unconscious. He compared the mind to an iceberg, with the majority of it below the surface in the unconscious, rather than conscious, realm. He believed that there were three basic components to the personality: the id, ego, and superego. The [id](#) is the part of

personality consisting of instincts. The id operates on a totally unconscious level and is not centered in reality. The id functions by seeking out pleasure and avoiding pain. According to Freud, very young children start out functioning at the id level. However, as children mature, the ego part of the personality is formed. As children experience the demands of real life, they learn that they must make decisions on the basis of rational rules and not just for pleasure. The **ego** is the part of the mind that functions in reality. It allows people to seek out pleasure within the norms of society. The ego is partially conscious. However, the id and the ego do not consider right or wrong. The **superego** is the structure that houses the “moral” branch of personality. It often is referred to as the *conscience*. The superego is partially conscious. In considering a moral dilemma, the superego is the structure that makes us think about whether an action is right or wrong.

In addition to theorizing on the structures of personality, Freud conceptualized five stages of psychosexual development in childhood. The ability of the child to progress successfully through these stages determines whether the person will be a well-adjusted adult. These stages are the oral stage, the anal stage, the phallic stage, the latency stage, and the genital stage (Table 17.1).

TABLE 17.1
Freud's Stages of Psychosexual Development

Age Range	Stage	Behaviors	Conflict
Birth to 18 mo	Oral	Mouthing, chewing, sucking, biting	Weaning
18 mo to 3 yr	Anal	Bowel elimination	Toilet training
3 to 6 yr	Phallic	Genital stimulation	Triggering of Oedipus/Electra complex
6 yr to puberty	Latency	Sexual urges sublimated into other social activities; friends of the same sex	Avoiding stress of conflicts
Puberty and beyond	Genital	Sexual reawakening, sexual gratification	Revisiting previous unresolved conflicts with parents

Oral Stage

The oral stage is the period of life from birth to 18 months. During this stage, the child gains pleasure primarily from the mouth area. Chewing, sucking, and biting are all activities believed to reduce tension during this phase.

Anal Stage

The anal stage is the time between 18 months and 3 years of age. The primary source of pleasure and tension release at this phase is the anus and eliminative functions associated with it. It is during this stage that many children learn bowel and bladder control.

Phallic Stage

Freud believed that the phallic stage extends between the ages of 3 and 6 years. Pleasure at this stage centers on the child's discovery that self-stimulation is enjoyable. Freud viewed the phallic stage as an important stage in personal development because this stage triggers the Oedipus complex. The Oedipus complex is the strong attachment the young male child develops to the parent of the opposite sex. The Electra complex is the same feeling in the female child. Freud believed that the child wants to replace the same-sex parent so as to gain the exclusive attention and affection of the opposite-sex parent. He theorized that later during the phallic stage, the child begins to fear punishment by the same-sex parent for this feeling. The child then begins to identify with the same-sex parent, to reduce this conflict.

Latency Stage

According to Freudian theory, between the age of 6 years and the onset of puberty, the child experiences the latency stage, during which all interest in sexuality is repressed. The child puts energy into emotionally safe activities, thereby avoiding the stress of the conflicts experienced in the phallic stage.

Genital Stage

The genital stage extends from puberty onward, and it is the fifth and final stage in Freud's theory of development. During this stage, sexual feelings are reawakened. Previous conflicts with parents that were unresolved from earlier stages of development reemerge. When these conflicts are resolved, the individual becomes able to develop mature adult relationships.

Erikson's Theory

Erik Erikson (1963) was trained by Freud as a psychoanalyst. He developed a theory of psychosocial development adapted from Freud's theory. Erikson believed that as people grow, they face a series of psychosocial crises that shape their personality. This series of psychosocial crises is divided into eight stages: trust versus mistrust, autonomy versus shame and doubt, initiative versus guilt, industry versus inferiority, identity versus role confusion, intimacy versus isolation, generativity versus stagnation, and integrity versus despair (Table 17.2). Nurses, particularly in psychiatrics, utilize these stages to assess whether an individual is in the appropriate state for their age, or whether progression has been delayed based on social behaviors observed.

TABLE 17.2**Erikson's Developmental Stages**

Age Range	Stage of Psychosocial Crisis	Behavior	Resolution of Crisis
Birth to 18 mo	Trust versus mistrust	Caregiver must meet all needs of the child.	Develop a sense of trust in others by having needs met.
18 mo to 3 yr	Autonomy versus shame and doubt	Child strives to make decisions for himself or herself.	Achieve a balance between holding on and letting go.
3 to 6 yr	Initiative versus guilt	Child explores his or her world and abilities (running, jumping, throwing).	Initiate activities without fear of reprimand from caregivers.
6 to 12 yr	Industry versus inferiority	Child refines skills acquired previously and develops a peer social network that exerts great influence on him or her.	Develop a sense of self-worth based on accomplishments while avoiding feelings of failure.
12 to 18 yr	Identity versus role confusion	Adolescent explores and integrates multiple roles: student, athlete, child, adult. Emotional fluctuation and stress are common as the adolescent struggles to sort out his or her identity.	Emerge from the stage with a strong sense of individuality.
18 to 35 yr	Intimacy versus isolation	Person searches for a partner who supports and complements him or her. Starting a family is common.	Seek fulfilling love and family relationships.
35 to 55 yr	Generativity versus stagnation	Person seeks involvement in creative and meaningful work and transmits culture and values to younger generations.	Develop a sense of self-worth as children leave the home.
55 yr and beyond	Integrity versus despair	Person reviews life events and accepts the finality of death.	Achieve a sense of fulfillment over life's accomplishments.

Trust Versus Mistrust

The first of Erikson's stages is trust versus mistrust, which extends from birth to the age of 18 months. During this phase, the consistent caregiver plays an important role in meeting the affection and food needs of the child. If the caregiver is inconsistent or unable to meet these needs, the child becomes

frustrated and develops a sense of mistrust in those around him or her. Children who do not have a consistent caregiver during this phase may have difficulty with emotional attachments at later stages in life.

Autonomy Versus Shame and Doubt

The second stage extends between the ages of 18 months and 3 years. In autonomy versus shame and doubt, the child has begun to walk and to speak in basic terms. Children in this stage strive to do things for themselves. The conflict lies in children's dual desires to hold on and to let go. The parents' role at this stage is best served by providing flexible but firm guidance, thereby allowing autonomy while providing safety and security. The child is given choices within reasonable boundaries. With parents who are overly controlling and restrictive, children may develop a sense of shame and doubt in their own abilities.

Initiative Versus Guilt

Between the ages of 3 and 6 years, the child is in the stage of initiative versus guilt according to Erikson. In this stage, children's maturing physical and verbal abilities encourage them to expand their world. Families can best encourage this sense of initiative by allowing children to run, jump, play, and throw. Children at this time are exploring what kind of people they may become. Parents who limit their children's attempts at initiative cultivate a sense of guilt in children during this stage that may persist into later life as well.

Industry Versus Inferiority

Industry versus inferiority is the stage that encompasses the ages of 6 to 12 years. When children enter school, their social realm expands. Peers and teachers take on more importance, while parental influence decreases. Children in this stage take great pride in accomplishments. Failure, whether incurred in a real sense or through an inability to meet one's own expectations, can lead to a sense of inadequacy or inferiority. It is the responsibility of parents and other adult role models to help children understand what constitutes success and failure.

Identity Versus Role Confusion

Erikson's fifth stage of development is identity versus role confusion, which coincides with adolescence. During this stage, the teen attempts to determine a sense of who he or she is. This stage is experienced as a time of great change. Not only is the body undergoing major physical changes, but pressures are emerging for the young person to make decisions about future education and career choices. Teens typically experiment with different sexual, occupational, and educational roles while they try to develop a sense of identity as they approach adulthood. When adolescents fail to figure out their sexual, occupational, or educational path, conflict results.

Intimacy Versus Isolation

On entering the phase of intimacy versus isolation, the young adult has achieved a sense of identity and has set a path for where he or she is going. The main task of this phase is to develop an intimate and trusting relationship with another person. The ideal relationship should complement the individuality of each partner without stifling growth. People who fail at developing such a relationship may retreat into isolation.

Generativity Versus Stagnation

Generativity versus stagnation is the stage of middle adulthood. Generativity can be accomplished by successfully rearing one's own children or by engaging in other activities that promote creativity and productivity. If the person fails to grow during this phase, the result may be stagnation with self-absorption (egocentric behavior) and self-indulgence.

Integrity Versus Despair

Erikson's eighth and final stage, integrity versus despair, begins with late adulthood, when the person looks back over his or her lifetime and resolves any final identity crisis. Accomplishments must be reconciled with failures and limitations for the person to develop a sense of integrity. The finality of death must be accepted. A person who fails to do so risks developing a sense of despair and regret over the way his or her life has turned out.

1. According to Erikson, what is E. M.'s stage of development? How might hospitalization affect her in this stage? What can be done to encourage continued development?

Havighurst's Theory

Robert Havighurst (1972) is credited with identifying the concept of developmental tasks. Havighurst's theory defines a developmental task as one that arises during certain periods in life. Successful achievement of the task allows the person to move on toward new experiences and challenges. Failure to accomplish such tasks can lead to feelings of inadequacy and failure in achieving future developmental tasks. The three sources from which developmental tasks arise are physical changes, personal sources, and societal pressures. Havighurst identifies six major age periods, each with its own developmental tasks (Table 17.3). See Chapter 18 for detailed information on adult development.

TABLE 17.3**Havighurst's Stages of Development**

Stage	Tasks
Infancy and early childhood	Taking food, learning to talk, and learning sex differences and sexual modesty
6 to 12 yr	Learning to get along with age-mates, developing a sense of conscience and morality, and achieving personal independence
12 to 18 yr	Preparing for marriage/relationship and a career, acquiring a set of values, and achieving socially responsible behavior
Early adulthood (19 to 29 yr)	Selecting a partner, starting a family, managing a home, establishing a career, and assuming civic responsibilities
Middle adulthood (30 to 60 yr)	Fulfilling civic and social responsibilities, maintaining a standard of living, assisting children into adulthood, adjusting to aging parents, adjusting to physiologic changes
Late adulthood (61 yr and beyond)	Adjusting to physiologic changes and health status changes associated with aging, adjusting to retirement and altered income, establishing living arrangements, and fulfilling civic and social responsibilities

Cognitive Development Theory

Cognitive development theory addresses how the process of thought develops in humans. Mental activities addressed in these theories include thinking, remembering, and developing language. The primary theorist in cognitive development is Jean Piaget.

Piaget's Theory

Jean Piaget (1969) was educated as a biologist but later became interested in psychology. His background in biology influenced his views on the process of cognitive development. He theorized that children progress through four stages (described next). He also believed that young children develop patterns of behavior called *schemes* (adaptation, assimilation, accommodation, and equilibrium), which older children and adults use to deal with objects in the environment. **Adaptation** is the process of adjusting behavior in response to stimuli within the environment. The

person adapts by using assimilation and accommodation. With **assimilation**, the child attempts to use a new object in the same way as that applied with more familiar objects. A young child encountering a tomato for the first time, for example, displays assimilative behavior in grasping it, saying “ball,” and then squeezing it—the child perceives a familiar toy and a tomato as identical in terms of size and shape. **Accommodation** occurs when the child discovers that the tomato cannot be played with in the same way as a more familiar toy ball. The child finds that the tomato bursts when squeezed; the child accommodates this discovery by changing the pattern of behavior on subsequent encounters with new, similar objects.

Equilibration is the process by which a balance between present understanding and new experiences is restored. Piaget believed that this process is critical to cognitive development. When equilibration is upset, the child has the opportunity to learn and grow. From the disequilibrium, new ways of thinking and dealing with the environment develop, preparing the child to progress to the next stage of development.

Sensorimotor Stage

As noted, Piaget described four distinct stages of development (**Table 17.4**). The first of these is the sensorimotor stage, extending from birth to 2 years of age. Children in this stage explore their environment by using their senses and developing motor skills. Initially, infants interact with the environment primarily through reflexes. For example, if a parent puts an object into the infant's hand, the infant will reflexively grasp it. As the child grows, however, learning occurs, and reflexes are controlled to produce desirable effects. Gradually, trial-and-error behaviors are replaced by planned behaviors. The child becomes capable of simple problem solving.

TABLE 17.4**Piaget's Stages of Development**

Age Range	Stage	Behaviors
Birth to 2 yr	Sensorimotor	The child explores the environment by using the senses.
2 to 7 yr	Preoperational	The child begins to use images and symbols to represent the world; is still unable to repeat mentally what he or she can do physically.
7 to 11 yr	Concrete operational	Logical reasoning gradually replaces intuitive thought.
11 yr and beyond	Formal operational	The person refines his or her ability to think logically; is capable of abstract thought.

Children at this stage develop an understanding of the concept of **object permanence**. Early on, children do not understand that something still exists when it is out of sight. For example, if a parent covers a toy with a blanket, the child does not understand that the toy is still there. By the age of 2 years, the child understands that the toy still exists even when it is out of sight. Attainment of this ability is key to development toward more advanced thinking skills.

Preoperational Stage

The preoperational stage encompasses the preschool and early school-age years, between the ages of 2 and 7 years. During this stage, children acquire the use of symbols to represent objects. This ability allows language skills to grow rapidly. However, other thinking skills are not yet developed. Children at this age still lack an understanding of the concept of conservation.

Conservation is the ability to recognize that objects remain the same even if they change in appearance. The child can focus on only one aspect of a dilemma. For example, if the preoperational child is confronted with two 6-ounce glasses of water, one tall and narrow and one short and wide, the child typically will insist that the taller glass contains more water. The child focuses only on the height of the glass as an indication of volume. Likewise, the child may think a cookie broken into two pieces is more than the same cookie in one piece. By focusing on only one aspect of an object, the child is exhibiting **centration** in his or her thought process.

Preschoolers demonstrate irreversibility in their thinking patterns. **Reversibility** is an important development in thinking patterns that enables older children and adults to change direction in their thinking to return to the starting point. If the preschooler had the ability of reverse thinking, he or she would understand that 6 ounces of milk initially poured into a tall narrow glass can then be poured into the short glass—mentally reversing the pouring process and accepting the implication that the volumes in the glasses are the same.

The preoperational stage is characterized by **egocentric** thinking. Children in this stage believe that everyone else sees the world exactly as they see it. They tend to interpret situations and events in terms of their own perceptions. For example, when these children are asked to describe a toy, they typically define the toy in terms of how they use it. When asked to describe a ball, the preoperational child may say, “I throw it.”

Concrete Operational Stage

The concrete operational stage extends between the ages of 7 and 11 years—that of the school-age child. At this stage, the child develops the ability to think logically and has acquired an understanding of conservation. The child's thinking is still grounded in familiar situations and concrete objects, however, and is not yet capable of abstraction.

One important skill that develops at this age is **seriation**, the ability to arrange things in a logical order. To do this, the child must be able to sort and classify objects using some criterion or characteristic. School-age children enjoy sorting and classifying objects and often have collections of a variety of items. Children in this age-group are moving from egocentric to decentered or objective thought, which allows them to view things from another's perspective.

Formal Operational Stage

Around the time of the onset of puberty, the child's thought patterns begin to take on adult characteristics. The child develops the ability to think abstractly and to problem-solve in a more systematic fashion than that seen in a child in the concrete operational stage. Adolescents in formal operations can reason about hypothetical situations and are not restricted to situations in

which they have experience. This ability to think abstractly and to form and test a hypothesis in a systematic fashion continues into adulthood, although it is thought that some people may never fully function in this stage.

2. According to Piaget, what is E. M.'s cognitive stage? What appropriate nursing care can be included that takes E. M.'s cognitive stage into account during her hospitalization?

Moral Development Theory

Moral development refers to how children develop a sense of right and wrong. As children develop, they internalize values and cultural norms that provide a framework for decisions later in life. Lawrence Kohlberg developed his theory of moral development on the basis of the cognitive theory of Jean Piaget and others.

Kohlberg's Theory

[Kohlberg \(1987\)](#) theorized that people progress through three levels of moral reasoning as they develop ([Table 17.5](#)). Each level is divided into sublevels, called *stages*. According to Kohlberg, reasoning is the important part of the process, not the end decision. Kohlberg believed that the person cannot comprehend or function at higher levels until he or she works through the lower levels.

TABLE 17.5**Kohlberg's Stages of Moral Development**

Level	Stage	Behaviors
Preconventional level	Stage 1	<i>Obedience and punishment orientation:</i> Rules are imposed by others, and punishment is to be avoided.
	Stage 2	<i>Individualism and exchange:</i> Judgments are guided by values of exchange, with the person's own wants and needs taking priority.
Conventional level	Stage 3	<i>Good/bad orientation:</i> The person is motivated by wanting to meet expectations of parents and other close family members; in return, the person receives love, respect, and admiration.
	Stage 4	<i>Law and order orientation (doing what is right, respecting authority, maintaining the social order):</i> The focus is on meeting the needs of society and doing one's duty in order to maintain social order. Many adults do not progress beyond this stage.
Postconventional morality	Stage 5	<i>Social contract and individual rights:</i> The person recognizes the need for order in society but is able to examine rules and respect the differing views of others.
	Stage 6	<i>Universal principles:</i> The person is able to ponder and identify universal principles of justice that are applicable to all. Most people do not consistently achieve this level of moral reasoning.

3. How might E. M. view why her illness happened to her from a moral standpoint?

Faith Development Theory

Whereas moral development involves *how* the person makes moral decisions, faith development is the *way* in which a person develops spiritually. Kohlberg and others did not focus on the development of religious beliefs. However, theorists (such as

Westerhoff) did address the process of a person's committing to a set of religious beliefs.

Westerhoff's Theory

John Westerhoff described a process of faith development. Faith, according to [Westerhoff \(2012\)](#), is a way of behaving that comprises knowing, being, and willing. He described four distinctive styles of faith through which a person may progress, given proper interactions and experiences: experienced faith, affiliative faith, searching faith, and owned faith ([Table 17.6](#)).

TABLE 17.6

Westerhoff's Theory of Faith Development

Stage	Age	Behavior
Experienced faith	Preschool and early childhood	The child explores, tests, observes, and copies adults. Children learn faith by what they see and experience from those around them.
Affiliative faith	Childhood and early adolescent years	The child acts with others in a community of faith, participating in community activities offered in youth groups, choirs, and service organizations.
Searching faith	Early adulthood	The person goes through three characteristic steps: doubt/critical judgment, experimentation, and commitment. These steps are needed to move from an understanding of community faith to ownership of faith.
Owned faith	Adulthood	The person attains full ownership of faith. Such people want to share their experience with others and are willing to stand up for their beliefs.

Behaviorist Theory

Behaviorist theory focuses on measuring observable behaviors that occur in response to stimuli. It is concerned not with how or why knowledge is obtained but with producing behaviors. Behaviorist theory focuses on the influences of the external environment on the person's behavior.

Skinner's Theory

B. F. [Skinner \(1953\)](#) believed that personality developed not as a result of inherited traits but as a result of the influences of the

external environment. He believed that operant conditioning influences the development of behavior. **Operant conditioning** is a form of learning based on reinforcement or punishment. **Positive reinforcement** occurs when a behavior is met with a positive consequence. **Negative reinforcement** occurs when a behavior is strengthened by removal of an unpleasant stimulus. Both types increase the chance that the behavior will be repeated.

Social Learning Theory

Social learning theory holds that people learn from observations, interactions, and imitation of others. It bridges concepts between behaviorist and cognitive theories.

Bandura's Theory

Albert **Bandura (1977)** believed that people learn from one another through their interactions, observations, and imitation of others. He theorized that there is a continuous interaction of cognitive, environmental, and behavioral influences. Bandura believed that four conditions are necessary for effective modeling of behaviors:

- *Attention*: Certain variables affect how much attention is given to a behavior. Some of these variables are the complexity of the situation and the personal characteristics of the observer of the situation.
- *Retention*: The ability to store the information that was given attention for later recall. Examples of tools used to aid retention are mental coding and symbolic images.
- *Reproduction*: The ability to reproduce the behavior at a later time.
- *Motivation*: The reason for imitating the behavior. Tradition, imagined incentives,

reinforcement, and punishment are motivators.

Bandura believed that the interaction of the environment and the person is what shapes behaviors. He termed this concept *reciprocal determinism*.

LO 17.2 Development From Conception to Birth

The process of physiologic development begins at conception and is ongoing, continuing up to death. It is predictable, proceeding in both cephalocaudal and proximal to distal directions. At times, growth occurs rapidly; at other times, it is slowed. Regardless of its speed, change in the human organism is occurring continuously.

Conception occurs with fertilization and implantation. The process of a sperm and an ovum uniting is called *fertilization*. The fertilized ovum is called a **zygote**, which begins as a single cell. Fertilization triggers a process of cell division. During the first 2 weeks, the developing zygote travels through a fallopian tube and into the uterus, where *implantation* into the uterine wall occurs. The period before implantation is the germinal period.

After 3 weeks, the zygote is known as an **embryo**. During this phase, the rate of cell differentiation increases and organs begin to form. By week 3, the neural tube that eventually becomes the spinal cord forms. The eyes appear at around 21 days, and by the 24th day, the cells of the heart begin to differentiate and soon will be beating rhythmically. By 8 weeks, an embryo weighs close to $\frac{1}{30}$ of an ounce and is approximately an inch long. Most of this rapid development occurs before many women realize that they are pregnant.

Two months after conception, an embryo is now called a **fetus**. The fetal period lasts until delivery of the infant. During this time, the fetus continues to grow and organs continue to mature. Weight increases to between 4 and 7 ounces and length to approximately 6 inches by 4 months (**Fig. 17.1**). By completion of the pregnancy between 37 and 41 weeks of gestation, the fetus has gained considerably more weight, and organs have matured enough to function outside the womb.

FIGURE 17.1 A fetus at 16 weeks of development.
(Copyright [Thinkstock.com.](https://www.thinkstock.com/))

The developing fetus is susceptible to a variety of substances from the outside environment called *teratogens*, or agents that can disrupt development. Teratogens include certain medications, illegal drugs, alcohol, radiation, and infectious agents. A pregnant woman's choices, health, and prenatal care have well-recognized impact on the developing fetus. Nurses should ask pregnant women about medications, drug use, alcohol use, tobacco use, and safe sex practices ([Box 17.1](#)). They also should ask pregnant women about the home and work environments, to screen for possible teratogens in these areas. Prenatal screening is discussed in [Box 17.2](#), and diversity concerns related to pregnancy are listed in [Box 17.3](#). Members of the health care team collaborate during prenatal care for the expectant mother ([Box 17.4](#)).

Box 17.1

Health Assessment Questions

Prenatal

Present Health

- What is your age?
- How many pregnancies have you had?
- What is your ethnic background?
- Do you drink alcohol? If so, how many drinks do you have per week?
- Do you smoke tobacco? If so, how many packs per day?
- Do you use any over-the-counter medications or herbal supplements? If so, what are they, and how much do you take?
- Do you use any illegal or street drugs?
- Where do you work? Are you exposed to any chemicals or radiation at home or at work?
- Do you have a cat? Who in the family is responsible for changing the litter box?
- What have you eaten in the past 24 hours? Is this a typical day's intake for you?
- Do you consume products with caffeine, such as coffee, cola, or chocolate?

Health History

- Have you ever had any infectious diseases, such as rubella?
- Do you have any health problems like diabetes or epilepsy?
- Are you taking any medications? If so, what are they and how often do you take each one?

Family History

- Are any of the following diseases present in your family: diabetes, heart disease, hypertension, stroke, respiratory problems, kidney problems, thyroid problems, bleeding disorders, epilepsy, or other disorders?
- Has anyone in your family had a child with a birth defect?

Box 17.2

Ethical, Legal, and Professional Practice

Prenatal Screening

- Fetal chromosome screening is recommended for all women, regardless of age, by the American College of Obstetricians and Gynecologists (ACOG).
- First-trimester screening includes a blood test to check for possible neural tube defects and for trisomy 21 (Down syndrome) (ACOG, 2017).
- An ultrasound examination is performed to check for fluid collection at the back of the fetus's neck. This nuchal translucency measurement may indicate the presence of chromosomal abnormalities, congenital heart defects, abdominal wall defects, diaphragmatic hernias, and other defects.
- More invasive procedures such as chorionic villus sampling and amniocentesis, along with genetic counseling, may be considered if the screening tests indicate a high risk for defects (ACOG, 2017).
- ACOG recommends second-trimester *quad screening*, a four-part test that detects neural tube defects, trisomy 18, and trisomy 21 with a high degree of accuracy. The timing of this test in the second trimester is important, because the levels of the substances measured change during pregnancy. These tests are combined with first-trimester screening for more accurate results (ACOG, 2017).
- Other testing includes complete blood count, blood type and Rh, rubella titer, tuberculosis (TB) skin testing (before 20 weeks of gestation), urinalysis, urine culture, renal function testing, and Papanicolaou (PAP) test. Testing for sexually transmitted infections such as those due to human immunodeficiency virus (HIV), *Neisseria gonorrhoeae*, and human papillomavirus (HPV) are completed at the first prenatal visit.
- A 1-hour glucose tolerance test is performed between 24 and 28 weeks of gestation to screen for gestational diabetes. If the

result is elevated, a 3-hour glucose tolerance test is ordered.

- At 35 to 37 weeks of gestation, a vaginal smear is obtained to check for group B streptococci.

Adapted from American College of Obstetricians and Gynecologists (ACOG), (2017). Prenatal Genetic Screening Tests. Retrieved from <https://www.acog.org/Patients/FAQs/Prenatal-Genetic-Screening-Tests>.

Box 17.3

Diversity Considerations

Life Span

- Pregnant women older than 35 years of age are at increased risk for having a child with Down syndrome. Women older than 35 have the option of screening tests that are offered to all pregnant women, or they can elect to have more invasive tests performed.

Culture, Ethnicity, and Religion

- Women of Eastern European and Ashkenazi Jewish descent are at increased risk for having children affected by Tay-Sachs disease. This is a fatal genetic lipid disorder. A simple blood test can identify carriers of the disease.
- Women of African, Southeast Asian, and Mediterranean descent are at increased risk for having children with red blood cell disorders, called *hemoglobinopathies* (such as, sickle-cell disease), and should have screening tests during pregnancy.
- Cultural diversity may encompass maternal diet, infant care beliefs, and cultural birth practices. It is important for the nurse to provide patient teaching that is culturally sensitive. The nurse helps parents plan ways to ensure a healthy pregnancy while honoring the family's cultural and religious beliefs.

- In discussions about prenatal screening, it is important to respect the patient's personal religious and cultural beliefs about the process. For example, some religions prohibit abortion for any reason.

Box 17.4

Interprofessional Collaboration and Delegation

Prenatal Care

Collaboration with other health care professionals may be necessary to offer the best care possible to the expectant mother.

- Referral to a dietitian is indicated when the pregnant woman is malnourished or suffering from hyperemesis. These disorders can adversely affect the developing fetus.
- Having a significant other or family member present at prenatal visits provides support for the expectant mother.
- Health care providers work closely together to provide referrals and support for smoking cessation and alcohol avoidance programs during pregnancy to avoid risks to the fetus that are associated with the use of tobacco or alcohol.
- Women who are older than 35 years of age, are pregnant with multiple babies, or have other medical conditions should be followed closely by their medical provider and may be referred to an obstetrician who specializes in high-risk pregnancies.

LO 17.3 Development During the Newborn Period

The newborn, or neonatal, period is from birth to 28 days of life (Fig. 17.2). The primary developmental task of the newborn is to adapt to the external environment. A full-term infant is born between 37 and 41 weeks of gestation. Some health concerns for newborns are infections, oxygenation, feeding difficulties, and safety issues. An infant is considered preterm if born earlier than 37 full weeks of gestation. Term births are further divided into subcategories of early term, term, and late term, given findings that demonstrate differences between a 37-week and a 41-week infant (Perry, Hockenberry, Lowdermilk, et al., 2014). Preterm infants are at increased risk for developmental delays and health problems, depending on gestational age at birth and birth weight, as well as other physical and socioeconomic factors. Sample health assessment questions for a newborn's office visit are listed in Box 17.5.

FIGURE 17.2 A full-term infant. (Copyright Shutterstock.com.)

Box 17.5

Health Assessment Questions

Newborn

When examining a newborn, it is important to ask the mother about her pregnancy.

- Were there any problems experienced during the pregnancy?
- Was the baby born early or on time?
- What was the method of delivery? If the baby was delivered by cesarean section, do you know the reason?
- Were any medications, drugs, alcohol, or tobacco products used during pregnancy?
- Is your baby breastfed or bottlefed? If bottlefed, what type of formula? Do you have to wake the baby to eat or does the baby awake on his own to eat? How long does it take the baby to eat?
- Can you tell me about the baby's eating patterns? bowel patterns?
- How about the baby's sleeping patterns?
- Does the baby seem to look at you?
- Does the baby startle when a loud sound occurs?
- Are you getting enough rest?
- Is the baby floppy (flaccid) when awake or is the baby wiggly?

Safe Practice Alert

Always use good handwashing technique when caring for newborns. Check facility protocols for additional requirements when entering and exiting newborn care areas.

Patient teaching during newborn visits is focused on helping parents with feeding, elimination, and sleep concerns. The nurse is a primary resource person for new parents, and a supportive atmosphere is important during this time.

LO 17.4 Infant Development

From 28 days after birth until 1 year of age, the child is considered an infant. Physical development progresses in a rapid yet sequential pattern. Physical growth progresses in cephalocaudal and proximodistal directions. At birth, the infant is dependent on the caregiver for everything from feeding to positioning. By 1 month of age, babies can lift the head when placed in a prone position. At approximately 4 months of age, babies can lift the head and chest. As neural connections increase and mature, so do the child's physical abilities. Some reflexes evident in the infant will persist into adulthood. These include blinking, coughing, and yawning. However, other reflexes will disappear. In some cases, these reflexes must diminish so that intentional skills can develop. Important developmental milestones to watch for in infants, as recommended by the Centers for Disease Control and Prevention (CDC, 2018), include those presented in Table 17.7. At well-child visits, the nurse performs screening tests, such as the Denver Developmental Screening Test, to make sure that each child is meeting developmental milestones.

TABLE 17.7

Developmental Milestones by Age

3 Months	7 Months	12 Months
Raises head and chest when prone	Rolls from front to back and from back to front	Gets to sitting position without assistance
Brings hands to mouth	Sits with support and then without it	Crawls forward on belly, using arms and legs to push
Follows a moving object with eyes	Transfers object from one hand to another	Assumes hands-and-knees position
Smiles at the sound of caregiver's voice	Responds to own name	Uses pincer grasp
Smiles socially	Uses voice to express pleasure	Says "da-da" and "ma-ma"
Babbles	Finds partially hidden objects	Tries to imitate words

Ideally, infants need only their mother's breast milk for nutrition for the first 6 months of life (Fig. 17.3). Iron supplementation is recommended between the ages of 4 and 6

months. Additionally, infants being exclusively breastfed may require vitamin D supplements in the first 2 months of life. Babies who are formula-fed should receive an iron-fortified infant formula. Whole milk should not be introduced until after the child is 1 year of age. Gradual introduction of solid foods usually begins somewhere between 4 and 6 months of life. Bland foods (such as rice cereal) are introduced first, with the addition of complex, richer foods one at a time in order to monitor for possible allergies.

FIGURE 17.3 Breast milk is the ideal nutrition during the first 6 months of life. (Copyright [istock.com](https://www.istock.com).)

In addition to meeting basic biologic needs, a stimulating environment is necessary for the infant to develop properly. Toys and mobiles with high-contrast color patterns are a good choice. Soft music, rattles, and chimes provide auditory stimulation. Fabrics of various textures and textured toys offer tactile stimulation ([Box 17.6](#)). Use of swings and push/pull toys as the child grows older encourages mobility.

Box 17.6

Patient Education and Health Literacy

Infant Safety

The nurse provides education for parents at each well-child visit, which may include:

- Caregivers should keep infant cribs clear of overstuffed pillows, blankets, and stuffed animals. Such objects present a suffocation hazard, especially to small infants.
- Caregivers should never leave small objects within the reach of an infant because of the risk of choking.
- Infants should never be put to sleep in the prone position because of this position's link with sudden infant death syndrome (SIDS).
- Parents should use good handwashing technique to prevent infections, especially before infant feedings and after diaper changes. Visitors should wash their hands when they come to an infant's home.

Safe Practice Alert

To prevent burns, microwaving breast milk or infant formula is not recommended. To warm milk or formula, place the container in a lukewarm or warm water bath for several minutes. Test the temperature by squirting a couple drops on the inner portion of caregiver's wrist before offering to infant. Never add water into a bottle to cool it down, because this upsets the precisely formulated concentration considered safe for the infant.

The hospitalized infant is at risk for developing mistrust ([Table 17.8](#)). If parents are unable to stay and provide care for the infant in the hospital, the nurse must ensure that infant needs (such as, feeding, bathing, and changing) are met. Additionally, it is important to ensure that the environment is both safe and stimulating for the infant. The use of developmentally appropriate

toys, such as mobiles, encourages continued progress toward developmental milestones.

TABLE 17.8**Age and Developmental Stages Across Theories**

Age Group	Erikson (Psychosocial)	Piaget (Cognitive)	Kohlberg (Learning)
Infant	<i>Trust versus mistrust</i> Dependent on others to meet needs	Sensorimotor: Primary circular reactions Actions reflexive in nature	Preconventional No sense of "good" or "bad" behavior Later, motivation is to avoid punishment
Toddler	<i>Autonomy versus shame</i> Beginning to assert authority over own actions	Sensorimotor: Tertiary circular reactions Realizes own actions cause reactions in others	Preconventional Behavior based on rules imposed by others; main motivation is to avoid punishment
Preschool child	<i>Initiative versus guilt</i> Focus is on energetic learning	Preoperational Preconceptual (2-4 yr): Egocentric thought processes, magical thinking Intuitive thought (4-7 yr): Beginning sense of others' perspectives	Preconventional Motivation for behavior is to avoid punishment; rules imposed by others. Does not understand reasons for the rules
School-age child	<i>Industry versus inferiority</i> Eager to develop skills; motivated to complete tasks	Concrete operations Able to use thought processes to experience events Less egocentric; able to see others' viewpoints Concept of conservation is mastered Able to classify objects	Conventional Early school age: Motivated by reward and punishment After age 7 yr: Able to judge actions by intentions rather than consequences

Age Group	Erikson (Psychosocial)	Piaget (Cognitive)	Kohlberg (Learning)
Adolescent	<i>Identity versus confusion</i> Focuses on who the adolescent is and who he or she wants to become	Formal operations Capable of abstract thought Can manipulate more than two categories of data at the same time Can think about the way others think	Conventional to postconventional Able to make decisions based on own set of internal moral values Questions the status quo and established rules

In assessing an infant's development, the nurse is not always able to observe behaviors. The nurse evaluates progress by asking the parent or caregiver questions about the infant's developmental behaviors (Box 17.7).

Box 17.7

Health Assessment Questions

Infant

1 to 3 Months

- Does your baby smile at you?
- Does your baby follow objects like a rattle with her eyes?
- Does your baby turn her head from side to side when she hears a noise?
- Does your baby seem to try to talk to you when you talk to her?
- Does your baby hold an object if you put it in her hand?
- Do you ever see your baby looking at her own hand?
- Does your baby ever squeal when she is excited?

4 to 6 Months

- Does your baby roll from back to side?
- Can your baby sit if propped?

- Does your baby play with his hands, clothing, and blankets?
- Does your baby try to reach for objects held in front of him?
- Does your baby put toys in his mouth?
- Does your baby laugh out loud?
- Does your baby hold his own bottle?
- Does your baby make sounds?
- Does your baby look for toys that are dropped?

7 to 9 Months

- Can your baby sit up either supported or unsupported?
- Does your baby pass toys from one hand to another?
- Can your baby focus on an object for longer periods of time than in previous months?
- Does your baby say “da-da” or “ma-ma”?
- Does your baby get upset when you leave the room?
- Is your baby crawling or trying to stand?
- Does your baby resist diaper changes or washing her face?

10 to 12 Months

- Can your child move from lying face down to sitting unassisted?
- Is your child trying to walk? If so, with or without support?
- What words does your child say?
- Does your child search for objects you hide?
- Does your child play games like peek-a-boo?

Some health concerns during infancy are sudden infant death syndrome (SIDS), colic, and abuse. SIDS is diagnosed when a baby dies while sleeping and no known cause can be found. Placing babies on their backs to sleep is believed to reduce the occurrence of SIDS, as does putting babies to sleep in their own cribs. Placing babies in the parents’ bed is dangerous, because suffocation can occur from clothing or bedding, or as a consequence of inadvertent pressure from a sleeping parent.

Babies become colicky when they have intestinal spasms, causing pain and making the infant very fussy. The cause is not known, but some babies respond well to a change in formula and others to a calmer environment.

Shaken-baby syndrome is a form of abuse that occurs in infants. This syndrome occurs when a frustrated or angry caregiver shakes the baby, causing trauma to the brain from the force of its hitting against the skull. Nurses should be aware of cues from parents (such as exhaustion, frustration, and anger) that might lead to abuse of the infant. Helping parents with coping skills and education about the risk of injury to infants are important components of the nurse's role.

Safe Practice Alert

Sudden infant death syndrome (SIDS) is a health risk during infancy. The best way to reduce the risk of SIDS is to instruct parents to always put babies to sleep on their backs ([Medline Plus, 2018](#)).

LO 17.5 Physical, Psychosocial, and Cognitive Development of the Toddler

The toddler stage begins around 1 year of age and ends around 3 years. Physical growth slows after the infant stage, but the child continues to develop rapidly in many ways. Visual acuity improves, and binocular vision is developed. Most body systems are matured. Heart and respiratory rates slow. The gastrointestinal system has matured, and the toddler can tolerate a variety of foods. By 12 to 13 months of age, children usually begin to ambulate, using a wide stance to support themselves and falling easily at first. This skill is gradually refined between the ages 2 and 3 years (Fig. 17.4). By age 2, toddlers are able to walk up and down stairs; by age $2\frac{1}{2}$, they are able to jump on two feet. Fine motor development is evident in increased skills. At 1 year of age, children can grasp small objects. By the time they are 15 months old, children can drop small objects into a bottle. They enjoy throwing objects down to watch others retrieve them. By 18 months of age, children can throw a ball overhand while maintaining balance (CDC, 2018). Some sample questions to ask at the well-child visit for a toddler are listed in Box 17.8.

FIGURE 17.4 The toddler progresses from standing to walking to climbing stairs.

Box 17.8

Health Assessment Questions

Toddler

- At what age did your toddler start walking?
- Is your toddler sleeping through the night?
- What kinds of foods does your toddler eat?
- Is your toddler saying words?
- Does your toddler interact with you and others?

Nutrition often is a concern for the toddler's parents. Growth rate slows during this time, so the child's need for calories and other nutrients also decreases. Toddlers often become picky eaters. It is important that mealtimes be enjoyable, without pressure to “clean your plate.” The general guide to a serving size

is 1 tablespoon of solid food per year of age. Toddlers often require planned snacks in addition to regular meals. Planned snacks that offer a variety of nutritious foods are a good way to avoid empty calories.

The toddler's developing sense of autonomy can be frustrating and confusing for parents. Often, toddlers will say *no* even when they really want to say *yes*. Two behaviors typical of toddlers in this stage, *negativism* and *ritualism*, are ways that help toddlers work through this conflict. It is important for toddler to have a consistent bedtime ritual (such as a calm environment, a darkened room, and reading books) to aid in readiness for sleep. Frustration often is exhibited in the form of temper tantrums. Parents must be supported in dealing with these often exasperating behaviors. Ritualism aids the child in maintaining security and sameness, which provides a sense of comfort. This security enables the toddler to explore the environment with the comfort of knowing that familiar people, places, and routines exist. [Box 17.9](#) offers suggestions for teaching parents how to keep young children safe in a car.

Box 17.9

Patient Education and Health Literacy

Car Safety

- Advise parents to insist on car seat use for all trips. The National Highway Traffic Safety Administration (NHTSA) recommends that children from birth to 3 years old travel in the back seat in a rear-facing car seat until they reach the car seat manufacturer's height or weight limit for the seat. Once children reach the limit, a forward-facing car seat with a harness is used in the backseat ([NHTSA, 2011](#)).
- Instruct parents to follow the instructions provided by the car seat manufacturer and their vehicle manufacturer for car seat installation.
- Recommend that parents have their car seat installation checked by a certified inspector. The geographically closest

inspector can be located at www.nhtsa.gov.

Safe Practice Alert

Avoid feeding toddlers foods that present choking hazards, such as hot dogs, hard candy, and fruit with pits.

Toddlers are beginning to understand that objects exist even when they do not see them. Parents must be constantly on the lookout for potential household dangers that can attract the curious toddler. It is helpful that toddlers are motivated to avoid punishment at this stage (see [Table 17.8](#)). To keep them safe, the parent should provide simple rules with just punishments for offenses and consistently follow the same rules. A simple explanation of what the child did wrong and, usually, a time-out are good ways to set limits with the toddler.

QSEN Focus!

Vigilance and monitoring by the nurse, family members, and other members of the health care team are valued in providing a safe caring environment for toddlers.

Toddlers in the hospital often find the experience upsetting, in part because it disrupts the comfort of their routine and separates them from their caregivers. The nurse may find it helpful to ask the parents about rituals and routines at home and try to incorporate them into the care of the child. The nurse can expect some regression to earlier behaviors in a child who is hospitalized. Often, toddlers will react with temper tantrums to even minor procedures or routine hygienic care. If possible, having the parents nearby to provide comfort and care is preferred.

Safe Practice Alert

Toddlers are mobile. Ensure that hospital crib side rails are up and locked into position and overhead rails are down and locked

into position before leaving the bedside.

LO 17.6 Growth and Development During the Preschool Years

Biologic growth slows for the preschool child. The average weight gain is approximately 5 pounds per year, and the average increase in height is $2\frac{1}{2}$ to 3 inches per year. Physical appearance changes from that of the toddler to the more streamlined appearance of the child. As gross and fine motor skills develop, the child becomes more graceful and agile than a toddler. By 3 years of age, the child not only can walk but also run, jump, and climb. Three-year-olds enjoy activities like riding a tricycle and throwing a ball. By 4 to 5 years of age, the child can skip, hop on one foot, and turn somersaults. Fine motor skill development is exhibited by increased interest and ability in drawing and printing letters. The child is able to dress without assistance. Sample health assessment questions for parents or caregivers of preschoolers are shown in [Box 17.10](#).

Box 17.10

Health Assessment Questions

Preschooler

- Has your child had frequent infections or colds?
- Is your preschooler toilet-trained?
- What types of activities does your preschooler enjoy? Can your preschooler ride a tricycle? Skip? Hop on one foot?
- Does your preschooler play with other children?
- What is your child's typical diet during the day?
- Does your child talk in sentences?
- Can your child write his or her own name?
- Does your preschooler play make-believe?

Nutrition requirements for the preschooler stay more or less the same as those for toddlers, although calorie and fluid requirements increase slightly. After 24 months of age, low-fat milk can replace whole milk. Whole fruits and vegetables are preferred to fruit and vegetable juices. Nonnutritive fruit drinks and soda should be avoided because they add empty calories and contribute to tooth decay. A variety of fruits and vegetables should be offered.

The preschool years are a period of active learning. Play is the primary method through which learning occurs. Preschoolers are physically active. They often are seen running, jumping, and rolling around (Box 17.11). They have vivid imaginations. It is not uncommon for some preschool children to have imaginary friends. These imaginary friends serve many purposes: They are there when the child is lonely, they can accomplish what the child is still working on, and they can experience situations that the child does not want to remember, such as breaking Mom's cell phone. Preschoolers like to imagine themselves in roles they see in their parents and other adults. It is common for preschoolers to pretend to be parents, nurses, firefighters, carpenters, or police personnel, or to assume other adult roles they have seen modeled (Fig. 17.5).

Box 17.11

Evidence-Based Practice and Informatics

Minimizing Aggressive Behavior in Children

Aggression is behavior that hurts a person or property. Preschoolers often exhibit aggressive behavior. Ways to avoid or minimize aggressive behavior include:

- Limit exposure to media (television, video games) to less than 1 to 2 hours of quality programming per day.
- Discourage television viewing for children younger than 2 years of age. Instead, focus on activities that promote brain development, such as talking, playing, singing, and reading together.

- Remove televisions, Internet connections, and video games from children's bedrooms.
- Monitor television programs that children are watching.
- View television programs with children to monitor content. Discuss controversial or violent content with children, and explore other methods of problem solving as alternatives to the violent solutions shown on programs.
- Establish a mealtime and bedtime “curfew” for media devices such as cell phones, tablets and video games. Reasonable, enforceable rules for use of social media and electronics are encouraged.
- Encourage alternative activities to television, such as athletics, hobbies, and creative play.

FIGURE 17.5 Preschoolers have vivid imaginations.
(Copyright Thinkstock.com.)

4. The nurse receives a new order to start an intravenous (IV) line for E. M. What reaction might the nurse expect from E. M. when the IV line is started? What might cause this reaction? How can the nurse help to alleviate E. M.'s concerns about the procedure?

Preschoolers are very egocentric in their thought processes. Objects are defined in terms of how the child uses them. If asked to define a crayon, the child will say, "I color with it." Another characteristic of preschool thought is *magical thinking*. Because of their egocentric thought processes, preschoolers believe that they can cause events by simply wishing them to happen. Often, hospitalized preschoolers will blame their illness on something they perceive they did wrong (see [Table 17.8](#)). The nurse must take this into consideration when caring for a preschool child. Even if the hospitalization is a result of injuries the child sustained as a result of not following rules (such as the rule of wearing a bicycle helmet), the nurse should avoid blaming the child or telling the child that this is punishment for breaking the rules.

5. What approach can the nurse use in explaining the illness to E. M.?

QSEN Focus!

The nurse should remove barriers to the presence of families and value an active partnership with parents and other caregivers in

planning, implementing, and evaluating care for children.

The nurse may notice a child who demonstrates inappropriate behavior, such as trying to touch another child in a sensitive area. This would alert the nurse that this child may either be experiencing or observing such behaviors in the home. These observations warrant further investigation, because the child may be a victim of abuse.

Child maltreatment is a term used to describe intentional physical abuse or neglect, emotional abuse or neglect, and sexual abuse of children. It is a significant problem in childhood. The nurse must be aware of signs of abuse and the proper procedures for handling suspected abuse in the work setting. The child may act withdrawn and afraid and may express fear of going home. Not all forms of abuse have obvious signs. Some warning signs of abuse include the following (Christian, 2015):

- Physical evidence of abuse or neglect, including previous injuries
- A vague explanation of how an injury occurred, or failure to offer any explanation at all
- An explanation that is inconsistent with the pattern, age, or severity of the injuries
- Markedly different stories from different witnesses about how an injury occurred

Safe Practice Alert

The presence of viral infection and the use of aspirin in children are linked to Reye syndrome, a potentially fatal toxic encephalopathy. Avoid use of aspirin and non-aspirin-containing salicylates during febrile illnesses in children.

LO 17.7 Development During the School-Age Years

Between the ages of 6 and 12 years, the child is said to be in middle childhood, or the school-age years. The pace of physical growth is slower than in preceding years, with the child growing an average of 2 inches per year and gaining approximately 4 to 6 pounds per year. The child's physical appearance becomes slimmer and even more graceful, and the child is more adept than in the preschool years. Fat diminishes further, and the skeleton lengthens along with an increase in muscle tissue. Boys and girls of this age have similar physical growth characteristics during the early years of the school-age period.

The body systems of the school-age child are more mature than they were in the preschool years. They are better able to fight infection, although early in this period children often have an increased rate of illness because of more exposure to other children. They are able to maintain a more stable blood glucose pattern. Caloric needs decrease, and an increase in stomach capacity enables children to eat less frequently. In most cases, full bowel and bladder control have been achieved, although young school-age children occasionally have toileting accidents as they adjust to the more controlled school environment. The skeletal system continues to develop, with bones lengthening and ossifying. Some sample health assessment questions for parents of school-age children are presented in [Box 17.12](#).

Box 17.12

Health Assessment Questions

School-Age Child

- Does your child get along with classmates?
- What are your child's favorite activities?
- Can your child ride a two-wheeled bike? Play ball?

- Does your child eat a well-balanced diet?
- Is your child sick frequently?
- Does your child have any problems seeing the blackboard at school or seeing words in a book?

Safety is a concern for the active school-age child. As children play outdoors, they are at risk for accidents while riding bicycles and skateboards. Bicycle safety is discussed in [Box 17.13](#). Children who are sedentary are at risk for developing childhood obesity and its side effects. This risk is higher in children who watch too much television or play video games instead of engaging in activities that involve movement.

Box 17.13

Patient Education and Health Literacy

Bicycle Safety

Teach parents and children about bicycle safety. Include the following information:

- All bicyclists must wear a properly fitting helmet that meets Consumer Product Safety Commission (CPSC) standards ([Fig. 17.6](#)).

FIGURE 17.6 Wearing a properly fitting helmet is important for bicycle safety. (Copyright [istock.com](https://www.istock.com).)

- Young children riding as passengers must wear a properly fitted helmet. They must ride in a bicycle-mounted seat or in a bicycle-towed child trailer. Children should never ride on the handlebars or cross bar.
- Helmets that are involved in a crash or are damaged must be replaced immediately. All helmets should be replaced every 5 years, or sooner if the child outgrows the helmet.
- Parents and children should be knowledgeable about bicycle safety rules and traffic laws.

Adapted from American Academy of Pediatrics. (2015). Bicycle helmets: what every parent should know. Retrieved from www.healthychildren.org/English/safety-prevention/at-play/Pages/Bicycle-Helmets-What-Every-Parent-Should-Know.aspx.

A growing concern that emerges in the school-age years and continues into adolescence is bullying. Bullying can be in the form of verbal taunts, physical abuse, or cyberbullying through e-mail and social media. Parents need to be vigilant in monitoring their children's activities and computer use and be aware when their child exhibits a change in behavior that may indicate feelings of sadness or depression. Bullying can lead to mental health problems including depression, low self-esteem, and suicide in both children and young adults. Emotional support from the nurse along with education about setting safe limits on social

media, being able to access their child's accounts for monitoring, and maintaining communication help promote the school-age child's well-being and safety.

The school-age child may continue to have strong food preferences. Children at this age, however, are more open to exploring a variety of foods. It is important that they be offered nutritious choices for meals and snacks, to avoid consumption of empty-calorie snack foods and high-fat fast foods. Parents should encourage children to make good choices by using the U.S. Department of Agriculture (USDA) MyPlate guidelines in planning meals and snacks (USDA, 2018). These dietary guidelines are discussed in detail in [Chapter 30](#). Good oral hygiene and food choices can help prevent tooth decay.

Safe Practice Alert

Children's bones are susceptible to injury or deformity from prolonged or excessive pressure and the pull of strong muscle groups. Talk to parents about limiting the weight of book bags and the possibility of accessing eBooks available from some schools. Backpacks distribute the weight more evenly, reducing strain on growing bones and joints. Specific limits have been set for safe backpack weights and vary by the size of the child.

Toward the end of the school-age period, the child enters preadolescence. During this time, discrepancies in growth patterns and maturation appear between boys and girls. Girls often are taller and heavier than boys.

School-age children delight in developing new skills (see [Table 17.8](#)). They gain confidence and a sense of satisfaction from peer interactions and from activities that they can carry through to completion. They enjoy competition and working together to accomplish goals. They become capable of making judgments based on reasoning rather than on just what they see. Around the ages of 5 to 7 years, children grasp the concept of conservation. This knowledge is transferred to mathematical equations, and children become able to reverse the arrangement to solve problems.

School-age children develop the ability to classify objects. They often enjoy sorting and grouping objects by different characteristics. For example, many children keep collections of items, such as rocks, stamps, and stickers.

School-age children in hospitals present some challenges for nurses. Fears are common at this stage, particularly fear of being hurt or of experiencing unknown procedures. Simple explanations before procedures are helpful in alleviating some of these fears. Additionally, separation from peers can be stressful. Encouraging visits, cards, phone conversations, and supervised e-mail and social media activities with friends and family can reduce anxiety and feelings of isolation. Preventive health is important during this time, and immunizations are brought up to date before starting school.

LO 17.8 Physical, Psychosocial, and Cognitive Development in Adolescents

Adolescence is a time of great change, both physically and socially. This period of development is referred to as [puberty](#). Hormonal changes that occur with the onset of puberty trigger the process of physical and sexual maturity.

In females, changes include the following:

- Breast enlargement
- Increasing height and weight
- Growth of pubic and axillary hair
- Menarche (onset of menstruation)

In males, changes include the following:

- Enlargement of testicles
- Growth of pubic, axillary, facial, and body hair
- Rapid increase in height
- Changes in larynx, causing lowering of the voice
- Nocturnal emissions

In both males and females, the final 20% to 25% of height generally is achieved during a 24- to 36-month period known as the *adolescent growth spurt*. In females, this usually begins between the ages of 9 and 14 years and ends 1 to 2 years after onset of menstruation. It occurs somewhat later in males, with the onset between the ages of 10 and 16 years and the end between the ages of 18 and 20 years.

Body systems mature, with increased size of the heart and lungs. As the heart and lungs grow to adult size, blood volume and blood components expand with them. The adolescent is better able to meet the physiologic demands of exercise. Subsequently, development of muscle mass and definition is apparent, particularly in males. Health assessment questions should be directed to the adolescent rather than to parents. Some sample questions for the adolescent are listed in [Box 17.14](#).

Box 17.14

Health Assessment Questions

Adolescent

- What are your favorite activities?
- What do you eat on a normal day?
- Tell me about school.
- Do you have friends?
- Do you get along with your parents? Siblings?
- Do you have a boyfriend or girlfriend?
- Are you having sex? If so, what type? How many partners?
- Have you ever used drugs? Tobacco products?
- Do you drink alcohol?
- Do you ever feel sad?

Nutritional needs increase during adolescence owing to increased rates of growth in height, weight, and muscle mass and with sexual maturation. Caloric and protein needs increase to one of the highest levels during the life span. These increased needs, combined with often hectic schedules, may lead to excessive consumption of high-fat and high-calorie snack foods. It is important to be sure that teens avoid skipping meals and have healthy, filling snacks (such as, fruits and vegetables) available. Overeating, fad dieting, and nutritional misinformation are common in this age group. Healthy dietary habits should be discussed with adolescents and periodically reinforced during

office visits, at school, and at home. Emphasis should be placed on good nutritional choices and physical activity as means of maintaining a healthy weight. Bulimia and anorexia are psychological problems that develop during adolescence, leading to nutrient deficiencies and being underweight. Some children may develop obesity due to sedentary lifestyle, overeating of high-fat, high-calorie foods, or psychosocial factors. Obesity can cause problems, such as early puberty and premature closure of growth plates. For further discussion of these disorders, see [Chapter 30](#).

Safe Practice Alert

Nonthreatening, nonjudgmental approaches work best when nurses are interviewing adolescents about their health practices.

Adolescence is a time of great physical and emotional upheaval. The need for privacy at this stage is very strong. Often, this need is triggered as teens struggle to accept the body image changes associated with adolescence. Adolescents often isolate themselves from the rest of the household in an attempt to exercise their independence and separate from their parents (see [Table 17.8](#)). At the same time, peer-group influence peaks ([Fig. 17.7](#)). Parents are often concerned about maintaining open communication with their teens. Although it may not seem so to them, parents still exert influence in the teen's life. Parents should be guided in exercising appropriate authority in the teen's decisions while encouraging increasing autonomy for the adolescent.

FIGURE 17.7 The adolescent relies on peers for friendship and support. (Copyright [Thinkstock.com.](https://www.thinkstock.com/))

Teens are able to make decisions based on the context of the situation, with consideration of all possible outcomes. However, this does not mean teens will always make good decisions. Teens commonly are exposed to drugs, tobacco, alcohol, and situational influences on sexual behavior. Nurses are in a position to educate teens about the risks of drugs, tobacco, and alcohol use and the consequences of unprotected sex.

Safe Practice Alert

Ensure confidentiality and privacy when interviewing adolescents. Conduct the interview without the presence of parents.

Because of the concurrent increase in physical size and ability, teens often develop a false sense of security and invincibility. Injuries, including those from sports accidents, are prominent in this age group. The Centers for Disease Control and Prevention (CDC) ([Kann, McManus, Harris, et al., 2016](#)), through its Youth Risk Behavior Surveillance project, monitors health risk behaviors. Behaviors that contribute to the leading causes of death and disability among youths and young adults include the following:

- Behaviors that contribute to unintentional injuries and violence
- Sexual behaviors that contribute to unintended pregnancy and sexually transmitted diseases, including human immunodeficiency virus (HIV)
- Alcohol and other drug use
- Tobacco use
- Unhealthy dietary behaviors
- Inadequate physical activity

In the United States, 71% of all deaths among youths and young adults aged 10 to 24 years result from four causes: motor vehicle crashes, other unintentional injuries, homicide, and suicide (Kann, McManus, Harris, et al., 2016). Teens are experimenting, often with risky behavior. Some may have the feeling that they have to try drugs or sex just to “fit in.” Others may feel as if they will never fit in at all. Suicide or suicide attempts may be the result of feelings of inadequacy, depression over bullying or breaking up with a boyfriend or girlfriend, or mental illness. Suicide is also more common in this age group, because their impulse control has not fully developed; thus they may act on an impulse without considering the consequences. Early identification of mood pattern changes is important in this age group. Nurses working with the adolescent population should be attuned to signs of depression and suicide. Accidents, particularly those involving motor vehicles, constitute the single most important cause of death in this age group (Box 17.15).

Box 17.15

Patient Education and Health Literacy

Safety Education for Teens

Teach teens to do the following:

- Use seat belts at all times.
- Use protective gear such as helmets and long pants when riding all-terrain vehicles (ATVs) and motorcycles.
- Participate in an approved driver education program.
- Avoid texting and other distractions while driving.

Most adolescents who are hospitalized can understand a lot of what is happening to them. Nurses should explain reasons for procedures and treatments in terms that adolescents can understand and should encourage them to ask questions. Both teens and their parents need to be included in the plan of care. Socialization is very important to adolescents, and they should be encouraged to keep in touch with their peers through phone calls, texting, social media, e-mail, or visits.

Summary of Learning Outcomes

LO 17.1 *Describe major theories of human development:* Many theories have evolved to describe human growth and development in cognitive, psychosocial, sexual, behavioral, and spiritual dimensions. Most of these theories outline developmental tasks and/or stages through which the person progresses toward higher levels of functioning.

LO 17.2 *Explain human development from conception to birth:* Conception occurs with fertilization and implantation. The zygote is known as an embryo after 3 weeks and then as a fetus after 8 weeks. Rapid development and cell differentiation occur during the early weeks of pregnancy. The fetus continues to grow and develop until delivery. The developing fetus is susceptible to a variety of teratogens, including certain medications, illegal drugs, alcohol, radiation, and infectious agents.

LO 17.3 *Identify the primary developmental tasks of the newborn:* The primary developmental tasks in the newborn period (birth to 1 month) involve adaptation to life outside the uterus and include learning to eat, developing sleep-wake patterns, and laying the groundwork for trust by having needs consistently met by the caregivers.

LO 17.4 *Outline infant developmental milestones:* The infant period (1 month to 1 year) is marked by rapid growth. Primary developmental tasks include developing trust, adapting to the environment, and beginning refinement of fine and gross motor skills.

LO 17.5 *Describe the physical, psychosocial, and cognitive development of the toddler:* The toddler attains control of bowel and bladder function, increases mobility, refines development of fine and gross motor skills, and expands language acquisition. Safety concerns in the toddler period include protection from injury as the child gains increased mobility in the environment.

LO 17.6 *Summarize growth and development during the preschool years:* Preschoolers develop a sense of initiative as they continue to refine gross and fine motor skills. Safety concerns in this period include protection from injury as preschoolers become more active.

LO 17.7 *Discuss development that occurs during the school-age years:* The school-age child grows in stature and weight and becomes capable of logical thought. Peer relationships exert a greater influence on the school-age child than on children in previous stages. Health and safety concerns in the school-age years include prevention of injury, particularly from play equipment, such as bicycles.

LO 17.8 *Articulate physical, psychosocial, and cognitive adolescent development:* Adolescents go through many physical changes. Peers become very important, and adolescents often try to isolate themselves from their parents. Teens make decisions based on the context of the situation and can understand much of what is happening when hospitalized. Safety concerns during the adolescent years include protection from injury. Health concerns include the promotion of a healthy diet and safe sexual practices and the support of mental health as the teen struggles with multiple physiologic and psychological changes.

Review Questions

1. Which action by a 3-month-old infant would the nurse interpret as an example of Piaget's sensorimotor stage of primary circular reaction?
 - a. Deliberately placing the thumb into the mouth
 - b. Accidentally kicking a ball
 - c. Searching for an object under a blanket
 - d. Shaking a rattle
2. The mother of a 5-month-old infant is concerned because her child is not yet sitting on his own. What is the nurse's best response to her concerns?
 - a. Informing the mother that this is not normal and recommending further evaluation
 - b. Telling the mother that this is normal development for a 5-month-old
 - c. Encouraging the mother to do sit-ups with the child to encourage muscle development
 - d. Asking the mother if the child had any trauma at birth
3. A 1-year-old child grabs an Easter egg and attempts to throw it across the room. The nurse knows that the child is exhibiting which scheme according to Piaget?
 - a. Adaptation
 - b. Assimilation
 - c. Accommodation

d. Equilibration

4. A preschooler's mother is concerned because her child behaves in a mean fashion toward her younger brother. The mother states, "She acts like she has no sympathy for him!" What is the nurse's best response?
- a. "She is very young to exhibit sibling rivalry."
 - b. "What does her brother do to her to make her act this way?"
 - c. "Do you fight at home? She is probably imitating you."
 - d. "Preschoolers are not capable of putting themselves in another's place."
5. A 2-year-old child insists on having a drink of water and having a story read to him and says, "Good night, sleep tight" at bedtime every night. The nurse knows the child is exhibiting which type of behavior?
- a. Controlling
 - b. Ritualism
 - c. Obsession
 - d. Compulsion
6. How is the toddler's need for autonomy best met?
- a. The parents' consistently meeting the child's needs
 - b. Encouraging imaginative play

- c. Allowing the child limited choices
 - d. Promoting experimentation to determine cause and effect
7. The nurse is performing a health assessment on a 15-year-old female patient. Which is the best way to obtain accurate information regarding her sexual activity?
- a. Ask the mother about the girl's sexual activity.
 - b. Privately ask the girl about her sexual activity.
 - c. Warn the girl about the dangers of sexual activity.
 - d. Ask the girl if she wants birth control.
8. When an injury to a child is suspicious for abuse, which is/are important to document? (*Select all that apply.*)
- a. Size and location of bruising
 - b. Distinguishing characteristics of injuries
 - c. Height and weight of the child
 - d. Time of last meal
 - e. General state of health of the child
9. What is the best activity for a hospitalized school-age child to encourage continued appropriate development?
- a. Watching favorite television shows for 2 hours per day
 - b. Keeping a journal of feelings while in the hospital

- c. Working on a paint-by-number project that can be completed in an afternoon
 - d. Playing a favorite video game each afternoon
10. A teenage girl faces a long hospitalization after surgery. How can the girl's continued development be fostered?
- a. Encourage her to write her feelings in a journal.
 - b. Divert her attention by playing video games.
 - c. Encourage her to work on craft projects.
 - d. Make sure her parents are constantly by her side.

CHAPTER 18

Human Development

Young Adult Through Older Adult

LEARNING OUTCOMES

Comprehension of this chapter content will provide students with the ability to:

- LO 18.1 Discuss theories on aging and adult development.
- LO 18.2 Describe changes that occur as the body ages.
- LO 18.3 Identify physiologic, cognitive, emotional, and social changes that affect the young adult.
- LO 18.4 Articulate health risks and concerns for the young adult.
- LO 18.5 Summarize the physiologic, cognitive, emotional, and social changes that occur in the middle adult age group.
- LO 18.6 Explain health risks and concerns for the middle adult.
- LO 18.7 Recognize the physiologic, cognitive, emotional, and social changes that affect the older adult.
- LO 18.8 Outline health risks and concerns for the older adult.

Case Study

Marilyn Dubois (M. D.) is a 58-year-old female who has spent the past 2 years caring for her 82-year-old mother who had dementia. M. D., who is divorced, had a managerial position in a corporate office with a good salary and benefits. She tried to continue working while caring for her mother, but eventually resigned her position and cared for her mother full time until her mother's death 3 months ago. While caring for her mother, she used her personal savings and borrowed from her retirement savings.

After her mother died, M. D. was unable to get another job at the same managerial level as that of her previous position. She took a job that pays an hourly wage with minimal health insurance benefits and a retirement plan to which employees can contribute.

M. D. came to her primary care provider's (PCP's) office complaining of a throbbing headache with pain described at 6 on a scale of 0 to 10, swelling in her feet, and dizziness. She stated that she feels restless. Multiple BP readings taken by the nurse were above 160/100. Vital signs were: T 36.6° C (97.9° F), P 96 and regular, R 22 and unlabored, pulse oximetry 97% on room air, height 160 cm (63 in.) and weight 66.2 kg (198 lbs). She had pitting edema of her ankles and feet. M. D. was diagnosed with hypertension, uncontrolled.

Patient teaching and outpatient plan are as follows:

- Low-sodium, low-calorie diet
- Referral to social service/grief counseling
- Exercise program
- Stress management/relaxation program
- Patient education: Hypertension

Laboratory/diagnostic test orders are as follows:

- Laboratory studies pending: Complete blood count (CBC), blood urea nitrogen (BUN), serum electrolytes, creatinine, fasting lipid panel, and urinalysis
- Chest x-ray
- 12-lead electrocardiogram (ECG)

Medication orders are as follows:

- Hydrochlorothiazide 25 mg PO (by mouth) once daily
- Metoprolol 50 mg PO twice a day
- Tylenol 500 mg two tablets every 8 hrs PRN (as needed)

Refer back to this case study to answer the critical-thinking questions throughout the chapter.

Adulthood is divided into three age groups: young adulthood, middle adulthood, and older adulthood. Young adulthood spans the ages of 18 to 34 years; middle adulthood includes people 35 to 65 years of age; and older adulthood includes those 66 years of age and beyond. At each stage, the person is tasked with achieving specific developmental milestones. Various researchers have developed theories and specified tasks that can be identified as evidence of transition through these life stages.

Lo 18.1 Theories on Aging and Adult Development

Biologic aging, or **senescence**, is defined as a normal physiologic process that occurs at the cellular and molecular levels and is universal and irreversible (McCance & Heuther, 2019). This process is the genetically influenced decline in the functioning of organs and systems that is universal in all living creatures. It can occur asynchronously, with some organ systems aging faster than others. Individual differences are great owing to genetics, lifestyle, stress, and culture. **Life expectancy** is the average number of years of life remaining at a given age. Life expectancy varies by gender, culture, and socioeconomic status and from country to country.

Loss of hormones, as the endocrine system gradually fails, contributes to aging. The decline in estrogen hormone, as seen with menopause, leads to a decrease in preserved calcium and bone density. It also affects many other bodily functions. A drop in growth hormone leads to loss of muscle and bone mass, additional fat, thinning of the skin, and a decline in cardiovascular function. Diet and physical exercise can slow some of these effects. Hormone therapy can reduce the loss of growth hormone, but side effects include risk of cancer. Declines in immune system function lead to susceptibility to infections, risk of cancer, and changes in blood vessel walls.

Wear-and-Tear Theory

The **Wear-and-Tear Theory of Aging** proposed that the body wears out from hard use. This theory was first introduced in 1882 by Dr. August Weismann, a German biologist. He believed that the body and its cells are damaged by overuse and abuse. The organs and organ systems are worn down by the adverse effects of toxins in the diet and in the environment; excessive consumption of fat, sugar, caffeine, alcohol, and nicotine; the ultraviolet rays of the sun; and the many other physical and emotional stresses to which the body is subjected. Wear and tear is not confined to organs; it also takes place on the cellular level (Moody & Sasser, 2017). Biologic changes occur at both the DNA/cellular level and the organ system level.

Aging at the Level of DNA and Body Cells

Cells vary in shape, size, and function; however, they all endure the aging process. According to [McCance and Heuther \(2019\)](#), it is difficult to determine the physiologic changes from the pathologic changes of aging. Areas of primary focus in the biology of aging include endocrine regulation through endocrine signaling pathways, nuclear architecture, genomic instability, decline in cell renewal by adult stem cells, and accumulation of cellular damage related to cancer and aging ([McCance & Heuther, 2019](#)). Cellular changes related to aging include cell atrophy, cell loss, and decreased cellular function. Loss of cellular function leads to hypertrophy and to hyperplasia of the remaining cells. DNA and RNA in aged cells are susceptible to injurious stimuli, increasing the cells' demise. Research suggests that in the aged cell the processes of DNA repair, which usually occur over time, are decreased, leading to the cells' being susceptible to mutations and neoplasia ([McCance & Heuther, 2019](#)). Theories that emphasize the cumulative effects of random events suggest that DNA is gradually damaged owing to changes in the DNA caused by internal or external forces. This leads to mutations that accumulate, and thus cell repair becomes less efficient or cancerous cells develop.

Free radicals are one cause of cellular abnormalities. They are naturally occurring, highly reactive chemicals that form in the presence of oxygen. These by-products of molecular oxygen chemical reactions can cause harmful alterations in cellular function similar to those seen in aging. Free radicals are related to many disorders of aging, including cancer, cataracts, heart disease, and arthritis. Antioxidants, vitamins C and E, and beta carotene can limit this damage.

Cross-Linking Theory of Aging

The **Cross-Linking Theory of Aging** also is referred to as the *Glycosylation Theory of Aging*. The Cross-Linking Theory of Aging suggests that, over time, protein fibers that make up the body's connective tissue form bonds, or links, with one another. When these normally separate fibers cross-link, tissue becomes less elastic, leading to negative outcomes, such as loss of flexibility, clouding of the lens of the eye, clogged arteries, and damaged kidneys ([Bjorksten, 1968](#)). The longer a person lives, the greater the possibility that cross-linking will occur, causing certain disorders.

Gould's Theory on Adult Development

In his book *Transformations*, Roger Gould (1979) describes adulthood as a stage of life during which people dismantle protective devices that gave them an illusion of safety as children. Gould postulates that this is a process of freeing oneself from childhood restraints and beginning the establishment of personal identity. According to Gould, this transformation occurs in a series of stages divided into the following age groups:

- Ages 18 to 22 years: Leaving the parents' world
- Ages 22 to 28 years: Getting into the adult world
- Ages 28 to 34 years: Questioning and reexamination
- Ages 34 to 43 years: Midlife decade
- Ages 43 to 50 years: Reconciliation and mellowing
- Ages 50 to 60 years: Stability and acceptance

Gould (1979) also identifies the following four false assumptions that adults need to resolve during their lifetimes:

- "I'll always live with my parents and be their child."
- "I'll always be there to help when my parents can't do things on their own."
- "Life is simple, and I can control it."
- "Death and evil are not real."

Gould's theory assumes that people are redefining their identities as they take on adult roles and the related task of adulthood.

Lo 18.2 Physical Changes Due to Aging

As aging occurs, the body goes through physical changes that are universal and irreversible. The changes that occur during young adulthood often go unnoticed. Many age-related functions peak before age 30 and gradually decline thereafter. Certain physical changes that may lead to illness and disease begin to take shape during young adulthood if prevention and wellness are not a specific focus of self-care. Disease and illness appear to be the primary cause of functional loss during old age. In many cases, declines that occur with aging may be due, at least in part, to environmental factors, lifestyle behaviors, and diet. [Table 18.1](#) highlights some of the normative changes seen with aging.

TABLE 18.1**Physical Changes Associated With Normal Aging**

BODY SYSTEM	PHYSICAL CHANGES
Bones and joints	Bones become less dense so are weaker and more likely to break. In women, loss of bone density speeds up after menopause, because less estrogen is produced.
Muscles and body fat	Loss of muscle mass begins around age 30 and continues throughout life. Muscles are used less and begin to shrink, and the levels of growth hormone and testosterone, which stimulate muscle development, decrease.
Eyes	The lens of the eye stiffens, making focusing on close objects harder. The lens becomes denser, making seeing in dim light more difficult. The pupil reacts more slowly to changes in light. The lens yellows, changing the way colors are perceived. The number of nerve cells decreases, impairing depth perception. The eyes produce less fluid, making them feel dry.
Ears	Changes in hearing are due to noise exposure and to aging. Exposure to loud noise over time damages the ear's structures involved in the ability to hear. Some changes in hearing occur as people age, regardless of their exposure to loud noise. As people age, hearing high-pitched sounds becomes more difficult. This change is considered age-associated hearing loss (presbycusis).
Mouth and nose	As people age, taste buds on the tongue decrease in number and sensitivity. This change affects tasting sweet and salt more than bitter and sour. The ability to smell diminishes because the lining of the nose becomes thinner and drier and the nerve endings in the nose deteriorate.
Skin	The skin becomes thinner, less elastic, drier, and finely wrinkled. However, exposure to sunlight contributes to wrinkling and to making the skin rough and blotchy. The fat layer under the skin thins. This layer acts as a protective cushion for the skin, and helps conserve body heat.
Brain and nervous system	<p>The number of nerve cells in the brain decreases with aging. However, the brain can partly compensate for this loss in several ways:</p> <ul style="list-style-type: none"> • As cells are lost, new connections are made between the remaining nerve cells. • New nerve cells may form in some areas of the brain, even during old age. • The brain has more neural pathways than it needs to do most activities—a characteristic called <i>redundancy</i>. <p>Nerve cells may lose some of their receptors for messages. Blood flow to the brain decreases.</p>
Heart and blood vessels	The heart and blood vessels become stiffer. The heart fills with blood more slowly. The stiffer arteries are less able to expand when blood is pumped through them. Thus blood pressure increases.
Muscles of breathing and the lungs	The muscles used in breathing weaken. The number of air sacs (alveoli) and capillaries in the lungs decreases. Thus slightly less oxygen is absorbed from air that is breathed in. The lungs become less elastic.

BODY SYSTEM	PHYSICAL CHANGES
Digestive system	The digestive system is less affected by aging than most parts of the body. The muscles of the esophagus contract less forcefully, but movement of food through the esophagus normally is not affected. Food is emptied from the stomach more slowly, and the stomach cannot hold as much food, because it is less elastic. In the large intestine, materials move through a little more slowly. The liver becomes smaller, because the number of cells decreases and less blood flows through it. Liver enzymes that help the body process drugs and other substances work less efficiently.
Kidneys and urinary tract	The kidneys become smaller because the number of cells decreases. Less blood flows through them, and by the age of approximately 30 years, they begin to filter blood less efficiently. They may excrete too much water and too little salt as aging occurs, making dehydration more likely.
Reproductive organs	<p><i>Women:</i> The effects of aging on sex hormone levels are more obvious in women than in men. In women, most of these effects are related to menopause, when the levels of female hormones (particularly estrogen) decrease, menstrual periods end permanently, and pregnancy is no longer possible. The decrease in female hormone levels causes the ovaries and uterus to shrink. The tissues of the vagina become thinner, drier, and less elastic (a condition called <i>atrophic vaginitis</i>).</p> <p><i>Men:</i> In men, changes in sex hormone levels are less sudden. Levels of the male hormone testosterone decrease, resulting in fewer sperm and a decreased sex drive (libido), but the decrease is gradual. Although blood flow to the penis tends to decrease, many men can have erections and orgasms throughout life. However, erections may not last as long, may be slightly less rigid, or may require more stimulation to maintain. Erectile dysfunction (impotence) becomes more common as men age.</p>
Endocrine system	The levels and activity of some hormones, produced by endocrine glands, decrease. Growth hormone levels decrease, leading to decreased muscle mass. Aldosterone levels decrease, making dehydration more likely. Insulin is less effective, and less insulin may be produced. The changes in insulin mean that the sugar level increases more after a large meal and takes longer to return to normal. For most people, the changes in the endocrine system have no noticeable effect on overall health. But in some, the changes may increase the risk of health problems. For example, the changes in insulin increase the risk of type 2 diabetes.
Immune system	<p>The cells of the immune system act more slowly. These cells identify and destroy foreign substances, such as bacteria, other infecting microbes, and probably cancer cells. This immune slowdown may partly explain several findings associated with aging:</p> <ul style="list-style-type: none"> • Cancer is more common among older people. • Vaccines tend to be less protective in older people. • Infections, such as pneumonia and influenza, are more common among older people and result in death more often. • Allergy symptoms may become less severe.

Lo 18.3 Young Adulthood: Ages 18 to 34

Compared to past generations, individuals transitioning into young adulthood today have more options to consider as they branch out from the protective shelter of their parents' homes. Some of the issues they face are decisions about college, vocational choices, gender identity and sexual preference, and gender stereotypes (e.g., men who choose nontraditional careers). According to the [Bureau of Labor Statistics \(2014\)](#), the young adult population (ages 16-24) account for approximately 15.4% of the workforce. It is projected that by the year 2020, this age group will account for 13.7% of the workforce. Between 2006 and 2009, the annual average health care expenditure among young adults was \$2400, which was spent on health care insurance, medical services, drugs, and medical supplies ([U.S. Census Bureau, 2011](#)).

Age Group Characteristics

The transition phase from adolescence to young adulthood, for people 18 to 34, is marked by many changes physically, psychologically, and socially. Approximately 27% of the population is between the ages of 18 and 34 years. A career, marriage, and economic independence are the signal for many that they have reached adulthood. Taking on career, household, and financial responsibilities brings a set of stressors for young adults, who often are inexperienced in dealing with these new issues. This experience is influenced by cultural and societal values, beliefs, and expectations, which make the journey an individual experience that cannot be ascribed to everyone in this age group. Little is normative, or socially expected, during this time, so routes to adult roles and responsibilities are highly diverse ([Coté, 2006](#)).

There have been many social, cultural, economic, and demographic changes in the last few generations, and these changes are challenging young adults' psychological and social development. Some adapt well and make good decisions about their educational or vocational paths, and their relationships with peers. Others struggle with this transition period in which definitive decisions about work, school, and life may be constrained by lack of resources

or education, early parenthood, and low-paying jobs or unemployment (Berlin, Furstenberg, & Waters, 2010). This transition phase may be marked by periods of experimentation with drugs, multiple casual or intimate relationships, and reckless behaviors that can and may have untoward consequences (Berk, 2018). Young adults may find themselves needing assistance from family, friends, their community, and society to successfully complete this phase of life. Some of the most recent 2010 U. S. Census Bureau statistics for this age group are cited in Box 18.1.

Box 18.1

Diversity Considerations

The following are statistics collected by the U.S. Census Bureau for marriage and educational diversity in the young adult age group:

Life Span

- Among people aged 25 to 34 years, 88.4% held a high school diploma or higher.
- Among high school graduates, 70% enrolled in college the year after graduating, compared with 60% in 1990 and 52% in 1970.
- Advanced degrees were attained by 8.9% of people aged 25 to 34.

Gender

- Age 20 to 24: 10.8% of males were married, compared with 19.2% of females.
- Age 25 to 29: 34.7% of males were married, compared with 47.6% of females.
- Age 30 to 34: 57.1% of males were married, compared with 63.8% of females.

From the U.S. Census Bureau. (2011). *Statistical abstract of the United States: 2012* (131st ed.). Washington, DC: Author. Retrieved from <https://www.census.gov/programs-surveys/decennial-census/decade.2010.html>.

Emerging Adulthood

In generations past, the transition to adulthood occurred rapidly. Enrollment in higher education and marriage were goals set in late adolescence, and high school graduation marked the beginning of the pathway to those goals. As recently as the late 1970s and early 1980s, the typical 21- to 22-year-old was engaged to be married or already married, caring for a newborn child or expecting one soon, about to graduate from college or done with education, or settled into a long-term job or full-time motherhood. Young adults grew up quickly and made serious, enduring choices about their lives at a relatively early age.

Today there is a much slower transition to adulthood, marked by indecision and lack of commitment to one fixed goal in life. This prolonged transition phase is now being called **emerging adulthood**. The life of a typical 21-year-old is quite different from that of his or her counterpart 40 or 50 years ago. Marriage is at least 5 to 10 years in the future. Some individuals begin parenting during this transition phase, but the commitment to marriage may be on hold until a later time. Education is often extended; the average undergraduate enrollment period is now 5 to 6 years in length, and the pursuit of graduate and/or professional school often follows. Changing jobs occurs frequently as emerging adults look for work that pays well and is personally fulfilling.

According to [Arnett \(2006\)](#), the explorations of emerging adults and their shifting choices in love and work make emerging adulthood an exceptionally full and intense period of life but an unstable one. From the late teens to the late 20s, a prolonged exploration of the possibilities available in love and work precedes commitment to enduring choices. To be a young-adult American today is to experience excitement and uncertainty, wide-open possibility and confusion, and new freedoms and fears ([Arnett, 2006](#)).

Physical Development in Young Adulthood

The young-adult stage is full of major changes in both physical and cognitive attributes. The body has finished fully developing, and the thinking process is carried out in a more complex manner. It is during this developmental stage that young adults can contemplate the views of another and put themselves in the other's place to gain a better understanding, thus achieving mature empathy.

During the young adult phase of life, individuals reach their peak growth physically. Young adults are at top physical condition between their late teens and early 30s, after which they may start to slow down physically and mentally (Fig. 18.1).

FIGURE 18.1 Young adults engaged in physical activity. (Copyright [Thinkstock.com.](https://www.thinkstock.com/))

This is an opportune time to do a complete assessment of the individual's lifestyle, emphasizing wellness, health promotion activities, and disease prevention for those individuals who see a health care provider on a regular basis. Areas that are assessed include family history, mental health, environmental and work-related exposures to hazardous materials, military service, and travel abroad, because these activities can expose individuals to health hazards. Assessment of lifestyle includes sensitive issues such as sexual orientation, safe-sex practices, sexually transmitted diseases (STDs), pregnancy prevention, domestic and intimate partner violence, and substance use and abuse.

Changes in Cognitive Development in Young Adulthood

Cognitive abilities are strong during young adulthood. Also typical is an increase in rational-thinking, motor, conceptual, and problem-solving skills as a result of formal education, occupational training, and overall life experiences.

According to [Piaget \(1969\)](#), by this stage the person no longer requires concrete objects to make rational judgments. The young adult is capable of deductive and hypothetical reasoning and has an ability for abstract thinking very similar to that of the more mature adult. For more information on Piaget's theory, see [Chapter 17](#).

Postformal thought is cognitive development past Piaget's formal operational stage. William Perry, a professor of education at Harvard University, studied college students to understand development during the college years. [Perry \(1981\)](#) found that students gradually changed their thinking in the face of reality and adult responsibility. He found that young adults engage in **dualistic thinking**, or dividing information, values, and authority into right and wrong, good and bad, "we" and "they." Truth is compared against abstract standards, and authority figures are respected simply because of their authority base.

In Perry's scheme, students have a nine-stage progression from dualistic to **relativist thinking**. Learners move from viewing truth in absolute terms of right and wrong (obtained from "good" or "bad" authorities) to recognizing multiple, conflicting versions of "truth" representing legitimate alternatives. The intent of the original research was to describe students' experience during the college years ([Perry, 1981](#)). Relativistic thinking occurs as students age and become aware of the diversity of opinions on any topic. Knowledge is seen as being embedded in a framework of thought. Truth is seen as being relative, based on context, rather than absolute. Thinking becomes more flexible, tolerant, and realistic. This transition in thinking may be unique to people pursuing extended education, with the diversity of opinions that they encounter in that environment. The underlying theme is **adaptive cognition**, in which thought is more responsive to context and less constrained by the need to find only one answer to a question ([Berk, 2018](#)).

Young adults are faced with many difficult decisions that involve relationship issues, home life, and work or occupation. An understanding of theories of cognitive development and learning regarding young adults allows the nurse to individualize patient education on the basis of knowledge of young-adult cognitive functioning.

Primary Developmental Tasks in Young Adulthood

Many theories offer help in understanding human development and the tasks associated with stages of development. According to the life span perspective, no age period is superior to another in terms of impact on the life course. The psychoanalytic perspective hypothesizes that individuals progress through a series of stages in which they confront conflicts between biologic and social expectations. The resolution of these conflicts determines the individual's ability to thrive. Conversely, those individuals who experience a life trauma during a developmental stage may have greater difficulty overcoming the conflicts specific to that stage even as the individual may have success achieving resolution in future stages.

According to [Sigmund Freud \(1923/1974\)](#), an individual's basic personality is developed during the preschool years as relations between the id, ego, and superego are established. Freud's theory has been criticized for its overemphasis on sexual feelings in child development. It should be noted that Freud's patients were not children but adults, who were asked to recall events that may have occurred very early in life. Adults are in what Freud called the *genital stage*, which occurs from puberty onward. Sexual feelings are reawakened. When conflicts from previous stages reemerge and are resolved, the individual is able to develop a mature adult relationship. See [Chapter 17](#) for more information on Freud's theory.

According to [Erikson \(1963\)](#), the initial stage of being an adult is intimacy versus isolation. Work is done on establishing intimate relationships with others. Young adults try to find satisfying relationships, primarily through marriage and friends, and many start a family. In today's society, family life may begin much later, with many individuals not having children until their late 30s. If people are able to negotiate this stage successfully, intimacy is experienced on a deeper level. For some, because of earlier disappointments in life, this intimacy is not achieved, resulting in isolation or limited interpersonal relationships ([Erikson, 1963](#)). Erikson explained that culture and life situations impact development. See [Chapter 17](#) for more information on Erikson's theory.

For the young adult, [Havighurst \(1953\)](#) identifies the following developmental tasks:

- Achieving new and more mature relations with age-mates of both sexes

- Achieving a masculine or feminine social role
- Accepting one's physique and using the body effectively
- Achieving emotional independence of parents and other adults
- Preparing for marriage and family life
- Acquiring a set of values and an ethical system as a guide to behavior
- Desiring and achieving socially responsible behavior
- Selecting an occupation

See [Chapter 17](#) for more information on Havighurst's theory in the context of development in childhood and adolescence.

Psychosocial Changes in Young Adulthood

Young adulthood is a time of dramatic change in personal relationships. Young adults seek emotional and physical intimacy in relationships with peers and romantic partners. Self-disclosure and a sense of belonging are important aspects of intimacy. Intimate relationships are associated with physical and mental health. Although the Internet, social media, and smartphone use offer expanded opportunities for communication, lack of personal contact may lead to a weakening of intimacy and a decline in psychological well-being. Most young adults have friends but have increasingly limited time to spend with them. Women's friendships usually are more intimate than men's. Attitudes toward premarital sex have been greatly liberalized, but men and women are less promiscuous than is sometimes believed.

Lifestyles in Young Adulthood

Many nontraditional family options are seen in the United States as people postpone marriage or chose to cohabit. The traditional family design still exists but has gone through some transformations over the years. Reasons for evolution of nontraditional lifestyles vary in accordance with environment, life situation, socioeconomic level,

and relevant legislation. Many young adults have postponed marriage until educational goals are met or career objectives accomplished. Being single can afford opportunities to travel for work and pleasure.

During these changing times, young adults face many stressors that may have an adverse impact on their lives. Attention is focused on the attainment of higher education and jobs that pay well in an attempt to improve lifestyle. With the economic downtrends early in the 21st century and corporate downsizing, many college graduates are forced to accept, or must debate acceptance of, employment in positions that are less fulfilling and for pay that will meet only basic needs. These factors and others require that family and friends provide financial and social support to sustain young adults.

Lo 18.4 Health Risks and Concerns During Young Adulthood

The challenge for nurses in planning and delivering care is to adequately account for how factors (such as age, gender, race, culture, lifestyle, and religious practices) influence young adults' lives. Thus strategies must be in place to address these influences as part of the provision of health care for young adults. The focus of nurses providing care for young adults should be on identifying factors that lead to unhealthy lifestyles and increase the risks of illness and injury.

Health Risks During Young Adulthood

As parental and other adult oversight decreases, young people assume increasing responsibility for their own decisions. These decisions include those that will directly affect their current and future health status (such as alcohol, cigarette, and illicit drug use; sexual activity; childbearing; exercise; risk-taking activities; and eating habits), as well as decisions that will indirectly affect their future health ([National Center for Health Statistics, 2014](#)).

Cigarette Smoking and Alcohol Use

By age 21, young adults in all 50 states can legally purchase tobacco products and alcohol. Among young adults up to age 24, approximately 13% are cigarette smokers; the percentage rises to nearly 18% in young adults age 25 and up ([Centers for Disease Control and Prevention \[CDC\], 2018c](#)). E-cigarettes are growing in popularity, and the health effects are not yet known.

Alcohol use contributes to increased mortality from unintentional injuries, including motor vehicle accidents while people are driving under the influence. Drinking in excess and binge drinking can cause immediate danger and long-term effects. For example, alcohol consumption accounts for 50% of all cases of pancreatitis. Holiday syndrome is another acute condition related to alcohol consumption; this syndrome occurs generally after individuals engage in binge drinking over a period of time. Withdrawal of alcohol can result in atrial and ventricular arrhythmias of the heart. Acute skeletal myopathy can occur after an individual consumes large amounts of

alcohol. Chronic alcohol consumption can result in esophageal varices, erosive gastritis, cirrhosis of the liver, and hepatitis.

