SUSAN SCOTT RICCI

ESSENTIALS of Maternity, Newborn, AND Women's Health Nursing

FOURTH EDITION

ESSENTIALS of **Maternity**, **Newborn**, AND **Women's Health Nursing**

FOURTH EDITION

Susan Scott Ricci, ARNP, MSN, M.Ed., CNE
Nursing Faculty
University of Central Florida
Orlando, Florida
Former Nursing Program Director and Faculty
Lake Sumter State College
Leesburg, Florida

Printed in China

Not authorised for sale in United States, Canada, Australia, New Zealand, Puerto Rico, and U.S. Virgin Islands.

LWW.com

This book is lovingly dedicated to my husband Glenn, for his unfailing patience, encouragement,—and whose support and sense of humor make anything possible. And also to my children, Brian and Jennifer, and my grandchildren—Alyssa, Leyton, Peyton, Wyatt, Michael, Rylan, and Brody—who continue to inspire me throughout my life. You make it all worthwhile.

Susan Scott Ricci

About the Author

Susan Scott Ricci earned a diploma in nursing from the Washington Hospital Center School of Nursing, with a BSN and MSN, from Catholic University of America located in Washington, D.C., a M.Ed. in Counseling from the University of Southern Mississippi. She is licensed as a Women's Health Nurse Practitioner (ARNP) from the University of Florida. She recently acquired her national certification as a Certified Nurse Educator (CNE). She has worked in numerous women's health care settings including labor and birth, postpartum, prenatal, and family planning ambulatory care clinics. Susan is a women's health care nurse practitioner, who has spent 30+ years in practice and in nursing education teaching in LPN, ADN, and BSN programs. She is involved in several professional nursing organizations and holds memberships in Sigma Theta Tau International Honor Society of Nursing, National Association of OB/GYN Nurses, Who's Who in Professional Nursing, American Nurses Association, and the Florida Council of Maternal–Child Nurses.

With Susan Scott Ricci's wealth of practical and educational experience, it is essential to concentrate on evidence-based nursing practice and reduce the amount of "nice to know" information that is presented to students. As an educator, she recognized the tendency for nursing educators to want to "cover the world" when teaching, rather than focusing on the facts that students need to know to practice nursing safely. With this mission in mind, Susan has directed

her energy to the *birth* of these essential facts in this textbook.

She recognizes that instructional time is shrinking as the world of health care is expanding exponentially. Therefore, with the valuable instructional time allotted, she has recognized the urgent need to present pertinent facts as concisely as possible to promote application of knowledge within nursing practice.

Reviewers

Vicki Aaberg, PhD, RN

Preface

This textbook is designed as a practical approach to understanding the health of women in a maternity context and the health of their newborns. Women in our society are becoming empowered to make informed and responsible choices regarding their health and that of their newborns, but to do so they need the encouragement and support of nurses who care for them. This textbook focuses on the reproductive issues of women throughout the lifespan and arms the student or practicing nurse with essential information to care for women and their families and to assist them to make the right choices safely, intelligently, and with confidence.

Since the health care focus of women and their families has expanded well beyond our nation's borders, more cultural and global aspects of maternity and women's health care have been added to this fourth edition. The United States is part of the international community, and as such nurses must understand and respect diverse cultures and their customs to truly play an important role as a global partner. Nurses care for a variety of women from many continents, thus they have to be armed with appropriate tools to meet their client's diverse needs. Also, more evidence-based research findings have been included in this fourth edition for nurses to validate their practice and interventions.

ORGANIZATION

Each chapter of this textbook reviews an important dimension of a woman's general health throughout her life cycle and addresses risk factors, lifestyle choices that influence her well-being, appropriate interventions, and nursing education topics to preserve her health and that of her newborn.

The text is divided into eight units.

Unit 1: Introduction to Maternity, Newborn, and Women's Nursing

Unit 1 helps build a foundation for the student beginning with the study of maternal–newborn and women's health nursing by exploring contemporary issues and trends and community-based nursing.

Unit 2: Women's Health Throughout the Life Span

Unit 2 introduces the student to selected women's health topics, including the structure and function of the reproductive system, common reproductive concerns, sexually transmitted infections, problems of the breast, and benign disorders and cancers of the female reproductive tract. This unit encourages students to assist women in maintaining their quality of life, reducing their risk of disease, and becoming active partners in their own health promotion activities and with their health care professional.

Unit 3: Pregnancy

Unit 3 addresses topics related to normal pregnancy, including fetal development, genetics, and maternal adaptation to pregnancy. Nursing management during normal pregnancy is presented in a separate chapter encouraging application of basic knowledge to nursing practice. This nursing care chapter covers maternal and fetal assessment throughout pregnancy, interventions to promote self-care and minimize common discomforts, and client education.

Unit 4: Labor and Birth

Unit 4 begins with a chapter on the normal labor and birth process, including maternal and fetal adaptations. This is followed by a chapter discussing the nurse's role during normal labor and birth, which includes maternal and fetal assessment, pharmacologic and nonpharmacologic comfort measures and pain management, and specific nursing interventions during each stage of labor and birth.

Unit 5: Postpartum Period

Unit 5 focuses on maternal adaptation during the normal postpartum period. Both physiologic and psychological aspects are explored. Paternal adaptation is also considered. This unit also focuses on related nursing management, including assessment of physical and emotional status, promoting comfort, assisting with elimination, counseling about sexuality and contraception, promoting nutrition, promoting family adaptation, and discharge planning.

Unit 6: The Newborn

Unit 6 covers physiologic and behavioral adaptations of the normal newborn. It also delves into nursing management of the normal newborn, including immediate assessment and specific interventions as well as ongoing assessment, physical examination, and specific interventions during the early newborn period.

Unit 7: Childbearing at Risk

Unit 7 shifts the focus to at-risk pregnancy, childbirth, and postpartum care. Pre-existing conditions of the woman, pregnancy-related complications, at-risk labor, emergencies associated with labor and birth, and medical conditions and complications affecting the postpartum woman are covered. Treatment and nursing management are presented for each medical condition. This organization allows the student to build on a solid foundation of normal material when studying the at-risk content.

Unit 8: The Newborn at Risk

Unit 8 continues to focus on at-risk content. Issues of the newborn with birth weight variations, gestational age variations, congenital conditions, and acquired disorders are explored. Treatment and nursing management are presented for each medical condition. This organization helps cement the student's understanding of the material.

RECURRING FEATURES

To provide the instructor and student with an exciting and user-friendly text, a number of recurring features have been developed.

Key Terms

A list of terms that are considered essential to the chapter's understanding is presented at the beginning of each chapter. Each key term appears in boldface, with the definition included in the text. Key terms may also be accessed on **thePoint**.

Learning Objectives

Learning objectives included at the beginning of each chapter guide the student in understanding what is important and why, allowing him or her to prioritize information for learning. These valuable learning tools also provide opportunities for self-testing or instructor evaluation of student knowledge and ability.

WOW

Each chapter opens with inspiring Words of Wisdom, which offer helpful, timely, or interesting thoughts. These WOW statements set the stage for each chapter and give the student valuable insight into nursing care of women and newborns.

Case Studies

Real-life scenarios present relevant maternity, newborn, and women's health information that is intended to perfect the student's caregiving skills. Questions about the scenario provide an opportunity for the student to critically evaluate the appropriate course of action.

Evidence-Based Practice

The consistent promotion of evidence-based practice is a key feature of the text. Throughout the chapters, pivotal questions addressed by current research have been incorporated into Evidence-Based Practice boxes, which cite studies relevant to the chapter content.

Healthy People 2020

Throughout the textbook, relevant *Healthy People 2020* objectives are outlined in box format. The nursing implications or guidance provided in the box serves as a road map for improving the health of women, mothers, and newborns.