Illicit Drug Use

Use of illicit drugs (such as marijuana, heroin, cocaine [including crack cocaine], methamphetamine, hallucinogens, and other illegal drugs used recreationally) and nonmedical use of prescription drugs (such as pain relievers, stimulants, and depressants) is associated with serious health and social consequences. These include injury, illness, disability, and death, as well as crime, domestic violence, and lost school or workplace productivity ([U. S. Department of Health and Human Services, 2010](#)). [Table 18.2](#) lists commonly abused drugs and the side effects of overuse and abuse of these drugs. Nurses need to ask young adults about illicit drug use and know the signs and symptoms of overuse and abuse of the most commonly used drugs.

TABLE 18.2**Commonly Abused Drugs**

SUBSTANCE CATEGORY WITH DRUG NAMES	SOME COMMERCIAL AND STREET NAMES	DRUG ENFORCEMENT AGENCY SCHEDULE AND HOW DRUG IS USED	INTOXICATION EFFECTS AND POTENTIAL HEALTH PROBLEMS
Cannabinoids • Marijuana • Hashish	<i>Marijuana:</i> Blunt, dope, grass, herb, joints, Mary Jane, pot, reefer, weed, boom, chronic, gangster, hemp <i>Hashish:</i> Hash, hash oil	Schedule I Swallowed, smoked	Increased heart rate, anxiety; panic attacks; euphoria, slowed thinking and reaction time, confusion, impaired balance and coordination; impaired memory and learning; cough, frequent respiratory infections; tolerance, addiction

SUBSTANCE CATEGORY WITH DRUG NAMES	SOME COMMERCIAL AND STREET NAMES	DRUG ENFORCEMENT AGENCY SCHEDULE AND HOW DRUG IS USED	INTOXICATION EFFECTS AND POTENTIAL HEALTH PROBLEMS
<p>Opioids and morphine derivatives</p> <ul style="list-style-type: none"> • Codeine • Fentanyl • Heroin • Morphine • Oxycodone • Hydrocodone 	<p><i>Codeine</i>: Captain Cody, schoolboy; <i>with glutethimide</i>: doors and fours, loads, pancakes and syrup</p> <p><i>Fentanyl (Actiq, Duragesic, Sublimaze)</i>: Apache, China girl, China white, dance fever, friend, goodfella, jackpot, murder 8, TNT, Tango and Cash</p> <p><i>Heroin</i>: Brown sugar, dope, H, horse, junk, skag, skunk, smack, white horse</p> <p><i>Morphine sulfate (Roxanol, Duramorph)</i>: M, Miss Emma, monkey, white stuff</p> <p><i>Oxycodone (OxyContin)</i>: Oxy, O.C., killer</p> <p><i>Hydrocodone-acetaminophen (Vicodin)</i>: Vike, Watson-387</p>	<p>Schedules II, III, IV, V</p> <p>Injected, swallowed</p>	<p>Respiratory depression and arrest; euphoria, drowsiness, confusion, sedation, unconsciousness, coma, death; nausea, constipation; tolerance, addiction</p>

SUBSTANCE CATEGORY WITH DRUG NAMES	SOME COMMERCIAL AND STREET NAMES	DRUG ENFORCEMENT AGENCY SCHEDULE AND HOW DRUG IS USED	INTOXICATION EFFECTS AND POTENTIAL HEALTH PROBLEMS
<p>Stimulants</p> <ul style="list-style-type: none"> • Amphetamine • Cocaine • Dimethoxy-methylamphetamine (DOM), • Methylenedioxy-methamphetamine (MDMA) • Methylphenidate • Nicotine 	<p>Amphetamine (Dexedrine), amphetamine-dextroamphetamine (Biphetamine) Adderall (amphetamine mixture): Bennies, black beauties, crosses, hearts, LA turnaround, speed, truck drivers, uppers Cocaine hydrochloride: Blow, bump, C, candy, Charlie, coke, crack, flake, rock, snow, toot MDMA: Adam, clarity, ecstasy, Eve, lover's speed, peace DOM: STP, X, XTC Methylphenidate (Ritalin): JIF, MPH, R-ball, Skippy, the smart drug, vitamin R Nicotine: Cigarettes, cigars, smokeless tobacco, snuff, spit tobacco, chew</p>	<p>Schedule II Injected, swallowed, smoked, snorted, chewed</p>	<p>Rapid or irregular heartbeat, increased blood pressure, heart failure, cardiovascular disease, stroke; increased metabolism; feelings of exhilaration, energy, increased mental alertness, nervousness, insomnia, tremor, loss of coordination; impulsive behavior, aggressiveness, psychosis, panic attacks, mild hallucinogenic effects, headaches; reduced appetite, weight loss; adverse pregnancy outcomes; chronic lung disease, seizures, cancer; tolerance, addiction</p>

SUBSTANCE CATEGORY WITH DRUG NAMES	SOME COMMERCIAL AND STREET NAMES	DRUG ENFORCEMENT AGENCY SCHEDULE AND HOW DRUG IS USED	INTOXICATION EFFECTS AND POTENTIAL HEALTH PROBLEMS
Hallucinogens <ul style="list-style-type: none"> • Lysergic acid diethylamide (LSD) • Mescaline • Psilocybin 	<i>LSD</i> : Acid, blotter, boomers, cubes, microdot, yellow sunshines <i>Mescaline</i> : Buttons, cactus, mesc, peyote <i>Psilocybin</i> : Magic mushroom, purple passion, shrooms	Schedule I Swallowed, absorbed through oral tissues	Altered states of perception and feeling, nausea, persisting perception disorder (flashbacks) <i>Also for LSD and mescaline</i> : Increased body temperature, heart rate, blood pressure; loss of appetite, sleeplessness, numbness, weakness, tremors, persistent mental disorders
Sedatives (depressants, hypnotics, tranquilizers) <ul style="list-style-type: none"> • Barbiturates • Benzodiazepines (other than flunitrazepam) • Flunitrazepam gamma-hydroxybutyrate (GBH) 	<i>Barbiturates (Amytal, Nembutal, Seconal, phenobarbital)</i> : Barbs, reds, red birds, phennies, tooies, yellows, yellow jackets <i>Benzodiazepines (Ativan, Halcion, Librium, Valium, Xanax)</i> : Candy, downers, sleeping pills, trunk <i>Flunitrazepam (Rohypnol)</i> : Forget-me pill, Mexican Valium, R2, Roche, roofies, roofinol, rope, rophies <i>GBH</i> : G, Georgia home boy, grievous bodily harm, liquid ecstasy	Schedules II, III, IV, V Injected, swallowed	Slowed pulse and breathing, lowered blood pressure; reduced anxiety, feeling of well-being, lowered inhibitions; poor concentration/fatigue, confusion; impaired coordination, memory, judgment; addiction

From National Institute on Drug Abuse (NIDA). (2016). Commonly abused drugs. *National Institutes of Health*. Retrieved from <https://www.drugabuse.gov/drugs-abuse/commonly-abused-drugs-charts>.

Other drugs abused by young adults include anabolic steroids, which can have serious side effects, and inhalants (such as glues and

gases), which can cause neurologic impairment and death. Education about the harmful aspects of drug, alcohol, and tobacco use should be provided at every health care visit.

In 2013, the rate of current illicit drug use in 18- to 25-year-olds was 21.5%. Levels in the 18-to-25 age group were higher than those among teenagers younger than 18 years or people 30 years of age and older ([Substance Abuse and Mental Health Services Administration, 2014](#)). Marijuana was the most commonly reported illicit drugs. Around 19% of 18- to 25-year-olds reported marijuana use in the past month.

Prescription drugs used for nonmedical purposes were the next most commonly reported illicit drugs; this category included pain relievers, tranquilizers, stimulants, and sedatives but not over-the-counter drugs. ([Substance Abuse and Mental Health Services Administration, 2014](#)). Statistics for the current heroin epidemic are not included in the aforementioned study. The most at risk population age group for heroin use is 18- to 25-year-olds at 7.3% ([CDC, 2015b](#)).

Safe Practice Alert

Always ask patients about their use of alcohol, nicotine products, and recreational drugs (such as marijuana, cocaine, crack, and heroin). Use of these substances has increased among young adults, thereby increasing the risk of associated diseases.

Intimate Partner Violence and Sexual Violence

Intimate partner and domestic violence, dating violence, and sexual violence are pervasive problems in the United States and other countries. Abuse can result in death or injuries, or in mistrust or a shattered sense of well-being that is a barrier to moving forward in life for some victims. Sexual violence may result in unwanted pregnancy. The United States has made progress in the last few decades in addressing this type of violence, resulting in a decline in its occurrence, but more work needs to be done to implement strategies to end it. Younger generations should be taught that exposure to violence in movies or video games and on television may influence behaviors negatively in the future. Health care providers need training to assess patients for signs of abuse. Workplace prevention and victim support programs are needed,

with the goal of making services available to all. In 2010, 1181 women were murdered by their intimate partners. According to data collected by the Centers for Disease Control and Prevention, 12 million men and women are victims of rape or intimate partner violence each year. Nearly three in ten women and one in ten men in the United States report experiencing violence by a current or former spouse or intimate partner at some point in their lives (CDC, 2014).

Consequences of Domestic Violence

In the United States the cost of intimate partner rape, physical assault, and stalking was estimated to be \$8.3 billion in 2003 for direct medical and mental health care services and lost productivity from paid work and household chores (CDC, 2014). Both physical health and mental health are affected by intimate partner violence that results in injury, disability, flashbacks, panic attacks, and low self-esteem. The stress can lead to depression and harmful health behaviors (such as smoking, drinking, using drugs, and having risky sex) as a way of coping with the trauma (CDC, 2014). Current technologies (such as smartphones, social media, texting, and webcams) have increased the methods employed by people to stalk, monitor, and harass victims.

Nurses have a responsibility to ask patients whether they are being abused. Knowing how to ask requires training on addressing such a sensitive issue without offending the patient. Phrasing the question correctly during a patient encounter can mean the difference between life and death (Box 18.2). Many screening tools are available that allow the patient to self-report abuse. It may not be practical to screen all patients, but some screening tools make this simple to do and can be incorporated into the health assessment forms used by most health care organizations. Most health care organizations have counselors and nurses trained to handle cases of abuse, so the novice nurse should seek help when needed (Box 18.3). See Chapter 24 for more information on handling cases of sexual abuse.

Box 18.2

Health Assessment Questions

Intimate Partner Violence

- Are you in a relationship with a person who physically hurts or threatens you?
- Has your partner or ex-partner ever hit you or physically hurt you? Has he or she ever threatened to hurt you or someone close to you?
- Do you feel controlled or isolated by your partner?
- Do you ever feel afraid of your partner? Do you feel you are in danger? Is it safe for you to return home?
- Has your partner ever forced you to have sex when you did not want to? Has your partner ever refused to practice safe sex?

Box 18.3

Interprofessional Collaboration and Delegation

Domestic Violence

- Nurses and other health care providers are uniquely positioned to address issues related to domestic and intimate partner violence.
- Health care providers in every discipline should collaborate to remove barriers to identifying and treating victims of domestic violence.
- All health care providers should:
 - Ask about abuse
 - Identify barriers for detection of abuse
 - Facilitate screening
 - Provide training on signs and symptoms and detection of abuse
 - Provide services
 - Empower patients

Safe Practice Alert

Nurses should include screening for domestic violence as part of the assessment of all patients, female and male, knowing that abuse occurs in both homosexual and heterosexual relationships.

Accidents and Violence

According to the National Adolescent Health Information Center (NAHIC), motor vehicle accidents accounted for 31% of deaths among adolescents and young adults in 2003, followed by homicides at 14.8%, suicides at 11.2%, and other unintentional injuries at 13.7% (NAHIC, 2006) (Box 18.4). Excessive drinking is the leading risk factor for injury in the United States and the third leading cause of preventable death (CDC, 2010). Texting, eating, or being otherwise distracted while driving contribute to motor vehicle accidents.

Box 18.4

Diversity Considerations

Life Span, Gender, and Ethnicity

Accidents and Fatal and Nonfatal Injuries

- Young males have a higher homicide mortality rate than females.
- Nonfatal violent crimes are more common than homicide but have decreased in the past decade.
- The homicide rate in 15- to -19-year-old males is much higher among African Americans compared with other ethnic groups: African American (38.47/100,000), Hispanics (13.99/100,000), whites (2.61/100,000), American Indians and Alaska Natives (8.21/100,000), Asian and Pacific Islanders (3.19/100,000).
- The leading causes of nonfatal, unintentional injuries among 18- to 34-year-olds of all races and both sexes were unintentional falls, unintentionally being struck by or against an object, and being an occupant in a motor vehicle.

From National Adolescent Health Information Center (NAHIC). (2007). 2007 fact sheet on violence: Adolescents and young adults. Retrieved from <http://nahic.ucsf.edu/downloads/Violence.pdf>.

Health Concerns During Young Adulthood

Health issues (such as diabetes, hypertension, obesity, alcohol abuse, drug abuse, and smoking) are becoming more prevalent among young adults. Health insurance is a key factor in these adults' access to medical services. In the United States, adults aged 20 to 29 years are more likely than adults aged 30 and older to lack health insurance ([National Center for Health Statistics, 2011](#)).

Health Screening and Health Promotion

Early detection of illness and disease can best be accomplished when young adults participate in periodic health screenings. For young women, these screenings include annual Papanicolaou (Pap) smears for those who are sexually active. Pap smears are the most accurate method of detecting cervical cancer in women. When young women become sexually active, the risk of exposure to the human papillomavirus (HPV) increases, thus increasing the risk for cervical cancer. Immunizations, including HPV, are recommended for this age group. A complete schedule of immunizations for adults is available at the CDC website ([CDC, 2018b](#)). Screenings for changes in the skin are advised, because many young adults spend a lot of time exposed to ultraviolet rays whether at work or at play. Nurses can serve as a catalyst to move young adults to action when it comes to health promotion activities. Nurses can also provide education on health promotion activities, as well as performing screenings at health fairs, in schools, and at employment sites.

Diet and Physical Activity

Young adults are often fixated on their bodies and on the idea of being appealing to the opposite sex. They are constantly bombarded by images of beautiful people in movies, on television, and in magazines. Advertisements for diets, makeup, and skin creams are prevalent. The desire to be thin and beautiful has led many young men and women to be anorexic or bulimic—two conditions that have led to death for some young adults. Most young adults want to be healthy but can be confused about what being healthy truly means. An abundance of food is available in the United States. However, healthy eating and maintaining a proper diet can be a challenge for some. Many young adults have grown up in the age of the microwave, where cooking fresh food and sitting down to eat

has been replaced by microwaving frozen foods and eating on the run. Fast-food restaurants have added to this trend by offering quick food that is high in saturated fats, which is filling but does not contain recommended nutrients. Nurses should emphasize proper nutrition and exercise to promote good health among young adults.

Nurses are equipped to teach the importance of good nutrition and the consequences of not having a proper diet. Patients in lower socioeconomic situations may feel that they cannot adhere to proper nutrition because of cost. Nurses can use the U.S. Department of Agriculture (USDA) MyPlate guidelines to teach patients about food substitutions that are nutrient-rich and economical.

Young adults often are very active, and many pursue exercise as a part of their daily routines. Others have not made physical activity a priority, and nurses should try to impress on them the benefits of exercise. Exercise helps decrease the risk of heart disease, obesity, diabetes, and cancer. It strengthens the heart, reduces anxiety, improves mood, and enhances overall subjective sense of well-being. Nurses can teach patients the current recommendations for exercise (Box 18.5).

Box 18.5

Patient Education and Health Literacy

Exercise

- Teach patients that most adults need at least 30 minutes of moderate physical activity (such as brisk walking or bicycling) at least 5 days per week.
- Encourage patients to find an exercise that they enjoy and to start slowly if they haven't been exercising regularly. Walking with a friend or joining a class may help keep motivated.
- Advise patients that adding stretching and weight training to their routine will improve strength and fitness.

From National Library of Medicine. (2017). Exercise and physical fitness. *MedlinePlus*. Retrieved from www.nlm.nih.gov/medlineplus/exerciseandphysicalfitness.html.

Mental Health in Young Adulthood

Mental, emotional, and behavioral (MEB) disorders—which include depression, conduct disorders, bipolar disorder, schizophrenia, and substance abuse—are seen in a large number of young adults. Posttraumatic stress disorder (PTSD) and depression are being diagnosed frequently among young men and women returning from combat. High rates of suicide are seen in these young adults. Studies indicate that MEB disorders constitute a major health threat and are commonplace today among young people. Almost one in five young people will have one or more MEB disorders at any given time. Among adults, half of all MEB disorders were first diagnosed by age 14 and three-fourths by age 24 (O'Connell, Boat, & Warner, 2009).

Many disorders have lifelong effects that include high psychosocial and economic costs not only for the young people but also for their families, schools, and communities. The financial costs in terms of treatment services and lost productivity are estimated at \$247 billion annually (O'Connell, Boat, & Warner, 2009). Beyond the financial costs, MEB disorders interfere with the young person's ability to accomplish age and culturally appropriate developmental tasks such as establishing healthy interpersonal relationships, succeeding in school, and making their way in the workforce. [Box 18.6](#) lists questions the nurse should ask to assess the mental health status of young adults.

Box 18.6

Health Assessment Questions

Mental Health Conditions

Anxiety Disorders

- How often have you been feeling anxious, on edge, or nervous?
- How often have you been unable to stop or control worrying?
- Do you feel that you worry too much about different things?
- Do you have trouble relaxing?
- Are you able to fall asleep within 15 to 30 minutes of going to bed?

- How often are you restless or do you have problems sitting still?
- Do you easily become annoyed or irritable?
- How often do you feel afraid that something bad will happen?
- Do your thoughts seem like they are racing?

Depression

- Have you recently lost pleasure or interest in things that previously brought you pleasure?
- Have you been having feelings of helplessness, hopelessness, or sadness?
- Are you having trouble falling asleep or staying asleep?
- Do you feel tired often?
- Has your appetite increased or decreased recently?
- Have you been feeling bad about yourself or feeling like a failure recently?
- Have you had thoughts of harming yourself or someone else?

Adapted from Spitzer, R. L., Williams, J. B., Kroenke, K., et al. (2018). GAD-7 and PHQ-SADS. *Patient Health Questionnaire (PHQ) Screeners*. Retrieved from www.phqscreeners.com.

Screening should be a part of nurses' assessment of young adults, with referral for mental health services when indicated. A quick assessment for depression and anxiety can be performed in approximately 5 to 10 minutes.

Sexual Behavior and Sexually Transmitted Diseases in Young Adulthood

Some young adults engage in risky sexual behaviors that can result in negative health outcomes. These behaviors, while signaling a certain freedom from commitment, can increase the risk of STDs in both males and females. The most common STDs include gonorrhea, chlamydial infection, herpes simplex, human immunodeficiency virus (HIV) infection, syphilis, and HPV infection (Box 18.7). According to the CDC (2012), chlamydial genital infection is the most frequently reported infectious disease in the United States, and

the prevalence is highest among people 20 to 24 years of age. For more information about signs and symptoms of STDs and their prevention, see [Chapter 24](#).

Box 18.7

Evidence-Based Practice and Informatics

Human Papillomavirus, Genital Warts, and Oral Cancer

- Human papillomavirus (HPV) is so common that nearly all of sexually active people will have genital HPV infection at some time in their lives.
- HPV is passed on through genital contact via vaginal or anal sex. There is no cure for HPV infection.
- Many strains of the HPV virus have been recognized. Some are considered low-risk strains, and some are considered high-risk.
- Low-risk HPV infections can cause genital warts.
- High-risk HPV infections can cause lesions that sometimes develop into cancer over time.
- Females and males can get vaccinated to protect against the types of HPV that most commonly cause health problems. The vaccine is most effective when people receive it before they have sexual contact with their first partners.
- HPV may contribute to the development of 20% to 30% of oral cancers.

From Centers for Disease Control and Prevention (CDC). (2017). Genital HPV infection fact sheet. Retrieved from <https://www.cdc.gov/std/hpv/stdfact-hpv.htm>.

Because of the temporary nature of many relationships among young adults, nurses should encourage all sexually active adults to get screened for STDs. Nurses have the knowledge and skills necessary to teach patients safe sex practices and signs and symptoms that need to be reported and investigated ([Box 18.8](#)).

Assure patients that their health information is confidential and that no disclosure will be made except if required by law.

Box 18.8

Patient Education and Health Literacy

Sexually Transmitted Disease

- Teach patients the signs and symptoms of common sexually transmitted diseases (STDs).
- Ask patients to verbalize an understanding of the importance of practicing safe sex.
- Teach patients that latex condoms, when used consistently and correctly, are highly effective in preventing the sexual transmission of human immunodeficiency virus (HIV), the virus that causes acquired immune deficiency syndrome (AIDS), and reducing the risk of other STDs, including diseases transmitted by genital secretions and, to a lesser degree, genital ulcer diseases.
- Demonstrate proper condom application to both males and females, with a return demonstration to assess knowledge.

Lo 18.5 Middle Adulthood: Ages 35 to 65

Middle adulthood is a time of adjustment for many adults. This transitional stage of life is marked by physical changes and adaptation to challenges, such as making career changes, children leaving home for college or returning home after college, and caring for aging parents. These changes produce increased stress, which manifests itself in different ways. In 2009, middle adults accounted for 60.3% of the U.S. labor force (U.S. Census Bureau, 2011). Middle adults' annual average health care expenditure between 2006 and 2009 was \$9254, which was spent on health care insurance, medical services, drugs, and medical supplies (U.S. Census Bureau, 2011). Each person's transition is an individual process, and no two people experience middle adulthood in exactly the same way. Some diversity considerations for middle adults are listed in Box 18.9.

Box 18.9

Diversity Considerations

Life Span and Gender

Marital Status

- Ages 35 to 39: 67.3% of males were married, compared with 69.4% of females.
- Ages 40 to 44: 68.0% of males were married compared with 70.1% of females.
- Ages 45 to 54: 69.7% of males were married compared with 68.3% of females.
- Ages 55 to 64: 73.9% of males were married compared with 66.9% of females.

Educational Attainment

- A high school diploma was *not* attained by 11.7% of adults ages 35 to 44, 10.4% of adults 45 to 54, and 10.4% of adults 55 to 64.

- A bachelor's degree or higher was attained by 33.1% of people ages 35 to 44, compared with 29.4% of people 45 to 54, and 31.7% of people 55 to 64.

From U. S. Census Bureau. (2011). Statistical abstract of the United States: 2012. (131st ed.). Washington, DC: Author. Retrieved from <https://www.census.gov/programs-surveys/decennial-census/decade.2010.html>.

Age Group Characteristics

Middle adulthood has its own developmental changes and issues not common to young adulthood. Middle adulthood is difficult to define, however, because people in this life stage exhibit wide variation in attitudes and behaviors. For some, certain personal choices have led to a very fulfilling life, whereas for others, such choices have led to significant changes and stresses in their lives. Children may leave home during this time, and retirement often looms. Attitudes about life determine the extent to which people act young or old during this period. Recent advances in medicine and technology offer the opportunity to live a better-quality life, with a slower transition to old age. Some predictable physical declines occur at this stage of life. It was long thought that some cognitive decline was associated with the normal aging process. This belief has since been disputed: One study by [Wilson, et al. \(2010\)](#) contradicts the idea of inevitable mental deterioration and asserts that forgetfulness and memory lapses are early changes that may signal dementia later in life.

Physical Changes in Middle Adulthood

Physical changes are evident as middle adulthood progresses; wrinkles begin to appear on the face, hair thins, and the waist thickens in most middle-aged adults. Muscle tissue (muscle mass) and muscle strength tend to decrease beginning in the thirties. This process is called **sarcopenia**, which means loss of flesh. Other physical changes with aging are listed in [Table 18.1](#) earlier in this chapter.

Changes in Cognitive Development in Middle Adulthood

Crystallized intelligence refers to skills that depend on accumulated knowledge, experience, good judgment, and mastery of social conventions. These skills are acquired because they are valued in our culture. Crystallized intelligence is evaluated through vocabulary tests, general information tests, verbal analogies, and logical-reasoning tests. This type of intelligence increases through middle adulthood as adults add to their knowledge and skills at work and in leisure activities and practice the skills daily (Berk, 2018).

Fluid intelligence represents basic information-processing skills: that is, the ability to detect relationships among stimuli, the speed with which information is analyzed, and the capacity of working memory (Berk, 2018). This type of intelligence supports reasoning, abstraction, and problem solving and is more inherited than culturally trained. Fluid-intelligence skills are evaluated through number-series tests, spatial visualization, picture sequencing, and symbol search (Berk, 2018).

Changes in mental abilities seem to be related to a general slowing of the central nervous system. The neural processing speed decreases. Well-practiced skills aren't noticeably affected, and adults find ways to compensate. Generalities do not explain individual and group differences. Some people lose cognitive function as a consequence of illness or adverse environments. Others remain creatively intellectual into very old age. Those who keep their intellect active usually are busy using their skills in work, leisure pursuits, travel, reading, cultural and arts endeavors, or civic commitments. People who have flexible personalities, have a lasting marriage to an intellectually challenging partner, are healthy, and live at a higher socioeconomic level will maintain their intellect longer (Berk, 2018). Some diversity considerations are listed in Box 18.10.

Box 18.10

Diversity Considerations

Life Span

- Numeric ability has declined, especially in younger middle adults, because of the reliance on calculators today.

- People who maintain higher levels of perceptual speed tend to have advantages in other mental abilities as well ([Belsky, 2016](#)).

Gender

- In early adulthood, women outperform men on verbal tasks and perceptual speed. Men excel at spatial skills. Losses over time are similar for both men and women.
- Aging women of the Baby Boomer generation perform better than aging women from earlier groups. This reflects the Baby Boomers' greater opportunities for education, technology, stimulation from work, and health care.

Ethnicity

- Ethnicity is not associated with rates of decline in cognition ([Massel & Peek, 2009](#)).
- Education and physical activity may be mediators of differences in cognitive test scores among Caucasian American, African American, and Hispanic middle-aged adults ([Massel, Raji, & Peek, 2010](#)).

Primary Developmental Tasks in Middle Adulthood

Middle adulthood is the time when many people reevaluate their lives, look for meaning in their existence, refine and strengthen their identities, and reach out to younger generations. For some middle-aged adults, this is a time for making adjustments in their daily lives, their outlook on life, and their goals. For others, it can be a time of crisis that can greatly affect their outlook on life and their future path in life ([Berk, 2018](#)).

1. Which developmental issues is M. D. dealing with?

Erikson's Theory: Generativity Versus Stagnation

Generativity means reaching out to others in ways that guide and give to the next generation. In midlife, this activity extends beyond the nuclear family to social groups and communities (Fig. 18.2). Personal life goals are now viewed in context with the welfare of the greater society. Generativity includes anything a person can develop and produce that can improve society and continue after the person's death. It is expressed through activities, such as mentoring in the workplace or with youth groups, volunteering at shelters and organizations, being involved in community issues of importance to the individual, and engaging in creative endeavors in fields (such as art, music, and dance). People want to be needed and to feel that they have had a lasting effect on the world.

FIGURE 18.2 Volunteering in the community. (Copyright [istock.com.](https://www.istock.com/))

The alternative to generativity is **stagnation**—becoming self-centered and narcissistic. In stagnation, people place their own comfort and security above challenges that include other people. They have a detachment even from their own children, with a self-centered focus on what they can get from others, not what they can give. They lose interest in being productive at work or developing talents.

2. Discuss M. D.'s status in regard to Erikson's stages.

Generative people are well adjusted, low in anxiety and depression, and high in self-acceptance and life satisfaction. They are more open to others' differences and points of view, have leadership qualities, care about the welfare of others, and care about more than financial gain in their work. Parenthood seems to enhance generativity in men more than in women. Women may have many ways to awaken to the needs of others, whereas men may need to feel the nurturance of a child to develop that outward concern. African Americans score higher in generativity in connection to religious groups, social support, and a view of themselves as models of wisdom for children (Belsky, 2016).

3. How can the nurse help M. D. achieve generativity?

Levinson's Seasons of Life

In Levinson's (1996) *Seasons of Life Theory*, middle adulthood begins with a transition (at ages 40 to 45 years), followed by entry into a life structure (45 to 50). This structure is reevaluated (50 to 55) and ends in a culminating life structure (55 to 60). Midlife transition occurs around age 40, when people evaluate their success in meeting adult goals. In response to this self-evaluation, some people make big changes in their lives (such as career changes, divorces, remarriages, and expressions of creativity), whereas others make smaller changes but remain in their marriages and maintain their current careers.

The self often becomes the middle adult's focus, as the person is less distracted by other people and things. Levinson's theory identifies the following four developmental tasks of middle adulthood:

- *Young/old*: Seeking new ways of being young and old and finding positive meaning in changes
- *Destruction/creation*: Reevaluating past hurtful acts and attempting to be kinder, more creative, and other-focused
- *Masculinity/femininity*: Integrating masculine and feminine aspects of the personality
- *Engagement/separateness*: Finding a balance between engagement with the outside world and interior needs

Havighurst's Developmental Tasks for Middle Adulthood

In Havighurst's theory of development, middle adulthood tasks are age-dependent, and all serve pragmatic functions dependent on age. According to [Havighurst \(1953\)](#), "The developmental tasks of middle years arise from changes within the organism, from environmental pressures, and above all from demands or obligations laid upon the individual by his own values and aspirations" (p. 268). Primary developmental tasks as hypothesized by [Havighurst \(1953, pp. 268-276\)](#) are as follows:

- Achieving adult civic and social responsibility
- Establishing and maintaining an economic standard of living
- Assisting teenage children to become responsible and happy adults
- Developing adult leisure activities
- Relating oneself to one's spouse as a person

- Accepting and adjusting to the physiologic changes in middle age
- Adjusting to aging parents

Lo 18.6 Health Risks and Concerns During Middle Adulthood

People in middle adulthood continue to have some of the health risks discussed in young adulthood. During middle adulthood, deaths due to complications from disease outnumber deaths due to accidents.

Health Risks During Middle Adulthood

Some leading causes of death in middle age are cancer and cardiovascular disease. The leading causes of nonfatal injury in middle adulthood are unintentional falls, unintentional overexertion, being struck by or against an object, and being an occupant in a motor vehicle accident (CDC, 2018a). Health promotion factors suggested by Berk (2018) are listed in Box 18.11.

Box 18.11

Patient Education and Health Literacy

Factors That Promote Well-Being in Midlife

- Good health and exercise
- Sense of control and life investment
- Positive social relationships
- A good marriage
- Mastery of multiple roles

From Berk, L. E. (2018). *Exploring lifespan development* (4th ed.). Boston, MA: Pearson.

Cancer

Cancer is the second leading cause of death in the U.S. The death rates for all cancers has been declining in the past 15 years due to earlier detection and advances in treatment. Lung cancer is the

leading cause of cancer deaths in women and men in the United States. Cigarette smoking is the primary cause of lung cancer. Death rates from lung cancer began to decline in 1991 for men and 2003 for women. Over the past decade, the number of lung cancer deaths is still declining, although lung cancer remains the top cause of cancer deaths ([American Cancer Society, 2018](#)). Patient teaching tips from the Mayo Clinic are listed in [Box 18.12](#).

Box 18.12

Patient Education and Health Literacy

Reducing Cancer Risk

To reduce the incidence of cancer and cancer deaths, teach patients to:

- Know the symptoms of cancer.
- Get regular check-ups, screenings, and immunizations.
- Avoid tobacco, sun exposure, pollutants, and x-ray exposure.
- Eat a healthful diet and maintain an appropriate weight.
- Drink alcohol only in moderation.
- Exercise most days.

Modified from Mayo Clinic Staff. Cancer prevention: 7 tips to reduce your risk, 2017. Retrieved from [https://www.mayoclinic.org/healthy-lifestyle/adult-health/in-depth/art-20044816?](https://www.mayoclinic.org/healthy-lifestyle/adult-health/in-depth/art-20044816?_ga=2.209162641.2098793204.1517348577-1148415983.1502400850)

Cardiovascular Disease

Cardiovascular diseases affect about one-fourth of middle-aged Americans. Many die from complications and effects of cardiovascular diseases. These diseases include high blood pressure, high blood cholesterol, and **atherosclerosis**, or buildup of plaque in coronary arteries around the heart. **Myocardial infarction (MI)**, blockage of blood flow to the heart, is the most extreme symptom and is largely due to a blood clot in a coronary artery. Lack of

oxygen and blood flow to the heart muscle produces excruciating pain. Every year over 700,000 Americans have MIs. Many die before ever reaching a hospital. Approximately 28% of MIs are seen in patients who have had previous MIs (CDC, 2015a). **Arrhythmia** is an irregular heartbeat that can prevent the heart from pumping enough blood. **Angina pectoris** is the crushing chest pain that is the first indication of an oxygen-deprived heart. Heart disease is treated with bypass surgery, medicines, arterial stents, pacemakers, and **angioplasty**—balloon surgery that flattens fatty deposits to open blood flow in blocked arteries. Diet and exercise are essential in the prevention of cardiovascular disease. Nearly three-quarters of all strokes occur in people aged 65 years or older. The chances of having a stroke double each decade after the age of 55. Strokes can—and do—occur at *any* age. Nearly 25% of strokes occur in people younger than 65 years of age. Stroke death rates are higher for African Americans than for whites, even at younger ages (CDC, 2010). Cardiovascular disease preventative measures suggested by the American Heart Association (AHA) are listed in **Box 18.13**.

Box 18.13

Patient Education and Health Literacy

Reducing the Risk of Cardiovascular Disease

The American Heart Association (AHA) recommends focusing on seven behaviors to lower the risk of stroke and heart disease, and stay heart healthy. The behaviors that will have the biggest impact are:

- Maintain a healthy weight
- Eat a healthy diet
- Get active
- Maintain a normal blood pressure
- Maintain a normal blood sugar
- Don't smoke
- Control cholesterol levels

Reprinted with permission www.heart.org. Copyright 2014 American Heart Association, Inc. Getting heart healthy one simple step at a time, 2014. Retrieved from http://www.heart.org/HEARTORG/HealthyLiving/Getting-Heart-Healthy-One-Simple-Step-at-a-Time_UCM_447728_Article.jsp#.WPU8wYjys2w.

Health Concerns During Middle Adulthood

Health assessments conducted in people in middle adulthood should address the physiologic and psychological problems that can be experienced during this period in life, such as heart disease, diabetes, obesity, hypertension, arthritis, chronic obstructive pulmonary disease (COPD), migraines, anxiety, and depression (Box 18.14). Information obtained should be used to guide the care and education of patients.

Box 18.14

Health Assessment Questions

Middle Adulthood

General Information

- Have you experienced any recent weight loss or gain?
- Have you experienced any fatigue lately?
- Do you have trouble falling asleep or staying asleep?
- Do you smoke? How many packs per day?
- Do you exercise regularly?
- Do you drink alcohol? How many drinks per week?
- Do you use any recreational drugs or substances?

Cardiovascular System

- Have you had chest pains?
- Do you have any rapid heartbeats?
- Do you become short of breath with exertion?

Respiratory System

- Have you been experiencing any shortness of breath?
- Do you snore loudly?
- Do you experience coughing or wheezing?

Gastrointestinal/Genitourinary System

- Do you have heartburn or indigestion?
- Have you had a change in your bowel habits?
- Have you noticed any bloody or black, tarry stools?
- Do you have pain with urination?
- Do you have to get up during the night to use the bathroom?
- Do you have concerns about your sexual function?

Integumentary System

- Have you noticed any changes to moles or any new moles?
- Do you have any rashes or itching or changes to your skin?

Endocrine System

- Have you experienced any recent heat or cold intolerance?
- Have you experienced any excessive sweating?

Neurologic System

- Have you experienced any of the following recently?
- Headaches
- Dizziness
- Fainting
- Falls
- Memory problems

Women Only

- Are you experiencing hot flashes or night sweats?

- Are you having irregular menstrual periods?
- When was your last mammogram?

Men Only

- When was your last prostate exam?
- Are you experiencing any penile discharge?

Domestic Violence Survey

- Does your spouse or partner hit, slap, or punch you?
- Are you afraid to return home?
- Are there firearms or guns in your home?

Health Screening and Health Promotion

Health promotion activities for middle adulthood should address adequate rest, leisurely activities, regular exercise, good nutrition, satisfactory sexual function, and reduction and cessation of tobacco and alcohol use. Adults should be encouraged to have regular health screenings, such as blood pressure checks, colonoscopies, prostate examinations for men, and mammograms and Pap smears for women. Domestic violence should be assessed in both men and women, as discussed in the Young Adulthood: Ages 18 to 34 section of this chapter.

Relationships at Midlife

Nine of 10 middle-aged adults live in families, most of them with a spouse ([U. S. Census Bureau, 2011](#)). This period of the family life cycle is called the “launching children and moving on” stage. In the past it was known as the “empty nest” period, but it is no longer seen in such a negative light ([Berk, 2018](#)). This period may last as long as 20 years before retirement. It relates to establishing different relationships with children and finding new relationships with in-laws and grandchildren. In addition, midlife adults must cope with elderly parents and their needs.

Marriage and Divorce

Households at the midlife stage tend to be better positioned economically and financially than they were previously. However,

recent changes in economic stability in the United States have affected the middle-aged adult, as well as other age groups. Adults between 45 and 54 years of age in the United States have the highest average annual income ([U.S. Census Bureau, 2011](#)), which in the past allowed for expansion of opportunities to learn or travel. Recently, many middle-aged adults have found that more savings are needed for retirement than was the case in the past. In addition, this period often is when marriages that have experienced some turmoil will end and former partners venture out for a new start. Most divorces occur in the first 5 to 10 years of marriage, but 10% occur after 20 years or more ([Berk, 2018](#)). At midlife, divorce seems to be more manageable emotionally. People who are better educated and employed are more likely to divorce because they can better support themselves. STDs are a concern in this age group when high-risk behavior is present, such as having an affair or dating and engaging in sexual activity with multiple partners after a divorce.

Grandparents Rearing Grandchildren

In the United States, approximately 4% to 5% of the child population live with grandparents and apart from parents, who are called the **skipped generation**. This arrangement may occur as a consequence of parental substance abuse, emotional illness, or physical illness. Sometimes a child welfare agency is involved and tries to place an at-risk child with a grandparent rather than in foster care. This arrangement may be difficult for the grandparent to maintain financially. Custodial grandparents often face high levels of stress and frustration and a decline in health as they attempt to provide stability for their grandchildren. In the children themselves, the disruption of normal family relations can lead to learning disabilities, depression, and even antisocial behavior. The grandparents often report being tired and emotionally drained, even depressed. They become important to the grandchildren, however, and these children often describe close relationships with their caregiving grandparents ([Berk, 2018](#)).

Middle-Aged Adults and Their Aging Parents

According to a [University of Michigan \(2011\)](#) study on health and retirement, almost 10 million adults over the age of 50 care for their aging parents. The study gives an updated look at adults who work and care for their parents and at the impact of caregiving on their earnings and lifetime wealth. The results found that the proportion

of adults providing personal care and/or financial assistance to a parent has more than tripled since the mid-1990s. Currently, 25% of adults—primarily Baby Boomers—provide care to a parent. Working and nonworking adults are almost equally likely to provide care to parents in need. Adults ages 50 and older who work and provide care to a parent are more likely to have fair or poor health than those who do not provide such care.

The term **sandwich generation** refers to middle-aged adults who are the caretakers of older and younger generations of their families. Middle-aged adults may be caring for their children or grandchildren, and for their aging parents.. These caretakers may experience stress and increased health risks as they care for others while neglecting their own health care needs. Overload may occur because the demands on the caretaker are numerous and may include financial obligations, work commitments, household responsibilities, and caregiver demands (Fig. 18.3).

FIGURE 18.3 Many middle adults care for their children and for their aging parents as well. (Copyright [Thinkstock.com](https://www.thinkstock.com/).)

The role of caring for a parent often has been compared with that of taking care of children, but the two are not the same. In caring for a child, the expectation is that the child will grow up and eventually leave home to prosper. In caring for an elderly parent, there is little hope that the parent will return to independence as the slow decline of aging takes place. Watching this process and feeling helpless to slow or stop it can lead to depression, exhaustion, and illness in the middle-aged caregiver (Boxes 18.15 and 18.16). Respite care is

available for some at a cost, but not all families can afford this. In some cases, nursing home placement must be explored; however, it too can pose a financial burden on the middle-aged caregiver and family.

Box 18.15

Evidence-Based Practice and Informatics

Chronic Stress Affects People in Different Ways

The National Institute on Mental Health reports that stress can affect people in different ways. Consequently, it is important for caregivers who experience chronic stress to:

- Recognize the signs
- Exercise regularly
- Talk with your health care provider
- Set goals and priorities
- Stay connected
- Try relaxing activities

From the National Institute of Mental Health. (2018). 5 things you should know about stress. Retrieved from <https://www.nimh.nih.gov/health/publications/stress/index.shtml>.

Box 18.16

Patient Education and Health Literacy

Tips for Dealing With Caregiver Stress

Advise caregivers to:

- Accept help from others.
- Join a support group or attend caregiver classes offered by organizations, such as the American Red Cross or the Alzheimer Association local chapter.

- Use community resources, such as respite care services or adult day care.
- Commit to keeping healthy; set personal health goals, as well as see your doctor for updates on screenings and immunizations.
- Avoid feeling guilty.
- Focus on what you are able to provide
- Set realistic goals
- Communicate with lawmakers and officials for information on policies that relieve financial burdens

4. What issues may have to be addressed by the nurse before M. D. can lead a fulfilling life?

Lo 18.7 Older Adulthood: Age 65 and Older

The American population is growing older. Society has defined the older adult as anyone older than 65 years of age. In some literature and textbooks, this age group is further divided into the *young-old* (up to 74 years old), *middle-old* (75 to 84 years), and *old-old* (85 years and older). According to the [U.S. Census Bureau \(2011\)](#), the average annual expenditure on health care between 2006 and 2008 was \$4779 for adults 65 to 74 years of age and \$4413 for those 75 years and older.

Age Group Characteristics

There are 47.8 million older Americans, with the number estimated to more than double to approximately 98 million by 2060. It is predicted that by 2040 people aged 65 and older will constitute 21.7% of the population (as compared with 14.9% in 2015), with those 85 and older increasing from 5.7 million to 14.1 million. Older women outnumber older men at a ratio of approximately nine to seven. The proportion of older people is higher among whites than in other populations, although the number of older adults in racial and ethnic minority populations is projected to increase from 22% in 2015 to 28% by 2030 ([Administration on Aging, 2016](#)). The older population in the United States is becoming increasingly more racially and ethnically diverse as the overall minority population grows and experiences increased longevity. As a result, it is critical that nurses understand that each person is unique, whether along the dimensions of race, ethnicity, gender, sexual orientation, socioeconomic status, age, physical abilities, religious beliefs, political beliefs or other ideologies. The increase in diversity can be expected to have an impact on almost every facet of nursing care for older adults because cultural background affects communication, values, health beliefs and health related-behaviors, and other aspects of functioning ([Miller, 2019](#)).

Dr. Robert [Butler \(1969\)](#) coined the term *ageism* and defined it as “the prejudices and stereotypes that are applied to older people on the basis of their age.” According to [Miller \(2019\)](#), ageism is an outcome of urbanization and industrialization resulting from the

emphasis on the negative and debilitating aspects of old age, and it is based on perceptions that older people are unproductive.

Physical Changes During Older Adulthood

Physical alterations seen in older adults include some of the changes listed in [Table 18.1](#). Age-specific differences in physical appearance and mobility involve changes in the skin, hair, facial structure, and body build. The physical capabilities of older adults are not the same as they were in earlier stages of life, although many older adults remain agile and physically fit in later life ([Fig. 18.4](#)). There are obvious signs of aging: Hair becomes gray, and facial skin and other parts of the body become wrinkled because of loss of skin elasticity and collagen content ([Feldman, 2018](#)). Height declines as the spine collapses with bone loss and decreased muscle tone. Reactions slow, and the senses become less acute. Cataracts and glaucoma may affect the eyes, and hearing loss is common. Mobility declines as muscle strength declines by 30% to 50% after age 70. Stretching exercises can reduce this decline.

FIGURE 18.4 Physical appearance changes and mobility declines in older adults. (Copyright [istock.com](https://www.istock.com).)

The changes of aging that affect the internal functioning of the organ systems are occurring simultaneously with the alterations that can be seen. The brain decreases in size but retains its structure and function in the absence of disease. The heart pumps less blood through the body. The respiratory system is less efficient. The digestive system produces smaller amounts of digestive juices, which affects the movement of food through the intestines and therefore increases the likelihood of constipation.

Taste and smell decrease in acuity over time, causing food to be less appetizing. This has an unfortunate side effect for older adults, who tend to eat less, because it can lead to undernutrition.

Cognitive Changes During Older Adulthood

During the normal aging process, mental health and cognition remain relatively stable. Severe changes in behavior and loss of cognitive function usually are symptoms of a physical or mental illness, such as Alzheimer disease, acute delirium, or serious depression. In 2014, the number of adults with Alzheimer disease was 5.2 million, or one in eight people (13%). Of people aged 85 and older, 38% have Alzheimer disease ([Alzheimer's Association, 2014](#)).

Alzheimer disease is the most common form of dementia (a group of disorders occurring almost entirely in the older adult population), in which structural and chemical brain deterioration is associated with gradual loss of many aspects of thought and behavior (Berk, 2018). Among the earliest warning symptoms are severe memory problems, such as forgetting names, appointments, and travel routes to familiar places in the community. Depression can often appear in the earlier stages of Alzheimer disease. The life expectancy of a person with Alzheimer disease can range from 1 year to as long as 15 years. At this time, a cure for this disease is lacking; however, several categories of drugs have been found to slow its progression. Researchers are testing drugs and nondrug approaches to treatment of this condition.

Depression is one of the psychiatric illnesses appearing most frequently in the older adult population. The prevalence of serious depression at any given time among adults aged 65 and older in community settings ranges from 1% to 5%; among medical outpatients, 5% to 10%; among medical inpatients, 10% to 12%; and among residents of long-term care facilities, 14% to 42% (Fiske, Wetherell, & Gatz, 2009). Depression is still underdiagnosed, because patients and health care providers believe that isolation, sleep problems, and diminished appetite are part of the normal aging process. People with severe depression typically report increased numbers of days in bed, increased pain, and decreased physical activities compared with older adults without depression. Arthritis, diabetes, and hypertension are risk factors for depression (Fiske, Wetherell, & Gatz, 2009).

Delirium is not a disease but a syndrome with multiple causes that result in a similar constellation of symptoms. *Delirium* is defined as a transient, usually reversible cause of cerebral dysfunction, and it manifests clinically with a wide range of neuropsychiatric abnormalities. The clinical hallmarks are decreased attention span and a waxing-waning type of confusion.

Delirium often is called *acute confusion*, which is a syndrome characterized by confusion, memory loss, disorientation, disorganized thinking, fatigue, sleep disturbance, fearfulness, excessive energy, altered perceptions including hallucinations and delusions, and personality changes. Delirium is a serious, preventable, and treatable disorder. Some factors that increase the risk for onset of delirium are advanced age, pain, polypharmacy, hospitalization, surgery, infections, and physiologic and pathologic

conditions (Miller, 2019). An attempt should be made to differentiate acute confusion (delirium) from chronic confusion (dementia), which has a gradual onset and is not reversible, as with Alzheimer disease.

Nursing interventions are based on history — what previously has been effective in patients with cognitive changes. Because polypharmacy is a primary cause for delirium, it is important for the nurse to thoroughly assess the patient's medication list. Drug therapies have been effective in slowing Alzheimer disease and managing serious depression. Important strategies for nurses caring for patients in this age group are to maximize safety by modifying the environment to compensate for cognitive losses, to plan and maintain a consistent routine, and to teach caregivers how to identify burnout from the daily care of older adults with cognitive changes.

Safe Practice Alert

Stimulating leisure activity helps facilitate cognitive functioning. Keeping the mind and body active is essential for older adults.

Primary Developmental Tasks

According to Erikson (1963), the developmental task of older adults is ego integrity versus despair. Older adults who attain ego integrity view life as wholeness, receiving satisfaction from past accomplishments, and accepting death as a completion of life. By contrast, older adults with despair often believe they made poor choices during the life journey and wish they could live their lives over again. Older adults have accumulated a lifetime of self-knowledge that leads to more secure and complex conceptions of themselves than at earlier ages (Berk, 2018). Some of the challenges of the older adult years center on retirement and maintaining independence and self-esteem.

According to Havighurst (1953), people who are 60 years of age and older must adjust to decreasing physical strength and health, retirement and reduced income, death of a spouse, and the processes of establishing an explicit affiliation with their age group, adopting and adapting to social roles in a flexible way, and establishing satisfactory physical living arrangements. A complete discussion of developmental tasks by age can be found in Chapter 17.

Psychosocial Changes in the Older Adult

The majority of income for people in the United States older than 65 years of age is from retirement benefits, according to statistics from the [Federal Interagency Forum on Aging-Related Statistics \(FIFAS\) \(2016\)](#). Those who are still able to work have a better income and sense of worth and are able to continue long-established routines. The retirement age established to receive federal benefits through the Social Security system has no relationship to the abilities of the worker. Some older adults need to work for economic reasons, because actual retirement would mean loss of essential income. In general, however, nonworking retired people are no longer governed by an alarm clock, and they have time to pursue projects, hobbies, or recreational activities that were deferred earlier in life.

Financial needs of the older adult vary considerably.

Approximately 10% of older adults in the United States live below the poverty level. Meeting food and medical costs can be a financial strain. Adequate financial resources, however, allow the older adult to remain independent. Older adults of minority groups have greater financial problems than white older adults, and older women of all ages usually have lower incomes than older men ([FIFAS, 2016](#)).

Qsen Focus!

The nurse engages older adult patients in an active partnership that promotes health, safety, well-being, and self-care management and appreciates shared decision making with empowered patients and families.

Living Arrangements

Living arrangements are influenced by a variety of factors, including marital status, financial well-being, the value placed on living independently or with family members, the availability of social services and social support, health status, family size and structure, and cultural traditions. As people are living longer, more living choices are becoming available. During late adulthood, many people relocate when their house or apartment becomes too large, expensive, or burdensome to maintain, or when decreased mobility requires different living arrangements. Chronic health problems

may require an environment that is adapted to meet the older adult's physical limitations, such as a larger bathroom to accommodate a wheelchair or a home with living space on one level. Making the decision to relocate is stressful even if it is voluntary, because the older adult often has to leave the neighborhood, friends, and home that have been a part of his or her life for many decades.

With increasing age, living arrangements may need to change to adapt to changing life circumstances. Many different types of living arrangements are available, and the selection should be based on the older adult's requirements. [Box 18.17](#) lists some of these options.

Box 18.17

Diversity Considerations

Life Span

Living Arrangements for Older Adults

- Assisted living is an option for older adults who need help with activities of daily living (ADLs). Assisted-living facilities provide older adults with the freedom to live in a semi-independent manner, while providing help with those tasks that they can no longer perform themselves on a daily basis, such as cooking, cleaning, and doing laundry.
- Adult day care is a solution for older adults who are incapable of caring for themselves and whose caregivers are not able to look after them during work hours.
- Adult foster care and group homes are suitable for older adults who can care for themselves but require some form of supervision for safety purposes.
- Long-term care facilities or nursing homes provide care for older adults who can no longer care for themselves, often because of mobility or memory impairment. These facilities can also provide short-term rehabilitation services for older adults until they are able to return to their independent living situation.
- Palliative care and hospice care are available for patients suffering from chronic illnesses. Hospice care differs from palliative care in that the aim is to provide the patient with the

best quality of life by relieving pain and other symptoms during the final days of life. In palliative care, the aim is symptom control in people with chronic illnesses, and the care is not related to life expectancy of the affected person.

- Retirement homes and communities are multiunit housing facilities that accommodate older adults with many different levels of care needs. Offering a wide range of living services, amenities, and activities, retirement homes give older adults a sense of daily enjoyment and personal belonging. A retirement community is a private, planned community for retirees or older adults. Such communities consist of a group of houses in a particular geographic area that share common amenities and features.
- Home care has become a preferred solution for many older adults who want to live in the comfort of their own homes but need some assistance with day-to-day responsibilities. Some of the types of care available are nursing care, housekeeping, and therapy.

Most older adults thrive on independence even if they are slow in performing activities of daily living (ADLs). Most prefer to live in an independent living environment as long as they can. Older adults appreciate the same respect for and acceptance of their abilities as expected for people of other age groups. Therefore nurses need to acknowledge the older adult's ability to think, reason, and make decisions.

Safe Practice Alert

Patients returning home from a hospital stay may require the assistance of a home care nurse until they are able to manage their own care. This potential need should be evaluated and be part of the nursing care plan before discharge.

Sexuality in Older Adulthood

Nurses may find it embarrassing or uncomfortable to discuss sexuality with older patients. Often, nurses working with older-adult patients are much younger than their patients; therefore nurses must have strong communication skills, scientific knowledge,

and self-awareness when working with this population. Older adults, whether healthy or frail, need to express sexual feelings, which include passion, affection, and admiration. Sexuality is a basic human need that has psychological, social, moral, and biologic components.

Sexuality in the older adult shifts from procreation to companionship, intimate communication, and a pleasure-seeking physical relationship. Sexual activity depends on the state of the person's sex drive and the presence of illness or chronic conditions that affect activity and mobility, as well as on individual interpersonal circumstances, opportunities, and moral and religious beliefs. Pain, fatigue, joint stiffness, other musculoskeletal limitations, heart disease, cerebrovascular accident (stroke), COPD, diabetes, cancer, and other conditions and diseases may interfere with sexual activity but need not curtail enjoyment of sexual intercourse. Nurses must have the requisite knowledge to assist the older adult in making the appropriate behavioral and practice changes to accommodate the individual's health condition.

Safe Practice Alert

Many older adults remain sexually active until late in life; nurses should include education and counseling on safe sex practices for the older adult.

Cultural Differences in Aging

Older adults fare best when they retain social status and opportunities for community participation. When older adults are excluded from social roles, their sense of well-being is reduced. Instead of fostering the integration and enhancement of wisdom that can be learned from the older adults, such exclusion can cause resentment between the generations. Ethnic and socioeconomic status variations in health tend to diminish with age. Still, compared with majority whites, minority older adults 65 to 80 years of age tend to have more health problems, and more of these adults exist at or below poverty ([U.S. Census Bureau, 2011](#)).

Lo 18.8 Health Risks and Concerns in Older Adulthood

Disease is not a normal outcome of aging, but chronic health problems and disabilities increase as age increases. Nurses need to recognize that assessing and promoting functional abilities in ADLs is vital for people 65 years of age and older, who have another 10 or more years to enjoy life. Emerging issues in the health care of older adults include the following:

- Coordinating care
- Helping older adults manage their own care
- Establishing quality measures
- Identifying minimum levels of training for people who care for older adults
- Researching and analyzing appropriate training to equip providers with the tools they need to meet the needs of older adults ([U.S. Department of Health and Human Services, 2010](#))

Health Risks During Older Adulthood

Many of the illnesses and diseases that are seen in older adults are not peculiar to this population; people of other age groups also suffer from cancer and heart disease. However, the probability that an older adult will become ill increases with age. Therefore the use of health care services also increases. The overall goal in the facilities providing care is promotion of health by encouraging independent functioning in a safe environment. The nurse assessing the older adult should keep in mind the changes that occur with aging ([Table 18.1](#)). Symptoms may be different in the older adult than in a younger person.

Common causes of death in the older adult are heart disease, cancer, cerebrovascular accident (stroke), lower respiratory disease, pneumonia, influenza, and complications from diabetes mellitus (DM) and Alzheimer disease ([FIFAS, 2016](#)). Because aging is associated with a weakening of the body's immune system, older

adults are more susceptible to infectious diseases (Feldman, 2018). Common chronic illnesses associated with significant impairment of function in older adulthood are osteoporosis, osteoarthritis, rheumatoid arthritis, COPD, hearing and visual alterations, and cognitive dysfunctions such as dementia. In addition, acute illnesses such as pneumonia, fractures, and trauma from falls and motor vehicle accidents may create chronic health problems (CDC, 2011).

Cardiovascular Disease

Stroke is the leading cause of long-term disability among adults in the United States. Strokes are cerebrovascular accidents that affect the cerebral circulation through blockage with occlusive thrombi and emboli in the subarachnoid and intracerebral spaces. Risk factors for stroke include diabetes, obesity, hypertension, hyperlipidemia, and some cardiac disorders (such as atrial fibrillation, MI, and valvular disease). Many older adults do not know the signs and symptoms of stroke; thus, when they seek medical attention, permanent damage may already have occurred.

Safe Practice Alert

Many patients in older adulthood who have had a stroke are maintained on anticoagulant medications. It is essential that caregivers and other family members be taught how to administer these medications and be instructed about signs to look for indicating bleeding or hemorrhage.

Hypertension is a major risk factor for experiencing other cardiac-related illnesses. An estimated 43 million Americans have hypertension. *Hypertension* refers to elevated blood pressure readings, either diastolic or systolic, or both, over a period of time. Systolic hypertension is common in older adults. The underlying causes of hypertension are not known in most cases. In a small percentage of affected people, specific causes can be identified; these include genetic differences in renal absorption of sodium, dysfunction of the renin-angiotensin-aldosterone system, insulin resistance, and autonomic nervous system dysfunction.

Untreated hypertension results in several physical changes in the body. Hypertension accelerates the rate of atherosclerosis formation in the arteries. Arteries become stiff as elastin is lost and collagen

increases. Stroke rates are increased in hypertensive patients. Assessment of the patient with hypertension includes taking accurate blood pressure readings and looking for evidence of target organ damage by means of urine analysis for the presence of protein. Regular ophthalmologic examinations are encouraged for hypertensive patients.

■ Safe Practice Alert

The changes caused by aging to the baroreceptors makes it vital for nurses to check postural blood pressures in the older adult to prevent postural hypotension and falls.

Cancer

Older adults are less likely than younger adults to be screened for cancer, so cancers in older adults often go undiagnosed or are discovered in later stages of the disease. Common cancers in older adults include lung, skin, breast, colon, ovarian, and brain cancers. In some older adults, the disease may lead to cognitive compromise; decision making about care may then become the responsibility of a family member or other caregiver (Miller, 2019). Decisions about treatment can be complicated by comorbid conditions. Although the numbers of cancers found among older adults are higher than the numbers in other age groups, research, education, and public health policies regarding cancer among older adults are scarce.

Respiratory Diseases

The exchange of oxygen and carbon dioxide is the primary function of the respiratory system. Age-related changes (senescence) occur over time that can affect the maximal inspiratory and expiratory force. Examples of senescence include: kyphosis (increased curvature of the spine), poor posture, a shortened thorax, chest wall stiffness, and an increase in the anteroposterior diameter of the chest wall result in diminished respiratory efficiency. Tobacco use (smoking) is a major factor in development of lung disease and impaired respiratory function. Chronic exposure to tobacco smoke has been confirmed to be harmful not only to the smoker but to everyone who is exposed to secondhand smoke. Secondhand smoke is known as *environmental tobacco smoke (ETS)* or *passive smoke*. The

effects of chronic exposure to air pollution and environmental toxins (such as housecleaning products) can cause complications in patients with chronic respiratory conditions.

COPD is a prevalent respiratory condition that may necessitate hospitalization of the older adult. Age and smoking are the two major risk factors for COPD, which is a group of diseases, including emphysema, chronic bronchitis, and a subset of asthma characterized by chronic airflow obstruction (Miller, 2019). The most common signs and symptoms are cough, dyspnea, wheezing, and increased sputum production. The condition is progressive, meaning that it will become more disabling as the person ages. In the interview with the older adult or caregiver, the nurse identifies risk factors that may affect the patient's respiratory system. Identifying potential and actual risk factors is an opportunity to address health promotion behavioral changes, such as cessation of smoking. Some assessment questions regarding COPD that the nurse may ask are shown in [Box 18.18](#).

Box 18.18

Health Assessment Questions

Chronic Obstructive Pulmonary Disease

- Have you had any respiratory problems in the past, such as asthma, pneumonia, or frequent respiratory infections?
- Have you ever had tuberculosis?
- Do you smoke?
- Do you experience shortness of breath with walking or lying down?
- Have you ever lived or worked in an area with heavy pollution from traffic, factories, or mining?

Safe Practice Alert

Check the patient's electronic health record for immunization dates for pneumonia and influenza vaccines.

Musculoskeletal Disorders

Normal changes of aging often bring about complaints of musculoskeletal pain and various joint limitations. These chronic conditions can limit mobility and impair the ability to perform self-care activities, such as bathing, dressing, and cooking; these changes may result in loss of independence. Osteoporosis and osteomalacia are metabolic bone diseases. Osteoarthritis, rheumatoid arthritis, and gout are joint diseases.

Nursing assessment of an older adult with any musculoskeletal conditions must include assessing the patient's functional ability to perform self-care activities—the skills of dressing, toileting, bathing, eating, and ambulating. An inability to perform any of these skills will affect the patient's independence. The nurse should assess the patient's ability to prepare a meal and safely use medications, monitor the patient's pain level, and check for risk factors that may impair musculoskeletal function, including the following:

- *Nutritional status:* Daily proteins, calcium, and vitamin D maintain optimal skeletal function.
- *Activity:* Exercise helps prevent age-induced declines in mobility.
- *Lifestyle factors:* Smoking, daily high intake of caffeine, inadequate calcium intake, sodium, and phosphorus can negatively affect calcium balance and increase the risk factors for osteoporosis (Miller, 2019).

Safe Practice Alert

Falls are a common problem in later adulthood. The combination of decreased visual acuity, loss of muscle strength, and slowed reaction time contributes to the increased risk of falls.

Diabetes Mellitus

DM is a highly prevalent disease that increases in incidence among people older than 65 years of age, particularly in racial and ethnic

minorities (Tabloski, 2019). Insulin is needed to transport glucose into cells for cell metabolism. In DM, there is a problem with insulin production or use. Two major types of DM affect the older adult: (1) type 1 DM and (2) type 2 DM. Type 1 DM, formerly called *juvenile-onset* or *insulin-dependent diabetes*, is the result of pancreatic islet cell destruction and a total deficit of circulating insulin. Type 2 DM, formerly called *non-insulin-dependent* or *adult-onset diabetes*, results from insulin resistance with a defect in compensatory insulin secretion.

The clinical signs and symptoms of DM in older adults include dehydration, confusion, delirium, decreased visual acuity, fatigue, nausea, recurrent infections, delayed wound healing, and paresthesia (Touhy & Jett, 2016). Complications that can develop due to poor glycemic control include the following (Tabloski, 2019):

- Eye disease, which can lead to partial loss of vision or even blindness
- Kidney failure
- Heart disease
- Nerve damage, which can cause pain or a loss of feeling in the hands, feet, legs, or other parts of the body (peripheral neuropathies)
- Stroke
- Peripheral vascular disease
- Poor wound healing due to impaired immune response and to poor tissue perfusion (Tabloski, 2019)

When assessing an older adult with newly diagnosed diabetes, the nurse focuses on acute and chronic complications and provides education about the factors that increase risk, such as smoking, lack of exercise, and elevated blood pressure and blood sugars. Treating adult-onset diabetes requires lifestyle changes, including monitoring dietary intake, exercising regularly, and losing weight. Adherence to these practices will promote glucose absorption, decrease abdominal fat, and lessen disease symptoms.

Safe Practice Alert

Examine the diabetic patient's feet at every clinical encounter.

Health Concerns During Older Adulthood

People in the United States are living longer than ever before. Many older adults live active and healthy lives, but as aging occurs, bodies and minds change. Eating a healthy diet, exercising regularly, and refraining from risky behaviors (such as smoking and drinking excessively) can help maintain health. Regular medical check-ups and immunizations are also beneficial. Screening tests needed depend on the person's age, gender, family history, and risk factors for certain diseases. For example, being overweight may increase the risk of developing diabetes and exacerbate many other comorbid conditions.

Health Screening and Health Promotion

Screening should be a primary focus of health promotion because of the potential for early detection of cancers, such as breast and colorectal cancer. Nurses should focus patient education on cancer prevention; vaccinations that protect against influenza and pneumococcal disease; screenings for the early detection of diabetes, lipid disorders, osteoporosis, and hypertension; fall risk assessment; elder abuse; and smoking cessation counseling (Miller, 2019). The nurse must remember to be sensitive to cultural, language, and other differences among older adults when providing health-promotion information. Nurses skilled in the assessment of the older adult know to look for atypical symptom presentation so that ailments do not go undiagnosed.

Changing Roles and Relationships

According to statistics from the Administration on Aging (2016), the older-adult population, 65 years and older, numbered 47.8 million in 2015, which represented 14.9% of the U.S. population. The older adult population will continue to grow significantly. In 2015, a small number (1.5 million), or 3.1%, of older adults lived in institutional settings, such as nursing homes (Box 18.19).

Box 18.19

Ethical, Legal, and Professional Practice

Ethical and Legal Issues in Nursing Homes

- The Nursing Home Residents' Bill of Rights is a federal law requiring all long-term care facilities to have a procedure in place whereby patients are informed of their rights, participate in their own care, have the right to complain, make independent choices, and have the right to privacy and confidentiality.
- Autonomy, individual rights, and quality of life for residents of long-term care settings create ethical issues, because it is not easy to balance individual patients' needs with those of the institution.

From Miller, C. A. (2019). *Nursing for wellness in older adults* (8th ed.). Philadelphia, PA: Lippincott, Williams & Wilkins.

The median income of older adults in 2015 was \$31,372 for males and \$18,250 for females. Households headed by a person aged 65 or older in 2015 reported median income of \$57,360. Almost all noninstitutionalized older adults were covered by Medicare in 2015; some had private health insurance, military-based insurance, or Medicaid ([Administration on Aging, 2016](#)).

Limitations in activities because of chronic conditions increase with age. In 2015, among Medicare beneficiaries, 90% of those institutionalized had difficulties with one or more ADLs, in contrast with 30% of those who were community residents ([Administration on Aging, 2016](#)). Many community-resident older adults with chronic disabilities receive either informal care from family or friends or formal care from services ([Box 18.20](#)). Nurses compromise their care of older adults when they fail to recognize the unique manifestations of aging and disease ([Miller, 2019](#)). Nurses must include assessment for abuse in older adults, especially those who are experiencing cognitive changes and those who rely on others for their care.

Box 18.20

Interprofessional Collaboration and Delegation

Home Care of Older Adults

Collaboration among health care agencies and providers is needed to provide care to older adults in the home.

- Home health care should be considered for older adults being discharged from the hospital.
- Services include skilled nursing care; physical, occupational, and speech-language therapies; medical social services; and home health aide care.
- Home health agencies conduct assessment in the patient's environment and determine the patient's ability to perform activities of daily living (ADLs) independently.
- Patient and family education is provided so that proper care continues even when the agency is not present.
- Report suspected abuse according to state laws.

QSEN FOCUS!

Integrating the contribution of others who help patients achieve health goals and valuing the expertise of health team members demonstrate teamwork and interprofessional collaboration.

Assistive Technology

Technologically, the world is advancing, and many more devices are being developed that permit people with disabilities to improve function. Such devices include computers and phones that can be dialed by voice command or can print out the spoken words of the caller, allowing blind or deaf people to remain independent. A computer chip can be placed on medicine bottles to remind older adults to take medicines on schedule. Architects are building “smart homes” with features that promote safety and mobility.

Summary of Learning Outcomes

LO 18.1 *Discuss theories on aging and adult development:* Senescence is the biologic process of aging influenced by genetic factors. Theories on aging include the Wear-and-Tear Theory, aging at the cellular level, and the Cross-Linking Theory. Developmental theories include Gould's Theory on Adult Development and the life stages theories of Havighurst, Erikson, and Piaget.

LO 18.2 *Describe changes that occur as the body ages:* Physical changes occur within all body systems as aging progresses and can affect mobility, cognition, and independence.

LO 18.3 *Identify physiologic, cognitive, emotional, and social changes that affect the young adult:* The transitions that occur during young adulthood are influenced by cultural beliefs, societal values, and individual beliefs and expectations.

Emerging adulthood is signified by a prolonged transition to adulthood as people pursue education and employment. The young adult is at a peak of cognitive and physical development.

LO 18.4 *Articulate health risks and concerns for the young adult:* Many young adults tend to ignore health issues and adopt a “wait and see” attitude. Health risk behaviors associated with young adulthood include increased alcohol use, illicit drug use, and frequent STDs. Domestic violence

is seen throughout adulthood but frequently begins in young adulthood.

LO 18.5 *Summarize the physiologic, cognitive, emotional, and social changes that occur in the middle adult age group:* Middle adulthood may be difficult to define as attitudes about life often determine the extent to which individuals feel and act young or old. During middle adulthood, men and women begin to experience changes that, if unacknowledged, can lead to illness and disability.

LO 18.6 *Explain health risks and concerns for the middle adult:* Cancer and cardiovascular disease are leading causes of death in middle adults. Disease prevention is an important aspect of patient education for this age group. Many middle adults are caring for children, grandchildren, and/or parents, adding unique stressors to life as they juggle career and family responsibilities.

LO 18.7 *Recognize the physiologic, cognitive, emotional, and social changes that affect the older adult:* Older adults are living longer, and many remain independent until death. Others experience cognitive and physical changes that require care in the home or in a health care facility.

LO 18.8 *Outline health risks and concerns for the older adult:* Many older adults are affected by aging in the form of chronic diseases that alter their independence. Musculoskeletal problems, respiratory disorders, cardiovascular diseases,

cancers, and diabetes are increasingly common in this age group.

Review Questions

1. From the nurse's knowledge about the emerging adult according to Arnett's theory, which behavior by a 21-year-old hospitalized male patient is most appropriate for his age group?
 - a. Talking about college courses that he is taking while working part-time at a restaurant
 - b. Requesting that his mom be present when his IV line is started
 - c. Stating that he cares for his disabled father and his 2-year-old daughter
 - d. Becoming upset that he is not giving back to his community
2. The nurse knows that which patient is an example of the Wear-and-Tear Theory of Aging?
 - a. A patient who is dying of cancer at age 35
 - b. A 55-year-old who runs half-marathons
 - c. A patient with depression and suicidal thoughts who is 65
 - d. An 88-year-old with heart failure, kidney failure, and osteoarthritis
3. The nurse is caring for a group of older adults. Which patient(s) in this group is/are exhibiting normal signs of aging? (*Select all that apply.*)
 - a. The patient with knee pain and wrinkles around the eyes
 - b. The patient who needs reading glasses and states that the food tastes bland

- c. The patient who is confused and does not know the current year
 - d. The patient who states that constipation is an increasing problem
 - e. The patient who is showing signs of depression and hopelessness
4. Which behavior by the young adult patient indicates an understanding of patient education aimed at reducing the health risks for that age group?
- a. Smoking only one pack of cigarettes per day
 - b. Limiting alcohol use to an occasional drink
 - c. Using drugs found in a roommate's drawer for anxiety
 - d. Having a relationship with a partner who was threatening in the past
5. While assessing a patient for domestic violence, the nurse knows that which statement is true regarding domestic violence?
- a. It is a health risk factor only during young adulthood.
 - b. It occurs across socioeconomic levels and cultural boundaries.
 - c. Young women aged 20 to 24 have the lowest incidence of rape and sexual assaults.
 - d. Women are the only victims of domestic violence whom nurses should be concerned about.

6. Which step(s) can nurses and health care providers take to remove barriers to identifying and treating victims of domestic violence? (*Select all that apply.*)
 - a. Call the police.
 - b. Ask about abuse.
 - c. Ask for proof of domestic violence.
 - d. Screen for domestic violence with all patients.
 - e. Disregard reported abuse in spouses.
7. Which group is referred to as the *sandwich generation*?
 - a. Older adults who are caretakers for their elderly parents
 - b. Younger adults who are reexamining their life choices
 - c. Middle adults who are caretakers for multiple generations of their family
 - d. Younger adults who are changing employment constantly
8. Which term indicates a mental health disorder that is frequently seen in older adults?
 - a. Schizophrenia
 - b. Bipolar disorder
 - c. Depression
 - d. Posttraumatic stress disorder (PTSD)
9. For which person seen at a physician's office appointment would patient and family education be most critical?

- a. A 24-year-old male patient with a cold virus and on no medications
 - b. A 45-year-old male patient on metformin for type 2 diabetes for the past 3 years
 - c. A 75-year-old female patient just prescribed the anticoagulant warfarin
 - d. A 40-year-old male asthmatic patient diagnosed 10 years ago and on albuterol
10. Which factor(s) is/are likely to influence the transition from adolescence to adulthood? (*Select all that apply.*)
- a. Cultural beliefs
 - b. Societal values
 - c. Personal beliefs and expectations
 - d. Governmental rules
 - e. Societal expectations

CHAPTER 19

Vital Signs

LEARNING OUTCOMES

Comprehension of this chapter's content will provide students with the ability to:

- LO 19.1 Explain the purpose of assessing vital signs.
- LO 19.2 Describe techniques for obtaining accurate temperature measurement.
- LO 19.3 Identify common assessment sites and techniques for assessing pulse.
- LO 19.4 Discuss assessment of respirations and blood oxygenation.
- LO 19.5 Summarize correct methods for measuring blood pressure.

KEY TERMS

- afebrile, [p. 277](#)
- apical pulse, [p. 282](#)
- apnea, [p. 287](#)
- arrhythmia, [p. 285](#)
- auscultation, [p. 284](#)
- auscultatory gap, [p. 292](#)
- blood pressure, [p. 275](#)
- bradycardia, [p. 285](#)
- bradypnea, [p. 287](#)
- core temperature, [p. 278](#)
- cyanosis, [p. 288](#)
- diastolic pressure, [p. 289](#)
- dyspnea, [p. 287](#)
- dysrhythmia, [p. 285](#)
- eupnea, [p. 286](#)
- febrile, [p. 279](#)
- fever, [p. 279](#)
- frostbite, [p. 278](#)

vital signs, p. 275

Case Study

Arthur Dyson (A. D.), a 79-year-old male, was just admitted from the emergency department with complaints of shortness of breath, dizziness, green-tinged sputum, and pain with deep inspiration. He started sleeping with two pillows 2 nights ago to ease his breathing. A chest x-ray shows pneumonia and exacerbation of heart failure. The arterial blood gas report is pending. Serum potassium is 3.0 mEq/L, and the white blood cell (WBC) count is 19,000/mm³. A urinalysis (UA) is ordered, but A. D. has not voided yet. His medical history includes hypertension, high cholesterol, and previous episodes of heart failure. He smoked one pack per day of cigarettes for 30 years but quit 20 years ago.

A. D.'s admission vital signs (VS) are T 38.89° C (102° F), P 104 regular, R 32 and shallow and labored, BP 160/94, pulse oximetry (SpO₂) of 89% on room air (RA). During assessment, the nurse notes a “barrel chest,” bilateral crackles, diminished lung sounds in the left lower lobe, pedal pulses that are not palpable but can be heard on Doppler examination, and 3+ pedal edema. The patient experiences dyspnea on exertion and when lying flat and exhibits use of accessory muscles to breathe. He has chest pain 5 of 10 with deep breathing. A 6.8-kg (15-lb) weight gain is noted over that measured at the outpatient clinic A. D. visited 1 week ago. His Braden score is 17, and his Morse Fall score is 48.

Treatment orders are as follows:

- VS q 4 h with pulse oximetry
- Fluid restriction of 1200 mL/24 h
- No-added-salt diet
- Up with assistance; fall precautions
- Intake and output
- Administer supplemental O₂ up to 4 L to keep SpO₂ greater than 92%
- Incentive spirometer (IS) and coughing and deep breathing (CDB) q 2 h

Medication orders are as follows:

- Digoxin 0.125 mg PO q day
- Furosemide 40 mg IV q day
- KCl 40 mEq PO q day
- Levofloxacin 750 mg IV q 24 h × 5 days
- Acetaminophen 325 mg, 2 tablets PRN for temperature of 38° C or greater

Refer back to this case study to answer the critical-thinking questions throughout the chapter.

Vital signs are a basic but very important component of physiologic assessment of the patient. They are used to monitor the functioning of body systems. Assessment of vital signs allows the nurse to detect changes in the health status of the patient, identify early warning signs of life-threatening health conditions, and evaluate the effectiveness of interventions.

Vital signs consist of body temperature (T), pulse (P), respirations (R), and blood pressure (BP). **Temperature** refers to the measurable heat of the human body. **Pulse** is the detectable rhythmic expansion of an artery that occurs with the pumping action of the beating heart; thus the pulse rate is measured as number of heartbeats per minute (bpm), with pulse intensity and pattern often specified as well. **Respiration** is the act of breathing, so respirations are assessed for frequency, or breaths per minute (BPM); abnormal quality and pattern of breathing also should be noted. **Blood pressure** is the measurable pressure of blood within the systemic arteries.

Since 2001 The Joint Commission (TJC) has required that every patient be assessed and treated for pain. Although some hospitals refer to pain as the “fifth” vital sign, TJC does not endorse pain as a vital sign (TJC, 2016). Therefore pain is not discussed in this chapter. Please refer to [Chapter 36](#) for pain assessment and management information.

Results of **pulse oximetry**, which measures the amount of oxygen available to tissues, typically are included with reported vital signs. The pulse oximeter reading is the percentage of hemoglobin that combines with oxygen (SpO₂).

LO 19.1 Vital Sign Measurement

Baseline values, or initial vital signs, are used to identify changes in patient status; a series of vital sign measurements establishes patient trends. The task of obtaining vital signs is relatively easy to learn, but interpreting the meaning of the values and incorporating the results into the management of patient care requires knowledge, problem solving, and clinical judgment. Although determination of vital signs is one of the most frequently performed nursing tasks, it is also important to assess the patient's clinical status (see [Chapter 20](#)).

The frequency of assessing vital signs is determined individually for each patient and depends on patient status. Patients may have vital signs checked every time they visit an outpatient clinic or once a week in some psychiatric settings or long-term care settings. Health care providers may order specific parameters for vital signs. Most inpatient facilities have a policy specifying the minimum frequency at which vital signs are obtained. Vital sign assessments typically are done every 4 or 8 hours for stable patients, every 15 to 60 minutes for postprocedure or postsurgical patients, and every 5 minutes or continuously for critical or unstable patients. Technology-based devices provide continuous monitoring of vital signs in critical care and surgical settings. The nurse providing care uses clinical judgment to determine the need to assess vital signs more frequently on the basis of the patient's condition. Situations in which vital signs are assessed are listed in [Box 19.1](#). Vital signs may be affected by many factors. Asking specific assessment questions ([Box 19.2](#)) related to vital signs helps the nurse interpret the measurement findings.

Box 19.1

Situations That Require Vital Sign Assessment

- On admission to a health care agency, to establish baselines
- As part of a physical assessment
- During an inpatient stay, as routine monitoring
- With any change in health status, especially complaints of chest pain and shortness of breath or feeling hot, faint, or dizzy
- Before and after surgery or invasive procedures to establish baselines and monitor effects
- Before and after administration of medications that affect cardiac, respiratory, or thermal regulation systems
- Before and after interventions such as ambulation
- In ongoing care, to detect improvement in patient condition
- Before discharge or transfer from a unit, to validate patient readiness

Box 19.2

Health Assessment Questions

Focus on Temperature

- Have you had anything to eat or drink or chewed gum in the last 15 minutes?
- Have you been exercising in the last 30 minutes?
- Have you been sleeping?
- Do you smoke? When was your last cigarette?
- Have you been feeling hot, sweaty, or cold?

Focus on Pulse

- Have you been exercising within the last 30 minutes?
- Are you feeling short of breath? tired?
- Are you having chest pain? feeling of racing pulse?
- Do you have swelling in your hands or feet?
- What medications are you taking?
- Do you smoke?
- Do you have a history of heart disease?

Focus on Respiratory Rate

- Are you feeling short of breath?
- Have you been exercising recently?
- Do you have a history of respiratory illness or diabetes?
- Have you had pain medication recently?
- Are you having pain?
- Are you a smoker?

Focus on Blood Pressure

- Have you recently been engaged in activity, exercise, or eating?
- What medications are you taking?
- Do you have a family history of hypertension?
- Do you exercise regularly?
- What do you eat in a typical day?
- How would you rate your pain level? stress level?
- What surgeries have you had?

Vital signs are interpreted on the basis of current health status and previously established (baseline) normal values for the patient. Normal values vary with patient age, and normal ranges for each vital sign component have been established for various age groups ([Table 19.1](#)).

TABLE 19.1**Vital Sign Ranges Across the Life Span**

AGE GROUP	TEMPERATURE	PULSE (bpm)	RESPIRATIONS (BPM)	SpO ₂ (%)	BLOOD PRESSURE (mm Hg)	
					SYSTOLIC	DIASTOLIC
Newborn	35.5°-37.5° C (96°-99.5° F)	80-160	30-80	>95	60-90	20-60
1 yr old	37.4°-37.6° C (99.4°-99.7° F)	80-140	24-40	>95	74-100	50-70
6 yr old	36.6°-37° C (98°-98.6° F)	75-110	15-25		84-<120	54-<80
15 yr old	36.1°-37.2° C (97°-99° F)	50-90	15-20	>95	94-<120	62-<80
Adult	35.5°-37.5° C (95.9°-99.5° F)	60-100	12-20	>95	90-<120	60-<80
Older adult	35°-37.2° C (95°-99° F)	60-100	15-20	>95	90-<120	60-<80

To interpret vital signs, the nurse begins by comparing the patient's measurements with expected normal values (see [Table 19.1](#)) and with the patient's baseline values, recognizing that it is always appropriate to recheck vital signs to verify any changes that occur. The nurse compares the most recent measurements with previous readings. Values may have increased or decreased from previous readings; such variations may indicate an improving or worsening condition or even a sudden change in status requiring emergency interventions. It is part of nursing judgment to determine that vital signs need to be assessed, sometimes as often as every 5 minutes, to monitor changes in the patient's condition. Understanding the patient's medical history and diagnosis is part of the nurse's interpretation of vital sign findings. For example, a patient with **hypertension** may have a blood pressure reading higher than normal. Blood pressure also may be increased in the patient experiencing pain, and pain medications may slow the respiratory and cardiovascular system, lowering the blood pressure, heart rate, and respiratory rate.

Many medical factors influence vital signs, such as infection and renal, respiratory, and cardiovascular disease. Other factors that affect vital signs include, but are not limited to, the physical environment, emotional state of the patient, medications, food and fluid intake, and activity level and tolerance. The nurse takes these factors into account when interpreting vital sign results for each patient.

Accuracy of vital sign values obtained depends on the precision of measurement. Careless measurement can result in inappropriate or missed interventions and care decisions. Expertise in the skill of vital sign determination is a critical nursing function, although this task may be delegated ([Box 19.3](#)). It is important to provide patient education for people who need to monitor vital signs in the home setting to manage their own or a family member's health. For example, patients receiving chemotherapy may need to have their temperature taken as ongoing monitoring for infection. Patients with hypertension may need to routinely check their blood pressure.

Box 19.3**Interprofessional Collaboration and Delegation****Vital Signs**

- The task of taking vital signs may be delegated to unlicensed assistive personnel (UAP), but before delegating this task, the nurse assesses patients to determine that they are medically stable.
- UAP may measure, record, and report vital signs for the stable patient, but interpretation of vital signs remains the responsibility of the licensed or registered nurse. Interpreting vital signs is done in relation to other assessment findings.
- The nurse ensures that the UAP knows the proper technique for taking vital signs and knows what values need to be reported immediately for each patient.
- It is the nurse's responsibility to ensure the accuracy of vital sign data and to report abnormal values in conjunction with additional physical symptoms.
- The nurse should double-check vital signs to verify abnormal values.

Both normal and abnormal vital sign results are appropriately documented and communicated to all members of the health care team. Values are recorded on the specified form or the electronic medical record used by the facility. With such documentation, multiple sets of vital signs typically are easily visible at a time, thereby showing trends for the patient.

Qsen Focus!

Nurses use informatics when identifying essential information such as vital signs that must be available in a common database to support patient care. Nurses must be able to navigate the electronic health record to view baseline patient data, and they must understand the technology that supports clinical decision making.

Safe Practice Alert

Sudden alterations in vital signs or values outside the normal range are indicators of a priority situation for the nurse. Further assessments and emergency measures should be initiated as indicated by the patient's status. The primary care provider is notified of alterations in vital signs.

LO 19.2 Temperature

Healthy people are able to maintain body temperature within the normal range even when exposed to temperature extremes for short periods. A person's ability to manage body temperature depends on certain behavioral abilities and thought processes, such as adequate mobility to leave an area of extreme heat or cold, the capacity to sense temperature discomfort, and the physical ability to add or remove clothing. For example, infants can sense discomfort but are unable to change their circumstances to adjust their temperatures. They cannot adjust the amount of clothing they wear or leave an environment that is too hot or too cold. Older adults may need assistance in adjusting to temperature changes because of cognitive impairment, physical issues, or both. Illness or an altered level of consciousness puts the affected person at risk for inability to maintain proper thermal control.

Normal Parameters of Body Temperature

Temperature is measured in degrees, represented by the symbol °. The core body temperature remains relatively constant within the range of 36.5° to 37.5° C (97.6° to 99.6° F); the average oral temperature is 37° C (98.6° F). A person who maintains this normal body temperature is considered to be **afebrile**. Body tissue and cells function best within this range. Axillary temperatures may be approximately 1° less than oral readings, which in turn are approximately 1° less than rectal temperatures. Normal tympanic temperatures fall between normal oral and rectal temperatures. [Table 19.2](#) compares average normal adult temperatures at different body sites.

TABLE 19.2

Average Normal Adult Temperature Ranges at Different Body Sites

ORAL	AXILLARY	RECTAL	TYMPANIC	TEMPORAL
36.0°-37.6° C (96.8° °99.68° F)	35.5°-37.0° C (95.9°-98.6° F)	34.4°-37.8° C (93.92°-100.04° F)	35.6°-37.4° C (96.08°-99.32° F)	36.1°-37.3° C (96.98°-99.14° F)

From Davie, A., & Amooore, J. (2010). Best practice in the measurement of body temperature. *Nursing Standard*, 24(42):42-49.

Physiology of Heat Production and Loss

Humans are warm-blooded, which means that they maintain a consistent internal temperature independent of the outside environment. Body temperature reflects the difference between the amount of heat produced by body processes and the amount of heat lost to the external environment. Heat is generated by metabolic processes in core tissues of the body and is transferred by circulating blood to the skin, where it is dissipated into the environment.

Thermoregulation comprises the physiologic and behavioral mechanisms that regulate the balance between heat production and heat loss. Regulation by neurologic mechanisms maintains this relationship of heat production and loss.

The hypothalamus in the brain acts as the body's thermostat. Even minor changes in body temperature are transmitted by thermal receptors located throughout the body to the hypothalamus by way of the spinal cord. The anterior hypothalamus controls heat loss through the mechanisms of diaphoresis (sweating) and vasodilation of blood vessels, which enable heat loss. The posterior hypothalamus conserves heat

through mechanisms such as vasoconstriction to reduce heat loss and shivering. Disease or trauma to the hypothalamus or spinal cord can therefore cause alterations in temperature control.

Heat Production

Heat produced in the body is a by-product of metabolism, the chemical process responsible for generating energy for cellular functions. Food is the primary fuel source for metabolism. The amount of heat produced is related to the rate of metabolism. Exercise, increased release of epinephrine and norepinephrine, and increased production of thyroid hormones all can increase heat production.

Heat Loss

Heat production and loss occur simultaneously. The skin regulates temperature through insulation of the body with subcutaneous tissue and fat, and, in conjunction with the circulatory system, it is the primary source of heat loss. Circulating blood brings heat to the skin surface, where connections between the arterioles and venules below the skin's surface open (vasodilate) to allow heat to dissipate or close (vasoconstrict) to retain heat. The sympathetic nervous system controls the opening and closing of these connections in response to changes in the **core temperature** (temperature of deep tissues) or environmental temperature (Heuther & McCance, 2017). Because skin is exposed to the environment, there is constant heat loss through radiation, conduction, convection, and evaporation, as follows:

- *Radiation*: Radiation is the transfer of heat as waves or particles of energy. No actual contact occurs between the object transmitting the heat and the object absorbing it. For example, peripheral vasodilation increases blood flow to the skin, thereby increasing radiant heat loss. Vasoconstriction minimizes heat loss from the skin. If the environmental temperature is higher than the skin temperature, the body also will absorb heat by radiation.
- *Conduction*: Conduction is the transfer of and reaction to heat through direct contact. Heat from the body is lost when it comes in contact with a cooler object, such as an ice pack or cool cloth.
- *Convection*: Convection is the transfer of heat by movement or circulation of warm matter such as air or water.
- *Evaporation*: Evaporation is the process by which a liquid is changed to a vapor through heat. Diaphoresis increases during exercise, emotional or mental stress, and fever. The process of evaporation lowers body temperature.