Teaching Guidelines

An important tool for achieving health promotion and disease prevention is health education. Throughout the textbook, Teaching Guidelines raise awareness, provide timely and accurate information, and are designed to ensure the student's preparation for educating women about various issues.

Drug Guides

Drug guide tables summarize information about commonly used medications. The actions, indications, and significant nursing implications presented assist the student in providing optimum care to women and their newborns.

Common Laboratory and Diagnostic Tests

Common Laboratory and Diagnostic Test tables in many of the chapters provide the student with a general understanding of how a broad range of disorders is diagnosed. Rather than reading the information repeatedly throughout the narrative, the student is then able to refer to the table as needed.

Common Medical Treatments

Common Medical Treatment tables in many of the nursing management chapters provide the student with a broad awareness of how a common group of disorders is treated either medically or surgically. The tables serve as a reference point for common medical treatments.

Nursing Care Plans

Nursing Care Plans provide concrete examples of each step of the nursing process and are provided in numerous chapters.[1] Found within the nursing process overview section of the chapter, the Nursing Care Plans summarize issue- or system-related content and outline a guide for delivering care.

Comparison Charts

These charts compare two or more disorders or other easily confused concepts. They serve to provide an explanation that clarifies the concepts for the student.

Nursing Procedures

Step-by-step Nursing Procedures are presented in a clear, concise format to facilitate competent performance of relevant procedures as well as to clarify any variations when appropriate.

Icons

Watch and Learn

A special icon throughout the book directs students to free video clips located on thePoint that highlight growth and development, communicating with children, and providing nursing care to the child in the hospital.

Concepts in Action Animations

These unique animations, also located on thePoint, bring physiologic and pathophysiologic concepts to life and enhance student comprehension.

Consider This!

In every chapter, the student is asked to *Consider This!* These first-person narratives engage the student in real-life scenarios experienced by their patients. The personal accounts evoke empathy and help the student to perfect caregiving skills. Each box ends with an opportunity for further contemplation, encouraging the student to think critically about the scenario.

Take Note!

The *Take Note!* feature draws the student's attention to points of critical emphasis throughout the chapter. This feature is often used to stress life-threatening or otherwise vitally important information.

Tables, Boxes, Illustrations, and Photographs

Abundant tables and boxes summarize key content throughout the book. Additionally, beautiful illustrations and photographs help the student to visualize the content. These features allow the student to quickly and easily access information.

Key Concepts

At the end of each chapter, Key Concepts provide a quick review of essential chapter elements. These bulleted lists help the student focus on the important aspects of the chapter.

References and Websites

References that were used in the development of the text are provided at the end of each chapter. The websites are located on thePoint. These listings enable the student to further explore topics of interest. Many online websites are provided as a means for the student to electronically explore relevant content material. These resources can be shared with women, children, and their families to enhance patient education and support.

Chapter Worksheets

Chapter worksheets at the end of each chapter assist the student in reviewing essential concepts. Chapter worksheets include:

- **Multiple-Choice Questions**—These review questions are written to test the student's ability to apply chapter material. Questions cover maternal–newborn and women's health content that the student might encounter on the national licensing exam (NCLEX).
- **Critical Thinking Exercises**—These exercises challenge the student to incorporate new knowledge with previously learned concepts and reach a satisfactory conclusion. They encourage the student to think critically, problem-solve, and consider his or her own perspective on given topics.
- **Study Activities**—These interactive activities promote student participation in the learning process. This section encourages increased interaction/learning via clinical, online, and community activities.

Instructor's Resources

Tools to assist you with teaching your course are available upon adoption of this text on thePoint at http://thePoint.lww.com/Ricci3e.

- An **E-Book** on thePoint gives you access to the book's full text and images online.
- A **Test Generator** lets you put together exclusive new tests from a bank containing o**ver 800 questions** (twice as many as last edition) to help you in assessing your students' understanding of the material. Test questions link to chapter learning objectives.
- **PowerPoint presentations** with **Guided Lecture Notes** provide an easy way for you to integrate the textbook with your students' classroom experience, either via slide shows or handouts. Multiple-choice and true/false questions are integrated into the presentations to promote class participation.
- An **Image Bank** lets you use the photographs and illustrations from this textbook in your PowerPoint slides or as you see fit in your course.
- **Case Studies** with related questions (and suggested answers) give students an opportunity to apply their knowledge to a client case similar to one they might encounter in practice.
- **Pre-Lecture Quizzes** (and answers) are quick, knowledge-based assessments that allow you to check students' reading.
- **Discussion Topics** (and suggested answers) can be used as conversation starters or in online discussion boards.
- **Assignments** (and suggested answers) include group, written, clinical, and Web assignments.
- Sample **Syllabi** provide guidance for structuring your pediatric nursing courses and are provided for four different course lengths: 4, 6, 8, and 10 weeks.
- **Journal Articles**, updated for the new edition, offer access to current research available in Lippincott Williams & Wilkins journals.

Contact your sales representative or check out LWW.com/Nursing for more details and ordering information.

Student Resources

An exciting set of free resources is available to help students review material and become even more familiar with vital concepts. Students can access all these

resources on thePoint using the codes printed in the front of their textbooks.

- **NCLEX-Style Review Questions** for each chapter help students review important concepts and practice for NCLEX. **Over 700 questions** are included, more than twice as many as last edition!
- **Multimedia Resources** appeal to a variety of learning styles. Icons in the text direct readers to relevant videos and animations:
  - **Watch and Learn Videos**
    A special icon throughout the book directs students to free video clips located on thePoint that highlight growth and development, communicating with children, and providing nursing care to the child in the hospital.
  - **Concepts in Action Animations**
    These unique animations, also located on thePoint, bring physiologic and pathophysiologic concepts to life and enhance student comprehension.
- A **Spanish–English Audio Glossary** provides helpful terms and phrases for communicating with patients who speak Spanish.
- **Journal Articles** offer access to current research available in Lippincott Williams & Wilkins journals.
- **And more!**

family
family-centered care

fetal mortality rate
infant mortality rate
informed consent
maternal mortality ratio
mortality
neonatal mortality rate

Learning Objectives

Upon completion of the chapter, you will be able to:

1. Characterize the key milestones in the evolution of childbirth in America.
2. Outline the major components, concepts, and influences associated with the nursing management of women and their families.
3. Compare the past definitions of health and illness with the current definitions.
4. Examine the factors that affect maternal, newborn, and women's health.
5. Evaluate how society and culture can influence the health of women and their families.
6. Distinguish the health care barriers affecting women and their families.
7. Review the ethical and legal issues that may arise when caring for women and their families.

Sophia Nappo, a 38-year-old woman pregnant with her third child, comes to the prenatal clinic for a routine follow-up visit. Her mother, Betty, accompanies her because Sophia's husband is out of town. Sophia lives with her husband and two children, ages 4 and 9. She works part-time as a lunch aide in the local elementary school. What factors may play a role in influencing the health of Sophia and her family?

Words of Wisdom

Being pregnant and giving birth is like crossing a narrow bridge: people can accompany you to the bridge, and they can greet you on the other side, but you walk that bridge alone.

INTRODUCTION

A person's ability to lead a fulfilling life and to participate fully in society depends largely on his or her health status. This is especially true for women, who commonly are responsible for not only their own health but that of others: their children and families. Thus, it is important to focus on the health of women and families. Habits and practices established during pregnancy and in early childhood can have profound effects on a person's health and illness throughout life. As a society, creating a population that cares about women and their families and promotes solid health care and lifestyle choices is crucial.

Maternal and newborn nursing encompasses a wide scope of practice typically associated with childbearing. It includes care of the woman before pregnancy, care of the woman and her fetus during pregnancy, care of the woman after pregnancy, promotion of a safe motherhood, and care of the newborn, usually during the first 6 weeks after birth. The overall goal of maternal and newborn nursing is to promote and maintain optimal health for the woman and her family.

Nurses today have an unprecedented opportunity to improve the health and well-being of women and families. Events from birth to death, and every health care emergency in between, will likely involve the presence of a nurse. Involvement of a knowledgeable, supportive, comforting nurse often leads to a positive health care experience. Skilled nursing practice depends on a solid base of knowledge and clinical expertise delivered in a caring, holistic manner. Nurses, using their knowledge and passion, help meet the health care needs of their clients throughout the life span, whether the client is a pregnant woman, a fetus, a partner, or a woman with health-related problems. Nurses fill a variety of roles in helping clients to live healthier lives by providing direct care, emotional support, comfort, information, advice, advocacy, support, and counseling. Nurses are often "in the trenches" advocating for issues, drawing attention to the importance of health care for the client, and dealing with the lack of resources, the lack of access to health care, and the focus on acute care rather than education and prevention.

This chapter presents a general overview of the health care of women and their families and describes the major factors affecting maternal, newborn, and women's health. It also addresses health care information available to women and their families and improvements in diagnosis and treatments. Nurses need to

be knowledgeable about these concepts and factors to ensure that they provide up-to-date professional care.

EVOLUTION OF MATERNAL AND NEWBORN NURSING

The health care of women has changed over the years due in part to changes in childbirth methods, social trends, changes in the health care system, and federal and state regulations. By reviewing historical events, nurses can gain a better understanding of the current and future status of maternal, newborn, and women's health nursing (Box 1.1).

Historical Perspective

Childbirth in colonial America was a difficult and dangerous experience. During the 17th and 18th centuries, women giving birth often died as a result of exhaustion, dehydration, infection, hemorrhage, or seizures (Mintz, 2013). Since most women gave birth to between five and eight children, their lifetime chances of dying in childbirth ran as high as one in eight. Death in childbirth was sufficiently common that many colonial women regarded pregnancy with dread. In addition to her anxieties about pregnancy, an expectant mother was filled with apprehension about the possible death of her newborn child. Approximately 50% of all children died before age 5 (King et al., 2015), compared with an infant mortality rate today of 6.17 infant deaths/1,000 live births (World Factbook, 2015).

Centuries ago, "granny midwives" handled the normal birthing process for most women. Midwifery skills have traditionally been passed from one woman to another within families, grandmothers to mothers to daughters, and also through apprenticeship with a more experienced midwife. Physicians usually were called only in extremely difficult cases, and all births took place at home (Simmons, Rothman, & Norman, 2013).

During the early 1900s, physicians attended about half the births in the United States. Midwives often cared for women who could not afford a doctor. Many women were attracted to hospitals because this showed affluence and hospitals provided pain management, which was not available in home births. In the 1950s, natural childbirth practices advocating birth without medication and focusing on relaxation techniques were introduced (Rabor, Taghipour, & Najmabadi, 2015). These techniques opened the door to childbirth education classes and helped bring the father back into the picture. Both partners could participate by taking an active role in pregnancy, childbirth, and parenting (Fig. 1.1).

Current Trends

In many ways, childbirth practices in the United States have come full circle, as we see the return of the nurse midwife and the *doula*. The concept of women helping other women during childbirth is not new; women who labored and gave birth at home were traditionally attended by relatives and midwives (Evidence-Based Practice 1.1). A **certified nurse midwife** (CNM) has postgraduate training in the care of normal pregnancy and childbirth and is certified by the American College of Nurse Midwives. A **doula** is a birth assistant who provides emotional, physical, and educational support to the woman and family during childbirth and the postpartum period. Many nurses working in labor and birth areas today are credentialed in their specialty so that they can provide optimal care to the woman and her newborn. Childbirth choices are often based on what works best for the mother, child, and family.

BOX 1.1

CHILDBIRTH IN AMERICA: A TIME LINE

1700s	Men did not attend births because it was considered indecent. Women faced birth, not with joy and ecstasy, but with fear of death. Female midwives attended the majority of all births at home.
1800s	There is a shift from using midwives to doctors among middle-class women. The word *obstetrician* was formed from the Latin, meaning "to stand before." Puerperal (childbed) fever was occurring in epidemic proportions. Louis Pasteur demonstrated that streptococci were the major cause of puerperal fever that was killing mothers after delivery. The first cesarean section was performed in Boston in 1894. The x-ray was developed in 1895 and was used to assess pelvic size for birthing purposes.
1900s	Twilight sleep (a heavy dose of narcotics and amnesiacs) was used on women during childbirth in the United States. The United States was 17th out of 20 nations in infant mortality rates. Fifty to 75% of all women gave birth in hospitals by 1940. Nurseries were started because moms could not care for their babies for several days after receiving chloroform gas. In 1933, Dr. Grantley Dick-Reed wrote a book entitled *Childbirth Without Fear* that reduced the "fear–tension–pain" cycle women experienced during labor and birth. In 1984, Dr. Fernand Lamaze wrote a book entitled *Painless Childbirth: The Lamaze Method* that advocated distraction and relaxation techniques to minimize the perception of pain. Amniocentesis was first performed to assess fetal growth in 1966. In the 1970s, the cesarean section rate was about 5%. By 2000 it rose to 34%, where it stands currently. The 1970s and 1980s saw a growing trend to return birthing back to the basics—nonmedicated, nonintervening childbirth. In the late 1900s, freestanding birthing centers—LDRPs—were designed, and the number of home births began to increase.
2000s	One in three women undergoes a surgical birth (cesarean). Certified nurse midwives once again assist couples at home, in hospitals, or in freestanding facilities with natural childbirths. Research shows that midwives are the safest birth attendants for most women, with lower infant mortality and maternal rates, and fewer invasive interventions such as episiotomies and cesareans. Childbirth classes of every flavor abound in most communities. According to the latest available data, the United States ranks 50th in the world in maternal deaths. The maternal mortality rate is approximately 11 in 100,000 live births. According to the latest available data, the United States ranks 41st in the world in infant mortality rates. The infant mortality rate is approximately 6 in 1,000 live births.

FIGURE 1.1 Today fathers and partners are welcome to take an active role in the pregnancy and childbirth experience. **A.** A couple can participate together in childbirth education classes. (Photo by Gus Freedman.) **B.** Fathers and partners can assist the woman throughout her labor and childbirth experience. (Photo by Joe Mitchell.)

EVIDENCE-BASED PRACTICE 1.1 WOMEN'S RESPONSE TO CONTINUOUS LABOR SUPPORT

Throughout history, women have been helping other women in labor by providing emotional support, comfort measures, information, and advocacy. However, in recent years, this practice has waned, and facilities frequently adhere to strict specific routines that may leave women feeling "dehumanized."

STUDY

A study was done to assess the effects on mothers and their newborns of continuous, one-to-one intrapartum care compared to usual care. The study also evaluated routine practices and policies in the birth environment that might affect a woman's autonomy, freedom of movement, and ability to cope with labor; who the caregiver was (a staff member of the facility or not); and when the support began (early or late in labor). All published and unpublished randomized clinical trials comparing continuous support during labor with usual care were examined. One author and one research assistant used standard methods for data collection and analysis and extracted the data independently. Clinical trial authors provided additional information. The researchers used relative risk for categorical data and weighted mean difference for continuous data. Twenty one studies from 15 countries involving 15,061 women were examined.