Factors Affecting Body Temperature

Many factors can alter the relationship between heat production and heat loss. Part of the nursing assessment is evaluating factors that are affecting the temperature of a patient. Typical factors that affect patient temperature include age (very young and very old), recent exercise, hormone fluctuations, circadian rhythms, stress, and environment (Box 19.4).

Box 19.4

Factors Affecting Body Temperature

- *Age:* Newborns have unstable body temperatures because of immature regulatory mechanisms. Even a mild rise in temperature is significant in infants younger than 3 months of age. It is common for the baseline temperature to drop as the person ages. Infants and elderly people are more susceptible to environmental temperature extremes.
- *Exercise:* Body temperature increases with exercise as carbohydrates and fats are metabolized to provide energy.
- *Hormone fluctuations:* Women typically have a higher temperature during ovulation. Thyroxine, epinephrine, and norepinephrine increase heat production and therefore can increase temperature.
- *Circadian rhythms:* The temperature of most people is lowest around 3 a.m. and highest around 6 p.m.
- *Stress:* The levels of epinephrine and norepinephrine can increase during emotional or physical stress.
- *Environment:* Extended exposure to extreme heat or extreme cold can affect core body temperature. Heat and cold application used as treatment for pain, injuries, or swelling can affect body temperature.
- *Smoking:* Smoking causes vasoconstriction, which can cause a drop in the temperature of the skin and mucous membranes.

Clothing allows the wearer to lose heat when it is hot or retain heat when it is cold. When a person is exposed to extreme cold without adequate protective clothing, heat loss can lead to **hypothermia** (low body temperature). Likewise, exposure to extreme heat for a prolonged time can lead to **hyperthermia** (high body temperature). Either of these extremes can cause serious illness or even death. The thermoregulation systems of the very young and the very old are not as efficient as in people of other age groups, placing them at higher risk for hypothermia and hyperthermia.

Signs of hypothermia include decreased body temperature and respirations, pale and cool skin, **hypotension** (decreased blood pressure), decreased muscle coordination and urinary output, disorientation, and drowsiness progressing to coma. Box 19.5 identifies measures recommended for elderly people to prevent hypothermia. **Frostbite** occurs from exposure to subnormal temperatures. Ice crystals form inside the cells, which may cause permanent circulatory and tissue damage. Common sites for frostbite are earlobes, the tip of the nose, fingers, and toes. The skin becomes white and firm, with a loss of sensation. Interventions for frostbite include gradual warming, pain management, and protection of the injured area.

Box 19.5

Evidence-Based Practice and Informatics

Preventing Hypothermia in Older Adults

Advise patients to:

- Dress in layers, even while at home. Long underwear may be worn under clothing, along with socks and slippers.
- Use a blanket or throw to keep legs and shoulders warm.
- When outside in cold weather, wear a hat, scarf, and gloves. A hat is especially important to maintain body heat.
- Keep extremities covered to prevent heat loss.
- Keep the thermostat at a minimum of 68° F.

Assistance with heating costs may be available through utility companies, local nonprofit organizations, or the National Energy Assistance Referral System. Refer patients for assistance if they express concern about paying their heating bill.

From National Institute on Aging, [National Institutes of Health \(NIH\)](https://www.nia.nih.gov/health/cold-weather-safety-older-adults). (2018). Cold Weather Safety for Older Adults. Retrieved from <https://www.nia.nih.gov/health/cold-weather-safety-older-adults>.

Fever (pyrexia) is a rise in body temperature above normal, caused by trauma or illness. A person with a fever is described as **febrile**. Fever may be associated with an infection, tissue injury, cancer, trauma, or surgery. Patients with a fever can experience loss of appetite (anorexia), headache, malaise, hot and dry skin, flushing, thirst, shivering, and a general feeling of not being well. Signs of fever include dehydration from the fluid loss associated with sweating, decreased urinary output, and rapid heart rate. Older people may demonstrate only a slight rise in temperature despite an illness process such as pneumonia.

Heatstroke occurs when prolonged exposure to the sun or high environmental temperatures overwhelms the body's heat loss mechanisms. This health emergency carries a high mortality rate. Risk factors include very young or very old age, cardiovascular disease, diabetes, and alcoholism, along with exercise or work out of doors in predisposing conditions. Signs and symptoms include confusion, delirium, excessive thirst, nausea, muscle cramps, and high temperature and heart rate. Hot, dry skin and absence of sweating are other features of heat stroke. **Heat exhaustion** occurs when extreme or prolonged environmental heat exposure leads to profuse sweating with consequent excessive water and electrolyte loss. Clinical manifestations are those of fluid volume deficit (see [Chapter 39](#) for a discussion of this metabolic disturbance).

Assessment of Temperature

Body temperature is measured in degrees on either the Fahrenheit or the Celsius scale. The reliability of temperature values depends on selecting the most appropriate site, using the correct equipment, and using the correct procedure to obtain the measurement. The five sites commonly used to measure temperature are the mouth, ear, rectum, forehead (where the temporal artery is close to the skin), and axilla.

Depending on patient status, any of these sites may be appropriate if the proper technique is used. Site selection is affected by patient age, state of consciousness, amount of pain the patient is suffering, and treatment the patient is undergoing, such as oxygen supplementation. Normal temperature varies among sites (see [Table 19.2](#)). Core temperatures can be measured with specialized equipment through the esophagus or pulmonary artery sites. The measuring device used depends on the site ([Fig. 19.1](#)). [Skill 19.1](#) describes the procedures for measuring body temperature at different sites with different types of thermometers.

FIGURE 19.1 Types of thermometers: (A) electronic; (B) temporal artery; (C) tympanic. (Copyright [istock.com](#).)

Oral Temperature

The most common site for measuring temperature is under the tongue. The patient must be able to close the mouth around the thermometer. Advantages of this site are that it is readily accessible and comfortable for the patient. Eating, drinking, smoking, and the use of oxygen by cannula or mask can affect measurements obtained at the oral site. It is not a preferred site for infants and young children, unconscious patients, post-oral surgery patients, or people with seizure disorders.

Rectal Temperature

Rectal temperature readings are considered to be very accurate. The rectum, however, is not a site preferred by patients. The rectal route is contraindicated in newborns, in patients who are neutropenic (manifested as a low white blood cell count), and in patients with spinal cord injury. It should not be used for patients with diarrhea or rectal disease, post-rectal surgery patients, or quadriplegic patients.

Safe Practice Alert

Taking rectal temperatures can cause rectal perforation in young infants, and the site should be used only when no other feasible option is available. If a rectal temperature must be taken, a well-lubricated thermometer, inserted no more than the length of the thermometer's bulb, should be used.

Safe Practice Alert

Taking the patient's temperature using the rectal route can cause bleeding in people with hemorrhoids.

Ear (Tympanic) Temperature

The tympanic membrane temperature is a core temperature. The thermometer does not touch the tympanic membrane. This site is easily accessed for both adults and children. Use of the tympanic route is appropriate for patients who are confused or unconscious. Readings are not significantly affected by otitis media (infection of the middle ear). Spread of infection from patient to patient is less of a concern with use of the tympanic site than with the oral and rectal sites. False-low readings from the tympanic site reflect poor technique, leading to an inaccurate temperature measurement at the site (Sund-Levander & Grodzinsky, 2013). An accurate tympanic reading is obtained by grasping the pinna and gently pulling up and back for ages 4 years to adult, or down and back for a child 3 years of age and younger; placing the covered probe snugly in the ear canal; and angling it toward the jaw line before activating the sensor.

The tympanic thermometer is battery-powered. The sensor probe, covered with a disposable cover, is placed in the ear canal, and the degree of infrared heat radiation is read from the tympanic membrane (eardrum). It is important to train users in proper technique to obtain accurate readings. Readings are obtained in approximately 2 seconds, making use of this site appropriate in young children older than 2 months of age and in emergency settings in which assessments need to be completed quickly. It is not appropriate for patients with ear drainage or eardrum scarring.

Forehead (Temporal Artery) Temperature

The temporal artery thermometer (TAT) is a small handheld unit that is scanned across the forehead to measure heat emitted from the temporal artery. This thermometer actually measures ambient air temperature and corrects the temperature reading for radiant heat loss. A covering on the head can affect the accuracy of the reading. This measurement is well tolerated by infants and young children. It is not affected by mild perspiration when performed correctly.

Current research is divided on the best use of TAT measurement due to variability when compared to core body temperature readings. Consensus seems to indicate that temperature measurement by TAT is appropriate when screening children younger than 5 years for fever in busy clinics and emergency departments (Odinaka, Edelu, Nwolisa, et al., 2014). But TAT may not be as accurate as an oral or tympanic measurement for detecting low-grade fevers, for monitoring acutely ill adults who have a fever, or when temperature will influence clinical decisions (Furlong, Carroll, Fin, et al., 2015; Kiekkas, Stefanopoulos, Bakalis, et al., 2016; Niven, Gaudet, Laupland, et al., 2015; Wolfson, Granstrom, Pomarico, et al., 2013).

Axillary Temperature

The axillary site may be used when the oral and rectal sites are contraindicated or inaccessible. It is the site frequently used for healthy newborns. The thermometer is placed in the center of the patient's axilla until the reading is obtained. The end of the sensor must remain in contact with the skin. The axillary route is acceptable for infants, children, and patients who cannot tolerate measurement by other routes.

Electronic Thermometers

Electronic and digital thermometers are commonly used in health care facilities to measure oral, rectal, or axillary temperature in less than 1 minute. The thermometer is battery-powered, with a temperature-sensitive probe attached to the unit. A disposable probe cover is used for infection control. Readings are given on a digital screen within several seconds. The same probe can be used for oral and axillary measurements. A separate probe, color-coded red, is used for rectal measurements. Inexpensive disposable digital thermometers often are used for patients in isolation.

Disposable Thermometers and Temperature-Sensitive Strips

Disposable paper thermometers are single-use or reusable strips of paper with liquid crystal dots or bars and a temperature sensor at one end that changes color to reflect body temperature. To obtain the temperature, the nurse reads the highest reading among the dots that have changed color. These strips are an excellent choice when asepsis must be maintained for infection control. The strips can be used for oral (1-minute reading) or axillary (3-minute reading) sites. Temperature-sensitive strips may be used to obtain a general indication of body surface temperature within a designated range. The temperature strip is placed on the forehead or abdomen; the skin must be dry, because perspiration can alter the reading. After the manufacturer's specified wait time (e.g., 15 seconds), a color appears on the temperature strip. The strip is discarded after the initial color change is noted. With use of color-change temperature strips in children younger than 2 years of age, abnormal results must be verified by another method.

◆Nursing Diagnosis

Examples of International Classification for Nursing Practice (ICNP) nursing diagnoses related to altered body temperature are as follows:

Hyperthermia

- Supporting Data: Infectious process, temperature of 38.89° C (102° F),

Hypothermia

- Supporting Data: Exposure to below-freezing temperature without adequate clothing, temperature of 93.6° F

Impaired Thermoregulation

- Supporting Data: Premature infant of 32 weeks' gestation, inability to maintain temperature within normal range

◆Planning

The planning stage of the nursing process involves prioritizing nursing diagnoses, evaluating resources, and setting goals (Table 19.3). The following are examples of goal statements:

TABLE 19.3
Care Planning

ICNP NURSING DIAGNOSIS WITH SUPPORTING DATA	NURSING OUTCOME CLASSIFICATION (NOC)	NURSING INTERVENTION CLASSIFICATION (NIC)
<i>Hyperthermia</i> Infectious process Temperature of 38.89° C (102° F),	<i>Thermoregulation</i> Reported thermal comfort	<i>Fever treatment</i> Administer medications to treat the cause of fever, as appropriate.

From Butcher, H. K., Bulechek, G. M., Dochterman, J. M., et al. (Eds.). (2018). *Nursing interventions classification* (NIC) (7th ed.). St. Louis: Mosby; Moorhead, S., Swanson, E., Johnson, M., et al. (Eds.) (2018). *Nursing outcomes classification* (NOC) (6th ed.). St. Louis: Mosby. ICNP is owned and copyrighted by the International Council of Nurses (ICN). Reproduced with permission of the copyright holder.

- Patient will exhibit temperature within normal range within 1 hour of receiving antipyretic (fever-reducing) medication.
- Patient will maintain temperature within normal range within 1 hour of placement on an aquathermia pad and initiation of warmed intravenous fluids.
- Patient will maintain temperature within expected parameters before discharge from the newborn intensive care unit.

For vital signs, planning focuses on selection of the best site and method for measuring each vital-sign component. Gathering the correct equipment before approaching the patient is important; equipment for measuring temperature includes electronic or digital thermometers, tympanic membrane thermometers, temporal artery (forehead) thermometers, and disposable paper thermometers. Glass mercury thermometers are no longer manufactured or sold and should not be used because of the risk for exposure to mercury (Box 19.6).

Box 19.6

Home Care Considerations

Proper Disposal of Mercury

Although use of glass mercury thermometers in health care settings is obsolete, many such thermometers are still used in the home. Mercury exposure can cause respiratory and gastrointestinal irritation and renal damage. Prolonged exposure can cause neurologic impairment.

Patients should be encouraged to properly dispose of glass thermometers and purchase a safer type. Teach patients what to do if a glass thermometer breaks:

- Do not touch spilled mercury droplets. If skin contact occurs, immediately flush the area with water for 15 minutes.
- Have everyone leave the area and close the door to the contaminated room. Do not allow children to help clean up the area.
- Using gloves, remove any items contaminated with mercury and place them in a zip-top bag.
- Wipe up mercury beads with a wet paper towel and place it in a zip-top bag.
- Shaving cream on a small paint brush or duct tape may be applied to small beads to facilitate pickup; place the item in a zip-top bag.
- Consult the local health department or fire department for disposal instructions.
- After the spill is cleaned, keep the area well ventilated for at least 24 hours.

From Environmental Protection Agency (EPA). (2018). What to do if a mercury thermometer breaks. Retrieved from <https://www.epa.gov/mercury/what-do-if-mercury-thermometer-breaks>.

The conceptual care map for A. D. can be found at <http://evolve.elsevier.com/YoostCrawford/fundamentals>. It is partially completed to indicate how to use the map as a learning tool. Complete the nursing diagnoses using the example conceptual care maps shown in **Chapters 8 and 25 to 33**.

◆ Implementation and Evaluation

Information from the patient history and assessment are used to formulate an individualized treatment plan. Nursing interventions are chosen on the basis of nursing diagnoses for each patient and are based on the patient's thermoregulation problem. Interventions for an increased or decreased temperature must be evaluated for appropriateness for the specific patient.

When treatment is indicated for an increased temperature, nonsteroidal drugs with antipyretic effect, such as ibuprofen and acetaminophen, may be ordered to lower the set-point of the hypothalamus. Cool sponge baths, cooling blankets, and cool packs

are used to reduce fever, but they can increase energy expenditure by stimulating shivering. Aspirin, also a nonsteroidal drug with antipyretic properties, should not be given to children younger than 2 years of age without medical supervision, nor should it be given to children or teenagers with a viral illness because of the associated risk for Reye syndrome (a serious illness affecting the liver and brain). If the fever is a result of bacterial infection, an antibiotic is administered as prescribed. Blood cultures may be ordered to identify causative organisms. Oxygen may be necessary to meet increased metabolic needs. Other interventions include monitoring the patient's temperature frequently to determine trends, monitoring other vital signs, monitoring intake and output, increasing the intake of fluids as appropriate for fluid balance, and maintaining oral hygiene for the comfort of the patient. Removal of extra blankets can help dissipate excessive heat. Because diaphoresis occurs with fever, a change of clothing and bedding often is needed. Nursing activities to restore normal body temperature include the following:

- Identify the underlying cause of the fever, to plan and provide effective treatment or obtain ordered culture specimens.
- Assess the patient frequently for changes so the care plan can be adjusted.
- Monitor body temperature and other vital signs by appropriate route every 2 hours or more frequently, as indicated by patient status, to measure treatment response, because the increased metabolic rate that accompanies fever increases pulse and respirations.
- Provide oral and/or intravenous fluids to replace fluid loss from increased respirations and diaphoresis.
- Provide prescribed interventions such as antibiotics to treat the underlying cause of the fever. Note that blood and other culture specimens may need to be obtained before antibiotics are started.
- Implement nonpharmacologic measures to reduce the fever without causing shivering, because shivering produces additional body heat.
- Keep clothing and bedding dry to reduce shivering.
- Encourage physical rest to reduce metabolic demands and oxygen use.
- Provide nutritional support to meet increased metabolic demands.

Hypothermia requires measures to raise body temperature. Gradual warming through external wraps, a head covering to prevent heat loss, and warm intravenous fluids are means of warming the body. Patients who are alert can drink hot liquids such as soup. Alcohol and caffeine beverages should be avoided. Some facilities have

blanket warmers. Survival of extreme cold situations, such as nearly drowning in cold water or being buried in snow, has occurred in some instances due to the cold body's decreased metabolic demands for oxygen.

Qsen Focus!

Through patient-centered care, the nurse provides physical comfort and emotional support while treating symptoms of altered body temperature.

Safe Practice Alert

Fires may result from attempting to warm blankets in a microwave oven or other nonapproved warming devices.

When evaluating a temperature reading, the nurse must compare the temperature measurement obtained against any baseline data, previous readings, and the normal range for the patient. The nurse interprets the findings by considering the patient's diagnosis, time of day, and other factors such as medications administered. The nurse performs any needed follow-up activities, such as medication administration, changes in the environment, increased fluid intake, or notification of the primary care provider (PCP) for additional orders. Nursing interventions are evaluated by comparing patient responses with the expected outcomes. If the nursing interventions are effective, the patient's temperature will return to normal range and other vital signs will stabilize.

LO 19.3 Pulse

The pulse is the palpable, bounding blood flow created by the contraction of the left ventricle of the heart. It can be assessed at various points on the body. The pulse is an indicator of circulatory status. Electrical impulses originating in the sinoatrial (SA) node of the heart stimulate cardiac muscle contraction, which sends a pulse wave. The number of pulsing sensations occurring in 1 minute is the pulse rate. Mechanical, neural, and chemical factors regulate the strength of ventricular contraction and the subsequent cardiac output. As the heart rate increases, less time is available for the heart to fill. An abnormally slow, rapid, or irregular pulse reflects an alteration in cardiac output, which may result in an inability to meet the physiologic demands of the body. The **apical pulse** is a central pulse that can be auscultated over the apex of the heart at the point of maximal impulse (PMI). **Peripheral pulses** are those that can be palpated over arteries located away from the heart—at the wrist or foot, for example. Normal pulse rates are listed in [Table 19.1](#).

Factors Affecting Pulse Rate

As noted earlier, pulse rate is expressed in beats per minute. The pulse rate is variable and depends on physiologic and emotional factors. The nurse should consider several patient-specific factors when assessing the pulse, including age, gender, exercise, presence of fever, medications, fluid volume status, stress, and underlying disease processes ([Box 19.7](#)).

Box 19.7

Factors Affecting Pulse Rate

- *Age*: As age increases from infancy to adulthood, the pulse rate decreases.
- *Gender*: After puberty, the average male pulse is lower than that of the average female.
- *Fever*: Pulse increases with fever because of the increased metabolic rate and peripheral vasodilation that occurs.
- *Medications*: Various medications may either increase or decrease the pulse rate.
- *Hypovolemia*: Loss of blood normally increases the pulse rate from sympathetic nervous system stimulation.
- *Hypoxia and hypoxemia*: When oxygen levels decrease, cardiac output increases to attempt to compensate, resulting in an increased pulse rate.
- *Stress*: Sympathetic nervous system stimulation from stress (e.g., fear, anxiety, and the perception of pain) increases the heart rate.
- *Pathology*: Heart conditions or illnesses that impair oxygenation can alter the pulse rate as cardiac output attempts to compensate for low oxygen levels. Head injuries can cause a drop in pulse to compensate for increased intracranial pressure.
- *Electrolyte imbalance*: Changes in potassium and calcium affect pulse rate and rhythm.

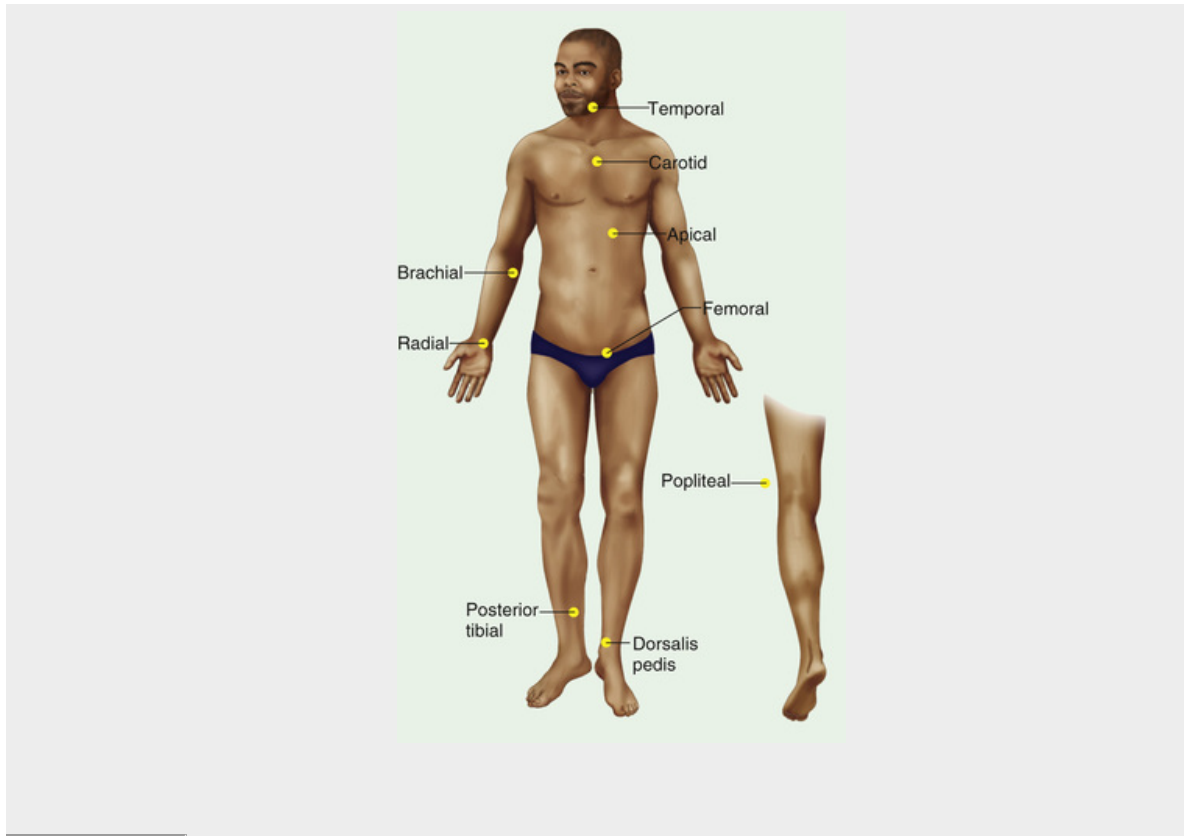

Sites for Assessing Pulse

Peripheral pulses are assessed where arteries lie over bony prominences. A pulse may be measured in several sites that are easily accessible (Box 19.8). These sites include the temporal artery of the head; the carotid artery in the neck; the brachial and radial arteries in the arms; and the femoral, popliteal, dorsalis pedis, and posterior tibial arteries in the legs and feet. The most definitive site used for pulse assessment is over the apex of the heart, where the apical pulse can be auscultated.

Box 19.8

Pulse Sites

1. *Temporal*: Where the temporal artery passes over the temporal bone of the head, above and lateral to the eye; used when the radial pulse is not accessible
2. *Carotid*: At the side of the neck where the carotid artery runs between the trachea and the sternocleidomastoid muscle; used in cases of cardiac arrest and for determining circulation to the brain
3. *Apical or Point of Maximal Impulse (PMI)*: Apical, at the apex of the heart, and PMI, at the fifth intercostal space, midclavicular line; used for infants and children up to 3 years of age, placed in the supine position, to determine discrepancies with radial pulse, and used in adults in conjunction with some diseases and medications and during a head-to-toe assessment
4. *Brachial*: At the inner aspect of the arm; used to assess pulse in pediatric emergencies and to measure blood pressure
5. *Radial**: On the thumb side of the inner aspect of the wrist where the radial artery runs along the radial bone
6. *Femoral*: Where the femoral artery passes alongside the inguinal ligament; used in cases of cardiac arrest and for assessing circulation to the leg
7. *Popliteal*: Behind the knee where the popliteal artery passes; used to determine circulation to the lower leg
8. *Posterior tibial*: Medial surface of the ankle; used to determine circulation to the foot
9. *Pedal (dorsalis pedis)*: Where the dorsalis pedis artery passes across the top of the foot; used to determine circulation to the foot

*The radial pulse typically is readily accessible. In elderly people, however, palpating the radial pulse may pose a challenge if tremors are present. Peripheral pulses also may be decreased in general as a consequence of cardiovascular changes with aging.

The most common site for assessing the quality, rate, and rhythm of the pulse is the radial artery. In an emergency or during cardiopulmonary resuscitation, the carotid or femoral pulse may be used to assess the pulse rate and adequacy of cardiac compressions. The brachial pulse is used in children during emergencies. The dorsalis pedis and posterior tibial artery pulses are used to evaluate the effectiveness of the peripheral vascular system but not to assess heart rate or rhythm.

Safe Practice Alert

Never palpate both carotid arteries at the same time. Doing so could limit blood flow to the brain, causing the patient to experience syncope (fainting).

Assessment of Pulse

Assessing the pulse includes measuring the rate, rhythm, and volume and comparing the findings on both sides of the body. The pulse is assessed by palpation (feeling with the middle three fingertips), **auscultation** (listening with a stethoscope) (Box 19.9), or electronic monitoring through specifically placed sensors. Too much pressure of the fingertips can obliterate the pulse, and pressure that is too light may not capture the pulsations. A Doppler ultrasound unit is used to assess pulses that are otherwise difficult to detect, especially pedal pulses (Box 19.10). Skill 19.2 reviews the steps for measuring a pulse.

Box 19.9

Evidence-Based Practice and Informatics

Using a Stethoscope

A stethoscope is a medical device that is critical in listening to internal sounds of the body. It commonly is used to listen to lung and heart sounds. It also is used to listen to intestinal activity and blood flow in arteries and veins. In combination with a sphygmomanometer, it is used for measurements of blood pressure. It is important that a stethoscope be used and cared for correctly.

- The earpieces should fit snugly and point toward the nose. This position follows the path of the ear canal. The chin is dropped toward the chest to determine the position where the earpieces fit the ears the best and room sounds are blocked out.
- If the stethoscope has a dual head, with a diaphragm and bell end piece, and if this end piece rotates, it must be rotated to be open to the head in use. The bell is designed to hear low-pitched tones; the diaphragm is designed to hear higher-pitched sounds.
- The head of the stethoscope is placed against the patient's skin with light pressure.
- The stethoscope should not be worn against the skin. Tubing made of polyvinyl chloride (PVC) will harden over time from skin oils.
- The stethoscope must be kept away from extreme heat or cold.
- Infection control issues include the following:
 - The head of the stethoscope must be cleaned with an antimicrobial wipe, or alcohol wipes before using it on a patient to prevent infection.
 - The stethoscope must not be sterilized with steam heat.
 - The earpieces should be cleaned routinely, as well as whenever shared with anyone else, to prevent infection. Earpieces may be removed for thorough cleaning.
 - The stethoscope should not be submerged in water; the tubing may be gently wiped with an antimicrobial wipe if needed.
 - To prevent the spread of infection, decorative coverings should not be placed over the stethoscope tubing.

Box 19.10

Nursing Care Guideline

Using a Doppler Ultrasound Unit to Obtain a Pulse

Background

- A Doppler ultrasound unit may be used to assess peripheral circulation when a pulse cannot be palpated.
- Each pulse wave makes a sound that the Doppler ultrasound unit amplifies.
- Pulses may be difficult to palpate for many reasons, including poor circulation, edema, obesity, and other obstructive issues.

Procedural Concerns

- Apply a small amount of ultrasound transmission gel to the skin or the tip of the ultrasound probe. The gel helps further transmit and amplify the sound waves.
- Turn on the machine, and adjust the volume control.
- Hold the tip of the ultrasound unit (also called the *transducer*) at a 45- to 90-degree angle against the skin and directed toward the site of the pulse.
- Slide the transducer until the pulse (similar to a “whoosh” sound) can be heard. The pressure used to hold the unit against the skin may need to be varied to obtain the strongest signal.
- Ensure presence of a consistent sound at the point where the pulse wave is heard before documenting that a pulse was obtained via Doppler technique.
- The transducer should be cleaned with a water-based solution.

Documentation Concerns

- Note the rate and rhythm of the pulse.
- Note the location of the pulse and use of the Doppler ultrasound unit for the assessment.

Safe Practice Alert

If the peripheral pulse is irregular, count an apical pulse for 1 full minute to ensure accurate measurement.

Safe Practice Alert

In infants and children younger than 2 years of age, the pulse rate is obtained by auscultating the apical pulse for a full minute.

Pulse Rate

Pulse rate is an indirect measurement of cardiac output obtained by counting pulse waves over a pulse point. An excessively fast heart rate (>100 bpm in the adult) is termed **tachycardia**. A slow heart rate (<60 bpm in the adult) is called **bradycardia**. Tachycardia decreases cardiac filling time, leading to a decreased cardiac output. Factors that lead to tachycardia include a drop in blood pressure; an elevated temperature; conditions such as anemia, which result in poor oxygenation; exercise; prolonged application of heat; pain; strong emotions, such as fear or anxiety; and some medications, including bronchodilators.

Bradycardia can occur in athletes, during sleep, in a state of hypothermia, in association with medications such as beta-blockers, during tracheal suctioning, in association with increased intracranial pressure, and in myocardial infarction. Bradycardia accompanied by difficulty breathing and decreased blood pressure should be reported immediately because this is an indication of imminent cardiopulmonary collapse.

The radial or apical pulse typically is assessed to measure the pulse rate. The **radial pulse** is palpated by placing the first two or three fingers of one hand over the radial artery at the groove along the radial, or thumb, side of the patient's inner wrist.

The apical pulse is the heart rate measured at the apex of the heart on the anterior chest wall. It is best heard between the left fifth and sixth intercostal spaces, over the midclavicular line (see [Skill 19.2](#) to review apical pulse landmarks). Assessing the apical rate requires auscultation with a stethoscope. The apical site is used if the patient has weak heart contractions, has an irregular rhythm, is taking medications that affect cardiac function, or needs a more accurate assessment. A **pulse deficit** is present when the patient's radial pulse rate is slower than the apical pulse rate because of cardiac contractions that are weak or ineffective at pumping blood to the peripheral tissues and extremities. A pulse deficit can indicate a serious cardiac event and should be reported to the patient's PCP or cardiologist immediately. To measure this deficit, two people count both pulses simultaneously.

Pulse Rhythm

Rhythm is the regularity of the heartbeat. An irregular rhythm in the pulse, caused by an early, late, or missed heartbeat, is referred to as a **dysrhythmia** or an **arrhythmia**. When an irregular rhythm is detected, the apical pulse is assessed. An electrocardiogram is necessary to define the specific dysrhythmia.

Pulse Intensity

The pulse intensity (also called *volume* or *amplitude*) is the strength of the pulse with each beat. It is described as normal (full and easily palpable), weak (thready and rapid), or strong (bounding). A normal pulse can be felt with moderate pressure of the fingers and obliterated with greater pressure. A forceful volume that is obliterated

only with difficulty is a bounding pulse, which may be caused by vasodilation and overhydration. A pulse readily obliterated is described as weak or thready. Causes include vasoconstriction, stiff vessel walls from disease, and shock.

A standard pulse-volume scale is used by the American College of Cardiology to document findings, with descriptions recorded using a range of 0 to 3 (Table 19.4). Be aware that some institutions may use a 0 to 4 scale with 0 = absent pulse, 1 = diminished pulse, 2 = normal pulse, 3 = strong pulse, and 4 = bounding pulse. It is important to know which scale is being used in each institution or hospital so accurate documentation of the patient's assessment occurs.

TABLE 19.4

Pulse Intensity Scale

SCALE	DESCRIPTION OF PULSE
0	Absent pulse (unable to palpate)
1	Diminished (weaker than expected; difficult to palpate)
2	Normal (able to palpate with normal pressure)
3	Bounding (may be able to see pulsation; does not disappear with palpation)

From Gerhard-Herman, M. D., Gornick, H. L., Barrett, C., et al. (2016). 2016 AHA/ACC guideline on the management of patients with lower extremity peripheral artery disease. *Journal of the American College of Cardiology*.

◆Nursing Diagnosis

ICNP nursing diagnoses related to pulse assessment include:

Impaired Peripheral Tissue Perfusion

- Supporting Data: Decreased peripheral circulation, pedal edema, the need to use Doppler ultrasound to detect pedal pulses

Activity Intolerance

- Supporting Data: Immobility, shortness of breath with ambulation, increased pulse rate with activity

Impaired Cardiac Output

- Supporting Data: Altered contractility of the heart, shortness of breath, peripheral edema, tachycardia

◆Planning

Goals for the patient experiencing abnormal pulse rate may include:

- Patient will exhibit increased perfusion as indicated by less than 1+ edema in lower extremities within 48 hours of beginning medication interventions.
- Patient will exhibit respirations, pulse, and blood pressure within patient's normal range during activity before discharge.
- Patient will demonstrate decreased episodes of shortness of breath, edema, and tachycardia after initiation of treatment plan.

◆Implementation and Evaluation

Hand hygiene is performed before caring for a patient. After selection of the appropriate site and method, the pulse rate is measured. An irregular pulse of new onset should be reported to the PCP. Interventions for an increased pulse rate include identification and treatment of the cause. Fluid replacement is used for tachycardia caused by hypovolemia. Measures to decrease anxiety are implemented for tachycardia related to emotional stress. By contrast, fluid removal by use of diuretic medications would be an appropriate intervention for tachycardia from fluid overload. Oxygenation status often is closely linked to pulse rates and should be stabilized for the patient who experiences deviations in pulse rate. Evaluation is accomplished by comparing the pulse rate with baseline data or to the normal range for the age of the patient. The pulse rate and volume are related to other vital signs, assessment data, and health status.

LO 19.4 Respirations

As noted, respiration is the act of breathing. Breathing (pulmonary ventilation) is the movement of air into and out of the lungs. Inspiration (inhalation) is the act of breathing in, and expiration (exhalation) is the act of breathing out. To survive, cells of the body must receive enough oxygen to meet metabolic requirements and release carbon dioxide. The purpose of respiration is to allow the exchange of oxygen and carbon dioxide among the alveoli, circulating blood, and tissue cells. Several physiologic events work together to meet the gas exchange needs of the body. Nurses assess for signs of changes in gas exchange. The process that is measured as a vital sign is pulmonary ventilation, or respirations. A normal respiratory rate is 12 to 20 breaths per minutes (BPM) for an adult (see [Table 19.1](#)).

Physiology and Regulation of Breathing and Ventilation

Respiratory centers in the medulla and pons are stimulated by impulses from chemoreceptors located throughout the body. Chemoreceptors located in the aortic arch and carotid arteries are especially sensitive to low oxygen levels in the blood (**hypoxemia**). Receptors in the medulla are especially sensitive to high levels of carbon dioxide (**hypercapnia**) and changes in pH. Additional stretch receptors in the lungs and receptors in muscles and joints provide input to the medulla and pons. Respiratory rate and depth change on the basis of input from these receptors, but the strongest respiratory stimulant is an increase in carbon dioxide, which causes an increase in respiratory rate and depth. The cerebral cortex of the brain allows voluntary control of breathing, for example, when singing.

Factors Affecting Respiration

Inspiration and expiration should be smooth and without conscious effort. Environmental or physiologic factors may cause increases or decreases in respiratory rate or depth. Factors that affect respiratory rate and depth include age, exercise, respiratory and cardiovascular disease, alterations in fluid and electrolyte balance, acid-base disturbances, medications, pain, and emotions ([Box 19.11](#)).

Box 19.11

Factors Affecting Respiratory Rate and Depth

- *Age:* Respiratory rate decreases with age through late adolescence, when it stabilizes.
- *Exercise:* Respiratory rate and depth increase with exercise.
- *Illness processes:* Cardiovascular disease and hematologic disorders such as anemia cause an increased respiratory rate. Sickle cell disease reduces the ability of hemoglobin to carry oxygen, resulting in increased respiratory rate and depth. Respiratory diseases can be manifested by difficulty breathing, use of accessory muscles, increased rate, and shallower depth. Smoking alters airways, resulting in an increased rate.
- *Acid-base balance:* Acidosis results in increased rate and depth of respirations in an attempt to rid the body of excess carbon dioxide. Alkalosis results in

decreased respiratory rate as the body tries to retain carbon dioxide.

- *Medications:* Some medications, such as narcotics and general anesthesia, slow respirations. Alternatively, drugs such as amphetamines and cocaine increase respirations. Bronchodilators slow the respiratory rate by dilating the airways.
- *Pain:* Acute pain increases respiratory rate while decreasing respiratory depth.
- *Emotions:* Fear or anxiety can cause increased respiratory rate and decreased depth.

Assessment of Respirations

Assessment of respirations always includes measurement of the breathing rate, depth, and rhythm, and it routinely includes measurement of levels of **oxygen saturation** (amount of oxygen in the arterial blood) by pulse oximetry. Before assessing respirations, the nurse needs to be aware of the patient's normal respiratory pattern, how the patient's health status affects respirations, any medications that may affect respirations, and the impact of cardiovascular system factors on the respiratory system.

Respiratory Status

The assessment of respirations begins with observing the chest and abdominal movements for effort and symmetry ([Skill 19.3](#)). The rate is assessed by counting the number of breaths taken per minute. One inspiration and expiration cycle is counted as one breath.

On inspiration, the rib cage raises and the diaphragm lowers, allowing air to fill the lungs. The muscles relax in expiration, causing the rib cage to lower and the diaphragm to rise, forcing the air out of the lungs. A complete respiratory assessment, including abnormal respiratory sounds, is described in [Chapter 20](#).

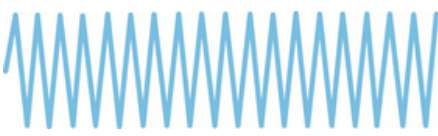

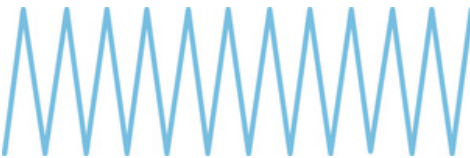

Respiratory Rate

Normal respiration with a normal rate and depth for the patient's age is termed **eupnea**. **Tachypnea** is an increase in respiratory rate to more than 24 BPM in the adult. Any condition that causes an increased need for oxygen, an increased metabolic rate (e.g., high altitude or fever), or an increase in carbon dioxide levels (e.g., chronic lung disease) will cause tachypnea. **Bradypnea** is a decrease in respiratory rate to less than 10 BPM in the adult. Bradypnea can be caused by medications, especially opioids, metabolic disorders, or brain injury.

Depth of Respirations

The depth of respirations normally varies from shallow to deep. Periodic sighs are deep inhalations that fill the lungs with more air than during normal inspiration. **Hypoventilation** is characterized by shallow respirations; it is associated with drug overdose and obesity, as well as chronic obstructive pulmonary disease (COPD) and cervical spine injury. **Hyperventilation** is exhibited by deep, rapid respirations; it is often caused by stress or anxiety. Different respiratory patterns have characteristic rates, rhythms, and depths ([Table 19.5](#)).

TABLE 19.5**Respiratory Patterns**

PATTERN	DESCRIPTION		ASSOCIATED FACTOR(S)
Eupnea	Quiet, regular breathing; 12-20 BPM		Normal pattern
Tachypnea	Breathing rate increased (>24 BPM), with quick, shallow breaths		Fever, exercise, anxiety, respiratory disorders
Bradypnea	Breathing rate abnormally slow (<10 BPM)		Depression of respiratory center by increased intracranial pressure, brain damage, or medications
Hyperventilation	Overexpansion of the lungs, characterized by rapid and deep breaths		Extreme exercise, fear, anxiety, diabetic ketoacidosis, aspirin overdose
Hypoventilation	Underexpansion of the lungs, characterized by shallow, slow respirations		Drug overdose, head injury
Cheyne-Stokes respirations	Rhythmic respirations, going from very deep to very shallow or apneic periods		Heart failure, renal failure, drug overdose, increased intracranial pressure, impending death
Kussmaul breathing	Respirations abnormally deep, regular, and increased in rate		Diabetic ketoacidosis
Apnea	Absence of breathing for several seconds		Respiratory distress, obstructive sleep apnea

PATTERN	DESCRIPTION	ASSOCIATED FACTOR(S)
Biot breathing	Respirations abnormally shallow for two or three breaths, followed by irregular period of apnea	Meningitis, severe brain injury

Quality of Respirations

Apnea is an absence of breathing; brain damage occurs after 4 to 6 minutes of apnea. **Dyspnea** is difficult, labored breathing, usually with a rapid, shallow pattern, that may be painful. Anxiety usually is present as well. Accessory muscles in the chest and neck are used in dyspneic breathing. Many patients experiencing dyspnea find it easier to breathe in an upright position, in which gravity lowers the organs of the abdomen away from the diaphragm, giving the diaphragm room to expand downward as the lungs expand with inspiration. Difficulty breathing experienced in positions other than sitting or standing is termed **orthopnea**.

Safe Practice Alert

Patients with dyspnea experience more distress when lying flat. Placing the patient in a semi-Fowler or Fowler position facilitates a better respiratory pattern. Maximal lung expansion can be achieved by having the patient assume a sitting position, leaning forward over a raised bedside table with arms resting on the table, in what is called the *tripod position*.

Oxygen Saturation

Measurement of respiratory rate is not a measurement of how much oxygen actually enters the bloodstream. The SpO_2 , which reflects the percentage of hemoglobin that combines with oxygen, normally is 95% to 100%. Factors that affect the SpO_2 include lung disease, decreased circulation, and hypotension. **Cyanosis**, bluish discoloration of the skin and mucous membranes, results from decreased oxygen levels in arterial blood. The level of consciousness is affected by changes in oxygen levels. Patients displaying signs of reduced oxygen require additional assessment of mental status, activity tolerance, and measurement of oxygen saturation.

Measurement of oxygen saturation is performed noninvasively and painlessly by means of pulse oximetry. A pulse oximeter is a small device that is clipped to a fingertip, a toe, the nose, or an earlobe. The most desirable site is the fingertip; alternative sites are used only when use of the fingertip is not appropriate. The device has an electronic display for oxygen saturation and pulse rate. Infrared light from one side of the sensor is read by a photo detector on the other side, which measures the amount of light absorbed by oxygenated and deoxygenated hemoglobin. Cold or injury to extremities, peripheral edema, and jaundice interfere with obtaining an accurate value. Movement at the site of sensor attachment, shivering, and some types of nail polish also affect the accuracy of the reading. The animation *Pulse Oximetry* explains the process of obtaining this measurement.®

Skill 19.4 explains how to measure oxygen saturation. The role of oxygen saturation readings in identifying changes in patient status is critical. It is important to maintain

vigilance in monitoring the patient's clinical condition, especially when abnormalities in vital signs or changes in vital sign measurements are present; any significant change must be reported promptly.

Arterial Blood Gases

Measurement of arterial blood gases (ABGs) is a way of assessing the respiratory component of acid-base balance and the adequacy of oxygenation. ABG values include the carbon dioxide level and pH, and they are used to determine the need for and response to treatment. (Refer to [Chapter 39](#) for a detailed discussion of ABG results.) Arterial blood is used for assessment because values for venous blood gases are highly variable, depending on the metabolic demands of the tissues that empty into the vein where the sample is drawn. ABG studies are used to establish baseline values, identify respiratory disorders, and evaluate the effectiveness of interventions. ABG samples also are drawn to monitor patients who are critically ill.

Safe Practice Alert

Signs of respiratory distress include the use of accessory muscles of the chest and neck and/or an exaggerated effort to breathe. Children and infants may exhibit nasal flaring or sternal retractions if they are having trouble breathing.

◆Nursing Diagnosis

Respiratory assessment provides supporting data for many ICNP nursing diagnoses, including:

Impaired Breathing

- Supporting Data: Increased intracranial pressure from traumatic head injury, hypoventilation

Impaired Gas Exchange

- Supporting Data: Alveolar changes, oxygen saturation of 89% on room air

Activity Intolerance

- Supporting Data: Decreased oxygenation levels, dyspnea on exertion

◆Planning

Goals related to respiratory rate assessment focus on ensuring an adequate level of oxygen to meet the physiologic needs of the body. Examples are as follows:

- Patient will exhibit regular breathing pattern with assistance from ventilator while in the intensive care unit.
- Patient will be free of signs of hypoxia with ABGs within the patient's normal range within 8 hours of admission.
- Patient will demonstrate ability to complete activities of daily living with no increase in dyspnea before discharge.

◆Implementation and Evaluation

Changes in respiratory rate and rhythm are a sign of many physiologic and emotional disorders. Interventions for the underlying disorder should improve an altered respiratory pattern and include positioning, supplemental oxygen, suctioning, and medications such as bronchodilators.

A watch with a sweep second hand is needed to count respirations for 1 minute. To ensure an accurate measurement, respirations are counted when the patient is unaware of the procedure to prevent voluntary control of breathing by the patient. If respirations are shallow and slow, a stethoscope may be needed to auscultate breath sounds. Respirations can be palpated by placing a hand on the lower chest or abdomen and counting the breaths felt. An apnea monitor is used to monitor chest movement with leads that are placed on the chest and set off an alarm according to preset parameters. Apnea monitors are used for ill or preterm infants, as well as adults who may have periods of apnea, especially during sleep to alert the nurse to changes in respiratory rates. Apnea monitors may be used in the home or during hospital admissions.

Evaluation of respiration must be done in conjunction with the other vital signs obtained and the medical status of the patient. A respiratory rate significantly above or below normal, any notable changes in pattern, and inadequate oxygenation must be reported to the PCP. Appropriate follow-up to prescribed interventions, such as evaluating the response to oxygen therapy, medications, and positioning, is essential.

LO 19.5 Blood Pressure

Blood pressure can adapt to various stimuli and still remain within a normal range. Knowing the baseline, or usual, blood pressure of an individual is important to be able to interpret a single measurement in a potential illness process. An increase or decrease of 20 to 30 mm Hg in a person's blood pressure is considered a significant change. Sustained change in blood pressure is considered abnormal.

Physiology of Blood Pressure

Blood pressure is the force of the blood against arterial walls. The left ventricle pushes blood through the aortic valve and into the aorta. The pressure rises as the ventricle contracts and falls as the heart relaxes, creating a pressure wave through the arterial system. The peak of the pressure wave is **systolic pressure**. The lowest pressure on arterial walls, which occurs when the heart rests, is **diastolic pressure**. Blood pressure is measured in millimeters of mercury (mm Hg) and recorded as a fraction. The numerator, or top number, is the systolic pressure, and the denominator, or bottom number, is the diastolic pressure. Pulse pressure is the difference between the diastolic and systolic pressures. For example, for a patient with a normal blood pressure of 110/72 mm Hg, 110 is the systolic pressure, 72 is the diastolic pressure, and the pulse pressure is 38 mm Hg.

The body regulates blood pressure by several mechanisms to maintain tissue perfusion. Arteries, arterioles, capillaries, venules, and veins form a continuous loop for circulation. Arterioles regulate the distribution of blood to the organs, tissues, and cells. To respond to the body's needs at any given moment, the arterioles are normally partially contracted, creating peripheral resistance. This resistance is a major factor affecting blood pressure. Arteries have elastic tissue that allows stretching and distention. The arteries stretch with the systolic pressure and relax with diastolic pressure, although a certain amount of pressure is always present in the arteries. This constant pressure maintains a continuous flow into capillaries rather than intermittent bursts of circulation. The arteries provide compliance, and the arterioles supply resistance. With the normal aging process, arterioles become less elastic, and this can contribute to increased pressure within the cardiovascular system.

The autonomic nervous system (ANS) manages mechanisms to maintain short-term regulation of blood pressure. The ANS responds to circulatory system signals as well as to triggers such as pain and cold. Additionally, the renin-angiotensin-aldosterone system controls vasoconstriction and water retention that affects circulatory fluid volume. Antidiuretic hormone (ADH) is released in response to decreased blood pressure, decreased blood volume, or increased blood osmolarity. Water is retained when ADH is released, and this increases blood pressure. The cardiac output is the amount of blood pumped per minute. An increase in cardiac output results in increased blood pressure; a decrease in cardiac output leads to a decrease in blood pressure.

Hypotension

Hypotension is systolic blood pressure of less than 90 mm Hg (or 20 to 30 mm Hg below the patient's normal blood pressure) or diastolic blood pressure of 60 mm Hg or less. Hypotension is caused by a disruption in cardiovascular dynamics, such as decreased blood volume (hemorrhage), decreased cardiac output (heart attack or heart failure), or decreased peripheral vascular resistance (shock). An initial compensatory response to decreased blood pressure is an increase in pulse. If the

falling blood pressure is not treated, the body's compensatory mechanisms will fail and the patient will manifest signs of shock: clammy skin, thready pulse, decreased urinary output, and confusion from decreased cerebral blood flow. Note that a consistently low blood pressure can be normal in highly trained athletes.

Orthostatic hypotension is a sudden drop of 20 mm Hg in systolic pressure and 10 mm Hg in diastolic pressure when the patient moves from a lying to sitting to standing position. The low pressure occurs from peripheral vasodilation with no rise in cardiac output for compensation. It occurs with aging and is a common side effect of several medications. Other risk factors for orthostatic hypotension include prolonged immobility, dehydration, and blood loss.

Hypertension

Hypertension, or elevated blood pressure, is the most common condition seen in primary care and leads to myocardial infarction, stroke, renal failure, and death if not detected early and treated appropriately (James, Oparil, Carter, et al., 2014). It is a global public health issue that disproportionately affects populations in low and middle-income countries where health systems are weak (World Health Organization [WHO], 2013).

Hypertension occurs when there is dysfunction of the neurohormonal system. When angiotensin and aldosterone are overstimulated, blood pressure increases, and the result may be permanent thickening of the blood vessels, leading to increased peripheral resistance. This resistance affects the brain, heart, and kidneys. Systolic blood pressure of 120 to 129 mm Hg is classified as elevated. Pressures of 130 to 139 systolic or 80 to 89 diastolic are classified as hypertension stage 1. Blood pressure readings of 140 systolic or 90 diastolic or greater are classified as hypertension stage 2 (Table 19.6) (Whelton, Carey, Aronow, et al., 2017).

TABLE 19.6

Categories for Blood Pressure Levels in Adults^a

CATEGORY	SYSTOLIC (mm Hg)		DIASTOLIC (mm Hg)
Hypotension	<90	or	<60
Normal	<120	and	<80
Elevated	120–129	and	<80
Hypertension stage 1	130–139	or	80–89
Hypertension stage 2	≥140	or	≥90

^aPeople 18 years of age and older who are not on medications for high blood pressure or other conditions that affect blood pressure.

From Whelton, P. K., Carey, R. M., & Aronow, W. S., et al. (2017). 2017 ACC/AHA/AAPA/ABC/ACPM/AGS/APhA/ASH/ASPC/NMA/PCNA guideline for the prevention, detection, evaluation, and management of high blood pressure in adults. *Journal of the American College of Cardiology*.

Primary (essential) hypertension occurs when there is no known cause for the high blood pressure. Secondary hypertension is caused by a known illness process, such as renal failure. Risk factors for hypertension include a family history of the disorder, sedentary lifestyle, obesity, and ongoing stress, as well as smoking, alcohol use, and a high-salt, high-fat-calorie diet. Important factors in self-management for patients with prehypertension or hypertension are outlined in Box 19.12.

Box 19.12

Home Care Considerations

Hypertension

Patients with risk factors for hypertension, or those who are prehypertensive, should be educated about the need to adopt health-promoting lifestyle changes. According to the National Institutes of Health's (NIH's) [National Heart, Lung, and Blood Institute \(2018\)](#), the following lifestyle changes have been shown to lower blood pressure:

- Maintain normal body weight.
- Adopt the Dietary Approaches to Stop Hypertension (DASH) eating plan, which includes reduced fat intake and increased intake of fruits and vegetables.
- Reduce dietary sodium intake to 2.3 g daily.
- Engage in regular aerobic physical activity at least 30 minutes a day, on most days of the week.
- Limit alcohol consumption: For men, two drinks a day; for women, one drink a day.

Factors Affecting Blood Pressure

Many factors affect blood pressure. Activities throughout the day, emotions, fluid balance, exercise, and medications can alter blood pressure ([Box 19.13](#)). It is important to maintain vigilance in monitoring vital signs in patients receiving narcotic pain medication. If any abnormalities in vital signs develop, they must be reported promptly.

Box 19.13

Factors Affecting Blood Pressure

- *Age*: With age, elasticity in arteries decreases; this increases peripheral resistance, leading to higher blood pressure.
- *Gender*: Blood pressure usually is lower in women than in men until menopause.
- *Race*: Hypertension is more prevalent in African American men and women.
- *Medications*: Oral contraceptives cause an increase in blood pressure in some women.
- *Weight*: Blood pressure usually is higher in people who are obese.
- *Circadian rhythm*: Blood pressure usually is lower in the morning and slightly higher by late afternoon.
- *Head injury*: Increased intracranial pressure from head injury causes increased blood pressure.
- *Increased blood volume*: Increased fluid in the cardiovascular system increases blood pressure.
- *Food intake*: Blood pressure increases after eating.
- *Emotions*: Anger, fear, and excitement cause blood pressure to rise until the emotion passes.

- *Pain*: Pain increases blood pressure.

Assessment of Blood Pressure

Blood pressure is measured during physical examination, at initial admission, and with routine vital signs, as well as whenever the patient status changes (Box 19.14). Blood pressure assessment requires excellent technique, correctly calibrated equipment, and proper interpretation of the sounds obtained. Blood pressure can be measured manually, through the use of a stethoscope and sphygmomanometer; electronically, through intermittent or continuous monitoring (Skill 19.5); or through placement of an arterial catheter. If the patient has severe hypotension or shock, a Doppler ultrasound may need to be used in place of a stethoscope to amplify the diminished sounds.

Box 19.14

Diversity Considerations

Life Span

- *Children*: All children aged 3 years and older need to have blood pressure assessed at least annually. Readings are difficult to obtain and may be inaccurate in a child who is upset or restless. A child can be prepared for the measurement by describing the procedure in terms of “a tight squeeze on your arm.” A pediatric stethoscope bell is helpful in hearing the Korotkoff sounds in a child.
- *Elderly people*: The skin of elderly patients may be fragile. Therefore the cuff pressure should not be left on any longer than necessary. The timing of antihypertensive medications affects blood pressure readings. Antihypertensive medications that cause vasodilation increase the risk for orthostatic hypotension. If the patient has contractures of the arm, the blood pressure may be taken by the palpation method or from the popliteal artery.

Gender

- After puberty, females usually have lower blood pressure than do males of the same age. Although this difference is not fully understood, female hormones may affect renal sodium handling and/or vascular resistance. After menopause, females generally have higher blood pressure than they did earlier in their lives (American Heart Association, 2015).

Culture, Ethnicity, and Religion

- African Americans tend to have higher blood pressure than do whites, Asians, or Hispanics of the same age (NIH, 2018).

Morphology

- Obesity in children and adults is linked to a higher incidence of hypertension (NIH, 2018).

From National Institutes of Health (NIH). (2018). National Heart, Lung, and Blood Institute: Risk factors for high blood pressure. Retrieved from <https://www.nhlbi.nih.gov/health/health-topics/topics/hbp/atrisk>.

Blood pressure measurements should be taken after the patient rests for at least 5 minutes and has not smoked or ingested caffeine for at least 30 minutes before the measurement. Because of the variations that occur during a typical day, readings on two or more occasions should be averaged before diagnosing high blood pressure. Hypotension accompanied by tachycardia, pallor, increased sweating, and confusion should be reported to the PCP immediately. These signs can indicate the critical loss of cardiovascular function, such as an impending acute myocardial infarction (heart attack).

Sites for Assessing Blood Pressure

Blood pressure can be measured in the upper or lower extremity. It is usually assessed manually or indirectly. The most common site for indirect blood pressure measurement is the upper arm at the brachial artery. A brachial artery reading should not be taken on a patient's arm if an arteriovenous fistula or shunt is present; when the arm, shoulder, or hand is diseased; if a cast or bulky dressing is in place; or when intravenous fluids are being infused. Blood pressure should not be taken on the side of the body where axillary nodes were dissected or a mastectomy was performed. The pressure exerted on the site when taking a reading in such patients can increase the risk for lymphedema. Clinical judgment is an important aspect of determining the appropriate site, with the appropriate equipment, for obtaining blood pressure.

In some cases, blood pressure is assessed by palpating the radial artery at the wrist or the posterior tibial or dorsalis pedis artery of the lower leg. Palpation requires only a sphygmomanometer. The nurse places two or three fingers over the artery pulse point, and the cuff is inflated 30 mm Hg above the point where the pulsation in the artery is no longer felt. As the air in the bladder is released, the nurse feels for the return of the pulse. As an example, if the palpated value was felt at 70 mm Hg, the blood pressure typically would be recorded as "70 palpable," with the understanding that it is a measurement of palpated systolic pressure.

If the brachial artery is not accessible, the popliteal artery behind the knee can be used for blood pressure measurement. Injuries such as trauma or burns or the presence of a cast, intravenous line, or arteriovenous shunt may mean that the blood pressure must be obtained on a lower extremity. The popliteal artery, found behind the knee in the popliteal space, is the site used for auscultation. The cuff is sized specifically to fit around the thigh, and the cuff is positioned 2.5 cm (1 inch) above the popliteal artery, with the cuff bladder over the posterior aspect of the thigh. The technique is the same as that used for the brachial artery. Systolic blood pressure in the leg is approximately 20 mm Hg higher than it is in the brachial artery; diastolic pressure usually is the same in the leg as in the brachial artery. It is necessary to document the site if one other than the brachial artery is used to take a blood pressure reading.

Orthostatic hypotension is measured by taking the blood pressure reading and pulse while the patient is in the lying position, sitting position, and standing position (Box 19.15). A drop in blood pressure of 20 mm Hg systolic or 10 mm Hg diastolic, or an increase in heart rate of 20 bpm, is indicative of orthostatic hypotension.

Box 19.15

Nursing Care Guideline

Assessing Orthostatic Hypotension

Background

- Orthostatic hypotension, also known as *postural hypotension*, is a condition in which there is an abrupt decline in blood pressure when a person moves from a supine to a sitting or standing position. An accompanying increase in heart rate is typical. An accurate assessment of orthostatic hypotension requires identifying a blood pressure decline of 20 mm Hg in the systolic pressure or 10 mm Hg in the diastolic pressure, or an increase in heart rate of 20 bpm, within 1 to 3 minutes of postural change.
- Orthostatic hypotension can be indicative of dehydration (leading to low blood volume) or anemia, or it may occur in conjunction with prolonged immobilization.
- Orthostatic hypotension is most commonly due to a problem with the autonomic nervous system and/or a delay of the circulatory response to adjust to rapid movement.
- Symptoms may include dizziness, fainting, changes in mental status, and anxiety. Nausea, rapid onset of pallor, and fast, shallow breathing are common during an episode of orthostatic hypotension.
- Because the condition has several different causes that vary from person to person, no single treatment for orthostatic hypotension can be recommended. However, its prevalence increases with age.

Delegation

- Assessment cannot be delegated to unlicensed assistive personnel (UAP), but UAP may assist in obtaining the measurements and in positioning the patient for safety.

Procedural Concerns

- It is best to evaluate the patient in the morning rather than during the afternoon and/or after meals.
- Have the patient remain in the supine position for 5 to 10 minutes before the procedure.
- Three blood pressure and heart rate measurements are taken 1 to 3 minutes apart while the patient is in three different positions:
 - Supine
 - Sitting
 - Standing
- The blood pressure and heart rate measurements must be taken as soon as the position change occurs.
- Assess the patient throughout the procedure for signs and symptoms of syncope: dizziness, weakness, pale skin, diaphoresis, light-headedness, blurry vision,

nausea, headache, and similar complaints.

- To ensure patient safety, stay with the patient throughout the procedure.

Documentation Concerns

- Blood pressure and heart rate are documented in conjunction with the position and time.
- Any signs, symptoms, or other complaints during the procedure should be documented.

Evidence-Based Practice

- An official diagnosis of orthostatic hypotension requires a 20 mm Hg drop in systolic blood pressure or a 10 mm Hg drop in diastolic blood pressure, with or without symptoms, within 3 minutes of the positional change. There usually is a corresponding increase in heart rate, although certain medications may prevent the heart rate from increasing ([Mayo Clinic, 2017](#)).

Blood Pressure Devices

Many styles of electronic, or automatic, blood pressure measurement devices are available ([Fig. 19.2](#)). Electronic blood pressure devices use an electronic sensor to detect vibrations caused by blood moving through the artery. It is appropriate to measure blood pressure electronically in the critically ill, potentially unstable patient or during or after invasive procedures.

A

B

FIGURE 19.2 Electronic blood pressure devices. (A, From Welch Allyn, Inc., New York, NY; B, Copyright [istock.com](https://www.istock.com).)

Low blood pressure may not be read as accurately with an electronic blood pressure device. If the accuracy of the blood pressure reading is questionable, manual measurement is used to ensure accuracy. It is inappropriate to use an electronic blood pressure device in patients with an irregular heart rate, shivering, seizure activity, or blood pressure less than 90 mm Hg systolic, because the device will not be able to accurately sense the blood pressure.

Arterial Lines

An arterial line is an indwelling catheter inserted into an artery by a physician or an advanced practice nurse to monitor blood pressure. This invasive procedure is used for patients with unstable blood pressure necessitating frequent monitoring. It may be used for patients who are dangerously hypotensive or hypertensive or who are receiving blood pressure medications requiring titration, or regulating, and monitoring. Special training is required for the use, care, and monitoring of an arterial line.

Safe Practice Alert

An arterial line is *never* used for infusion of intravenous medications or fluids. These solutions are irritating to the vessel and may impair tissue perfusion beyond the catheter.

Korotkoff Sounds

The sounds for which the nurse listens when assessing blood pressure are called **Korotkoff sounds**. In some adults these sounds are distinct, and in other adults only the beginning and ending sounds are heard. [Table 19.7](#) summarizes the features of Korotkoff sounds by specific phases.

TABLE 19.7

Korotkoff Sounds

PHASE	DESCRIPTION
Korotkoff I	The initial presentation of faint but clearly audible tapping sounds, which gradually increase in intensity to a thud or loud tap; the first sound is recorded as the systolic pressure
Korotkoff II	Muffled, swishing sounds
Korotkoff III	Crisp, loud sounds as the blood flows through an opening artery
Korotkoff IV	A distinct, abrupt muffling sound
Korotkoff V	The last sound heard before silence; this is the diastolic measurement

An **auscultatory gap** may occur in the latter part of phase I and during phase II. The auscultatory gap is the absence of Korotkoff sounds noted in some patients after the initial systolic pressure; the gap may cover a range as wide as 40 mm Hg. Failure to recognize an auscultatory gap may lead to major errors in measuring blood pressure.

Normally, blood pressure is recorded as a two-number fraction. The first sound heard during measurement, the onset of phase I, represents the systolic pressure and is recorded as the top number on the blood pressure fraction. The second number, the bottom of the fraction indicates the level at which the sounds stop. For example, if the blood pressure is recorded as 122/78, the number 122 represents the systolic pressure, and the number 78 represents the diastolic pressure. The American Heart Association recommends that when an abrupt change followed by the cessation of sounds occurs, all three numbers be recorded, such as 122/86/78. The middle number would be the Korotkoff phase IV sound. On some occasions, sounds may be heard all the way to zero on the blood pressure cuff. This measurement would be recorded as 122/78/0. Each facility will have a procedure on how to record blood pressure; this procedure should be followed for consistency in measurements.

Safe Practice Alert

When using a continuous blood pressure device, be sure to set high and low alarm limits for systolic and diastolic pressures. Do not turn off alarms. Check the position of the cuff frequently, and remove the cuff regularly to assess skin integrity.

Nursing Diagnosis

Sample ICNP nursing diagnoses for altered blood pressure are:

Risk for Fall

- Supporting Data: Orthostatic hypotension and dizziness when standing, blood pressure 136/70 lying and 96/60 standing

Impaired Cardiac Output

- Supporting Data: Altered stroke volume, estimated blood loss of 500 mL during surgery, irregular heart rate

Fluid Imbalance

- Supporting Data: Renal compromise, increased blood pressure, dyspnea, orthopnea

◆ **Planning**

Patient goals related to blood pressure focus on maintaining blood pressure throughout the body to maintain functioning of all organs. Examples of goals or outcome statements are:

- Patient will be free from injury throughout hospitalization.
- Patient's blood pressure and peripheral pulses will be within defined parameters for patient within 24 hours postsurgery.
- Patient will have vital signs within patient's expected norm within 48 hours of admission.

◆ **Implementation and Evaluation**

Different devices are available to measure blood pressure. The most common equipment used by the nurse is a stethoscope and sphygmomanometer (blood pressure cuff). Blood pressure can be measured with a Doppler stethoscope, estimated by **palpation** (assessment by feeling with the hand or fingers), or measured by an electronic, or automated, cuff. Equipment needs to be monitored to ensure that it is in proper working order, with recalibration or repair as needed.

A stethoscope is used to hear the sounds created by blood flowing through the artery. The stethoscope used should be properly fit to the person using it and should be used accurately. A sphygmomanometer consists of a cuff and the manometer. The cuff consists of a flat, rubber bladder covered with stiff cloth. Two tubes are attached to the bladder within the cuff. One is connected to the manometer, and the other is attached to the bulb used to inflate the bladder. The bladder is inflated until the blood flow through the artery is obstructed. A valve on the bulb allows the bladder in the cuff to be deflated, releasing the pressure and allowing blood to flow through the artery again, which creates the first sound, or systolic pressure reading. Electronic blood pressure devices sense vibrations within the artery wall and display the pressure readings in digital numbers. Electronic sphygmomanometers frequently are used by patients who self-measure their blood pressure.

Cuff sizes range from neonate to adult thigh sizes (Fig. 19.3). The width of the cuff should be approximately 40% of the circumference of the extremity being used, and the bladder of the cuff should be approximately 60% to 80% of the circumference of the extremity being used. If the cuff is too narrow, the reading can be erroneously high. (A common source of this error is use of a normal-size cuff on an overweight person.) Conversely, if the cuff is too wide, the reading can be erroneously low. Table 19.8 presents a review of factors that contribute to blood pressure assessment errors. It is possible to measure blood pressure directly in the artery by means of a catheter

inserted into an arterial line. The tip of the catheter senses the pressure and transmits the readings to an electronic device that displays the waveform. Arterial lines typically are used in an intensive care unit.

FIGURE 19.3 Blood pressure cuffs come in different sizes.

TABLE 19.8

Factors That Contribute to Blood Pressure Assessment Errors

ERROR	CONTRIBUTING FACTORS
Inaccurate reading	Defective equipment Equipment not calibrated Improper use of equipment Patient not positioned correctly
Falsely low reading	Hearing deficit in assessing person Arm positioned above heart level Extraneous noise in surrounding environment Use of a cuff that is too wide Ear tips of stethoscope placed incorrectly Breaks or kinks in cuff tubing Cuff deflated too rapidly Stethoscope bell not placed directly over artery Failure to follow all steps in recommended blood pressure procedure
Falsely high reading	Assessing blood pressure too soon after patient smoking or exercise Use of a cuff that is too narrow Releasing the pressure valve too slowly Reinflating the bladder before it has completely deflated

Many factors cause an inaccurate blood pressure measurement. It is important that the nurse not take the routine task of blood pressure measurement lightly, because this measurement can give critical information regarding the overall cardiac status of the patient. Because the cardiovascular system affects all other body systems, care is taken to obtain accurate blood pressure readings by using proper equipment and technique. Many factors affect blood pressure values. It is important to compare current measurements with previous measurements to identify any significant changes. Considerations in interpretation of blood pressure include medication effects, correlation with other vital sign measurements, and the underlying clinical status of the patient.

1. The nurse administers the intravenous dose of a diuretic, furosemide, to reduce fluid volume overload. Which assessments will assist the nurse in evaluating whether the medication was effective?

2. The nurse evaluates the patient's vital signs. What data would account for the observed deviations from normal values?

3. On day 2 of the hospitalization, A. D.'s vital signs are T 37° C (98.6° F), P 88 regular, R 24 and unlabored, BP 140/84, and pulse oximetry (SpO₂) of 93% on 2 L of oxygen via nasal cannula. He has lost 5.5 kg (12 lb). What treatments and medications have contributed to his improvement in vital signs?

SKILL 19.1 Measuring Body Temperature

Purpose

- Determine the patient's baseline temperature. Body temperature may be measured in degrees Fahrenheit or Celsius.
- Identify whether the body temperature is within normal range.
- Monitor the patient for fever or an inability to maintain normal body temperature.
- Monitor the patient for change in physical condition or during treatments such as blood transfusions.
- Monitor temperature changes for response to medications.

Resources: All Methods

- Thermometer
- Vital-sign flow sheet and pen or an electronic health record

Interprofessional Collaboration and Delegation

- Measuring a temperature may be delegated to unlicensed assistive personnel (UAP) after the initial assessment of the patient.
- Assistive personnel should report the following to the nurse:
 - Deviations from baseline temperature
 - Complaints related to temperature regulation
 - Sores, wounds, irritations, and/or lesions in the area where the temperature is being measured
 - Any difficulties performing the procedure
- UAP should be instructed in:
 - Appropriate placement of the thermometer/probe
 - Appropriate use of equipment (verifying accurate results)
 - Appropriate documentation

Evidence-Based Practice

- Besides fever due to illness, body temperature may be raised by vigorous exercise, external temperature, eating, or taking

certain medications. Temperature measurement should occur at least 1 hour after exercise or bathing and 30 minutes after smoking or consuming hot or cold food or beverages ([US National Library of Medicine, 2018](#)).

- Baseline oral temperature tends to decrease slightly with age ([Waalén & Buxbaum, 2011](#)).

Special Circumstances: All Methods

1. **Assess:** Has the patient undergone exercise or physical therapy within the last 30 minutes?
Intervention: Physical exercise increases body temperature; have the patient rest for 30 minutes before assessing temperature.
2. **Assess:** Does the temperature deviate from the normal range in either direction?
Intervention: Validate equipment accuracy and proper use.
 - Assess the room temperature.
 - Assess the patient for clinical manifestations of hyperthermia or hypothermia.
 - Retake the patient's temperature using different equipment or a different method (if needed).
 - Check the PCP orders and care plan for further interventions.

Resources and Special Circumstances: Specific Methods

Oral Method

Resources

- Electronic or digital thermometer
- Disposable probe covers or plastic thermometer sheaths

Special Circumstances

1. **Assess:** Has the patient consumed cold or hot food or beverages, chewed gum, or smoked within the past 30 minutes?
Intervention: Wait 30 minutes from the last oral intake to assess oral temperature or use a different method.
2. **Assess:** What is the patient's level of consciousness? Is the patient awake, alert, and oriented?
Intervention: Select an alternative method to measure temperature, if necessary.
3. **Assess:** Are there any mouth lesions or sores?
Intervention: Select an alternative method to measure temperature, if necessary.

Temporal Artery Method

Resources

- Temporal artery thermometer
- Alcohol wipes

Special Circumstances

1. **Assess:** Does the patient exhibit extreme perspiration?
Intervention: Use a different method. Extreme perspiration interferes with the accuracy of the temperature reading.
2. **Assess:** Is the patient lying on his or her side?
Intervention: Use the side of the patient's face that is not on the pillow. The side of the face that is on the pillow has an artificially high temperature.
3. **Assess:** Do you suspect an inaccurate or unreliable result?
Intervention: Wait 30 seconds before repeating the temperature measurement. It takes at least 30 seconds for the skin temperature to normalize.

Axillary Method

Resources

- Electronic or digital thermometer
- Disposable probe covers or plastic thermometer sheaths

Special Circumstances

1. **Assess:** Has the skin recently been washed?
Intervention: Wait 15 minutes after bathing before assessing axillary temperature to allow time for the skin temperature to normalize or use a different method.
2. **Assess:** Is the axilla moist or diaphoretic?
Intervention: Use the other arm; use a different method; or dry the axillary region with a towel, using a patting motion, because perspiration causes inaccurate results.
3. **Assess:** Are lesions, wounds, skin irritations, or sores present?
Intervention: Use the other axilla or use a different method because skin problems may raise temperature.

Rectal Method

Resources

- Electronic or digital thermometer
- Disposable probe covers or plastic thermometer sheaths
- Lubricant (water-soluble)
- Toilet paper or cloth
- Paper towel or tissue

- Waterproof pad

Special Circumstances

1. **Assess:** What is the reason for using this method?
Intervention: If a less invasive method can be used, use it. Patient comfort is important, and other methods have been shown to be as accurate as the rectal method.
2. **Assess:** Is there a patient history of rectal surgery or bleeding?
Intervention: Rectal method is contraindicated. Use a different method to avoid risk for injury.
3. **Assess:** Is the patient on an anticoagulant or having diarrhea?
Intervention: Use a different method to avoid the risk for bleeding or stimulating a bowel movement.
4. **Assess:** Are lesions, wounds, hemorrhoids, or other sores present?
Intervention: Use a different method to avoid risk for injury.

Special Circumstances Arising During Procedure

1. **Assess:** Is there difficulty in inserting the temperature probe?
Intervention: Remove the probe; assess the site; use a different method; and document the methods and findings.
2. **Assess:** Does the patient faint or become lightheaded or dizzy?
Intervention: Remove the probe; assess blood pressure and heart rate; obtain assistance if needed; notify the PCP; use a different method; document; and notate “no rectal temps” because of the risk for vasovagal response.

Tympanic Method

Resources

- Tympanic thermometer
- Disposable probe covers
- Alcohol wipes

Special Circumstances

1. **Assess:** Is there a history of recent or current ear surgery or infection?
Intervention: Use the other ear or a different method to avoid risk for injury.
2. **Assess:** Are there hearing aids or personal stereo or other listening device(s) in the ear(s)?
Intervention: Use the other ear if one device is present; if two devices are present, remove one and wait 5 minutes before taking the temperature. These devices have retained heat inside the ear canal, artificially making the temperature higher; it takes at least 3 minutes for the ear canal to normalize its temperature.
3. **Assess:** Is the patient lying on his or her side?
Intervention: Use the ear that has not been resting on the pillow. The ear on the pillow has an artificially high temperature.

4. **Assess:** Is cerumen present in the ear?

Intervention: Use the other ear if only one ear is affected, or use a different method if both are affected; document excessive cerumen accumulation. Cerumen obstructs the probe's interaction with the tympanic membrane, so the result is inaccurate.

5. **Assess:** Do you suspect an inaccurate or unreliable result?

Intervention: Wait 5 minutes before repeating the measurement. Taking a temperature with a tympanic probe causes the ear canal to cool because the probe is at room temperature, which is cooler than ear temperature. It takes at least 3 minutes for the ear canal temperature to normalize.

Preprocedure

I. Check PCP orders and the patient care plan.

Knowledge of patient-specific orders is critical for safe patient care.

II. Gather supplies and equipment.

Preparing for the patient encounter saves time and promotes patient trust.

III. Perform hand hygiene.

Frequent hand hygiene prevents the spread of microorganisms.

IV. Maintain standard precautions.

Use of the correct personal protective equipment (PPE) is required whenever contact with bodily fluids is possible, to reduce the transfer of pathogens.

V. Introduce yourself.

Initial communication establishes the role of the nurse and begins a professional relationship.

VI. Provide for patient privacy.

It is important to maintain patient dignity.

VII. Identify the patient, using two identifiers.

Identifying a patient involves scanning barcodes or comparing the patient's stated name and birthdate to information on the patient's wristband or health record. The correct person must receive the correct treatment.

VIII. Explain the procedure to the patient.

The nurse has a responsibility to inform a patient before initiating care. Information may ease patient anxiety and facilitate cooperation.

Procedure

Oral Temperature

Follow preprocedure steps I through VIII.

1. Obtain electronic thermometer with blue probe.
Blue is standard for oral use.
2. Remove temperature probe; machine will beep and digital display will appear.
Indicates the machine is charged, accurate, and ready for use.
3. Place probe in disposable cover; cover will click into place.

STEP 3 (Copyright Mosby's Clinical Skills: Essentials Collection.)

Secures the fit so the cover will not fall off. The cover reduces transmission of microorganisms.

4. Insert probe tip into posterior sublingual pocket of mouth, holding it along the side of the probe positioned slightly off the center of the jaw; patient's lips must be closed around probe.

STEP 4 (Copyright Mosby's Clinical Skills: Essentials Collection.)

Provides the best location to achieve the most accurate temperature in the mouth. Holding along the side of the probe prevents accidentally pushing the button that ejects the probe cover.

5. Hold probe in place until reading is completed; machine will beep to indicate measurement is completed.
Keeps the probe tip in place for accuracy.
6. Remove probe from patient.
7. Note temperature reading on display.
Needed for documentation.
8. Discard probe cover; push the eject button at the end of the probe to release cover into trash can.
Prevents the spread of microorganisms.

Follow postprocedure steps I through VI.

Rectal Temperature

Follow preprocedure steps I through VIII.

1. Obtain electronic thermometer with red probe.
Red probe = Rectal. Red probe is standard for rectal use; use of a dedicated probe prevents the spread of microorganisms.
2. Raise bed to comfortable working height and flatten bed as tolerated by patient.
Prevents provider discomfort and possible injury; the flat bed provides for patient comfort.
3. Position patient in Sims position, with upper leg flexed and lower leg straight.

STEP 3

Promotes comfort; allows visualization of the buttocks.

4. Apply clean gloves. Cover patient, except for buttocks.
Gloves are standard precautions when there is possible exposure to blood and body fluids. Provides warmth, comfort, and privacy.
5. Remove temperature probe; machine will beep and digital display will appear.
Indicates the machine is charged, accurate, and ready for use.
6. Place probe in disposable cover; cover will click into place.
Secures the fit so that the cover will not fall off. The cover reduces transmission of microorganisms.
7. Apply water-soluble lubricant to 1 to $\frac{1}{2}$ inch of the probe tip; can be done three different ways:
 - a. *Packets: Dip probe in packet.*

STEP 7A (Copyright Mosby's Clinical Skills: Essentials Collection.)

Use with single-use packets to prevent the spread of microorganisms; packets are an appropriate size to cover the tip.

- b. *Direct application: Squeeze directly onto probe; cover all around tip; do not touch tube tip to probe tip.*
Use with single-use packets or multiuse tubes to prevent the spread of microorganisms.
- c. *Indirect application: Squeeze onto paper towel or tissue; dip probe to cover tip; do not touch tube tip to paper towel or tissue.*
Use with single-use packets or multiuse tubes to prevent the spread of microorganisms.

8. Separate buttocks with one hand.
Visualize anus.
9. Ask patient to breathe slowly and relax.
Relaxes muscles; allows for easier insertion.
10. Insert probe tip 1 to $\frac{1}{2}$ inches in adults, pointing toward the umbilicus (Rectal temperature measurement is contraindicated in young infants. Check facility policy for use in children).

STEP 10 (Copyright Mosby's Clinical Skills: Essentials Collection.)

Location for obtaining the most accurate temperature; blood vessels are against the rectal wall.

11. Hold probe in place until reading is completed; machine will beep to indicate measurement is completed.
Keeps the probe tip in place for accuracy.
12. Remove probe from patient.
13. Note temperature reading on display.
Needed for documentation.
14. Discard probe cover; push the eject button to release cover into trash can.
Prevents the spread of microorganisms.
15. Clean probe tip with alcohol wipe before returning probe to case.
Prevents the spread of microorganisms.
16. Clean patient; reposition.
Removes extra lubricant and possible feces; provides comfort.

Follow postprocedure steps I through VI.

Axillary Temperature

Follow preprocedure steps I through VIII.

1. Obtain electronic thermometer with blue probe.
Blue is standard for oral use and is also used for axillary temperatures.
2. Remove temperature probe; machine will beep and digital display will appear.
Indicates the machine is charged, accurate, and ready for use.
3. Place probe in disposable cover; cover will click into place.
Secures the fit so that the cover will not fall off. The cover reduces transmission of microorganisms.
4. Remove clothing from axillary area; place probe tip in middle of the axilla.

Location for obtaining the most accurate temperature; blood vessels are closest to the skin.

5. Arm should be held down, close to the body or across chest.

Keeps the probe tip in place for accuracy.

6. Hold probe in place until reading is completed; machine will beep to indicate measurement is completed.

Keeps the probe tip in place for accuracy.

7. Remove probe from axilla.
8. Note temperature reading on display.

Needed for documentation.

9. Discard probe cover; push end of probe to release cover into trash can.

Prevents the spread of microorganisms.

Follow postprocedure steps I through VI.

Tympanic Temperature

Follow preprocedure steps I through VIII.

1. Obtain tympanic thermometer unit; remove thermometer portion from base.

The special unit is needed for measuring temperature in the ears.

2. Inspect lens; if dirty, clean with alcohol wipe and allow to air-dry for 5 minutes.

Interference from dirt on the lens can cause an inaccurate reading; using a cloth to dry the alcohol may smudge the lens.

3. Insert probe tip into disposable probe tip cover until it clicks into place.

The cover reduces transmission of microorganisms; maintains accuracy of temperature reading by keeping the lens clean.

- a. Some units beep, and digital display appears; proceed to step 4.

Indicates the machine is on and ready.

- b. Some units have manual on/off: Push the on/off button; wait for beep to sound and for digital display to appear; proceed to step 4.
Indicates the machine is on and ready.
4. Remove hearing aids if present, and wait 5 minutes. Make sure ear canal is clean. Insert probe tip snugly into ear: Are you right-handed? Measure temperature in right ear. Are you left-handed? Measure temperature in left ear.
Ear canal must be accessible. This angle of approach provides a snug fit, ensuring accuracy.
5. Pull top of ear up and back for ages 4 years to adult, or down and back for a child 3 years of age and younger; rotate thermometer in line with jaw.

STEP 5

- Lines up the tympanic membrane with the lens to get an accurate reading.*
6. Push "Start" or "Activate" button
Tells the machine that probe is in place.
7. Support probe until reading is complete; machine will beep.
Keeps the probe tip in place for accuracy.
8. Remove probe from patient.
9. Note temperature reading on display.
Needed for documentation.
10. Discard probe cover; push end of probe to release cover into trash can.
Prevents the spread of microorganisms.

Follow postprocedure steps I through VI.

Temporal Artery Temperature

Follow preprocedure steps I through VIII.

1. Obtain temporal thermometer unit; remove protective cap from lens.
The special unit is needed for measuring temperature on the forehead near the temporal artery.
2. Inspect lens; if it is dirty, clean with alcohol wipe and allow to air-dry for 5 minutes.
Interference from dirt on the lens can cause an inaccurate reading; using a cloth to dry the alcohol may smudge the lens.
3. Place probe on center of the patient's clean, dry forehead; push "Scan" button; keep button pressed throughout steps 4 and 5.

STEP 3 (Copyright Mosby's Clinical Skills: Essentials Collection.)

The temporal artery is located midline center of the forehead, 1 mm beneath the skin; keeping the button depressed signals the device that a temperature measurement is occurring. Moisture affects temperature measurement when using this device.

4. Slide probe straight across forehead to hairline near the temple.
Ensures accurate reading; takes an average of 1000 readings while scanning the forehead.
5. Lift probe; if perspiration is present, touch probe behind earlobe on skin over mastoid process.
Ensures an accurate reading; averages skin, temporal artery, and room temperatures.
6. Release "Scan" button.
Signals to the device that temperature measurement is completed.
7. Remove probe from patient.
8. Note temperature reading on display.

STEP 8 (Copyright Mosby's Clinical Skills: Essentials Collection.)

Needed for documentation.

9. Clean lens with alcohol wipe; allow to air-dry for 5 minutes.
Prevents spread of microorganisms. Interference from dirt on the lens can cause an inaccurate reading; using a cloth to dry the alcohol may smudge the lens.
10. Replace cap on lens.
Keeps the lens protected; maintains equipment for optimal use and accuracy.

Follow postprocedure steps I through VI.

Postprocedure

I. Return the bed to its lowest position, raise the top side rails, and verify that the call light is within reach for the patient.
Precautions are taken to maintain patient safety. Top side rails aid in positioning and turning. Raising four side rails is considered a restraint.

II. Assess for additional patient needs and state the time of your expected return.
Meeting patient needs and offering self promote patient satisfaction and build trust.

III. Properly dispose of PPE.
Gloves, gowns, and masks must be appropriately discarded to prevent the spread of microorganisms.

IV. Clean or dispose of equipment if it was in contact with the patient; see specific manufacturer instructions.
Disinfection eliminates most microorganisms from inanimate objects.

V. Perform hand hygiene.
Frequent hand hygiene prevents the spread of infection.

VI. Document the date, time, assessment, procedure, and patient's response to the procedure.
Accurate documentation is essential to communicate patient care and to provide legal evidence of care.

SKILL 19.2 Assessing Pulses

Purpose

- Determine the baseline heart rate and rhythm.
- Monitor the heart rate and rhythm.
- Assess blood flow from the heart to the body.
- Monitor the patient for changes in physical condition.
- Monitor the patient's response to medications.
- Monitor the patient's response to therapy.
- Evaluate the symmetry of peripheral pulses by assessing both the right and left side of each site (except carotid) simultaneously.

Resources

- Clock or watch that has a second (or “sweep”) hand or a digital display
- Vital signs flow sheet and pen or electronic health record
- Stethoscope

Interprofessional Collaboration and Delegation

- Obtaining the beats per minute of a radial or peripheral pulse may be delegated to UAP after the initial assessment of the patient.
- Assessing pulse intensity and apical pulse usually are not delegated unless the UAP has received special training. Check with the facility's guidelines and procedures.
- UAP should report the following to the nurse:
 - Deviations from normal pulse range
 - Complaints related to chest pain or discomfort
 - Irregular pulse, including a weak or thready pulse
 - Pulse in adults less than 60 bpm or greater than 100 bpm
 - Difficulties in obtaining pulse
 - Any changes in pulse rate or rhythm
- UAP should be instructed in:
 - The appropriate technique and method required for obtaining a pulse

- Appropriate use of equipment (Doppler, stethoscope, electronic vital sign machines)
- Appropriate documentation

Special Circumstances

1. **Assess:** Has the patient participated in exercise or physical therapy within 10 minutes?
Intervention: Physical exercise increases the heart rate; have the patient rest 10 minutes before assessing pulse.
2. **Assess:** Is the patient upset or anxious because of stress or pain?
Intervention: Stress raises the heart rate; therapeutic communication may calm the patient before assessing pulse.
3. **Assess:** What is the patient's history for medications? Pacemakers? Cardiac disease? Cardiac clinical manifestations?
Intervention: Know the baseline pulse measurement; measure the pulse for 1 minute; notify the PCP of any change and document the findings.
4. **Assess:** What should you do if you are unable to find the point of maximal impulse (PMI) at the fifth intercostal space, along the midclavicular line, when measuring apical pulse?
Intervention: Turn the patient slightly to the left side. (Heart disease may obscure the PMI when the patient is in a supine or sitting position; using the left-side position moves the apex of the heart closer to the chest wall and may assist in locating the PMI. Ventricular hypertrophy may be present if the PMI is at the sixth intercostal space.)
5. **Assess:** Is the pulse irregular, with intensity differences? Has there been a new onset of clinical manifestations?
Intervention: Assessment should not be delegated if the pulse is irregular, with intensity differences. Perform apical and radial pulse measurements:
 - Measure both radial and apical pulses simultaneously to determine any further assessment needs. Auscultate the apical pulse at the PMI, and palpate the radial pulse. If a pulse deficit (apical pulse exceeds the radial pulse) is present, two nurses should assess the patient's pulse at the same time, with one nurse counting the radial pulse and one counting the apical.
 - Document the apical and radial (AR) pulse rates and rhythm and any pulse deficit.
6. **Assess:** Is the patient's pulse outside the normal range?
Intervention: If the pulse deviates from the normal range of 60 to 100 bpm for adults:
 - Retake the patient's pulse, using a different site.
 - Check the documentation for the previous site assessment.
 - Check the documentation for rhythm and intensity notations.
 - Assess the patient for clinical manifestations of an abnormal pulse (shortness of breath, dizziness, weakness, fatigue).
 - If the patient has a fever, give antipyretics, as ordered; fever raises the pulse rate.
 - Check the PCP orders and care plan for further interventions.

Preprocedure

I. Check PCP orders and the patient care plan.

Knowledge of patient-specific orders is critical for safe patient care.

II. Gather supplies and equipment.

Preparing for the patient encounter saves time and promotes patient trust.

III. Perform hand hygiene.

Frequent hand hygiene prevents the spread of microorganisms.