Findings

Women receiving continuous intrapartum support had a greater chance of a spontaneous vaginal birth, reduced intrapartum analgesia, caused no harm; labors were shorter, and women were less likely to have a cesarean section or instrumental birth, regional analgesia, or a newborn with a low 5-minute Apgar score. These women also reported increased satisfaction with their labor and childbirth experience. Overall, the support, when provided by someone other than a facility staff member and initiated early in labor, proved to be more effective.

Nursing Implications

Based on this research, it is clear that women in labor benefit from one-to-one support during labor. Nurses can use the information gained from this study to educate women about the importance of having a support person during labor and birth. Nurses can also act as client advocates in facilities where they work to foster an environment that encourages the use of support persons during the intrapartum period. The focus of nursing needs to be individualized, supportive, and collaborative with the family during their childbearing experience. In short, nurses should place the needs of the mother and her family first in providing a continuum of care.

   Although the study found that support is more effective when provided by someone other than a staff member, support from an individual is the key. Assigning the same nurse to provide care to the couple throughout the birthing experience also fosters a one-to-one relationship that helps meet the couple's needs and promotes feelings of security. By meeting the couple's needs, the nurse is enhancing their birthing experience.

Hodnett, E. D., Gates, S., Hofmeyr, G. J., Sakala, C., & Weston, J. (2013). Continuous support for women during childbirth. *Cochrane Database of Systematic Reviews*, 7(2), CD003766.

CORE CONCEPTS OF MATERNAL, NEWBORN, AND WOMEN'S HEALTH NURSING

Maternal, newborn, and women's health nursing provides evidence-based care to the client within the context of the family unit. This care involves the implementation of an interdisciplinary plan in a collaborative manner to ensure continuity of care that is cost effective, quality oriented, and outcome focused. It involves family-centered, evidence-based, case-managed care.

Family-Centered Care

Family-centered care is the delivery of safe, satisfying, high-quality health care that focuses on and adapts to the physical and psychosocial needs of the family. It is based on mutual trust and collaboration between the woman, her family, and the health care provider. It is a partnership approach of families and their caregivers that recognizes the strength and integrity of the family. These are the basic principles of family-centered care:

• Childbirth is considered a normal, healthy event in the life of a family.

• Childbirth affects the entire family, and relationships will change.

• Families are capable of making decisions about their own care if given adequate information and professional support (Young, 2014).

The philosophy of family-centered care recognizes the family as the constant. The health and functioning of the family affect the health of the client and other members of the family. Family members support one another well beyond the health care provider's brief time with them, such as during the childbearing process or during a child's illness. Birth is viewed as a normal life event rather than a medical procedure.

Family-centered care requires the nurse to apply sensitivity to the client's and family's beliefs and those supporting their culture. This involves listening to the family's needs and shifting the nurse's authoritarian role to the family to empower them to make their own decisions within the context of a supportive environment. A true family perspective should be applied in maternity care and the new parents viewed as a family unit, not as a medical case. Nurses providing family-centered care means that they identify, respect, and care about client's differences, values, preferences, and expressed needs; relieve pain and suffering; coordinate continuous care; listen to, clearly inform, communicate with, and educate clients; share decision making and management; and continuously advocate for them (Denham et al., 2016).

With family-centered care, support and respect for the uniqueness and diversity of families are essential, along with encouragement and enhancement of the family's strengths and competencies. It is important to create opportunities for families to demonstrate their abilities and skills. Families can also acquire new abilities and skills to maintain a sense of control. Family-centered care

promotes greater family self-determination, decision-making abilities, control, and self-efficacy, thereby enhancing the client's and family's sense of empowerment. When implementing family-centered care, nurses seek caregiver input; these suggestions and advice are incorporated into the client's plan of care as the nurse counsels and teaches the family appropriate health care interventions. Today, as nurses partner with various experts to provide high-quality and cost-effective care, one expert partnership that nurses can make is with the client's family. Nurses empower mothers with freedom of choice based on knowledge of alternatives. This means the mother's birth plan would be honored in an environment where the mother's choices are respected. Nurses must partner with women and their families for optimal care and quality outcomes (Beal, Dalton, & Maloney, 2015).

The impact of family-centered care can be seen in the models of care delivery for women. Families are kept together after childbirth, not separated as in past years. From the 1980s to the present, increased access to care for all women (regardless of their ability to pay) and hospital redesigns have focused on keeping families together during their childbirth experience (Clark, Beatty, & Reibel, 2015). Hospital redesigns include labor, delivery, and recovery rooms that incorporate all three activities in one room, and labor, delivery, recovery, and postpartum (LDRP) spaces that incorporate all four activities in one room, so that families don't have to move from place to place during the birth experience (Fig. 1.2).

FIGURE 1.2 Providing an opportunity for the "big brother" to interact with his new siblings is an important component of family-centered nursing care.

Evidence-Based Care

Evidence-based practice (EBP) is a problem-solving approach to making nursing clinical decisions (Hanrahan et al., 2015). It involves the collection, interpretation, and integration of validated research-derived evidence from a variety of resources such as research findings, internal evidence from outcome management or process improvement processes, and patient preferences. Nurses need to find a way to integrate the best available evidence to translate into practice to achieve the best outcomes consistent with the aim of health care—to improve the experience of care, to improve the health of mothers and infants, and to reduce the costs of health care (Hain & Kear, 2015). **Evidence-based nursing practice** involves the use of research to establish a plan of care and to implement that care. This model of nursing practice includes the use of the best current evidence in making decisions about care. Widespread use of EBP may lead to a decrease in variation of care while at the same time increase in quality.

Scientific research findings help nurses not only stay current in their clinical specialties, but also in their choice of the most effective interventions. Many of the professional organizations—for example, the Association of Women's Health, Obstetric and Neonatal Nurses (AWHONN), the American Nurses Association (ANA), and the National League for Nursing (NLN)—have developed evidence-based clinical practice guidelines for the safest and most effective delivery of family-centered nursing care. Nurses should be diligent in seeking out these evidence-based guidelines to ensure excellence in their daily practice. When EBP is delivered in a context of caring and in a supportive organizational culture, the highest quality of care and best client outcomes can be achieved. The landmark report by the Health and Medicine Division (HMD) (2011), *The Future of Nursing: Leading Change, Advancing Health*, listed EBP as a competency required to enhance patient care quality and safety. Thus, it is no longer an option to incorporate EBP into our practice, but a necessity!

Case-Managed Care

Modern health care focuses on an interdisciplinary plan of care designed to meet a client's physical, developmental, educational, spiritual, and psychosocial needs. This interdisciplinary collaborative type of care is termed **case management**, a process of assessment, planning, application, coordination, follow-up, and evaluation of the options and services required to meet an individual's health needs through communication and available resources to promote quality cost-effective results. Operational excellence, quality of care, and sound financial performance are increasingly linked as key drivers of health care performance. Quality case management for all families contributes toward fewer complications, reductions in length of stay, and lowered costs. Case management is a continuous process that requires critical thinking about how care is delivered and its effect on the entire care progression of a client. It has, at its core, the values of care coordination, utilization management, and client advocacy across the continuum of care (Summers, 2016) and involves the following components:

• Advocacy, communication, and resource management

• Client-focused comprehensive care across a continuum

• Coordinated care with an interdisciplinary approach (Treadwell et al., 2015)

When the nurse effectively functions in the role of case manager, client and family satisfaction is increased, fragmentation of care is decreased, and outcome measurement for a homogenous group of clients is possible.

Think back to Sophia and her mother, Betty, who were described at the beginning of the chapter. Sophia and her husband are planning to use natural childbirth and to have their children present for the birth. While Sophia is waiting to be called for her appointment, Betty says, "Things have changed so much since I was pregnant. It's amazing what happens nowadays." Explain how things have changed in maternal and newborn health care, focusing on the concept of family-centered care.