IV. Maintain standard precautions.

Use of the correct personal protective equipment (PPE) is required whenever contact with bodily fluids is possible, to reduce the transfer of pathogens.

V. Introduce yourself.

Initial communication establishes the role of the nurse and begins a professional relationship.

VI. Provide for patient privacy.

It is important to maintain patient dignity.

VII. Identify the patient, using two identifiers.

Identifying a patient involves scanning barcodes or comparing the patient's stated name and birthdate to information on the patient's wristband or health record. The correct person must receive the correct treatment.

VIII. Explain the procedure to the patient.

The nurse has a responsibility to inform a patient before initiating care. Information may ease patient anxiety and facilitate cooperation.

Procedure

Radial Pulse

Follow preprocedure steps I through VIII.

1. Patient may be sitting or supine. Support the patient's arm. Find pulse with your index and middle fingertips by gently placing fingertips over the area next to the distal end of the radius and applying just enough pressure to palpate pulse.

STEP 1

Fingertips are sensitive to pulsation; feeling with both fingers ensures not feeling other vibrations. The thumb cannot be used because it has its own pulse, which would interfere with an accurate reading. Too much pressure might occlude the pulse and make measurement difficult or inaccurate. Radial pulse is used to count heart rate and assess blood flow to the hand.

2. Instruct patient to remain still and not to talk.
Ensures an accurate reading.
3. Count beats for 30 seconds; if beat is irregular and/or rate or rhythm changes during that time, count for 1 minute.
Ensures precise reading if pulse is irregular.
4. Calculate rate: If pulse is regular, count beats for 30 seconds and multiply by 2 to calculate beats per minute (bpm); if pulse is irregular, count beats for 60 seconds and record findings as bpm. (Some facilities allow pulse to be counted for 15 seconds and multiplied by 4 in patients who have a regular rhythm.)
Pulse typically is recorded as beats per minute (bpm).
5. Note pulse rhythm (regular versus irregular) and intensity (volume or amplitude: *Absent = 0; Weak = 1; Normal = 2; Bounding = 3*).
Data for documentation.

Other Pulse Sites

Follow preprocedure steps I through VIII.

1. Note the guidelines for the different pulse areas described next.
Other sites usually are not used to assess the pulse rate. Most sites are used to assess intensity and rhythm only.
 - a. *Temporal*: Both sides of the head may be assessed simultaneously.

STEP 1A

Temporal sites may be compared for intensity.

- b. *Carotid*: The pulse must be assessed on one side of the neck at a time.

STEP 1B

Compares intensity of carotid pulses. This site often is used in children. Bilateral palpation of carotid pulses could block blood flow to the brain, causing the patient to experience syncope. The carotid is a main vessel often used in emergencies when the pulse is not obtainable from other sites.

c. *Brachial*: The arm is held straight out and supported.

STEP 1C

This arm position prevents muscle contraction. The site is used to assess blood flow to the lower arm and most often to measure blood pressures. It is easily palpated in infants and young children but can be difficult to palpate in adults because of their heavier muscle mass.

d. *Femoral*: Assessment involves deeper palpation in groin area.

STEP 1D

Large, deep main vessel in thigh. This site often is used in emergencies when pulse at other sites is not palpable. It is used to assess blood flow to the legs.

e. *Popliteal*: Knee flexed slightly; leg muscles relaxed.

STEP 1E

Used to assess blood flow to the lower leg.

f. *Dorsalis pedis (pedal)*: If this pulse is not palpable, use of a portable Doppler ultrasound machine may be required.

STEP 1F

The pulse often is difficult to find. This site is used to assess blood flow to the foot.

- g. *Posterior tibial:* Located posterior to the medial malleolus, may feel both extremities simultaneously.

STEP 1G

Compares intensity of the pulse between both extremities. This site is used to assess blood flow to foot.

2. Document pulse rhythm and strength.
Data for documentation.

Follow postprocedure steps I through VI.

Apical Pulse

Follow preprocedure steps I through VIII.

1. Locate PMI.
 - a. Place hand at angle of Louis (sternal notch near neck where second rib attaches).
Easy anatomic landmark for use in locating the correct site to find the PMI.
 - b. Starting with left second intercostal space, count down to the left fifth intercostal space.
The angle of Louis intersects at the second intercostal space; the PMI usually is felt at the left fifth intercostal space.
 - c. Follow the left fifth intercostal space laterally to midclavicular line; stop halfway between shoulder and angle of Louis.
The PMI usually is located near this point, called the left midclavicular line.
 - d. Palpate pulsations near this point with fingertips; this is the PMI.

STEP 1D (Copyright Mosby's Clinical Skills: Essentials Collection.)

The PMI is where the apex of the heart is located (usually within 1 to 2 inches of this area); the apex is closest to the skin, and it is easy to feel heart pulsations in this area.

- e. Turn patient slightly onto left side if difficulty is encountered palpating pulse.

This brings the heart closer to the chest wall, enabling palpation of the pulse.

2. Place a clean, warm stethoscope on PMI to count apical pulse for 1 minute.

STEP 2 (Copyright Mosby's Clinical Skills: Essentials Collection.)

Because the PMI is at the apex and closest to the skin, it is easiest to hear heart sounds in this area.

3. Listen to heartbeat; “lub-dub” is one beat.
Normally, one heartbeat has two sounds: S_1 and S_2 ; listening before counting ensures accuracy.
4. Instruct patient to remain still and not to talk.
Ensures an accurate reading.
5. Count beats for 30 seconds; if beat is irregular, rate or rhythm change during that time or the patient is on cardiovascular drugs, count for 1 full minute.
Ensures precise reading if pulse is irregular.
6. Calculate rate: If pulse is regular, count beats for 30 seconds and multiply by 2 to calculate beats per minute (bpm); if pulse is irregular, count beats for 60 seconds and record findings as bpm.
Pulse is typically recorded as beats per minute (bpm).
7. Note pulse rhythm (regular versus irregular) and intensity.
Data for documentation.

Follow postprocedure steps I through VI.

Postprocedure

I. Return the bed to its lowest position, raise the top side rails, and verify that the call light is within reach for the patient.
Precautions are taken to maintain patient safety. Top side rails aid in positioning and turning. Raising four side rails is considered a restraint.

II. Assess for additional patient needs and state the time of your expected return.
Meeting patient needs and offering self promote patient satisfaction and build trust.

III. Properly dispose of PPE.
Gloves, gowns, and masks must be appropriately discarded to prevent the spread of microorganisms.

IV. Clean or dispose of equipment if it was in contact with the patient; see specific manufacturer instructions.
Disinfection eliminates most microorganisms from inanimate objects.

V. Perform hand hygiene.
Frequent hand hygiene prevents the spread of infection.

VI. Document the date, time, assessment, procedure, and patient's response to the procedure.
Accurate documentation is essential to communicate patient care and to provide legal evidence of care.

SKILL 19.3 Assessing Respirations

Purpose

- Determine the rate, rhythm, quality, and depth of respiration.
- Monitor the patient's respirations and respiratory changes.
- Monitor for change in the patient's physical condition.
- Monitor the patient's response to medications.
- Monitor the patient's response to therapy.

Resources

- Clock or watch with a second hand or digital display.
- Vital sign flow sheet and pen or an electronic health record.

Interprofessional Collaboration and Delegation

- Assessing a respiratory rate may be delegated to UAP after the initial assessment of the patient.
- UAP should report any of the following findings to the nurse:
 - Difficulty breathing or any change in respiratory rate, rhythm, or depth (report immediately)
 - Patient's complaints related to breathing difficulty or chest discomfort
 - Irregular respiratory rhythm
 - Rates less than 12 or greater than 20 breaths per minute (BPM)
 - Any difficulties in obtaining respiratory rates
- UAP should be instructed in:
 - Appropriate technique
 - Appropriate documentation

Special Circumstances

1. **Assess:** Has the patient undergone exercise or physical therapy within the past 5 minutes?
Intervention: Physical exercise increases respiratory rate; have the patient rest 5 minutes before measuring respirations.
2. **Assess:** Is the patient experiencing pain?
Intervention: Pain changes breathing characteristics; administer pain

medication if prescribed, and reassess respirations after an appropriate time interval.

3. **Assess:** Is the patient upset, anxious, or emotional?

Intervention: Emotional stress increases respiratory rate; therapeutic communication or medication may calm the patient before assessing a respiratory rate.

4. **Assess:** Does the patient's respiratory rate deviate from the normal breathing pattern?

Intervention:

- Respirations vary with age; know the normal range parameters expected for the patient.
- Assess the environment for factors such as increased temperature and altitude. These conditions can increase respirations.
- Assess the patient's other vital signs, use of accessory muscles, SpO₂, and color.
- Reposition the patient, and reassess the respiratory rate.
- Check the chart for respiratory side effects from any administered medications, and monitor the patient.
- Reassess respiratory rate if needed.
- Check the PCP orders and care plan for further interventions.

5. **Assess:** Is the patient experiencing changes in respiratory rhythm?

Intervention: Assess the respiratory rhythm. Variations or change in respiratory rhythm (e.g., Cheyne-Stokes respirations, Kussmaul breathing) may indicate a change in the patient's condition.

Preprocedure

I. Check PCP orders and the patient care plan.

Knowledge of patient-specific orders is critical for safe patient care.

II. Gather supplies and equipment.

Preparing for the patient encounter saves time and promotes patient trust.

III. Perform hand hygiene.

Frequent hand hygiene prevents the spread of microorganisms.

IV. Maintain standard precautions.

Use of the correct personal protective equipment (PPE) is required whenever contact with bodily fluids is possible, to reduce the transfer of pathogens.

V. Introduce yourself.

Initial communication establishes the role of the nurse and begins a professional relationship.

VI. Provide for patient privacy.

It is important to maintain patient dignity.

VII. Identify the patient, using two identifiers.

Identifying a patient involves scanning barcodes or comparing the

patient's stated name and birthdate to information on the patient's wristband or health record. The correct person must receive the correct treatment.

VIII. Explain the procedure to the patient.

The nurse has a responsibility to inform a patient before initiating care. Information may ease patient anxiety and facilitate cooperation.

Procedure

Follow preprocedure steps I through VIII.

It is recommended that this procedure be performed while measuring the radial or apical pulse.

1. Keep hand or stethoscope placed as if taking pulse; see [Skill 19.2](#) (under "Radial Pulse" or "Apical Pulse").
Observation or auscultation of respiratory rate occurs after taking the pulse, by either radial or apical site.
2. a. *Radial pulse method:* Observe rise and fall of chest after assessing the radial pulse.

STEP 2A (Copyright Mosby's Clinical Skills: Essentials Collection.)

- b. *Apical pulse method:* Observe rise and fall of chest; feel rise and fall of chest by placing hand over chest wall, or auscultate respiratory rate with stethoscope on chest.

STEP 2B (Copyright Mosby's Clinical Skills: Essentials Collection.)

Patients may alter respiratory rate or depth when aware that they are being measured.

3. Count breaths for 1 full minute; rise and fall of chest = 1 breath. Or, if respirations are regular, count for 30 seconds and multiply by 2 to get BPM or respiratory rate.
Ensures accuracy.

4. Note rate, rhythm, and depth of respirations.
Data for documentation.

Follow postprocedure steps I through VI.

Postprocedure

- I. Return the bed to its lowest position, raise the top side rails, and verify that the call light is within reach for the patient.
Precautions are taken to maintain patient safety. Top side rails aid in positioning and turning. Raising four side rails is considered a restraint.
- II. Assess for additional patient needs and state the time of your expected return.
Meeting patient needs and offering self promote patient satisfaction and build trust.
- III. Properly dispose of PPE.
Gloves, gowns, and masks must be appropriately discarded to prevent the spread of microorganisms.
- IV. Clean or dispose of equipment if it was in contact with the patient; see specific manufacturer instructions.
Disinfection eliminates most microorganisms from inanimate objects.
- V. Perform hand hygiene.
Frequent hand hygiene prevents the spread of infection.
- VI. Document the date, time, assessment, procedure, and patient's response to the procedure.
Accurate documentation is essential to communicate patient care and to provide legal evidence of care.

SKILL 19.4 Assessing Pulse Oximetry

Purpose

- Determine the patient's baseline SpO₂ (percentage of hemoglobin that combines with oxygen).
- Monitor any underlying respiratory disease.
- Monitor the patient's recovery from anesthesia.
- Assess the patient for any change in physical condition.
- Assess complaints of respiratory difficulty.
- Monitor patient response to medications.
- Monitor patient response to oxygen therapy.

Resources

- Pulse oximeter with probe attachment
- Alcohol wipes
- Nail polish remover
- Vital sign flow sheet and pen or an electronic health record

Interprofessional Collaboration and Delegation

- Assessing SpO₂ may be delegated to UAP after initial assessment of the patient.
- UAP should report any of the following to the nurse:
 - Readings less than 92% or other designated saturation, as determined by the nurse or PCP
 - Complaints related to breathing difficulty or chest discomfort
 - Situations in which the patient is not using oxygen or it is not at the appropriate level according to the PCP orders
 - Any difficulties in procedure
- UAP should be instructed in:
 - Appropriate placement of oximeter probe (finger, toe, bridge of nose, or earlobe)
 - Appropriate equipment use (verifying accurate results)
 - Patient oxygen use and frequency of monitoring
 - Appropriate documentation

Special Circumstances

1. **Assess:** Has the patient undergone exercise or physical therapy within the past 5 minutes?
Intervention: Have the patient rest 5 minutes before measuring SpO₂; if the PCP order is for exercise oximetry, see the respiratory therapist for assistance.
2. **Assess:** Is the patient wearing fingernail polish or artificial nails?
Intervention: Remove polish or artificial nails before measuring SpO₂, or use an alternative location to take the measurement if permitted by equipment and facility policy.
3. **Assess:** Are there any sores, wounds, or irritations at the site?
Intervention: Use a different site, and document the location and reason for using it.
4. **Assess:** Does the patient have hand or arm tremors?
Intervention: Use the patient's other arm or a different site (toe, earlobe, bridge of nose).
5. **Assess:** Does the patient have carbon monoxide poisoning?
Intervention: Obtain an order for arterial blood gas instead, because the SpO₂ is falsely elevated.
6. **Assess:** Does the SpO₂ differ from the baseline measurement?
Intervention:
 - Assess the patient for clinical manifestations of hypoxemia resulting in hypoxia, such as cyanosis or pallor, dyspnea, restlessness, decreased level of consciousness, increased pulse and blood pressure, or use of accessory muscles for breathing.
 - Reposition the patient and reassess SpO₂.
 - Check the oxygen therapy equipment/flow rate, orders, and weaning status.
 - Check the PCP orders and care plan for further interventions.
7. **Assess:** Is there impaired circulation to the extremity on which the oximeter probe is applied?
Intervention: Impaired circulation might result in a false SpO₂; apply the probe to a different site.

Preprocedure

- I. Check PCP orders and the patient care plan.
Knowledge of patient-specific orders is critical for safe patient care.
- II. Gather supplies and equipment.
Preparing for the patient encounter saves time and promotes patient trust.
- III. Perform hand hygiene.
Frequent hand hygiene prevents the spread of microorganisms.
- IV. Maintain standard precautions.
Use of the correct personal protective equipment (PPE) is required

whenever contact with bodily fluids is possible, to reduce the transfer of pathogens.

V. Introduce yourself.

Initial communication establishes the role of the nurse and begins a professional relationship.

VI. Provide for patient privacy.

It is important to maintain patient dignity.

VII. Identify the patient, using two identifiers.

Identifying a patient involves scanning barcodes or comparing the patient's stated name and birthdate to information on the patient's wristband or health record. The correct person must receive the correct treatment.

VIII. Explain the procedure to the patient.

The nurse has a responsibility to inform a patient before initiating care. Information may ease patient anxiety and facilitate cooperation.

Procedure

Follow preprocedure steps I through VIII.

1. Obtain pulse oximeter and appropriate probe.
2. Place probe on appropriate site; instruct patient to breathe normally and not to move body part where oximeter is attached.
A finger is the most common site; the oximeter will give an inaccurate reading with movement.
3. Turn on oximeter.
Sends signal to oximeter that probe is in place and ready for reading.
4. Observe oximeter reading when pulse waveform is present and beats are constant; compare oximeter pulse reading with patient's radial pulse.

STEP 4 (Copyright Mosby's Clinical Skills: Essentials Collection.)

Ensures accuracy of the SpO₂ reading. Most oximeters display the pulse, which can then be compared with the pulse measurement taken by the nurse.

5. **Reading:** Depending on model of oximeter, device may emit an audible beep when a single reading is complete (when SpO₂ reaches a constant value) or, if continuous monitoring is necessary (e.g., with critical care), may beep with each heartbeat to indicate that device is detecting pulse.

Knowledge of how the equipment works ensures an accurate reading.

6. Note SpO₂ reading on display, and note whether patient is on supplemental oxygen.
Data for documentation.
7. Remove probe from patient (if not performing continuous monitoring).
8. Clean probe and wire with alcohol wipe.
Prevents the spread of microorganisms.

Follow postprocedure steps I through VI.

Postprocedure

- I. Return the bed to its lowest position, raise the top side rails, and verify that the call light is within reach for the patient.
Precautions are taken to maintain patient safety. Top side rails aid in positioning and turning. Raising four side rails is considered a restraint.
- II. Assess for additional patient needs and state the time of your expected return.
Meeting patient needs and offering self promote patient satisfaction and build trust.
- III. Properly dispose of PPE.
Gloves, gowns, and masks must be appropriately discarded to prevent the spread of microorganisms.
- IV. Clean or dispose of equipment if it was in contact with the patient; see specific manufacturer instructions.
Disinfection eliminates most microorganisms from inanimate objects.
- V. Perform hand hygiene.
Frequent hand hygiene prevents the spread of infection.
- VI. Document the date, time, assessment, procedure, and patient's response to the procedure.
Accurate documentation is essential to communicate patient care and to provide legal evidence of care.

SKILL 19.5 Measuring Blood Pressure: Manual and Electronic

Purpose

- Determine the baseline blood pressure.
- Monitor blood pressure.
- Assess the heart's pumping ability and the patency of blood vessels.
- Monitor for changes in physical condition.
- Monitor the patient's response to medications.
- Monitor the patient's response to therapy.

Resources

- Sphygmomanometer with bladder and cuff
- Stethoscope with a bell and diaphragm
- Electronic blood pressure or vital sign machine with bladder and cuff
- Vital sign flow sheet and pen or an electronic health record

Interprofessional Collaboration and Delegation

- Electronic measurement of blood pressure may be delegated to UAP after initial assessment of the patient.
- Manual measurement of blood pressure may be delegated if the UAP has received special training. Check the facility's guidelines and procedures.
- UAP should report any of the following findings to the nurse:
 - Deviations from normal range of blood pressure
 - Complaints related to chest pain or discomfort
 - Systolic blood pressure greater than 140 or less than 90 or diastolic blood pressure greater than 90 or less than 60
 - Difficulties in obtaining blood pressure
- UAP should be instructed in:
 - The appropriate technique and method required for the patient

- Appropriate equipment use (verifying accurate results with stethoscope, sphygmomanometer, electronic vital sign devices, appropriate cuff size, and site choice)
- Sites and conditions that are contraindicated: Intravenous lines, arteriovenous (AV) fistulas or shunts, amputations, breast surgery, and casts or bandages
- Appropriate documentation

Evidence-Based Practice

- Blood pressure increases with age leading to a higher incidence of hypertension in older persons (Stergiou, Ntineri, & Kollias, 2014).
- Systolic blood pressure, diastolic blood pressure, and heart rate are significantly increased in veterans with posttraumatic stress disorder (PTSD) compared with those without PTSD (Paulus, Argo, & Egge, 2013).
- Accuracy of the automated device may be limited if patients are hypertensive, hypotensive, or have cardiac dysrhythmias (American Association of Critical Care Nurses [AACN], 2016).

Special Circumstances

1. **Assess:** Has the patient undergone exercise or physical therapy within the past 15 minutes?
Intervention: Physical exercise raises blood pressure; have the patient rest 15 minutes before assessing blood pressure.
2. **Assess:** Is the patient upset, anxious, or emotional?
Intervention: Emotional stress raises blood pressure; therapeutic communication may calm the patient before assessing blood pressure.
3. **Assess:** What is the patient's medication, pacemaker, and cardiac history?
Intervention: Compare current findings to the baseline; review the chart and history; determine possible effects of medications on blood pressure; notify the PCP of any change; and document all findings.
4. **Assess:** Is the patient complaining of cardiac clinical manifestations?
Intervention: Compare the current findings to the baseline; compare other assessments with the baseline; review the patient's chart and history; obtain assistance if needed; notify the PCP of any changes; and document all findings and actions.
5. **Assess:** What is the patient's arm size?
Intervention: Obtain the correct cuff size for the patient. A cuff size that is too small could result in a false-high reading, and a cuff size that is too large could result in a false-low reading.

6. **Assess:** Has the patient had any caffeine or tobacco intake within the past 30 minutes?

Intervention: Caffeine intake or smoking can raise blood pressure. If possible, wait 30 minutes from intake; if waiting is not possible, document the intake.

7. **Assess:** Does the patient have special circumstances that prevent taking blood pressure in one or both arms?

Intervention: If the patient has an intravenous line or has had a mastectomy, use the opposite arm. If both arms are affected, blood pressure can be taken on the lower extremity.

8. **Assess:** Does the blood pressure deviate from the normal range?

Intervention:

- Check the documentation for previous site assessment and method.
- Check the documentation for trends and the most recent medications.
- Assess the following factors, because they may influence blood pressure: pain, time of day, patient position, emotional stress, environmental temperature, patient's temperature, and laboratory values.
- Assess the patient for clinical manifestations of hypertension and hypotension.
- Reassess blood pressure using a different site or method.
- Check the PCP orders and care plan for further interventions.

Preprocedure

I. Check PCP orders and the patient care plan.

Knowledge of patient-specific orders is critical for safe patient care.

II. Gather supplies and equipment.

Preparing for the patient encounter saves time and promotes patient trust.

III. Perform hand hygiene.

Frequent hand hygiene prevents the spread of microorganisms.

IV. Maintain standard precautions.

Use of the correct personal protective equipment (PPE) is required whenever contact with bodily fluids is possible, to reduce the transfer of pathogens.

V. Introduce yourself.

Initial communication establishes the role of the nurse and begins a professional relationship.

VI. Provide for patient privacy.

It is important to maintain patient dignity.

VII. Identify the patient, using two identifiers.

Identifying a patient involves scanning barcodes or comparing the patient's stated name and birthdate to information on the patient's

wristband or health record. The correct person must receive the correct treatment.

VIII. Explain the procedure to the patient.

The nurse has a responsibility to inform a patient before initiating care. Information may ease patient anxiety and facilitate cooperation.

Procedure

Two-Step Manual Method: Upper Extremity

Follow preprocedure steps I through VIII.

1. Obtain blood pressure cuff (correct size for patient) and stethoscope.

STEP 1(1) (Copyright Mosby's Clinical Skills: Essentials Collection.)

STEP 1(2) (Copyright Mosby's Clinical Skills: Essentials Collection.)

Ensures accuracy: Cuff too small = false high; cuff too large = false low. The bladder of the blood pressure cuff should be approximately 60% to 80% of the circumference of the extremity being used, and the width of the cuff should be approximately 40% of the circumference of the extremity. Most cuffs have markings indicating the range of arm circumference appropriate for that particular cuff.

2. Remove clothing and bedding from upper arm. Patient is in sitting or supine position with arm at level of heart, supported by mattress or table; feet on floor or supported by mattress; legs uncrossed.

Placing the cuff directly on the arm ensures accuracy; supporting the arm keeps the patient from flexing muscles; and having the arm at the level of the heart and feet uncrossed ensures accuracy.

3. Palpate brachial and radial pulses (see [Skill 19.2: Assessing Pulses](#)).

Provides a baseline; checks for adequate circulation in the arm; and locates placement for the stethoscope.

4. Position appropriately sized cuff 1 inch above antecubital fossa, with the arrow on the cuff pointing to brachial artery. Position of manometer gauge is vertical

and at eye level.

STEP 4 (Copyright Mosby's Clinical Skills: Essentials Collection.)

Positioning the cuff with the bladder centered on the brachial artery ensures accuracy.

5. Palpate brachial pulse; instruct patient to remain still and not to talk; close valve on pump by turning implement clockwise.

Prepares for reading and ensures accuracy.

6. Inflate cuff to 30 mm Hg above point at which brachial pulse disappears; note that point.

Starting point for determining how much to inflate the cuff. Overinflation may be painful for the patient and damage small blood vessels.

7. Deflate cuff slowly; note point at which pulse reappears; then fully deflate cuff quickly.

STEP 7 (Copyright Mosby's Clinical Skills: Essentials Collection.)

Approximates systolic blood pressure.

8. Wait 2 minutes before taking additional measurement.

Allows blood pressure to return to baseline as the blood refills the veins; ensures accuracy.

9. Place clean stethoscope diaphragm over brachial pulse, and insert ear attachments, positioning them slightly forward.

STEP 9 (Copyright Mosby's Clinical Skills: Essentials Collection.)

Sound is heard more clearly when earpieces are positioned to follow the direction of the ear canal.

10. Inflate cuff to the point noted in step 6, 30 mm Hg above the point where the brachial pulse disappeared.

Ensures cuff is inflated above the level of the systolic blood pressure.

11. Deflate cuff slowly (2 mm Hg/second). Note reading at first sound (when heartbeat first becomes audible); note reading at last sound (when individual heartbeats are no longer audible).
Deflating quickly results in inaccurate measurement. First sound = systolic blood pressure; last sound = diastolic blood pressure.
12. Deflate cuff quickly and completely; remove equipment from patient and note the results.
Keeps the equipment calibrated to ensure accuracy, keeps the patient comfortable, and prevents wounds and skin irritation. Data needed for documentation.
13. Clean equipment as needed.
Prevents the spread of microorganisms.

Follow postprocedure steps I through VI.

Two-Step Manual Method: Lower Extremity

Follow preprocedure steps I through VIII.

1. Obtain blood pressure cuff (correct size for patient) and stethoscope.
Ensures accuracy: cuff too small = false high; cuff too large = false low. The bladder of the blood pressure cuff should be approximately 60% to 80% of the circumference of the extremity being used, and the width of the cuff should be approximately 40% of the circumference of the extremity.
2. Remove clothing and bedding from lower extremity. Patient is in supine, side-lying, or prone position with legs uncrossed.
Placing the cuff directly on the leg ensures accuracy; supporting the leg with the mattress keeps the patient from flexing muscles.
3. With patient in the supine, side-lying, or prone position, check popliteal and pedal pulses (see [Skill 19.2](#)).
Provides a baseline; checks for adequate circulation in the leg; locates placement for the stethoscope.
4. Position appropriately sized cuff 1 inch above knee, with the arrow on cuff pointing to the popliteal artery; make sure gauge is in direct line of vision.
Positioning the cuff with the bladder centered on the popliteal artery ensures accuracy.
5. Palpate popliteal pulse; instruct patient to remain still and not to talk; close valve on pump by turning implement clockwise. Make sure that gauge is in direct line of vision.
Prepares for reading and ensures accuracy.
6. Inflate cuff to 30 mm Hg above point at which popliteal pulse disappears; note that point.
Starting point for determining how much to inflate the cuff. Overinflation may be painful for the patient and damage small blood vessels.
7. Deflate cuff slowly; note point at which pulse reappears; then fully deflate cuff quickly.
Approximates systolic blood pressure.
8. Wait 2 minutes before taking additional measurement.
Allows blood pressure to return to baseline as the blood refills the veins; ensures accuracy.
9. Place stethoscope diaphragm over popliteal artery.

STEP 9

Stethoscope diaphragm is meant for lower sound frequency.

10. Inflate cuff to the point noted in step 6.
Ensures that the cuff is inflated above the level of the systolic blood pressure.
11. Deflate cuff slowly (2 mm Hg/second): Note reading at first sound (when heartbeat first becomes audible); note reading at last sound (when individual heartbeats are no longer audible).
Deflating quickly results in inaccurate measurement. First sound = systolic blood pressure; last sound = diastolic blood pressure. Data needed for documentation.
12. Deflate cuff quickly and completely; remove equipment from patient.
Keeps the equipment calibrated to ensure accuracy; keeps the patient comfortable; and prevents wounds and skin irritation.
13. Clean equipment as needed.
Prevents the spread of microorganisms.

Follow postprocedure steps I through VI.

Electronic (Automated) Method

Follow preprocedure steps I through VIII.

1. Obtain electronic blood pressure machine with appropriate cuff size for patient.

STEP 1 (Courtesy Welch Allyn.)

Ensures accuracy: Cuff too small = false high; cuff too large = false low. The bladder of the blood pressure cuff should be approximately 60% to 80% of the circumference of the upper arm.

2. Remove clothing and bedding from upper arm. Patient is in a sitting or supine position with arm at level of heart, supported by mattress or table; feet on floor or supported by mattress; legs uncrossed.

Placing the cuff directly on the arm ensures accuracy; supporting the arm keeps the patient from flexing muscles; and having the arm at the level of the heart and feet uncrossed ensures accuracy.

3. Palpate brachial and radial pulses (see [Skill 19.2, Assessing Pulses](#)).
Provides a baseline; checks for adequate circulation in the arm; and locates placement for the stethoscope.
4. Position cuff snugly.
Ensures accuracy.
5. Instruct patient to remain still and not to talk.
Prepares for reading and ensures accuracy.
6. Push on/off button: Machine will beep and digital display will appear.
Indicates machine is charged and ready for use.
7. Push Start button: Cuff will inflate and deflate; display will appear.
Machine detects pulses in conjunction with cuff pressure.
8. Note readings or obtain readings from the memory of the unit.

STEP 8 (Courtesy Welch Allyn.)

Data needed for documentation; most machines have a built-in memory.

9. Remove equipment from patient.

Keeps patient comfortable; prevents wounds and skin irritation.

10. Clean equipment as needed; plug unit into electrical outlet.

Prevents the spread of microorganisms. Most units require recharging after use.

Follow postprocedure steps I through VI.

Postprocedure

I. Return the bed to its lowest position, raise the top side rails, and verify that the call light is within reach for the patient.
Precautions are taken to maintain patient safety. Top side rails aid in positioning and turning. Raising four side rails is considered a restraint.

II. Assess for additional patient needs and state the time of your expected return.

Meeting patient needs and offering self promote patient satisfaction and build trust.

III. Properly dispose of PPE.

Gloves, gowns, and masks must be appropriately discarded to prevent the spread of microorganisms.

IV. Clean or dispose of equipment if it was in contact with the patient; see specific manufacturer instructions.

Disinfection eliminates most microorganisms from inanimate objects.

V. Perform hand hygiene.

Frequent hand hygiene prevents the spread of infection.

VI. Document the date, time, assessment, procedure, and patient's response to the procedure.

Accurate documentation is essential to communicate patient care and to provide legal evidence of care.

Summary of Learning Outcomes

LO 19.1 *Explain the purpose of assessing vital signs:* Vital signs include temperature, pulse, respirations with oxygen saturation, and blood pressure. The measurement of vital signs gives critical information about a patient's psychological and physiologic status. Nursing judgment determines how frequently vital signs are assessed.

LO 19.2 *Describe techniques for obtaining accurate temperature measurement:* Body temperature can be measured orally, tympanically, rectally, and temporally, as well as by axillary methods and internally through an arterial probe. The most appropriate route depends on patient status and age.

LO 19.3 *Identify common assessment sites and techniques for assessing pulse:* The radial pulse is the most common site to measure pulse rate. Eight other sites can be used to assess the character and intensity of the pulse. The apical pulse is measured in specific cases such as when the rate is irregular, the patient is taking certain medications, or the radial pulse is not palpable.

LO 19.4 *Discuss assessment of respirations and blood oxygenation:* Normal respirations are quiet, effortless, and automatic. Assessment of respirations includes observing the patient's breathing and assessing the effectiveness of ventilation, perfusion, and diffusion. Pulse oximetry measures the percentage of hemoglobin saturated with oxygen that is available for use by body tissues.

LO 19.5 *Summarize correct methods for measuring blood pressure:* Blood pressure reflects cardiac output, peripheral vascular resistance, and blood volume and viscosity. It measures the highest pressure (systolic) and lowest resting pressure (diastolic) of the blood in the vessels. A blood pressure cuff that is too small or too large or is applied improperly will cause errors in the reading.

Review Questions

1. The nurse is measuring blood pressures as part of a community health fair. Which blood pressure reading would cause the nurse to refer the patient for follow-up regarding hypertension?
 - a. 108/70
 - b. 116/78
 - c. 128/80
 - d. 138/88
2. The nurse is admitting a stable patient for a minor outpatient procedure. What site would the nurse most commonly use to assess pulse rate?
 - a. Radial site
 - b. Apical site
 - c. Brachial site
 - d. Carotid site
3. The unlicensed assistive personnel reports vital signs for a patient to the nurse: temperature of 99.2° F (37.3° C) oral, pulse of 88 bpm and regular, respirations of 18 BPM and regular, blood pressure of 178/112 mm Hg, and oxygen saturation of 96%. Which vital sign should the nurse be most concerned about?
 - a. Temperature
 - b. Pulse
 - c. Respirations
 - d. Blood pressure
4. From the nurse's understanding, which statements regarding temperature and heat production in the body are accurate? (*Select all that apply.*)
 - a. Heat generates energy for cellular functions.
 - b. Hormones, such as thyroid hormones, decrease metabolism and heat production.
 - c. Exercise decreases heat production through muscular activity.
 - d. Expected temperature readings vary by the route selected for measurement.

- e. Women tend to have more fluctuations in temperature than do men.
5. The nurse is performing an initial assessment of a patient with a severe infection at hospital admission. Vital signs for the patient indicate hypotension and tachycardia. Which data would support this evaluation?
 - a. Pulse 78, blood pressure 140/88
 - b. Pulse 86, blood pressure 120/76
 - c. Pulse 100, blood pressure 118/68
 - d. Pulse 114, blood pressure 88/56
 6. The nurse places a patient with a high fever on a cooling blanket. How is heat loss achieved with this treatment?
 - a. Radiation
 - b. Convection
 - c. Conduction
 - d. Evaporation
 7. Which clinical patient scenario is associated with the most critical need for the nurse to obtain vital signs?
 - a. Ambulating for the first time after surgery
 - b. Complaining of pressure in the chest
 - c. Completing ambulating 100 feet after a stroke
 - d. Complaining of hunger while NPO (nothing by mouth)
 8. The nurse understands that which statement is correct regarding respiratory rates?
 - a. Infants have a lower respiratory rate than adults.
 - b. Healthy adults breathe between 12 and 20 times a minute.
 - c. A compensatory response to a fever is to breathe at a slower rate.
 - d. An increase in intracranial pressure results in an increased rate.
 9. The nurse is caring for a patient who has a blood pressure of 184/110. An hour after administering an antihypertensive medication, the nurse returns to recheck the blood pressure, only to find the patient in the chair pale, sweaty, and feeling

faint. Which is the expected explanation for the nurse's observations?

- a. The blood pressure is 184/110; the medication has not had an effect.
 - b. The blood pressure is 118/76; the sudden drop has caused the signs.
 - c. The blood pressure is 174/96; the medication has made the patient sick.
 - d. The blood pressure is 130/82; the symptoms are from another cause.
10. It is 6 a.m. and the unlicensed assistive personnel reports to the nurse that the patient has a temperature of 96.7° F (35.9° C) tympanic. Which factor explains this reading?
- a. The patient's room is cold.
 - b. The patient was drinking cold water.
 - c. The patient is exhibiting a normal circadian rhythm.
 - d. The patient just completed a warm shower.

CHAPTER 20

Health History and Physical Assessment

LEARNING OUTCOMES

Comprehension of this chapter's content will provide students with the ability to:

- LO 20.1 Apply strategies used to conduct a patient interview, health history, and review of systems.
- LO 20.2 Discuss the environmental and patient care activities that should be completed before and during history taking and physical examination.
- LO 20.3 Use the four physical assessment techniques when examining each body system.
- LO 20.4 Discuss factors for consideration during the general survey.
- LO 20.5 Demonstrate a focused and head-to-toe physical assessment, noting opportunities for patient education.
- LO 20.6 Describe the activities and specific documentation that are required at the completion of the physical assessment.

Case Study

Rose Thatcher (R. T.), an 85-year-old recent widow, comes to the health clinic for her annual physical examination. She reports feeling more tired than usual and has noticed that her feet are swelling. R. T. states that sometimes she feels short of breath after climbing the steps to her bedroom on the second floor. Her intake vital signs are T 36.78° C (98.2° F), P 100 and slightly irregular, R 24 and shallow, and BP 116/68. The nurse is acquainted with R. T. and notices that she is walking more slowly than usual to the examination room.

Refer back to this case study to answer the critical-thinking questions throughout the chapter.

Physical assessment is an integral part of the first step in the nursing process, which begins with comprehensive data collection followed by systematic physical examination. Collecting a patient's health history is achieved through two methods: conducting a patient interview to gather subjective data or symptoms and reviewing past medical records for significant medical and surgical history, which are objective data. (Refer to [Chapter 6](#) for additional information on subjective and objective data.) The physical assessment that follows is a head-to-toe examination of each body system during which the nurse gathers more objective data, or signs. The patient's health status and the extent of physical impairment, as well as the location and timing of the patient's interaction with the nurse, influence the accuracy and intensity of physical assessment. It is the nurse's responsibility to gather either comprehensive or focused

assessment data during each patient encounter. Assessment findings are used to formulate individualized plans of care.

LO 20.1 Patient Interview

Obtaining a health history begins with a patient interview. The patient's first impression of the health care system during the interview often sets the tone for subsequent interactions with members of the health care team (Box 20.1). The interview has three phases: orientation (or introduction), working, and termination. During the interview process patients express their emotional and physical concerns. Some of the factors that affect the patient interview include privacy, interruptions, the environment, and communication techniques. A sense of privacy may be achieved by using a private room or curtain partitions and by minimizing interruptions during the interview. The environment should be comfortable and conducive to a professional interaction. A comfortable room temperature, sufficient lighting, reduction of extraneous sound, and removal of distracting objects contribute to patient comfort. The patient and the nurse conducting the interview should be comfortably seated at eye level, without barriers.

Box 20.1

Evidence-Based Practice and Informatics

Nursing Behaviors During the Interview

Research has identified several nursing behaviors that contribute to patient satisfaction and safety and should be implemented during the interview process:

- Summarizing and repeating information
- Explaining medical terminology
- Providing a room with adequate privacy
- Involving family and friends as requested by the patient

From Uphoff, E., Wennekes, L., Punt, C. J., et al. (2012).
Development of generic quality indicators for patient-centered

cancer care by using a RAND Modified Delphi Method. *Cancer Nursing*, 35(1), 29-37.

Nurses need to be attentive throughout the interview process. Maintaining a relaxed and open posture, leaning slightly toward the patient, and showing interest with occasional gestures all communicate concern. Negative nonverbal cues such as distracting gestures (e.g., tapping a pen, swinging a foot, looking at a watch), inappropriate facial expressions, or lack of eye contact communicate disinterest.

1. What action is required by the nurse before initiating R. T.'s patient interview?

Different forms of communication can be used to obtain patient information. Open-ended questions encourage narrative responses from patients. Closed-ended, focused, or direct questions elicit specific information such as a patient's address or birth date. It is appropriate to use direct questions to gather information about a patient's past health history or during the review of body systems when a "yes" or "no" answer is adequate. Direct questions can be expanded on with open-ended questions if more extensive information is needed. Refer to [Chapter 3](#) for an in-depth discussion on therapeutic communication techniques that are helpful during the patient interview.

2. Identify four activities by the nurse that might communicate disinterest or the need to hurry through R. T.'s examination.

Health History

A patient's health history is collected through the interview process. The health history consists primarily of subjective data obtained from verbal interaction with the patient or family and objective data gathered through observation and review of medical records. A significant amount of demographic data can be obtained from the electronic health record (EHR) before meeting the patient. The health history is organized to make essential patient data available for reference by all members of the health care team. During the last phase of the health history, the nurse conducts a review of systems before initiating a thorough physical assessment. There are several ways to organize health history and physical assessment data: by body systems, from head to toe, or by Gordon's Functional Health Patterns (Gordon, 2016). Refer to Chapter 6 for more information on data organization during assessment. Using a structured order for collecting data during the interview process facilitates completion of a thorough patient health history. Box 20.2 provides a framework for collecting health history data.

Box 20.2

Framework for Collecting Health History Data

- *Demographic data:* Name, address, telephone numbers, stated age, birth date, birthplace, gender identity, sexual orientation, marital status, race, cultural background or ethnic origin, spiritual or religious preference, educational level, occupation
- *Chief complaint or present illness:* Reason for seeking care, onset of symptoms

- *Allergies and sensitivities*: Medication, food (e.g., peanuts, eggs), environmental agents (e.g., latex, tape, detergents), reaction to reported allergens (e.g., rash, breathing difficulty, nausea and vomiting)
- *Medications, vitamins, and herbal supplements*: Prescriptions; over-the-counter medications and herbal remedies; dosage, frequency, and reason for use, including as-needed (PRN) medications
- *Immunizations*: Childhood and adult immunizations, date of last tuberculin skin test, date of last vaccines (e.g., flu, pneumonia, shingles)
- *Medical history*: Childhood illnesses, accidents, and injuries; serious or chronic illnesses; hospitalizations, including obstetric history for female patients; dates of occurrence; present treatments
- *Surgical history*: Type of surgery, date, any complications
- *Family history*: Age and health status of parents, grandparents, siblings, and children; age and cause of death of immediate family members; genetic diseases or traits, familial diseases (e.g., cardiovascular disease, high blood pressure, stroke, blood disorders, cancer, diabetes, kidney disease, seizure disorders, drug or alcohol dependencies, mental illness)
- *Social history*: Caffeine intake; use of tobacco, alcohol, or recreational drugs; environmental exposures; animal exposures and pets; living arrangement; safety concerns (e.g., intimate partner violence, emotional or physical abuse, recent domestic or foreign travel)
- *Cultural and spiritual or religious traditions*: Primary language, dietary restrictions, values, and beliefs related to health care
- *Activities of daily living (ADLs)*: Nutrition (e.g., meal preparation, shopping, typical 24-hour dietary intake), any recent changes in appetite, self-care activities (e.g., bathing, dressing, grooming, ambulation), use of prosthetics or mobility devices, leisure and exercise activities, sleep patterns (e.g., hours per night, naps, sleep aids)
- *Cognitive and emotional status*: Cognitive functioning (long-term and short-term memory), personal strengths, self-

esteem, support system (e.g., family, friends, support groups, professional counseling)

Review of Systems

Completion of a patient's health history through the interview process continues with a review of systems. The review of systems begins by having patients describe their general health status. The nurse then asks about current conditions or concerns related to each body system. Questions that can be asked to obtain a patient's general health information at the beginning of the review of systems are listed in [Box 20.3](#). Questions for each body system can be found in a box at the beginning of each physical examination section in this chapter.

Box 20.3

Health Assessment Questions

General Health Information

- How are you feeling?
- What concerns do you have about your health?
- Are you in pain? If so, where is the pain located? On a scale of 0 to 10 with 10 being the most severe pain, how do you rate your pain? Describe the pain. How long have you had the pain? Does it radiate anywhere? What relieves the pain or makes it worse?
- Describe your energy level. Are you able to participate in your daily activities without being fatigued?
- Describe any significant life stresses you are experiencing.

LO 20.2 Preparation for Physical Assessment

Before initiating a **physical assessment** (physical examination, or physical exam), the nurse needs to organize the environment and gather necessary equipment to enhance patient comfort, cooperation, and attention throughout the examination. Too many interruptions or disorganization during the physical examination can lead to the collection of erroneous information, resulting in incomplete or insufficient data and unnecessary frustration for the patient.

Physical Environment

Physical examination requires privacy, whether the examination is conducted in the patient's home setting, a hospital room, or a clinic. In the home a physical examination is often performed in the patient's bedroom or living area; in clinics or hospitals a ward or private room may serve as the assessment environment. Any room or setting needs to have adequate lighting for clear assessment of patient anatomy and physiologic features. The room should have a space where the patient can safely stand, sit, and lie down. Controlling room temperature, eliminating drafts, and providing warm blankets or towels help to ensure patient warmth and comfort.

Examination tables should be cleaned between patients with a bactericidal cleanser, and examination table paper or barrier surface material should be replaced. Examination tables often are firm and unsupportive to back muscles and spinal curvature when the patient lies supine, and thus the head of the table should be raised to a 30-degree angle and a small pillow offered for placement beneath the patient's head. If the patient is being examined in bed, the bed should be raised to allow the nurse easier access to the patient during the examination.

Equipment

The equipment used during the physical examination should be readily available and arranged in the order in which it will be used by the nurse. Medical asepsis is used in preparation of the equipment, and all devices are checked for proper function before the start of the examination. Hand hygiene is performed by the nurse before setup and as needed during the examination. Soiled equipment is discarded in the appropriate receptacle (if one-time-use or disposable devices) or placed in a designated container for recycling or decontamination per facility policy. See [Box 20.4](#) for equipment used during the physical examination.

Box 20.4

Equipment Used for Physical Examination

- Patient gown
- Scale
- Height assessment tool
- Sphygmomanometer with cuff
- Stethoscope with bell and diaphragm
- Thermometer
- Wristwatch
- Pulse oximeter
- Disposable pads and/or examination table paper
- Bath blanket or sheet
- Gloves
- Cotton applicators and/or cotton balls
- Eye chart
- Flashlight or penlight
- Otoscope and ophthalmoscope
- Tuning fork
- Tongue depressor
- Reflex hammer
- Tape measure or ruler
- Specimen containers, as needed

Patient Preparation

The patient's physical and emotional comfort and safety are top priorities for ensuring optimal cooperation and accuracy during the examination. The patient's identity should be verified. Patients should be given the opportunity to empty their bladder and bowels before the start of the examination. This facilitates a more thorough and comfortable abdominal examination for patients. If needed, proper collection of urine or fecal material is explained at this time, as well as disposal of any contaminated specimens. All specimen containers should be handled with gloves, wiped clean of debris, and properly labeled after collection and before sending the specimen to the laboratory.

Preparation of the patient for physical examination requires that the patient be properly dressed and covered to ensure privacy. Hospitalized patients can be dressed in gowns and covered with a sheet or bath blanket. In an outpatient setting, such as a clinic or health care provider's office, the patient will need to undress and wear a paper or light-cloth gown. If the examination involves only specific body systems, the patient may not have to undress entirely but may be asked to expose certain areas. Ensuring privacy and an ample amount of time for undressing is necessary to reduce the embarrassment that can occur from walking into a room while the patient is in the process of disrobing. After donning appropriate attire, the patient may sit or lie on the examination surface with a cover or blanket draped discreetly over the lower torso or lap. Nurses should indicate their presence by a knock on the door or announcement before entering the room.

In addition to providing for physical needs, nurses must be sensitive to the emotional needs of patients. This may include the need for others to be present during a physical examination. It is entirely appropriate for a patient to request the presence of a third person (or chaperone) during a physical assessment. Former abuse or cultural norms, as well as the level of comfort felt by patients, are all factors that influence the desire for a support person to be present. Evaluation of the mental stability of patients, their potential for falling, and the use of protective equipment such as side rails can help ensure the safety of patients throughout the physical examination process.

Privacy and Confidentiality

Patients' emotional and physical responses often depend on their level of comfort or anxiety about the physical assessment. Ideally, an examination room is soundproof or separated from other patients and staff in the vicinity. The patient should be reassured that confidentiality will be maintained throughout the examination and that data collected during the interview will be released only to providers or caregivers directly involved with the patient's care.

QSEN Focus!

Nurses must protect the confidentiality of protected information in EHRs.

Patients may ask to review their charts. When this happens, a written request from the patient may be required by the health care institution before a personal chart review. Patients are better able to understand their health records if a nurse or a primary care provider knowledgeable in health care documentation is present during the review to decipher medical terminology used to document health visits or conditions. The patient's written permission, with a witness's signature, is required for the release of the patient's health records to a third party, such as an insurance company or employer, unless the release is associated with a worker compensation claim. See [Box 20.5](#) for specific guidelines on sharing patient medical information.

Box 20.5

Ethical, Legal, and Professional Practice

Sharing Medical Information

Nurses who are conducting patient physical examinations need to be aware of the following guidelines for sharing medical information:

- Patients or their personal representative are permitted to review their personal medical records.
- Documentation must always be factual and nonjudgmental.
- Patients' review of their records should take place in the presence of the RN or primary care provider to ensure accurate interpretation of the documentation.
- Family members may review the patient's medical records only with the written consent of the patient.
- Primary care providers are permitted to share patient medical information with specialists to whom the patient is referred without additional consent.
- Health care facilities require that patients sign a release form when requesting copies of their medical records or diagnostic test records.
- Nurses must respect the right of patients to know with whom their medical information can be legally shared.

<http://www.hhs.gov/ocr/privacy/hipaa/understanding/consumers/index.html>.

3. List three or more physical considerations that the nurse should address before having R. T. enter the examination room.

Positioning the Patient

The ability to assume the positions required for physical assessment depends on the patient's level of mobility, physical strength, and **comorbid** conditions (i.e., two or more medical conditions existing simultaneously). Age and level of cognitive

ability can be an issue when the patient is expected to follow directions for position changes. For example, a child often requires an adult's assistance when changing clothes. An older patient with arthritis or limited joint mobility also may need help and extra time for clothing and position changes. Small children, infants, and older patients should never be left unattended in an examination room or on an examination table. Likewise, confused, uncooperative, combative patients or those who are physically or chemically restrained should never be left unsupervised during examination because of the potential for falls or injury from medical equipment.

To limit the patient's time and energy spent in changing positions, a sequential organization of steps for the examination is helpful. All techniques requiring a sitting position are done at the same time, followed by techniques requiring a supine position, until the physical examination is complete. At times, it may be necessary to have the patient return to a position that was previously examined to verify a result. In such instances, explain to the patient the reason for verifying that portion of the examination and assist the patient to the position needed. [Table 20.1](#) illustrates specific positions used during physical examination. Attention to draping provides for exposing only the area being examined.

TABLE 20.1**Physical Examination Positions**

Position	Uses and Potential Concerns
<p data-bbox="268 405 488 443">Supine position</p> 	<p data-bbox="906 405 1374 546">To examine the head and neck, anterior thorax and lungs, breasts, axillae, heart, abdomen, extremities, and pulses</p> <p data-bbox="906 551 1342 622">Relaxed position; easy access to critical anatomy</p> <p data-bbox="906 627 1362 763">Patient may become short of breath; this position is difficult for a patient who has back pain or kyphosis of the spine</p>
<p data-bbox="268 770 639 808">Dorsal recumbent position</p> 	<p data-bbox="906 770 1374 911">To examine the head and neck, anterior thorax and lungs, breasts, axillae, heart, and abdomen</p> <p data-bbox="906 916 1374 1019">Promotes relaxation of abdominal muscles and removes pressure from the lower spine</p> <p data-bbox="906 1023 1353 1128">Patients with weak lower extremities and knees will find this position challenging</p>
<p data-bbox="268 1135 488 1173">Fowler position</p> 	<p data-bbox="906 1135 1374 1254">To examine the head and neck, anterior thorax and lungs, breasts, axillae, heart, abdomen, lower extremities, and pulses</p> <p data-bbox="906 1258 1362 1384">Comfortable position for patients who are short of breath; most relaxing position</p> <p data-bbox="906 1388 1337 1471">Difficult to assess the abdomen owing to shortened space</p>

<p data-bbox="268 853 544 887">Knee-chest position</p> 	<p data-bbox="903 853 1386 920">Provides maximal exposure of rectal area</p> <p data-bbox="903 927 1386 1066">Uncomfortable; many patients will not be able to assume this position owing to physical limitations</p>

Integration of Assessment Skills With Nursing Activities

Typically, when a patient is admitted to the hospital or enters the health care system for the first time, a complete physical examination is performed. Nurses assess patients already hospitalized at least once per shift. A complete physical examination requires systematic assessment of each body system. However, the patient's **chief complaint** (presenting problem) or **clinical manifestations** (signs and symptoms) or the timing of the examination may require a **focused assessment**, in which only specific, relevant areas are examined. A patient with an acute problem, such as a cut or wound, who is otherwise healthy may not require a full physical examination; assessment of only the affected area may be appropriate.

A patient undergoing an annual physical examination for preventive care is evaluated based on the patient's age or health

risk. General health promotion information, such as nutritional recommendations, optimal weight maintenance, and abstinence from at-risk behaviors, such as smoking and excessive alcohol use, should be shared during all patient visits, even when a complete physical examination is not indicated. Nurses who routinely conduct annual physical examinations should be knowledgeable about current seasonal and scheduled immunizations and preventive health screening information based on government research guidelines that help define standards of care.

Nursing skills for physical assessment require a well-organized and systematic approach so that important details are not overlooked. A head-to-toe technique is systematic and includes all body systems, allowing the nurse and the patient to anticipate the next system to be examined. A systematic examination method allows continuity between providers that, in turn, helps to ensure consistency in examination outcomes.

LO 20.3 Assessment Techniques

The four assessment techniques used to complete a comprehensive physical examination are inspection, palpation, percussion, and auscultation. Hand hygiene is a standard precaution before, during, and after performing a physical examination. Clean gloves should be readily available for use by the nurse at various stages of the assessment. Appropriate personal protective equipment (PPE) should be worn as needed. See [Chapter 26](#) for detailed instructions on donning gowns, masks, and sterile gloves.

Inspection

Inspection involves the use of vision and smell to closely scrutinize physical characteristics of a whole person and individual body systems. Distinguishing between normal and abnormal findings for patients of different age groups begins the moment the nurse first observes and meets the individual and continues throughout the examination.

Begin an assessment by observing a patient's ability to ambulate. Then conduct the examination of individual body systems, using each person as his or her own control. Symmetry should be assessed by comparing the right and left sides of the body. The human body is usually anatomically symmetric, so observing for abnormalities on either side is vitally important to noting anatomic deviations.

The quality of the inspection phase of the physical examination depends on several variables, including (1) the nurse's ability to identify normal variations among patients, (2) good lighting, with adequate exposure of anatomic surfaces, and (3) the time allotted for attention to detail. After inspection, further examination is performed using palpation. In many instances, palpation is done at the same time as inspection or shortly afterward.

Palpation

Palpation uses touch to assess body organs and skin texture, temperature, moisture, **turgor** (tension due to fluid content),

tenderness, and thickness. **Consistency** measures organ location and size against the expected anatomic norm, any distention or masses, and vibration or pulsation associated with movement. Palpation can be used to affirm details observed during inspection. Rigidity, **crepitation (crepitus)** (crackling or rubbing), and the presence of lumps can be detected through palpation. Ask the patient to describe areas that are sensitive or painful, and note any nonverbal signs of distress or discomfort the patient may express, such as **guarding** (positioning to prevent movement of a painful body part) or **rebound tenderness** (discomfort experienced after stimulation is discontinued). During palpation, the patient should be relaxed and comfortable. Muscle tension during palpation may be misinterpreted by the nurse. Palpation is performed immediately after inspection, except during assessment of the gastrointestinal system. Palpation and percussion of the abdomen are delayed until after inspection and auscultation to prevent false assessment findings secondary to stimulation of the bowel.

Various parts of the hand are best suited for assessing different anatomic areas. The fingertips are used for fine tactile discrimination of texture, vibration, or pulsations. The palmar surface of the fingers and finger pads, the most sensitive parts of the hand, are used to determine the position, size, consistency, and shape of an organ or mass and its surrounding structures. The back, or dorsal, surface of the hand is best for determining temperature because the skin is thinner than that on the palms.

Palpation should be completed in a relaxed, gentle, and systematic way, with tender areas palpated last. The nurse should have warm hands and short fingernails; hands can be warmed by rubbing them together or holding them under warm water. Begin with light palpation, depressing the area approximately 1 cm ($\frac{1}{2}$ inch). Intermittent pressure is applied for brief intervals during light palpation, using the fingertips of three or four fingers held together (Fig. 20.1).

FIGURE 20.1 Light palpation. (From Ball, J. W., Dains, J. E., Flynn, J. A., et al. [2019]. *Seidel's guide to physical examination* [9th ed.]. St. Louis: Elsevier.)

After light palpation, deep palpation is used to examine organ structures. Deep palpation typically is performed by an advanced practice nurse or a physician. The area being examined is depressed approximately 4 cm (2 inches), using one hand to identify organ location and consistency. Caution is exercised to avoid injury to the patient during deep palpation. When using two hands, or bimanual deep palpation, the nurse places one hand lightly over the area to be examined, and the top hand is used to apply pressure to the hand closest to the skin ([Fig. 20.2](#)).

FIGURE 20.2 (A) Deep palpation. (B) Deep bimanual palpation. From Ball, J. W., Dains, J. E., Flynn, J. A., et al. [2019]. *Seidel's guide to physical examination* [9th ed.]. St. Louis: Elsevier.)

When performing palpation, the nurse must consider the body area being palpated, the reason for palpation, and the patient's condition. For example, palpation should not be performed on an enlarged thyroid gland or neck mass. In this instance, palpation or rubbing the area may release excessive thyroid hormone or cause pain. Palpation over major arteries or vascular structures is contraindicated because it may obstruct blood flow, causing damage or dysfunction to the area and surrounding tissues.

Percussion

Percussion is an advanced practice examination technique used to assess body tissues and structures. **Percussion** involves tapping the patient's skin with short, sharp strokes that cause a vibration to travel through the skin and to the upper layers of the

underlying structures (Fig. 20.3). Vibration is reflected by the tissues, and the character of the sound heard depends on the density of the structures that reflect the sound. Knowing how the various densities reflect or absorb sound helps the advanced practice nurse locate or approximate the size, shape, and borders of organs, masses, and fluid. An abnormal sound implies that an organ or area is possibly compromised with another substance, such as air, blood, or other bodily fluids. Percussion requires dexterity and practice for useful data to be obtained.

FIGURE 20.3 Percussion can help to identify the outline of organs and the possible presence of masses. (From Ball, J. W., Dains, J. E., Flynn, J. A., et al. [2019]. *Seidel's guide to physical examination* [9th ed.]. St. Louis: Elsevier.)

Auscultation

Auscultation is the technique of listening to sounds made by body organs or systems such as the heart, blood vessels, lungs, and abdominal cavity, with and without the assistance of a stethoscope. Some sounds, such as stridor, wheezing, or congestion, may be heard by the naked ear. The characteristics of auscultated sounds depend on the body tissue or organ being assessed. Sounds are typically documented according to their duration, frequency, intensity, and quality. A stethoscope is required to hear more distant sounds.

It is important for the nurse to be able to recognize normal body sounds. This knowledge will contribute to the nurse's ability to identify abnormalities and areas within the body that typically

remain silent. To auscultate correctly, the nurse needs intact hearing, an adequate stethoscope, and an understanding of how to use a stethoscope.

A stethoscope typically has two different heads, a diaphragm and a bell. The diaphragm is flat and is used to hear high-pitched sounds, such as breath sounds, bowel sounds, and normal heart sounds. The bell is a concave, cuplike shape used for assessing soft, low-pitched sounds, such as extra or distant heart sounds and murmurs. Both are held directly on the patient's skin to ensure contact and prevent auditory interference. Practicing auscultation with a stethoscope will help establish good technique, to avoid auditory interference from inadvertent movement of the tubing or rubbing of the diaphragm or bell head against the body's surface, clothing, or other fabric.

During auscultation, difficulty hearing sounds may be due to extraneous noise in the room or poor skin contact with the head of the stethoscope. The nurse may need to ask patients or visitors to refrain from talking and may need to turn down audio on electronic devices during auscultation. Special amplified stethoscopes are available for purchase by nurses with hearing limitations.

Auscultation normally is the last step in physical assessment for all body systems except the abdomen. When examining the abdomen, the nurse performs auscultation before palpation to prevent stimulation of bowel sounds that may cause hyperactivity, leading to false assessment findings. Stethoscopes should be cleaned between patients to help prevent the spread of healthcare-associated infections (HAIs) (Box 20.6).

Box 20.6

Evidence-Based Practice and Informatics

Avoiding Potential Stethoscope Contamination

Research has shown that poor hand hygiene can transfer pathogens to the nurse's stethoscope.

- Stethoscopes may be a vector for cross-contamination and potentially spread infection among patients.
- Stethoscopes should be cleaned with a disinfecting agent, preferably chlorhexidine, after each patient encounter to reduce the incidence of cross-contamination of pathogens.
- The nurse should inform the patient that the stethoscope may feel cool upon initial use.

From Alvarez, J., Ruiz, S., Mosqueda, J., et al. (2016).
Decontamination of the stethoscope membranes with
chlorhexidine: Should it be recommended? *American Journal of
Infection Control*, 44(11), e205-e209.

LO 20.4 General Survey

The general survey is the visual assessment and evaluation of the whole patient. It covers the patient's primary reason for seeking care and current health status, as well as any obvious deviations from normal. The general survey expands on findings recorded in the patient's health history and includes initial observations. The nurse begins a general survey by noting the patient's overall appearance and behavior and then observes hygiene, body image, affect and mood, gait, speech, and developmental status. The general survey compares patients with typical characteristics associated with accepted cultural, societal, and behavioral norms. Observing significant cultural norms is critical to providing culturally competent care during physical assessment. See [Box 20.7](#) for special considerations related to the examination process.

Box 20.7

Diversity Considerations

Life Span

- A parent or guardian should be present during the assessment of an infant, child, or adolescent minor. The adult should be able to verify subjective data shared by the school-age child or adolescent. If abuse is suspected, ask the adult to step out of the room before an in-depth interview or further investigation.
- Assistance is required to safely assess an infant or small child. This is also true for individuals with special physical or psychological needs and for elderly patients who have limited dexterity and mobility.

Gender

- When possible, honor a patient's request to have a nurse or care provider of a preferred gender. Even though many

elderly women have male physicians, they may prefer a female nurse, which they view as traditional.

- Ask patients if they would prefer an additional person in the room during the physical examination. If so, invite a professional colleague to stay in the examination room for support. Be sure to provide for the patient's privacy regardless of who is present during the examination.

Culture

- Provide interpretation for patients whose native language is different from that of the health care environment.
- A person's economic and educational levels can have an impact on the person's appearance and ability to interact within the health care system. Be sure to assess these factors and avoid judgmental attitudes or actions when interacting with all patients.
- If unfamiliar with the customs of a patient's cultural background, ask about personal patient preferences that would allay the patient's fears and enhance the examination experience.

Morphology

- Patients who are morbidly obese need to be assessed using special equipment, including large blood pressure cuffs and adapted scales to ensure accuracy. Make sure the appropriate equipment is assembled before initiating the physical examination, to limit potential embarrassment to the patient.
- During the annual physical, provide a referral to local programs, if available, that focus on exercise, nutrition, and emotional support for obese children and their families.
- Refer patients who exhibit signs of anorexia nervosa or bulimia to programs and health care providers specializing in treatment of these conditions. Early nutritional and emotional intervention is critical to behavior modification.

Age

Patients should appear to be their stated age. If they do not, because of premature aging, sun exposure, or tobacco use, the phrase “appears older/younger than stated age” may be used in documentation. Chronologic age determines which screening examinations and general health maintenance activities are recommended for patients to prevent illness and promote healthy lifestyle behaviors.

Race

Physical features, such as skin color or pigmentation, hair texture, and stature, related to genetic background are noted. Certain conditions are more prevalent among people of specific races, such as hypertension in people of African and Mediterranean descent and skin cancer in people of Northern European backgrounds.

Sex and Gender Identity

The patient's sex is noted as well as gender identity, when relevant. Some conditions are specific to or more prevalent in one sex. Certain conditions specific to the anatomy and physiology of the female and male genitalia are explored through physical examination, discussed later in the chapter.

Sexual Orientation

Lesbian, gay, bisexual, and transgender (LGBT) patients are a historically marginalized group that faces varying levels of discrimination in society. It can be difficult for LGBT patients to feel safe revealing themselves and sharing information that may be important in the provision of excellent patient-centered care by the nurse. An open and nonjudgmental attitude by the nurse may help alleviate these concerns and decrease the disparity in the provision of important screening assessments and behavioral health care. The [National LGBT Health Education Center \(2018\)](http://www.lgbthealtheducation.org/wp-content/uploads/COM-2111-Brief_Collecting-SOGI-Data.pdf) offers resources on collecting data from LGBT patients. (http://www.lgbthealtheducation.org/wp-content/uploads/COM-2111-Brief_Collecting-SOGI-Data.pdf).

Clothing

Many factors affect how a patient dresses. Personal preferences are based on culture, lifestyle, and socioeconomic level, as well as age and activity level. Note whether the patient's clothing is appropriate to the climate and current weather conditions, looks clean, and fits the body. Infants and older adults often wear several layers of clothing to preserve body temperature and may have clothing with Velcro or large-button closures due to issues with dexterity. If a patient appears unkempt or inappropriately dressed for the season or circumstance (e.g., wearing undergarments on top of outerwear), this should be documented. It may be a manifestation of an underlying medical condition such as cognitive impairment or dementia or a psychiatric–mental health disorder.

Hygiene and Grooming

Note the appearance of nails, skin, and hair. Unpleasant body odors are evaluated to determine whether they are caused by physical activity or exercise, poor hygiene, or specific disease states. Be sensitive to religious or cultural beliefs about bathing that may have an impact on the perceived hygienic condition.

Affect and Mood

A patient's affect can be observed or assessed through various displays of emotion. The nurse should note whether a patient's verbal and nonverbal communication is congruent. Observations should include whether the patient's mood is appropriate to the situation, with specific attention to the patient's facial expressions during data collection.

In most situations, the patient's level of distress or comfort is obvious in the form of clinical manifestations or behavior. For example, symptoms of pain or discomfort can be indicated through facial grimacing, splinting the painful area, or displaying a flat affect, as in some cases of emotional pain. Cultural norms related to the appropriate expression of emotion must be considered. In some cultures, extremely dramatic behavior is accepted as normal, and free verbalization or display of emotion is expected, whereas in others, stoic behavior in times of pain or

crisis is promoted. Detection of symptoms that cause a change in mental status or are potentially life threatening is a high priority in the examination.

Safety

Issues of patient safety fall into three general categories: (1) use of assistive devices or equipment, such as walkers, scooters, hearing aids, or eyeglasses; (2) environmental safety; and (3) personal safety and security. The nurse should observe and ask patients about the use of assistive devices. If patients use any assistive equipment, such as walkers or canes, they should be able to demonstrate the proper technique for use of the devices. Lack of attention to maintaining assistive equipment in working order, such as not replacing batteries in hearing aids or improperly fitting prostheses, may be a sign of busyness, neglect, economic hardship, or mental health alterations, which require follow-up evaluation by the nurse.

Some environmental concerns about which patients should be asked are living conditions, air quality at home and work, the presence of stairs or rugs, and means of transportation. These are especially important issues for the chronically ill, infants, children, and elderly people. Overcrowded living conditions predispose people to communicable diseases, and smoke from air pollution or cigarettes and cigars increases the affected person's susceptibility to an asthma attack and diseases such as lung cancer. Presence of rugs and stairs, especially in the home, can affect the ability to ambulate safely and are of concern when patients are prone to dizziness or are unable to walk without using assistive devices or dragging their feet. Depending on the patient's age and physical condition, driving safety should be evaluated. The use of public transportation or assistance from a family member or friend for transportation to reach appointments should be noted to facilitate planning clinic visits accordingly. To address personal safety, the nurse is required to ask patients directly if they feel safe in their living environment. Questions related to personal safety are asked when the patient and nurse are in a totally private setting to promote honesty and protection from potentially abusive family or friends. Observe for signs of withdrawal or hesitation when patients are answering. The

prevalence of domestic violence and emotional abuse makes it imperative that nurse–patient interactions include concern for this critical aspect of patient safety.

Providing for patient safety in each category may require that the nurse complete an extensive community assessment, which is discussed in [Chapter 23](#). All nurses who discharge patients for home care should become familiar with resources available to patients and their families. See [Box 20.8](#) for support services that affect the ability of patients of all ages to live in their own homes while undergoing medical treatment and nursing care.

Box 20.8

Home Care Considerations

Support Services

Government and Community Resources

- Transportation
- Schools and tutoring services
- Library resources
- Fire and safety resources
- Economic resources
- Recreation

Social Service Agencies

- Meal preparation and delivery
- Utility assistance
- Day care facilities for all age groups
- Cleaning and home maintenance assistance

Public and Home Health Services

- Immunizations

- Environmental surveillance
- Medical equipment
- Medication delivery

Alcohol, Tobacco, or Recreational Drug Use

Ask patients about their level of alcohol, tobacco, and recreational drug use. Inquire in a nonjudgmental manner so the impact of these substances on the patient's health and lifestyle can be accurately determined. Knowing a patient's level of alcohol, tobacco, or drug use will assist in planning health promotion activities and avoid unanticipated complications with anesthesia if the patient is scheduled for surgery.

Speech

Speech patterns typically are assessed by their rate, clarity, tone, and volume. Normal speech is understandable, neither rapid nor too slow and loud enough to be heard without excessive volume. Difficulty with articulation may indicate neurologic impairment. The pace of conversation should be moderate, with a steady stream of talking that is fluent. Word choice should be effortless and appropriate to a person's age and educational level, with older children and adults speaking in complete sentences, including occasional pauses for thought. Note when a patient is multilingual. Remember that speech patterns of patients born outside of the United States or recently immigrated may vary.

Listen for patients who are speaking too rapidly or slowly. Patients whose lips are moving without speech, talking to themselves, or whispering to real or imagined people or objects may be demonstrating signs of emotional or mental disturbances. Speech impediments can be warning signals of impaired emotions or neurologic damage.

Gait

Observe patients when they are walking into the examination room or at the bedside (if they are ambulatory). Erect body posture with a straight spine, freely swinging arms, and slightly rounded shoulders is normal. If the patient is slumped over,

limping, or holding a certain part of the body, this should be noted. Ambulation should be smooth, purposeful, and well balanced. Observe the patient for asymmetric steps or hesitant forward motion of one or both feet with movements that are coordinated or uncoordinated. Note tremors, shuffling, limping, and cogwheel movement of the limbs or gait as abnormal findings.

Vital Sign Assessment

Vital sign assessment is conducted at the beginning of the physical examination. The findings serve as a baseline for future assessments to determine the patient's status. Vital sign measurements include temperature, pulse, respirations, and blood pressure. Pain can be assessed at this time. Refer to [Chapter 19](#) for in-depth information on vital sign assessment, and [Chapter 36](#) for pain assessment.

Height and Weight and Body Mass Index

Assessment of height and weight and body mass index (BMI) is helpful in screening for overall changes in health status. A person's weight will vary daily and throughout each day, depending on food intake and fluid retention or loss. Weight gain or loss can be intentional or unintentional. Height is most often affected by normal growth, aging, or degenerative diseases such as osteoporosis. A patient's baseline height (shoes should be removed) and weight are used to determine medication dosages and to properly size antiembolic stockings, splints, and other assistive devices such as crutches.

Height and weight are measured throughout the person's life span and used to calculate BMI. Head circumference is measured for infants and children up to age 3. The findings are compared with standardized clinical growth charts to determine the percentile into which the child falls relative to physical development. The clinical growth charts are available at http://www.cdc.gov/growthcharts/clinical_charts.htm.

To accurately evaluate trends in weight, it is important to weigh patients at the same time of day, on the same calibrated scale, and in clothes similar or identical to the ones worn when the previous weight was taken. If possible, the patient's shoes should be

removed before recording weight. Accuracy of weight can be the deciding factor in many instances of care, including changes in treatment decisions or admission to an acute care facility.

Standing scales, bed scales, platform scales, and chair scales are available for weight measurement in most clinic or hospital settings. Scales should be properly calibrated to zero with sheets or other objects, such as diapers, that will be weighed with the patient. Attention to patient transfers is critical to prevent falls or injury to the provider or patient. More than one care provider should be used in any instance of uncertainty about a safe transfer of the patient to the measurement device.

Measure height vertically by using the post attached to a standing scale or horizontally with a measuring tape for infants, children, or adults lying in a supine position. A complete listing of healthy height and weight assessments for adults, children, and infants can be found at the Centers for Disease Control and Prevention (CDC) website, <http://www.cdc.gov/healthyweight/assessing/index.html>.

LO 20.5 Physical Examination

Examination of each body system should progress in an organized fashion. Typically, this is achieved by starting with skin assessment and proceeding head to toe. Clinical judgment is used by the nurse to determine how extensive a physical examination needs to be on the basis of the patient's condition, timing, and the location of the interaction.

Skin, Hair, and Nails

The integumentary system is made up of the skin, hair, scalp, and nails. As the largest organ of the body, the skin helps to regulate body temperature, sense stimuli, and protect underlying structures. Fig. 20.4 illustrates the three skin layers, nerve endings, and blood supply. The condition of the skin reflects overall well-being. Nutritional, metabolic, and hydration status are evident during skin assessment, as is a person's oxygenation and circulatory condition. Skin appearance also may indicate a person's emotional state, reaction to medications, and daily work or leisure activities.

FIGURE 20.4 Cross section of skin layers.

Examination of various parts of the integumentary system begins with inspection of the entire skin surface. Box 20.9 provides skin assessment questions to assist with completing a thorough nursing history. Collection of subjective data can take place both before and during visual inspection. The technique of palpation is performed after inspection, with special care taken in patients who bruise easily, have open skin lesions, or have painful skin surfaces.

Box 20.9

Health Assessment Questions

Skin, Hair, and Nails

- Have you observed any noticeable changes in the consistency, color, or texture of your skin, hair, or nails recently? Is your skin normally dry, oily, or a combination of both?
- Has anyone in your family ever had skin cancer? Do you have any birthmarks, moles, or tattoos? Have any of them changed in color, size, or shape?
- List any allergic skin reactions you have ever had to food, drugs, plants, or other daily encountered substances.
- Do you have any problems with perspiration, malodorous skin in the absence of perspiration, or itching?
- How much sun or tanning-bed exposure do you have in the average week? What type of sun protection do you use and how often?
- In your daily activities or occupation, is your skin exposed to chemicals, excessive temperatures, petroleum, bleach, or caustic cleaning products?
- Describe your normal hair texture. How often do you wash your hair? What types of grooming products do you typically use, and how often? Do you ever use chemicals on your hair?
- Have you noticed any generalized hair loss, bald spots, or loss of hair in a specific location? Have you noticed any lumps or painful areas around hair follicles?
- Have you experienced recent changes in your diet or appetite?
- Have you recently undergone chemotherapy or radiation treatment? Are you on any new medications that may cause hair loss or growth?
- Do you have a familial history of male pattern baldness? If so, at what age did it begin?
- Describe any changes you have had in the appearance or condition of your nails.
- Do any skin, hair, or nail problems limit your normal activities?

Natural light is best for assessing skin color in all patients and is especially preferred for inspecting dark skin. An overly warm room can lead to superficial dilation of the skin, causing increased redness and sweating, whereas an overly cool room can induce vasoconstriction, causing the patient to appear pale or cyanotic. Clean, disposable gloves should be worn for palpation to inspect skin folds or for protection if the patient has any open wounds or unusual skin lesions. Visualizing the entire skin surface and palpating skin folds or lesions ensures a thorough skin assessment.

Skin Inspection

The major portion of the skin assessment can be conducted while the patient is sitting on an examination table or bed. To properly inspect the skin of the buttocks and dorsal aspects of the legs or lower torso, the nurse can ask the patient to stand or can position the patient on the side or abdomen. During skin assessment, privacy is maintained by exposing only the body part being examined. If abnormalities are

noticed during inspection, the involved areas should be palpated. A mental note should be made of the distribution and symmetry of hair, skin coloring, markings, and lesions. Observations of each part of the body are precisely documented, including pressure areas, skin breakdown, skin odors, unusual position of leg folds, condition of axillae skin and the area under the breasts, and any lesions or incision sites. For patients at risk for development of pressure ulcers, nurses and other health care professionals use the Braden scale to reliably score the potential for this complication. Refer to [Chapter 29](#) for the complete Braden scale.

Skin Color Alterations

The amount of pigment in skin determines its color intensity and hue. Small amounts of melanin are common in whiter skin, whereas larger amounts of melanin result in darker or olive-hued skin tones. Carotene is responsible for yellow-tinted skin tones. Exposed skin on the hands, neck, face, and lower legs usually has darker pigmentation than areas less exposed to the sun and elements, such as skin on the abdomen and genitalia. Normal skin pigmentation varies in tone, depending on the location of the skin and on age, culture, and ethnicity.

Each person's skin color has fairly uniform characteristics of tone and shading. Normal skin color variations include ivory or light pink, ruddy to light tan, light to dark black, and bronze or olive tone. In older patients, skin color tends to be uneven owing to varying pigmentation or more pronounced birthmarks.

It is more difficult to detect skin color changes and rashes in patients with dark or olive-toned skin. Skin located in skin folds and creases is darker than skin at other areas of the body in people with darker skin tones. Several common skin alterations should be looked for during inspection.

Absence of Pigment

Albinism is a congenital loss of pigmentation characterized by a generalized lack of melanin pigment in the eyes, skin, and hair or, in rare instances, in the eyes alone. It is a hereditary trait that causes the affected person to have pale skin, pinkish eyes, and almost white hair from birth.

Cyanosis

Cyanosis is a blue discoloration of the skin, nailbeds, or mucous membranes that results from vasoconstriction or deoxygenated hemoglobin in blood vessels near the skin's surface. Central cyanosis is often due to cardiac or respiratory conditions that lead to poor blood oxygenation. Peripheral cyanosis, causing blue discoloration in the fingers or extremities, is most often due to local vasoconstriction or inadequate peripheral circulation. All factors contributing to central cyanosis also can lead to peripheral symptoms; however, peripheral cyanosis is most often observed in the absence of heart or lung conditions, such as exposure to cold for an extended period of time.

Erythema and Purpura

Erythema is redness of the skin caused by congestion or dilation of the superficial blood vessels in the skin, signaling circulatory changes to an area. It can occur with any skin injury, sunburn, infection, fever, or inflammation and disappears when pressure is applied. A temperature elevation may accompany erythema if the

redness is associated with dilation of blood vessels in the deeper layers of the skin. Erythema is not easily detected in dark-skinned people but may be present in an area of the skin that is edematous (swollen) or warmer than the surrounding skin. **Purpura** (bleeding underneath the skin) and red pigmentation that does not blanch with pressure are nonspecific signs. Purpura may indicate vascular, coagulation, or platelet disorders.

Jaundice

Jaundice is a yellow hue to the skin, mucous membranes, or eyes seen in both light- and dark-skinned people. The yellow pigment results from excess bilirubin, a by-product of red blood cell destruction, or liver failure. The best site for evaluation of the patient for jaundice is the sclera or, in darker-skinned people, the hard palate.

Pallor

Pallor, a pale or lightened skin tone, is usually uniformly disseminated throughout the skin surface. Pallor can be caused by illness, emotional shock or stress, decreased exposure to sunlight, or anemia or may be a genetic trait. It is most easily observed on the face, oral mucosa, nailbeds, palms of the hands, and conjunctiva of the eye. Pallor can develop suddenly or gradually, depending on the cause. Localized pallor usually is not clinically significant unless it is accompanied by general pallor that is not typical of the patient's normal skin tone. It should be noted as unique from conditions such as vitiligo.

Vitiligo

Vitiligo is a loss of skin pigment. It is thought to result from an autoimmune response. Patches of depigmented skin most often are noted on the hands, face, and genital areas. Although vitiligo may occur in people of all skin types, it is most noticeable in dark-skinned people.

Skin Lesions

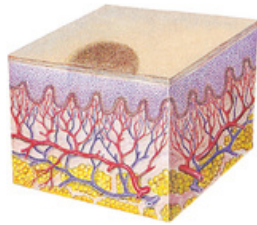

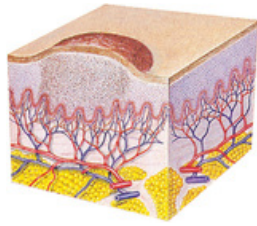

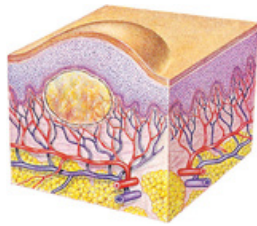

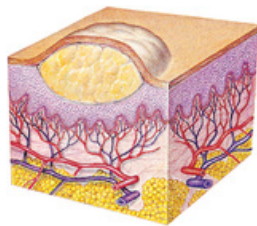

Benign, age-related skin conditions include age spots, skin tags, cherry angiomas (ruby red, often slightly raised papules), keratosis (thickened patches of skin), warts, and freckles. Inspection and palpation evaluates for lesions or disruptions in continuity of the skin. Skin lesions appear in a variety of shapes, sizes, and colors. When a lesion is identified, it is inspected for size, shape, color, location, and distribution. Measure skin lesions with a clear, flexible ruler, documenting the breadth, circumference, and height, as appropriate. Measure a lesion's depth if it extends below the skin's surface. Any type of exudate associated with a lesion is documented in terms of color, approximate amount of drainage, consistency, and odor. Pressure injuries that develop as a consequence of poor circulation, inactivity, infection, or traumatic injury require extensive assessment and treatment, which is discussed in [Chapter 29](#), in the context of wound care.

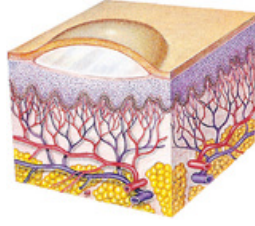

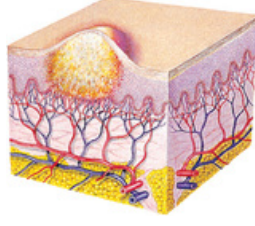

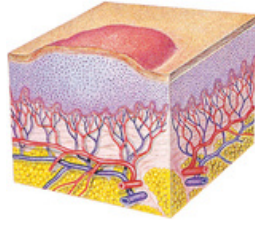

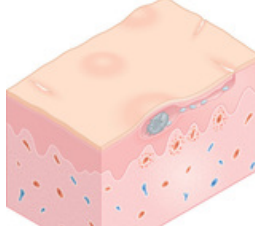

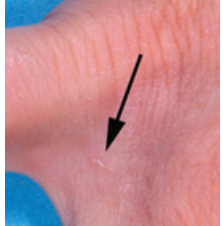

Skin lesions are classified as primary lesions (arising from normal skin) or secondary lesions (resulting from changes in primary lesions due to scratching, trauma, infection, or the healing process). Primary skin lesions include **petechiae** (tiny, dark red spots that indicate hemorrhage under the skin), warts, psoriasis, poison ivy, or insect bites. Examples of secondary lesions are pressure injuries,

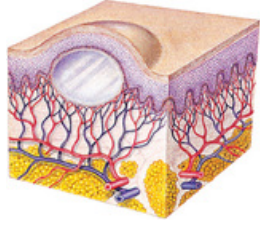

scars, and wound dehiscence. [Table 20.2](#) presents a review of skin lesions, with illustrations, as they appear both above and below the skin's surface.

TABLE 20.2

Primary Skin Lesions

Description	Examples	Skin Cutaway	Actual Case
Macule/Patch			
Flat, not detectable with palpation Changes in color Size <1 cm >1-cm macule: Called a <i>patch</i>	Port wine stain Flat moles		 (Habif, 2004)
Papule/Plaque			
Solid, raised lesion with distinct borders Variety of shapes: Domed, flat-topped, umbilicated Often associated with secondary features: Crusts or scales Size <0.5 cm >0.5-cm papule: Referred to as a <i>plaque</i>	Wart Psoriasis Actinic keratosis		 (Weston & Lane, 2007)
Nodule			
Raised solid mass with defined borders Extends into the dermis or beyond Deeper and more solid than a papule Size 0.5–2 cm	Lipomas Squamous cell cancers		 (Goldman & Fitzpatrick, 1994)
Tumor			
Solid mass that extends through subcutaneous tissue May have undefined borders Not always cancerous; may be larger lipomas Nodules that typically are >1–2 cm	Larger lipomas Cancerous lesions		 (Lemmi & Lemmi, 2000)
Vesicle/Bulla			

Description	Examples	Skin Cutaway	Actual Case
Circumscribed, raised lesions Filled with serous (clear) fluid Size <0.5 cm Vesicles >0.5 cm: Referred to as <i>bullae</i>	Chickenpox (varicella) Poison ivy Second-degree burn blisters		 (Farrar, et al., 1992)
Pustule			
Similar to vesicle Circumscribed, elevated lesion containing pus instead of clear fluid Most commonly infected	Impetigo Acne		 (Weston, Lane, & Morelli, 1996)
Wheal			
Irregularly shaped area of edema Caused by serous fluid in the dermis Varies in color and size	Hives (urticaria) Insect bites		 (Ferrar, et al., 1992)
Burrow			
Linear or circular in appearance Caused by infestation and tunneling of parasitic organisms	Scabies mites Ringworms		 (Marks & Miller, 2014)
Cyst			

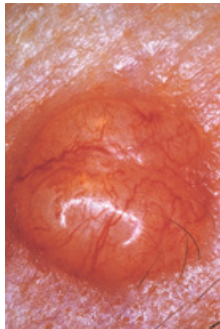

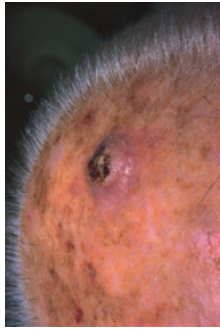

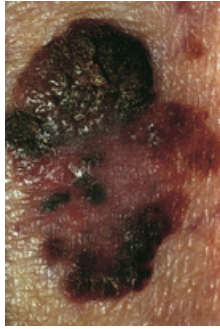

Description	Examples	Skin Cutaway	Actual Case
Encapsulated fluid-filled or semisolid mass Extends into the dermis or subcutaneous tissue	Sebaceous cyst		 (Weston & Lane, 2007)

Skin Malignancies

Inspection of the skin is a key component for early detection of abnormalities and malignancy of the integumentary system. When detected and treated early, many skin cancers are highly curable. The U.S. Department of Health and Human Services and World Health Organization have declared tanning beds a carcinogen (CDC, 2018). Research indicates that indoor tanning before the age of 35 increases a person's risk for the deadliest form of skin cancer, melanoma, by 59% with each exposure (American Academy of Dermatology, 2018). Nurses are responsible for screening examinations and preventive education that helps protect patients from risk factors associated with skin cancer. Encourage patients to inspect their own skin regularly for lesions that are growing, changing shape, bleeding, or itching (American Academy of Dermatology, 2018). Types of skin cancer with perceptible changes on inspection during screening include basal cell carcinoma, squamous cell carcinoma, and melanoma (Table 20.3). The American Cancer Society (ACS) and American Academy of Dermatology have established a mnemonic, ABCDE, which is presented in Table 20.4, to aid in screening for melanoma.

TABLE 20.3**Types of Skin Cancer**

Description	Risk Factors	Symptoms	Photo
Basal Cell Carcinoma (BCC)			
<p>Most common skin cancer worldwide</p> <p>Slow growing</p> <p>Usually does not metastasize</p> <p>May cause destruction and disfigurement of surrounding tissues</p>	<p>Sun exposure</p> <p>Fair complexion</p> <p>Familial history of skin cancer</p> <p>Weakened immune system</p> <p>History of radiation therapy</p> <p>Increased age</p>	<p>Bump or scaly growth</p> <p>Does not heal within 2 wk</p> <p>Begins to itch or bleed</p> <p>May begin at size of 0.5–1 cm and grow</p> <p>Slightly raised or flat</p>	 <p>(Kumar, Abbas, & Aster, 2015)</p>
Squamous Cell Carcinoma (SCC)			
<p>Second most common form of skin cancer</p> <p>Grows more rapidly than BCC</p> <p>May metastasize if left untreated</p>	<p>Chronic sun exposure</p> <p>Additional risk factors same as those for BCC</p>	<p>Red, crusted or nonhealing nodule or ulcer</p>	 <p>(Kumar, Abbas, & Aster, 2015)</p>
Melanoma			
<p>Least common skin cancer</p> <p>Accounts for 75% of skin cancer deaths^a</p> <p>Elevation indicates a more advanced stage</p>	<p>Sun exposure</p> <p>Fair complexion, freckling, light hair</p> <p>Multiple moles</p> <p>Male gender</p> <p>Familiar or personal history of melanoma</p> <p>Immune suppression^b</p>	<p>Brown, flat, lesion with irregular borders</p> <p>Variegated pigmentation with poorly defined margins</p> <p>May begin as only 0.5–1.0 cm in diameter</p> <p>Changing size and shape of an existing mole</p> <p>Possible tenderness, bleeding or itching</p>	 <p>(Kumar, Abbas, & Aster, 2015)</p>

Safe Practice Alert

Early detection of melanoma is essential to prevent or limit metastasis to other areas of the body. Once a melanoma lesion elevates or ulcerates below the skin, metastasis is more likely to have occurred.