HEALTH STATUS GOALS

At one time, health was defined simply as the absence of disease; health was measured by monitoring the mortality and morbidity of a group. During the past century, however, the focus on health has shifted to disease prevention, health promotion, and wellness. The World Health Organization (WHO, 2015a) defines health as "a state of complete physical, mental, and social well-being, and not merely the absence of disease or infirmity." The definition of health is complex; it is not merely the absence of disease or an analysis of mortality and morbidity statistics.

Healthy People 2020

In 1979, a surgeon general's report titled *Healthy People* presented a prevention agenda for the nation that identified the most significant preventable threats to the health of the United States. *Healthy People* is a set of goals and objectives with 10-year targets designed to guide national health promotion and disease prevention efforts to improve the health of all people in the United States. The current initiative is *Healthy People 2020,* which is the country's comprehensive, nationwide health promotion and disease prevention agenda that promotes the goal of improving the health and well-being of women, infants, children, and families (U.S. Department of Health & Human Services [USDHHS], 2015a). Ten specific health indicators serve as a way to evaluate progress made in the public health arena and to coordinate the national health improvement efforts. *Healthy People 2020* highlights the major health indicators of the 21st century that need to be addressed. This also outlines major goals intended to increase the quality and years of healthy life and to eliminate health disparities among ethnic groups by targeting the lifestyle choices and environmental conditions that contribute to over half of all premature deaths in the United States. *Healthy People 2020* identifies specific national health goals related to maternal, infant, and child health.

Improving the well-being of mothers, infants, and children is an important public health goal for the United States. Their well-being determines the health of the next generation and can help predict future public health challenges for families, communities, and the health care system. The objectives of the maternal, infant, and child health topic area address a wide range of conditions, health behaviors, and health system indicators that affect the health, wellness, and quality of life of women, children, and families (USDHHS, 2015a).

Measuring health status is not a simple or convenient process. For example, some individuals with chronic illnesses do not see themselves as ill if they can control their condition through self-management. A traditional method used in this country to measure health is to examine mortality and morbidity data. Information is collected and analyzed to provide an objective description of the nation's health.

HEALTHY PEOPLE *2020* • *1.1*

Major Health Concerns of the 21st Century

- Physical activity
- Overweight and obesity
- Tobacco use
- Substance abuse
- Responsible sexual behavior
- Mental health
- Injury and violence
- Environmental quality
- Immunizations
- Access to health care

Healthy People objectives based on data from http://www.healthypeople.gov.

HEALTHY PEOPLE *2020* • *1.2*

National *Health* Goals—Maternal, Infant, and Child Health

- Reduce the rate of fetal and infant deaths.
- Reduce the rate of maternal mortality.
- Reduce the 1-year mortality rate for infants with Down syndrome.
- Reduce maternal illness and complications due to pregnancy.
- Reduce cesarean births among low-risk (full-term, singleton, vertex presentation) women.
- Reduce low-birth-weight (LBW) and very-low-birth-weight (VLBW) births.
- Reduce preterm births.
- Increase the proportion of pregnant women who receive early and adequate prenatal care.
- Increase abstinence from alcohol, cigarettes, and illicit drugs among

pregnant women.
- Increase the proportion of pregnant women who attend a series of prepared childbirth classes.
- Increase the proportion of mothers who achieve a recommended weight gain during their pregnancies.
- Increase the proportion of women of childbearing potential with an intake of at least 400 μg of folic acid from fortified foods or dietary supplements.
- Reduce the proportion of women of childbearing potential who have low red blood cell folate concentrations.
- Increase the proportion of women delivering a live birth who received preconception care services and practiced key recommended preconception health behaviors.
- Reduce the proportion of persons aged 18–44 years who have impaired fecundity (i.e., a physical barrier preventing pregnancy or carrying a pregnancy to term).
- Reduce postpartum relapse of smoking among women who quit smoking during pregnancy.
- Increase the proportion of women giving birth who attend a postpartum care visit with a health worker.
- Increase the proportion of infants who are put to sleep on their backs.
- Increase the proportion of infants who are breast-fed.
- Increase the proportion of employers that have worksite lactation support programs.
- Reduce the proportion of breast-fed newborns who receive formula supplementation within the first 2 days of life.
- Increase the proportion of live births that occur in facilities that provide recommended care for lactating mothers and their babies.
- Reduce the occurrence of fetal alcohol syndrome.
- Reduce the proportion of children diagnosed with a disorder through newborn blood spot screening who experience developmental delay requiring special education services.
- Reduce the proportion of children with cerebral palsy born as LBW infants (less than 2,500 g).
- Reduce occurrence of neural tube defects.
- Increase the proportion of children with special health care needs who receive their care in family-centered, comprehensive, coordinated systems.

- Increase appropriate newborn blood-spot screening and follow-up testing.
- Increase the proportion of VLBW infants born at level III hospitals or subspecialty perinatal centers.

Healthy People 2020 objectives based on data from http://www.healthypeople.gov.

Mortality

Mortality is the incidence or number of individuals who have died over a specific period. This statistic is presented as rates per 100,000 and is calculated from a sample of death certificates. The National Center for Health Statistics, under the USDHHS, collects, analyzes, and disseminates the data on mortality rates in the United States.

Maternal Mortality

The **maternal mortality ratio** is the annual number of female deaths from any cause related to or aggravated by pregnancy or its management (excluding accidental or incidental causes) during pregnancy and childbirth or within 42 days of termination of pregnancy, irrespective of the duration and site of the pregnancy. It is reported as a ratio of deaths per 100,000 live births, for a specified year.

In the United States, the maternal mortality ratio is mixed depending on ethnic background. African American women suffer maternal mortality ratios three-to-fourfold increase when compared to those of any other ethnic group: about 35.6 of 100,000 African American mothers die due to childbirth, as compared with much lower rates in Whites (11.7), and women of other races (17.6) (Centers for Disease Control and Prevention [CDC], 2015a). The federal government has pledged to improve maternal–child care outcomes and thus reduce mortality ratios for women and children by endorsing the *Healthy People 2020* agenda, but the WHO (2015d) data show that the United States ranks 50th out of approximately 240 nations in the world for maternal mortality—with maternal mortality ratios higher than almost all European countries, as well as several countries in Asia and the Middle East. This statistic places the United States near the bottom of the top quartile of developed countries. For a country that spends more than any other country on health care and more on childbirth-related care than any other area of hospitalization—US $86 billion a year—this is a shockingly poor return on investment (International Center for Research on Women, 2015).

During the past several decades, mortality and morbidity have dramatically decreased as a result of an increased emphasis on hygiene, good nutrition, exercise, and prenatal care for all women. However, women are still

experiencing complications at significant rates. The United States is one of the most medically and technologically advanced nations and has the highest per capita spending on health care in the world, but the maternal mortality rate has steadily increased over the years. The United States is one of only eight countries where maternal mortality is on the rise. The other countries include Afghanistan, Greece, Africa, and Central America (Kassebaum et al., 2014). Our current mortality rates indicate the need for improvement. For example:

• Two or three women die in the United States every day from pregnancy complications, and more than 30% of pregnant women (1.8 million women annually) experience some type of illness or injury during childbirth (Abel, 2015).

• The United States ranks 50th (in other words, below 49 other countries) in rates of maternal deaths (deaths per 100,000 live births) (WHO, 2015d).

• Most pregnancy-related complications are preventable. The top five leading causes of pregnancy-related mortality are embolism (20%), hemorrhage (17%), preeclampsia and eclampsia (16%), infection (13%), and cardiomyopathy (8%) (Chescheir, 2015).