Palpation

Palpation is performed to assess the patient's skin for texture, warmth, turgor, edema, and moisture. Palpation can be used to corroborate suspicious results noted during inspection. Gloves are worn during palpation when potentially infectious or contagious exudate may be present on the skin that may not be visible during inspection. Palpation helps to identify the characteristics of lesions with consideration to the contour (flat, raised, or sunken), stability, and consistency (soft or firm). Use gentle pressure to palpate both over and around the lesion. Gently assess areas of tenderness, noting the extent of any discomfort.

Texture

Skin texture is palpated using two or three fingertips. Patient skin can be described as soft, supple, or firm, smooth or rough, and thin or thick. Skin typically is thicker on the palms of the hands and the soles of the feet. Age and environmental exposure are contributing factors to skin consistency. In older patients, skin becomes thinner, wrinkled, and more prone to variations in temperature because of reduced collagen, muscle tone, subcutaneous fat, and sweat glands. People repeatedly exposed to extreme environmental elements such as the sun or extreme cold tend to have thicker, more leathery, or wrinkled skin with numerous freckles or moles. Skin texture may be altered because of underlying disease or illness.

Skin Temperature

Skin temperature depends on the amount of blood circulating through the dermis. Temperature is assessed by palpating the skin with the back of the hand, and it is compared symmetrically on each body area. Skin temperature should be uniform throughout the body, with minor variations from one area to another. Environment often determines the temperature and appearance of the skin. In warmer environments, blood vessels close to the skin dilate, producing a flushed or reddened appearance, whereas in cooler environments, constricted blood vessels

shunt blood away from the skin surface, causing it to be pale and cool to touch. Detailed assessment is always performed on patients at risk for impaired circulation. Areas of redness often are warmer owing to increased blood flow. Palpation is especially critical to determine the level of circulation distal to injuries or immobilized areas.

Turgor

Turgor describes the skin's elasticity or ability to resist deformity after being displaced. Skin turgor is assessed by grasping a fold of skin ($\frac{1}{2}$ to 1 inch in thickness) on the forearm or over the sternum along the second or third intercostal space and gently pinching the fingertips together and then releasing (Fig. 20.5). Skin that is well hydrated and free of underlying disease lifts easily and returns without delay to its original position. Avoid assessing turgor over areas that are wrinkled or scarred, because they are consistently loose or indurated.

FIGURE 20.5 Skin turgor assessment of the forearm. (From Ball, J. W., Dains, J. E., Flynn, J. A., et al. [2019]. *Seidel's guide to physical examination* [9th ed.]. St. Louis: Elsevier.)

When skin turgor is poor, the skin will stay pinched or will return to its original state more slowly. Decreased skin turgor is a sign of moderate to severe dehydration. If skin turgor remains poor or compromised, the patient is susceptible to skin breakdown or invasion by opportunistic organisms, against which healthy skin acts as a barrier.

Edema

Edema (swelling) is caused when there is a buildup of fluid in underlying tissues. Common causes of edema are localized trauma to an area and impairment of venous return. Edema secondary to poor venous return usually is most prominent in the lower extremities or dependent areas of the body (e.g., the feet, ankles, and lower legs).

Edematous skin usually appears stretched and glossy, depending on the amount of fluid in the underlying tissues and the elasticity of the skin. In older patients, edematous skin can have more subtle changes, often appearing boggy as a result of decreased underlying muscle tone and loss of skin elasticity. Edematous areas should be palpated to determine pain, mobility, and consistency of the underlying tissue involvement.

If the palpation causes an indentation that persists for some time after the release of the pressure, the edema is referred to as *pitting edema* (Fig. 20.6). The degree of

pitting edema is assessed by pressing the edematous area with the thumb or forefinger for 1 to 2 seconds and then releasing. Pitting edema is documented according to the depth of indentation ([Box 20.10](#)). Caution should be exercised when assessing pitting edema in patients with underlying conditions associated with venous or arterial insufficiency. Even slight pressure that causes indentation in edematous skin can produce tissue trauma, leading to [ecchymosis](#) (bruising), ulceration, or permanent damage requiring skin grafting.

FIGURE 20.6 Pitting edema. (From Patton, K. T., & Thibodeau, G. A. [2016]. *Anatomy and physiology* [9th ed.]. St. Louis: Elsevier.)

Box 20.10

Documentation of Pitting Edema

1+	Slight pitting, 2 mm
2+	Deeper pit, 4 mm
3+	Deep pit, 6 mm; dependent extremity enlarged
4+	Very deep pit, 8 mm; dependent extremity extremely distorted

Hair and Scalp Inspection and Palpation

Normal hair structure consists of keratinized cells. Hair is found over most parts of the body except lips, palms of the hand, soles of the feet, nipples, labia minora, and the penis. Two general types of hair cover body surfaces: vellus and terminal. *Vellus* hair is short, fine, and pale and covers most of the body's surfaces. *Terminal* hair (e.g., on the scalp and in the axillae) is coarse and darker, more visible, and longer than vellus hair. Puberty initiates the development of terminal hair in both sexes in the perineum, axillae, and legs. Pigment production determines the color and type of hair of an individual. A lack of pigment or inclusion of air spaces within the hair follicle produces gray or white hair color variations. Hair serves as a protective covering for the body (e.g., scalp) and filters airborne debris and dust to prevent it from entering body orifices, such as the ears, nose, and eyes.

Inspection begins with noting the condition and distribution of body hair and continues through all phases of the physical assessment. Ask the patient to remove any hair pins, clips, or wigs. Explain that assessment of the hair and scalp requires separating layers of the hair to detect irregularities beginning at the hair shaft. Obtain subjective data by asking questions similar to those found in [Box 20.9](#).

Inspect the patient's hair color, quantity, distribution, thickness, and texture, as well as moisture surrounding areas of body hair. When inspecting scalp hair color, remember that variations range from pale blonde or flaxen to black to silver or gray. Understand that color variations can be chemically altered due to the patient's use of rinses or dyes. Patients of African American and African heritage often have coarse or wiry hair texture that requires less frequent washing to maintain a healthy sheen.

Recognize that normal hair growth and distribution vary with age and gender. In older adults, scalp hair often becomes light gray, yellow, or white, and terminal hair in the pubic areas, scalp, and axillae becomes thinner and sparser. Older men usually experience decrease in density of facial hair, whereas older women tend to develop hair on the upper lip and chin with a decrease in estrogen levels. Dry, brittle hair may occur with overuse of chemical products for coloring and/or straightening, and such changes are commonly seen with aging. Note whether younger patients have experienced hair growth associated with puberty in the pubic and axillary areas, as well as coarsening of facial hair in adolescent boys. Both genders experience an increase in coarse hair growth, evenly distributed, on the lower extremities during changes associated with puberty. Cultural norms, religion, or style trends usually dictate whether body hair, including scalp hair, is groomed in a particular manner.

Changes in hair growth or loss can have either positive or negative effects on the patient's sense of well-being or body image. Patients with hormone disorders often report and exhibit unusual patterns of hair growth and distribution. **Hirsutism** is a condition affecting both men and women in which hair growth on the upper lip, chin, and cheeks becomes excessive and vellus body hair becomes thicker and coarser. This condition is common in patients with hormone imbalances. Permanent or temporary hair loss (**alopecia**) and extreme thinning of hair, in which the scalp is clearly visible, often are related to genetic predisposition, endocrine disorders, severe febrile illness, chemotherapy, or scalp disease. In patients with thyroid disease and diabetes, hair becomes sparser, brittle, and fine, because of decreased blood flow to underlying capillary beds supplying the skin. Dull, dry, stringy-looking hair is characteristic of poor grooming practices and nutritional deficits, such as in anorexia nervosa, alcoholism, or malabsorption syndromes. Venous or atrial insufficiency can be the cause of hair loss or lack of growth in areas where circulation is compromised, usually involving the lower extremities.

Parasites can be found in scalp and pubic hair follicles. Observe for the presence of head lice, bedbugs, cockroaches, or other parasitic insects. Lice infestations usually produce severe **pruritus** (itching) from bites that also are visually detectable. When bites become infected from the host's scratching the affected area, or as a consequence of the body's immune response, pustular eruptions can be observed close to the hair roots, where skin surfaces come in contact with each other, such as in the axillae and the groin.

Palpate the patient's scalp and hair while wearing gloves for protection from any hidden lesions, parasites, or hygiene concerns. Scalp palpation should evaluate for lesions or bumps by separating strands of hair in a systematic method until every portion of the scalp is evaluated. The scalp normally is smooth, even-toned, and supple, with hair follicles evenly dispersed. If scalp lesions or bumps are found, ask the patient about any recent trauma to the area. Describe characteristics associated with abnormalities (e.g., pain, size, drainage), and note whether the patient has been scratching the area or using home remedies on the site for relief. Moles and

birthmarks on the scalp are common and can bleed if combed or brushed too hard. Dry patches of scalp can be found in patients with decreased sebum production in skin covering the scalp. More commonly, overuse of products that wash away the skin's natural oils and lubricants leads to dandruff or to aggravation of underlying skin conditions, causing flakiness, dryness, and pruritus of the scalp.

Nail Inspection and Palpation

Nails are hard, keratinized plates of epidermal cells that originate and grow from a root beneath a skin crease called the *cuticle* or *eponychium*. The crescent-shaped, whitish area located at the base of the nail, where it meets the cuticle, is called the *lanula*. The most visible portion of the nail is the nail plate, a transparent layer of epithelial cells that extends over the entire nailbed (Fig. 20.7). The underlying nailbed normally is light pink to reddish brown–tinged. Nailbed color results from the supply of superficial capillary blood vessels found in the skin beneath the nail and is dependent on the patient's race or genetic makeup. The nails' primary function is to protect the distal ends of the fingers and toes.

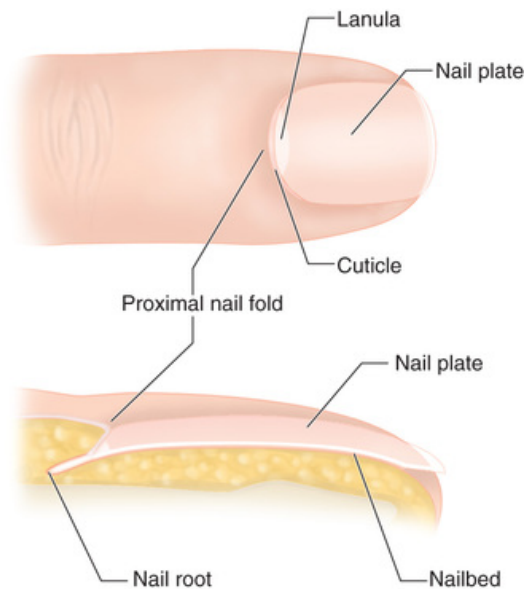

FIGURE 20.7 Nail anatomy.

The nails often are reflective of the patient's general level of health, nutritional status, and hygiene habits. The nailbed should be inspected for grooming and cleanliness, color, markings, and shape. The length of the nail is taken into consideration; however, nail length can vary greatly from person to person on the basis of personal preference and is not always indicative of poor grooming or health problems.

Observe the angle between the nail plate and nail and the condition of the lateral and proximal nail folds. The nail folds and the cuticles should be smooth, with intact skin that is without redness or inflammation. The patient's occupation, grooming habits, or culture can influence the nail appearance and texture. For example, people who are employed as mechanics or construction workers tend to have damaged, dirty, or brittle nails. Such changes occur despite adequate nail care and frequent handwashing performed by the patient. All components of the nail

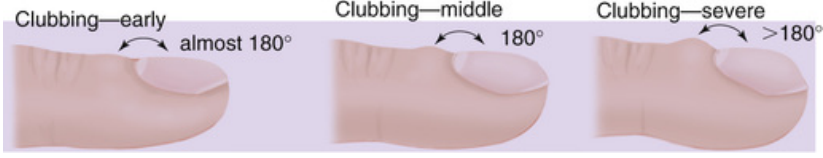

and nailbed should be clean and intact; otherwise, the patient is at greater risk for infection or permanent damage to the nail and its underlying structures.

Nails normally develop at a steady rate and can grow slightly faster on one side of the body than the other. The thickness of nails changes with aging, usually becoming harder and thicker, with nail growth occurring more slowly than in younger patients. As a patient ages, nails appear more opaque, yellow, and striated, rather than transparent, smooth, and pinkish. Such changes often are due to decreased calcium and mineral intake, poor circulation, or the progression of generalized disease processes.

On inspection, the nailbed is normally at a 160-degree angle between the nail and the nail plate. Nails should be hard and relatively immobile. A larger angle and decreased firmness of the nailbed can indicate chronic circulation or oxygenation concerns ([Table 20.5](#)). For example, clubbing of the nails typically is a result of chronic peripheral oxygen deprivation, as seen in cardiac or pulmonary disease.

TABLE 20.5

Nail Shape and Curvature Abnormalities

Abnormality	Cause(s)
<p><i>Splinter hemorrhage</i>: Red or purple-brown streak in nailbed</p> 	<p>Minor trauma, trichinosis, subacute bacterial endocarditis</p>
<p><i>Paronychia</i>: Inflammation of the skin at the base of the nail</p> 	<p>Local infection Acute: <i>Staphylococcus aureus</i>, herpes simplex virus Chronic: <i>Candida albicans</i>, <i>Pseudomonas</i> spp.</p>
<p><i>Clubbing</i>: Enlargement of the fingertips, softening of the nailbed, and flattening of the nail; angle between the nail plate and the nail often greater than 180 degrees</p> 	<p>Chronic hypoxia from heart and/or pulmonary disease</p>
<p><i>Beau's lines</i>: Transverse ridging in nails due to a temporary halt in nail growth</p> 	<p>Nail injury, systemic injury, eczema, psoriasis, paronychia</p>
<p><i>Koilonychia</i>: Concave curves of the nail, with thinning of the nail plate; also called "spoon nail"</p> 	<p>Iron deficiency anemia, repeated chemical trauma, syphilis</p>
<p><i>Muehrcke lines</i>: Double band of white lines (leukonychia)</p> 	<p>Renal disease</p>

Palpate nails to assess for texture and consistency, noting if the nail plate is firmly attached to the nailbed. To test for **capillary refill** (an indication of peripheral blood flow), use the thumb to gently depress the patient's nail tip for approximately 1

second and release (Fig. 20.8). As pressure is applied, the nailbed will blanch or appear white. The pink tone should return immediately when the pressure on the nail is released. Capillary refill is measured in seconds, and blanching that occurs with pressure should reverse, with return of the nailbed to normal color in less than 2 to 3 seconds; this response is referred to as *brisk*. Capillary refill lasting longer than 2 to 3 seconds (slow or sluggish capillary refill) usually is a sign of respiratory or cardiac disease associated with hypoxia, anemia, or conditions linked to circulatory insufficiency.

FIGURE 20.8 Assessment of capillary refill on the fingers (A) and toes (B).

Calluses and corns are areas of thickened skin that may occur in areas of pressure, typically on the fingers or toes as a result of continuous rubbing, tight footwear, or gait abnormalities. For example, professional guitarists often develop calluses on their strumming fingers. A callus is generally a more diffuse thickening of the skin. Corns are more focused areas that appear as horny, thickened, or cone-shaped masses, typically found over bony prominences on the feet.

Serious complications can occur in people with poor circulation and peripheral neuropathy. Document any abnormalities such as thickening or ulceration of the nails and skin surfaces of the hands or feet.

Safe Practice Alert

Toenails should be cut straight across and filed with an emery board or nail file. Remind diabetic patients to seek professional help immediately if they notice an ingrown toenail developing. Failure to act quickly may result in a serious infection that can be difficult to treat and can spread systemically.

Head, Ears, Eyes, Nose, and Throat

Examination of the head and neck requires general assessment of the head as well as external and limited internal assessment of the eyes, ears, nose, mouth, throat, and neck. The information in Box 20.11 can provide a foundation for collecting health history information related to each of these areas. Advanced practice nurses and physicians conduct extensive internal examination of these organs. Assessment of the carotid arteries, jugular veins, lymph nodes, thyroid gland, and trachea are included during this part of the physical examination. Assessment techniques for the head and neck frequently incorporate inspection and palpation simultaneously, followed by systematic auscultation of individual anatomic landmarks.

Box 20.11

Health Assessment Questions

Head, Ears, Eyes, Nose, and Throat (HEENT)

Head and Neck

- Do you have a history of any head injuries (e.g., concussion), subdural hematoma, or recent lumbar punctures? Have you ever experienced dizziness or had a tumor or seizure disorder? Have you lost consciousness for any period of time or become confused and/or dazed for an unknown reason? Do you have a history of high or low thyroid hormone levels?
- Do you have a history of headaches? If so, what are the typical onset, duration, and resolution of the headaches? Have you ever been diagnosed with migraines?
- Is there a risk for head injury in your employment? Do you wear a hard hat? Do you wear head protection when participating in sports? Do you wear a motorcycle or bicycle helmet?

Eyes

- Have you noticed any change in your vision? Have you experienced halos around lights, floaters, light sensitivity, or double vision (diplopia)?
- Do you have a history of glaucoma or cataracts? Have you ever had eye surgery?
- Do you wear contact lenses or glasses?
- Do you have any superficial or deep pain in or around the eye? Have you noticed any burning, itching, or discharge?
- When was your last eye examination?

Nose

- Do you have a history of allergies, sinus infections, or trauma to the nose? Do you experience nasal discharge? If so, describe its character, including color, odor, amount, and duration.
- Do you experience sinus pain or tenderness, postnasal drip, daytime cough, headache, or face pain?
- Do you snore? If so, when is it most common for you to snore? Does it wake you or your partner? Do you feel tired after sleeping all night? Do you need frequent naps?
- Do you have a history of nosebleeds? If so, describe the frequency, amount of bleeding, and treatment.

Ears

- Do you have a history of dizziness or vertigo, earache, or hearing loss?
- Do you ever experience ringing in the ears?

- Do you wear hearing aids or use another type of hearing assistive device? Do you wear ear protection for your work?
- When was your last hearing test?

Mouth and Throat

- Is there a personal or family history of mouth or throat cancer?
- Do you experience frequent bleeding of the gums, tooth pain, tonsillitis, cold sores, dry mouth, or cracked lips?
- Do you have any difficulty swallowing or do you feel as though something is caught in your throat?
- When was your last dental examination?

Head Inspection and Palpation

Begin examination of the head and neck by inspecting the patient's head position. The patient's head should be held upright, in a midline to trunk position, and remain motionless during inspection. Tremors or other neurologic disorders may be present if jerking movements are noted.

Inspect the skull contour for size, shape, and symmetry. Make note of any abnormal lesions, incisions, masses, or nodules that are distinct in appearance, texture, or contour from the skin nearby. Gently palpate the skull in a circular pattern, progressing systematically from front to back. The adult skull should feel smooth and seamless, with the bones indistinguishable from one another. Overall, the scalp should move freely over the skull without tenderness, swelling, or depressions. Enlargement of the skull due to **hydrocephalus** (accumulation of cerebrospinal fluid in the ventricles of the brain) in children most often is a congenital condition, whereas in adults it may occur as a result of tumor growth. In adults with disorders of the adrenal glands that cause excessive growth hormone secretion, enlarged jaws and facial bones may result in acromegaly in both male and female patients.

The size, shape, and contour of the head and eye and ear location should be mostly symmetric. Inspection of the eyes, eyebrows, and mouth should yield consistency and overall uniformity in the shape and contour of the features during rest, movement, and expression. If facial asymmetry is present, note whether all features on one side or portion of the face are affected and whether there are any accompanying abnormalities, such as edema, swelling, pallor, or pigmentation. Suspect facial nerve paralysis when an entire side or hemisphere of the face is involved. Facial nerve weakness is seen primarily in cases in which the lower half of the face is symptomatic. When only the mouth is involved, consider peripheral trigeminal nerve damage as the causative factor. Spasmodic muscular contraction or tics noted in the face, head, or neck of the patient are often associated with varying amounts of pressure on facial nerves and/or with psychogenic or degenerative changes to underlying facial structures. Examples are nerve damage caused by cosmetic procedures, traumatic injury from airbag deployment, and varicella-zoster virus infection.

Eye Inspection and Palpation

Eye examination includes assessment of normal eye structures (Fig. 20.9), extraocular movements, and visual acuity. The nurse should determine the patient's level of eye function in relation to deficits or alterations that have an impact on ambulation, self-care, and completion of activities of daily living.

FIGURE 20.9 Normal eye anatomy. (From Patton, K. T., & Thibodeau, G. A. [2016]. *Anatomy and physiology* [9th ed.]. St. Louis: Elsevier.)

Alignment

Normally, both eyes move together, receiving the same image on corresponding areas of both retinas simultaneously. The brain fuses these images into a single three-dimensional image. **Strabismus** (crossed eyes) is a disorder in which one or both eyes deviate out of alignment owing to muscle weakness or paralysis, most often outwardly (divergent strabismus) or toward the nose (convergent strabismus). In this case, the brain receives two different images, and either it suppresses one or the condition results in the person's seeing double (**diplopia**). Depending on the underlying cause, by maneuvers to weaken or strengthen the appropriate muscles to center the eyes, the affected person may be able to correct strabismus. For example, if an eye turns upward, the muscle at the bottom of the eye could be strengthened to correct the misalignment.

Positioning

The eyes are positioned on each side of the nasal bone, approximately 1 to 2 inches apart from one inner canthus to the other and are housed in the anterior portion of the skull. On inspection, they appear equally situated below the forehead and eyebrows and above the nose and mouth, just above or at the midline of the patient's ears. Abnormal eye protrusion can be due to tumors or inflammation of the orbit. "Bulging" eyes often indicate hyperthyroidism or severe increased intraocular pressure from trauma or glaucoma.

Eyebrows and Eyelids

The eyebrows and eyelids should be inspected for position, color, alignment, and movement. Eyebrows normally grow symmetrically and extend to the temporal canthus of the eye. Excessive coarseness, flakiness, or brittleness of hair and failure to extend beyond the temporal canthus can be due to conditions such as hypothyroidism or adrenal disease. Thinned or lightened eyebrows can result from grooming techniques such as plucking, coloring, or waxing or can be caused by normal aging. Ask patients to raise and lower the eyebrows. Observe for symmetry in movement. Difficulty performing this task can indicate a facial nerve palsy or facial cranial nerve VII dysfunction.

When the eye is open, the superior (upper) eyelid should cover a portion of the iris but not the pupil itself. Observe the patient's ability to completely open and close the eyelid and to blink. The lids normally close symmetrically. Under normal circumstances, people blink both eyes simultaneously and involuntarily up to 25 to 30 times a minute. The blink reflex serves to lubricate the cornea and surrounding tissues. Fasciculation (twitching) or tremors noted with the eyelids closed tightly can be a sign of hyperthyroidism.

Note whether the superior eyelid covers more of one iris than the other or whether it extends over the pupil. When abnormal drooping of the eyelid occurs, the condition is known as **ptosis**. It can indicate a congenital or acquired weakness of the levator muscle or can result from paralysis affecting all or portions of the oculomotor cranial nerve III. Ptosis more often is seen in older adults, in whom age-related loss of elasticity, muscle weakness, and excessive skin can interfere with eyelid opening or movement. The nurse should note whether the lids are turned inward, a condition known as *entropion*, or whether the lids are turned away from the eye, a condition called *ectropion*. Entropion causes the lashes to turn inward, which may cause corneal and conjunctival irritation that increases the risk for secondary eye infection. Ectropion may result in excessive tearing or watery-appearing eyes, because the tear-collecting structure cannot collect the secretions of the lacrimal gland, causing them to spill over onto the face.

A hordeolum, or stye, may result from the blockage or infection of a sebaceous gland at the base of an eyelash, causing an erythematous or yellow lump on the upper or lower eyelid. Styes are painful but typically do not cause any lasting damage.

Inspect the orbital area for edema, puffiness, or sagging tissue below the orbit. Although these signs also may be congruent with the normal aging process, periorbital edema is never a normal finding. It can indicate the presence of thyroid hypoactivity, allergies, renal disease, or infection. Slightly raised, flat, irregularly shaped, yellow-tinted lesions on the periorbital tissues are called *xanthelasma* and are suggestive of an abnormality of lipid metabolism. These elevated plaques of cholesterol most commonly are deposited on the nasal portion of either the upper or lower lid. Edema of the eyelid can prevent the lids from closing entirely. Conditions such as facial nerve paralysis, unconsciousness, or drug use can prevent the lids from closing entirely, which can expose the cornea to drying that leads to risk for infection. Note how often the lids close and whether closing is symmetric, infrequent, rapid, or unocular (one-eyed).

Palpate the eyelids for nodules, and then gently palpate the eye itself with the eyelids closed. Determine whether it feels hard or if gentle pressure causes discomfort. Extreme firmness and rigidity of the eyeball on palpation can be a sign of glaucoma, hyperthyroidism, or retroorbital tumor. The lids should feel smooth and typically are the same color as that of facial skin.

Conjunctiva and Sclera

The conjunctiva covers the visible surface of the sclera and extends to the external border of the cornea. The conjunctiva normally is free of redness or exudate. The presence of erythema, exudate, or discoloration can indicate an allergic response or infective conjunctivitis. Conjunctivitis (“pinkeye”) is a highly contagious infection that is spread through contact with the crusty drainage that collects on the eyelid margins. It is characterized by intense itching and redness of the sclera.

The sclera is examined to check its color and ensure that it is intact, without lesions. In white patients, the appearance of the sclera is a pearly white color. In dark-skinned patients, the sclera is light yellow to pale gray. In the presence of certain conditions, such as liver disease, the sclera becomes pigmented or discolored, turning yellow (jaundice) or copper-colored. A sunken appearance of the orbit or sclera can indicate dehydration, retinal damage, or trauma.

Safe Practice Alert

Hand hygiene should be performed before and after examination of the eye. Wear gloves in the presence of any exudate or irritation. Examine the healthy eye first. Take special precautions to avoid transferring organisms found in one eye to the other eye.

Clarity of the Lens and Cornea

The cornea is the transparent front layer of the eye that covers the iris, pupil, and anterior chamber. Together with the lens, the cornea refracts light and accounts for approximately two thirds of the eye's total optical power. The refractive power of the lens is roughly one third of the eye's total power. Examine the cornea for clarity by asking the patient to focus on a point straight ahead while shining a light at an angle that covers the entire corneal surface. The corneal surface should appear transparent, glossy, and even. Because the cornea is avascular, blood vessels should not be present. Any irregularities or blood present on the corneal surface can indicate a corneal abrasion or tear, leaving the area susceptible to infection or pain with movement. Corneal sensitivity is tested by touching a wisp of cotton to the outer edge of the cornea. The expected response is a blink, demonstrating that the sensory fibers of cranial nerve V and the motor nerve of cranial nerve VII (facial nerve) are intact.

The lens is examined by shining a light indirectly toward the cornea. It may appear gray or yellow; however, clarity is better assessed during examination of the lens with the ophthalmoscope. **Cataracts** cause the lens of the eye to become cloudy and impair vision. They grow slowly over time and often are left untreated until they become opaque or dense, significantly compromising the patient's ability to see clearly and adversely affecting quality of life.

Lacrimal Glands

The lacrimal glands are responsible for tear production and assist in lubrication of the outer surface of the eye. They are located in the upper, anterolateral aspect of the bony orbit of each eye and normally are not palpable. Inspect the area of the lacrimal gland, and palpate the upper and lower rim of the eye orbit, working from the inner canthus outward. If the lateral aspect of the upper lid feels full or elicits a pain response, gently evert the lid and examine the area around the lacrimal gland.

Lacrimal ducts may be blocked, with obstruction of the flow of tears, causing redness or swelling of the eyelids and conjunctiva.

Iris and Pupil

The anterior surface of the iris reveals the color of a person's eyes. The iris of both eyes should be clearly visible and the same color. The iris has a deeply pigmented posterior surface and prohibits the entrance of light, except through the pupil.

Pupils are examined for size, shape, symmetry, reaction to light, and accommodation. The pupils should be round, black, and equal in size; they are normally 3 to 7 mm in diameter. Estimate individual pupil size while referring to a standardized chart (Fig. 20.10), and then compare the pupils for equality and size variation.

FIGURE 20.10 Pupillary size chart.

Cloudy pupils indicate the presence of cataracts. Verify whether a patient has had surgery to reduce intraocular pressure (as in glaucoma) if a V-shaped portion of the pupil is missing. Pupillary constriction to less than 2 mm (pinpoint pupils) and failure to dilate generally are caused by ingestion of opioids such as morphine or medications that control glaucoma. Pupillary dilation of more than 6 mm and failure of the pupils to constrict with light stimulation may result from trauma, neurologic dysfunction, glaucoma, or ophthalmic drugs introduced into the eye for examination or surgery. In situations in which extreme trauma or permanent neurologic damage has taken place, pupils that do not respond to light and remain dilated over time may be documented as fixed and dilated.

Pupillary reflexes and accommodation

Pupillary reflexes are evaluated in a darkened environment using a penlight. To check for light reflexes, approach the patient's eyes from one side while asking the patient to focus straight ahead into the distance (Fig. 20.11). Ask the patient to avoid looking directly into the light. The pupil closer to the light should constrict immediately in response to exposure to the indirect light, followed by constriction of the opposite pupil (consensual constriction) more distant from the light. Repeat the procedure on the opposite eye.

FIGURE 20.11 Assessing pupillary light reflex. (A) Begin by approaching one eye with a penlight from the side. (B) Observe the closest pupil for immediate constriction followed by consensual constriction of the opposite pupil.

Testing pupillary reflexes for **accommodation** evaluates the ability of the eyes to focus on near objects. Accommodation is facilitated by movement of ciliary muscles and increased curvature of the lens, neither of which is visible. It is assessed by observing whether the pupils converge and constrict when focused on an object at close range. Have the patient focus on a distant object and then on a pen or unlit penlight held just a few inches in front of the patient's nose. Slowly move the pen or penlight closer to the patient's nose, observing for bilateral convergence and constriction of the pupils. Documentation of a normal pupillary reflex examination is recorded as PERRLA (pupils equal, round, reactive to light and accommodation).

Extraocular Movement

Movement of the eyes in all directions is controlled by the combined function of three cranial nerves (III, oculomotor; IV, trochlear; and VI, abducens) and six extraocular muscles. A critical aspect of assessing extraocular movement is examination of the six fields of vision. This examination is completed by having the patient and the nurse seated or standing approximately 2 feet away from each other at eye level. Ask the patient to follow a finger (or pen) with just the eyes, as it proceeds through the six fields of gaze (Fig. 20.12). Move the finger (or pen) in a smooth, gliding motion to the right, the left, and diagonally within each of the patient's fields of vision, approximately 6 to 12 inches from the patient's eyes. Then ask the patient to move the eyes to the extreme lateral position (toward the ears), both left and right. As the patient looks in each direction, note the presence of normal parallel and equal eye movement and lid position or any signs of abnormal movement.

FIGURE 20.12 Examining the six fields of vision. (From Ball, J. W., Dains, J. E., Flynn, J. A., et al. [2019]. *Seidel's guide to physical examination* [9th ed.]. St. Louis: Elsevier.)

Nystagmus is rapid, shaking, involuntary movement of the eyes. It is especially noticeable when the patient is asked to look to the side and quickly return the gaze to the front. Depending on the cause, movements can be in both eyes or in just one eye. Prolonged nystagmus (lasting longer than 1 to 2 seconds) can be due to inner ear disorders, multiple sclerosis, narcotic use, or brain injury (secondary to motor vehicle accidents, strokes, or tumors).

Visual Acuity

Assessment of visual acuity examines the patient's ability to see at a distance and at close range. It evaluates cranial nerve II (optic nerve) patency and central vision. To assess near vision, ask the patient to read printed material at a comfortable distance (approximately 35 cm, or 14 inches) from the eyes in adequate lighting. If the patient normally wears glasses, the patient should wear them during this part of the assessment. Be sure to take language and reading ability into consideration before initiating this test. If the patient has difficulty reading, move on to other aspects of the examination.

A Snellen chart comprises increasingly smaller lines of letters and is used to test distant or far vision. The Snellen chart should be placed on a wall or door at eye level. Patients stand 20 feet from the chart and cover one eye at a time, reading each line of letters until they can no longer identify them. An E chart can be used to test visual acuity with patients who are unable to read or are unfamiliar with the English alphabet. Patients are asked to point in the direction of the open end of the E (Fig. 20.13). Vision usually is tested first without glasses or corrective lenses.

FIGURE 20.13 Visual acuity assessment tools. (A) Snellen chart. (B) E chart. (Copyright Thinkstock.com.)

Each line of the Snellen or E chart is followed by a fraction indicating 20 over the distance at which a person with normal vision would be able to see the line without assistance. Results of acuity testing are documented with a fraction: The numerator is 20 (indicating the distance the patient is standing from the chart) and the denominator is the number indicating the distance for the last full line of print read correctly by the patient. With normal vision, the numerator is 20 (feet) and the denominator also is 20 (feet), and the person is documented as having 20/20 vision. If the denominator in the fraction is greater than 20, the patient's visual acuity for distance is reduced, and the myopia (ability to see close objects clearly but not distant objects) worsens as the denominator increases. Thus vision measured as 20/200 means that the patient can read at 20 feet what the average person can read at 200 feet. Various conditions that affect visual acuity, along with associated risk factors, prevention strategies, and treatments, are listed in [Box 20.12](#). Vision not improved with correction to better than 20/200 is considered legal blindness.

Box 20.12

Patient Education and Health Literacy

Conditions Affecting Visual Acuity

Cataracts

- Opacity or clouding of the eye lens

- Risk factors include:
 - Increasing age, female gender
 - Prolonged sun exposure
 - Cigarette smoking, alcohol or steroid use
 - Diet low in antioxidants
- Prevention strategies include:
 - Wearing sunglasses and hats when outside
 - Quitting smoking and limiting alcohol consumption
 - Increasing intake of vitamins E and B
- Treatment is:
 - Surgery to replace the cloudy lens with a clear, artificial lens implant

Glaucoma

- Optic neuropathy, usually associated with increased intraocular pressure
- Risk factors include:
 - Increased age, African or Hispanic ancestry
 - Migraines, diabetes, low blood pressure
 - Increased intraocular pressure
 - Family history
 - Eye injury
- Prevention strategies include:
 - Having regular eye examinations by an ophthalmologist
 - Wearing protective eyewear at work, during construction projects, or while participating in sports to prevent injury
 - Limiting caffeine intake, increasing water consumption
 - Engaging in regular physical exercise
- Treatments are:
 - Medicated eyedrops to lower intraocular pressure
 - Laser or open-eye surgery

Macular Degeneration

- Deterioration of the macula, the area on the retina that is responsible for central vision, allowing for clear vision of fine details; Two types: dry and wet
- Risk factors include:
 - Family history, white ancestry
 - Overactive immune system causing inflammation
 - Smoking, hypertension, hypercholesterolemia
- Prevention strategies include:
 - Wearing sunglasses when outside
 - Taking dietary supplements including vitamins E, C, B₆, and B₁₂, as well as beta carotene, zinc oxide, and copper
 - Eating a healthy, well-balanced diet
- Treatments are:
 - Medication injection treatments
 - Thermal laser therapy
 - Photodynamic therapy

Myopia

- Nearsightedness, caused by a refractive error focusing objects on the front of the retina
- Associated with increased risk for detached retina, glaucoma, and cataracts
- Risk factors include:
 - Familial history
- Treatment is:
 - Eyeglasses, contact lenses, or Lasik surgery

Hyperopia

- Farsightedness, caused by a refractive error focusing objects behind the retina
- Risk factors include:
 - Familial history
- Treatment is:
 - Eyeglasses, contact lenses, or Lasik surgery

Presbyopia

- Age-related loss of near vision due to increased lens rigidity
- Risk factors include:
 - Age older than 40 years
- Treatments are:
 - Reading glasses, bifocal or progressive eyeglasses, or contacts
 - Conductive keratoplasty (CK), Lasik or refractive lens exchange surgery

Data from American Academy of Ophthalmology: Diseases and conditions, 2017. Retrieved from <http://www.geteyesmart.org/eyesmart/diseases/index.cfm>.

Use of the Ophthalmoscope

Examination of the internal structures of the eye is performed by an advanced practice nurse using an ophthalmoscope. The appearance of the optic disc and retinal vasculature is the main focus of examination during ophthalmoscopy. Abnormalities in the appearance of the internal ocular structures may indicate eye disease or a chronic condition such as hypertension, diabetes, or brain injury.

Ear Inspection and Palpation

Physical examination of the ear begins with direct inspection and palpation of the outer ear, including the auricle (pinna), tragus, and lobule (Fig. 20.14). Inspection of the auditory canal and tympanic membrane (eardrum) is then completed using an otoscope. Assessment of the middle and inner ear by testing hearing acuity, sound conduction, and equilibrium is the final step in examination of the auditory system.

FIGURE 20.14 Normal ear anatomy. (From Patton, K. T., & Thibodeau, G. A. [2014]. *The human body in health and disease* [6th ed.]. St. Louis: Elsevier.)

Alignment, Shape, and Positioning

A person's ear auricles typically are equal in size, aligned with the corner of the eyes, and almost vertical in orientation (within a 10-degree angle). While the patient is seated, inspect the size and shape of the auricle, tragus, and lobule. Note symmetry, color, earlobe attachment, and positioning in relation to facial features. Misaligned or low-positioned ears can be a feature of genetic disorders associated with genitourinary tract malformations or of chromosomal anomalies such as Down syndrome. Auricles should have the same color as that of the facial skin and be free of lesions. Erythema may be due to elevated temperature or inflammation; pallor can indicate decreased circulation, frostbite, skin disease, or hypoxia.

Auricles should be smooth and curved and should shape the upper ear. Earlobes may be “soldered” (tightly attached with no visible lobe), attached, or free. People of Asian ancestry are more likely to have soldered or attached lobes than are those of African or European descent. The Darwin tubercle, a thickening on the upper ridge of the outer auricle but sometimes present on the front of the upper auricle, is a normal variation in appearance.

Palpate the auricles and mastoid area for tenderness, nodules, or swelling. The auricles should be firm and pliant, without masses. Gentle pushing or palpation during any portion of the external ear examination should not cause pain. If the auricle or tragus is painful, otitis externa may be present; pain behind the ear can indicate otitis media. Mastoiditis is suspected if there is tenderness or swelling over the mastoid process. There should be no discharge from the external ear.

Cerumen and Discharge

Inspect the external ear canal for discharge or drainage. If any is present, note the color and presence of odor. Discharge that is **purulent** (containing pus) or is accompanied by an odor can indicate infection or foreign body penetration of the middle ear. Severe head trauma or brain injury can produce bloody or serous discharge, suggestive of a skull fracture or cerebrospinal fluid leakage.

A small amount of earwax (**cerumen**), which may be yellow to dark brown, is the only discharge that should be present during inspection of the external auditory canal. Cerumen assists the ear with removal of particles and debris that may cause damage to the inner ear or tympanic membrane. Excess cerumen, when visible, should be gently cleaned away from the outer ear canal, before the otoscopic examination.

Otoscopic Examination

Although complete otoscopic examinations typically are conducted by advanced practice nurses, it is helpful for all nurses to be familiar with ear examination procedures because they often are involved in checking the ears for cerumen and in hearing aid care. An otoscope is used to inspect the auditory canal and tympanic membrane. The otoscope is an ophthalmoscope handle with a magnified lens and cone-shaped viewer, called a *speculum*, which fits into the ear canal (Fig. 20.15). Disposable plastic speculum covers are available in a variety of sizes for one-time use. To properly visualize structures, the nurse should select the largest speculum size that fits comfortably into the patient's ear (usually 5 mm for an adult).

FIGURE 20.15 An otoscope is used to examine the ear canal and tympanic membrane. (Copyright [istock.com](https://www.istock.com).)

The ear canal is straightened by gently pulling the auricle of the ear up and back in adults and down and back in small children. Insert the speculum no more than 1 to 1.5 cm ($\frac{1}{2}$ inch) into the ear canal, being careful not to touch the canal wall, because touching it will cause pain.

Do not advance the speculum past the inner third of the auditory canal or as far as the tympanic membrane. Advancing it that far may cause severe pain or damage the auditory canal. Inspect the ear canal, looking for discharge, redness, foreign bodies, or swelling. The ear canal normally appears uniformly pink, with tiny hairs located in the outer third of the canal. A small amount of dry or moist cerumen may be present. During the examination, it is appropriate to ask patients what techniques they use to clean the ear canal and surrounding structures. If piercings are present, inquire about cleaning techniques, infections, or previous allergic reactions.

Safe Practice Alert

Patients with excessive cerumen production should be instructed to clean the outer-ear canals by using a warm, damp cloth or by gently flushing the ear canals with warm water from an ear syringe to promote motility and softening of the cerumen, allowing it to move outward. A softening agent may be needed in some cases. Impacted cerumen in the external auditory canals can contribute to conductive hearing loss.

Light from the otoscope allows the nurse to visualize landmarks characteristic to the tympanic membrane. The normal tympanic membrane is slightly concave and has a translucent, pearly gray, shiny appearance. The surface should be smooth. Look for retraction, perforation, or a bulging tympanic membrane. Red, bulging eardrums indicate acute otitis media, whereas visible white spots most often are due to scarring secondary to infection. Eardrum retraction results from an obstructed eustachian tube. Any deviation from normal requires follow-up treatment to prevent hearing loss.

Hearing Evaluation

Assessment of auditory function begins when a patient responds to the nurse's questions and instructions. Hearing loss becomes apparent when a patient fails to respond to conversation or verbal cues. Speech without inflection or appropriate volume may indicate a hearing deficit. All patients should be asked if they experience **tinnitus** (ringing, buzzing, or roaring in the ears), which may contribute to hearing loss, indicate overuse of salicylates, or be symptomatic of diseases that cause **vertigo** (disequilibrium, spinning sensation) such as Ménière's disease. Hearing loss may result from trauma, aging, heredity, disease, medication, and prolonged exposure to high-decibel sound.

The three primary types of hearing loss are sensorineural, conductive, and mixed. *Sensorineural* hearing loss is due to inner ear damage that prevents sound from being converted to nerve impulses. Possible causes include prolonged exposure to loud sounds and ototoxic medications, such as aminoglycosides, loop diuretics, and antineoplastic agents. Presbycusis is a form of gradual sensorineural hearing loss common in older people that is due to degeneration of the cochlea or vestibulocochlear nerve.

Conductive hearing loss occurs when something interferes with the transmission of sound via vibration to the inner ear. Fluid in the middle ear and cerumen accumulation are the most common causes of vibration interruption. Atrophy of the tympanic membrane or otosclerosis results in conductive hearing loss in older adults. *Mixed* hearing loss results from middle-ear and nerve damage.

Patency of the eighth cranial (acoustic or vestibulocochlear) nerve is assessed in evaluating a patient's hearing acuity. Although the nurse can conduct a primitive evaluation of a patient's ability to hear by whispering and asking the patient to repeat what is heard, the only precise method of determining the quality and limits of a person's hearing is audiometry. Audiometry is conducted by a professional audiologist in a controlled, soundproof environment with equipment that transmits various sound frequencies through headphones.

Weber test

The Weber test can be conducted if a patient complains of hearing loss in one ear. Through use of a tuning fork, the advanced practice nurse can determine whether

the patient is experiencing conductive or sensorineural hearing loss. If the patient reports “hearing” sound from the tuning fork in the poor ear, lateralization of sound to the poor ear has occurred, and conductive hearing loss is indicated. If the patient reports lateralization of sound to the good ear, sensorineural hearing loss is the most likely cause.

To conduct the Weber test, strike the tuning fork softly with the back of the hand and place the base of the vibrating tuning fork against the center of the patient's head or forehead (Fig. 20.16). Placement on the midline is critical. Ask the patient if the sound is heard better in one ear or the other or heard the same in both. Vibration detected equally in both ears indicates no hearing loss.

FIGURE 20.16 The Weber test evaluates lateralization of sound via bone conduction. (From Ball, J. W., Dains, J. E., Flynn, J. A., et al. [2019]. *Seidel's guide to physical examination* [9th ed.]. St. Louis: Elsevier.)

Rinne test

The Rinne test compares bone and air conduction. It is carried out by gently placing the base of a vibrating tuning fork against the mastoid process behind the ear. The nurse asks the patient to indicate when sound is no longer audible. After the patient has indicated that sound is no longer audible, the tines of the tuning fork are placed in front of the external auditory canal and the patient is again asked to indicate when sound is no longer heard (Fig. 20.17). The length of time sound was heard by bone conduction (BC) versus air conduction (AC) is determined. Air-conducted sound should be heard twice as long as bone-conducted sound. Patients with conductive hearing loss will hear bone conduction sound for longer than, or as long as, air conduction sound ($BC \geq AC$). If the patient has sensorineural hearing loss, air conduction sound is heard for only slightly longer than bone conduction sound ($AC > BC$), if sound is heard at all.

FIGURE 20.17 The Rinne test assesses the patient's ability to hear sound via bone versus air conduction. (A) Place the tuning fork on the mastoid bone for bone conduction. (B) To test for air conduction, hold the tuning fork 1 to 2 cm ($\frac{1}{2}$ to 1 inch) from the ear with the tines facing forward. (From Ball, J. W., Dains, J. E., Flynn, J. A., et al. [2019]. *Seidel's guide to physical examination* [9th ed.]. St. Louis: Elsevier.)

Equilibrium

An important function of the inner ear is to aid the person's ability to maintain balance by sensing head movements and position. Patients with inner ear disorders often experience a loss of equilibrium and vertigo.

Romberg test

The Romberg test is conducted to assess the patient's equilibrium (Fig. 20.18). Patients are asked to stand with their feet together and arms at their sides, first with their eyes open and then with their eyes closed. Patients should be able to maintain balance for at least 20 seconds without moving their feet or starting to fall. Inability to stay balanced with eyes closed may indicate some type of vestibular disease.

FIGURE 20.18 Romberg test. (From Monahan, F. D., Sands, J. K., Neighbors, M., et al. [2007]. *Phipps' medical-surgical nursing* [8th ed.]. St. Louis: Mosby.)

Safe Practice Alert

The nurse should instruct the patient to open the eyes during the Romberg test if he or she feels about to fall. The nurse also should “spot” the patient (encircling the patient with the nurse's arms, without touching the patient) while conducting the test. This will avoid patient injury from falling.

Nose and Sinus Inspection and Palpation

The nose and sinuses are inspected and palpated with the patient seated. Inspection involves the use of a penlight for examination of each naris and surrounding structures. Assessment of the deeper nares using a nasal speculum or otoscope is conducted by an advanced practice nurse. However, knowledge pertaining to results of speculum examination of the nose is useful for providing nursing care in a patient with nasal or sinus conditions. Each of the sinus cavities is palpated to assess for tenderness or swelling.

Nose

Inspect the nose for color, shape, symmetry, swelling, and tenderness. The nares should be without drainage, and the patient should be free of nasal flaring or narrowing. The skin on and around the nose should be smooth, even, and consistent with the color of facial skin tones.

The central column (septum) of the nose should be straight and midline. A nose that appears crooked may have a deviated septum caused by a traumatic injury or congenital condition. The nares (nostrils) usually are semioval or oval and are symmetrically positioned on each side of the nasal column. The overall shape of the

nose extending to the tip varies, depending on the patient's genetic makeup, history of fractures, and clinical manifestations of disease (e.g., skin cancer, alcoholism).

Inspect the mucosa of the patient's nares. Normal mucosa is pink and moist, without lesions or tears. Nasal mucosa may appear swollen or bluish-gray in patients with allergies. The mucosa becomes red and swollen in upper respiratory tract infections. Watch for polyps, which appear as small, round, firm masses. Polyps typically are seen in patients with chronic allergies. Observe for inflammation, ulceration, or a perforated septum, which may be secondary to trauma, chronic infection, or cocaine use. Treatment with nasogastric tubes or nasal cannulas may cause skin breakdown and drying of the nasal mucosa. Frequent assessment of the skin and nares will prevent redness or skin **excoriation** (abrasion due to rubbing or scratching).

Air should pass freely through the nose when the patient breathes. Ask the patient to breathe through one nostril at a time, while the opposite nostril is pressed closed with a fingertip. Inability to sniff through each nostril independently may be due to congestion, swelling, or obstruction by a foreign object. Flaring of the nostrils during breathing may indicate difficulty with inhalation of air.

If nasal discharge is present, note the character, amount, and color of the discharge and whether it is unilateral or bilateral. Drainage may range from excessive watery discharge to thick yellowish-green, purulent mucous to blood. Watery discharge accompanied by sneezing and nasal congestion often indicates an allergy or a response to environmental irritants. A clear, watery discharge occurring after head trauma can be cerebrospinal fluid leakage from a skull fracture. Mucous or purulent discharge is typical of rhinitis, abscess, and upper respiratory tract infection. Bloody nasal discharge often results from **epistaxis** (nosebleed) or trauma, but it can be caused by conditions such as high blood pressure or diabetes.

Palpate the ridge and soft tissues of the nose by placing one finger on each side of the nasal arch and gently pressing the fingers from the nasal bridge to the tip of the nose. Note any displacement of bone or cartilage, tenderness, masses, or lumps. The nasal structures should feel firm yet slightly flexible and should return to their previous shape after palpation. A depression of the nasal bridge can result from a fracture. Palpation should not elicit nasal discharge or irritation.

Sinuses

Inspect the maxillary sinus areas below the eyes for swelling and discoloration, which may be associated with a history of sinusitis, allergies, or recent viral illness. Next, palpate the frontal sinuses by using the thumbs to press up on the eyebrows without pushing on the eyes. Move down to both sides of the nose, and press gently with thumbs up to palpate the maxillary sinuses. [Fig. 20.19](#) illustrates palpation of the maxillary and frontal sinuses. No tenderness or swelling should be elicited when light pressure from palpation is applied to soft tissue over sinus areas. Further assessment for tenderness, using percussion, and transillumination of the sinuses, using a light source, is best performed by nurses with advanced clinical experience.

FIGURE 20.19 Palpating the maxillary and frontal sinus cavities. (A) Maxillary. (B) Frontal.

Mouth, Throat, and Neck Inspection and Palpation

Assessment of the mouth, throat, and neck provides the nurse with the opportunity to evaluate many aspects of the patient's health status, including:

- Oral hygiene
- Condition of the teeth and gums
- Hydration status
- Airway patency
- Ability to meet nutrition needs
- Patency of cerebral blood flow

The patient may be seated or lying down, with the head of the table or bed elevated approximately 45 degrees during this aspect of the examination. Clean gloves, a penlight, a single 2 × 2 gauze pad, and a tongue depressor are needed to assess the oral cavity, including the lips, buccal mucosa, gums, teeth, tongue, palate, floor of the mouth, and pharynx. A stethoscope is required to assess carotid artery patency in the neck.

Mouth

With the patient's mouth in a closed and relaxed position, inspect the lips for color, patency, scarring, and hydration. Lip color varies, ranging from pink in light-skinned patients to bluish or freckled in darker skinned individuals. The lips normally are moist, smooth, and symmetric. Palpate the surface of the lips and the skin around them. All surfaces should be without lesions (such as cold sores) or swelling. Patients who had cleft lip repair during childhood may have residual scarring. Note the presence of any piercings or lip enhancement.

Changes in the color or texture of the lips can be influenced by various conditions. Edema most often is the result of an allergic reaction. Pallor is seen if a patient is anemic or in shock, whereas a vibrant red color is typical in cases of ketoacidosis or carbon monoxide poisoning. Acute or chronic respiratory and cardiovascular disorders cause circumoral cyanosis (a bluish-purple hue of the lips and surrounding skin), often extending to the facial tissue around the mouth. Dry,

cracked lips (**cheilitis**) often indicate dehydration from limited oral intake or exposure to excessive heat (hyperthermia) or cold. Some nutritional deficiencies may result from poor dental hygiene or jaw dysfunction.

Dental Assessment

Inspection of the teeth determines the quality of dental hygiene and the ability of the patient to chew food for nutritional intake. Inspection begins with asking the patient to smile broadly, observing the teeth for occlusion and alignment. Generally, the upper incisors slightly override the lower incisors, and the upper molars are directly over the lower molars, without spaces or gaps. To test cranial nerve VII (facial nerve) function, ask the patient to demonstrate clenching the teeth and then smiling. The ability to perform this maneuver indicates normal facial nerve functioning.

Next, inspect the teeth for color, irregular shape, and cavities (caries). Loose and missing teeth should be noted, as well as rotted, blackened, or severely decayed teeth. The teeth generally appear ivory or white and are smooth and glossy. A tongue depressor can be used to retract the lips, cheeks, and tongue when viewing the upper and lower molars. The risk for systemic, bacterial infection is greater in teeth with compromised surfaces or cracks that extend below the gum line.

Safe Practice Alert

A variety of patients with artificial heart valves, congenital heart conditions, and artificial joint replacements should be referred to their dentists for prophylactic antibiotics before dental care to prevent infective endocarditis or infection at the joint replacement site. Guidelines developed in cooperation among the [American Dental Association \(2018\)](#), the American Heart Association, and the Academy of Orthopedic Surgeons are available at <http://www.ada.org/2157.aspx>.

Oral Mucosa, Gums, Tongue, Uvula, Tonsils, and Palate

Using a tongue blade and penlight, inspect the buccal mucosa, teeth, gums, tongue, uvula, tonsils, and palate for color, texture, lesions, ulcers, bleeding, and patency ([Fig. 20.20](#)). Move the light source systematically throughout the mouth to illuminate and view both the anterior and posterior oral cavities. The mucous membranes should be pale pink to pinkish red in appearance, with a moist, smooth, uninterrupted surface.

FIGURE 20.20 Oral cavity assessment.

Gently insert a clean tongue blade into the patient's mouth and depress the anterior half of the tongue 2 to 3 cm. This maneuver causes the soft palate to rise, offering better visualization of the oropharynx. Be careful not to insert the tongue depressor onto the posterior aspect of the tongue or near the uvula, because this may stimulate the gag reflex. View the condition of the hard palate, which forms the anterior roof of the mouth, and the soft palate, which forms the posterior roof of the mouth. Observe for any clefts (splits or elongated openings) or signs of palate repair. A yellow or whitish coating over the lining of the pharynx suggests postnasal drip or sinus inflammation. Ask the patient to vocalize the “ah” sound when the tongue is depressed. The soft palate should move symmetrically, with the uvula slightly retracting but remaining centered in the oral cavity. This movement verifies proper function of the glossopharyngeal and vagus nerves (cranial nerves IX and X). If the soft palate does not rise bilaterally with vocalization, the vagus nerve may be damaged, causing the uvula to move to the unaffected side.

Observe the uvula and tonsils for enlargement, edema, and discoloration. Tonsils reach their largest size at puberty and gradually atrophy with aging. Enlarged or inflamed tonsils (tonsillitis) may necessitate surgical removal (tonsillectomy) to prevent chronic infections, airway obstruction, or sleep apnea. White patches or pustules on the tonsils or pharynx typically indicate a bacterial infection requiring antibiotic treatment. Infection within the pharynx may cause palpable enlargement of exterior lymph nodes.

Gently retract the patient's lower lip away from the teeth to inspect the gum line and gums. Gum color should be consistent with the buccal mucosa and covered with a light sheen of saliva, causing the gums to appear shiny. Normal gum tissue appears slightly ridged, with a distinct, firm margin bordering each tooth. Repeat the process for the gum line of the upper jaw. Small, yellow-white, raised areas that appear on the buccal mucosa are an expected variant known as Fordyce spots, which are ectopic sebaceous glands. Discoloration due to jaundice, anemia, or cardiopulmonary conditions is readily observed in the oral mucosa.

Note any abnormalities of the tongue, including unusual size, deep fissures, or lesions, by asking the patient to stick out the tongue. Observe for alignment and tremors that may indicate hypoglossal (cranial nerve XII) damage. A small tongue suggests malnutrition, and an enlarged tongue implies hypothyroidism or Down

syndrome. Color deviations suggest various vitamin or nutritional deficiencies. Deep fissures may be due to dehydration.

Before palpating the oral cavity, describe the procedure to the patient to ensure cooperation with manual examination of the mouth. While wearing gloves, insert the index finger into the patient's mouth and carefully palpate the gums and oral mucosa for any lesions, masses, pain, or thickening. No tenderness, bleeding, or swelling should be present.

Using the 2 × 2 gauze pad, gently grasp the tongue and visualize the bottom of the mouth to check for possible lesions or abnormalities. Enlargement or thickening of the gums is expected during pregnancy and at puberty. Leukoplakia (precancerous white spots or patches) may be present owing to chronic irritation or smoking. Oral thrush (candidiasis) is a fungal infection that manifests as a white film over red tissue that bleeds easily. Thrush develops in a variety of patients, including those with a weakened immune system secondary to chemotherapy or steroid therapy. Gingivitis or periodontal disease often is associated with swollen gums that bleed easily and pitted crevices between the teeth and the gum margins. Debris or plaque buildup along the tooth margins significantly contributes to oral mucosa infection, gum disease, and tooth decay. Patients with any of these conditions should be referred for further evaluation by a specialist.

Jaw

Two bones, the maxilla (upper) and the mandible (lower), hold the teeth and form the jaw. The mandible meets the temporal bone at the temporomandibular joint (TMJ). Jaw examination includes inspection for redness or swelling and palpation for edema or warmth. Facing the patient, look for facial asymmetry, indicating swelling or malocclusions. Ask the patient about recent trauma, surgery, or dental procedures. Consider that jaw pain may accompany symptoms of life-threatening disorders such as an impending myocardial infarction. While the patient opens and closes the mouth, listen for any clicking, and note any reported pain. Referral of the patient to a specialist for further evaluation for possible temporomandibular joint disorder (TMD) may be necessary.

Lymph Nodes

The lymph system produces lymphocytes and antibodies that serve as a defense against infection and abnormal cells. Several lymph nodes are located in the head and neck (Fig. 20.21). The superficial lymph nodes in the neck, which are not palpable under normal circumstances, are readily accessible for examination. An entire group (or chain) of lymph nodes becomes enlarged when it receives drainage from a specific area of infection or disease. For this reason, an understanding of drainage patterns of the lymph system is necessary for the nurse to focus the assessment on the corresponding affected area of the body.

FIGURE 20.21 Lymph nodes of the head and neck. (From Ball, J. W., Dains, J. E., Flynn, J. A., et al. [2019]. *Seidel's guide to physical examination* [9th ed.]. St. Louis: Elsevier.)

To begin examination of the lymph nodes of the neck, ask the patient to raise the chin and slightly tilt the head to one side and then the other. Inspect the neck for bilateral symmetry and abnormalities by comparing the superficial skin features. Ask the patient to face directly forward with the chin slightly elevated. Using the pads of the middle two or three fingers of both hands, gently palpate the lymph nodes on each side of the patient's neck simultaneously, comparing one side with the other. Begin palpation at the top of a lymph group, rotating the fingers in a circular motion down the sides of the neck.

Note the size, shape, location, and consistency of any palpable nodes. Consider the warmth of the skin over the area and note whether palpable nodes are mobile or stationary compared with the surrounding structures. Any tenderness with palpation or movement of the neck should also be documented. Small, soft, nontender nodes are typically benign discoveries during routine examination. Abnormal results consist of lymph nodes that are hard, fixed (immobile), or enlarged and usually are associated with pain and/or inflammation. Enlarged lymph nodes are common in patients with immunocompromised and autoimmune conditions, such as HIV infection, allergies, malignancy, or systemic lupus erythematosus.

Neck

Assessment of the neck includes inspection, palpation, and auscultation. Neck muscles are examined for flexibility, strength, and discomfort. Patients should be able to move the head up and down and from side to side without limitation or pain. Strength and full range of motion of the neck are assessed during the musculoskeletal part of the physical examination.

Jugular veins

The jugular veins are observed for distention and blood flow. Increased blood volume or conditions interfering with the flow of blood into the right side of the heart can increase jugular vein distention (JVD). Observe the jugular veins while the patient is seated, with the head of the table or bed elevated approximately 45 degrees (Fig. 20.22). Document the findings of jugular vein assessment by noting whether JVD is present or absent.

FIGURE 20.22 Position for assessment of jugular vein distention.

Carotid arteries

The carotid arteries, which provide blood supply to the head, are assessed for patency of blood flow. The nurse inspects the carotid arteries to see whether bounding pulses are visible. One at a time, palpate each carotid artery. It is vital to palpate only one carotid artery at a time, to avoid limiting blood flow to the brain and causing the patient to experience syncope and pass out. After completion of palpation, each carotid artery is auscultated (Fig. 20.23) for the presence of a **bruit** (abnormal “swooshing” sound). Bruits are audible during auscultation when blood flow is partially or significantly obstructed.

FIGURE 20.23 Auscultation of the carotid artery.

Thyroid gland and trachea

The last two areas of the neck to examine are the thyroid gland and the trachea. Inspect the thyroid gland for position and enlargement. The thyroid gland is the largest endocrine gland in the body. It produces thyroid hormones necessary to increase the metabolic rate of cells in the body. The thyroid gland should appear

midline in the neck (Fig. 20.24A) and move up and down without discomfort when the patient swallows. Any thyroid enlargement (see Fig. 20.24B) should be noted for further palpation by an advanced practice nurse or physician.

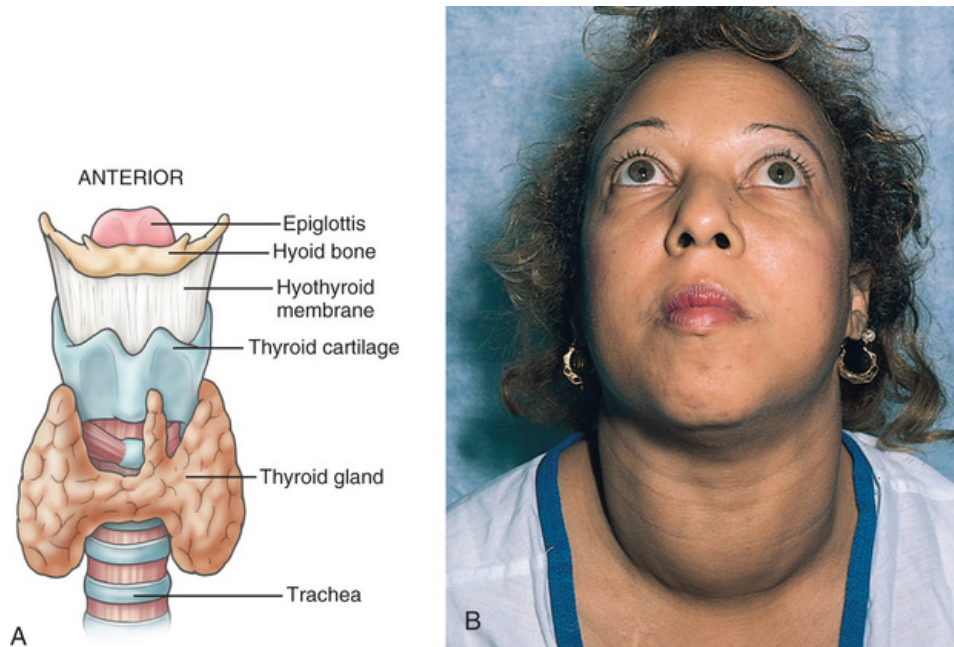

FIGURE 20.24 Thyroid gland. (A) Location. (B) Enlargement. (A, from Rothrock, J. C. [2019]. *Alexander's care of the patient in surgery* [16th ed.]. St. Louis: Elsevier. B, from Swartz, M. H. [2015]. *Textbook of physical diagnosis* [7th ed.]. St. Louis: Saunders.)

The trachea consists of cartilage rings and is positioned anterior to the esophagus and midline in the neck directly above the sternal notch. It provides a passage for air from the lungs to the upper respiratory system. It should be palpated by feeling for the cartilage rings at the sternal notch. Tumors, thyroid gland enlargement, or conditions such as pneumothorax may cause the trachea to be deviated to one side.

Any abnormalities, limitations to movement, or emergent conditions found in the neck region should be promptly identified and addressed to prevent permanent disability or loss of function.

Respiratory Assessment

Assessment of respiratory status begins with questioning the patient about risks for pulmonary complications by using the health assessment questions in [Box 20.13](#). Data gathered on all body systems are synthesized to determine the extent and effect of lung alterations within the body, because oxygenation affects all tissues and organs.

Box 20.13

Health Assessment Questions

Respiratory System

- How far can you walk on level ground?
- How many stairs are you able to climb without becoming short of breath?
- Do you have a cough? If so, when did it start?
- Do you cough up mucus or blood? If so, describe the color and consistency.
- Can you lie flat when sleeping?
- Do you snore?
- Do you use oxygen or breathing machines at home? If so, how often and at what setting?
- Do you ever experience shortness of breath either at rest or with exercise?
- Do you have any pain with breathing?
- Is the pain associated with coughing, shortness of breath, trauma, nasal congestion, or sore throat?
- Does chest pain cause splinting, shallow breathing, or uneven chest expansion, or does it radiate to the back, neck, or arms?
- What relieves the chest pain associated with respiration?
- Do you have any recent history of trauma or infection?
- Do you have a history of chronic conditions that affect respiration, including allergies, emphysema, chronic obstructive pulmonary disease, tuberculosis, cystic fibrosis, or asthma?
- Do you have a history of tumors or lung cancer?
- Do you use tobacco or marijuana? If so, how many years and packs per day?
- Have you been exposed to dust, fumes, or smoke in the environment at work or home?
- Have you traveled out of the country recently?

Safe Practice Alert

If at any time a patient appears to be in significant respiratory distress or complains of severe chest pain or shortness of breath, seek help immediately.

The nurse performs the assessment with knowledge of the structure and function of the respiratory system. [Fig. 20.25](#) illustrates the organs of respiration.

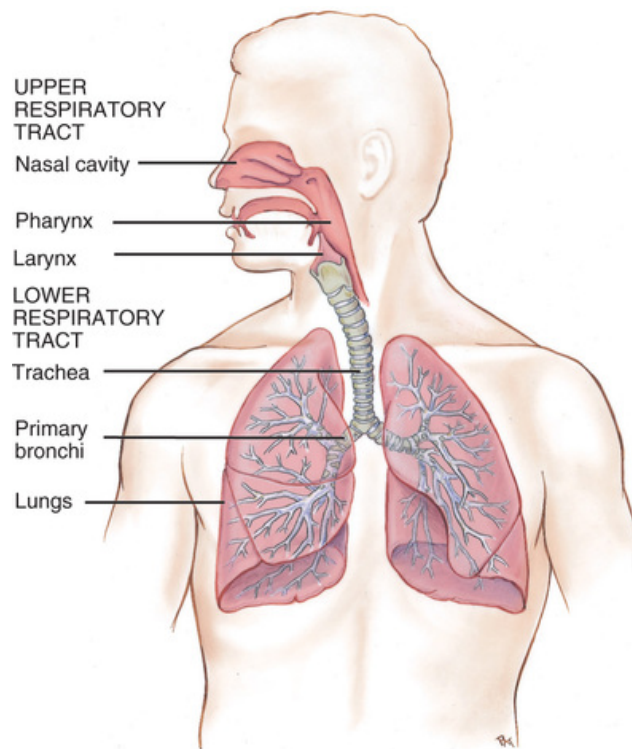

FIGURE 20.25 Respiratory system. (From Applegate, E. [2011]. *The anatomy and physiology learning system* [4th ed.]. St. Louis: Elsevier.)

Inspection of the Chest and Breathing

Inspection of the chest requires access to the patient's thoracic area. Patients are asked to disrobe to the waist. A gown is offered to preserve privacy. Sitting is the best position for assessment of the posterior and lateral chest. For examination of the anterior chest, the patient can sit or lie down.

Shape and Configuration

Inspect the anterior and posterior thorax for symmetry and shape. Observe chest hair for color, thickness, and even distribution across the chest and upper abdomen. Nipples should be centered on either side of the sternum. Observe the spine, which normally is midline and straight. Ribs should slope downward, with symmetric intercostal spaces. The scapulae lie flat on either side of the spine. The normal anteroposterior (AP) measurement of the chest is less than the transverse (across-the-chest) measurement, with normal ratios of 1:2 to 5:7. Note any lesions, scarring, or grossly asymmetric features.

Accessory muscles of breathing—the sternocleidomastoid, intercostal, trapezius, and abdominal muscles—require little effort or movement with normal, passive respiration. In situations in which effort is needed to breathe, such as with exercise or pulmonary disease, the accessory muscles respond to the increased demand by contracting and relaxing to provide respiratory support. In such situations, retraction of the intercostal muscles can be seen during inspiration.

Breathing Patterns

Observation of the patient's breathing pattern is done during inspection of the anterior chest while the patient breathes passively. Normal breathing patterns are

relaxed, automatic, and effortless. Respiratory rates in adults usually are between 12 and 20 bpm. The chest expands symmetrically, with regular and even inspiratory and expiratory effort. Normal breathing is quiet and produces no noise. Respirations are barely audible near the open mouth or with normal nasal patency. Observe the patient's posture during respiration. The patient should appear relaxed, with the arms comfortably at the sides or with the hands folded in the lap.

Abnormal Assessment Findings

When cerebral palsy, rib fracture, or severe skeletal muscle deformities such as kyphosis are present, movement of the thoracic cage may be limited. This impairment can cause decreased oxygenation or lead to greater susceptibility to infection from pooled secretions or air trapped in the lungs.

In patients with chronic lung disease such as emphysema and chronic obstructive pulmonary disease (COPD), the AP depth of the chest often is equal to the transverse width of the chest, resulting in a “barrel chest” appearance. With this altered anatomy, the ribs become horizontal, losing their downward slope, and the neck muscles undergo hypertrophy from aiding with forced respirations. Chronic lung disease causes hyperinflation of the lungs and forces the patient to adopt a tripod-type posture (leaning forward with the arms braced against the knees, chair, or bed) for the most effective breathing. A tripod posture (Fig. 20.26) provides leverage and stability to the patient so that the abdominal, intercostal, and accessory muscles of the neck can assist in expiration. Pursed-lip breathing usually is observed during expiration to encourage deep breathing, release trapped air in the lungs, and prolong exhalation to slow the patient's rate of breathing and assist with decreasing respiratory effort.

FIGURE 20.26 Patient sitting in tripod position due to shortness of breath.

Chest pain, shortness of breath, coughing, or diaphoresis may occur when one of the two types of **venous thromboembolism (VTE)** known as a **pulmonary embolism (PE)** is present. The other type of VTE is a **deep vein thrombosis (DVT)**, a blood clot that develops in peripheral circulation. PE is a blood clot in the lungs, and requires immediate medical attention. PE is the most common identifiable cause of death in hospitalized patients in the United States (Laryea & Champagne, 2013).

Unequal excursion of the chest occurs when part of the lung is obstructed or collapsed. This can be due to trauma, infection, or chronic lung disease that causes remodeling of lung tissue. If the patient is experiencing pain in the chest, guarding, splinting (holding an object, such as a pillow, to apply pressure), and grimacing may be seen. Patients with cerebral hypoxia from pulmonary alterations can demonstrate changes in mental status ranging from excessive drowsiness and restlessness to anxiety, irritability, and disorientation.

Palpation of the Chest

Palpate the patient's anterior and posterior thorax to evaluate chest size, shape, and movement. Beginning at the patient's shoulders and moving downward, gently press portions of the thorax with the middle three fingertips of both hands to identify underlying structures. Avoid sliding the hands over the skin or hair on the thorax, to prevent discomfort or abrasions. The chest wall normally is nontender and free of masses or lesions. Note any superficial lumps or masses, increased skin temperature, moisture, or tenderness during palpation. If lesions or masses are present, lightly palpate around the area for size, quality, and shape of the lesion. Avoid deep palpation to tender areas if there is a possibility that the patient has rib fractures. Rib fractures can contain fragments that are easily dislodged into vital organs. Note whether any pain, exudate, or erythema is elicited during palpation.

Tactile fremitus is a palpable vibration transmitted through the chest wall that occurs with the movement of the vocal cords during speech. It normally is symmetric on both sides of the chest and is best felt on the posterior chest. The nurse palpates for tactile fremitus by placing the fingers of one hand on the patient's chest while the patient repeats the words *ninety-nine*. Begin at the top of the lungs, and palpate from one side to the other for comparison. The vibrations should feel the same on each side. Normally, fremitus is more noticeable between the scapulae and around the sternal borders because the major bronchi and bronchioles are more superficial at these sites. Fremitus vibrations commonly decrease with downward palpation, because more tissue and posterior placement of the lungs combine to impede sound transmission. Tactile fremitus is decreased or absent in patients with conditions that obstruct lung tissue, such as pneumothorax, tumors, pleural effusion, or COPD. It can be increased in patients with pneumonia or consolidation close to the chest wall.

Evaluation of the patient's chest excursion, or depth of breathing, is done when there is a concern about chest expansion. Place warmed hands on the posterolateral chest wall, with the thumbs at the approximate level of T9 to T10 on either side of the spine (Fig. 20.27). Move the hands toward the spine (medially) to create a small skin fold between the thumbs. Ask the patient to inhale deeply through the mouth, and note thumb movement during inspiration and expiration. The thumbs should move apart symmetrically by approximately 3 to 5 cm (1 to 2 inches). Common causes of decreased or asymmetric chest excursions include pain, musculoskeletal deformity, postural anomalies, lung collapse, obesity, and muscle fatigue or weakness. Chest movement declines with age because of increasing costal cartilage rigidity, atrophy of the diaphragm, and the effects of osteoporosis on the vertebral bodies.

FIGURE 20.27 Assessment of chest excursion.

Auscultation of the Lungs

Breath sounds are produced by air moving through the structures of the respiratory tract during inspiration and expiration. They are heard through auscultation with a stethoscope placed directly on the skin. Normal breath sounds are categorized by the airways that transmit them to the chest wall, with the larger airways producing louder and higher-pitched sounds (Table 20.6).

TABLE 20.6

Normal Breath Sounds

Breath Sound	Pitch	Quality	Amplitude	Duration	Location
Tracheal	High	Harsh	Loud		Over the trachea
Bronchial	High	Hollow	Loud	Inspiration < expiration	Over the main bronchi
Bronchovesicular	Medium	Mixed	Medium	Inspiration = expiration	Posterior between the scapulae; anterior around the upper sternum in the first two intercostal spaces
Vesicular	Low	Blowing	Soft	Inspiration > expiration	Over most of the lung fields

Inspiration normally is longer than expiration in adults. Breath sounds are more difficult to auscultate in obese patients owing to increased tissue mass. Gently moving breast tissue away from the chest wall may be necessary for a more accurate assessment. In children, breath sounds are louder because the chest wall is thinner. When normal lung tissue is displaced by air (emphysema or pneumothorax) or fluid (pleural effusion), breath sounds may be decreased or absent. They may be diminished on auscultation if the patient has **atelectasis** (collapse of all or part of the lung) or absent if the patient has had a lobectomy.

To auscultate posterior breath sounds, stand at the patient's side. Position the patient sitting with the head bent forward. Using the diaphragm of the stethoscope, begin auscultating at the top of the lungs over the posterior chest wall between the ribs at approximately C7. Ask the patient to inhale and exhale through the mouth with slow breaths that are a little deeper than usual. Use a side-to-side sequence to systematically move downward on the posterior chest wall, comparing sounds from

one side with those from the other. Auscultate an entire cycle of inspiration and expiration at each location. Auscultate both sides laterally from the axillae down to the seventh or eighth intercostal space, with the patient's arms slightly raised. With the patient sitting or lying supine, auscultate the anterior chest, beginning at the top and following a side-to-side pattern. See [Fig. 20.28](#) for placement of the stethoscope during auscultation. Note the quality, location, and characteristics of sounds throughout the thorax. Understanding sounds caused by normal respiration can assist the nurse with better recognition of sounds associated with airway impediment or abnormality.

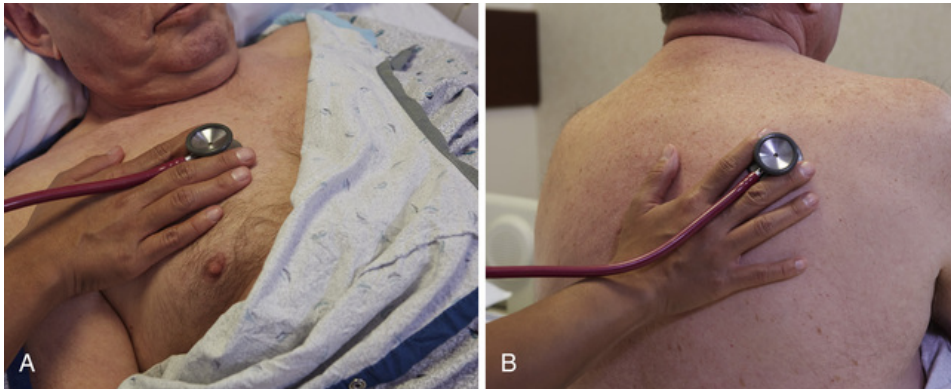

FIGURE 20.28 Placement of the stethoscope for anterior (A) and posterior (B) auscultation of the chest.

Abnormal sounds that originate in the lungs and airways are referred to as **adventitious breath sounds**. Such sounds are a result of either airway narrowing or fluid accumulation. Adventitious breath sounds are described in [Table 20.7](#).

TABLE 20.7**Adventitious Breath Sounds**

Sound	Site	Cause	Character
Crackles (formerly called <i>rales</i>)	Right and left lung bases	Sudden opening of small airways and alveoli collapsed by fluid or exudate; heard in patients with cystic fibrosis, asthma, COPD, bronchitis, and pulmonary edema from left-sided heart failure	Brief crackling, popping sounds heard when a blocked airway suddenly opens; more common during inspiration; often described as fine, medium, and coarse: <i>Fine crackles:</i> Soft, high-pitched, and very brief sounds during late inspiration and not cleared by coughing <i>Medium crackles:</i> Lower pitched, moist sounds best heard at the inspiratory midpoint <i>Coarse crackles:</i> Loud, effervescent sounds heard best during inspiration and not relieved after coughing
Rhonchi	Over the trachea and bronchi, but can be referred to all lung fields	Increased secretions in large airways due to pneumonia, increased airway turbulence from mucus or muscle spasm	Low-pitched, snoring sounds heard either during inspiration or expiration and usually cleared with coughing; lower in pitch than wheezes, with a sonorous quality
Wheezing	All lung fields	High-velocity airflow through severely constricted or obstructed airways due to asthma, foreign objects, bronchiectasis, or emphysema	High-pitched, whistling sound heard on inspiration or expiration but most obvious and loudest during expiration; also called <i>sibilant wheezing</i>
Stridor	Trachea and large airways	Turbulent airflow in the upper airway; may be indicative of serious airway obstruction from epiglottitis, croup, a foreign body lodged in the airway, or a laryngeal tumor	Intense, high-pitched, and continuous monophonic wheeze or crowing sound, loudest during inspiration when airways collapse owing to lower internal lumen pressure; often heard without the aid of a stethoscope
Pleural friction rub	Anterior lateral thorax	Inflamed pleural surfaces rubbing together during respiration, due to pneumonia or pleuritis	Low-pitched, grating, or creaking sound heard during inspiration or expiration and not cleared by coughing

Cardiac and Peripheral Vascular Assessment

Assessment of the cardiac and peripheral vascular systems builds on information gained while reviewing the respiratory system. Concerns with any one of these systems can have a direct impact on the functioning of the other. [Box 20.14](#) lists questions that can be used to gather critical information for a patient regarding cardiovascular health.

Box 20.14**Health Assessment Questions****Cardiovascular System**

- Are you experiencing chest pain? If so, describe the pain. When was its onset or when did the pain begin? What is its duration or how long have you had this

pain? What are the characteristics of the pain (sharp, stabbing, aching, burning, viselike)? Where is the pain? Does the pain radiate? What relieves the pain? Are there any other symptoms associated with the pain?

- Do you have any palpitations or extreme fatigue?
- Do you have any difficulty breathing or difficulty lying flat when sleeping?
- Do you have any past medical history of cardiac surgery or hospitalizations for cardiac events or disorders?
- Have you ever had acute rheumatic fever, swollen or painful joints, or inflammatory rheumatism?
- Do you have any chronic illnesses such as hypertension, hyperlipidemia, diabetes, coronary artery disease, congenital heart defects, or bleeding disorders?
- Do you have a family history of diabetes, heart disease, hypertension, hyperlipidemia, obesity, congenital or acquired heart defects, or sudden death at a young age? If so, include age at the time of diagnosis and death of first-degree relatives.
- Are you on an anticoagulant? Do you have a coagulation disorder?
- Does your employment include physical demands, emotional stress, or environmental hazards such as chemicals, heat, sunlight, or dust?
- Do you use tobacco? If so, at what age did you start? How many packs per day? Have you stopped using it?
- How often do you use alcohol or recreational drugs? If used, what type of alcohol or recreational drugs do you prefer?
- What is your nutritional status? Have you lost or gained weight recently?
- What do you do to relax?
- Do you exercise? How much and how often?
- Do you have aching, cramping, or pain in the legs while walking or exercising? If so, when did it start, how long have you had it, and what are its characteristics? Does anything relieve the pain?
- Have you ever had loss of consciousness or transient syncope? If so, was the episode associated with any other symptoms?
- Does shortness of breath interfere with your activities of daily living?
- Do you have any tingling, numbness, or coldness in your hands or feet?
- Do you have edema or swelling in your hands, feet, or ankles? If so, what makes it worse? What reduces the edema?
- Have you had any recent change in hair loss or growth on your hands, feet, or ankles?
- Has anything restricted blood flow to your extremities (cast, surgery, trauma, tight clothing)?

Assessment of the cardiovascular system requires that the nurse understand the anatomy of the heart and the function of the circulatory system throughout the body. Cardiovascular health is dependent on rhythmic, electrical cardiac impulses and adequate blood supply throughout the body by arteries and veins. [Fig. 20.29](#) shows the structure of the heart, which lies under the anterior chest wall. See [Chapter 38](#) for a more detailed description of cardiac function in the context of oxygenation.

FIGURE 20.29 Structure of the heart. (From Patton, K. T., & Thibodeau, G. A. [2016]. *Anatomy and physiology* [9th ed.]. St. Louis: Elsevier.)

Inspection and Palpation of the Heart

Assist the patient into a supine position, or raise the head of the bed 45 degrees. Inspect and palpate following a systematic sequence according to anatomic position. Cardiac function is assessed through the anterior chest wall. The right ventricle makes up most of the heart's anterior surface. A portion of the left ventricle is in close proximity to the fourth and fifth intercostal spaces of the anterior chest, medial to the left midclavicular line.

Begin with the base of the heart, and move in the direction of the apex. Inspect and palpate the angle of Louis and sternal ridge. There are anatomic landmarks on the chest wall where heart valve closures are best palpated and auscultated. Find the second intercostal space on the right to locate the first of these landmarks, the aortic area. The second area, the pulmonic region, can be found at the second or third intercostal space on the left. The tricuspid area is found at the fourth or fifth intercostal space, along the sternum. The mitral area is located at the fifth intercostal space, to the left of the sternum, and laterally to the left midclavicular line. The apical impulse, or point of maximal impulse (PMI), is located in the mitral area at the left fifth intercostal space at the midclavicular line. The PMI is felt as a brief pulsation in the area 1 to 2 cm ($\frac{1}{2}$ to $\frac{3}{4}$ inch) around the region of the apex. It is not uncommon to visualize the apical impulse when the patient sits up, because the heart moves closer to the anterior chest wall.

The final anatomic landmark is the epigastric area just below the tip of the sternum. The abdominal aorta is located in the upper midline abdomen, 2 to 3 inches above the umbilicus and below the xiphoid process. It is best palpated by applying gentle, downward pressure with the flattened fingers of both hands to indent the epigastrium toward the spine. Applying firm pressure can dampen aortic pulsations or cause unnecessary discomfort. Ask the patient to completely relax the abdominal muscles. In extremely obese people or in those with very developed abdominal musculature, aortic pulsation may not be detected. Bounding aortic pulsations may indicate an abdominal aortic aneurysm.

The size and stature of the patient are considered in performing a heart assessment. People who are tall or have a greater torso-to-leg length often have a heart that is positioned more centrally in the thorax and is suspended more vertically. By contrast, people who are stocky, have shorter torsos, or are short in stature tend to have a heart that sits more horizontally and to the left side of the thoracic cavity.

Auscultation of the Heart

Auscultation of the heart focuses on identifying low-intensity sounds created by heart valve closures. It detects normal heart sounds, murmurs, gallops, and other extra heart sounds. Heart sounds are heard in relation to physiologic activity of the cardiac cycle. On auscultation, two distinct heart sounds known as S1 (“lub”) and S2 (“dub”) are heard. An entire S1 plus S2 (“lub-dub”) cycle constitutes one heartbeat. S1 is the sound of the mitral and tricuspid valves closing and marks the beginning of systole. The S1 sound is dull and low-pitched and is heard best at the apex of the heart. It should coordinate with carotid artery pulsation. S2 is the sound of the aortic and pulmonic valves closing and marks the end of systole and the beginning of diastole. It is best heard in the aortic region.

In some cases, rapid ventricular filling creates a third heart sound, S3 (“lub-dub-dub”), which is heard more often in children and adolescent patients or trained athletes. Presence of an S3 sound usually is a benign condition that the affected person outgrows as the cardiac vasculature becomes thicker and stronger. An S3 murmur is considered abnormal in adults older than 25 to 30 years of age. When atria contract to enhance ventricular filling, a fourth heart sound, S4, is created. It is heard just before S1 (“lub-lub-dub”). An S4 heart sound is not a normal finding in adults, but it can be heard in healthy older adults, children, and athletes. Because it may indicate an abnormal condition, the presence of an S4 heart sound should be documented and reported to the patient's primary care provider.

Safe Practice Alert

A new onset of S4, a pulse deficit, or extra heart sounds should be reported to the patient's primary care provider for further investigation.

In a quiet environment, auscultate for the complete cycle of heart sounds (“lub-dub”), using the diaphragm first and then the bell of the stethoscope at each of the anatomic locations (Fig. 20.30) associated with cardiac valves and blood flow. Take time to isolate each sound, and listen for as many beats as necessary to evaluate the sounds. Glide the stethoscope systematically through each of the anatomic areas in a sequence moving from the base to the apex of the heart. Breast tissue may need to be gently moved to allow heart sounds to be heard more clearly. Use firm pressure with the diaphragm and light pressure with the bell for better auscultation of heart murmurs. Usually, auscultation in all areas is performed with the patient in the supine, sitting, and left lateral recumbent positions if the patient's condition permits.

FIGURE 20.30 Anatomic locations for heart auscultation. (In Linton, A. D. [2012]. *Introduction to medical-surgical nursing* [5th ed.]. St. Louis: Saunders. From Monahan, F. D., Drake, D. T., & Neighbors, M. [Eds.]. [1998]. *Medical-surgical nursing: Foundations for clinical practice* [2nd ed.]. Philadelphia: Saunders.)

To count an apical pulse, listen over the mitral area for 1 full minute. Note the interval between S1 and S2, as well as the interval between S1 and the next S1 cycle. The intervals between each heartbeat should be regular, with a distinct silent pause between S1 and S2. A regular rhythm involves equal intervals of time between each cardiac cycle of heartbeats. Failure of the heart to beat at regular, successive intervals is called **dysrhythmia**. Dysrhythmias can be life threatening, depending on the portion of the cardiac cycle affected. Dysrhythmia, a disturbance in the normal rhythm of the heart, can prevent the ventricles from effectively pumping blood to the lungs and body. The atrioventricular (AV) node, responsible for the conduction of the heart's electrical impulse from the atria to the ventricles, restricts the number of impulses that can pass through it in a given period. This functional limit prevents the ventricles from contracting at disproportionate or excessive rates when atrial disease produces atypical impulses. The electrical activity of the heart correlates with the heart cycle and can be seen on an electrocardiogram.

When listening to an irregular heart rhythm, assess apical and radial pulse rates at the same time to determine whether a pulse deficit exists. A **pulse deficit** is present when the patient's radial pulse rate is slower than the apical pulse rate because of cardiac contractions that are weak or ineffective at pumping blood to the peripheral tissues and extremities. A pulse deficit can indicate a serious cardiac event, and the patient's primary care provider should be notified immediately.

Assess for extra heart sounds at each cardiac landmark by using the bell of the stethoscope and listening for low-pitched extra heart sounds such as an S3 or S4 gallop, clicks, and rubs. In some patients, extra heart sounds are heard more clearly with position changes. If clicks, snaps, or scratching sounds are heard on auscultation, the primary care provider should be notified so that a determination can be made about referral to a cardiologist.

During auscultation at cardiac landmarks, listen for cardiac murmurs. **Cardiac murmurs** are blowing or swishing sounds heard in systole or diastole. They are caused by increased or abnormal blood flow through the valves of the heart. Heart murmurs tend to be common in children and disappear in adulthood as the cardiac and vascular systems mature. Murmurs may be asymptomatic or benign, with some affected people unaware of the condition throughout life. In other cases, a murmur is a sign of heart disease and can be symptomatic. Documentation of the location, characteristics, and intensity of a murmur will enable the health care provider to determine whether further diagnostic studies are necessary. Assess murmurs for location and radiation to other areas, such as the neck or back. In some instances, a **thrill** (an abnormal vibration felt on palpation) is detected with a murmur. Murmurs are graded according to intensity:

Grade 1: Scarcely audible with a good stethoscope in a quiet room

Grade 2: Quiet but readily audible with a stethoscope

Grade 3: Easily heard with a stethoscope

Grade 4: A loud, obvious murmur with a palpable thrill

Grade 5: Very loud with a palpable thrill; heard over the pericardium and elsewhere in the body (radiates)

Grade 6: Heard with a stethoscope off the chest; thrill palpable and visible

Auscultation for bruits should be performed over the abdominal aorta using the bell of the stethoscope. Abdominal bruits or pulsations can be a sign of an abdominal aortic aneurysm.

Peripheral Vascular Assessment

Inspection and palpation of the peripheral vascular system include assessment of peripheral pulses and blood flow, which the nurse performs while assessing other body systems. A critical aspect of a peripheral vascular examination is assessment of the jugular veins and carotid arteries, which is conducted during examination of the neck (see earlier discussion under **Head, Ears, Eyes, Nose, and Throat**). Auscultation is performed to obtain a blood pressure reading and to listen for bruits over the peripheral arteries. A Doppler ultrasound unit may be used to assess weak peripheral pulses.

Inspection and Palpation of Peripheral Pulses

A head-to-toe physical examination includes the assessment and documentation of arterial pulses in all superficial locations. While assessing the patient's pulse, the nurse notes its intensity, rate, and rhythm, as well as the existence of blood vessel tenderness, **tortuosity** (bending and twisting), or nodularity. Problem areas identified during inspection of skin and nails may indicate arterial or venous impairment, requiring a more focused assessment.

The rate and rhythm of the radial artery pulse are assessed when vital signs are obtained. Normal pulses are felt at regular intervals from one heartbeat to the next. If an interval is interrupted by an early, late, or missed beat, the pulse is recognized as irregular and should be compared with the carotid artery pulse and apical heart rate for confirmation.

Palpation of the brachial, radial, ulnar, femoral, popliteal, dorsalis pedis, and posterior tibial arteries is done using the fingertips. Peripheral pulses are compared

side to side for strength and symmetry. See Fig. 20.31 for anatomic locations of the major arteries to be assessed. Intensity or volume of peripheral pulses is graded on a scale of 0 to 3:

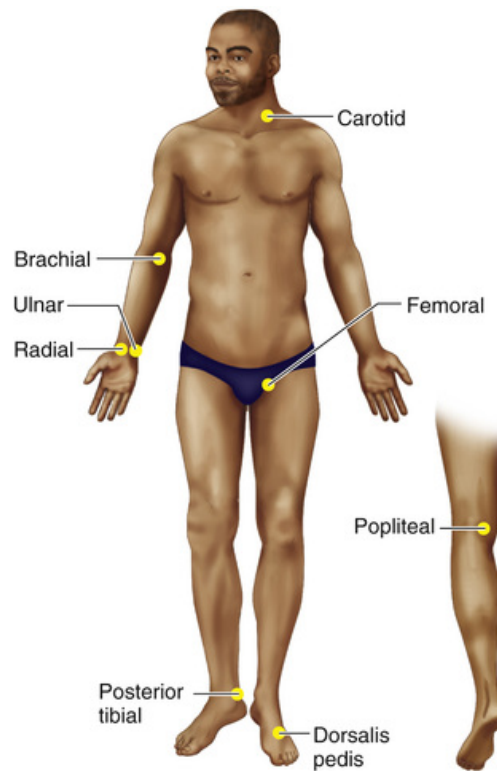

FIGURE 20.31 Anatomic locations of major arteries to be assessed for peripheral pulses.

0	Absent pulse (unable to palpate)
1	Diminished (weaker than expected; difficult to palpate)
2	Normal (able to palpate with normal pressure)
3	Bounding (may be able to see pulsation; does not disappear with palpation)

Data from Gerhard-Herman, M. D., et al. (2016). 2016 AHA/ACC guideline on the management of patients with lower extremity peripheral artery disease. *Journal of the American College of Cardiology*, doi: 10.1016/j.jacc.2016.11.007.

Normal peripheral arteries are palpable and elastic. After palpation of a peripheral pulse, the artery should return to its previous shape immediately. Abnormal findings include arteries that are hard and pulses that are not equal when compared side to side. Either abnormality could indicate an obstruction, peripheral vascular disease, or impaired circulation. Palpation of arterial pulses is performed with the fingertips of the first three fingers. In thinner patients, inspection can assist with pulse location, because arterial pulses may be visible on the skin's surface.

Safe Practice Alert

Always use the fingertips to palpate pulses. Use of the thumb is not recommended because the nurse's own radial pulse might be felt, causing confusion and an erroneous assessment finding.

Brachial pulses

To assess the brachial pulse (Fig. 20.32), support the patient's forearm in an abducted position, with the elbow slightly flexed and the forearm externally rotated. Locate the anterior aspect of the elbow, and palpate along the course of the artery just medial to the biceps tendon. The positions of the hands should be switched when probing the opposite arm.

FIGURE 20.32 Locating the brachial pulse is necessary for accurate blood pressure measurement on the upper arm.

Radial pulses

The radial artery (Fig. 20.33) is palpated on the inner aspect of the wrist in the groove closer to the thumb. On the opposite side of the wrist, the ulnar artery can be felt. The ulnar pulse is less prominent than the radial pulse and is assessed only in circumstances in which the radial pulse is not palpable. The hand normally is supplied by blood from the ulnar and radial arteries.

FIGURE 20.33 Assessment of the radial pulse is performed on the thumb side of the wrist. (Copyright Mosby's Clinical Skills: Essentials Collection.)

The Allen test (Fig. 20.34) is used to evaluate for collateral circulation to determine the patency of the arteries of the hand before arterial blood tests. The Allen test is performed by having the patient elevate the extremity and make a fist. The examiner occludes the radial and ulnar arteries, using pressure. The patient's hand should lose color. The patient then opens the fist, and the pressure is released

from the ulnar artery. The normal pink color should return to the hand within 10 seconds, showing good circulation.

FIGURE 20.34 Conducting the Allen test. (A) Occlude both the radial and ulnar arteries simultaneously. (B) Release pressure on the ulnar artery and observe for return of color to the hand.

Femoral pulses

The femoral artery ([Fig. 20.35](#)) surfaces in the upper thigh from beneath the inguinal ligament in the center of the groin. It is best palpated with the nurse standing on the same side as the femoral artery being palpated. The fingertips of the nurse's hand are firmly pressed into the groin area. Auscultation of the femoral arteries is done in the same area, which should be free of bruits.

FIGURE 20.35 Femoral pulses are best assessed with the patient in the supine or low Fowler position.

Popliteal pulses

The popliteal artery ([Fig. 20.36](#)) extends vertically through the deep portion of the popliteal space just lateral to the midline of the area behind the knee. It is difficult to

palpate and locate in obese or very muscular people. The popliteal pulse is palpated with the patient in the supine position, and the nurse uses both hands to encircle and support the knee while the patient relaxes the leg. The pulse is detected by pressing deeply into the popliteal space with the fingertips. Popliteal pulses should be assessed if more distal pulses are impalpable or unable to be heard with a Doppler.

FIGURE 20.36 Assessing the popliteal pulse.

Pedal pulses

One of two pedal pulses is assessed by palpating the posterior tibial artery (Fig. 20.37), which lies just behind the medial malleolus of the inner ankle. It can be felt by placing the fingertips around the ankle and gently indenting the soft tissues in the space between the medial malleolus and the Achilles tendon.

FIGURE 20.37 Assessing the posterior tibial pulse.

The dorsalis pedis artery (Fig. 20.38) is the other pedal pulse assessed. The nurse places the fingertips across the top of the forefoot halfway between the toes and the ankle. The artery lies superficially near the center of the long axis of the foot, between the extensor tendons of the great toe and second toe. In some people, it

may be in a slightly different location, necessitating palpation across the dorsum of the foot.

FIGURE 20.38 Assessing the dorsalis pedis pulse.

Obesity, dehydration, vasoconstriction, diminished cardiac output, edema, genetic abnormalities, or peripheral vascular disease may prevent successful detection of pedal pulses. Doppler assessment can be used to detect weak peripheral pulses ([Fig. 20.39](#)). See [Box 19.10](#) for specific Doppler procedural information and documentation.

FIGURE 20.39 Assessing a pulse using a Doppler.

Assessment for Venous and Arterial Insufficiency

To assess for venous or arterial insufficiency, observe the patient's skin characteristics, especially in the lower extremities, in both sitting and standing positions. Note any swelling, redness, nodules, protruding superficial veins, or peripheral edema. Varicose veins are enlarged superficial veins that may result from pregnancy, obesity, advanced age, or standing for long periods.

Dependent edema most often is seen in the lower extremities and usually is caused by venous insufficiency. Gross amounts of swelling in the calves and lower leg can indicate more serious conditions, such as congestive heart failure or liver disease. Assess whether the edema is pitting (see Fig. 20.6) or nonpitting by using the procedure discussed in the section on skin assessment, earlier in this chapter. Refer to Box 20.10 for documentation guidelines for pitting edema.

Phlebitis may be noted during assessment of the peripheral vascular system. **Phlebitis** is the inflammation of a vein. It typically is due to irritation, often from intravenous solutions, or infection. Assessment of the area may reveal redness, swelling, warmth, and tenderness. Measurement of the calf may show enlargement on one side of the body. Blood clots may form in areas where phlebitis is present, causing the potentially serious complication of DVT.

Safe Practice Alert

In the past, the Homans sign was used to detect phlebitis in the lower extremities. This clinical sign consists of occurrence of pain in the calf on dorsiflexion of the foot. Testing for a Homans sign is now contraindicated owing to its documented unreliability and tendency toward false-positive results and the possibility of dislodging a clot. Never use the Homans sign to assess a patient suspected of having a DVT. Do not massage a reddened area that is a suspected DVT.

Patients with arterial insufficiency often exhibit the five Ps of circulation: pain, pallor, pulselessness, **paresthesia** (numbness or tingling), and paralysis. To determine whether distal extremities are receiving adequate blood supply, assess the patient's capillary refill (see Fig. 20.8) and document it as either less than or greater than 2 to 3 seconds. Other indicators of circulatory insufficiency include lack of hair growth over distal extremities, recurring ulcers of the feet or lower legs, and brittle, thin skin.

4. Write a minimum of 10 health assessment questions that the nurse would want to ask R. T. that are specific to the purpose of her examination.

Musculoskeletal Assessment

Assessment of musculoskeletal function determines the range of joint motion, muscle strength, and associated skeletal stability (Box 20.15). Determining musculoskeletal health is especially important when the patient reports pain or loss of function in a joint or muscle or has difficulty carrying out activities of daily living.

Box 20.15

Health Assessment Questions

Musculoskeletal System

- Do you have any pain or stiffness in your joints, muscles, or back? If so, when did it begin? Where is the pain or stiffness? What is its quality? Is the pain burning, aching, shooting, constant, or intermittent? Does anything aggravate or relieve the pain?
- Are you able to perform activities of daily living, such as dressing or preparing meals, without musculoskeletal discomfort?
- Can you climb stairs and walk without limping?
- Do you have numbness or tingling in your extremities?
- Are you able to engage in strenuous activity or exercise?
- Have you experienced any recent trauma to any of your bones, joints, soft tissue, or nerves?
- Do you have any chronic illnesses that may affect the musculoskeletal system, including cancer, osteoporosis, arthritis, and renal or neurologic disorders?
- Do you have any known skeletal deformities or a congenital history that may affect the musculoskeletal system?
- Do you have any family history of arthritis (rheumatoid, osteoarthritis, ankylosing spondylitis), back problems (scoliosis, spina bifida), or genetic disorders (osteogenesis imperfecta, rickets, dwarfing syndrome)?
- Does your diet include adequate calcium and vitamin D?

Disorders that affect the musculoskeletal system arise from injury, disease conditions, metabolic disorders, and neurologic dysfunction. For further information on musculoskeletal functions, see [Chapter 28](#). Muscle strength varies from person to person, depending on the size, strength, and development of skeletal muscle in each individual. A functional and intact neurologic system with innervation to muscles is necessary to maintain the ability of muscular contraction and purposeful movement.

Inspection and Palpation of the Musculoskeletal System

Physical examination of the musculoskeletal system begins by observing the patient's gait. In walking normally, the arms swing freely at the sides with the left arm swinging forward when the right foot takes a step and vice versa. The function of muscles, joints, and bone alignment is assessed while the patient assumes several positions, including sitting, standing, prone, and supine. During these observations, the nurse notes how the patient walks, sits, changes positions, and rises from a lying or sitting position. Observe the patient in a standing position. Normally, the head is held erect, and standing posture is upright, with parallel alignment of the hips and shoulders. The body should appear symmetric when compared side to side. The spine should be aligned, with some gentle curving.

Several postural irregularities can be detected on inspection ([Fig. 20.40](#)). **Lordosis** is a condition that causes an increased lumbar curvature just above the buttocks area. **Kyphosis** is an outward curvature of the thoracic spine. **Scoliosis** is a

sideways or S-shaped curvature of the spine and is always abnormal. Minimal, not exaggerated, kyphotic and lordotic curvature is normal in most patients.

FIGURE 20.40 Abnormal curvatures of the spine. (A) Lordosis. (B) Kyphosis. (C) Scoliosis. (From Patton, K. T., & Thibodeau, G. A. [2014]. *The human body in health and disease* [6th ed.]. St. Louis: Elsevier.)

Assess the patient for signs of osteoporosis. Osteoporosis is a condition that causes weakened bones due to mineral loss. It can lead to musculoskeletal abnormalities such as exaggerated kyphosis or pathologic fractures of the spine, hip, or wrist not resulting from trauma. Osteoporosis may affect both males and females of all age groups, including children and adolescents, but it is seen primarily in older adults, especially postmenopausal women. Sudden and severe loss of height and back pain secondary to vertebral fractures often are the first clinical manifestations of osteoporosis.

With the patient in the sitting and then the standing position, evaluate the muscles, cartilage, bones, and joints for overall size, gross deformity, alignment, contour, symmetry, and position. Inspect the muscles for gross hypertrophy or atrophy, spasms, and symmetry of size. Slight differences may be noted, with somewhat increased muscle mass on the patient's dominant side. Occasionally, hands and feet are larger on the dominant side.

Carefully palpate all bones, joints, and muscles. Muscles should feel firm and normally are without masses, pain, or tenderness on palpation. A more detailed focused assessment and range-of-motion (ROM) evaluation are indicated for any area that is abnormal.

Mobility and Strength

Musculoskeletal examination includes joint ROM assessment (see [Chapter 28, Fig. 28.4](#)). Ask the patient to move all joints and extremities through their full ROM. If the patient can achieve independent movement of all four extremities, document that the patient “moves all extremities” (MAE). If the patient is unable to perform active ROM, assist the patient, using passive ROM to assess joint mobility. Normal muscle contraction and relaxation are not painful, and slight resistance to movement through the entire range is expected. Joints usually are free of pain, stiffness, swelling, inflammation, or instability. If abnormalities are detected in any joint, note the surrounding skin color and palpate for warmth and tenderness. If the

patient has **hypertonicity**, an increase in muscle tone, greater resistance will be evident on passive-movement ROM. In **hypotonicity**, a decrease in muscle tone, the muscle feels loose and flaccid during passive ROM.

Assessment of upper extremity strength can be completed by having the patient squeeze the nurse's hands and then push and pull against them. Having the patient push and pull each foot against the nurse's hands will provide an evaluation of lower extremity strength. Document assessment findings, making sure to note any difference in strength from side to side.

Deep Tendon and Cutaneous Reflexes

Deep tendon and cutaneous reflexes can be diminished or absent owing to defects in muscles, sensory neurons, lower motor neurons, and the neuromuscular junction. Acute upper motor neuron lesions and mechanical factors such as joint disease can dampen the impulse of deep tendon reflexes (hyporeflexia). Abnormally increased reflexes (hyperreflexia) are associated with upper motor neuron lesions. Note that reflexes can be influenced by age, metabolic factors (such as thyroid dysfunction or electrolyte abnormalities), and anxiety level of the patient.

Check the deep tendon reflexes by tapping areas using a reflex hammer (Fig. 20.41). The limbs should be in a relaxed and slightly stretched position, supported by the examiner, because reflex amplitude cannot be elicited in a contracted muscle group. Assess cutaneous reflexes by stroking the designated area with the handle end of a reflex hammer or the hard end of a cotton-tipped applicator. Table 20.8 describes how some of the most common deep tendon and cutaneous reflexes are assessed. As in muscle strength testing, it is important to compare each reflex side to side so that asymmetric differences can be detected. When reflexes are very brisk, clonus is sometimes seen. **Clonus** is a repetitive vibratory contraction of the muscle that occurs in response to muscle and tendon stretch.

FIGURE 20.41 Assessment of the patellar reflex. (Copyright Thinkstock.com.)

TABLE 20.8**Deep and Cutaneous Tendon Reflex Assessment**

Reflex	Technique	Normal Response
Biceps	Place your thumb on the base of the biceps tendon in the antecubital fossa of the patient's partially flexed arm. Tap your thumb with a reflex hammer.	Biceps contraction and flexion
Triceps	Hold the upper arm of the patient at a 45-degree angle away from the patient's body, while it is limp, or hold the patient's wrist across the patient's chest for flexion. Tap the triceps tendon just above the elbow.	Extension of the forearm
Quadriceps or patellar <i>knee jerk</i>	Allow the patient's leg to dangle freely. Tap the quadriceps tendon just below the patella.	Extension of the leg
Achilles <i>ankle jerk</i>	Hold the patient's dorsiflexed foot with the leg flexed and the hip externally rotated. Tap the Achilles tendon slightly above and behind the inner heel area.	Plantar flexion of the foot
Plantar	With the patient lying in supine position, stroke the bottom of the patient's foot gently from the heel to the toes, in the shape of an upside down J ending below the big toe.	<i>Adults and children:</i> Plantar flexion of the toes and forefoot <i>Infants:</i> Dorsiflexion of the big toe and fanning out of the toes (positive Babinski sign)

Reflex responses are documented using a subjective scale as follows:

4+	Very brisk, hyperactive with clonus
3+	Brisker than average, slightly hyperactive
2+	Average, normal
1+	Sluggish or diminished
0	No response

Because reflex evaluation is subjective based on the practitioner's perception, it should always be conducted within the context of a thorough neurologic examination.

Neurologic Assessment

The nervous system is the axis point for all forms of mental activity, including thought, behavior, learning, and memory. Evaluation of the motor, autonomic, behavioral, sensory, and cognitive elements of neurologic function is one of the most multifaceted segments of the patient's physical assessment (Box 20.16).

Box 20.16

Health Assessment Questions

Nervous System

- Do you have any weakness, tremors, numbness, or tingling in your arms or legs?
- Are you experiencing a loss of balance or difficulty walking?
- How would you describe your mood? Do you ever feel nervous, anxious, depressed, or confused?

- Have you noticed any problems with remembering?
- Have you ever had trauma to the head, spinal cord, or back?
- Do you have a history of meningitis or encephalitis?
- Have you ever had circulatory problems, an aneurysm, or a stroke?
- Do you have a history of seizures or convulsions? If so, when did they first occur? Describe what happens when the seizures occur. Are you on anticonvulsant medications?
- Are you having any pain? If so, where? Describe the pain.
- Do you have headaches? If so, what do they feel like?
- Do you have any dizziness, light-headedness, or fainting spells?
- Do you have any weakness or paresthesias?
- Are you having any problems with coordination or balance?
- Is there a family history of any neurologic disorders?
- Have you ever been diagnosed with a learning disability?
- List any medical or metabolic disturbances such as thyroid disease, diabetes mellitus, and hypertension.
- Do you use alcohol, recreational drugs, or prescription drugs that have mood-altering effects?
- Are you exposed to environmental or occupational hazards such as exposure to lead, insecticides, organic cleaning solvents, arsenic, or other chemicals?

The central nervous system consists of the brain and spinal cord encased in the skull and vertebrae. The peripheral nervous system consists of 31 pairs of spinal nerves that arise from the spinal cord and exit at each vertebral foramen located in the spine. Within the spinal cord, individual spinal nerves separate into ventral and dorsal roots.

A complete neurologic assessment is extensive. Neurologic screening examinations are conducted in all patients as part of the head-to-toe assessment. If abnormal findings are discovered, an in-depth assessment is performed. Knowledge of the function of each area of the brain (Fig. 20.42) and of the location of nerves within the spinal cord enables the nurse to determine the area involved when abnormal findings are discovered during an assessment.

FIGURE 20.42 Functions of each area of the brain.

Cranial Nerve Assessment

A complete cranial nerve assessment involves testing all 12 of the cranial nerves in their numbered order (Fig. 20.43). Dysfunction or irregularity alerts the nurse to an alteration in the pathway of nerve conduction along with the distribution of the cranial nerve. A popular method for remembering the order of cranial nerves is use of the rhyming phrase “On Old Olympus’ Towering Tops, A Finn And German Viewed Some Hops.” The first letter of each word in the phrase is the same as the first letter of the name of each cranial nerve listed in Table 20.9. The “Cranial Nerves” animation provides more information.📺

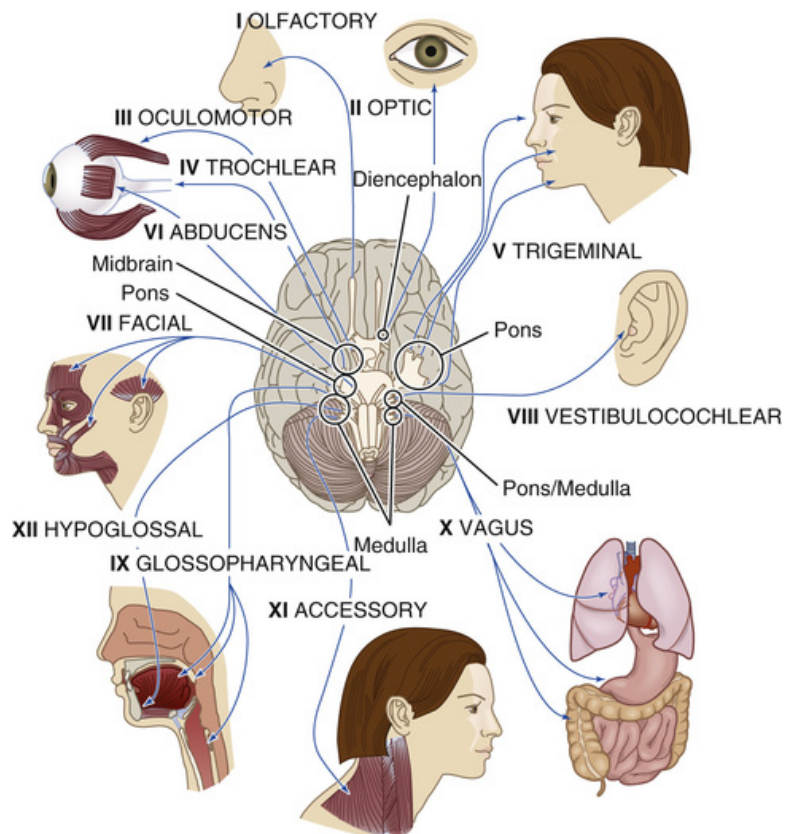

FIGURE 20.43 The cranial nerves are numbered according to the order in which they leave the brain. (Redrawn from McCance, K. L., & Huether, S. E. [2019]. *Pathophysiology: The biologic basis for disease in adults and children* [8th ed.]. St. Louis: Elsevier.)

TABLE 20.9**Cranial Nerve Function and Assessment**

Origin	Function	Assessment	Symptoms of Damage
Cranial Nerve I: Olfactory (Sensory)			
Upper nasal passages	Transmits the sense of smell	After assessing patency of both nares, have the patient close the eyes, obstruct one nare, and inhale to identify a common scent.	Bilateral decreased sense of smell occurs with age, tobacco smoking, allergic or chronic rhinitis, overexposure to chemical substances, and cocaine use. Unilateral loss of sense of smell can indicate a frontal lobe lesion.
Cranial Nerve II: Optic (Sensory)			
Eyes	Transmits visual information to the brain; located in the optic canal	Check visual acuity (have the patient read newspaper print or use a Snellen chart), and test visual fields for each eye.	Unilateral blindness can indicate a lesion or pressure in the globe or on the optic nerve. Loss of the same half of visual field in both eyes can indicate a lesion of the opposite-side optic tract, as in a cerebrovascular accident.
Cranial Nerve III: Oculomotor (Motor)			
Midbrain	Innervates four of the six muscles that collectively execute most eye movements; responsible for pupillary constriction and dilation	Assess pupil size and light reflex; note direction of gaze.	A unilaterally dilated pupil with unilateral absent light reflex and/or an eye that will not gaze upward can indicate an internal carotid aneurysm or increased intracranial pressure.
Cranial Nerve IV: Trochlear (Motor)			
Midbrain	Innervates muscles responsible for downward and inward gaze of the eyes	Ask the patient to gaze downward, temporally, and nasally. (<i>NOTE:</i> Cranial nerves III, IV, and VI are examined together because they control eyelid elevation, eye movement, and pupillary constriction.)	If the eyes will not move through the inward and downward gazes, the patient may have a fracture of the eye orbit or a brainstem tumor.
Cranial Nerve V: Trigeminal (Sensory and Motor)			
Pons	Is responsible for the corneal reflex; receives sensation from the face and innervates the muscles of mastication	<i>Motor:</i> Palpate jaws and temples while patient clenches teeth. <i>Sensory:</i> With the patient's eyes closed, gently touch a cotton ball to all areas of the face.	Unilateral deficit is seen with trauma and tumors.
Cranial Nerve VI: Abducens (Motor)			
Pons	Innervates muscles responsible for outward gaze of the eyes	Assess directions of gaze.	Inability to gaze outward may indicate a fracture of an orbit or a brainstem tumor.
Cranial Nerve VII: Facial (Sensory and Motor)			

Origin	Function	Assessment	Symptoms of Damage
Pons	Provides motor innervation to the muscles of facial expression; receives the sense of taste from the anterior two thirds of the tongue; provides innervation to the salivary glands (except parotid) and the lacrimal gland	<i>Motor:</i> Check symmetry of the face by having the patient frown, close eyes, lift eyebrows, and puff cheeks. <i>Sensory:</i> Assess the patient's ability to recognize taste (sugar, salt, lemon juice).	An asymmetric deficit can be found in traumatic injury, Bell's palsy, cerebrovascular accident, tumor, and inflammation.
Cranial Nerve VIII: Vestibulocochlear or Auditory-Vestibular (Sensory)			
Medulla oblongata	<i>Vestibular branch:</i> Carries impulses for equilibrium <i>Cochlear branch:</i> Carries impulses for hearing	Assess the patient's ability to hear a spoken and whispered word.	Impairment may result from inflammation or occlusion of the ear canal, infection, drug toxicity, or a possible tumor or may cause vertigo.
Cranial Nerve IX: Glossopharyngeal (Sensory and Motor)			
Medulla oblongata	Receives taste from the posterior third of the tongue; provides innervation to the parotid gland; and provides motor innervation for swallowing	<i>Sensory:</i> Assess the patient's ability to taste sour or sweet on last two thirds of tongue. <i>Motor:</i> Check for presence of the gag reflex by inserting a tongue blade two thirds into the pharynx.	Deficits in taste or gag reflex can indicate a brainstem tumor or neck injury.
Cranial Nerve X: Vagus (Sensory and Motor)			
Medulla oblongata	Supplies innervation to the larynx and soft palate responsible for speech and swallowing; provides parasympathetic fibers to nearly all thoracic and abdominal smooth muscles	Depress the tongue with a tongue blade, and have the patient say "ah" or yawn. The uvula and soft palate should rise and be symmetric. Assess speech for hoarseness.	Dysphagia can indicate swallowing problems and the potential for aspiration.
Cranial Nerve XI: Spinal Accessory (Motor)			
Medulla oblongata (cranial root) and spinal cord (spinal root)	<i>Cranial root:</i> Works with vagus nerve to control the muscles of the soft palate, pharynx, and larynx <i>Spinal root:</i> Innervates muscles of the neck and back	Have the patient rotate the head and shrug the shoulders against passive resistance.	If the patient is unable to perform a shoulder shrug or head rotation, this may indicate a neck injury.
Cranial Nerve XII: Hypoglossal (Motor)			
Medulla oblongata	Provides motor innervation to muscles of the tongue not innervated by the vagus nerve and to other glossal muscles; is important for swallowing and speech articulation	Assess tongue control (e.g., have the patient stick out the tongue and move it from side to side).	Inability to stick out the tongue may be associated with swallowing or articulation difficulties.

Sensory Nerve Assessment

The central nervous system is composed of sensory pathways that detect and conduct sensations of pain, temperature, vibration, position, and touch. Sensory receptors transmit messages to the spinal cord, from which they then travel to the brain to be interpreted. Screening for sensory nerve dysfunction can be accomplished during other parts of the physical examination, such as during skin assessment. With eyes closed, the patient should feel dull and sharp sensory stimuli equally on both sides of the body. Ask the patient to describe the quality of each stimulus, and note the presence or absence of bilateral symmetry when the stimuli are applied to the patient's extremities and trunk. Compare distal with proximal sensations. [Fig. 20.44](#) illustrates the dermatomes of the body associated with each spinal nerve. Knowledge of the dermatomes will help locate problem areas. If any

abnormalities are found, such as numbness, tingling, or lack of sensation, further assessment should be performed. For example, if numbness is present in the index and middle fingers of either hand or bilaterally, a neurologic lesion or spinal compression of C7 or C8 vertebrae may be the causative factor.

FIGURE 20.44 Dermatomes. (From Linton, A. D. [2012]. *Introduction to medical-surgical nursing* [5th ed.]. St. Louis: Saunders.)

Motor Nerve and Coordination Assessment

Assessment of motor function can be combined with musculoskeletal assessment. The focus of this combined evaluation is the body's motor responses and cerebellar function, including synchronized muscular activity, posture, and balance. Motor skill tests examine the movement of muscles in the body. Motor skills are divided into two groups: gross motor skills, which include the larger movements of arms, legs, or the entire body (e.g., walking, running, jumping), and fine motor skills,

which include activities using the smaller muscles of the fingers, hands, or feet and hand–eye coordination. To test gross motor skills during the assessment, assess the quality of the patient's actions for smoothness and ease of movement. Older adults normally exhibit a slower reaction time, which causes movements to be delayed or to appear less fluid.

To test fine motor skills and function, have the patient perform actions such as transferring an object from one hand to the other successfully, picking up and holding two or more objects in the same hand, turning pages one at a time, and writing a signature. To assess the lower extremities for fine motor movement, place a hand just below the toes on the bottom of the patient's foot and have the patient tap the foot in quick, successive, movements. Test each foot to establish symmetry. When testing fine motor movements, understand that the feet do not move as rapidly or as precisely as the hands.

Balance can be assessed using any of several methods. The Romberg test, which is conducted during ear assessment to evaluate equilibrium, is one method (see [Fig. 20.18](#)). A loss of balance indicates a positive result on Romberg testing and may be due to a cerebellar lesion or dysfunction. Another method of assessing balance is to ask the patient to close the eyes and stand on one foot and then the other, holding each position for at least 5 seconds. Normally, patients are able to maintain balance for a minimum of 5 seconds with the eyes closed. A third method is to have the patient walk in a straight line (with eyes open) by placing the heel of one foot directly in front of the toes of the other foot while maintaining balance. Normally, patients are able to walk heel to toe without losing balance.

Safe Practice Alert

Always protect the patient from falling by remaining close during balance testing. Instruct patients to open their eyes if they lose their balance or feel that they are going to fall.

Mental Status Assessment

The patient's mental status indicates the level of cerebral function. Obtaining a baseline appraisal of the patient's abilities helps the nurse plan patient education, assess understanding of instruction, and determine the patient's capacity to make decisions. Assessment of mental status evaluates brain function related to intellect, behavior, language, memory, knowledge, judgment, association, attention, level of consciousness, decision making, and abstract thinking.

The Glasgow Coma Scale is an objective assessment tool used to define a person's level of consciousness by assigning a numeric value to the person's level of arousal. The scale is divided into three areas: eye opening, verbal response, and motor response. Each area is scored separately, and a number is assigned to the person's best response. The three numbers are added, and the total score reflects the patient's level of consciousness. A fully alert, normally responsive patient will have a score of 15. Scores from multiple assessments can be plotted on a graph to provide a visual illustration indicating that the patient is stable, improving, or deteriorating. A score of less than 7 reflects a patient who is comatose. Refer to [Table 20.10](#) for the Glasgow Coma Scale.

TABLE 20.10**Glasgow Coma Scale**

Response	Level of Arousal	Scoring (Points)
Eye opening	Spontaneous	4
	To verbal command	3
	To pain	2
	None	1
Verbal	Oriented	5
	Confused but able to answer questions	4
	Inappropriate responses, words discernible	3
	Incomprehensible speech	2
	None	1
Motor	Obeys commands	6
	Purposeful movement to painful stimulus	5
	Withdraws from pain	4
	Abnormal (spastic) flexion, decorticate posture	3
	Extensor (rigid) response, decerebrate posture	2
	None	1
Possible total score range		3–15

During initial encounters, the nurse can gather a great deal of information about the patient's cognitive and mental abilities by conversing with the patient. The patient's responses to questions enable the nurse to determine thought processes, knowledge, and behavior. Level of orientation and mental status are assessed by determining the patient's ability to identify person, place, time, and situation.

Person: "What is your full name?"

Place: "Where are you?"

Time: "What (day, month, season, or year) is it?"

Situation: "What happened that caused you to come to the hospital?"

If a patient is able to respond appropriately to all four questions, the nurse documents that the patient is alert and oriented $\times 4$ (A & O $\times 4$). In some cases, hospitalized patients may have difficulty recalling the current date or time but remain completely oriented to person and place, making them alert and oriented $\times 2$. In some healthcare settings, orientation is assessed by using only three parameters; person, place, and time. If the patient responds accurately to all three, the nurse documents that the patient is alert and oriented $\times 3$ (A & O $\times 3$). Assessment of orientation and mental status continues whenever the nurse observes the patient's behavior and ability to concentrate during each interaction.

Assess the patient's short- and long-term memory. Ask the patient to demonstrate short-term memory by having the patient recall three words or numbers chosen by the nurse. Later in the interview, ask the patient to repeat the same three words or numbers used earlier in the assessment. The patient should be able to accurately recite the list. Another way to test patient short-term memory is to ask what occurred earlier in the same day. This can be validated with another staff member or a family member. To assess long-term memory, ask the patient to recall a date or name from the past that can be verified with a family member.

To assess cognitive abilities such as knowledge, decision making, and judgment, ask questions about health status and any chronic or current illnesses. Listening to the patient's description of illness, treatment, and medications enables the nurse to assess language use, patient understanding, and decisions made by the patient

concerning health care. On the basis of information shared by the patient during knowledge assessment, the nurse can interpret the need for patient teaching and reinforce needed information at follow-up visits.

Abstract thinking and association are higher level cognitive functions. To determine a patient's ability to interpret abstract concepts, ask the patient to explain a common idiom, such as "penny wise and pound foolish." If patients are able to interpret idioms, it is more likely that they will be able to comprehend and apply medication and treatment instructions. Keep in mind that a person whose primary language is different from that of the examiner may be unable to interpret idioms regardless of having intact higher level cognitive functions. To assess association, ask the patient to relate concepts such as parrot and bird or guitar and music. Be sure to use simple concepts that are appropriate to the patient's culture and developmental level. If the patient is able to explain idioms and the relationship between associated concepts, higher level cognitive functions are intact. Assessment tools are being updated to assess higher level cognitive function that take into consideration the influence of culture and language.

Emotional Assessment

The patient's emotional state can be quickly assessed by noting general demeanor and facial expressions, which play a crucial role in interpersonal communication, during interactions with the patient. Assess whether the patient appears calm and comfortable and is at ease with the surroundings. Some discomfort related to the nature of the visit or hospitalization may be evident, but overall the patient should appear relaxed. Note any signs of emotional stress, which may be triggered by a crisis that places the nervous system under severe strain. This could be an event such as losing a loved one, seeing someone die, or experiencing a life-threatening situation. Emotional stress chemically alters how the brain works and can affect the immune system, making the affected person more susceptible to infection or disease. Severe emotional trauma can lead to development of posttraumatic stress disorder.

Emotional stress is not always due to sudden events. It can arise from stressors that accumulate over time to an overwhelming level that prevents the patient from thinking about anything other than problems that appear to have no solution. Emotional stress can lead to detachment, inability to concentrate, fatigue, and memory problems. Assessment of the patient's emotional status is completed throughout the physical examination, with a particular focus on patient reports of the inability to fall asleep and stay asleep at night, decreased or increased appetite, and weight gain or loss.

Abdominal Assessment

Abdominal assessment focuses on both the gastrointestinal and urinary systems. In seeking information about these systems, however, it is important to broaden the focus to include areas outside of the abdomen ([Box 20.17](#)).

Box 20.17

Health Assessment Questions

Abdomen

Gastrointestinal Tract

- Do you have any pain or difficulty with swallowing?
- Have you experienced difficulty eating, weight change, or lack of appetite?
- Do you have nausea, vomiting, regurgitation of food, heartburn, indigestion, or bloating? If so, what do you do to relieve the symptoms?
- Are you experiencing abdominal pain? If so, what are the characteristics of the pain? Are there any associated symptoms? Does anything relieve the pain?
- What is your typical 24-hour food intake?
- Have you experienced any changes in bowel habits: Diarrhea, constipation, incontinence, or frequent passing of gas?
- Have you noticed any blood in your stool?
- Do you have problems with hemorrhoids?
- Have you ever had abdominal surgery?
- Do you or any family members have a history of abdominal illnesses such as gallbladder disease, cancer, or irritable bowel syndrome?

Urinary Tract

- Are you experiencing any difficulty with urination: Frequency or difficulty starting or stopping your stream of urine?
- Do you have a history of urinary tract or kidney infections or kidney stones?
- Is there pain or burning when you urinate?
- Have you noticed a change in your frequency of urination: Less often or more often than previously?
- Do you feel that you empty your bladder when you urinate?
- Do you have to get up at night to urinate? If so, how many times?

Abdominal assessment begins with inspection, followed immediately by auscultation, and is completed with palpation and percussion. The nurse performs auscultation before palpation because pressure on the abdomen disturbs the gastrointestinal tract, altering the occurrence and character of bowel sounds. The most common way to assess the abdomen is to visualize dividing it into four quadrants with a horizontal and a vertical line through the umbilicus (Fig. 20.45). The upper border of the abdomen is the xiphoid process, and the lower is the symphysis pubis. Knowledge of the location of abdominal cavity organs, including the liver, spleen, pancreas, gallbladder, stomach, urinary tract, and bladder and intestines, enables the nurse to detect normal and abnormal findings during abdominal assessment.

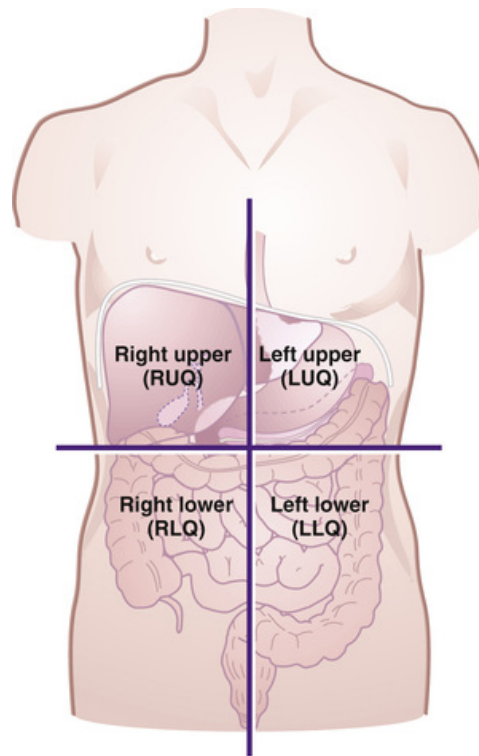

FIGURE 20.45 Abdomen divided into four quadrants at the umbilicus for bowel sound assessment. (From Black, J. M., & Hawks, J. H. [2009]. *Medical-surgical nursing: Clinical management for positive outcomes* [8th ed.]. St. Louis: Saunders.)

The gastrointestinal and urinary systems lie within the abdominal cavity and consist of vital organs for energy processing and waste disposal. The organs within the abdominal cavity are surrounded by the peritoneum, a serous membrane that forms the protective cover over the abdominal structures. Bowel elimination is discussed further in [Chapter 40](#). Additional discussion of urinary elimination can be found in [Chapter 41](#).

Abdominal Inspection

The nurse progresses through the examination using a systematic method of assessment to ensure that all abdominal organs are fully evaluated. Visually divide the abdomen into right upper quadrant, left upper quadrant, right lower quadrant, and left lower quadrant and picture the organs in each quadrant.

Ask the patient to lie supine, in the dorsal recumbent position, with arms at the sides and knees slightly bent. A small pillow may be used to provide support for the knees. Expose only the area of the abdomen between the xiphoid process and the symphysis pubis. Ask the patient to point out any areas of pain or tenderness during inspection, and be careful to assess those areas last during palpation. Patients with severe abdominal pain may have diminished respiratory movement and tight abdominal muscles and may use their hands or arms to guard or splint the abdomen in an effort to prevent further pain.

The nurse visually inspects the skin over the abdomen, noting color, tone, scars, bruises, lesions, venous patterns, **striae** (stretch marks resulting from pregnancy or from weight loss or gain), drains, tubes, and stomas. The skin color and characteristics should be similar to those of the rest of the body, and underlying

venous patterns should appear faint. Scars are inspected for keloid formation (a raised scar after an injury has healed). Any abnormal findings should be discussed with the patient to determine the origin. Incisions or scarring may be the result of surgery or accidental injury and could indicate changes in the internal organs. Bruising may be a sign of accidental injury, bleeding disorders, injection sites, or physical abuse. Inspect the abdomen for visible protrusion or bulges, which may be due to abdominal or umbilical hernias. A slight lump or protrusion can occur over a distended urinary bladder or loops of bowel.

Normally the abdomen is without bruising, pain, lumps, or scars. The umbilicus should be midline, and hair should be evenly distributed across the abdominal skin surface. Movements or pulsations of the abdomen can indicate an abdominal aortic aneurysm or can be a normal finding in very thin patients. To examine the abdominal musculature, ask the patient to link the hands behind the head or neck; then flex the head forward in a semicrunch position. This position permits any superficial abdominal wall masses, herniation, and muscle irregularities to become obvious. The abdomen may be flat, concave, or convex, but with all shapes, the abdominal contour should be symmetric and without masses. Obese patients may have a large amount of adipose tissue in the abdominal area, causing a convex appearance.

Symmetric swelling of the abdomen, also known as *distention*, occurs when intestinal gas (flatus), excess fluid, or a tumor is present in the abdominal cavity. The skin over the abdomen may appear stretched and shiny, and the sides (flanks) of the patient's abdomen may bulge, depending on the cause of distention.

Normally the bladder is not visible on inspection. A palpable large, firm area in the lower abdomen above the pubis symphysis often is due to a distended bladder. The inability of the bladder to empty may be caused by a condition called *neurogenic bladder* (bladder paralysis). In patients with this condition, the bladder is unable to fully contract because of impaired nerve innervation. This deficit causes it to become flaccid and distended, resulting in only partial emptying and continual dribbling of small amounts of urine. Neurogenic bladder can occur at any age, but it is especially common among older patients with chronic disease conditions that directly or indirectly affect the vasculature, innervations, musculature, or output of the bladder. Bladder paralysis is seen in quadriplegic people and some paraplegics, depending on the level of spinal injury or impairment.

Auscultation of the Abdomen

Auscultation of the abdomen is performed for the detection of altered bowel sounds, rubs, or vascular bruits. Normal **peristalsis** (progressive wave action causing movement of contents through the gastrointestinal system) creates bowel sounds that may be altered or absent owing to certain clinical conditions or diseases. Auscultation is performed before palpation or percussion of the abdomen to avoid artificial stimulation of the bowel, which may alter bowel sounds. Avoid auscultation of the abdomen immediately before and after meals.

To begin auscultation of the abdomen, position the patient comfortably in the supine position, as just described for inspection. The diaphragm of the stethoscope is placed on the abdomen with gentle pressure, and the nurse listens over each of the four quadrants of the abdomen for the presence of bowel sounds. Normally, as air and fluid move through the intestinal tract, they create soft gurgling sounds that occur in an irregular pattern every 2 to 5 seconds. Sounds can be brief or last a few seconds, depending on bowel stimulation or motility. Under normal circumstances,

it takes up to 30 seconds to hear bowel sounds. Bowel sounds can be described as normal, audible, absent, hypoactive (occurring infrequently), hyperactive, or distant. If bowel sounds are not readily audible, listen for 5 minutes in each quadrant to verify a total absence of bowel sounds.

The absence of bowel sounds is an abnormal finding that occurs below a bowel obstruction or in patients with paralytic ileus (paralysis due to lack of peristalsis) or peritonitis. After any type of abdominal surgery or childbirth by cesarean section, intestinal activity frequently is reduced or temporarily inactive, causing bowel sounds to be distant, hypoactive, or absent. As the bowel recovers from surgical stress or manipulation, bowel motility increases, and bowel sounds should become active and audible again.

If the intestinal tract is overstimulated or has increased motility, hyperactive bowel sounds, known as **borborygmi**, are heard as a loud “grumbling.” Hyperactive sounds can be caused by diarrhea, intestinal inflammation, laxative use, intestinal bleeding, and anxiety. Hyperactive bowel sounds may be audible above the level of a bowel obstruction.

Auscultation for abdominal bruits is the next phase of abdominal examination. Bruits are “swooshing” sounds heard over the major arteries that are caused by **stenosis** (narrowing) of the vessels. Auscultation with the bell of the stethoscope over all four quadrants (renal arteries in the upper quadrants and iliac arteries in the lower quadrants), over the epigastric region (aorta), and in the groin (femoral arteries) can detect bruits. Under normal conditions, no vascular sounds are heard over the aorta or renal, iliac, or femoral arteries. Loud systolic bruits are due to atherosclerotic plaques within the arteries, producing turbulent flow. These plaques are common in the aorta and iliac arteries and less common in the renal arteries.

Palpation of the Abdomen

Ask patients with abdominal pain to point to the area of discomfort so that palpation of that area can be performed last. Palpate each quadrant systematically. When palpating the abdomen, begin with light palpation, using the fingertips of one hand to examine the patient's abdominal wall. Light palpation can detect bladder distention and any irregularities of the abdominal wall such as lipomas or hernias and can reveal tenderness, assess muscle integrity, and identify masses.

When abdominal tenderness is elicited, it should be described according to its location (quadrant), depth of palpation required to elicit it (superficial or deep), and the patient's response (mild or severe). Spasm or rigidity is the involuntary tightening of the abdominal musculature that occurs due to inflammation of underlying abdominal structures. Rigidity can be caused by conditions such as peritoneal inflammation, appendicitis, or acute cholecystitis. Guarding is a voluntary contraction of the abdominal wall musculature to avoid pain. Guarding often can be overcome by having the patient purposely (consciously) relax the muscles.

Rebound tenderness is abdominal pain that occurs immediately after the removal of the examiner's hand after depression of an abdominal area. Palpation for rebound tenderness usually is a difficult skill for the beginning nurse to master. The most common error is removal of the hand too quickly, with an exaggerated motion that surprises the patient. Observe the patient for pain, facial grimace, or spasm of the abdominal wall during palpation. Both tenderness and rebound tenderness can be elicited by palpation in an opposite or different quadrant. Thus palpation of the left lower quadrant may produce tenderness and rebound tenderness in the right

lower quadrant in appendicitis. This transfer of the discomfort is called *referred tenderness* or *rebound*.

Palpation is used to evaluate the patient for ascites, an abnormal accumulation of fluid in the peritoneal cavity. A rounded, symmetric contour of the abdomen that is taut with bulging flanks is seen during inspection of the patient with ascites. Palpation of the abdomen in patients with ascites often yields a wavelike, almost fluctuant sensation. In advanced cases, the abdominal wall is stretched because of distention from excessive fluid. Gas-filled intestines will float to the top of an abdomen filled with fluid.

Breasts and Genitals

Assessment of the male or female patient's breasts and genitals for cancer or tissue abnormalities begins with attention to the patient's safety and privacy, as well as respect for the patient's feelings about preventive care concerning reproductive health. Comfort with the examination for both males and females can be achieved through correct positioning of the patient and the use of a calm and relaxed approach by the nurse. A matter-of-fact approach in asking questions that deal with potentially sensitive issues helps the patient relax and feel safe (Box 20.18). Remember to take the age of the patient into consideration when preparing to examine the breasts and genitalia.

Box 20.18

Health Assessment Questions

Breasts and Genitals

Breasts: Male and Female

- Have you noticed any changes in the look or feel of your breasts?
- Do you have mammograms done? If so, how often? When was your last mammogram?
- Have you had any nipple discharge or discomfort?
- Do you or any family members have a history of breast cancer?
- Have you ever had surgery on your breasts?

Female Genitals

- When was your last menstrual period? Do you have symptoms associated with your period?
- Have you ever been pregnant? If so, when? Do you have living children? If so, how many?
- Are you sexually active? Do you practice safe sex?
- Have you ever been diagnosed with a sexually transmitted infection (STI) or sexually transmitted disease (STD)?
- Do you use contraception?
- Are you having any pain or difficulty associated with intercourse?

- Have you used hormones for contraception or for postmenopausal symptoms?
- Do you drink caffeine or alcohol?
- Have you experienced vaginal discharge, painful lumps or tissue abrasions or tears in the perineal area, or genital warts or lesions?
- Do you have a family history of endometrial, ovarian, or cervical cancer?

Male Genitals

- Have you noticed any changes in urination flow or frequency? Does your urine have an odor?
- Are you sexually active? Do you practice safe sex?
- Have you ever been diagnosed with a sexually transmitted infection (STI) or sexually transmitted disease (STD)?
- Do you have any pain, swelling, or discharge from your penis?
- Have you noticed any lumps, enlargement, or pain in your testicles?
- Do you do a monthly self-testicular examination?
- Do you have swelling or any protrusion in your groin? If so, does it get worse when you cough or lift heavy objects?
- Do you have difficulty with achieving or maintaining an erection or with the process of ejaculation?

Breast Assessment

A primary responsibility of the nurse during breast assessment is to discuss the importance of women and men being familiar with the look and feel of their breasts and reporting any changes to their primary care providers immediately. The American Congress of Obstetricians and Gynecologists (ACOG, 2017) recommends breast self-awareness rather than breast self-examination (BSE), and annual mammograms for women beginning at age 40. Multiple research findings indicate a lack of support for BSE as a reliable screening tool for breast cancer, citing a high number of false-positive results and unnecessary biopsies (ACS, 2018). However, BSE may be a valuable tool for breast self-awareness. Information on BSE is available at http://www.breastcancer.org/symptoms/testing/types/self_exam.

Breast cancer screening guidelines vary among the American Cancer Society (ACS), United States Preventative Services Task Force (USPSTF), and the National Comprehensive Cancer Network (NCCN). Decisions as to what screening guidelines to follow need to include several factors including patient preference, patient age, and identified risk factors (Baron, Drucker, Lagdamen, et al., 2018). Breast cancer risk assessment tools may also be helpful for decision making. An example is available from the National Cancer Institute at <https://www.cancer.gov/bcrisktool/>.

Clinical breast examinations are recommended every 1 to 3 years for women 29 to 39 years old and annually for women 40 and older (ACOG, 2017). Clinical breast examinations are typically conducted by physicians, certified nurse midwives, or nurse practitioners. Depending on the purpose of a physical exam, concerns of the patient, or lack of access to primary care providers, the nurse may conduct a breast assessment.

Inspection of the Breasts

If indicated, begin breast assessment with the patient standing or sitting with the arms hanging loosely at the sides. Have the patient lower the gown so that both breasts can be compared for symmetry, size, and shape. The breasts normally are almost symmetric in shape and size, with one breast often slightly larger than the other. As a normal sign of aging, the supporting ligaments of the breasts, known as *Cooper ligaments*, become weak and elongate from the effects of gravity, causing the breasts to sag and the nipples to lower with the surrounding tissue. Even with this elongation, the shape and symmetry of the breasts usually are preserved.

Observe breast contour and the skin covering the breast tissue. Note any lumps, masses, flattening, retraction, or dimpling of the breast tissue, as well as any drainage, bruising, or excoriation. The shape of the breast varies from one person to another and can be described as convex, pendulous, conical, or flat. Nipples can be inverted, everted, or flat and should not have any visible drainage unless the patient is a female who is breastfeeding.

To assess the breasts for symmetry, ask the patient to raise the arms above the head, then press the hands against the hips, and then extend the arms straight ahead while sitting and leaning forward. Observe the breasts for any retraction or dimpling that can result from invasion of underlying ligaments and tissues by tumors. If a tumor or malignancy is present, the ligaments of the affected breast will pull the skin and tissues toward the tumor, forming a retraction or dimpled area. Document the location of any abnormalities using a systematic approach that divides the breast into four quadrants extending into the axillary areas (Fig. 20.46).

Right breast

FIGURE 20.46 The breast divided into four quadrants for systematic examination.

The skin covering the breast can give important clues about the underlying breast tissue. Note the color, venous pattern, and presence of lesions, erythema, dimpling, or inflammation. Lift large or pendulous breasts to observe the underside and the lateral aspects. Patients with large or pendulous breasts or those who wear undergarments that are too tight or conforming can have redness or excoriation on the outer surface of the skin around the breasts, caused by rubbing of the garments or skin-to-skin contact. Patients with excessive moisture from sweat or wet garments can develop a rash or skin excoriations.

Observe the nipples and areolas for size, shape, color, texture, lesions, and discharge. Areolas should be symmetric, pink to dark brown, and round. Nipples normally are everted and point in the same direction relative to the breast. Abnormal findings include dimpling, rashes, or sores anywhere on the breast, extreme asymmetry, and bleeding or discharge from the nipples.

Palpation of the Breasts

Although breast palpation is typically done by an advanced practice nurse or physician when concerns arise, it is important for all nurses to be aware of how to assess underlying breast tissue and the local lymph nodes. Because of the location of glandular tissue, a large portion of lymphatic drainage from the breasts circulates through the axillary lymph nodes. Metastatic cancers or malignancies can rapidly spread to the axillary lymph nodes and beyond. Therefore the axilla is palpated bilaterally when doing a breast assessment. To palpate the lymph nodes, ask the patient to sit with the hands and arms relaxed at the sides. Face the patient, and stand on the side that is to be examined. Support the patient's arm in the flexed position, and raise the arm away from the chest wall. Palpate the axillary area using the hand not supporting the patient's arm. Using the fingertips, gently depress the skin surface, and gently roll the soft tissue underneath the fingertips. Examination includes palpating the entire axilla, the pectoralis major and lateral oblique muscles, and the chest wall in the midaxillary line, as well as along the clavicular ridges. Under normal circumstances the lymph nodes are not palpable. If lymph nodes are felt, note their location, consistency, mobility, size, and number. Palpable nodes that are suspect for malignancy are firm, tender, and nonmobile. Repeat the procedure on the patient's other side.

Instruct the patient to lie down in the supine position and raise one arm behind the head. This position causes the breast tissue to flatten against the chest wall. On the side with the arm raised, use the pads of the first three fingers to compress the breast tissue gently against the chest wall, noting the characteristics of the fleshy tissue. Breast malignancies most frequently are located in the upper outer quadrant. Any abnormalities or new findings should be discussed immediately with the patient's health care provider for further diagnostic studies.

The consistency of normal breast tissue can vary across the life span, from person to person, and between genders. The breasts of a younger patient usually are firm and elastic, with denser tissue mass. In older patients, breast tissue feels soft, nodular, and fibrous. When palpating large or pendulous breasts, support the breast in one hand while using the other hand to gently palpate the breast tissue. Palpation of the breasts should not elicit a pain response. A benign condition, fibrocystic breast disease, typically is characterized by lumpy, unilateral or bilateral cysts that can be painful on palpation. The cysts are more noticeable just before, during, and for a short period after menses and can be exacerbated by increased caffeine intake. Cystic breasts contain palpable lumps that are soft and movable and appear in the same area monthly.

When palpating the nipple and areola, note the consistency of the underlying tissue and any color changes that occur with gentle compression. Carefully pinch the nipple, encompassing the surrounding tissue just beneath. Observe for discharge, and palpate for masses. It is not uncommon for malignancies to be located just beneath the nipple as a barely perceptible mass. Although breast cancer is rare in men, those who have a first-degree relative (father, mother, or sister) with a history of breast cancer are at greater risk for developing the disease and need to be alert to any changes.

The importance of a healthy lifestyle on breast cancer reduction in women has been the focus of extensive research during the past decade. [Box 20.19](#) summarizes research findings that address the impact of lifestyle changes on risk reduction. The performance of a physical examination is an excellent time for the nurse to discuss disease prevention strategies with patients.

Box 20.19

Evidence-Based Practice and Informatics

Breast Cancer Risk Reduction

Several modifiable factors have been shown to potentially reduce the risk for breast cancer in women.

- It is estimated that approximately 23% of breast cancers in postmenopausal women could potentially be prevented by those women maintaining a body mass index (BMI) of less than 25 (Engmann, et al., 2017).
- Some research indicates that women who participate in aerobic activity approximately 3 to 4 hours per week have a 20% to 40% lower risk of breast cancer. Reported risk reduction for physically active women varies between 20% and 80%, depending on the study (Office of Disease Prevention and Health Promotion, 2018).
- Research indicates that both premenopausal and postmenopausal women benefit from increased physical activity (Kraschnewski & Schmitz, 2017). Vigorous exercise and walking are associated with reduced risk for breast cancer in women, including African American women (Gong, et al., 2016).
- Many studies reveal a relationship between consumption of one or two alcoholic drinks per day by women and a 30% to 50% increase in the incidence of breast cancer. Current recommendations are for women to refrain from alcohol consumption or limit their alcohol intake to no more than one drink per day (Centers for Disease Control and Prevention, 2018).
- A dose-dependent relationship exists between long-term alcohol consumption and breast cancer (Jayasekara, MacInnis, Room, & English, 2016).
- Extensive research has been conducted on the effect of a low-fat diet (with increased consumption of fruits and vegetables) on breast cancer risk. The evidence suggests that the effect of dietary intake on breast cancer risk is much greater during adolescence and young adulthood (Jung, et al., 2016).
- Smoking has been associated with a higher risk of breast cancer for many years. Studies indicate that high pack-years and early initiation of smoking is associated with an increased breast cancer risk (Mehta, et al, 2018).

Assessment of the Female Genitalia

Explain the procedure and reasons for genital assessment before the examination. Correct positioning and draping provides privacy and assurance that only the portions of anatomy that need to be exposed are being viewed. Examination includes assessment of the reproductive organs, external genitalia, and anus using inspection and palpation (Fig. 20.47). Examination of the internal reproductive organs using a vaginal speculum and digital examination of the rectum are usually performed by an advanced practice nurse or a physician.

FIGURE 20.47 External female genitalia. (From Herlihy, B. [2018]. *The human body in health and illness* [6th ed.]. St. Louis: Elsevier.)

Safe Practice Alert

Always wear gloves during assessments that may involve contact with mucous membranes.

Apply clean gloves before beginning the examination. With the patient in the dorsal recumbent position, inspect the outer genitalia for redness, swelling, lesions, masses, or infestations. Note the hair growth and distribution in the pelvic area. Preadolescents have no pubic hair; however, adolescents may have sparse hair growth along the labia that becomes darker and coarser toward the mons pubis. In adults, pubic hair, which usually has a curly, coarse texture, grows in a triangular pattern across the mons pubis and perineum and can extend along the inner thigh. Pubic hair thins, lightens, and becomes more sparse with aging.

Safe Practice Alert

Always palpate female genitalia from front to back. This pattern will prevent contamination of the urinary meatus by microorganisms commonly found near the anus.

Palpate the inguinal area for presence of lymph nodes. Carefully separate and palpate the labia majora and minora. Inspect the labia, the folds in between, and the clitoris. Note any redness, swelling, lesions, or discharge. Normally, the skin of the perineum is clean, smooth, and a slightly darker pink color than the skin surrounding it. The mucosal surface should be warm and moist. The labia folds should be symmetric and without lesions. The size of the clitoris can vary from woman to woman; however, it normally does not exceed 2 cm in length and approximately 0.5 cm in width. Note any inflammation, abnormal color, or atrophy. The presence of syphilitic lesions or chancres can be noted during external physical

examination of the skin folds. They often appear as small open ulcers with purulent or serous drainage. Note the urethral meatus in relation to the other structures of the perineum. The urethral meatus is anterior to the vaginal orifice and should appear smooth, moist, and pink. Inspect the vaginal orifice for color, smoothness, and moisture.

Inspect the anus, noting any redness, swelling, or hemorrhoids. Palpate the perianal area for lesions or nodules. When examination of the female genitalia is complete, replace the drape or covering. Remove gloves and wash hands, using standard precautions.

Assessment of the Male Genitalia

Assessment of the male genitals includes inspection and palpation of the external genitalia, the inguinal ring, and the inguinal canal (Fig. 20.48). It is an essential part of any health maintenance examination for all age groups. The patient can stand or lie supine, appropriately draped for privacy. Clean gloves should be worn by the examiner throughout the assessment.

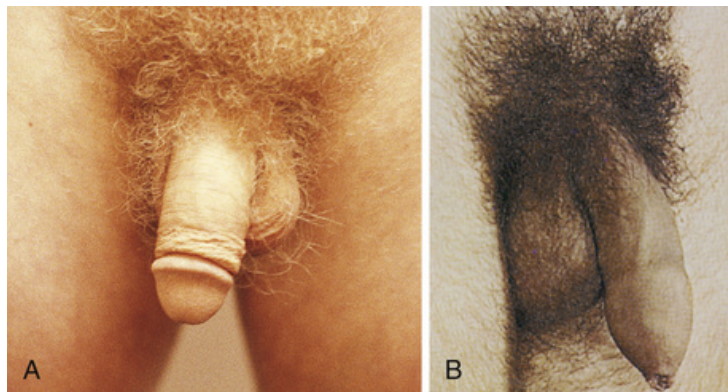

FIGURE 20.48 External male genitalia. (A) Circumcised. (B) Uncircumcised. (From Ball, J. W., Dains, J. E., & Flynn, J. A., et al. [2019]. *Seidel's guide to physical examination* [9th ed.]. St. Louis: Elsevier.)

Explain the parts of the examination before manipulating the genitals, and use efficient examination techniques to avoid causing unnecessary stimulation or discomfort. Note the level of sexual maturity of the patient, and take into consideration any embarrassment or anxiety that is age sensitive or culturally related.

Begin the assessment with inspection, noting the size and shape of the penis and testes, as well as the distribution of pubic hair across the perineal area. Before puberty, in preadolescents, pubic hair is absent in the groin area. With the advent of puberty, the secondary sex characteristics begin to develop, including enlargement and darkening of the testicles, appearance of pubic hair, and lengthening of the penis. Scrotal wrinkling is a normal finding by the end of puberty, and the pubic hair is coarse and thick. The skin in the pubic area should be free of rashes, lesions, masses, and obvious deformity.

When inspecting the penis, note whether the penis is circumcised or uncircumcised and whether the foreskin retracts easily. Observe for **smegma** (a whitish substance under the foreskin) or abnormal discharge. If discharge or lesions are present, a sample of material from the area should be obtained for culture. Note

the appearance of the urethral meatus. It should be located on the ventral surface of the glans, slightly off the tip of the penis. In some patients with congenital defects, the meatus is displaced along the shaft of the penis, and surgery using the foreskin can be performed to correct the condition.

Carefully pinch the glans between the thumb and index finger to open the urethral meatus for examination (Fig. 20.49). Normally, the opening appears smooth, glossy, and light pink. Return the foreskin to its original position, and continue by inspecting the entire shaft of the penis, including the posterior surface. Palpation is performed by compressing the shaft of the penis between the thumb and the first two fingers at incremental intervals from the base to the glans. Note any tenderness or pain response elicited during the examination. Document any lesions or scars and swelling or edema noticed during inspection and palpation. Palpate the inguinal area for presence of enlarged lymph nodes.

FIGURE 20.49 Self-examination of the penis. (From Ball, J. W., Dains, J. E., & Flynn, J. A., et al. [2019]. *Seidel's guide to physical examination* [9th ed.]. St. Louis: Elsevier.)

Examination of the male genitalia includes inspection and palpation of the scrotum and testes (Fig. 20.50). The scrotum should be carefully examined for tenderness, masses, and potential malignant lesions. The scrotum is separated internally into two sections. Each section contains a testicle, vas deferens, and epididymis that are connected by the vas deferens to the inguinal ring. The testes are equal in size; however, when the male is standing, it is normal for the left testicle to be lower than the right within the scrotal sac. Observe the scrotum for any lesions, rashes, or edema. It should be without lesions and symmetric in contour. The scrotal skin usually is darker in color than the surrounding body tissue and has a coarse texture. The skin hangs loose over the testes; however, it may become tightened because of edema. The size of the scrotum can change with variation in temperatures, lifting the scrotum toward the body in cold temperatures and relaxing the scrotum to hang away from the body in warmer weather to protect the viability of sperm, which are temperature sensitive. Continue with the examination by lifting the scrotum to view the posterior surface.

FIGURE 20.50 Self-examination of the testicles. (From Ball, J. W., Dains, J. E., & Flynn, J. A., et al. [2019]. *Seidel's guide to physical examination* [9th ed.]. St. Louis: Elsevier.)

When palpating the scrotum, be cautious because the underlying testes are very sensitive. Severe pain during palpation is not a usual finding. The testes normally are oval and approximately 1 to 2 inches in size. Palpation is performed by gently pressing the testes between the thumb and first two fingers, moving from the base to the distal portion in an incremental manner until the entire surface has been examined. The procedure is then repeated on the other side. The testes should feel smooth and pliable and should be free of nodules. Note the size, shape, and symmetry of the organs, as well as any pain or discharge from the penis during testicular palpation. Testicular cancer usually is a painless, solid mass that is palpable as a small hard lump on the anterior aspect of the testes. During assessment of the testicles, assess the patient's knowledge concerning testicular self-examination. The ACS outlines the procedure for men with risk factors such as previous testicular cancer, undescended testicle, or a family history of testicular cancer to perform a testicular self-examination at <http://www.cancer.org/cancer/testicularcancer/moreinformation/doihavetesticularcancer/do-i-have-testicular-cancer-self-examination>.

The ACS recommends a discussion about prostate screening at the age of 50 years for most men, with follow-up screening to be determined on an individual basis. The ACS (2016) recommendations call for men at higher risk for prostate cancer—African American men or men with a family history of prostate cancer—to start prostate cancer screening at age 45. The prostate-specific antigen (PSA) blood test is used to assess the prostate. The prostate is examined through digital rectal examination (DRE) by an advanced practice nurse or a physician.

5. What three body systems would be critical to assess during R. T.'s physical examination? State a rationale for each. Discuss a minimum of three

additional actions that the nurse should take as part of the assessment process.

LO 20.6 Completion of the Physical Assessment

Allow the patient time to dress and offer supplies necessary for hygiene or personal needs. Return the examination area to its original condition. Use PPE and infection control protocols specific to the facility when disposing of potentially infectious waste and while cleaning or removing soiled instruments or linens. If the physical examination was performed in a hospitalized patient, ensure that bed linens are unsoiled; the bedside table is clean, clear, and accessible; and the call light is within reach.

Record the complete assessment in the patient's EHR in a timely manner. Review the results and documentation for accuracy and attention to detail. Be sure to notify the nurse practitioner or the physician of any serious abnormalities or questionable findings. Document that members of the health care team have been notified. It is the responsibility of the patient's primary care provider to thoroughly investigate suspected medical conditions through diagnostic and laboratory testing and examination. Document any education provided to the patient or the patient's family related to the physical examination.

Summary of Learning Outcomes

LO 20.1 *Apply strategies used to conduct a patient interview, health history, and review of systems:* Controlling the physical environment, preventing interruptions, and limiting the number of people present are essential to conducting a thorough patient interview that protects patient privacy. Various forms of therapeutic communication are used to encourage patient sharing of critical information. Using a structured order for collecting data during the interview process facilitates completion of a thorough patient health history. Data may be collected and organized according to body system, from head to toe, or by Gordon's functional health patterns. Health assessment questions help to identify concerns related to each area of the body during the review of systems.

LO 20.2 *Discuss the environmental and patient care activities that should be completed before and during history taking and physical examination:* Patient safety and comfort are primary concerns during physical examination. Room temperature, drafts, accessibility of the examination table, and availability of blankets and pillows to assist with positioning and comfort are taken into consideration. Physical assessment equipment is collected and organized before initiation of an examination. Patients are gowned and draped as needed to ensure access to assessment areas. Family members or care providers may be present during an examination to assist in positioning and to prevent patient injury from falls. Permission for others to be present during the physical examination is obtained from competent adult patients.

LO 20.3 *Use the four physical assessment techniques when examining each body system:* Inspection, palpation, percussion, and auscultation techniques are used to various degrees in assessing each body system. Auscultation precedes palpation and percussion during abdominal assessment to avoid stimulation of bowel sounds that may cause erroneous assessment findings.

LO 20.4 *Discuss factors for consideration during the general survey:* Special consideration to age, cultural preferences, gender concerns, and morphologic issues is required to provide safe and patient-centered care. Taking these factors into consideration enhances a patient's experience and results in greater patient satisfaction.

LO 20.5 *Demonstrate a focused and head-to-toe physical assessment, noting opportunities for patient education:* After gathering subjective data during the interview, health history, and review of systems, the nurse initiates the physical examination in an organized manner. A head-to-toe assessment is completed on hospitalized patients at least once per shift, with special attention to areas related to their admitting diagnoses. Focused assessments examine specific areas of concern in emergent and outpatient encounters. A complete head-to-toe examination usually is conducted during an initial patient–primary care provider interaction or referral to a specialist. Patient education focused on prevention, physical care, emotional concerns, stress reduction, nutrition, and exercise can be shared with patients during a physical assessment.

LO 20.6 *Describe the activities and specific documentation that are required at the completion of the physical assessment:* Findings of the assessment must be recorded in the patient's EHR in a timely manner. It is important to review the examination results and documentation for accuracy and attention to detail. The nurse practitioner or the physician should be notified of any serious abnormalities or questionable findings. Documentation is included indicating that members of the health care team have been notified.

Review Questions

1. Objective data can be gathered from the patient during which aspects of the physical assessment process? (*Select all that apply.*)
 - a. Patient interview
 - b. Health history
 - c. General survey
 - d. Physical examination
 - e. Laboratory testing
2. Which sequence best identifies the order in which the nurse should complete an abdominal assessment?
 - a. Inspection, palpation, percussion, auscultation
 - b. Auscultation, inspection, palpation, percussion
 - c. Auscultation, palpation, percussion, inspection
 - d. Inspection, auscultation, palpation, percussion
3. During examination of a patient's neck with the bell of the stethoscope, the nurse identifies a carotid bruit. When are bruits audible in the neck?
 - a. When jugular vein distention is present
 - b. During normal examination of the neck
 - c. When the carotid artery is partially occluded
 - d. With complete occlusion of both carotid arteries
4. A nurse is preparing to auscultate a patient's chest. In which area should the nurse listen to evaluate the patient's aortic valve?
 - a. Second right intercostal space
 - b. Third left intercostal space
 - c. Fifth right intercostal space
 - d. Fifth left intercostal space along the midclavicular line
5. Which assessment finding would be most important to document in a patient with known liver disease who has a distended, taut abdomen?

- a. Abdominal girth
 - b. Dentition condition
 - c. Benign cardiac murmurs
 - d. Daily ambulatory distance
6. The nurse notes the presence of ptosis when assessing an adult patient's eyes. Which potential cause would be considered of most concern, requiring further evaluation as soon as possible?
- a. Loss of skin elasticity
 - b. Levator muscle weakness
 - c. Congenital ocular abnormality
 - d. Oculomotor cranial nerve III paralysis
7. Which action by a patient with a family history of macular degeneration would demonstrate use of a prevention strategy that has been found to help prevent deterioration of the macula?
- a. Using medicated eyedrops
 - b. Avoiding the use of sunglasses
 - c. Taking vitamin B₆ and B₁₂ supplements
 - d. Minimizing dietary intake of antioxidants
8. The nurse begins the assessment of patient breath sounds and notes diminished breath sounds at the base of the right lung. What action should the nurse take next?
- a. Refer the patient for a chest x-ray.
 - b. Listen to the base of the patient's left lung.
 - c. Notify the patient's primary care provider.
 - d. Palpate the patient's lung fields bilaterally.
9. What actions should the nurse take to assess whether a patient with a left above-the-knee amputation has adequate lower extremity circulation to the stump? (*Select all that apply.*)
- a. Palpate the stump for warmth.
 - b. Assess pedal pulses bilaterally.
 - c. Evaluate the left popliteal pulse rate.

- d. Inspect the stump and right leg for color.
 - e. Check the left femoral pulse for strength.
10. Which action by the nurse would be most effective in determining whether a patient has muscle hypertonicity?
- a. Watching the patient walk to the bathroom
 - b. Asking the patient to squeeze both hands of the nurse
 - c. Performing passive range-of-motion exercises with the patient
 - d. Checking the patient's spine for the presence of postural irregularities

CHAPTER 21

Ethnicity and Culture

LEARNING OUTCOMES

Comprehension of this chapter's content will provide students with the ability to:

- LO 21.1 Compare characteristics of culture and ethnicity.
- LO 21.2 Explain cultural concepts that affect a nurse's ability to provide culturally congruent care.
- LO 21.3 Identify factors that contribute to cultural identity acquisition.
- LO 21.4 Articulate an understanding of transcultural nursing.
- LO 21.5 Discuss qualities required by nurses to demonstrate cultural competence.
- LO 21.6 Describe how to develop culturally competent individualized plans of care using cultural assessment tools and the nursing process.

KEY TERMS

- acculturation, p. 382**
- assimilation, p. 382**
- cultural competence, p. 384**
- cultural openness, p. 384**
- cultural sensitivity, p. 384**
- culturally congruent care, p. 385**
- culture, p. 379**
- discrimination, p. 381**
- emic, p. 384**
- enculturation, p. 380**
- ethnicity, p. 380**

ethnocentrism, p. 383
etic, p. 384
gender identity, p. 390
generalization, p. 381
health disparity, p. 381
health care disparity, p. 381
infrastructure, p. 381
prejudice, p. 381
race, p. 382
racism, p. 382
rituals, p. 384
rule of descent, p. 382
social structure, p. 381
socialization, p. 383
stereotype, p. 381
superstructure, p. 381
symbols, p. 380
transcultural nursing, p. 384

Case Study

Sofia Gomez (S.G.), a 24-year-old Latina mother, arrives at the community hospital's emergency department with her 4-year-old daughter, Maria. S.G. speaks broken English, and none of the nurses who speak Spanish are currently on duty.

The nurse is able to determine that Maria has not been eating for the last several days. S.G. says that she has tried to make her daughter drink, but Maria refuses. On physical examination, Maria has sluggish skin turgor, is lethargic, and does not communicate with her mother or the nurse. Her vital signs are T 39.6°C (103.3°F), P 125 and irregular, R 30 and shallow, and BP 86/58. Maria's throat is reddened, and lung auscultation reveals bilateral fine crackles.

When the nurse explains to S.G. that an IV line needs to be placed in Maria's arm, S.G. says it can't be done until her husband arrives. When Mr. G arrives, he speaks very little English and is skeptical of the need for IV placement. Maria is diagnosed with dehydration, strep throat, and pneumonia, requiring her to be admitted to the hospital.

Refer back to this case study to answer the critical-thinking questions throughout the chapter.

Ethnicity and culture dramatically affect daily life for people throughout the world. Literally thousands of ethnic and cultural groups are recognized globally as well as within entire countries and regions. Statistics from the U.S. [Central Intelligence Agency \(CIA\) *The World Factbook* \(2018\)](#) indicate that Algeria has a population made up of only two primary ethnic groups, whereas the Democratic Republic of the Congo has more than 200 African ethnic groups represented. In the United States, the 2017 race and Hispanic origin data identify a population of more than six different races, not including Hispanics or Latinos (who may be of any race), with 2.6% of people identifying with two or more races ([U.S. Census Bureau, 2017](#)). [Fig. 21.1](#) shows U.S. population statistics by race.

FIGURE 21.1 United States population by race, 2017. (Data from <https://www.census.gov/quickfacts/fact/table/US/PST045217>.)

Migration of people creates nations of diverse cultures and ethnicities. Relocation of individuals and families into foreign countries or regions with cultures different from their own causes challenges to both the immigrants or refugees and the health care providers in the area. Research indicates that patient populations experience lower-quality care and poorer outcomes associated with factors such as race, ethnicity, and language (AHRQ, 2018). Health care equity and the elimination of health disparities related to social, economic, and environmental factors is a goal of the *Healthy People 2020* initiative (Healthy People.gov, 2019).

Title VI of the United States Civil Rights Act of 1964 prohibits discrimination based on national origin and limited English proficiency (The United States Department of Justice, 2016). The Joint Commission (2018) has accreditation standards that health care facilities must meet to improve communication and provide culturally competent care. It is imperative that people who are traveling or have relocated from a foreign country have access to health care information and treatment in their own language that is sensitive to cultural norms. Transcultural nursing as a specialty seeks to address the multifaceted aspects of ethnicity and culture (Fig. 21.2). All nurses need to achieve increasing levels of cultural competence throughout their careers in order to provide unbiased, holistic care.

FIGURE 21.2 Nurses are required to collect data regarding the patient's language and ethnic, cultural, spiritual, and dietary preferences when the patient is admitted to a health care facility.

LO 21.1 Culture and Ethnicity

Culture is defined as the totality of socially transmitted behavioral patterns, beliefs, values, customs, lifeways, arts, and all other products of human work and thought characteristics of a population of people that guide their worldview and decision making (Purnell, 2018).

Ethnicity is the person's identification with or membership in a particular racial, national, or cultural group and observation of the group's customs, beliefs, and language. Ethnicity is based on cultural similarities and differences within a society or nation. Similarities occur with members of the same group; differences occur between members of the group and others (Kottak, 2017). Ethnicity may or may not include a reference to skin color because group membership often is based on national origin, which may encompass a particular race. Ethnicity is frequently a central consideration in providing culturally appropriate nursing care.

All aspects of behavior can have cultural origins; thus, culture may be viewed as a complex whole in which all parts are related. Culture has a family and group component, but it is not transmitted biologically. The values, beliefs, and traditions of a group must be learned by each person within the family and social community. Culture includes social constructs such as knowledge, beliefs, art, morals, and customs, as well as law (Spector, 2016).

Culture involves mostly unconscious thoughts and actions that have a dramatic influence on health and illness. It is imperative that nurses and all health care providers recognize and respect patients' cultural beliefs and make every effort to incorporate these beliefs into their treatment plans. Doing so is a critical skill in providing patient-centered care.

Characteristics of Culture

The art, literature, costumes, customs, language, religion, and religious rituals of a particular group of people are manifested by their culture. Thus people and their patterns of life make up the culture of a particular region or country, and cultures vary throughout the world. Such differences extend across geographic boundaries, and this diversity in cultures results in the diversity of people everywhere.

Because culture consists of a system of beliefs held by the people of a region as well as their principles and moral values, behavioral patterns of people from a particular geographic region of the world contribute to the region's culture. Four basic elements of culture are recognized: Culture is (1) learned, (2) symbolic, (3) shared, and (4) integrated.

Culture Is Learned

Culture is learned, and it is not biologically inherited. According to the nineteenth-century seminal work of Tylor (1871), culture is passed on through attributes that a person acquires by growing up in a particular society and being exposed to traditions. **Enculturation** is the process whereby a culture is passed from generation to generation.

Enculturation begins at birth as parents and family members begin to teach the child what is expected in terms of familial responsibilities and contributions. This learning process occurs consciously and unconsciously through interactions with friends, schoolteachers, and a variety of community members. Culture can be taught directly, for example, as with a mother teaching her child a family recipe, or indirectly, as occurs when a son observes the behavior of his father and other males in his family. By paying attention to things that happen around them, children modify their behaviors on the basis of the actions of other family members.

Culture Is Symbolic

Culture is based on symbols. Much of human behavior is mediated and moderated by **symbols**—signs, sounds, clothing, tools, customs, beliefs, rituals, and other items that represent meaningful concepts. Language is the most important symbolic aspect of culture. Language represents the most extensive use of symbols in a culture because words are used to represent objects and ideas.

Language is a structure of verbal symbols used to communicate and share cultural beliefs and ideas that can be manipulated and used as tools by individuals and groups to organize their lives. Nonverbal symbols are images, such as flags of countries, that represent shared ideas or beliefs. The International Federation of Red Cross and Red Crescent Societies uses a single red cross and red crescent side by side on trucks and armbands as a symbol of its relief efforts (Fig. 21.3); many religions use water as a symbol of rebirth through the process of baptism. Cultural symbols are passed on and accepted throughout generations. The mention of certain symbols automatically conjures up images and associations.

FIGURE 21.3 The International Federation of Red Cross and Red Crescent Societies uses this symbol to represent its relief efforts when providing care for people in many countries.

Culture Is Shared

Culture is an attribute of essentially all members of a group, not just individuals. People who grow up in a particular culture often have shared values, beliefs, ideals, and expectations. These shared attributes are absorbed and transmitted through generations of teaching and sharing ideas, traditions, and rituals. According to [Haviland et al. \(2013\)](#), culture is the “common denominator” that makes the actions of a person intelligible to other group members. One shared element found in all cultures is an understanding of gender roles, the roles that a particular culture assigns to men and women. Although the world is changing, certain values and beliefs regarding gender roles remain unchanged in many cultures.

Culture Is Integrated

Cultures are integrated, patterned systems ([Kottak, 2017](#)). According to [Haviland et al. \(2013\)](#), the foundation of culture includes three structural elements that work together to keep the culture strong: An **infrastructure** provides the basic necessities of life; a **social structure** determines how people interact with one another; and a **superstructure**, or worldview, provides a belief system that helps people identify themselves, their society, and the world around them.

As one part of a cultural system changes, other parts of the system change as well. For example, during the 1950s, most American women were stay-at-home mothers and wives; their career was being a housewife. However, the perception of the female role in society changed, and the goal of many women today is to attend college and pursue a professional career. This change is representative of the

integration of new beliefs, ideas, attitudes, and behaviors into the previous cultural system.

Within the culture of nursing, the nursing cap was a traditional symbol of the nursing profession. However, because of the expanded role of the nurse, the increased numbers of men entering the profession, and the relaxed nature of society as a whole, the cap has been abandoned in most practice settings.

LO 21.2 Cultural Concepts

To more fully understand the complexities of ethnicity and culture, nurses must be aware of both helpful and detrimental concepts that affect cultural competence. By becoming familiar with these ideas, nurses can better provide culturally sensitive care.

Generalization

A **generalization** is a statement, idea, or principle that has a broad application. Generalizations typically infer or draw conclusions from many factors. According to Galanti (2015), generalizations are a beginning point; one should gather more information to ascertain whether a generalized statement is appropriately applied to an individual or group. Generalizations tend to be applied broadly regarding common beliefs, behaviors, and patterns shared by a particular culture.

Generalizations may be applied when traits that are fairly consistent across cultures can be identified within a particular group, while keeping the importance of individual differences in mind. Certain behaviors may be anticipated and understood by using generalizations. However, differences are invariably present among individuals within cultures, and nurses need to consider these differences when providing care.

Stereotypes

Kottak (2017) defines **stereotype** as a set of fixed ideas, often unfavorable, about members of a group. According to Galanti (2015), the difference between a stereotype and a generalization lies not in the content but in the usage of the information. For example, consider the assumption that all Mexicans have large families. If a patient is Mexican and the nurse thinks that the patient *must* come from a large family, this is stereotyping. However, if the nurse thinks a patient is Mexican and *may* come from a large family, this is a generalization. The acceptance of stereotypes ignores the individuality of people within a cultural group. Stereotyping ignores the fact that people belong to many cultural groups, including those based on ethnicity, religion, generational status, educational level, gender, sexual orientation, and socioeconomic level.

In the patient–nurse relationship, there is no place for stereotypes, because they are detrimental to providing patients with necessary care. False opinions, perceptions, or beliefs are developed as a consequence

of an unwillingness to obtain all of the information necessary to make fair judgments about particular people or situations. In the absence of confirmed knowledge, stereotypes allow people to make unfounded assumptions.

Stereotyping can have negative results in health care when nurses and other health care professionals assume that all people of a specific culture or ethnicity act in similar ways. For example, if a nurse previously encountered an Asian patient who requested care from only Asian nurses and a new Asian patient is admitted to the unit when no Asian nurses are available to provide care, stereotyping may lead to neglect of the newly admitted patient. In all cases, stereotyping of individual patients should be avoided. The nurse needs to interview and assess each patient with an open mind to obtain accurate information for planning patient-centered care.

Prejudice

Prejudice is the process of devaluing an entire group because of assumed behavior, values, or attributes (Kottak, 2017). People demonstrate prejudice when they apply group stereotypes to individuals and assume that all people within a group will act in a predetermined manner. Prejudice includes “labeling” groups or cultures—for example, as lazy or materialistic.

Nurses are guilty of prejudicial thinking if they anticipate certain patient behavior based on a patient's appearance or on previous interactions with people of similar ethnicity or culture. There is no room for prejudice in professional nursing practice. Unchecked prejudicial thoughts and actions may lead to discrimination and unequal care of individual patients.

Discrimination

Discrimination refers to policies and practices that harm a group and its members. The principle of distributive justice (fair allocation of resources) along with the ethical principles of nonmaleficence and beneficence expects health care providers to provide safe, quality health care without discrimination. Nurses are most often concerned with discrimination related to health and health care disparity. **Health disparity** (a higher burden of illness, injury, or mortality) and **health care disparity** (inequality related to access, use, and quality of care) exist depending on a person's age, race or ethnicity, socioeconomic status, sexual orientation, gender, disability, and physical location (Artiga, 2016). In the United States, “Hispanics, Blacks, American Indians/Alaska Natives, and low-income individuals are more likely to

be uninsured relative to Whites and those with higher incomes. Low-income individuals and people of color also face increased barriers to accessing care, receive poorer quality care, and experience worse health outcomes” (Artiga, 2016, p. 1).

Worldwide health disparities have a tremendous impact on the social and economic well-being of both individuals and societies. According to the [United Nations Children's Fund \(2017\)](#), 15,000 children die *every day* before celebrating their fifth birthday, and nearly 85% of deaths from noncommunicable diseases occur in low- and middle-income countries ([WHO, 2018](#)). Discrimination in all forms, including through health and health care disparities, harms people and societies in general.

Race

Race is thought by many to have a biologic basis. However, this assumption is not true. **Race** is a socially constructed concept that tends to group people by common descent, heredity, or physical characteristics.

It has been a practice in the United States to use the rule of descent to categorize people by race. The **rule of descent** arbitrarily assigns a race to a person on the basis of a societal dictate that associates social identity with ancestry. For example, in some states, if people have any ancestors of minority descent, they are classified as a member of that minority, no matter how remote the ancestry ([Kottak, 2017](#)). This practice divides society and perpetuates disparities in health care because it assigns people to groups that have been historically deprived of equal access to health care, wealth, power, and privilege.

Racism

Racism is an unfounded belief that race determines a person's character or ability and that one race is superior or inferior to another. Scientific evidence indicates that no one race is culturally or psychologically superior to another, and past studies that have reached other conclusions have been found to be seriously flawed in their methodology or inherently biased. Despite the preponderance of these scientific findings, some people still maintain that their race is superior to all others.

According to [Purnell \(2018\)](#), “race includes physical characteristics that are similar among members of the same group such as skin color, blood type, and hair and eye color. Although there is less than a 1% genetic difference among the races, those differences are significant when it comes to conducting health assessments and prescribing medications” (p. 3). Health care professionals play a vital role in

counteracting racism by providing unbiased, equal access, and culturally sensitive care to people of every race and culture.

LO 21.3 Acquisition of Cultural Identity

People develop and maintain their cultural identity through a variety of methods. When relocating to a new country or region, members of some cultural and ethnic groups choose to integrate into their new cultural environment, whereas others within these groups prefer to retain their traditional patterns of dress and behavior. Recognizing these differences allows nurses to appreciate the needs of culturally diverse patient populations.

Acculturation

Acculturation is a mechanism of cultural change achieved through the exchange of cultural features resulting from firsthand contact between groups (Kottak, 2017). The culture of one or both groups may be changed over the course of time; however, each group remains distinct. Firsthand contact between groups may bring about cultural changes in language, technology, food, clothing, music, and other aspects. [Box 21.1](#) provides an example of language development in acculturation.

Box 21.1

Language Development in Acculturation

Pidgin

Pidgin is an example of how language develops during the acculturation process. Pidgin English is the local language in some regions of the world.