The maternal mortality and morbidity rates for African American women have been three to four times higher than those for Whites (Creanga et al., 2015). This major racial disparity has persisted for more than 60 years, with African American women having at least a doubled risk of pregnancy-related death when compared with White women. This striking difference in the pregnancy-related mortality ratio is the largest disparity in the area of maternal and child health. Researchers do not entirely understand what accounts for this disparity, but some suspected causes of the higher maternal mortality rates for minority women include low socioeconomic status, limited or no insurance coverage, bias among health care providers (which may foster distrust), and quality of care available in the community. Language and legal barriers may also explain why some immigrant women do not receive good prenatal care. Lack of care during pregnancy is a major factor contributing to a poor outcome. Prenatal care is well known to prevent complications of pregnancy and to support the birth of healthy infants, but not all women receive the same quality and quantity of health care during their pregnancy. Pregnancy-related mortality is on the rise in the United States. The *Healthy People 2020* goal for maternal deaths is 11.4 per 100,000 live births (USDHHS, 2015a). African American pregnant women had higher

degrees of hypertension and lower hemoglobin levels on admission and had presented for prenatal care much later, on average, than White women or not at all (Creanga et al., 2015).

The Centers for Disease Control and Prevention (CDC) has noted that the disparity in maternal mortality rates between women of color and White women represents one of the largest racial disparities among public health indicators. Eliminating racial and ethnic disparities in maternal–child health care requires enhanced efforts at preventing disease, promoting health, and delivering appropriate and timely care (CDC, 2015a). The CDC has called for more research and monitoring to understand and address racial disparities, along with increased funding for prenatal and postpartum care. Research is needed to identify causes and to design initiatives to reduce these disparities, and the CDC is calling on Congress to expand programs to provide preconception and prenatal care to underserved women.

Fetal Mortality

The **fetal mortality rate** or fetal death rate refers to the spontaneous intrauterine death of a fetus at any time during pregnancy per 1,000 live births. Fetal deaths later in pregnancy >20 weeks of gestation are also referred to as stillbirths. Fetal mortality may be attributable to maternal factors (e.g., malnutrition, disease, or preterm cervical dilation) or fetal factors (e.g., chromosomal abnormalities or poor placental attachment).

Fetal mortality is a major, but often overlooked, public health problem. This refers to spontaneous intrauterine death at any time during pregnancy. The fetal mortality rate in the United States is 6.2 per 1,000 live births (CDC, 2015b). The goal of *Healthy People 2020* is to reduce it to 5.6 fetal deaths (USDHHS, 2015a). Much of the public concern regarding reproductive loss has concentrated on infant mortality, because less is known about fetal mortality. However, the impact of fetal mortality on families in the United States is considerable, because it provides an overall picture of the quality of maternal health and prenatal care.

Neonatal and Infant Mortality

The **neonatal mortality rate** is the number of infant deaths occurring in the first 28 days of life per 1,000 live births. The United States now ranks 41st in the world in terms of neonatal mortality, the death rate of infants less than 1 month old. The neonatal mortality rate is 4.5 per 1,000 live births (USDHHS, 2015b;

World Bank, 2015). The goal of *Healthy People 2020* is to reduce it to 4.1 (USDHHS, 2015a). Each year the deaths of 2 million babies are linked to complications during birth or within the first month and the burden is inequitably carried by the poor. Evidence-based strategies are urgently needed to reduce the burden of intrapartum-related deaths (CDC, 2015c). The reliability of the neonatal mortality estimates depends on the accuracy and completeness of reporting and recording of births and deaths. Underreporting and misclassification are common, especially for deaths occurring early in life.

The perinatal mortality rate encompasses late and early neonatal mortalities and is defined as the number of stillbirths and deaths in the first week of life per 1,000 live births; it is also a useful health status indicator. Work is ongoing to improve estimates of stillbirth rates, a major component of perinatal mortality (WHO, 2015b). Perinatal mortality rate is a sum total of the following:

• Fetal mortality rate—the death of a fetus prior to expulsion or extraction from the mother. Fetal death is determined by no signs of life after birth.

• Neonatal mortality rate—the number of neonates dying before reaching 28 days of life, per 1,000 live births in a given year.

The **infant mortality rate** is the number of deaths occurring in the first 12 months of life. It is also documented as the number of deaths of infants younger than 1 year of age per 1,000 live births. Neonatal mortality and postneonatal mortality (covering the remaining 11 months of the first year of life) are reflected in the infant mortality rate. The infant mortality rate is used as an index of the general health of a country. Currently, about two thirds of infant deaths in the United States occur before 28 days, with the remaining third occurring in the postnatal period between 28 days and under 1 year (USDHHS, 2015a). Generally, this statistic is one of the most significant measures of maternal and child health. In the United States, the infant mortality rate is 6.17 (World Fact Book, 2015). *Healthy People 2020*'s goal is to reduce it to 6.0 (USDHHS, 2015a).

Despite the rapid decline in infant mortality for industrialized countries during the 21st century, the infant mortality rate in the United States has declined only marginally. Racial and ethnic disparities in infant mortality have persisted and increased, as have the percentages of preterm and low-birth-weight births. Infant mortality is a complex and multifactorial problem that has proved resistant to intervention efforts (McGill, 2015).

The infant mortality rate varies greatly from state to state as well as among

ethnic groups. The United States has one of the highest gross national products in the world and is known for its technological capabilities, the United States continues to lag behind in preserving infant's lives when compared with other industrialized countries (CDC, 2015d). The main causes of early infant death in this country include problems occurring at birth or shortly thereafter. These include prematurity, low birth weight, congenital anomalies, sudden infant death syndrome (SIDS), and respiratory distress syndrome (Oza et al., 2015).

Take Note!

African American and American Indian/Alaska Native infants have consistently had higher infant mortality rates than other ethnic groups (Kail & Cavanaugh, 2016).

Congenital anomalies remain the leading cause of infant mortality in the United States. Low birth weight and prematurity are major indicators of infant health and significant predictors of infant mortality (Wang et al., 2015). The high incidence of low birth weight (<2,500 g) in the United States is a significant reason why its infant mortality rate is higher than that of other countries (Redding et al., 2015).

After birth, other health promotion strategies can significantly improve an infant's health and chances of survival. Breast-feeding has been shown to reduce rates of infection in infants and to improve their long-term health (King et al., 2015). Emphasizing the importance of placing an infant on his or her back to sleep will reduce the incidence of SIDS. Encouraging mothers to join support groups to prevent postpartum depression and learn sound child-rearing practices will improve the health of both mothers and their infants.

Morbidity

Morbidity indicates a diseased state or condition. Many women enter their pregnancy with a chronic medical disease, an infection, or anemia or engage in lifestyle habits (smoking and drinking alcohol) that are detrimental to the well-being of the fetus. Any or all of these can lead to a poor pregnancy outcome.

Morbidity and Women

Women today face not only diseases of genetic origin but also diseases that arise from poor personal habits. Even though women represent 51% of the population, only recently have researchers and the medical community focused on their special health needs. A significant study identified an urgent need to improve women's access to health insurance and health care services, to place a stronger emphasis on prevention, and to invest in more research on women's health (National Women's Law Center [NWLC], 2010). It identified 26 indicators of women's access to health care services, measuring the degree to which women receive preventive health care and engage in health-promoting activities (Box 1.2). The report card gave the nation an overall grade of "unsatisfactory," and not a single state received a grade of "satisfactory." As reported in the NWLC's *2010 National Report Card,* the nation has met several benchmarks since 2010: colorectal cancer screenings have increased; annual dental visits have increased; death rates from coronary heart disease have declined considerably; and a steady decline in the number of women who smoke and get mammograms. The nation missed many of the other benchmarks. Other substandard findings included the following:

• No state has focused enough attention on preventive measures, such as smoking cessation, exercise, nutrition, and screening for diseases.