- Pidgin is a mixed language that develops to facilitate communication between members of different groups who come in contact with one another.
- It usually develops as a result of trade or colonialism and is a simplified form of English. It blends the basics of English with the grammar and pronunciations of the native language.
- Pidgin English was first used for commerce in Chinese ports and developed in other forms in Papua New Guinea and West Africa (Kottak, 2017).
- Nurses who practice in areas where Pidgin English is spoken need to be fluent in Pidgin and English, although most medical terms

sound similar in both dialects.

Assimilation

Assimilation is the process by which individuals from one cultural group merge with, or blend into, a second group. The concept of assimilation originated in anthropology and generally refers to a group process, although assimilation also can be defined and examined at the individual level. Assimilation involves a transformation in which members of one group, usually the minority group, enter into and become a part of a second group through continuous social interaction. Quite often during this process, the minority group may lose self-identified members of its group and/or aspects of its culture. For centuries, scholars have called the results of assimilation the *melting pot* process and regarded this process as a natural and necessary aspect of immigrant adaptation to life in a new country.

One of the more extreme forms of assimilation involves intergroup marriage. Consider, for example, a Chinese-speaking Buddhist woman who immigrates to England and marries an English-speaking Jewish male. If the woman learns English, changes her maiden name, adopts the Jewish religion, and becomes a British citizen, she will have fully assimilated into mainstream English culture while abandoning many of her native cultural ways. Entering into another cultural group may result in relinquishing important aspects of cultural identity.

People who fully assimilate within a culture different from the one into which they were born undergo psychological changes in cultural orientation (beliefs, attitudes, values) and cultural behaviors (customs, traditions) as well as in personal identity, to the point of losing many of the aspects of their original native culture. Accordingly, the effect of full assimilation on the psychological and social well-being of human beings may cause concern.

Ethnocentrism

Ethnocentrism is the belief that one's own culture is superior to that of another while using one's own cultural values as the criteria by which to judge other cultures (Kottak, 2017). One ethnocentric view can be found in Western medicine. Western medical practitioners tend to believe that their approach to health and healing is far superior to that of non-Western practitioners. Many Western practices, especially the use of pharmacologic interventions, can find their roots in the practices of Eastern and Native American cultures, where plants and plant extracts are a mainstay. According to Giger (2017), even in the nursing profession, there is a tendency to lean toward ethnocentrism; thus

nurses must remain cognizant of the fact that their ways are not necessarily the best and that other people's ideas are not “ignorant” or “inferior.” Nurses need to realize that knowledge and ideas possessed by laypersons may be valid, may be reasonable, and may influence health behaviors and the health status of individuals.

Ethnocentrism poses serious ethical and quality-of-care concerns. Issues of and decisions about care for diverse cultural groups require that nurses and other health care providers be knowledgeable about the principles, concepts, and theoretical frameworks of transcultural care. Being culturally sensitive and culturally competent is important, because preconceived ideas about certain cultures can lead to racial stereotyping of patients, families, and communities by health care providers. Nurses must recognize that their own cultural beliefs are not necessarily superior, and they should refrain from thinking of another person's ideas as ignorant or inferior (Giger, 2017). The ideas of laypeople and family members may be valid and important and may influence the health care behaviors of patients as well as their health care status.

Socialization

Socialization is the process of being reared and nurtured within a culture and acquiring its characteristics. This process can and does occur on many different levels: within families, communities, schools, and spiritual or religious groups. Socialization usually occurs within the structure of a group that influences the health care behaviors and beliefs of its members and can directly and indirectly affect the administration of health care by the nurse.

Family

The family is the basic unit of society in all cultures. From an economic perspective, a family is a social unit that works together to meet material needs. From a sociologic perspective, a family is a social unit that interacts within the larger society. Family also may be viewed as the basic unit in which personality develops and subgroup relationships, such as that between parent and child, are created.

Societal changes in the family unit have created variations of the basic family unit, such as single-parent families, extended families, and blended families. All of these variations will have an impact on how the nurse delivers care to members of these family groups.

Community

Community is defined as a group of people having a common interest or identity. This concept goes beyond the physical environment and includes the physical, social, and symbolic characteristics that connect people within a group. According to [Purnell \(2013\)](#), the physical concept of community can be defined by such things as mountains, water, rural versus urban, and even railroad tracks can help define a community. Symbolic characteristics of community include sharing a specific dialect or language, lifestyle, history, art, dress, or music. Much of the care that nurses deliver today takes place in the community. Therefore the nurse must be cognizant of the cultural influences within the community that can affect the delivery of care.

Delivery of care in the community setting requires that the nurse be comfortable with patients from diverse cultures and socioeconomic levels. Acquiring knowledge about a community's culture begins by conducting a careful assessment of patients and their families in their own environment. Cultural data that have implications for nursing care are collected from patients, families, and the environment during the assessment phase and are discussed with the patient and family to develop mutually shared goals ([Andrews & Boyle, 2016](#)).

School

A school is the official place where generational transmission occurs of a society's accumulated knowledge and skills. Schools are places where a society's cultural values, traditions, and official heritage are taught. The school curriculum can reinforce what is learned in the family, but it also can challenge family socialization. A curriculum is geared toward learning social behaviors that are appropriate for peer groups that are not necessarily friendship groups but become the model for secondary group interactions. In this setting, people learn to communicate or negotiate with, or dominate, peers who are outside their immediate social circle and often are from diverse social backgrounds. In many ways, a social curriculum reinforces and deepens the gender role socialization that starts in the family and continues into the peer group.

Spiritual and Religious Institutions

Spiritual and religious institutions have a profound impact on individual and group socialization. These institutions can greatly influence health beliefs and often provide an entry point for health care access in impoverished communities and less developed countries. Religious practices usually are rooted in culture. Religions may have a set of beliefs that define health and the behaviors that prevent or treat illness. For example, most Jehovah's Witnesses oppose receiving blood

transfusions based on their religious beliefs. Nurses caring for known members of the Jehovah's Witness faith community should verify and document patient preferences to ensure that religious beliefs are respected during medical treatment.

Rituals

Rituals are formal, stylized, and repetitive actions performed in special places at special times. These actions convey information about participants and are used to inform others about the beliefs and traditions of a culture. Rituals, through their repetitive nature and generational transmission, translate into enduring messages, values, and sentiments (Kottak, 2017). These repetitive actions include participation in individual and group activities, such as praying, dancing, fasting, singing, meditating, and reading sacred texts. Death and birth rituals vary greatly from one culture to another. All of these activities have implications for the delivery of nursing care. Rituals can sustain and provide support for patients during a time of illness or suffering. In caring for patients, nurses need to be aware of their own beliefs and feelings regarding certain rituals, as well as understand how these rituals may affect their patients and families.

LO 21.4 Transcultural Nursing

Transcultural nursing focuses on human caring–associated differences and similarities among the beliefs, values, and patterned life ways of cultures to provide culturally congruent, meaningful, and beneficial health care (McFarland & Wehbe-Alamah, 2017). It is both a specialty and a general practice area that focuses on worldwide cultures and comparative cultural caring, health, and nursing phenomena.

Established as a formal area of inquiry and practice in the 1970s, the goal of transcultural nursing is to provide culturally congruent care. The founder and central leader of transcultural nursing is Madeleine Leininger, who, as a graduate clinical nurse specialist in psychiatry, discovered major cultural differences among children and parents. She was among the first to realize the need to address culture as a critical and missing dimension of care.

Transcultural nurses provide knowledgeable, competent, and safe care to people of diverse cultures. Research in transcultural nursing focuses on discovering or explaining largely unknown and vaguely known cultural care and health concerns from two perspectives: The **emic** perspective focuses on the local, indigenous, and insider's culture; the **etic** perspective focuses on the outsider's world, and especially on professional views (Leininger, 2000).

Transcultural nurses are specialists, generalists, and consultants. Functioning in diverse clinical practice settings and in schools of nursing, they assist others to become sensitive to and knowledgeable about diverse cultures. They may identify cultures that are neglected or misunderstood and may help health care systems assess how they serve, or fail to serve, diverse cultures in a community. Transcultural nurses are committed to **cultural openness**, a lifelong commitment that promotes cultural self-awareness and continuing development of transcultural skills.

Leininger developed the Sunrise Model to depict the essential components of her Theory of Cultural Care Diversity and Universality. A basic tenet of Leininger's theory is that human beings are inseparable from their cultural background and social structure, world view, history, and environmental context. Gender, race, age, and class are embedded within the social structure. Biology, emotions, and other dimensions are studied from a holistic view and are not fragmented or separated. Leininger's work stresses the importance of comprehensive cultural assessment. Fig. 21.4 illustrates the Theory of Cultural Care Diversity and Universality and the Sunrise Model.

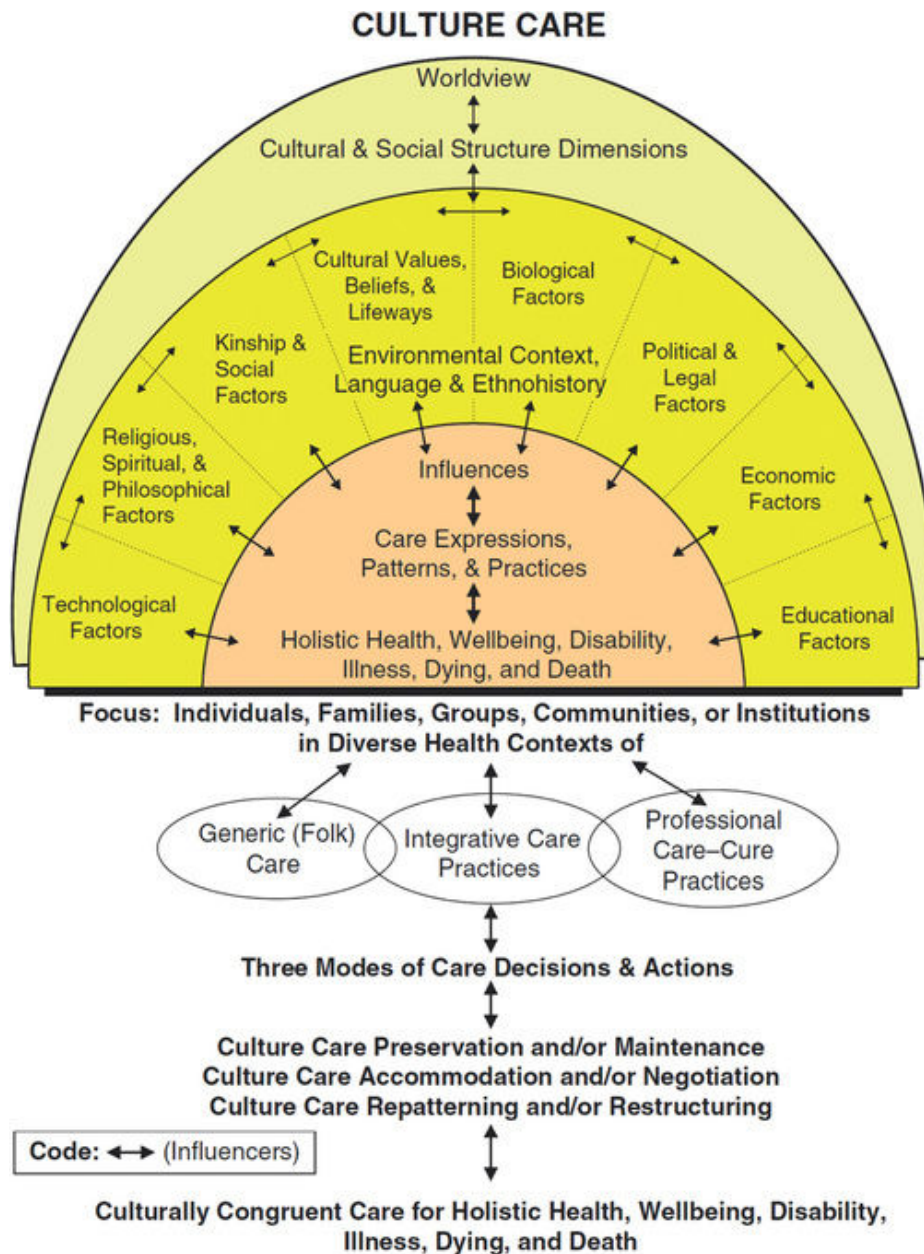

FIGURE 21.4 Leininger's Sunrise Enabler to Discover Culture Care. (From McFarland, M. R., Wehbe-Alamah, H. B. (2018). *Transcultural nursing concepts, theories, research, and practice*. (4th ed). New York: McGraw-Hill Education. Used with permission.)

LO 21.5 Cultural Competence

Attaining **cultural competence** (the ability to interact with and appreciate people of different cultures and beliefs) is a lifelong process. It requires intentional effort to more fully understand individuals of different cultures and ethnicities. There is a general consensus that cultural competence can be divided conceptually into two major categories: (1) individual cultural competence, which refers to the care provided for an individual patient by one or more nurses, physicians, social worker, etc. and (2) organizational cultural competence, which focuses on the collective competencies of the members of an organization and their effectiveness in meeting the diverse needs of their patients, staff, and community (Andrews & Boyle, 2016). Nurses use a variety of strategies including cultural sensitivity and culturally congruent care to demonstrate cultural competence in their patient care.

Cultural Sensitivity

Cultural sensitivity begins with the recognition of the often pronounced differences among cultures. These differences are reflected in the ways that different groups communicate and relate to one another, and they carry over into interactions with health care providers. Cultural sensitivity does not mean, however, that a person need only be *aware* of the differences to interact effectively with people from other cultures. If health care providers and their patients are to interact effectively, they must move beyond both cultural sensitivity and cultural biases that create barriers. Developing this kind of culturally competent attitude is an ongoing process.

Culturally Congruent Care

A culturally competent clinician realizes the importance of caring for patients as people with unique experiences, beliefs, values, and language. How people perceive health care delivery and respond to diagnoses and treatment depends on a variety of cultural factors. **Culturally congruent care** uses culturally based knowledge in sensitive, creative, safe, and meaningful ways to promote the health and well-being of individual people or groups and improve their ability to face death, disability, or difficult human life conditions (McFarland & Wehbe-Alamah, 2017). *Culturally congruent care* and *culturally competent care* are terms that often are used interchangeably.

Multidimensional Cultural Competencies

Cultural competence requires the complex integration of knowledge, attitudes, beliefs, skills, practices, and cross-cultural encounters that includes effective communication and the provision of safe, affordable, quality, accessible, evidenced-based, and efficacious nursing care for individuals, families, groups, and communities of diverse and similar cultural backgrounds (Andrews & Boyle, 2016). To reach cultural competence, the health care professional needs to engage in a cultural self-assessment. This self-assessment will reveal personal cultural beliefs, attitudes, values, biases, and practices that may affect the kind of care the nurse is willing and able to provide for patients from diverse backgrounds and cultures.

Experts have noted that in addition to cultural competence, linguistic competence is needed to offer appropriate care and responses to patients with culturally diverse backgrounds. When health care providers and organizations are culturally and linguistically competent, they can more effectively respond to the needs of the patients and communities they serve. Nurses skilled at cross-cultural communication, including verbal and nonverbal communication, communication dialects, and communication styles within various cultural groups, constitute valuable resources for health care agencies serving highly diverse populations. Box 21.2 provides web resources for nurses seeking additional information and research on cultural and linguistic competence.

Box 21.2

Evidence-Based Practice and Informatics

Cultural Competency Resources for Nurses

Many agencies or organizations provide helpful resources, including evidence-based practice research, to support cultural competency in nursing.

National Culturally and Linguistically Appropriate Standards (CLAS) from the U.S. Department of Health and Human Services identify methods for providing culturally competent care and guidelines for their implementation. These standards address language access, organizational support, diverse and culturally competent staff, existing laws, data collection, and information dissemination. The CLAS standards are provided in [Box 21.3](#).

Box 21.3

Ethical, Legal, and Professional Practice

National Standards for Culturally and Linguistically Appropriate Services

1. Provide effective, equitable, understandable, and respectful quality care and services that are responsive to diverse cultural health beliefs and practices, preferred languages, health literacy, and other communication needs.
2. Advance and sustain organizational governance and leadership that promotes Culturally and Linguistically Appropriate Services (CLAS) and health equity through policies, practice, and allocation of resources.
3. Recruit, promote, and support a culturally and linguistically diverse governance, leadership, and workforce that are responsive to the population in the service area.
4. Educate and train governance, leadership, and workforce in culturally and linguistically appropriate policies and practices on

- an ongoing basis.
5. Offer language assistance to individuals who have limited English proficiency and/or other communication needs, at no cost to them, to facilitate timely access to all health care and services.
 6. Inform all individuals of the availability of language assistance services clearly and in their preferred language, verbally and in writing.
 7. Ensure the competence of individuals providing language assistance, recognizing that the use of untrained individuals and/or minors as interpreters should be avoided.
 8. Provide easy-to-understand print and multimedia materials and signage in the languages commonly used by the populations served.
 9. Establish culturally and linguistically appropriate goals, policies, and management accountability, and infuse throughout the organization's planning and operations.
 10. Conduct ongoing assessments of the organization's CLAS-related activities and integrate CLAS-related measures into measurement and continuous quality improvement activities.
 11. Collect and maintain accurate and reliable demographic data to monitor and evaluate the impact of CLAS on health equity and outcomes and to inform service delivery.
 12. Conduct regular assessments of community health assets and needs and use the results to plan and implement services that respond to the cultural and linguistic diversity of populations in the service area.
 13. Partner with the community to design, implement, and evaluate policies, practices, and services to ensure cultural and linguistic appropriateness.
 14. Create conflict and grievance resolution processes that are culturally and linguistically appropriate to identify, prevent, and resolve conflicts and complaints.
 15. Communicate the organization's progress in implementing and sustaining CLAS to all stakeholders, constituents, and the general public.

From U.S. Department of Health and Human Services Office of Minority Health (OMH), The National CLAS Standards, 2018. Retrieved from <https://minorityhealth.hhs.gov/omh/browse.aspx?lvl=2&lvlid=53>.

To provide culturally competent patient-centered care, nurses must recognize personal attitudes related to working with patients from different cultural and ethnic backgrounds and actively seek to overcome prejudices or feelings that might have a negative impact on their nursing practice.

Balancing Multiple Cultures

The cultural competence of a nurse and positive patient outcomes are dependent on an awareness of the interaction of multiple cultures (Dauvin & Lorant, 2015). Every nurse brings at least two cultures into a relationship with patients. The first culture is the nurse's own. The qualities and characteristics of the nurse's personal culture are key determinants of personal and professional behavior. The second culture, which is equally important, is that of the health care delivery system. The nurse represents the health care system and helps the patient and family acquire access to this system, which also has its own separate and unique culture. Both of these cultures, that of the nurse and of the health care system, must strike a balance with a third culture, that of the patient. When additional health care providers collaborate to provide care, even more cultures must be balanced to provide culturally competent care and achieve positive patient outcomes.

LO 21.6 Cultural Competence and the Nursing Process

An understanding of patients from diverse backgrounds begins with a cultural assessment and continues with the development of culturally sensitive individualized care plans. Nurses must understand the specific factors that influence health and illness behaviors within a culture in order to provide culturally competent care.

Assessment

Some nonnursing models for cultural assessment were used before the development of various transcultural nursing assessment models. Madeleine Leininger's Transcultural Theory and Assessment Model was the first tool developed for nurses to appropriately assess a patient's culture and evaluate the impact of culture on nursing care. Since the development of Leininger's assessment tool, other nursing models have been developed to assist nurses in providing culturally congruent and competent care.

The Giger and Davidhizar Transcultural Assessment Model ([Giger, 2017](#)) is a framework for collecting data related to six cultural domains: communication, space, social orientation, time, environmental control, and biologic variation ([Fig. 21.5](#)).

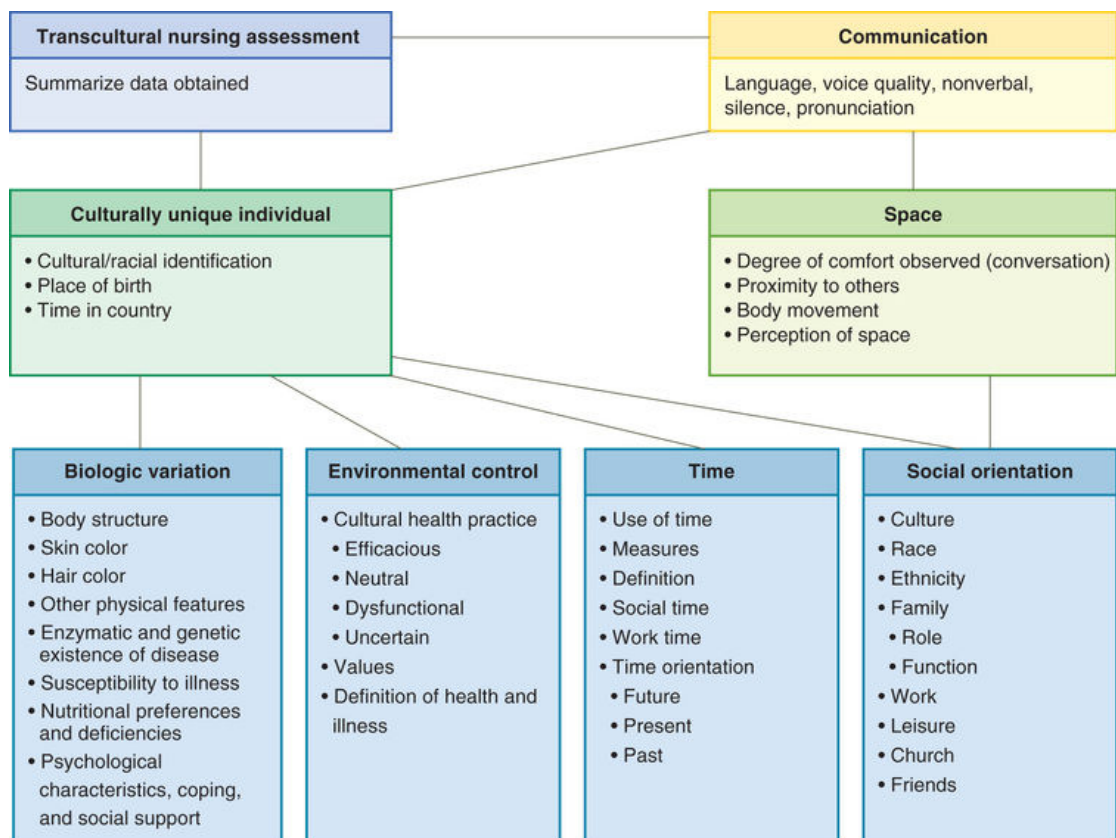

FIGURE 21.5 Giger and Davidhizar's Transcultural Assessment Model. (From Giger, J. (2017). *Transcultural nursing: Assessment and intervention* (7th ed.). St. Louis, MO: Mosby.)

Box 21.4 provides examples of interview questions for assessment of each cultural domain within the Transcultural Assessment Model. Using these questions, and others that are similar, will help identify and address the cultural needs of patients and families.

Box 21.4

Health Assessment Questions

Cultural Domains

Assessment of each cultural domain requires questions in several different categories:

Communication

- What do you do to help others understand what you are trying to say?
- Do you like communicating with friends, family, and acquaintances?

- When asked a question, do you usually respond in words, body movement, or both?
- If you have something important to discuss with your family, how do you approach them?

Space

- When you talk with family members, how close do you stand?
- When you communicate with co-workers and others, how close do you stand?
- If a stranger touches you, how do you react or feel?
- If a loved one touches you, how do you react or feel?
- Are you comfortable with the distance between us now?

Social Organization

- How do you define social activities?
- What are some activities you enjoy?
- What are your hobbies? What do you do in your free time?
- Do you believe in a supreme being?
- What is your role in the family unit?
- What is your function in the family unit?
- When you were younger, who influenced you the most?
- What does work mean to you?
- Describe your past, present, and future jobs.

Time

- What device do you use to keep track of time?
- If you have an appointment at 2 p.m., what is an acceptable arrival time?
- If the nurse tells you that you will receive a medication in “about half an hour,” realistically, how much time will you allow before you call the nurses’ station about the medication?

Environmental Control

- How often do you have visitors to your home?
- Is it acceptable to you for visitors to drop in unannounced?

- What is your definition of good health?
- What is your definition of poor health?
- What home remedies have you used that worked?
- Will you use these home remedies again?

Biologic Variations

- What illnesses or diseases are common in your family?
- Have any members of your family been told they have a genetic susceptibility to a particular disease?
- How do you respond when you are angry?
- Who or what helps you cope during difficult times?
- What foods do you and your family like?
- Have you ever had any cravings for unusual things such as red or white clay? Laundry starch?
- What foods are family favorites or traditional foods?

Modified from [Giger J. \(2017\)](#). *Transcultural nursing: Assessment and intervention* (7th ed.). St. Louis: Elsevier.

[Galanti \(2008\)](#) developed the 4 Cs of Culture, a mnemonic for health care professionals, to aid in providing culturally responsive, patient-centered health assessment and care ([Table 21.1](#)). The 4 Cs stand for *call*, *caused*, *cope*, and *concerns*. According to [Galanti \(2015\)](#), the key factor in achieving cultural competence is learning to ask the right questions to elicit an understanding of the patient's point of view.

TABLE 21.1**The 4 Cs of Culture: A Mnemonic for Health Care Professionals**

QUESTION	RATIONALE
What do you <i>call</i> your problem?	<ul style="list-style-type: none"> Remember to ask, “What do you think is wrong?” The answer to this question gives the nurse the patient's perception of the problem. (Do <i>not</i> literally ask, “What do you call your problem?”) The same symptoms may have very different meanings in different cultures, and this may result in barriers to adherence. Understanding the patient's point of view can help the health care provider address potential barriers to adherence.
What do you think <i>caused</i> your problem?	<ul style="list-style-type: none"> This question is aimed at discovering the patient's thoughts regarding the source of the problem. Not everyone thinks disease is caused by germs. In some cultures, disease is thought to be caused by an upset in body balance, a breach of taboos (similar to the idea held by some people that diseases are caused by “sin” and are a punishment from God), or spirit possession. Treatment must be appropriate to the cause; otherwise, patients will not perceive themselves as being cured.
How do you <i>cope</i> with your condition?	<ul style="list-style-type: none"> This question should be asked to remind the practitioner to ask, “What have you done to try to make it better? Who else have you been to for treatment?” Answers to these questions will give the health care provider important information on the use of alternative healers and treatments. It is important that health care providers ask about traditional remedies in a nonjudgmental manner. Occasionally, a traditional remedy may be dangerous or could lead to a drug interaction with a prescribed medication.
What are your <i>concerns</i> regarding the condition and/or recommended treatment?	<ul style="list-style-type: none"> This question can take the form of “How serious do you think this is? What potential complications do you fear? How does it interfere with your life or your ability to function? Do you know anyone else who has tried the treatment that is recommended? What was that person's experience?” The nurse or other health care provider needs to ask these questions to understand the patient's perceptions and fears about the course of the illness so that any concerns can be addressed and misconceptions can be corrected. Asking about what aspects of the condition pose a problem for the patient may uncover something very different from what the provider expects. It is important to know the patient's concerns about any treatments that may be prescribed to avoid problems of nonadherence. Some patients do not adhere to treatments due to misplaced concerns that are based on past experiences. By asking questions, the health care provider can correct any misconceptions that can interfere with treatment.

From Galanti, A. (2015). *Caring for patients from different culture* (5th ed.). Philadelphia: University of Pennsylvania Press.

Regardless of the format used to conduct a cultural assessment, the nurse needs to be sensitive to several factors that affect how people from culturally diverse backgrounds may interact with others and their environment and how they may view health care. Recognizing the

potential impact of these factors will help nurses develop culturally sensitive treatment plans that meet each patient's individual needs.

Communication

Communication practiced within and among cultural groups dictates how feelings, ideas, decision making, and strategies for exchanging information are expressed both verbally and nonverbally. When a patient and nurse are from different cultures, the chances of misunderstanding one another are greatly increased, which can have a detrimental effect on the nurse–patient relationship and result in negative patient outcomes.

[Galanti \(2015\)](#) provides an example of a verbal misunderstanding between health professionals: A nurse reported that her patient was “getting cold feet” about an upcoming surgical procedure; a Chinese-born physician misinterpreted this expression and ordered vascular studies to rule out circulatory problems. In some cultures, facial expressions, body posture, eye behaviors, and the use of touch can have a multitude of meanings. For example, in some Asian cultures, it is considered disrespectful to make direct eye contact with individuals of authority because doing so implies equality.

Some factors that influence communication include the following ([Giger, 2017](#)):

- Physical health and emotional well-being
- The situation being discussed and its meaning to the patient
- Personal needs and interest
- Communication skills
- Knowledge of the subject matter being discussed
- Background, including cultural, social, and philosophical values
- Experiences that relate to the situation
- The senses involved and their functional ability
- Attitudes toward the person and subject being discussed
- The environment in which the communication takes place
- Distractions to the communication process

- The personal tendency to make judgments and to be judgmental

Safe Practice Alert

Use of a professional interpreter is necessary if the nurse and the patient do not speak the same language fluently. Avoid translation of medical information by a patient's family members or friends to ensure privacy and accuracy of essential, personal information.

Skin Color

Skin color probably is the most significant biologic variation nurses encounter in the delivery of culturally competent care. Variations in skin color may be attributable to genetic makeup or may be the result of mutations and environmental factors. The darker a patient's skin is, the more challenging assessment for changes becomes. Procedures used in assessing dark-skinned people are quite different from those used in assessing light-skinned people. Skin color varies in conditions such as jaundice, pallor, and some rashes. In assessing a dark-skinned patient for oxygenation, it is very important to examine the least pigmented areas, such as the buccal mucosa, lips, tongue, nail beds, and palms of the hands. The examiner should not rely on the skin tone alone. A baseline skin color can be established by assessing a patient in direct sunlight or by asking family members who are extremely familiar with the patient's appearance ([Purnell, 2013](#)).

Gender Roles

Nurses need to be mindful that equalization of genders is predominantly a Western phenomenon, and that many non-Western cultures do not adhere to this cultural ideology. Accommodations must be made to respond to patient preferences in regard to gender. Some patients will require direct care from nurses of the same gender, while others may limit speaking or eye contact with people of the opposite gender.

Gender equality exhibited through shared decision making is a concept not universally accepted in many cultures. For example, some women are not permitted to make health care decisions for themselves or their children. In some families, decision making is viewed as the responsibility of the men. Nurses should be sensitive when a female patient defers to her husband or father, recognizing that although the woman has the legal right in various parts of the world to consent to a

procedure, she may not feel that she has the authority to give consent from a cultural standpoint.

Gender Identity

Gender identity refers to a person's basic sense of being a man or boy, a woman or girl, or another gender (e.g., transgender, bigender, or gender queer—a rejection of the traditional binary classification of gender) (National Academy of Medicine, 2011). Gender identity can be congruent or incongruent with one's sex assigned at birth based on the appearance of the external genitalia. *Transgender* has come to be widely used to refer to a diverse group of individuals who cross or transcend culturally defined categories of gender and depart significantly from traditional gender norms. Lesbian, gay, bisexual, transgender, and queer or questioning (LGBTQ) individuals experience unique health disparities. LGBTQ is used as an umbrella term and the health needs of this community are often grouped together; however, each of these letters represent a distinct population with its own health concerns (National Academy of Medicine, 2011). Although LGBTQ individuals live in most geographic areas throughout the United States, studies have shown higher proportions in urban areas on the East and West coasts (National Academy of Medicine, 2011).

Time Orientation

Time orientation varies by culture. Cultures tend to be oriented to time in the context of past, present, or future events. No single person or cultural group looks exclusively to the past, present, or future, but different cultures tend to emphasize one period of time over the others (Galanti, 2015). Cultures that are oriented to the past tend to look to traditional approaches to health and healing rather than to new approaches, procedures, and medications. People of these cultures tend to believe that if certain solutions worked for their ancestors, such solutions will work for them. According to Galanti (2015), Australian, British, and Chinese cultures tend to be time-oriented in the past; middle-class Anglo-American culture tends to be more future oriented, and Hispanics and African Americans are more present time oriented.

Cultures oriented to the present are less likely to embrace preventive health care. The orientation of these cultures is focused on the “here and now,” and people in these cultures often use the way they are feeling during the present time to dictate future health practices. For example, if people from present-oriented cultures are diagnosed with a specific disorder but still “feel good,” they may reason that prescribed medication is an unnecessary expenditure, because they are not having

symptoms. Their orientation is not geared toward preventing the long-term effects of the disorder; rather, they adopt a wait-and-see approach. Nurses also need to be mindful that certain economic pressures can force patients into a present-time orientation. When finances dictate that day-to-day survival takes priority over future needs, patients often make choices that are in conflict with the recommendations of nurses and other health care professionals.

According to [Giger \(2017\)](#), African American and Hispanic cultures tend to think of time in a linear fashion. People in these cultures tend to believe that a particular task or spending time with another has to be accomplished in the “here and now” because that opportunity can never be regained. Some people in these cultures also share the belief that time is flexible and events will begin when they arrive at a destination. This belief has led to a more lenient perception of time, and arriving 30 minutes to an hour late is considered acceptable behavior.

Middle-class Americans, regardless of ethnic or cultural origin, tend to be future-oriented ([Giger, 2017](#)). People in the middle class tend to delay immediate personal gratification if a purchase interferes with their ability to pursue plans for the future, such as buying a home, planning a family, or pursuing higher education. Middle-class people tend to structure time rigidly, adhering to a time-structured schedule as a way of life. The nurse providing care to such patients should be reminded to speak of events in relationship to the future and stick to a schedule of planned events.

Safe Practice Alert

If a patient is late to a scheduled appointment, the nurse should assess the reason for tardiness to determine whether it is due to cultural factors or to reliance on public transportation or other means over which the patient has little control. The nurse will need to decide whether it is appropriate to explain the potential consequences of lateness, such as having to reschedule an appointment or compromise the patient's health. Caution is required to avoid discouraging patients from seeking needed health care.

To give culturally competent care, nurses need to have an understanding of time as it applies to diverse cultural groups. Time orientation and punctuality vary from group to group and from place to place. It is important for the nurse to identify the time orientation of the patient (past, present, future) and realize that nursing care may have to be adapted to the patient's time orientation. This adjustment may seem

cumbersome and unnecessary; however, the nurse needs to keep in mind that time orientation dictates many activities in patients' lives and that intolerance of a patient's cultural time perception may have a negative impact on the nurse–patient relationship and affect patient care.

Body Odor

Body odor may result from poor hygiene, the inability to care for oneself, or a cultural acceptance that natural body odors are normal. In some parts of the world, the fear of offensive natural smells is connected with the concept of attractiveness, and great efforts are made to prevent or mask unpleasant odors. Some cultures stress frequent bathing and may criticize others for not bathing as much as they should. Nurses need to assess a patient's norms associated with body odor and encourage healthy personal hygiene practices that promote health and wellness, but they must do so while demonstrating sensitivity to cultural implications.

Nutritional Needs

Understanding a patient's food patterns is critical to providing culturally congruent dietary counseling. The role of food in a culture, food rituals, common foods and spices, dietary limitations, and nutritional deficiencies are all factors to be assessed by the nurse. For example, nurses may be viewed as culturally incompetent if they attempt to prescribe a diet including pork products to a patient of Middle Eastern background.

Food has a significant role in socialization in a majority of cultures. The celebration of specific holidays often centers on the preparation and sharing of traditional foods with family and friends (Fig. 21.6). In addition to cultural influences, socioeconomic status may dictate food selection. Individuals and families with limited financial resources may have to choose between purchasing healthy foods or purchasing economical foods. The inability to afford foods for a healthy diet leads to severe nutritional deficiencies in many cultures. In view of the cross-cultural variation in diets, nurses need to ask about the specific diets and traditional foods of their patients. Box 21.5 identifies guidelines nurses can use to assess nutrition.

FIGURE 21.6 People from around the world celebrate holidays with traditional foods. (Copyright [Thinkstock.com](https://www.thinkstock.com/).)

Box 21.5

Health Assessment Questions

Nutrition

- What foods do you commonly eat?
- What are your favorite foods?
- Which foods do you eat to be healthy? How often do you eat them?
- What kinds of food do you like to eat when you are not feeling well, and which ones do you avoid?
- Do you have access to the types of food you need?
- Which foods do you eat on holidays or special occasions?
- Are there foods you do not eat for cultural or religious reasons? If so, what are they?

Spirituality and Religious Orientation

Rooted in the culture of groups, spirituality and religious orientation help define many health beliefs and health practices. Different cultures have differing views of religion; for example, some people view religion as their connection to supernatural beings, whereas others view it as an expression of an instinctual reaction to cosmic forces (Johnstone, 2016). Religion may be viewed as a method of receiving guidance and directional messages from a deity (Giger, 2017).

Spirituality involves more than the formal beliefs and rituals seen in most religious groups. *Spirituality* refers to behaviors and beliefs that strengthen a person and provide meaning to his or her life. Some people may identify themselves as being spiritual without an affiliation with an organized religious group. Spirituality is a component of health related to the essence of life and is a vital human experience that is shared by most people (Purnell, 2013). Spirituality, for many people, is a stabilizing force among mind, body, and spirit. For a nurse to complete a thorough cultural assessment, the nurse must inquire about religious preferences and determine the extent to which spirituality or religion affects a patient's physical and emotional well-being. In many cases, aspects of religion and spirituality significantly affect patients' ability to cope with adversity and health-related challenges. Refer to [Chapter 22](#) for methods of assessing religious and spiritual needs.

Health Beliefs

Health beliefs vary significantly among and within cultures. It is critical for nurses and all health care professionals to remember that the health beliefs and opinions of people of the same culture vary according to life

experience, education, family values, and many other factors. Asking questions to determine the health beliefs of each patient is essential to provide culturally competent care. Some knowledge of traditionally held beliefs can help guide assessment of health care seeking and treatment options. Refer to [Box 21.2](#) for research resources on how cultural and ethnic factors may affect patient care and outcomes.

Socioeconomic Level

Nurses need to be cognizant of the impact of patients' socioeconomic status on health care. It is important to determine the overall economic factors that influence the patient. Historically, patients from lower socioeconomic levels have poorer health and tend to have shorter life expectancies. Research has suggested that a lack of insurance and access to health care often leads to late diagnosis of disease, when medical intervention is less effective.

Unfortunately, the level of poverty found in minority populations within all cultures is disproportionately higher than that in the nonminority population. Assessment of a patient's employment status, insurance coverage, and educational background can provide data on financial resources that affect access to and adherence with health care. Economic assessment data are helpful in determining interventions and community resources available for treatment.

After gathering, reviewing, and organizing a patient's health assessment data in a culturally competent manner, the nurse is ready to develop a care plan that acknowledges the role of culture in patient-centered care.

1. List some additional assessment data that should be collected on Maria and her family before her admission to the hospital.

2. List a minimum of four cultural factors, including rationales for each, the nurse should take into consideration while assessing Maria and planning for her care.

Care Plan Development

No nursing diagnoses address cultural concerns in a unique way. Therefore it is vitally important for the nurse to view patient ethnicity and cultural influences as significant pieces of assessment data, without considering them the only cause of a problem or concern. Just as with any patient, many different nursing diagnoses may be applicable to a patient's situation depending on the health care problem being addressed.

It is particularly important for nurses to avoid cultural bias when identifying potential nursing diagnoses in situations in which the patient and nurse are from dramatically different ethnic and cultural backgrounds. For example, a patient who speaks a language other than that of the nurse does not have *Impaired Verbal Communication (ICNP)*; rather, the patient simply speaks another language. Being familiar with the actual definition of a nursing diagnosis will help prevent choosing a nursing diagnosis in a culturally insensitive manner.

The culturally competent nurse develops a plan of care by analyzing the assessment data, both subjective and objective, prioritizing needs, and discussing potential goals with patients and their families or support system before formulating a plan of care. [Leininger \(McFarland & Wehbe-Alamah, 2017\)](#) suggests three types of professional action and decision-making strategies that promote patient-centered care based on a nurse's knowledge of a patient's culture:

- *Cultural maintenance*: Helps people of a particular culture retain and/or preserve relevant care values so that they can maintain their sense of well-being, recover from illness, or face handicaps and/or death
- *Cultural care accommodation or negotiation*: Helps people of diverse cultures adapt to or negotiate with

others for beneficial or satisfying health outcomes with professional health care providers

- *Cultural care repatterning or restructuring*: Respects the patients' cultural values and beliefs while helping patients reorder, change, or modify their lives and adopt new, different, and beneficial health care patterns

Each of these strategies may be beneficial in establishing realistic goals or outcome statements for patients from ethnically and culturally diverse backgrounds.

Potential interventions to be included in a plan of care for people of diverse cultures should be discussed with the patient, family, and significant others (e.g., extended family, cultural healers, identified support system) to determine their level of acceptance in advance. Interventions to relieve anxiety for a person who has recently moved to a foreign country and speaks a language other than that of the care providers include the following:

- Arranging for a professional interpreter to be available by phone in challenging situations
- Identifying community agencies that work specifically with people of the patient's culture
- Seeking social service care from a specialist who speaks the patient's language

The more a plan of care reflects patient preferences, the more likely it is to be accepted and successful. If it becomes necessary to revise the plan of care, the nurse must discuss this with the patient and redefine mutual patient-nurse goals. [Box 21.6](#) addresses some cultural tendencies that should be taken into consideration during the planning stage of the nursing process.

Box 21.6

Diversity Considerations

It is critical that nurses seek specific information based on each unique patient care situation to provide culturally competent care. Some

general population and research findings about various cultures and ethnic diversity may be a helpful foundation from which to ask questions and pursue further cultural inquiry with patients.

Family

- [Strom and Strom \(2017\)](#) found several differences in grandparent attitudes and behavior across cultures when studying African Americans, Caucasian Americans, and Mexican Americans. Time spent by a grandparent with a grandchild was the most significant variable.
- Self-care is valued by many American families, with elderly adults living independently, in retirement communities, or in extended care facilities.
- Generational differences exist among individuals within most cultures. It is essential for nurses to listen and ask questions to develop patient-centered plans of care that encompass the needs of all family members when one member requires the care of others.

Gender

- Gender roles differ greatly among and within cultural groups.
- Women in Latino and many other cultures may adhere to a traditional wife/mother/housewife role.
- Men may act as the decision makers in traditional South American, Middle Eastern, and Indian cultures.

Culture, Ethnicity, and Religion

- Most Orthodox and some Conservative Jewish patients require a kosher diet.
- Many Jehovah's Witnesses refuse blood transfusions based on their interpretation of scriptural restrictions on receiving blood.
- Many Muslim patients prefer diets that do not include pork products.
- Seventh Day Adventists regard the body as a temple and typically do not eat meat or consume caffeine, alcohol, or tobacco products.

Morphology

- The results in a study of 25- to 35-year-old Asian and white men indicates that Asians have smaller bones and are shorter and weigh less than whites without any difference in bone strength (Kepley, Nishiyama, Zhou, Wang, Zhang, McMahon ... Nickolas, 2017).
- Research indicates that the relationship between body mass index (BMI) and mortality risk is stronger in whites than it is in American blacks. This implies that BMI may be a better way to predict mortality risk in American whites than blacks (Jackson et al., 2014).
- According to a study by Kim et al. (2017), there are significant differences in the size and shape of knees within the East Asian, white, and black populations. These differences have an impact on the development of total knee replacement prostheses and may affect the success of total knee arthroplasty surgery.

Language and Linguistics

An essential aspect of planning interventions for patients from culturally diverse backgrounds involves language and literacy. When the nurse and the patient speak different primary languages, the use of abbreviations and acronyms in speech should be avoided. The nurse should use a slower speech pattern to enhance the patient's ability to comprehend what is being said. Speaking more slowly gives the patient additional time for processing information. The nurse should avoid speaking loudly to the patient. Yelling does not increase a person's ability to understand what is being said. The use of humor, slang, and jargon should be limited. Puns, sarcasm, and colloquialisms are not easily comprehended or interpreted by those who speak a different primary language.

Providing written or audiovisual materials that can be comprehended by patients is essential to culturally competent care. Nurses must assess the ability of patients to read and write regardless of their native language. Often, illiterate patients try to hide their inability to read or write by asking others to read to them or by simply agreeing to “read” the pamphlet after the nurse has left the room. [Box 21.7](#) highlights some of the critical factors necessary to provide appropriate patient education resources to a culturally diverse population.

Box 21.7

Patient Education and Health Literacy

Assessment Before Teaching

Nurses should consider language barriers, the ability of patients to read and write, and their education level when planning patient education interventions.

- Can the patient read and write English, or is another language preferred?
- Are health-related materials available in the patient's primary language?
- What is the patient's highest education level?
- What learning style best suits the patient: Written? Oral? Videos?
- Does the patient's education level affect health behaviors?
- Does the patient's education level affect his or her knowledge level concerning health literacy?
- Does the patient need an interpreter?

Safe Practice Alert

It is critical that health care providers verify that patients and families understand information. Consistently positive verbal responses from a patient or frequent head nodding may simply indicate that the patient heard the information without comprehending it. Ask questions and seek feedback or a return demonstration from patients to confirm their understanding.

Individualized Care

A patient's inclusion in care-planning activities is extremely important in the managed care climate, in which patient outcomes and satisfaction with the care provided by nurses and others are used as indicators of the provision of quality health care. Nurses need to ensure that the instruments and processes used by health care organizations are culturally appropriate. The feedback obtained from patients from diverse cultures should be used to improve nursing care for people of all cultural backgrounds. Nursing care plans that blend diverse cultural values, beliefs, and health care practices will increase adherence and patient satisfaction. This is clinically essential to avoid nontherapeutic outcomes. Understanding the underlying principles of culturally competent care gives the nurse the ability to see more than one way to achieve the same outcome. For many people of culturally diverse backgrounds, working with community agencies that provide interpretive services and government support is essential.

3. Identify the most important nursing intervention to be implemented initially, to ensure culturally competent patient-centered care. Describe ways in which the nurse can implement the intervention identified.

Community Referrals

Collaboration among health care providers, community leaders, and health consumers is required to provide culturally relevant services in the community. A high level of nursing knowledge and skill is needed to help patients from different cultures navigate community services. Nurses need to understand how to form partnerships with community leaders and health care providers who can meet the needs of patients from culturally diverse backgrounds (Box 21.8).

Box 21.8

Interprofessional Collaboration and Delegation

Methods for Nurses to Enhance Culturally Competent Care

- Contact interpreters, specific cultural resource centers, and refugee or migration specialists in the community to become better informed about services available to culturally diverse patients
- Share pertinent information with members of the health care team that will assist in meeting the cultural, language, and spiritual needs of patients and family members
- Assist patients and families with accessing culturally appropriate community services and organizations by providing them with referrals, web-based links, or phone contacts
- Work or volunteer with health care professionals and leaders in community outreach programs to increase awareness of resources

Cultural factors determine whether patients from diverse cultures accept community services. Cultural traditions within a community can dictate the structure of community support systems as well as the types of resources available. [Giger \(2017\)](#) suggests guidelines for nurses caring for patients from cultures different from their own that include:

- Examine personal beliefs about people from different cultures before initiating care
- Plan care that includes sensitivity to communication variables and cultural background
- Communicate in a nonthreatening manner, using an interpreter to share information and verify patient understanding
- Empathize with patients, family members, or caregivers who may feel frightened in a care setting in which the traditions are different and medical professionals speak an unfamiliar language

Determining the effectiveness of interventions to address the needs of culturally diverse patient populations requires sensitivity to the norms and expectations of individual patients and their support systems. It is important to refer to mutually agreed-on goals and outcome criteria. The degree to which goals are met should be evaluated on the basis of the patient's perception and the nurse's professional judgment. Input from both sources as well as ideas from community collaborative partners will help determine the effectiveness of a plan of care and the need to continue, modify, or discontinue treatment interventions.

Nurses need to understand that culture can and does influence how they view patients as well as the quality of care that is delivered. Nurses have to avoid projecting their own cultural worldview onto their patients. To deliver culturally sensitive care, nurses must remember that each individual is unique—the product of experiences, beliefs, and values that have been learned and passed down from generation to generation.

Therefore the culturally competent nurse must be guided by culturally relevant information when assessing, diagnosing, planning, and implementing care for diverse patients. The nurse must carefully examine the fit between the diagnosis and the patient for whom it is

intended. The culturally competent nurse is sensitive and flexible while providing outstanding professional care to all patients.

Summary of Learning Outcomes

LO 21.1 *Compare characteristics of culture and ethnicity:* Culture is symbolic, learned, shared, and integrated. Culture includes knowledge of values, beliefs, and ways of life of a particular group that are generally transmitted from one generation to another. Culture influences an individual's thinking and decision-making patterns. Ethnicity is expressed by identity with a particular racial, national, or cultural group, including observation of the group's customs, beliefs, and language.

LO 21.2 *Explain cultural concepts that affect a nurse's ability to provide culturally congruent care:* Some cultural concepts such as generalization may be helpful in guiding nursing practice within certain cultural settings. Others, such as stereotyping, discrimination, ethnocentrism, and racism, have a negative effect on a nurse's ability to provide culturally congruent care.

LO 21.3 *Identify factors that contribute to cultural identity acquisition:* People develop and maintain their cultural identity through a variety of methods. Assimilation and enculturation take place through interaction with family, friends, and the community in which people reside. How people choose to identify with or conform to a culture is determined by the extent to which they ascribe to the norms and traditions of the culture.

LO 21.4 *Articulate an understanding of transcultural nursing:* Transcultural nursing focuses on a broad understanding of global health care. It includes

working in diverse clinical practice settings and collaborating with a variety of community leaders to meet the needs of individuals from many different cultures.

LO 21.5 *Discuss qualities required by nurses to demonstrate cultural competence:* Nurses need to exhibit cultural sensitivity and provide culturally congruent care that balances multiple cultures to display cultural competence.

LO 21.6 *Describe how to develop culturally competent individualized plans of care using cultural assessment tools and the nursing process:* Cultural assessment requires the gathering of data in multiple areas of concern, such as language and traditional health practices. Each aspect of a patient's care plan should be determined after collaboration with patients and should reflect cultural sensitivity to their individual needs.

Review Questions

1. Which statement best serves as a guide for nurses seeking to learn more about ethnicity?
 - a. Ethnicity, like culture, generally is based on genetics.
 - b. A patient's ethnic background is determined by skin color.
 - c. Ethnicity is based on cultural similarities and differences in a society.
 - d. Culture and socialization are unrelated to the concept of ethnic origin.
2. Which action taken by a nurse would reflect application of an appropriate generalization in a

patient care setting?

- a. Assigning same-gender nurses to all patients admitted to the unit
 - b. Asking the dietary intern to verify with Middle Eastern patients whether or not they eat pork
 - c. Telling the radiology technician that every non-Hispanic family is late for appointments
 - d. Assuming that extended families share financial responsibility for medical bills
3. Which statements reflect the practice of transcultural nursing? (*Select all that apply.*)
- a. May be considered a general and specialty practice area
 - b. Focuses on the world view rather than patient needs
 - c. Challenges traditional ethnocentric nursing practice
 - d. Aims to identify individual patient care preferences
 - e. Focuses patient care on the nurse's cultural norms
4. Which of the following questions are appropriate to ask during a transcultural assessment? (*Select all that apply.*)
- a. How do you act when you are angry?
 - b. What is your role in your extended family?
 - c. Why do you continue to speak German at home?
 - d. When communicating with friends, how close do you stand?

- e. What is the purpose of not preparing beef with milk products?
5. How best can a nurse evaluate goal attainment for a patient with a culturally diverse background?
 - a. Assume that gender roles will be a challenge to overcome regardless of the patient's ethnicity.
 - b. Base decisions on feedback from the patient and the nurse's professional judgment.
 - c. Collaborate with future community care providers to determine patient strengths.
 - d. Seek input from members of the patient's support system to avoid biased patient responses.
 6. What aspect of culture is a full-time employed granddaughter of an elderly female exhibiting if she asks the social worker to place her grandmother in an extended-care facility against the wishes of her parents?
 - a. System change
 - b. Gender role
 - c. Cultural norms
 - d. Shared attributes
 7. Culturally competent care would encourage which action by a patient's family?
 - a. Asking the family's spiritual advisor to visit the patient
 - b. Speaking English to everyone involved in patient care
 - c. Adhering to highly publicized restrictive unit visiting hours

- d. Limiting food consumption to items provided by the cafeteria
8. If a patient's primary language differs from that of the health care professionals providing care, which action is most appropriate for the nurse to take?
- a. Use colorful pictures, whiteboards, and gestures to communicate all important information.
 - b. Verify patient understanding of questions asked when the patient responds with continuous affirmative answers.
 - c. Arrange for a professional language translator to be present 24 hours each day.
 - d. Decrease interaction with the patient and family to avoid making them uncomfortable for not understanding.
9. Which ICNP nursing diagnosis is most appropriate for a young immigrant who expresses concern for the safety of his family members who were unable to relocate with him out of a war zone?
- a. *Risk for Spiritual Distress*
 - b. *Impaired Role Performance*
 - c. *Impaired Family Process*
 - d. *Difficulty Coping*
10. What is the best method for the nurse to ensure that a Croatian patient's nutritional needs are met during hospitalization?
- a. Preorder a diet that is consistent with the typical Croatian patient's dietary preferences.
 - b. Ask a Croatian co-worker for ideas on what would be best to order for the patient's meals.

- c. Request that a variety of dietary entrees be provided to the patient to provide options.
- d. Check with the patient on admission to determine dietary limitations and preferences.

CHAPTER 22

Spiritual Health

LEARNING OUTCOMES

Comprehension of this chapter's content will provide students with the ability to:

- LO 22.1 Describe spirituality and spiritual practices in which people may engage.
- LO 22.2 Discuss religion and religious practices that can promote spiritual health.
- LO 22.3 Identify ways in which nurses provide spiritual care.
- LO 22.4 Explain the use of spiritual assessment frameworks.
- LO 22.5 Articulate nursing diagnoses appropriate for the care of patients with spiritual concerns.
- LO 22.6 Describe the interdisciplinary aspects of planning when spiritual needs are identified.
- LO 22.7 Create a care plan that includes personalized spiritual care interventions and evaluation criteria.

transcendence, p. 398

Case Study

Richard Gardner (R. G.) is extubated by the nurse who has provided his care for several days. When he begins to talk, he exhibits an easy sense of humor and shares with the nurse how much he misses being at home with his wife and how much she likes chocolate. He jokingly wonders how he can “sneak out” to buy her a box of candy.

During medical rounds the attending physician walks into R. G.'s room and bluntly, yet gently, tells R. G. that he has bronchoalveolar carcinoma that is untreatable in its advanced state and that the cancer will lead to his death. The physician suggests that R. G. start thinking about whether he wants to be intubated or resuscitated in the event of respiratory distress or cardiac arrest. No family members are present when the physician conveys this information, and R. G. is left to tell his family about his recent diagnosis.

When the physician leaves, the nurse holds R. G.'s hand and expresses sadness regarding his situation. He shares with the nurse that he just wants to go home so that he can die in his own bed. The nurse points out that the doctor did not say that he was going to die right away, and reminds R. G. that he has a box of chocolates to buy, which makes him laugh. He starts wondering aloud if he should tell his son or his wife first. He begins to talk about his children and grandchildren whom he will “leave behind.” The nurse listens to his stories, providing compassionate presence, and holds his hand for quite a while because it is evident that he wants company.

Refer back to this case study to answer the critical-thinking questions throughout the chapter.

Nursing has a long history of recognizing and integrating spiritual care into nursing care, beginning with the religious orders in the Middle Ages and continuing with Florence Nightingale in the 1800s to the present. Research has demonstrated that higher levels of spiritual health are associated with increased adherence to treatment regimens, less symptom distress, decreased pain levels, lower anxiety, better anger management, enhanced quality of life, longer survival with chronic illness, less depression, and lower mortality rates (Ganocy, Goto, Chan, et al., 2016; van Groenestijn, Reenen, Visser-Meily, et al., 2016; Ironson & Dremer, 2016; Mefford, Thomas, Callen, & Groer, 2014; World Health Organization, 2006). Particularly in the oncology patient population, higher levels of spiritual well-being are associated with increased levels of general health, hope, coping, social functioning, self-rated health, and quality of life and with less depression, financial strain, and suicidal ideation (Allmon, Tallman, & Altmaier, 2013; Canada, Murphy, Fitchett et al., 2016; Edward, Welch, & Chater, 2009; Krause, 2006; Motyka, Nies, Walker, & Schim, 2010). Ruth-Sahd et al. (2018) report that spirituality impacts patient length of stay and level of satisfaction associated with care. The body of spirituality research led to The Joint Commission's (TJC's) requirement to provide spiritual care within a multidisciplinary environment in hospitals.

Traditionally, chaplains were the primary providers of spiritual care, but with the adoption of the TJC requirement, spiritual care became multidisciplinary in focus. Aspects of spiritual care are included in the American Nurses Association (ANA) scope and standards of practice (ANA, 2015b), Social Policy Statement (ANA, 2010), and Code of Ethics (ANA, 2015a). The American Association of Colleges of Nurses (AACN) *Essentials of Baccalaureate Education* (2008) requires registered nurse graduates to be capable of conducting a spiritual assessment and recognizing the impact of spirituality on health care. Integrating spiritual needs into a patient's plan of care is imperative to providing holistic care.

Spirituality and religion are complementary yet distinctly different concepts. *Spirituality* focuses broadly on the search for meaning in life, death, and existence, whereas *religion* is an organized, structured method of practicing faith and faith tradition, which expresses one's spirituality. Nurses must explore and appreciate the roles both play in people's lives to better understand the attitudes of patients toward health, illness, and health care.

Lo 22.1 Spirituality

Spirituality is the expression of meaning and purpose in life (Siddall, Lovell, & MacLeod, 2015). It is the manifestation of the innermost self. Human beings express spirituality through their unique capability for thought, contemplation, and exploration of meaning and purpose in life. That unique human dimension of self is the **spirit**; the expression of the spirit is spirituality. People have different belief systems defining *spirit*. Some believe the spirit to be the brain, whereas others believe it to be a complex entity or phenomenon that connects with a higher power, or God. Regardless of the belief system, humans are capable of high levels of thought, and this exploration of meaning and purpose in life affects behavior and health. Therefore spirituality is universal among humans and is a central dimension of health, affecting its physical, psychological, and social aspects.

Spirituality involves movement toward growing as a human being throughout life. Such growth happens over time in an ebb-and-flow fashion. **Transcendence** is the process of moving beyond one's current self (Siddall et al., 2015). Spirituality requires **faith**, a belief beyond self that is based on trust and life experience rather than scientific data. The ability to have faith allows people to demonstrate **hope** (confident expectation) of a positive outcome in the face of challenging circumstances. Both faith and hope are related to how people practice spirituality.

Spiritual Practices

People search for meaning and purpose by engaging in activities to promote their spirituality (Burkhart & Hogan, 2008). These activities are called *spiritual practices*. Overall, spiritual practices promote three types of activities: connecting with oneself through reflection, connecting with others through relationships, and connecting with a higher power through faith rituals. **Reflection** is the process of contemplating experiences, sometimes even life-changing experiences, and searching for meaning in those events. For example, many nursing students choose to enter nursing school because they have had a life experience that called them into nursing (e.g., a death in the family, observation of nurses in

action, a desire to help people). The process of choosing nursing as a career involves engaging in reflection and finding personal meaning in the nursing profession. Not all life experiences require reflection, but those that do often help the person grow spiritually. Many people use methods such as intellectual, artistic, and meditative practices as well as communing with nature to facilitate the process of reflection (Fig. 22.1).

FIGURE 22.1 Artistic endeavors and enjoyment of nature facilitate the process of reflection. (Copyright [istock.com.](https://www.istock.com/))

People may express their spirituality within relationships with others. Great meaning can be found in friendships, family relationships, and partner and spouse relationships. These connections with other people can support and contribute to spiritual growth. Nursing students frequently discuss meaningful clinical experiences with other nursing students to search for meaning and purpose in their chosen profession and help cope with stressful life experiences. This sharing process helps those

involved discern meaning and promote spiritual growth and transcendence.

Some people find meaning in **prayer**, which is spoken or unspoken communication with a higher power. The specific mode of praying often is influenced by the person's religious or faith belief system.

Lo 22.2 Religion

Religion provides a structure for understanding spirituality and involves rites and rituals within a faith community. Many people express their spirituality through religion. Most religions celebrate life events such as birth, marriage, and death with rituals such as baptism, marriage ceremonies, and funerals (Fig. 22.2). Religion can provide a process of discerning meaning and purpose during crises, particularly crises involving health. Therefore religious faith rituals are important in promoting health.

FIGURE 22.2 Religious rituals provide a framework for honoring life events such as birth, marriage, and death. (Top left, Copyright [istock.com](https://www.istock.com). Bottom left and right, Copyright [Thinkstock.com](https://www.thinkstock.com).)

Religious traditions may challenge accepted medical culture, such as when people of the Jehovah's Witness faith refuse lifesaving blood transfusions for themselves or family members. During the assessment process, nurses need to seek information from patients regarding their personal religious practices that may affect medical treatment. An important point in this context is that although some religions are known for specific faith traditions or rituals, not all members of a religious community may subscribe to commonly held beliefs or customs. It is always better for nurses to ask patients about specific spiritual needs or beliefs rather than assume their adherence with those of the general religion to which they belong. [Table 22.1](#) briefly describes the spiritual beliefs of several major world religions and summarizes corresponding traditional health beliefs and spiritual practices.

TABLE 22.1**Common World Religions, Health Beliefs, and Spiritual Practices**

FOUNDATIONAL BELIEFS	HEALTH BELIEFS AND PRACTICES
Buddhism	
<p>The two different types of Buddhism are Mahayana and Theravada.</p> <p>The four noble truths are:</p> <ul style="list-style-type: none"> • Life is suffering. • Origin of suffering is want. • Cessation of suffering is to not want (middle path – moderation). • Think right in terms of view, intent, speech, conduct, means of livelihood, endeavor, mindfulness, and meditation. <p>Karma – cause and effect, rebirth – is the concept that what happens in the next life is contingent on how the person lived the previous life. Rebirth occurs until the person reaches nirvana. There is collective karma, which affects social behavior. Thus government should promote health because it is the right thing to do.</p>	<p>Health is a balance of mind, body, emotion, and spirit.</p> <p>Death includes both physical and mental termination. The family stays with the body for 2 hours before it is transferred off the nursing unit. Bodies are cremated.</p> <p>Meditation calms the mind and body.</p>
Christianity	
<p>Abrahamic religion (descended from Abraham)</p> <p>Beliefs include that Jesus Christ was incarnate of God and that the Trinity is the Father, Son, and Holy Spirit as one.</p> <p>There are an estimated 43,000 different denominations of Christianity worldwide (Heim, 2017), including those listed, with different rituals and sacraments.</p> <ul style="list-style-type: none"> • Catholic • Orthodox • Anglican • Episcopal • Lutheran • Presbyterian • United Methodist • Baptist • United Church of Christ • Nondenominational <p>Sacraments practiced in some denominations include baptism, confirmation, matrimony, penance, anointing of the sick, and communion.</p>	<p>Health is viewed as a balance or integrated whole of physical, psychological, social, ethical, and spiritual dimensions at the individual and societal levels. It is important to love God, self, and others within this integrated whole.</p> <p>Providing health care is very important at the individual and global levels.</p> <p>Health care should help relieve both pain and suffering, whether physical, psychosocial, or spiritual.</p> <p>Forgiveness is a major theme. Many Christians believe in prayer as a means of healing. Both proximal and distant intercessory prayers are encouraged.</p>

FOUNDATIONAL BELIEFS	HEALTH BELIEFS AND PRACTICES
Confucianism, Taoism, Buddhism, Chinese Folk Religion, and/or Combinations of These	
<p>Ethical principles and empathy may be applied to everyone throughout life, creating a moral social order.</p> <p>Five family relationships represent characteristics that are the basis of a moral, well-ordered, harmonious society:</p> <ul style="list-style-type: none"> • Gentility/humility (older/younger brothers) • Righteous behavior/obedience (husband/wife) • Consideration/deference (elders/children) • Benevolence/loyalty (ruler/subject) • Chi is life energy manifested in a balance between yin (feminine energy) and yang (masculine energy) <p>Spiritual immortality is achieved through noninterference with and removal of obstructions to the natural flow of chi, creating harmony with Tao, or one's own human nature.</p>	<p>Health is balanced chi.</p> <p>Health practices to restore yin-yang balance may include:</p> <ul style="list-style-type: none"> • Acupuncture • Nutrition • Herb therapy • Exercise (yoga, tai-chi-chuan, chi-kung) • Moxibustion (burning of the mugwort herb to produce heat for promoting circulation) • Cupping (external suction therapy to improve circulation; usually used for pain, respiratory, or digestive problems) • Gua sha therapy (rubbing or scraping oiled skin to produce intentional surface bruising, to treat fever and pain) • Meditation • Inclusion of family in decision making
Hinduism	

FOUNDATIONAL BELIEFS	HEALTH BELIEFS AND PRACTICES
<p>This ancient religion was originally polytheistic and is now monotheistic. Brahma is the ultimate God; different lesser gods are various aspects of the one God: Brahma (creator), Vishnu (preserver), Shiva (destroyer).</p> <p>Basic beliefs include:</p> <ul style="list-style-type: none"> • Vedas is the law. • Samara is reincarnation. There is a cycle of birth and rebirth. • Karma is consequence. Bad or good experiences are a result of past bad or good behaviors. • Moksha is the path of liberation toward ultimate harmony and occurs through reincarnation. • Dharma is moral conduct. 	<p>Health is a harmonic balance of body, mind, and spirit in relation to the environment.</p> <p>Illness is a buildup of toxins. External toxins include pollution and infection. Internal toxins include fear, anger, greed, sorrow, or grief.</p> <p>In death the soul, or atman, is immortal, whereas the body perishes. Atman is reborn through moksha toward ultimate Brahma.</p> <p>Ayurvedic medicine focuses on cleansing the body of toxins and restoring balance. It includes dietary and elimination patterns. Restoring the balance of mind, body, and spirit includes yoga or meditative practices.</p> <p>Health practices include:</p> <ul style="list-style-type: none"> • Fasting to remove toxins (hot or cold food and drink also help remove toxins) • Yoga or meditative practices • Preference for modesty and same-sex caregivers • Astrology, which can be part of decision making • Belief that pain and suffering are due to bad karma • Dietary restrictions, prayer, and jewelry, which are part of rites and rituals • Vegetarianism
<p>Islam</p>	

FOUNDATIONAL BELIEFS	HEALTH BELIEFS AND PRACTICES
<p>Abrahamic religion Beliefs include that there is one God and that Muhammad is the prophet. Teachings are from the Koran (divine word) and Sunnah (Muhammad's life), for moral imperatives and spiritual values. Rituals include the five pillars of Islam:</p> <ul style="list-style-type: none"> • Believe in one God. • Pray five times a day, facing Mecca. • Give alms for the less fortunate. • Fast during Ramadan. • Make a pilgrimage to Mecca. 	<p>God gave life, and it is the responsibility of people to maintain dignity and take care of the body. Life on earth is a testing ground for the afterlife. Therefore following rituals is critical at all times. Religious practices affecting health care include:</p> <ul style="list-style-type: none"> • Privacy for prayer • Preference for modesty and same-sex caregivers • Family involvement in decision making • Imam (religious leader) sometimes involved in decision making • Dietary restrictions (no pork) • No or limited alcohol consumption
Judaism	
<p>Abrahamic religion Beliefs include that there is one God and that God established a covenant with the Jewish people. Life is a gift from God and is precious. There are many movements or denominations, with varying levels of observance. The most common are identified by their beliefs and practices:</p> <ul style="list-style-type: none"> • Orthodox • Conservative • Reform (Progressive) <p>Rites and rituals include specific foods and holiday observance. Sabbath is Friday night to Saturday night.</p>	<p>Everything possible should be done to preserve life. Religious practices affecting health care include:</p> <ul style="list-style-type: none"> • Kosher diet includes restrictions on pork and shellfish, no mixing of meat and dairy, and consumption only of food that has been designated as kosher. Adherence to a kosher diet varies. • Holiday observance varies. • A newborn son may be circumcised on the eighth day of life in a ritual called a <i>bris</i>. Circumcision is typically not performed in the hospital. • Restrictions on work during Sabbath may affect health care treatment.
Native American Spirituality	

FOUNDATIONAL BELIEFS	HEALTH BELIEFS AND PRACTICES
<p>Mother Earth and nature are sacred. Relationships to people and nature are valued. Listening, seeing, and peace are central to life. Sacred traditions vary depending on the tribe or nation with which a person identifies. There are 567 federally recognized tribes and nations in the United States (U.S. Department of Indian Affairs, 2017) Rituals, ceremonies, and storytelling are central to the religion.</p>	<p>Health is a balance of mind, body, and spirit and is connected to and continually interacting cyclically with nature. Illness is an imbalance. Healing is restoring that balance. Death is the journey to the afterlife. Rituals assist in that journey; the spirit needs to be released. The rituals differ by tribe. The shaman, or medicine man or woman, helps restore the balance between the person and natural forces within a new relationship context. Healing rituals include:</p> <ul style="list-style-type: none"> • Herbal medicines • Dances, songs, and prayers • Sweat lodge ceremonies (incorporate prayers and sauna conditions in sweat lodge structures) • Storytelling
Sikhism	
<p>The leader, Guru, is more than a teacher and is aligned with divine. Belief focuses on God, equality, truthful living, avoidance of superstition, and study of the teachings of the gurus. Meditation is used to reveal inner light. Five physical symbols, or 5K, are worn by devotees:</p> <ul style="list-style-type: none"> • Uncut hair • A wooden comb • A steel bracelet • Cotton underwear • A ceremonial sword 	<p>Health and disease are a continuum. Health is not viewed only physically. Ceremonies are conducted at birth. Body preparation is completed upon death. Religious leaders and families may participate in decision making. Medical care is welcomed along with religious rituals. Religious practices affecting health care include:</p> <ul style="list-style-type: none"> • Daily bathing • Scripture reading • Shaving restriction • Modesty • Wearing of a turban head covering

Lo 22.3 Spiritual Care

Spiritual care in nursing practice is a mutual, purposeful, interactive process between a nurse and a patient, which may include family, to promote the patient's spiritual health (Burkhart & Hogan, 2008). Nurses provide spiritual care when they recognize the interconnectedness of the physical, cultural, and spiritual realms and actively seek to understand and provide for each patient's holistic needs. Overall, spiritual interventions foster the exploration of meaning and purpose by promoting patient self-reflection, promoting connections with others, and/or promoting connections with a high power, as appropriate. Specific interventions to achieve these aims will vary. The nurse may encourage the patient to discuss the meaning of a new diagnosis or encourage the patient to share that meaning with loved ones. The nurse also may refer a patient to a chaplain or preferred spiritual adviser for support, to baptize an at-risk infant in an emergency situation, to pray with a patient on request, or to facilitate implementation of faith-related rituals for a patient facing a life-changing experience such as birth or death. Spiritual care differs according to the patient's developmental age. Spiritual care needs to be provided in a manner consistent with a patient's own faith developmental level, as further described in [Box 22.1](#).

Box 22.1

Diversity Considerations

Life Span

Fowler's Theory of Faith Development (1981, 2002) describes the developmental phases of faith:

- *Infant (primal faith)*: Building trust and loving relationships is fundamental.
- *Toddler/preschool (intuitive projective faith)*: With language development comes the ability to find meaning in stories and an understanding of good versus evil.

- *School age (mythic-literal faith)*: Spiritual growth happens as a result of finding meaning in social relationships and applying principles of ethical and moral reasoning.
- *Adolescence (synthetic-conventional faith)*: Beginning with abstract thinking and the development of self-identity, this is the time of rejecting concrete rules and finding personal meaning in one's own faith beliefs, which may not be thoroughly examined.
- *Young adulthood (individuating-reflective faith)*: Self-identity is established with a greater understanding of self and appreciation of different perspectives. At this level, decisions are based on a broader world view.
- *Middle adulthood (conjunctive faith)*: The person has the ability to accept that multiple interpretations of reality exist. An openness to various religions and faith traditions is exhibited in a person who reaches this stage.
- *Older adult (universalizing faith and the God-grounded self)*: The person understands self as part of a universal “whole” of love and justice.

Gender

Gender differences include the following:

- Women more often want communication and reflection with others, along with personal spiritual and religious practices.
- Men typically want facts and information to assist in decision making and participate less in daily spiritual practices than women (Jacobs-Lawson, Schumacher, Hughes, & Arnold, 2010).

Culture, Ethnicity, and Religion

- Religious traditions differ in spiritual practices. People of various cultural backgrounds, including African Americans, Asians, and Hispanics, particularly those with chronic illness, find spiritual care to be important to health (Chai, Krageloh, Shepherd, & Billington, 2012; Simoni, Frick, & Huang, 2006).

- Life experiences affect the need for spiritual care. People with chronic illness require more spiritual care (Canada, Murphy, Fitchett, & Stein, 2016; van Groenestijn, et al., 2016; Ironson & Dremer, 2016; Logan, Hackbusch-Pinto, & De Grasse, 2006).
- Cultural practices surrounding illness and death vary depending on the faith tradition of patients and their families. Nurses must ask about preferences and try to accommodate requests as much as possible.

Disability

- Parents of chronically and terminally ill children report God and spirituality as their most frequent coping resources (Haley, 2017).
- Professional support by faith or religious leaders, family, friends, and counselors for intellectually and developmentally disabled people who are grieving is critical to their ability to understand and cope with loss (Read, 2014).

Research has shown that adult patients want nurses to promote hope, positive perspectives, giving love to others, finding meaning and understanding, and relating to God (Taylor, 2006). Creating an environment of compassion and caring so that patients and families feel comfortable in expressing their spiritual needs is a prerequisite to providing spiritual care. If the patient does not experience compassionate warmth from the nurse, the patient will not accept spiritual care. Patients who describe themselves as being an **atheist** (believing that God or higher powers do not exist) or an **agnostic** (believing that the nature or existence of God is unknowable) require compassionate, nonjudgmental care similar to that for all other patients. It is essential for nurses to respect the personal beliefs of everyone, even if they are dramatically different from their own. If the beliefs of a patient change because of a health crisis, referral to a chaplain, member of the clergy, or a spiritual adviser may become appropriate.

Providing spiritual care is essential to meeting patients' needs and a vital component of patient-centered care.

Faith Community Nursing

Registered nurses may provide spiritual care through **faith community nursing** (formerly parish nursing), an area of nursing practice that originated from the work of the Reverend Dr. Granger Westberg in the mid-1980s. Some roles of a faith community nurse are health adviser, health educator, advocate, liaison to faith and community resources, coordinator of volunteers, and developer of support groups. Faith community nurses seek to provide holistic care by focusing on the mind, body, and spirit in addition to community wellness. Parish nursing was designated as a specialty by the ANA in 1997. *Faith Community Nursing: Scope and Standards of Practice*, 3rd ed (ANA and Health Ministries Association, 2017) defines the parameters of faith community nursing. Faith community nurses come from many faith traditions; recognized groups include Jewish Congregational Nurses and Muslim Crescent Nurses, as well as registered nurses working within a wide variety of Christian traditions. The Westberg Institute, formerly known as the International Parish Nurse Resource Center, provides educational and resource materials for this specialty in collaboration with the ANA and the Health Ministries Association. More information about the Westberg Institute and faith community nursing is available at <https://westberginstitute.org/>.

Lo 22.4 ♦ Assessment

Spiritual assessment is a process of determining spiritual needs and can take many forms. To comply with TJC's requirement, many institutions incorporate initial spirituality-focused questions into the hospital admission process (Box 22.2). The admissions office or the admitting care provider may ask initial screening questions about the patient's religious tradition, whether the patient's faith community should be notified, and whether care providers need to know of the patient's spiritual or religious needs or practices (Boxes 22.3 and 22.4). Some spiritual assessment frameworks use acronyms to structure this information (Table 22.2).

Box 22.2

Health Assessment Questions

Spiritual Health

- Do you have family in the area? (Assess for family importance, relationships, and meaningful experiences at this time.)
- Is there anyone you would like to call?
- How are you handling this hospitalization or illness?
- What faith practices or beliefs will help you cope with this illness or hospitalization?
- Do you have any dietary or treatment guidelines/restrictions related to your spiritual/religious beliefs?
- Do you belong to a faith community? Do you want the community to be notified? Would you like a chaplain to visit?

Box 22.3

Ethical, Legal, and Professional Practice

Responsibilities Associated With Spiritual Care

- Because of privacy and HIPAA requirements, health care providers cannot contact a faith community without the consent of the patient. Therefore most health care institutions ask, as part of the admission process, whether a faith community should be notified.
- [The Joint Commission \(2018\)](#) requires a spiritual assessment be conducted with patients receiving care in a variety of settings including hospitals, long-term care facilities, or homes. The health care facility or organization determines the exact content of the spiritual assessment.
- Provision 1 of the [ANA Code of Ethics for Nurses with Interpretive Statements \(2015a\)](#) stresses the importance of considering religious and spiritual beliefs when planning patient-, family-, or community-centered care.
- The [International Council of Nurses Code of Ethics for Nurses \(2012\)](#) urges all nurses to promote environments in which the human rights, customs, spiritual beliefs, and values of individual patients, families, and communities are respected.

Box 22.4

Evidence-Based Practice and Informatics

Spiritual Assessment Data Accessibility in Electronic Health Records

- Most electronic health records (EHRs) incorporate spiritual assessment and intervention flowsheets for documentation of spiritual care. Health care agencies integrate spiritual assessment tools such as the FICA Spiritual History Tool, HOPE Questions for Spiritual Assessment, or organization-specific flow sheets to monitor progress and ensure evidence-based care ([Adams, 2015](#)).

- Because spiritual care is multidisciplinary, spiritual documentation needs to be viewed by all health care providers, including physicians, nurses, chaplains, and social workers to ensure integrated, patient-centered care.

TABLE 22.2

Formal Spiritual Assessment Frameworks

FRAMEWORK	COMPONENTS
FICA (Puchalski & Romer, 2000)	<i>F</i> : Faith and belief <i>I</i> : Importance of faith <i>C</i> : Faith community involvement <i>A</i> : Address spirituality or spiritual practices in care
SPIRIT (Maugans, 1996)	<i>S</i> : Spiritual belief system <i>P</i> : Personal spirituality <i>I</i> : Integration and involvement in a spiritual community <i>R</i> : Ritualized practices and restrictions <i>I</i> : Implications for medical care <i>T</i> : Terminal-events planning (advance directives)
HOPE (Anandarajah & Hight, 2001)	<i>H</i> : Sources of hope, meaning, comfort, strength, peace, love, and connection <i>O</i> : Organized religion <i>P</i> : Personal spirituality and practice <i>E</i> : Effects on medical care and end-of-life issues

Nurses assess for spiritual needs on an ongoing basis to determine what holds meaning and purpose in the patient's life. The assessments happen during conversations about family and friends, social supports, employment, or day-to-day life activities outside the health system. Nurses should encourage the patient to lead these conversations and pay attention to nonverbal cues such as facial expression or tone of voice; for instance, when a patient's eyes brighten at the mention of a particular event or person, that subject can be identified as a meaningful aspect of the patient's life.

Patients are at high risk for **spiritual distress** (belief or value system disruption) in certain health situations that threaten their meaning and sense of purpose in life. For example, patients may have spiritual needs when learning of a life-changing diagnosis or experiencing a health crisis. Patients may require spiritual care when making health care decisions. These types of situations require that patients reflect on meaning and purpose in life, personal values, and the way their decisions affect others. Patients

may need assistance during these at-risk times to lessen the degree of their spiritual distress. Nurses must be alert to such situations so that they can intervene appropriately.

Patients exhibit spiritual needs using both verbal and nonverbal cues. In many cases, spiritual distress may be expressed as anger, depression, neediness, or crying. Nurses need to be attentive to the patient's health situation and behaviors to determine whether spiritual care is needed.

Nurses should be observant of potential religious needs. Religious people often use certain expressions such as in their day-to-day conversations—“God willing” or “blessings.” Religious objects in the patient's room, such as holy books, religion-oriented jewelry, or prayer objects, may indicate a religious orientation to spirituality. To promote spiritual health, nurses must be attentive to these verbal, nonverbal, environmental, and situational patient cues indicating a need for spiritual care and must recognize the patient's spiritual or religious orientation. Examples of patient cues are provided in [Table 22.3](#).

TABLE 22.3
Spiritual Assessment Cues

PATIENT CUE CATEGORY	EXAMPLES
Verbal	<ul style="list-style-type: none"> • Asks for prayer or chaplain • Asks if the nurse has time to talk • Talks about topics related to life, death, or purpose • Talks about faith • Uses religious words in conversation • Asks frequent questions about diagnosis; needs to talk • Expresses concerns about family
Nonverbal	<ul style="list-style-type: none"> • Exhibits neediness • Is angry or noncompliant • Seems depressed or withdrawn • Has emotional outbursts and cries quietly
Environmental	<ul style="list-style-type: none"> • Has religious books, jewelry, or symbols and/or has prayer objects • Displays family pictures
Situational	<ul style="list-style-type: none"> • Has a life-threatening diagnosis or life-changing condition • Is facing death • Faces treatment decisions

1. What situational and verbal cues in R. G.'s case indicate a need for spiritual care?

Lo 22.5 ♦ Nursing Diagnosis

Multiple nursing diagnoses are available to help address patient concerns related to spirituality. After a thorough spiritual assessment, the nurse can determine which nursing diagnoses are most appropriate to address the patient's unique needs.

International Classification for Nursing Practice (ICNP) nursing diagnoses that may be identified for patients exhibiting spiritual needs include:

Spiritual Distress

- Supporting Data: Chronic illness, expressions of hopelessness, statements indicating concern over the recent inability to pray

Moral Distress

- Supporting Data: Cultural conflict between medical treatment and religious beliefs, expressions of concern about rejection by religious community, hesitation in accepting blood transfusion

Decisional Conflict

- Supporting Data: Unclear personal beliefs, questioning of personal beliefs while making decisions, delayed decision making

Lo 22.6 ♦ Planning

TJC standards affirm the importance of spirituality and spiritual well-being with regard to improved patient outcomes. Based on assessment findings and identified nursing diagnoses, nurses must individualize and prioritize care for every patient (Table 22.4). It is the nurse's responsibility to decide the order in which spiritual concerns and other patient problems need to be addressed.

TABLE 22.4
Care Planning

ICNP NURSING DIAGNOSIS WITH SUPPORTING DATA	NURSING OUTCOME CLASSIFICATION (NOC)	NURSING INTERVENTION CLASSIFICATION (NIC)
<i>Spiritual Distress</i> Chronic illness Expressions of hopelessness Statements indicating concern over the recent inability to pray	<i>Coping</i> Reports increase in psychological comfort	<i>Coping enhancement</i> Encourage the use of spiritual resources, if desired.

From Butcher, H. K., Bulechek, G. M., Dochterman, J. M., & Wagner, C. (2018). *Nursing interventions classification (NIC)* (7th ed.). St. Louis, MO: Mosby; Moorhead, S., Swanson, E., Johnson, M., & Maas, M. (Eds.) (2018). *Nursing outcomes classification (NOC)* (6th ed.). St. Louis, MO: Mosby. ICNP is owned and copyrighted by the International Council of Nurses (ICN). Reproduced with permission of the copyright holder.

As appropriate, the spiritual needs component of the care plan should include specific goals or outcome statements, as in the following examples:

- “Patient will report the ability to pray after counsel by the hospital chaplain.”
- “Patient will report acceptance of medical interventions that are consistent with personal

religious beliefs and medical necessity within 48 hours.”

- “Patient will discuss treatment choices with a trusted confidant to explore acceptable options before beginning treatment next week.”

A patient's spiritual adviser, clergy person, rabbi, or imam is an important member of the interdisciplinary health care team. In the absence of a personal spiritual adviser identified by the patient, many medical facilities have interfaith chaplaincy departments to assist in providing appropriate spiritual care. When nursing diagnoses involving spiritual concerns emerge during the assessment process, collaboration with and patient referrals to the hospital chaplain may be indicated ([Box 22.5](#)).

Box 22.5

Interprofessional Collaboration and Delegation

Chaplains as Members of the Health Care Team

- Nurses should make chaplaincy referrals when a patient demonstrates or verbalizes a need for spiritual care, and they should follow up to make sure that patient's spiritual needs are being met. Research indicates that nurses make the most patient referrals to chaplains than any other members of the health care team ([Marin, Sharma, Sosunov, et al., 2015](#)).
- In health care facilities with well-functioning departments of spiritual ministry, frequent communication takes place with the interdisciplinary team that consists of nurses, chaplains, physicians, social workers, case managers, and other care providers.
- Chaplains should be asked to attend care conferences at which they can provide spiritual insight and participate in planning holistic health care for patients.

- Chaplains constitute an excellent resource for providing spiritual counseling for nurses who work on all types of units, especially those that are spiritually challenging, including emergency departments, pediatric burn or oncology units, and hospice or intensive care units, where the patient's spiritual needs often are intense (O'Brien, 2014).
- Patient satisfaction scores after hospitalization are consistently higher when chaplains have visited during the patient's hospital stay (Marin, Sharma, Sosunov, et al, 2015).

QSEN Focus!

Nurses need to value the unique attributes of all members of the health care team, including spiritual advisors and clergy, to provide care that fully addresses the spiritual needs of patients.

Lo 22.7 ♦ Implementation and Evaluation

Spiritual care interventions are purposeful actions to promote another person's spirituality. Recognizing a spiritual need and providing spiritual interventions may happen spontaneously. When the nurse recognizes a patient cue, it is important to first be present and actively listen to the patient in a compassionate manner with eye contact. The nurse can further determine whether the patient requires assistance that promotes reflection, connections with others, or faith rituals. The nurse may initiate reflective interventions by stating, "This must be a difficult time for you. Much has changed. What are your thoughts (or feelings)?" In many cases such discussions involve exploring and searching for meaningful aspects of a situation and the subsequent impact on loved ones. Discussion also may include life plans or health care decision making.

Promoting connectedness with others implies that family and friends are providing the spiritual care; the nurse's role is to encourage that connection and/or to eliminate barriers in the environment that are inhibiting this connectedness. Appropriate interventions can include navigating policies and procedures related to visitation and assisting families to overcome fear related to medical equipment and technology (such as ventilators or cardiac monitors).

To initiate connections with others, the nurse may ask, "Is there someone with whom you would like to talk? Can I call family or friends?" If family is available, the nurse may encourage interaction by saying: "You have much to talk about. Is there anything I can do? Do you need more information? Let me give you privacy so you can talk." Nurses need to individualize their spiritual care based on careful assessment of the environment and recognition of spiritual connections among family members.

2. What spiritual care was provided by the nurse to R. G.?

To promote connection with a higher power, nurses can call the chaplain for patients. Board-certified chaplains are sensitive to patients' cultural and faith differences, understand the dynamics of the health care system, and are fully accountable members of the health care team (Ruth-Sahd et al., 2018). Some nurses offer to pray with patients, but this is contingent on the institution's policies and procedures as well as the nurse's comfort with prayer. If the patient asks the nurse to pray and the nurse is uncomfortable participating in this practice, it is best to allow the patient to lead the prayer. Spiritual care includes facilitating religious rituals. Some religious rituals may be contrary to hospital policy (e.g., lighting candles). Nurses need to collaborate with chaplains and administration to maximize religious expression. A variety of nursing interventions can be implemented for patients experiencing spiritual concerns:

- Allow time and opportunity for self-disclosure by the patient.
- Be physically present and actively listen when the patient speaks.
- Support avenues to spiritual growth that are meaningful to the patient, such as praying, meditating, listening to music, viewing or creating art, or reading or writing poetry.
- Arrange for regular visits from religious advisers.
- Monitor and promote supportive social contacts.

- Integrate the family into spiritual practices, as appropriate.
- Avoid sharing personal beliefs that are in direct conflict with those of the patient.
- Refer the patient to or arrange for the patient to engage in a support group or counseling, as appropriate.

3. List additional spiritual care measures that may be helpful to R. G.

Impact on the Nurse

Although the purpose of providing spiritual care is to promote the patient's spiritual health, providing spiritual care also can affect the nurse. Nurses frequently encounter spiritually upsetting situations that may place them at risk for spiritual distress themselves. Nurses who are in spiritual distress may not have the energy to provide spiritual care to their patients. Research has indicated that poor spiritual health can lead to burnout.

To avoid the long-term negative effects of spiritual distress, nurses must attend to their own spiritual health by engaging in spiritual practices that promote their own personal reflection. Because reflection is a time of searching for meaning in a past experience, it can be facilitated by journaling, quiet time, gardening, music, artwork, exercise, or prayer and meditation. Reflecting on a patient–nurse encounter can transform a sad, spiritually distressing encounter (e.g., death of a patient) into a positive spiritual memory, thereby facilitating spiritual growth.

Code Lavender is an evidence-based emotional support strategy implemented in some hospitals after extremely stressful

situations such as patient deaths. It is implemented “when challenging situations threaten unit stability, personal emotional equilibrium, or professional functioning” (Stone, 2018). Code Lavender teams may include chaplains, holistic nurses certified in complementary therapies, music therapists, art therapists, employee assistance representatives, and ethics professionals. In research conducted by Davidson et al. (2017), 100% of participants in a Code Lavender experience found it to be helpful and 84% would recommend it to others.