• Too many women lack health insurance coverage: nationally, nearly one in five women has no health insurance.

• No state has adequately addressed women's health needs in the areas of reproductive health, mental health, and violence against women.

• Limited research has been done on health conditions that primarily affect women and that affect women differently than men (NWLC, 2010).

The passage of the **Affordable Care Act** (ACA) as well as *Healthy People*

2020 hold great promise for women's health. The emphasis on access to preventive health care will hopefully make a positive impact on addressing the areas of deficiency identified in the *2010 Report Card*. It is essential that women take advantage of the new benefits, expansions, improvements included in the new law. Nurses have a critical role to play in monitoring the implementation of ACA to make sure all women receive the health care they need and deserve.

The health status of women all across the United States must be improved. Far too many states fail to meet the *Healthy People 2020's* goals for satisfactory health status, and states are only slowly grappling with policy changes that can make improvements in women's health. Since 2010, more states have made positive changes in their policies, but there is still a great distance to go. Much more needs to be done to improve access to health insurance and health care providers and services and to increase access to reproductive health services. Additionally, women need help attaining economic security, which, if achieved, would greatly improve their health and the health of their families. The NWLC report card brought to light problems and their possible solutions for creating a nation of healthy women, for the benefit of themselves, their families, and their communities. It is up to all women to advocate for improvement in their own health by writing a letter to their Congressional representatives demanding that they implement heath policies that promote all women's health. This political action is vital, since all women's health in the nation hangs in the balance.

Major Health Issues for Women

CARDIOVASCULAR DISEASECardiovascular disease (CVD) is the number one cause of death of women, regardless of racial or ethnic group. More than 500,000 women die annually in the United States of CVD—about one death per minute (Alexander et al., 2014). Women who have a heart attack are more likely than men to die. Heart attacks in women are often more difficult to diagnose than in men because of their vague and varied symptoms. Heart disease is still thought of as a "man's disease," and thus a heart attack may not be considered in the differential diagnosis when a woman presents to an emergency department.

Nurses need to look beyond the obvious "crushing chest pain" textbook symptom that heralds a heart attack in men. Symptoms may be atypical: dyspnea rather than chest pain. Causes of heart disease differ between men and women in several other ways—for example, menopause (associated with a significant rise in coronary events); history of preeclampsia; diabetes, high cholesterol levels,

and left ventricular hypertrophy; smoking, including secondhand smoke; gestational hypertension; polycystic ovary syndrome; blood vessel inflammation and repeated episodes of weight loss and gain (increased coronary morbidity and mortality) (Manson & Bassuk, 2015). Nurses have a major role in empowering women to engage in a healthy-heart lifestyle to prevent them from becoming mortality statistics.

CANCER

Cancer is the second leading cause of death among women (American Cancer Society [ACS], 2015a). Women have a one-in-three lifetime risk of developing cancer, and one out of every four deaths is from cancer (Alexander et al., 2014). Although much attention is focused on cancer of the reproductive system, lung cancer is the number one killer of women (ACS, 2015b). This is largely the result of smoking and secondhand smoke. Lung cancer has no early symptoms, making early detection almost impossible. Thus, lung cancer has the lowest survival rate of any cancer: more than 90% of people who get lung cancer die of it (Islami et al., 2015).

Breast cancer occurs in one in every eight (12%) women in a lifetime. It was estimated that in 2015 about 231,840 new cases of invasive breast cancer would be diagnosed among women in the United States. An estimated 40,290 women were expected to die from the disease in 2015 (ACS, 2015c). White women get breast cancer at a higher rate than African American women, but African American women are more likely to get breast cancer before they are at age 40 and are more likely to die from it at any age. The causes of this inequality are complex and are thought to reflect social and economic disparities more than biologic differences associated with race. Socioeconomic disparities include inequalities in work, wealth, income, education, housing, and overall standard of living, as well as barriers to high-quality cancer prevention, early detection, and treatment services (ACS, 2015d).

Women living in North America have the highest rate of breast cancer in the world. As of 2015, there are over 3 million breast cancer survivors in the United States. It is the most common malignancy in women and second only to lung cancer as a cause of cancer mortality in women (ACS, 2015c). Although a positive family history of breast cancer, aging, and irregularities in the menstrual cycle at an early age are major risk factors, others risk factors include excess weight, not having children, oral contraceptive use, excessive alcohol consumption, a high-fat diet, and long-term use of hormone replacement therapy

(ACS, 2015c). Breast cancer rates have dropped recently, possibly due to the decreased use of long-term hormone replacement therapy that occurred after the *Women's Health Initiative* report was released in 2002 and the *Million Women Study* in 2003 (Mirkin et al., 2015). However, early detection and treatment continue to offer the best chance for a cure, and reducing the risk of cancer by decreasing avoidable risks continues to be the best preventive plan.

PREGNANCY AND HEALTH ISSUES

Pregnant women are by no means immune to any of the above health issues. Many start a pregnancy with health conditions that might include hypertension, obesity, CVD, diabetes, autoimmune diseases, anemia, asthma, sexually transmitted infections (STIs), depression, or cancer. Although the majority of pregnant women are young and fairly healthy, the incidence of many chronic health issues in young women and childhood obesity is increasing secondary to the obesity epidemic in the United States. Obesity by itself increases the risk of blood clots, surgical births, preterm birth, macrosomia, diabetes, gestational hypertension, and postpartum infections (DeJoy & Bittner, 2015).

Women's health is a complex issue, and no single policy is going to change the overall dismal state ratings. Although progress in science and technology has helped reduce the incidence of and improve the survival rates for several diseases, women's health issues continue to have an impact on our society. By eliminating or decreasing some of the risk factors and causes of prevalent diseases and illnesses, society and science could minimize certain chronic health problems. Focusing on the causes and effects of particular illnesses could help resolve many women's health issues of today.

FACTORS AFFECTING MATERNAL, NEWBORN, AND WOMEN'S HEALTH

From conception, children are shaped by a myriad of factors such as genetics and the environment. As members of a family, they are also members of a specific population, community, culture, and society. As they learn and grow, they are affected by multiple, complex, and ever-changing influences around them. For example, dramatic demographic changes in the United States have led to shifts in majority and minority population groups. Globalization has led to an international focus on health. Access to and the types of health care available have changed due to modifications in health care delivery and financing. In addition, the United States is still grappling with issues such as immigration, poverty, homelessness, and violence. Prenatal care is important to monitor the pregnancy, detect and treat complications early, prevent diseases through immunization and good nutrition, and promote healthy lifestyles after childbirth. All of these services are needed for a healthy pregnancy outcome (McFarlane, 2015).

These factors may affect the person positively, promoting healthy growth and development, or negatively, increasing the person's health risks. Nurses, especially those working with women and their families, need to understand how these influences affect the quality of nursing care and health outcomes. They must examine the impact of these variables to gain the knowledge and skills needed to plan effective care, thereby achieving the best possible outcomes.

Family

The **family** is considered the basic social unit of our society. The way that families are defined has changed (Table 1.1). The United States Bureau of the Census (2015) defines family as a group of two or more people related by birth, marriage, or adoption and living together. Earlier definitions of family emphasized the legal ties or genetic relationships of people living in the same household with specific roles.

The family greatly influences the development and health of its members. For example, children learn health care activities, health beliefs, and health values from their family. The family's structure, the roles assumed by family members, and social changes that affect the family's life can influence the woman's and newborn's health status. Families are unique; every family has different views and requires distinct methods for support (Fig. 1.3).