Providing spiritual care, coupled with reflective practice, can help the nurse grow spiritually. Nurses who work in specialties that require frequent spiritual care (e.g., hospice, oncology) typically report that upon reflection, they are able to find meaning and a sense of privilege in this work. Without reflective practice, providing frequent spiritual care in distressing situations can lead to spiritual distress and an inability to provide spiritual care in the future. Research has consistently demonstrated that people in spiritual distress have difficulty providing spiritual care (Baldacchino, 2007; Wallace et al., 2008). Therefore nurses need to attend to their own spiritual health to provide spiritual care. Spiritual care is central to nursing practice, is fulfilling, and is one of the reasons that nurses stay in the profession.

4. What reflective activities did the nurse perform herself while caring for R. G.?

Safe Practice Alert

Spiritual care is a nursing care requirement. Promoting spiritual health in patients promotes physical, psychological, and social well-being.

Evaluation

After each intervention designed to help patients meet their spiritual care goals, evaluation of the outcome criteria must be completed. Evaluation of goals to address spiritual needs may be difficult to quantify. Nurses should be attentive to physical indications of patient improvement, nonverbal cues, and statements regarding patients' spiritual well-being. Congruency between objective and subjective evaluation data is important to discuss with the patient to help validate goal attainment. After determining the degree to which the patient's spiritual goals were met, the nurse works with the patient to continue, modify, or discontinue the plan of care.

The importance of providing holistic patient care that includes spiritual care cannot be overstated. Nurses must recognize the impact of spirituality on personal health and facilitate the ability of patients to stay connected to their sources of spiritual support during illness or crises.

Summary of Learning Outcomes

LO 22.1 *Describe spirituality and spiritual practices in which people may engage:* Spirituality focuses broadly on the meaning of life and existence. Engaging in reflection, connecting with others through relationships, and connecting with a higher power through faith rituals are spiritual practices that enhance spiritual wellness.

LO 22.2 *Discuss religion and religious practices that can promote spiritual health:* Religion is an organized, structured method of practicing or expressing one's spirituality. Religious rituals such as ceremonies celebrating births, marriages, and the lives of individuals who have died help people share significant events that bring meaning to life.

LO 22.3 *Identify ways in which nurses provide spiritual care:* Nurses provide spiritual care when they recognize the interconnectedness of the physical, cultural, and spiritual realms and actively seek to understand and provide for a patient's holistic needs. Faith community nursing is a professional specialty in which registered nurses practice holistic care within a faith community.

LO 22.4 *Explain the use of spiritual assessment frameworks:* Spiritual assessment frameworks guide nurses in gathering key assessment data

such as identification of patient faith and belief systems, valued religious rituals, and implications for medical care.

LO 22.5 Articulate nursing diagnoses appropriate for the care of patients with spiritual concerns:

Spiritually focused nursing diagnoses include *Spiritual Distress, Decisional Conflict, Moral Distress, and Conflicting Religious Belief.*

LO 22.6 Describe the interdisciplinary aspects of planning when spiritual needs are identified:

Spiritual advisers are an integral part of the interdisciplinary health care team and should be included in care conferences with nurses, physicians, social workers, case managers, and others when spiritual concerns emerge during the assessment process.

LO 22.7 Create a care plan that includes personalized spiritual care interventions and evaluation criteria:

Spiritual care interventions are purposeful actions to promote another's spirituality that include encouraging conversation on topics of concern, actively listening when spiritual matters are shared, and promoting interaction with support people, including spiritual advisers, friends, and family. Evaluation of goals to address spiritual needs may be difficult to quantify. Nurses should be attentive to physical indications of patient improvement, nonverbal cues, and statements regarding the patient's spiritual well-being.

Review Questions

1. The nurse is caring for a 16-year-old boy receiving chemotherapy for testicular cancer. He says that his parents are religious and left a cross next to his bed for “good luck.” What is the most appropriate response by the nurse?
 - a. “Would you like to talk with a chaplain?”
 - b. “Sounds like you are not very religious.”
 - c. “How well do you get along with your parents?”
 - d. “What helps you get through tough times?”
2. Which interventions are considered helpful to assist nurses coping with the unexpected death of a patient for whom they cared for many weeks? (*Select all that apply*).
 - a. Attending a Code Lavender with unit colleagues
 - b. Journaling personal reflections surrounding the death of the patient
 - c. Scheduling to work to a different shift than the one regularly worked
 - d. Arranging a consultation with the unit manager to discuss a possible unit transfer
 - e. Setting aside time for relaxation activities such as painting, gardening, or exercising
3. The nurse has been caring for a patient who just died. The patient's daughter is crying

uncontrollably, saying, "She was my best friend. I thought she would make it! I don't know what I am going to do." What is the nurse's best response?

- a. Express sympathy and ask if she would like to talk with a chaplain.
 - b. Give the daughter time to cry in her mother's room alone.
 - c. Ask the daughter if her father is still living.
 - d. Inquire if the daughter would like to pray.
4. A nurse assigned to the neonatal intensive care unit (NICU) has spent most of a day working with a critically ill infant, with the mother standing by. The infant experiences a cardiac arrest and does not survive. The mother spends an hour crying and holding the baby, saying good-bye. Which spiritual care interventions are most appropriate for the nurse to implement? *(Select all that apply.)*
- a. If desired, briefly hold the baby to say good-bye after the mother leaves.
 - b. Follow procedures to prepare the body for transport to the morgue.
 - c. Visit the mother the next day to see how she is doing.
 - d. Call the family spiritual adviser or the chaplain.

- e. Ask the mother if you could call a family member or friend to be with her.
5. Which statement by a patient best illustrates reflection on a spiritual need?
- a. "My husband told me what to do about this situation, and I'm sure he's right."
 - b. "There is little I can do now to change my circumstances. I just need to adapt."
 - c. "I need to think a little more about how I feel about undergoing this treatment."
 - d. "Whatever the physician wants to do is fine. I don't have much of an option."
6. What is the most important aspect of providing spiritual care in nursing practice?
- a. Call a chaplain.
 - b. Complete the FICA spiritual assessment and refer as needed.
 - c. Recognize situations and patient behaviors indicating a spiritual need.
 - d. Spend some time in self-reflection.
7. When caring for patients who are Jewish, how best can the nurse address their religious needs?
- a. Order a kosher diet.
 - b. Allow time for prayer before each meal.
 - c. Ask about religious holidays, particularly religious practices around the Sabbath.
 - d. Ask about religious practices affecting care.

8. The nurse is caring for a 45-year-old woman who is a breast cancer survivor. What activity associated with her cancer experience will promote this patient's spiritual well-being?
 - a. Attending church every week
 - b. Ensuring she follows her medication regimen
 - c. Genetic testing on family members
 - d. Speaking about her cancer experience to increase breast cancer awareness

9. The nurse is caring for a religious patient who is going to surgery the next day. The patient states that she is afraid and asks the nurse to pray with her, although the nurse is not religious. What is the most appropriate response by the nurse?
 - a. "I am not confident praying, but I will think about you tomorrow."
 - b. "I need to take care of other patients right now, but I will be back."
 - c. "I am uncomfortable praying. May I call the chaplain for you?"
 - d. "I don't do that. Nurses are not allowed to do that at our hospital."

10. How do people who participate in organized religion differ from nonreligious people?
 - a. Religious people are healthier than spiritual people.
 - b. Religious people are more spiritual than nonreligious people.

- c. Religious people express their spirituality through faith traditions.
- d. Religious people have spiritual practices, whereas nonreligious people do not have spiritual practices.

CHAPTER 23

Community Health, Public Health, and Home Health Care

LEARNING OUTCOMES

Comprehension of this chapter's content will provide students with the ability to:

- LO 23.1 Describe various types of community health nursing.
- LO 23.2 Identify examples of the three levels of prevention.
- LO 23.3 Discuss factors affecting the health of a community.
- LO 23.4 Articulate an awareness of various target populations, including vulnerable groups within a community.
- LO 23.5 Discuss the data collection tools used to complete a community or home health assessment using data collection tools such as the windshield survey and the OASIS data set.
- LO 23.6 Identify nursing diagnoses for client or populations of interest.
- LO 23.7 Use measurable goals to develop plans of care for community health concerns.
- LO 23.8 Implement collaborative interventions to address and evaluate the needs of the identified target population or client.

Case Study

Jean is a certified school nurse working full time at the middle school in a multicultural community. On the weekends Jean provides home care for her elderly father-in-law, who is confined to a hospital bed and enjoys visits from family, including his 3-month-old great-grandchild. In Jean's role as a school nurse, she collaborates with the local public health department nurses to develop strategies to educate and vaccinate as many children and adults as possible in her school and community.

Refer back to this case study to answer the critical-thinking questions throughout the chapter.

This chapter focuses on the last phrase in the American Nurses Association (ANA) definition of *nursing*: “the care of individuals, families, groups, communities, and populations” (ANA, 2018). The concept of community health takes the nurse out of the acute setting and places the practice of nursing within a population or in the client's home. Public health, occupational, school, corrections, private-duty, faith-based, camp, forensic, home, hospice, and palliative care nurses are a few of the many nursing specialists who practice within what is broadly considered the field of community health.

LO 23.1 Community Health

Community health addresses issues of health, disease, and disability found within a defined group of people (or population) or in a specific person as a member of that community. Community-based nursing provides personal care to individual clients or families. Public health nursing focuses primarily on populations. Population groups may be narrowed or expanded to a particular area or geographic region, such as a neighborhood, school system, city, state, nation, or continent.

Public Health Nursing

Public health nursing examines the greater community as a whole—the city, county, state, nation, continent, world—and designs collaborative and interdisciplinary strategies to keep the population healthy by preventing or controlling disease and threats to human health (Fig. 23.1). In referring to groups of clients within a community (young, elderly, homeless, inmates, or residents of particular cities or other geographic or government-defined areas), the term **target population** or **population of interest** is used. This designation connotes that the plan of care focuses on more than one person and includes groups of people residing within a defined geographic area. Examples of interventions performed by public health nurses are advocating with housing authorities to ensure accessible and safe housing; planning multilingual, culturally based immunization clinics to increase participation; and investigating the **incidence** (rate of occurrence) of foodborne illness.

FIGURE 23.1 The 10 essential public health services. (From Centers for Disease Control and Prevention. (2017). Essential public health services, 2017. Retrieved from <https://www.cdc.gov/stltpublichealth/publichealthservices/essentialhealthservices.html>.)

Scope and Standards of Public Health Nursing Practice

In 1999 the Quad Council of Public Health Organizations convened to develop standards to guide the evolution and development of nursing practice aimed at population-based care, which evolved into core competencies for public health. The skills reflected in these standards are similar to those used in acute and ambulatory care settings. The focus of competencies, however, is working with populations rather than just one person or family. Using the nursing process, public health nurses coordinate services, provide health education, promote healthy lifestyles, consult with government officials, and participate in regulatory activities (ANA, 2013). The ANA's *Public Health Nursing:*

Scope and Standards of Practice (2013) requires participation in research, responsible resource utilization, ethical behavior, leadership, and advocacy similar to the standards of practice for all nurses.

Public Health Versus Community Health

The terms *public health* and *community health* are often used interchangeably. According to [Stanhope and Lancaster \(2016\)](#), public health nursing is focused on populations. It is not limited to a particular setting, but instead focuses on disease prevention, health protection, and health promotion within identified populations. Assessment, policy development, and ensuring essential services are provided are the three core functions of public health. Nursing plays a unique role in public health; however, it is not the only health care profession engaged in the practice of improving the health of populations. Medicine, dentistry, dietetics, biostatistics, epidemiology, finance, and health policy makers are a few of the disciplines and collaborative colleagues nurses work with to assess, plan, implement, and evaluate systems of care for target community groups or populations of interest. The goals of collaboration are to prevent disease and disability and to promote the highest level of wellness within target groups.

According to [Nies and McEwen, \(2019\)](#), community health extends public health by including organized community health initiatives of both private and government agencies and groups. Private efforts may include philanthropic health-focused foundations such as the Susan B. Komen Foundation, which is committed to working with providers and researchers to eradicate breast cancer.

Nurses are ideal community health practitioners because of their foundation and preparation for nursing practice, which is grounded in the sciences, liberal arts, and social sciences. In addition, the nursing process incorporates evidence-based interventions along with the critical components of assessment, planning, and outcome evaluation. It is not uncommon to see nurses leading community planning meetings with other collaborative disciplines as initiatives are developed to improve the health of a target group, community, or nation. The National Academy of Medicine's public health reports and *Healthy People 2020* are examples of science-based plans to (1) reduce targeted illnesses and disabilities, (2) address health care disparity at certain socioeconomic levels, and (3) identify much-needed services. The United Nations–sponsored World Health Organization (WHO) develops programs to address health concerns globally in response to data collection and analysis conducted worldwide.

Community-Based Nursing

The provision of skilled nursing care in community or [ambulatory care](#) settings (physician's office or outpatient clinic) is referred to as [community-based nursing](#). Community-based nursing focuses on interventions necessary to help individuals prevent illness, maintain or regain their health, or die with dignity while living in a community. The term *client*, rather than *patient*, is commonly used in this area of nursing practice to identify the person seeking care. As is true in all areas of nursing practice, the relationship between the nurse and the client is participatory and collaborative. Effective and critical roles played by community-based nurses include advocating for clients, conducting routine checkups, caring for the sick or dying, providing client education, and managing chronic client conditions at outpatient, community, or government health care facilities. Additionally, community-based nurses provide home care, which includes coordinating multidisciplinary health care teams to optimize the delivery of care.

Health Literacy

A key role of both public health and community-based nurses is education. Both populations and individual clients must be assessed for health literacy levels. The nurse needs to provide information and educational materials in the client's language at a reading level that can be easily understood ([Box 23.1](#)). For additional information on health literacy, see [Chapter 14](#).

Box 23.1

Client Education and Health Literacy

Development of Written Resources

When providing health care education, the nurse may develop or use existing written materials to introduce or reinforce the presentation of information. For these materials to be effective in educating individual clients or populations about health-related matters, nurses must match the content and readability level of written resources to the client's literacy level. Educational materials can be assessed through use of specific tools:

- Readability assessment tools, such as the Fry readability formula, determine the reading level of material.
- Content can be assessed through tools such as the Patient Education Materials Assessment Tool. It is imperative that written resources use language familiar to the clients, address their key concerns, and align with their learning needs ([Agency for Healthcare Research and Quality, 2015](#); [French, 2015](#)).

Home Health Care Nursing

The purpose of [home health care nursing](#) is to promote, maintain, or restore health to an optimal level of functioning and to reduce the effects of disability and illness for homebound clients and their families. Home health care, an alternative to a hospital or a nursing home, is a component of a comprehensive health services system that is provided to individuals and families at their place of residence ([Nies & McEwen, 2019](#)). Home health care, an integral part of community-based nursing, can be described as a dynamic field of care delivery that provides services for diverse health-related issues in the client's home. [The National Association for Home Care and Hospice \(NAHC\) \(2016\)](#) identified over 33,000 agencies nationwide. The health-related services are provided across the clinical spectrum—acute illness, long-term health conditions, permanent disability, and terminal illness. Clients who receive home health care include a variety of age groups, ranging from children to elderly people. Annual expenditures for home care in the United States are projected to reach \$133.3 billion in 2022 ([Centers for Medicare and Medicaid Services \[CMS\], 2018](#)).

Home Care Considerations

Home care nurses should remember that they are guests in the client's place of residence. Respect for the client's personal environment, resources, and caregivers must be demonstrated throughout the visit. In many cases, home care nurses do not have supplies that are readily available in the acute or ambulatory care setting, making improvisation necessary to ensure client safety and positive outcomes. It is vitally important for home care nurses to establish trusting relationships and to interact effectively with clients, their families, and other caregivers; these efforts are key to promoting open communication and adherence with procedures that need to be performed routinely when the nurse is not present ([Fig. 23.2](#)).

FIGURE 23.2 Home health nurses provide critical services to clients and their families. (Copyright [Thinkstock.com](https://www.thinkstock.com/).)

Reimbursement for Home Health Care Services

Home health care services are reimbursed by Medicare, Medicaid, and private health insurance. Medicare is a U.S. federal government–sponsored program. To be eligible for home health services, the client must be homebound and care provided must be medically necessary, short-term, and skilled. Skilled services are provided by a licensed health care professional. Skilled services may include nursing and respiratory care, intravenous therapy, chemotherapy, ostomy/wound management, diabetes self-management training, and renal dialysis. Unskilled services include homemaker and personal care tasks, such as meal preparation, cleaning, laundry, bathing, and feeding assistance. Homemaker service is provided by a home care aide and is only reimbursable by Medicare if a client is receiving a professional skilled service. Private insurance may cover both skilled and unskilled services, depending on individual plans and the needs of the client (CMS, 2018; Nies & McEwen, 2019).

Vital Roles of the Home Care Nurse

The coordination of home health care services most often is provided by the registered nurse, but a multidisciplinary team may be involved, depending on the needs of the client. The team members may include physical therapists, occupational therapists, social workers, pharmacists, registered dietitians, advanced practice nurses, and physicians, as well as unlicensed assistive personnel such as home care aides.

Registered nurses who are employed by a home health care agency may have an associate degree, a diploma, or a baccalaureate or master's

degree. Nurses who have special certifications also may be employed by a home health care agency. The special certifications may be in diabetes care, wound/ostomy care, or infusion therapy. The ANA (2014) has developed specific standards for home care and defined the unique scope of practice for this specialty (Table 23.1). The role of the registered nurse in home health care is essentially autonomous in that the nurse must be highly proficient in health assessment (physical and psychosocial), be well versed in complex technical and clinical skills, possess strong critical-thinking and clinical reasoning abilities, and demonstrate excellent organizational skills.

TABLE 23.1
Standards of Practice for Home Health Nursing

STANDARD	DESCRIPTION OF THE ROLE OF THE REGISTERED NURSE
1. Assessment	Collects comprehensive data about the client's health and situation
2. Diagnosis	Analyzes the assessment data to determine the diagnosis or needs.
3. Outcomes Identification	Identifies expected outcomes for plan of care.
4. Planning	Develops an individualized plan of care that prescribes strategies to attain expected outcomes.
5. Implementation	Implements the plan of care.
6. Evaluation	Evaluates progress toward the attainment of outcomes.
7. Ethics	Practices ethically.
8. Education	Attains knowledge and competence reflective of current practice.
9. Evidence-Based Practice and Research	Integrates research findings and evidence into practice.
10. Quality of Practice	Contributes to quality nursing practice.
11. Communication	Communicates effectively in many formats in all areas of practice.
12. Leadership	Demonstrates leadership in the professional setting and in the profession.
13. Collaboration	Collaborates with clients, families, caregivers, interprofessional team members, and others.
14. Professional Practice Evaluation	Evaluates own nursing practice in relation to professional standards, guidelines, and regulations.
15. Resource Utilization	Uses appropriate resources to plan and provide safe, effective, and financially responsible nursing services.
16. Environmental Health	Practices in an environmentally safe and healthy manner.

Data from American Nurses Association. (2014). *Home health nursing: Scope and standards of practice* (2nd ed.). Silver Spring, MD: Author.

Case Management

The home health care nurse serves as a **case manager** (coordinator) of client care, needed services, and needed supplies in the home setting.

The nurse must be well versed as a financial resource manager, who needs to be aware of what is or is not covered on the client's insurance plan. If consultation or referral is needed, the home care nurse should be cognizant of community agencies or resources within the client's community, such as the local pharmacy or "Meals on Wheels" program. The home health care nurse must have strong teaching skills to instruct clients and families about health practices and technical procedures related to their care. The nurse may counsel clients and families, serve as a client advocate, or refer or secure referrals to other disciplines, as needed.

Hospice and Palliative Care

Some home health care nurses specialize as hospice or palliative care nurses. End-of-life care for the terminally ill is called [hospice care](#). [Palliative care](#) is comfort care offered to clients at any stage of a serious illness. The goals of hospice nursing are to relieve suffering throughout the illness, to be of support to the client and family, and to work with the family, providing grief support after the death of the client. Hospice and palliative care nurses provide care for clients and families in the community setting in their homes, residential facilities, or long-term care facilities. Refer to [Chapter 42](#) for further information on hospice and palliative care nursing.

LO 23.2 Levels of Health Care

Community health care services are designed with a focus on primary, secondary, and tertiary prevention. **Primary prevention** strategies include interventions designed to prevent disease or disability. Examples are immunization programs, employee wellness initiatives, fitness classes, and nutrition education to increase the consumption of fresh fruits and vegetables in homes, schools, and the community at large.

Secondary prevention focuses on early identification of an illness or phenomenon and limitation of its impact or recurrence. Blood pressure screening, routine blood sugar testing, or asking clients about their exposure to domestic violence are examples of secondary prevention screening interventions. Secondary prevention to address childhood obesity might be initiated by a school nurse to assess individual student body mass index (BMI), encourage less consumption of processed foods, and promote extended periods of physical activity. Designing **early intervention** programs (strategies introduced at the first detection of a possible health problem) that involve clients, families, and caregivers can change health outcomes for community members of all ages.

Tertiary prevention involves interventions for those already experiencing symptoms of disease or disability. Tertiary care focuses on maintenance or restoration of health, and rehabilitation. Tertiary interventions include client support groups, pain management counseling, and cardiac rehabilitation programs. For children already diagnosed with diabetes, the school nurse might be responsible for monitoring blood glucose levels or for administering required insulin injections. In addition to school nurses, public and community-based health nurses work tirelessly to identify, prevent, and treat health issues that compromise the well-being of community members. **Fig. 23.3** illustrates the three levels of prevention as they relate to cardiovascular disease.

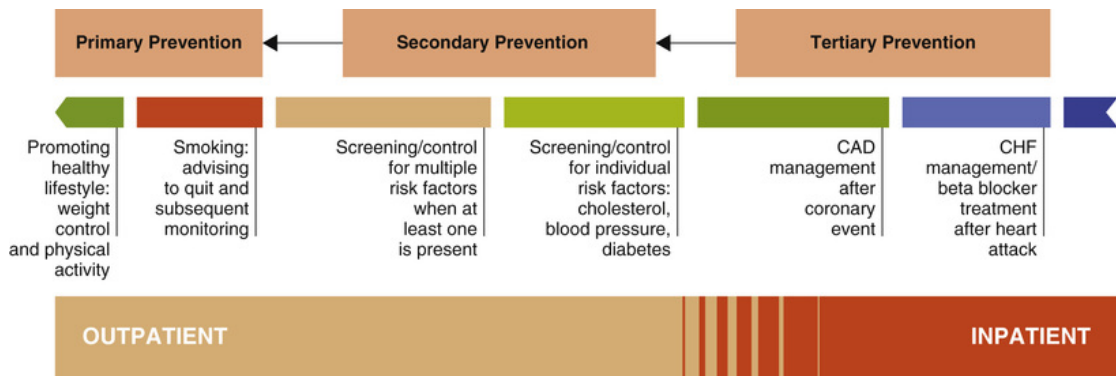

FIGURE 23.3 Cardiovascular care continuum. *CAD*, Coronary artery disease; *CHF*, congestive heart failure. (From Quality Profiles: The Leadership Series. Retrieved from <http://store.ncqa.org/index.php/catalog/product/view/id/2780/s/quality-profiles-the-leadership-series-focus-on-cardiovascular-disease-epub/>. Focus on Cardiovascular Disease material is reproduced with permission from the National Committee for Quality Assurance (NCQA website.)

1. List six areas of concern for Jean as a certified school nurse working in the middle school of a multicultural community.

LO 23.3 Factors Affecting Community Health

Social determinants of health and many other factors can affect the health of a community, including [agents of disease](#) and [etiologic factors](#) (contributors to disease causation) such as excessive or deficient nutritional intake, chemical and airborne agents (such as carbon monoxide or ragweed), physical agents (such as radiation), and infectious agents (such as bacteria and viruses). Clearly, such factors, if left unchecked, can spread through an entire community, with the potential for major impact.

Social Determinants of Health

[Social determinants of health](#) are “the conditions in which people are born, grow, work, live, and age, and the wider set of forces and systems shaping the conditions of daily life” ([WHO, 2018](#)). Distribution of wealth, power, resources, and organizational and government policies affect a specific population's social determinants. Income, education, health literacy, where people live or work, early childhood development, social exclusion, family structure, the status and role of women, and vaccination adherence are just some of the social determinants of health recognized worldwide. These factors must be assessed and analyzed by public health nurses to determine their potential impact on the health of the populations the nurses serve. Social determinants can cause a population to be healthy or vulnerable to disease and disability. When nurses practice population-based care, they look beyond the individual client to the broader society for interventions and strategies to improve the health of entire groups. Many initiatives are focused on reducing the impact of health disparities. The Robert Wood Johnson Foundation's (RWJF) Building a Culture of Health initiative is one example of a nationwide program that looks at the population in its totality and emphasizes improving health for all ([RWJF, 2018](#)). Nurses from all disciplines can play a critical role in initiatives such as this to improve health of across the nation and world ([Box 23.2](#)).

Box 23.2

Ethical, Legal, and Professional Practice

Advocating for Human Rights and Health Equity

- Professional standards for community nurses require ethical practice.
- The World Health Organization asserts that every human being has a fundamental right to enjoy the highest standard of health possible (WHO, 2018).
- Vulnerable populations often face disparities or inequalities in health care access and health outcomes. Nurses in the community can collaborate with community stakeholders to promote equity for vulnerable populations by allocating resources equitably, ensuring the underserved receive the needed care.
- Community nurses can improve policies or practices that discriminate against a person or group.
- Community health nurses are responsible for providing care for individuals and populations that promotes basic human rights (Ivanov & Oden, 2013).

Agents of Disease and Etiologic Factors

Host factors, or **intrinsic factors**, are individual variables such as genetics, age, gender, ethnic group, immunization status, and human behavior that affect a person's health. **Environmental factors** or **extrinsic factors** relate to the immediate physical environment, the biologic environment (including food sources and vectors of disease such as animals and insects), and socioeconomic influences, such as workplace conditions or residence in an urban versus a rural setting, and the potential impact of social unrest or disaster on a community. It can be confusing to examine the reams of data encountered in exploring the health of a community. However, specific tools are available to assist nurses and public health practitioners to understand the factors affecting the health of the community.

Epidemiology

Epidemiology is the study of disease incidence and **prevalence** (pervasiveness or extent). Health care professionals who specialize in epidemiology study factors that determine and influence the frequency and distribution of disease, injury, and other health-related events and their causes in a defined human population. The purpose of their work is to establish programs to prevent the development of disease and control its spread.

Descriptive epidemiology consists of studies that are conducted once a disease is evident. Data collected in descriptive epidemiology studies include the time and place of occurrence of the disease and the characteristics of people affected by the disease. In examining a cohort of community members, the nurse would describe the characteristics of those who have a certain disease and those who do not. This analysis would help determine which variables are most associated with people who have the disease.

Analytic epidemiology generates a hypothesis as to why the disease might be occurring in the community and then tests the hypothesis. Considerations in this dual process would include intrinsic factors related to ethnic groups and cultural dietary and health practices. Also included would be environmental, or extrinsic, factors, such as those observed by the nurse during an analysis of pollution levels and community resources, including parks and grocery stores.

LO 23.4 Targeted Populations In Community Health

Well-recognized target groups within communities include children, adults, teens, elderly people, the homeless, the poor, single and expectant parents, abused children or adults, and substance abusers. Additional target groups of concern include those in communal living environments in which communicable diseases can spread more easily and quickly, such as prisons, dorms, and extended-care facilities.

Vulnerable populations (defined groups of people at high risk for health problems) are of particular concern to community health nurses (Box 23.3). For each of these populations, variables to be identified include age, marital status, income, educational level, economic status, crime level, and use of illegal or regulated substances (tobacco, alcohol), to name a few. The community nurse can study and plan interventions that pertain to any target population of interest—which is one reason that community-focused nursing practice is exciting and seemingly limitless in its potential to improve the health of a community, a nation, or even the world.

Box 23.3

Vulnerable Populations

People who are at particular risk for compromised health as a result of lack of resources, beliefs, life experiences and circumstances, or dependency include the following:

- Refugees and immigrants
- People who have experienced a natural disaster, such as an earthquake, or a human-caused disaster such as a terrorist attack
- Military personnel and veterans
- Workers exposed to chemicals or radiation
- Homeless people or families
- Minority groups within a larger population, including members of various cultural, racial, religious, age, and gender groups who may be denied equal services based on their differences from the general population
- Mentally ill and disabled people
- Substance abusers or people with severe chronic illnesses

- People who have been emotionally, physically, or sexually abused or neglected
- Age-specific populations such as the very young, adolescents, or elderly people
- International (foreign) travelers

By examining vital statistic records, often available on the Internet, for global, national, state, county, or community regions, nurses can identify the leading causes of disease and death in those areas in regard to noncommunicable diseases, such as heart disease, cancer, hypertension, and diabetes. Reference websites also help community nurses identify the incidence and prevalence of communicable diseases, such as tuberculosis (TB), sexually transmitted infections (STIs), and HIV/AIDS, and the life expectancy of target populations. Useful demographic assessment tools and community health planning resources include the following:

- WHO data and statistics (available at <http://www.who.int/topics/research/en/>)
- United States Census data (<http://www.census.gov>)
- State and local department of health websites
- Centers for Disease Control and Prevention (<http://www.cdc.gov>)
- *Healthy People 2020* (<http://www.healthypeople.gov>)
- Occupational Safety and Health Administration (<http://www.osha.gov>)
- Geocoding Public Health Surveillance (<https://www.hsph.harvard.edu/thegeocodingproject/>)

Collaboration with public health officials facilitates coordination of care and promotes use of evidence-based interventions to address identified concerns within target populations.

LO 23.5 ♦ Assessment

Many assessment tools are available to help the community nurse assess both communities and home clients. As can be seen in [Box 23.4](#), some community assessment questions are broad and open-ended to help discern general information, whereas others seek to assess specific concerns within a community, such as nutritional resources or the availability of walking and biking trails. Assessment begins with broad-based collection of data on both communities and individual clients.

Box 23.4

Health Assessment Questions

Community Focus

- What is the history of the community?
- What sources of information are available to help with identifying key data?
- What are the environmental and sanitation services that protect the water supply, inspect restaurants, and license day care facilities?
- What health promotion and educational services exist, and where are they located? Are there school nurses in each building? Are there public health clinics and health fairs?
- What preventive services are available, where, and to what populations? Are target populations able to gain access to these services where they are located?
- What matters to individual members of the community?
- Who are the stakeholders in the community, and what are their main concerns?

Community Assessment

Various community health assessment instruments have been tested for their usefulness, reliability, and validity. The community or public health nurse may drive or walk through a community and perform a [windshield survey](#), observing factors such as the following:

- Whether people are walking or are engaged in physical activity
- Availability of single- or multiple-family private and public housing units
- Availability of health, safety, and social services agencies located along a bus route or other public transportation line
- Presence of spiritual or religious places of worship, educational institutions, and news and media services, as well as types of open and closed businesses and industries
- Availability of grocery stores
- General appearance and condition of neighborhoods

This process begins the initial needs assessment by collecting data through observation of the community's geography, population, environment, industry, education, recreation, communication, transportation, and public services.

QSEN Focus!

Collecting data on the social, cultural, and ethnic traditions that affect community, family, and client values is essential to providing patient-centered care in the community or home setting.

After data are collected on the community, the nursing process is used to (1) diagnose the greatest problems or needs; (2) establish goals; (3) plan interventions for primary, secondary, and tertiary prevention levels; and (4) evaluate the effectiveness of the interventions in meeting community health care goals. In community and public health nursing, it is especially critical to collaborate with many types of professionals and agencies to attain positive outcomes that can dramatically improve community health ([Box 23.5](#)).

Box 23.5

Interprofessional Collaboration and Delegation

Potential Community Intervention Resources

Nurses collaborate with a wide variety of professionals and agencies within the community to plan, implement, and evaluate community interventions. Such collaborations may involve working with the following:

- Nurse educators
- Exercise physiologists
- Administrators of child and adult day care centers
- Primary health care providers
- Visiting nurse association representatives and leaders
- Public officials, including governors, mayors, and council members
- City parks and recreation department officials
- Community hospital administrators and staff
- Public health department officials
- Media outlets (television, radio, newspaper, and online resources, including social media sites)

Home Care Assessment

In home health care, a comprehensive client assessment tool that encompasses both quality assessment and performance improvement must be completed by nurses working for Medicare-certified home health agencies (CMS, 2018). It is known as the Outcome and Assessment Information Set (OASIS). OASIS is a data set of outcome measures for adult home health care clients that is used to track outcome-based quality improvement. Assessment data documented in the OASIS form are summarized in Box 23.6. For adult clients who receive skilled care, OASIS is used to track the plan of care, note client characteristics, and evaluate and improve the clinical performance of each home health care agency. The OASIS-C2 assessment tool, implemented in 2017, is 27 pages long. It is completed by the responsible home health care nurse at the start of care, every 2 months until care is completed, and at discharge (CMS, 2017). The complete OASIS-C2 data assessment document is available from the Centers for Medicare & Medicaid Services.

Box 23.6

Home Care Considerations

OASIS Data Set

Nurses use the OASIS data set to assess home care patients in each of the following areas:

- Current and past medical and surgical history
- Influenza and pneumococcal vaccination status
- Living arrangements, safety and functional abilities
- Sensory status and neurologic, emotional, and behavioral status
- Integumentary status
- Respiratory and cardiac status
- Elimination status
- Neurologic/emotional/behavioral status
- Medication regimen and client and caregiver understanding of required medications and schedule
- Therapy needs and plan of care
- Emergent needs

From [Centers for Medicare and Medicaid Services. \(2017\)](https://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/HomeHealthQualityInits/Downloads/OASIS-C2-AllItems-10-2016.pdf). Home health patient tracking sheet. Retrieved from <https://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/HomeHealthQualityInits/Downloads/OASIS-C2-AllItems-10-2016.pdf>.

During a home care assessment, the nurse focuses on the client's direct health care needs as well as a vast number of environmental factors with potential impact on client safety. These factors include conditions affecting mobility, such as the presence of steps, carpeting or throw rugs, safety railings, and pull bars in the tub or shower. Of concern may be the height of a toilet and the client's ability to ambulate and transfer to the toilet. The nurse notes the client's ability to obtain access to and prepare food or light meals. The client's level of hygiene and ability to groom, dress independently, and bathe are assessed. Living conditions are evaluated for safety and infection control purposes: Is the home relatively clean, with functioning smoke alarms? Is the client able to use the telephone in case of an emergency? As is

evident, the role of the home care nurse in assessment is even broader than that of the acute care nurse.

2. Identify a minimum of four areas that Jean should assess while caring for her elderly father-in-law.

LO 23.6 ♦ Nursing Diagnosis

Identifying nursing diagnoses based on community assessment data is like the process used for an individual. A variety of needs may emerge as a result of a thorough community assessment, making it necessary for the nurse to prioritize diagnoses before initiating goals and interventions in collaboration with community partners.

Some International Classification for Nursing Practice (ICNP) nursing diagnoses that may be used to identify community and home care problems are as follows:

Lack of Community Services

- Supporting Data: Inadequate immunization programs for children and adults in the community, increased incidence of pertussis

Risk for Injury

- Supporting Data: Potential exposure to toxic chemicals

Caregiver Stress

- Supporting Data: Around the clock caregiving responsibilities, fatigue, insufficient time to meet personal needs

LO 23.7 ♦ Planning

Once the greatest concerns of the community or home health client are determined, the nurse can establish goals and desired outcomes to address the needs (Table 23.2). Determining goals for community health must include key **stakeholders** (individuals or groups with an investment or significant interest in a topic). For instance, if the occupational health nurse in a large manufacturing plant identifies a risk for injury from inconsistent use of safety goggles by drill press operators, the owners of the company and the workers themselves would be stakeholders. In this case the nurse would want to collaborate with representatives from both groups to establish a safety-related goal acceptable to all parties. This approach would help ensure adherence with agreed-on procedures, thus increasing the likelihood that the best possible outcome, consistent use of safety goggles, would be achieved.

TABLE 23.2
Care Planning

ICNP NURSING DIAGNOSIS WITH SUPPORTING DATA	NURSING OUTCOME CLASSIFICATION (NOC)	NURSING INTERVENTION CLASSIFICATION (NIC)
<i>Lack of Community Services</i> Inadequate immunization programs for children and adults in the community Increased incidence of pertussis	<i>Community immune status</i> Incidence of vaccine-preventable disease at or below recommended national rate	<i>Communicable disease management</i> Provide vaccine to targeted populations, as available

From Butcher, H. K., Bulechek, G. M., Dochterman, J., & Wagner, C. (2018). *Nursing interventions classification (NIC)* (7th ed.). St. Louis, MO: Mosby; Moorhead, S., Swanson, E., Johnson, M., & Maas, M. (Eds.) (2018). *Nursing outcomes classification (NOC)* (6th ed.). St. Louis, MO: Mosby. ICNP is owned and copyrighted by the International Council of Nurses (ICN). Reproduced with permission of the copyright holder.

LO 23.8 ♦ Implementation and Evaluation

As is evident, designing interventions and evaluation methods for community problems involves a collaborative effort and the assumption of multiple roles by the nurse. An important point in this context is that community health nurses coordinate care both as case managers and as home health care nurses. They must be familiar with budget planning and the financial resources available to fund community programs. A key intervention by the home health nurse is discharge planning in collaboration with acute care nurses, discharge planners, social workers, client caregivers, family, and community resources. There are many resources to help community health nurses find policies and programs that can improve the health of their community. County Health Rankings and Roadmaps has an extensive list of scientifically supported programs at <http://www.countyhealthrankings.org/policies> (Box 23.7).

Box 23.7

Evidence-Based Practice and Informatics

Early Childhood Home Visiting Programs

Extensive evidence demonstrates that pregnancy and early childhood home visiting programs are very effective in improving outcomes for mothers and their children. These programs use nurses or trained health workers to provide long-term home visits for vulnerable parents and children. The Patient Protection and Affordable Care Act (ACA) funds approved programs for that include one or more of the listed interventions and can document positive outcomes in specific areas.

Interventions may include:

- Case management
- Promotion of smoking and substance abuse cessation
- Childbirth preparation
- Parenting education
- Contraception education
- Referral to community resources

Evidence of effectiveness in:

- Reduction of child maltreatment
- Improved cognitive and social development of children
- Improved parenting behaviors
- Improved birth outcomes and infant health
- Reduced rates of early subsequent pregnancy rates for teen mothers ([County Health Rankings and Roadmaps. 2018](#)).

From County Health Rankings and Roadmaps: What works for health: Early childhood home visiting programs. 2014. Retrieved from <http://www.countyhealthrankings.org/policies/early-childhood-home-visiting-programs>.

QSEN Focus!

Informatics is critical for communicating with a variety of health care professionals to coordinate client care in the community setting. It is essential that nurses use technology effectively while maintaining client confidentiality.

One of the most important aspects of a community health nurse's role is to be familiar with referral agencies. Awareness of the scope of an agency's influence and services helps the community nurse pinpoint which agencies are best able to address specific needs. It is essential that the nurse build relationships with agency representatives. Meaningful collaborative relationships facilitate better client care and community cooperation in addressing and evaluating client and program outcomes.

3. Name three public health issues that should be considered before implementation of strategies to reduce pertussis incidence in Jean's community.

Evaluation

Just as interventions must be collaborative within the community setting, so must evaluation of programs and services. The nurse can lead

the evaluation process by designing strategies and tools that will determine whether outcome criteria are met. Data and statistical analysis to support outcome findings is especially significant in working with business owners and government agencies that invest financially in primary-, secondary-, and tertiary-prevention programs.

QSEN Focus!

Evaluating care outcomes demonstrates a commitment to quality improvement for populations served within a greater community.

Although the role of the community health nurse is varied and nontraditional in many ways, it is critical to the well-being of people of all ages. Its focus on safety, disease prevalence, health promotion, disability prevention, and collaborative care illustrates the tremendous impact the nurse can have within the life of a community. Making a difference in the lives of millions of people in the world or thousands of people within a community or in the life of one homebound person is what a community health nurse does every day.

Summary of Learning Outcomes

LO 23.1 *Describe various types of community health nursing:* Three major types of community health nursing are public health, community-based, and home health care. Public health nursing focuses on addressing the needs of populations in collaboration with interdisciplinary teams. Community-based nursing provides care for individuals within the community in areas, such as ambulatory care clinics. Home health nurses assess and treat homebound clients requiring direct care.

LO 23.2 *Identify examples of the three levels of prevention:* Primary prevention includes activities designed to prevent disease and disability. Secondary prevention focuses on screening and limiting the impact or recurrence of an illness or phenomenon with early detection and intervention. Tertiary prevention is directed at treatment of individuals already diagnosed with a disease or disability.

LO 23.3 *Discuss factors affecting the health of a community:* Factors include social determinants, disease agents, such as bacteria or viruses, as well as other etiologic factors such as excessive or deficit nutritional intake, chemical agents, physical agents, and socioeconomic factors (e.g., where one works, whether one lives in an urban or rural setting, and the impact that social unrest or disaster can have on the health of a community).

LO 23.4 *Articulate an awareness of various target populations, including vulnerable groups within a*

community: Target populations include groups of people who have or are at risk for injury, disease, or disability, including those most vulnerable, such as the homeless, infants, elderly people, substance abusers, the mentally ill, and refugees and immigrants.

LO 23.5 *Discuss the data collection tools used to complete a community or home health assessment using data collection tools such as the windshield survey and the OASIS data set*: Windshield surveys help community health nurses conduct observations of a range of factors in their area. Demographic and epidemiologic data collection tools for community assessment are available for use and analysis at the international, national, state, and community levels. The OASIS assessment instrument is designed to collect comprehensive data on home health care clients.

LO 23.6 *Identify nursing diagnoses for clients or populations of interest*: Examples of nursing diagnoses used to address the needs of clients in different types of community nursing are *Lack of Community Services*, *Risk for Injury*, and *Caregiver Stress*.

LO 23.7 *Use measurable goals to develop plans of care for community health concerns*: Developing measurable goals in community nursing may involve collaboration with a variety of health care providers as well as stakeholders who have a significant interest in the outcomes of the goals.

LO 23.8 *Implement collaborative interventions to address and evaluate the needs of the identified target population or clients*; Interventions in community health

settings often require referrals and advocacy to help populations and clients successfully reach established goals. It is vital that nurses establish and maintain strong relationships with community agency personnel to enhance cooperation.

Review Questions

1. Which actions describe the primary scope of practice of a public health nurse? (*Select all that apply.*)
 - a. Assesses populations within the community
 - b. Emphasizes health promotion and disease prevention using evidence-based strategies
 - c. Focuses on individual, setting specific care.
 - d. Collaborates with community stakeholders to assure that essential health services are available to the community.
 - e. Promotes health policies to protect health
2. Which intervention should the college health clinic nurse implement as a secondary prevention strategy to identify students at risk for diabetes?
 - a. Nutrition education on high-protein food availability
 - b. Promotion of registration in fitness classes
 - c. Blood glucose screening at the health fair
 - d. Administration of prescribed insulin
3. What action would be most appropriate for the home care nurse to take if an intrinsic factor appears to be contributing to a client's illness?
 - a. Report the presence of multiple insects in the home to the health department.
 - b. Document the intrinsic factor in the client's electronic health record.
 - c. Explore the possible impact of changing jobs for stress reduction.

- d. Discuss the danger of having multiple throw rugs with the client.
4. When developing treatment plans, which assumption should the nurse consistently make about individual clients within vulnerable populations?
 - a. Educational levels are minimal.
 - b. Economic resources are strong.
 - c. Personal beliefs are important.
 - d. Support systems are extensive.
 5. When the nurse is establishing goals for a community health initiative, which strategy is most important to incorporate in the planning process?
 - a. Collaboration with key stakeholders
 - b. Help from professional interpreters
 - c. Location of schools and businesses
 - d. Gender of primary care providers
 6. What is the best method for the public health nurse to determine whether community members are involved in outdoor physical activity?
 - a. Meet with the parents of high school children.
 - b. Complete a windshield survey of the community.
 - c. Evaluate the number of community health club members.
 - d. Check the local health statistics for the incidence of obesity.
 7. Which intrinsic factors would be of major concern to the nurse when the community has an outbreak of pertussis? (*Select all that apply.*)
 - a. Age

- b. Gender
 - c. Ethnic group
 - d. Cultural background
 - e. Immunization status
8. Whom should the school nurse engage in discussion when conducting a needs assessment related to the high incidence of obesity in the school system? (*Select all that apply.*)
- a. Parents
 - b. Students
 - c. School staff
 - d. Community members
 - e. Firefighters and police
9. The outpatient clinic nurse develops a plan of care focusing on diet, exercise, and glucose monitoring for a preteen recently diagnosed with early-onset type 2 diabetes. On what type of interventions has the nurse based the client's care plan?
- a. Primary
 - b. Proactive
 - c. Secondary
 - d. Tertiary
10. A client with metastatic cancer shares with the clinic nurse that he has only days or weeks to live. What type of community service would be most appropriate for the nurse to suggest to this client?
- a. Home health care
 - b. Hospice care
 - c. Forensic care

d. Acute care

CHAPTER 24

Human Sexuality

LEARNING OUTCOMES

Comprehension of this chapter's content will provide students with the ability to:

- LO 24.1 Explain sexual development throughout the life cycle.
- LO 24.2 Describe the structure and function of the male and female reproductive systems.
- LO 24.3 Differentiate among sex, sexuality, and gender identity.
- LO 24.4 Describe the sexual response cycles of men and women.
- LO 24.5 Identify contraception options.
- LO 24.6 Discuss sexually transmitted diseases and their causes and treatments.
- LO 24.7 Summarize factors that affect sexuality.
- LO 24.8 List factors that affect sexual function.
- LO 24.9 Recognize the impact of family dynamics on sexuality.
- LO 24.10 Implement a sexual assessment.
- LO 24.11 Identify nursing diagnoses appropriate for the care of patients with potential or identified sexuality concerns.
- LO 24.12 Develop a patient-centered care plan designed to address sexuality needs.
- LO 24.13 Implement interventions to support enhanced patient sexuality before evaluating their effectiveness.

KEY TERMS

abstinence, p. 430

anorgasmia, p. 429

bisexual, p. 428

transvestite, p. 428
tubal ligation, p. 431
vaginismus, p. 429
vasectomy, p. 431

Case Study

Gary Wells (G. W.), a 56-year-old patient with a history of hypertension and mild congestive heart failure (CHF), arrives at the outpatient clinic. While taking his health history and completing his assessment, the nurse notes that G. W. is taking aspirin 325 mg PO daily, a diuretic (furosemide, 20 mg) daily, and an antihypertensive/angiotensin-converting enzyme (ACE) inhibitor (lisinopril 10 mg) bid. He has been married for 30 years, has two grown children, is employed as a teacher, and has no current health restrictions. His current BP is 148/86, and his pulse is 78, regular, and strong. His respirations are 16 and unlabored. In the course of conversation during the assessment, G. W. mentions that he loves his wife and does not understand why he is unable to achieve an erection. The nurse asks him when he first noticed his concern, and offers that his erectile dysfunction (ED) may be caused by the medications he is taking for his elevated blood pressure. He is encouraged to share his concern with the primary care provider (PCP). After examination of the patient, the PCP orders a complete blood count (CBC), prostate-specific antigen (PSA), and urinalysis. G. W. is given a pamphlet on ED and sent home with an appointment to return to the clinic in 1 week for follow-up evaluation.

Refer back to this case study to answer the critical-thinking questions throughout the chapter.

Sexuality is a component of the human experience for all people across the life span and is influenced by many factors. How a person identifies with his or her sexuality influences expression of personality and general well-being. Although sexuality has an impact on every person, both nurses and patients often find the topic uncomfortable to discuss. Gaining information about sexuality and sexual health will help the nurse manage any personal reservations and then be able to advocate for the patient dealing with sexuality issues.

Sexuality encompasses many critical topics, including:

- Sexual health and development across the life span
- Gender identity
- Sexual response
- Contraceptive options
- Sexually transmitted diseases (STDs) or infections (STIs)
- Factors that affect sexuality and sexual function

Sexuality affects family dynamics, including decision making and roles. Depending on the circumstances, the nurse may need to complete a thorough sexual health assessment with special attention to the identification of STDs and instances of sexual abuse or assault. Gathering accurate information aids in the development of a personalized plan of care that includes nursing diagnoses related to sexual concerns, as well as appropriate goals and interventions to address those issues. A multidisciplinary approach to treatment may include referral for an in-depth physical examination or sexual counseling. Sexuality influences every aspect of a person's life.

LO 24.1 Sexual Development

Sexual development follows the steps of psychological and physical growth and development ([Table 24.1](#)). Freud noted that during infancy and early childhood, the first 3 years of life are crucial in gender identification development. This is the period during which trust is developed, setting the groundwork for all future relationships. Self-exploration of the body, including the genitals, is considered to represent normal development at this stage.

TABLE 24.1**Sexual Health Characteristics Across the Life Span**

AGE	CHARACTERISTICS	NURSING IMPLICATIONS
Infancy		
Birth to 12 months	<ul style="list-style-type: none"> • Gender assignment • Beginning of gender identification • Body exploration 	<ul style="list-style-type: none"> • Sexual self-manipulation is normal. • Teach parents that this is expected behavior for this stage.
Toddler		
1 to 3 years	<ul style="list-style-type: none"> • Continued development of gender identification • Ability to identify own gender 	<ul style="list-style-type: none"> • Toddler needs interaction with both male and female adults. • Self-exploration and manipulation are still normal.
Preschool		
3 to 5 years	<ul style="list-style-type: none"> • Increased self-awareness • Start of asking questions associated with sex • Ability to identify body parts and name them • Exploration of own body parts and those of playmates not uncommon 	<ul style="list-style-type: none"> • Provide simple and direct answers to sex questions. • Do not respond negatively to child's self-exploration. • Identify body parts with appropriate names. • Teach parents the above guidelines.
School Age		
6 to 12 years	<ul style="list-style-type: none"> • Participation in same-sex friendships • Questions about physical and emotional aspects of sex • Development of primary and secondary sexual characteristics possible • Increased modesty • Strong identification with parent of same sex 	<ul style="list-style-type: none"> • Answer sex-related questions honestly. • Provide written information to assist with understanding. • Discuss topics of sex, menses, and reproduction by the time the child is 10 years old. • Discuss human papillomavirus (HPV) vaccination for both male and female children in the target age range of 11-12. • Respect modesty. • Teach parents the above guidelines.
Adolescence		
13 to 18 years	<ul style="list-style-type: none"> • Value system establishment • Development of primary and secondary sexual characteristics • Opposite-sex relationship development • Risk for pregnancy, sexually transmitted diseases (STDs), sexual abuse • Exploration of masturbation or homosexual relationships possible 	<ul style="list-style-type: none"> • Recognize the importance of peer group influences. • The adolescent's relationship with the opposite sex sets the stage for future relationships. • Teach pregnancy and STD information.
Young Adult		

AGE	CHARACTERISTICS	NURSING IMPLICATIONS
18 to 40 years	<ul style="list-style-type: none"> • Active sex life possible • Establishment of values and lifestyle • Sharing of household and finances • Family planning and infertility • Homosexual identity established 	<ul style="list-style-type: none"> • Provide information on pregnancy prevention and STDs. • Partners need open communication to work through issues of being a couple.
Middle Adult		
40 to 65 years	<ul style="list-style-type: none"> • Reduced male and female hormone influences • Perimenopause/menopause • Quality versus quantity of sexual activity now important 	<ul style="list-style-type: none"> • Role adjustment occurs in response to family stressors and physiologic changes.
Older Adult		
65 years and older	<ul style="list-style-type: none"> • Continued interest in sex • Reduced sexual intercourse frequency • <i>Female</i>: Reduced vaginal secretions and breast atrophy • <i>Male</i>: Reduced sperm production and need for more time to achieve erection and ejaculation 	<ul style="list-style-type: none"> • Recognize older adults' continued interest in sex. • Teach adaptation techniques to deal with any physical limitations that may interfere with sexual satisfaction.

During the school-age years, children tend to have same-sex friends and to adopt the behaviors of their biologic gender. At this time, they need accurate and appropriate information concerning their many questions pertaining to the physical and emotional aspects of sex. [Box 24.1](#) addresses parents' attitudes concerning the need for sex education for school-age youths.

Box 24.1

Evidence-Based Practice and Informatics

Support for Early Sexuality Education

A longitudinal study was done to assess the effectiveness of a 3-year comprehensive sex education program that followed a cohort of 6th graders (N=2453) through the end of 8th grade (with 56% of the students completing the surveys all 3 years, and the remaining 44% completing various parts of the 3-year study). The design used random assignment of 24 schools into treatment and comparison conditions. The analysis of the data assessed differences in delay of sexual activity between the intervention and comparison groups.

The tool used for intervention was *Get Real: Comprehensive Sex Education That Works*, a middle school sex education program

developed by the Planned Parenthood League of Massachusetts that aims to delay sexual intercourse. As a comprehensive program, it emphasizes delaying sex as a healthy choice while providing medically accurate information about protection. It includes nine lessons each in Grades 6, 7, and 8 and provides culturally sensitive and age-appropriate information. The program designates parents as the primary sexuality educators of their children while the school-based curriculum provides knowledge and skill-building. Family activities (eight in each grade) give parents (or other caring adults) an opportunity to transmit their values about sex and relationships.

Results included:

- The adjusted rate of sexual debut (or the implied likelihood of sexual debut) for girls in the treatment group, 22.4%, was 15% lower than the adjusted rate for girls in the comparison group, 26.3%.
- The adjusted rate of sexual debut (or the implied likelihood of sexual debut) for boys in the treatment group, 33.2%, was 16% lower than the adjusted rate for boys in the comparison group, 39.6%.
- A second set of models estimated variability in risk within the treatment group by examining predictive effects of *Get Real* lesson attendance (dosage) and completion of family activities (parental involvement).

Results included:

- Neither dosage nor family activity effects were statistically significant for girls
- Effect of completing family activities during Grade 6 was statistically significant for boys

Overall effect of participating in *Get Real* remains statistically significant for both girls and boys and early support for family communication was particularly critical for boys' sexual health, as family activities may encourage parents to talk with their sons earlier and more frequently (Grossman, Tracy, Charmaraman, Ceder, & Erkut, 2014).

Application to Nursing Practice

- Parents should be encouraged to have open communication with their children regarding sexuality education
- Nurses should use this evidence to actively advocate for evidence-based sex education in schools.

At puberty, adolescents need factual information regarding sexuality and sexual activity as well as guidance to establish a personal value system to serve as a framework for decision making. Areas of concern for education and parental guidance include contraception, unwanted pregnancy, STDs and human immunodeficiency virus (HIV) infection, sexual abuse, and sexual orientation.

When adolescents reach young adulthood, the focus is on intimacy and sexuality. Areas of concern from adolescence continue as well as the issues of conception and **infertility**, which occurs when a couple has not conceived after 12 months of contraceptive-free intercourse if the female is younger than 34 years or after 6 months of contraceptive-free intercourse if the female is older than 35 years of age.

Middle-adulthood sexual development focuses on social and emotional changes as children leave home to begin their lives, no longer dependent on the parents. The “empty nest” scenario can result in stress because of the perception of no longer being needed, as well as the adjustment of the relationship with a spouse or significant other now that the children are gone. Physical changes and changing appearance due to aging may alter sexuality and sexual function. Areas of concern include **perimenopause** (phase prior to the onset of menopause and the first year after menopause) and **menopause** (permanent cessation of menstrual activity), as well as sexual dysfunction that may result from illness or medication side effects or from injury or aging.

Although the common myth is that elderly people do not engage in or enjoy sexual intimacy, **Masters and Johnson (1966)** noted that older adults continue to enjoy sexual relationships throughout each decade of their lives. **Tabar (2014)** identified intimacy and sexuality as important to human identity and well-being throughout the lifespan. Research indicates that older adults are still interested in sex, engage in sexual activity, and find their sexual activity pleasurable (**March, 2018**).

The male reproductive system gradually changes as age advances. There is a reduction in testosterone levels, sperm production decreases as the testes’ size and firmness decrease, and the prostate enlarges. The frequency of intercourse usually decreases, along with the perception

of sensation; however, erection attainment speed, ejaculation force, and sexual interest, thoughts, and activity continue through old age (Fig. 24.1).

FIGURE 24.1 It is a common myth that elderly people do not engage in or enjoy sexual intimacy. (Copyright Ariel Skelley/Blend.)

LO 24.2 Normal Structure and Function of the Male and Female Reproductive Systems

To gain insight into sexuality and assist patients in achieving sexual health, the nurse is required to have knowledge of sexual development, the normal structure and function of the male and female reproductive systems, male and female sexual response, and gender identity. The reproductive organs are key components of sexual response.

Male Reproductive System

The male reproductive system has external and internal organs ([Fig. 24.2](#)). The external organs are the scrotum and the penis. The scrotum is a loose sac that contains the testes, or male gonads. The testes produce spermatozoa—male sex cells—as well as the male hormone testosterone. The penis is composed of a glans and shaft, which is cylindrical, pendulous, and erectile. Inside the penis is the urethra, which is an outlet for urine from the bladder, as well as seminal fluid. The glans is the cone-shaped head of the penis that is covered with the foreskin (prepuce) at birth. If the male is circumcised, the glans is exposed. If the male is uncircumcised, the foreskin needs to be retracted for cleansing and intercourse.

FIGURE 24.2 Male reproductive system.

The internal male reproductive organs are the seminal vesicles, the testes, and the prostate. Seminal fluid is produced and stored in these organs. Spermatozoa combine with seminal fluid, resulting in semen, which is ejaculated from the erect penis during male orgasm. [View the animation on the male reproductive system for further information.](#)

Female Reproductive System

The female reproductive system also has external and internal organs (Fig. 24.3). The external female genitalia have several components, known collectively as the *vulva*. These components include the mons pubis, the fatty tissue covering the symphysis pubis; the labia majora, tissue that forms the lateral borders of the vaginal orifice; the labia minora, thinner folds of tissue just inside the labia majora borders; and the clitoris, the female counterpart to the penis, in that it responds to stimulation that can lead to orgasm. Additionally, Skene glands, located inside and posterior in the urethra, and Bartholin glands, which are small mucous glands in the vaginal vestibule, both produce small amounts of vaginal lubricant during sexual stimulation.

FIGURE 24.3 Female reproductive system.

The female internal genitalia include the vagina, uterus, fallopian tubes, and ovaries. The vagina is the connection between the external vulva and the internal uterus. It is composed of muscle and mucous membrane cells and has the ability to expand during intercourse and childbirth. The uterus has three parts: the cervix, which connects the uterus to the vagina; a hollow cavity; and the upper section called the *fundus*. The uterus is pear-shaped and muscular and has the capacity to expand, as in pregnancy. The two fallopian tubes are narrow ducts that extend out the left and right sides of the uterus and end in fingerlike tissue near, but not connected to, the ovaries. The ovaries are two almond-size organs in the left and right sides of the pelvis that contain ova (female reproductive cells) and the female hormones estrogen and progesterone. [View the animation on the female reproductive system for further information.](#)

Menstruation is the female's cyclic periodic discharge of bodily fluid from the uterus during the reproductive years, encompassing the ages of approximately 12 to 50 years. The cycle is monthly, averaging every 28 days, with a range of 21 to 35 days. This cycle is under hormonal influence from the hypothalamus (gonadotropin-releasing hormone), which stimulates the pituitary (follicle-stimulating hormone [FSH] and luteinizing hormone [LH]). The hormones in turn cause ovarian production of estrogen and progesterone, which stimulate the vagina, uterus, and breast to prepare for potential pregnancy. If pregnancy does not occur, levels of estrogen and progesterone drop, the menstrual cycle (menses, period) occurs, and the entire process restarts via the feedback mechanism.

Breasts are included as female reproductive organs because estrogen and progesterone, the hormones of reproduction, influence them, and they are the organs of **lactation**, which is the production and release of milk by the breasts (mammary glands). They are fatty glandular tissue that contains lobes, which have the ability to produce milk that then drains through ducts to the nipples (Fig. 24.4). Touch and stimulation of the breasts can be satisfying during sexual activity.

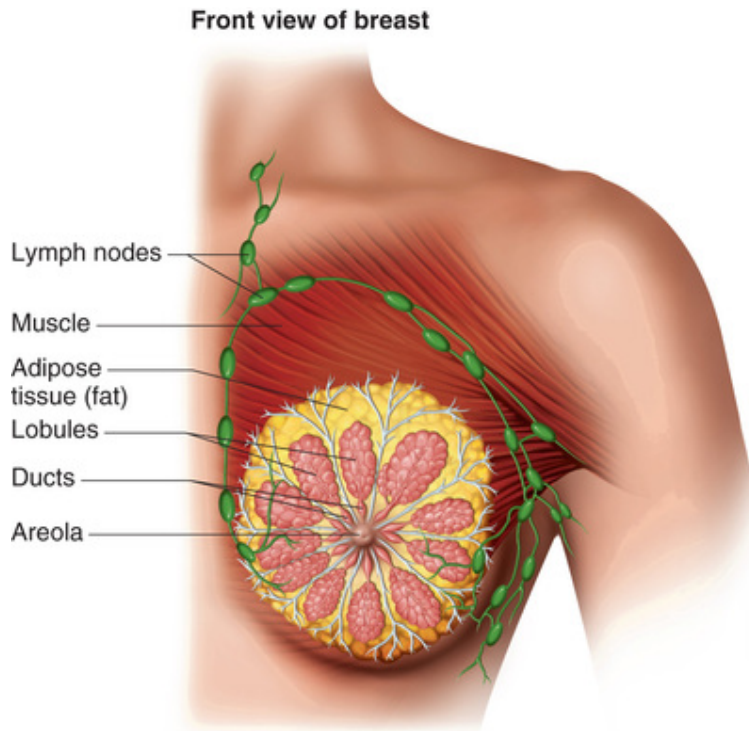

FIGURE 24.4 Breast anatomy.

LO 24.3 Sex, Sexuality, and Gender Identity

Nurses need to understand the terminology associated with sexuality and differentiate among the various terms' meanings. **Sex** is the term often used to express "sexual intercourse," as in "having sex." It can be further defined in the psychological sense to mean the individual's self-image of his or her gender, which may be at variance with the person's morphological sex (sex as determined by the internal and external genitalia). **Sexuality** is considered the collective characteristics that mark the differences between male and female. Further, it is the nature and life of an individual as related to sex and all that pertains to intimacy, whether associated with sex organs or not. **Gender identity** is defined as a personal conception of oneself as male or female (or, rarely, both or neither). This concept is intimately related to the concept of gender role, which is defined as the outward manifestations of personality that reflect the gender identity (Shuvo, 2015). The nurse needs to recognize that both these concepts impact the person's sexuality.

A person's sex is defined by the internal and external genitalia, and this determination usually can be made by visual inspection at birth. How the person self-identifies with respect to gender is affected by a variety of influences. Family experiences and values, association with or lack of a relationship with the same-sex parent, parental identification of gender from birth, self-concept, and confidence about one's sexual identity all influence a person's gender identification. Terms associated with gender identity are defined in [Box 24.2](#).

Box 24.2

Gender Identity Terminology

- **Gender role** is the set of behaviors of a person as either a male or female and the perception of what constitutes gender-appropriate actions.
- **Sexual orientation** is a person's attraction to his or her own sex, the opposite sex, or both sexes when choosing a sexual partner.
- **Heterosexual** is defined as a person who has sexual interest in or sexual intercourse exclusively with partners of the opposite sex.

- **Homosexual** is defined as a person who has sexual interest in or sexual intercourse exclusively with members of his or her own sex. **Gay** is a term most often associated with male homosexuality, whereas **lesbian** refers exclusively to female homosexuality.
- **Bisexual** describes a person who is emotionally or sexually attracted to people of either sex.
- **Intersex** describes a person who is born not fitting the characteristic definitions of male or female, either based on their anatomy, chromosome makeup, or other related differences.^a
- **Questioning** refers to someone who is unsure or exploring his or her sexual orientation or gender identity.
- **Transgendered** refers to having a gender identity or gender perception different from one's phenotypic gender.
- **Transvestite** is a person who has the desire to dress in the clothes of and be accepted as a member of the opposite sex.
- **Transsexual** is a person who self-identifies as a member of the opposite sex. The sexual anatomy is not consistent with the gender identity. Transsexuals may choose cross-dressing (dressing in the clothing of the other sex) or seek to have their external sex organs changed by transsexual surgery.

^aFrom Luke, M., & Goodrich, K. (2013). Investigating the LGBTQ responsive model for supervision of group work. *Journal for Specialists in Group Work*, 38(2), 121-145.

Sexual Expression

Methods through which individuals express themselves sexually vary depending on social norms and personal preferences. Some people prefer only vaginal intercourse, using a variety of positions. Others engage in oral-genital stimulation, anal intercourse, or masturbation (alone or with a partner). Some people remain celibate, choosing abstinence as a lifestyle. Sexual expression may vary extensively throughout a person's life span, depending on a variety of factors, some of which are addressed in [Box 24.3](#).

Box 24.3

Diversity Considerations

Life Span

- Sexual identity changes as a person moves through the stages of life.
- A person moves from friendships with same-sex schoolmates during the school-age years to dating during adolescence.
- Young adults experience a need for intimacy and for establishing a relationship with a significant other to become a couple.
- If parenthood occurs, that person moves from the role of mate to the role of parent. This role may consume the person to the point of losing the sexual identity of being part of a couple for a period of time.
- Middle adults encounter changes that are a result of children's growing up and relying less on the parent, who often needs to reestablish sexual identity with his or her mate. In addition, hormonal changes that occur with age influence sexual performance, and adjustments in expectations may need to occur.
- Older adults may continue to desire the satisfaction of sexual activity but need to adjust to accommodate physical and cognitive changes.

Gender

- Gender diversity frequently is noted as sexual orientation, the gender preference of a person in relation to the person's sexual attraction.
- Included in gender diversity are heterosexual, homosexual, bisexual, intersex, transvestite, and transsexual.

Culture, Ethnicity, and Religion

- Cultural, ethnic, and religious issues occur in the area of sexual diversity.
- Some religions have a strict doctrine that forbids all forms of sexual expression other than heterosexuality.
- Practices and attitudes regarding contraception, sex education, and sex outside of a marriage all may be affected by religious teachings.

- **Circumcision**, the surgical removal of the foreskin of the penis, is considered a religious rite for some individuals of the Jewish and Muslim faith.
- Buddhism followers believe in a holistic approach to health, which may potentially affect choices for birth control and infertility treatment options.
- Most religions do not condone abortion as a form of birth control. Catholic Church doctrine opposes abortion in all circumstances.
- Persons of the Islamic faith may prefer family members be involved in decision making regarding sexual-related topics, such as tubal ligation.

Disability

- Disabilities resulting from illnesses, injury, or surgery may alter the sexual experience.
- Physical restrictions from decreased mobility have the potential to reduce sexual function.
- Medication side effects may have a negative impact on sexual expression.
- Adaptation of positioning during sex, as well as the need for oral or manual stimulation to obtain sexual satisfaction, may be deterrents to sexual activity for those with disabilities.

LO 24.4 Sexual Response

Female

Four phases constitute the female sexual response cycle. The phases—excitement, plateau, orgasm, and resolution—consistently occur in this sequence, although the duration of each phase is variable. Arousal typically ends with orgasm or climax, but at times this may not occur. Unlike in males, the response cycle in females does not have a refractory phase, during which sexual response cannot occur, and thus multiple orgasms are possible.

In the female sexual response, two physiologic responses, vasocongestion and mytonia, occur. Vasocongestion of the vagina's blood supply leads to engorgement, increased lubrication, and genital swelling and enlargement, all as a result of sexual stimulation. Mytonia (vaginal muscle spasms) results from muscle tension that leads to both voluntary and involuntary muscle contraction.

Issues of female sexual expression include **dyspareunia** (painful intercourse), **vaginismus** (contraction of the vaginal muscles to the degree that the penis cannot be inserted), and **anorgasmia** (inhibited female orgasm).

Male

The phases of the male sexual response are stimulation, erection, emission, ejaculation, and detumescence. Both the sympathetic and parasympathetic nervous systems impact the male response. Sexual arousal can be achieved through psychological stimulation, as from sexual thoughts, as well as by genital stimulation. Erection involves the shunting of blood into the penis. Emission causes sperm to move from the epididymis to the urethra. Ejaculation is the expulsion of the sperm from the urethra, which is then followed by **detumescence**, in which the penis is no longer erect. Male orgasm is the period of emission and ejaculation. After the male sexual response, a refractory period occurs, during which there is resistance to muscle or nervous system stimulation.

Issues of male sexual expression include **erectile dysfunction (ED)**, or impotence, which is the inability to achieve or maintain a penile erection for sexual intercourse, and premature ejaculation, which occurs if a male ejaculates before his sex partner achieves orgasm in more than 50% of their sexual encounters (**Masters & Johnson, 1966**).

LO 24.5 Contraception Options

Contraception is the prevention of conception. Contraceptive methods are used for birth control, to prevent pregnancy. Various contraceptive methods are available for males and females, some with and some without the need for a prescription (Table 24.2 and Fig. 24.5).

Effectiveness of any method is dependent on accuracy and consistency of use. Additionally, contraceptive methods do not necessarily protect against STDs.

TABLE 24.2**Contraception Methods**

METHOD	FUNCTION
Abstinence	No sexual intercourse occurs; 100% effective at preventing conception.
Withdrawal of the penis before ejaculation	Semen (sperm) is deposited outside the vagina to reduce the chance of conception.
Timing of sexual intercourse with ovulation and menses (rhythm method)	Intercourse is prohibited during fertile days to reduce the chance of conception.
Male or female condom	Barrier method prevents entry of sperm into the vagina to reduce the chance of conception.
Spermicide (creams, sponges, foams, or jellies)	Agent is inserted into the vagina before intercourse, serving as a barrier to reduce the chance of conception.
Oral contraceptive	Hormonal changes alter the uterine environment and thicken cervical mucus to reduce the chance of conception and stop ovulation. Pills need to be taken daily.
Intrauterine device (IUD)	Device is inserted into the uterus through the cervix by provider. Mechanism of action is not well understood. Various processes are thought to inhibit the ability of either the egg or the sperm or both to unite with one another, so that fertilization does not occur.
Hormonal injection, implant under the skin, or transdermal patch	Hormonal changes alter the uterine environment and thicken cervical mucus to reduce the chance of conception. Prolonged effectiveness of these methods improves adherence.
Diaphragm/cervical cap	Barrier method device is inserted into the vagina and used with spermicidal cream or jelly to reduce the chance of conception.
Vaginal ring/transdermal system	Small, flexible ring is inserted by a woman into her vagina for 3 weeks every month and removed for the remaining week; contains the same hormones as in oral contraceptives and is considered easier to use.
Emergency contraception (morning-after pill)	Taken within 3 days after intercourse to prevent the ovaries from releasing an egg, making pregnancy impossible. Will not abort a fertilized egg. Limited effectiveness in women with body mass index (BMI) >25.
Hysteroscopic sterilization	Nonsurgical procedure occludes the fallopian tubes with small metal springs. The coils trigger scar tissue growth over time, causing the tubes to be permanently blocked.
Surgical sterilization <i>Male:</i> Vasectomy <i>Female:</i> Tubal ligation	This is the most effective contraceptive method other than abstinence. Both vasectomy and tubal ligation are surgical procedures that prevent conception and are considered highly effective.

FIGURE 24.5 Types of contraceptive devices.

Abstinence (going without sexual intercourse), timing of intercourse in connection with the menstrual cycle, and barrier methods are all nonprescriptive contraceptive methods. A **condom**, a thin latex or non-latex sheath that covers the penis to prevent sperm from entering the vagina, and spermicidal products (foam, cream, jelly, sponge) are barrier methods. Abstinence currently is the only method that is 100% effective for pregnancy prevention.

The prescription methods of contraception are hormonal contraception; use of a diaphragm, **intrauterine device (IUD)**, or cervical cap; and surgical sterilization. Hormone-based contraception includes oral contraception (“the pill”), as well as intramuscular injection, transdermal patch, subdermal implant, vaginal ring, and IUD. IUDs are placed through the cervix into the uterus and may contain progesterone or copper, which change the uterine lining, thus reducing the chance of implantation.

The **diaphragm**, a flexible, round rubber dome, is used with a spermicidal jelly or cream and inserted into the vagina to cover the entire cervix. The cervical cap functions in the same fashion, but it is smaller and covers only the opening to the cervix.

Sterilization is possible in both genders. Male sterilization (**vasectomy**) is the severing of the vas deferens, which carry sperm out of the testes. When the male ejaculates during sexual intercourse, there are no sperm in the semen. Female sterilization (**tubal ligation**) is the ligation of the fallopian tubes. When the tubes are ligated (tied off or severed), the egg cannot travel through the tube and the sperm cannot

get to the egg, thus preventing fertilization. These procedures are the most effective contraceptive methods other than abstinence.

Safe Practice Alert

Teach the patient to use a water-based lubricant with a condom. Oil-based lubricants, such as petrolatum (Vaseline), will break down the latex, making the condom ineffective.

LO 24.6 Sexually Transmitted Diseases and Infections

A **sexually transmitted disease (STD)** is any disease that may be acquired as a result of sexual intercourse or other intimate contact with an infected person. The term **sexually transmitted infection (STI)** is used if an infection is present without actual signs of disease ([American Sexual Health Association \[ASHA\], 2018](#)). Despite this difference, the terms *STD* and *STI* are often used interchangeably, because the designation of “infection” is thought to carry less stigma than “disease.”

Identification of an STD can be difficult, because symptoms may go unnoticed or be ignored. Common STD symptoms include pain during sex (dyspareunia) or on urination; genital blisters or lesions; discharge from the penis, anus, or vagina; and elevated temperature ([Centers for Disease Control and Prevention \[CDC\], 2018](#)). Patients may be embarrassed to admit to having STD symptoms or may find it difficult to discuss sexual practices. Nurses should be nonjudgmental and empathetic in their communication to foster trust and enhance the patient's ability to share personal information.

STDs include conditions caused by bacteria, viruses, protozoa, and fungi. Gonorrhea, syphilis, and chlamydial infection all are caused by bacteria and usually can be treated and cured with antibiotics. The viral diseases, including genital warts (caused by human papillomavirus [HPV]) and genital herpes (due to herpes simplex virus type 1 [HSV-1]), can be treated but not cured. All STDs, including HPV infection, can be contracted by both males and females. [Table 24.3](#) presents general information on the symptoms, transmission, and prevention of these relatively common STDs.

TABLE 24.3**Common Sexually Transmitted Diseases**

SYMPTOMS	TRANSMISSION	PREVENTION
Chlamydia		
May be totally asymptomatic; flulike symptoms, genital discharge in men or women accompanied by burning with urination	During vaginal, oral, or anal sex or during vaginal delivery	<ul style="list-style-type: none"> • Abstinence • Monogamous relationship with uninfected partner • Consistent and correct use of latex male condoms • Annual testing of all sexually active women aged 25 or younger, older women with new or multiple sex partners, and all pregnant women
Gonorrhea		
May be asymptomatic; genital discharge, burning, and pain	Contact with the mouth, penis, vagina, or anus	<ul style="list-style-type: none"> • Abstinence • Monogamous relationship with uninfected partner • Consistent and correct use of latex male condoms
Genital Herpes		
Genital discomfort, sores that heal within 2-4 weeks	Contact with sores during an outbreak or with infected skin between periods of outbreak	<ul style="list-style-type: none"> • Abstinence when lesions or symptoms are present • Use of condoms to reduce risk
Human Papillomavirus (HPV)		
May be totally asymptomatic, especially in males; genital warts with some human papillomavirus (HPV) types, which vary in size and shape; can undergo transformation to various forms of cancer in both men and women	Through vaginal, oral, or anal sex or genital-to-genital contact	<ul style="list-style-type: none"> • Vaccines <i>Girls and women:</i> Cervarix and Gardasil <i>Boys and men:</i> Gardasil • Use of condoms, which may lower risk
Syphilis		

SYMPTOMS	TRANSMISSION	PREVENTION
Three stages: Begins with sores, advances to a rash with mucous membrane lesions, and ends with a latent, late stage affecting the central nervous system; may lead to blindness, paralysis, and psychosis	Direct contact with syphilis sore (chancre) during vaginal, oral, or anal sex	<ul style="list-style-type: none"> • Avoidance of alcohol and drugs, because their use may lead to risky sexual behavior • Monogamous relationship with uninfected partner • Consistent and correct use of latex condoms covering infected areas, which may reduce risk

From Centers for Disease Control and Prevention (CDC). (2018). Sexually transmitted diseases (STDs). Retrieved from www.cdc.gov/std/default.htm.

Safe Practice Alert

Teach patients taking antibiotics for STDs to take the full course of therapy, even if signs and symptoms decrease or disappear.

Human Immunodeficiency Virus Infection

HIV infection is caused by a blood-borne virus that may be acquired by sexual contact through exchange of bodily fluids. Risk behaviors include unprotected vaginal, anal, and/or oral sex, use of contaminated intravenous (IV) needles, and transfusion of infected blood or blood products. During the initial phase of HIV infection, which lasts approximately 1 month after onset, the patient may have flulike symptoms. The condition then moves into the clinical latency phase, a variable length of time during which the patient has no infection symptoms. In the third phase, symptoms become evident, and HIV infection becomes acquired immunodeficiency syndrome (AIDS), which is serious and may be fatal. Survival time for patients with AIDS has improved with the use of antiretroviral (ARV) drugs, given in combination, and identified as antiretroviral therapy (ART). This protocol is individualized to the patient and is usually taken in combination of three or more drugs, to have the greatest reduction of HIV in the body (CDC, 2018.)

Safe Practice Alert

Strict use of standard precautions, including washing hands and wearing clean gloves, is imperative for nurses providing care to

patients with suspected or verified STDs.

LO 24.7 Factors Affecting Sexuality

Sexuality and *sexual function* are not synonymous concepts. Sexual function begins at birth, continues throughout the life span, and involves the physical ability to perform a sex act. Sexuality is more encompassing. It includes the character and life of a person as related to sex along with all the dispositions related to intimacy, whether associated with sex organs or not. [Table 24.4](#) summarizes factors affecting sexuality and nursing implications related to those factors.

TABLE 24.4**Factors Affecting Sexuality**

FACTOR	SEXUAL HEALTH-RELATED CHARACTERISTICS	IMPACT AND NURSING IMPLICATIONS
Family values and beliefs	<ul style="list-style-type: none"> • Family constraints on or endorsement of sexuality taught during childhood influence behavior throughout life's stages. 	<ul style="list-style-type: none"> • Explore family influences when gathering a sexual history. • Recognize the impact of various value systems on patients' decisions in relation to their sexuality.
Culture and religion	<ul style="list-style-type: none"> • Culture and religious beliefs influence family structure, roles within the family, who the dominant figure is within that structure, and how and whether sexuality is displayed. • Guilt and resentment may result from cultural or religious constraints. 	<ul style="list-style-type: none"> • Be knowledgeable about cultural and religious variances and expressions of sexuality. • Remain nonjudgmental. • Teach this information to patients and families.
Self-concept, ego, and body image	<ul style="list-style-type: none"> • Altered body image, either in reality or by perception, can influence sexuality and sexual expression. • Confidence in sexual expression may be impacted by the perception of altered body image. 	<ul style="list-style-type: none"> • Differentiate reality from perception. • Teach acceptance. • Be nonjudgmental.
Previous experiences and relationships	<ul style="list-style-type: none"> • Unstable relationships, fear, and power issues can exert a negative impact on one's sexuality. 	<ul style="list-style-type: none"> • Provide a safe environment so that the patient can share past experiences without fear.
Cognition and intellect	<ul style="list-style-type: none"> • Alterations in cognition or intellect do not equate with alteration of one's sexuality or desire for sexual satisfaction. 	<ul style="list-style-type: none"> • Recognize sexuality regardless of the patient's intellect or cognition level.
Environment	<ul style="list-style-type: none"> • Privacy may be an essential element for both sexual discussion and sexual activity. 	<ul style="list-style-type: none"> • Comply with all privacy guidelines. • Maintain respect for the patient. • Provide a nonjudgmental environment.
Personal expectations	<ul style="list-style-type: none"> • Social and peer group interaction may influence personal expectations of sexual experiences. 	<ul style="list-style-type: none"> • Be supportive and nonjudgmental. • Be a resource for education and personal expectations clarification.

FACTOR	SEXUAL HEALTH-RELATED CHARACTERISTICS	IMPACT AND NURSING IMPLICATIONS
Ethics	<ul style="list-style-type: none"> • Family and religious influences impact ethical decision making as it relates to sexuality. • Ethical differences between partners may lead to denial of experiences or conflict. 	<ul style="list-style-type: none"> • Be aware of the patient's cultural and religious individuality. • Do not impose personal beliefs or value system into interactions with the patient.

LO 24.8 Factors Affecting Sexual Function

Many factors affect sexual function, ranging from physical to lifestyle to developmental. [Table 24.5](#) details factors, influences, and outcomes affecting sexual function. Remember that individuals have many different influences and factors that impact their sexuality.

TABLE 24.5**Factors Affecting Sexual Function**

FACTOR CATEGORY	INFLUENCES	OUTCOMES
Physical	Minor or chronic illnesses, medications (number or combination), fatigue, pain or discomfort as a result of sex ^a	Decreased intimacy, personal stress and/or stress with partner, reduction in the frequency of sexual relations
Functional	Diseases that limit sensation or movement (e.g., diabetes, rheumatoid arthritis, multiple sclerosis), acute illnesses, chronic illnesses ^b , infertility, aging changes Medications with side effects that may hinder sexual desire or performance (e.g., antidepressants, central nervous system depressants, narcotics, antihypertensives)	Decreased intimacy, personal stress and/or stress with partner, reduction in the frequency or satisfaction of sexual relations
Relationship	Stress, differences in value systems, communication issues, intimacy changes, control issues	Decreased intimacy, personal stress and/or stress with partner, reduction in the frequency or satisfaction of sexual relations
Lifestyle	Work issues, children, family responsibilities, abuse of drugs or alcohol, lack of time or sleep	Fatigue, decreased intimacy, personal stress and/or stress with partner, reduction in the frequency or satisfaction of sexual relations
Developmental	Immature or inappropriate expectations	Personal stress and/or stress with partner, changes in intimacy, changes in frequency and/or satisfaction of sexual relations
Self-concept	Poor body image; altered self-esteem; history of rape, incest, or abuse; negative role models; unrealistic expectations; lack of adequate sex education	Lack of intimacy, personal stress, changes in frequency or satisfaction of sexual relations

^aFrom Coady, D. (2015). Chronic sexual pain. *Contemporary OB/GYN*, 60(9), 18-28.

^bFrom Mollaoğlu, M., Tuncay, F. Ö., & Fertelli, T. K. (2013). Investigating the sexual function and its associated factors in women with chronic illnesses. *J Clin Nurs*, 22(23/24), 3484-3491.

Side effects of medications can adversely affect sexual performance by reducing sexual response and satisfaction. When conducting a sexual history with a patient, the nurse should ask about medication use and educate the patient about the potential side effects of medications being used (Box 24.4). In many cases, if a sexual side

effect arises, the patient should be aware that a change in medication may eliminate the sexual function issue.

Box 24.4

Patient Education and Health Literacy

Potential Side Effects of Medications

- *Anticonvulsants*: Phenytoin can have a sedating effect and cause a decrease in sexual desire and function.
- *Antidepressants*: Tricyclics, monoamine oxidase inhibitors (MAOIs), and lithium can cause male impotence and some reduction in testosterone levels. Selective serotonin reuptake inhibitors' (SSRIs) side effects may include delayed ejaculation, absent or delayed orgasm, and diminished sexual desire.
- *Antihistamines*: The sedative effect can be associated with decreased desire and reduced female vaginal lubrication.
- *Antihypertensives*: Angiotensin-converting enzyme (ACE) inhibitors, alpha and beta blockers, and calcium channel blockers may decrease male and female desire and cause erectile dysfunction (ED).
- *Antipsychotics*: These drugs may reduce desire and cause ED and ejaculation dysfunction.
- *Antispasmodics*: These drugs relax smooth muscle, which may lead to male impotence.
- *Narcotics*: Increased dependence can result in further sexual impairment: ED and ejaculation dysfunction are common; decreased male and female desire and decreased testosterone and semen production are other possible adverse effects.
- *Alcohol (ethyl alcohol)*: A moderate amount reduces inhibition and may improve sexual function. Increased consumption leads to reduced sexual function. Chronic alcoholism results in male impotence, permanent dysfunction, and sterility; in females, reduced desire and orgasmic dysfunction are possible.
- *Marijuana*: Initially, this drug may cause reduced inhibitions and increased sexual function; with chronic use, sexual desire is decreased in both males and females, and male impotence may occur.

1. In addition to antihypertensive medication, list three potential causes of sexual dysfunction in an adult.

LO 24.9 Family Dynamics

Age, ethnicity, culture, and religion may affect family dynamics when a sexual health issue arises. Communication of a sexual health concern is often impeded due to embarrassment, anxiety, or fear. The value systems specific to age groups within a family may be so different as to block dialogue when a question or problem occurs. Religious teachings may affect the family's choices pertaining to abortion, sterilization, contraception, and sexual preferences. Cultural attitudes and practices may curtail the dynamics between sexual partners, limiting the expression of personal needs or desires. Gender and sexual preference issues may have different impacts within a family, depending on the age of all involved.

In a family where decision making is done unilaterally by one partner instead of by both as a couple, it is possible that the partner who makes the family decisions also may be the one who makes decisions pertaining to intimacy and sexual practices. This inequity may result in resentment, sexual frustration, or anger from the partner who is not the decision maker. In a relationship in which power is shared and roles are equal between the partners instead of dominant and submissive, opportunities for sexual expression and satisfaction are enhanced.

Families dealing with gender identity issues must work to overcome prejudices, as well as gain knowledge about the specific gender issue. Personal and public acceptance, along with open communication, should be the family goal. Such acceptance, however, may not be attained because of cultural, religious, or moral constraints.

To meet the needs of such a diverse group as a family, the most appropriate professional often is the home health nurse. [Box 24.5](#) details home care considerations related to sexuality.

Box 24.5

Home Care Considerations

Sexual Health Foci for the Home Care Nurse

- Patients being monitored by the home health nurse for chronic illness (diabetes, hypertension, heart failure) should be assessed regarding their sexual health. Any deficit findings should be

evaluated to determine if they are related to prescribed treatment and/or medication regimens.

- Patients under postoperative follow-up care (such as after heart surgery, hysterectomy, or knee replacement) should be asked about sexual health concerns during the initial assessment with the home health nurse. Concerns should be noted and become part of the patient's plan of care.
- The initial home health care visit to new mothers should provide education on contraceptive choices, as well as newborn and post-delivery care. Depending on the circumstances, the visit may include education on sexually transmitted disease (STD) and human immunodeficiency virus (HIV)/acquired immunodeficiency syndrome (AIDS) prevention.
- Home health care visits to the elderly should include assessment and teaching on the subject of sexual health. Education to meet the individualized needs of the aged patient should be provided and routinely reinforced.
- Home health care follow-up for a patient with a reported STD should include education on the signs and symptoms of STDs, HIV/AIDS prevention, avoidance of high-risk behaviors, and treatment methods.

LO 24.10 ♦ Assessment

Using a matter-of-fact, organized approach to data collection regarding a patient's sexual health can alleviate anxiety on the part of the patient and unnecessary hesitation on the part of the nurse (Box 24.6).

Health Assessment Questions

Sexual Focus

- How do you feel about the sexual aspect of your life?
- Have you noticed any changes in the way you see yourself (as a man, woman, husband, wife, partner)?
- How has your illness, surgery, or medication affected your sex life?
- Are you sexually active?
- Do you have problems or concerns regarding your sexual abilities, performance, or satisfaction?
- How many sexual partners have you had in your lifetime?
- What are or have been your sexual practices?
- Do you feel safe in your environment?

Nurses are aware that assessing sexuality, diagnosing sexuality problems, and evaluating outcomes of interventions to address patients' sexuality concerns are part of holistic care. However, they often do not perform sexuality assessment in practice for reasons that include: they consider discussion as intruding on the individual's privacy, they do not feel sufficiently informed about providing proper nursing intervention, they have not developed interpersonal and counseling skills, they feel embarrassed, or they lack sufficient time (Ayaz, 2013).

Use of an assessment tool may help the nurse become more comfortable when asking questions dealing with sexual health. One such tool is the PLISSIT model, which provides a format to help the nurse initiate and maintain the discussion of sexuality by asking

sequenced open-ended questions (Annon, 2015). The PLISSIT model is defined as follows:

P: Obtaining *permission* from the patient to initiate sexual discussion

LI: Providing the *limited information* needed to function sexually

SS: Giving *specific suggestions* for the person to proceed with sexual relations

IT: Providing *intensive therapy* surrounding the issues of sexuality for the patient

Using this model, the nurse has a framework for initiating the discussion of sexual issues with the patient and providing guidance for follow-up evaluation or referral.