TABLE 1.1 EXAMPLES OF FAMILY STRUCTURES IN TODAY'S SOCIETY

Nuclear family	Husband, wife, and children living in same household	May include natural or adopted children Once considered the traditional family structure; now less common due to increased divorce rates and child rearing by unmarried persons
Binuclear family	Child who is a member of two families due to joint custody; parenting is considered a "joint venture"	Always works better when the interests of the child are put first and above the parents' needs and desires
Single-parent family	One parent is responsible for care of children.	May result from death, divorce, desertion, birth outside marriage, or adoption. These families likely to face challenges because of economic, social, and personal restraints; one person serves as the homemaker, caregiver, and financial provider.
Commuter family	Adults in the family live and work apart for professional or financial reasons, often leaving the daily care of children to one parent.	Similar to single-parent family
Step- or blended family	Adults with children from previous marriages or from the new marriage	May lead to family conflict due to different expectations on the part of the child and adults; they may have different views and practices related to child care and health
Extended family	Nuclear family and grandparents, cousins, aunts, and uncles	Need to identify the decision-maker and primary caretaker of the children Popular in some cultures, such as Hispanic and Asian cultures
LGBT family	Adults of the same sex living together with or without children	May face negative attitudes about their "different" lifestyle; are part of the American fabric. Two million children are being raised by LGBT parents. Public policy has not kept up with the changing reality of the American family.
Communal family	Group of people living together to raise children and manage household; unrelated by blood or marriage	May face negative attitudes about their "different" lifestyle Need to determine the decision-maker and caretaker of the children
Foster family	A temporary family for children who are placed away from their parents to ensure their emotional and physical well-being	May include the foster family's children and other foster children in the home Foster children are more likely to have unmet health needs and chronic health problems because they may have been in a variety of health systems.

Grandparents-as-parent families	Grandparents raising their grandchildren due to the inability or absence of the parents	May increase the risk for physical, financial, and emotional stress on older adults May lead to confusion and emotional stress for child if biologic parents are in and out of child's life
Adolescent families	Young parents who are still mastering the developmental tasks of their childhood	Are at greater risk for health problems in pregnancy and delivery; more likely to have premature infants, which then leads to risk of subsequent health and developmental problems Probably still need support from their family related to financial, emotional, and school issues

Changes in Parental Roles Over Time

Parental roles have evolved over time due to social and economic changes as well as family changes. Traditionally, the role of a provider was assigned to the father and the mother performed the role of a nurturer. However, with more women in the workplace and more households with two parents working, today both parents are often the providers as well as the nurturers. Technological expansion has also played a part in affecting traditional roles, allowing some parents to work from home and therefore maintain the provider role while simultaneously fulfilling the nurturer and health manager roles. In addition to fathers taking on greater responsibilities related to household management, and infant and child care, the number of single-father parent families and grandparent families is increasing. One in three children born in the United States is to a single-parent family (Federal Interagency Forum on Child and Family Statistics [FIFCFS], 2015).

While mothers have services that aid their transition from the workplace into motherhood and then back into the workplace, fathers rarely have the same assistance. As fathers have begun to fill a more holistic role, society has realized that they have a tremendous impact on their children's lives starting at an early age. Therefore, it is important that men receive the same assistance as women during transitional periods, such as paternity time off from work and more flexible work schedules (FIFCFS, 2015). Providing assistive services will aid and empower men to be better parents in their children's lives.

Being a parent is one of the most challenging jobs a person will ever do. However, there is no manual that teaches how to be successful at it. Nurses must encourage involvement of both parents by inviting both mother and father to the maternity suites, learning their names, directing questions at them, and listening to their answers. By ensuring that both parents feel involved and important from the very first signs of pregnancy, during childbirth, and afterward, the building blocks can be laid with improved cognitive and socioemotional development of their children. Family well-being provides a foundation for positive parenting and child well-being (Newland, 2015).

Recall Sophia, the pregnant woman described at the beginning of the chapter. Identify the parental roles assumed by Sophia. How might these roles be different from those of her mother when she was Sophia's age?

Genetics

Genetics (the study of heredity and its variations) has implications for all stages of life and all types of diseases. The newborn's or infant's biologic traits, including gender, race, some behavioral traits, and the presence of certain diseases or illnesses are directly linked to genetic inheritance. New technologies in molecular biology and biochemistry have led to a better understanding of the mechanisms involved in hereditary transmission, including those associated with genetic disorders. These advances are leading to better diagnostic tests and better management options.

FIGURE 1.3 Nurses must take into account family dynamics when providing health care. There are many different family structures, and they influence the client's needs. **A.** The traditional nuclear family is

composed of two parents and their biologic or adopted children. **B.** The extended family includes the nuclear family plus other family members, such as grandparents, aunts, uncles, and cousins. **C.** Gay and lesbian families comprise two people of the same sex sharing a committed relationship with or without children.

Gender

Gender is established when the sex chromosomes join. A person's gender can influence many aspects, such as physical characteristics and personal attributes, attitudes, and behaviors. Some diseases or illnesses are more common in one sex; for example, scoliosis is more common in females and color blindness in males (Snustad, 2015).

Race

Race refers to the physical features that distinguish members of a particular group, such as skin color, bone structure, or blood type. Some physical features that are normal in a particular race may be considered a sign of a disorder in other races. For example, epicanthic folds (the vertical folds of skin that partially or completely cover the inner canthi of the eye) are normal in Asian children, but may occur with Down syndrome or renal agenesis in other races. In addition, certain malformations and diseases are found more commonly in specific races. For example, sickle cell anemia occurs more often in African and Mediterranean population groups, and cystic fibrosis is seen more often in individuals from the Northwestern European population group (Donaldson et al., 2015).

   Public awareness is important in educating couples at genetic risk about the benefits of screening programs and proactively seeking preconceptional genetic counseling to consider options that could include preimplantation genetic diagnosis (the use of in-vitro fertilization technology to screen for unaffected embryos). Preimplantation genetic diagnosis was developed as an alternative to prenatal diagnosis for couples with a family history of genetic disease (Cunningham, Goldsmith, & Skirton, 2015). The lack of engagement by ethnic minorities might simply reflect a lack of genetic awareness. Nurses can take the lead in assisting couples to gain the needed awareness that will empower them to make intelligent reproductive decisions.

Society

Society has a major impact on the health of women and their families. Major influences include social roles, socioeconomic status, the media, and the expanding global nature of society. Each of these may influence a person's self-concept, where he or she lives, the lifestyle he or she leads—and, thus, his or her health.

Social Roles

Society often prescribes specific patterns of behaviors: certain behaviors are permitted and others are prohibited. These social roles are often an important factor in the development of self-concept. Social roles influence a person's ideas about himself or herself. Social roles are generally carried out in groups with which the individual has intimate daily contact, such as the family, school, workplace, or peer groups.

Socioeconomic Status

Another dominant influence on health is a person's socioeconomic status, his or her relative position in society. This includes the family's economic, occupational, and educational levels. Low socioeconomic status typically has an adverse influence on an individual's health. Health care costs are continuing to rise, as are health insurance premiums. The family may not be able to afford food, health care, and housing; meals may be unbalanced, erratic, or insufficient. Housing may be overcrowded or have poor sanitation. Some families may not be able to afford or be aware of the importance of preventive care. As a result, they may be exposed to health risks such as lead poisoning or may not be immunized against communicable diseases.

The Media

Social networks and mass media have long influenced human behavior. Until recently, information exchange via various media was slow and limited. Today, given the 24-hour news cycle, information spreads like electronic wildfire. Although everyone is part of a social network, each person is only vaguely aware of his or her friends' friends and the ensuing global network to which all

are connected electronically (Oeldorf-Hirsch & Sundar, 2015).

The mass media—the vehicles by which information reaches large numbers of people, e.g., television, the Internet, radio, movies, and newspapers—frequently cover health-related topics, and for some women can be leading sources of information about their health. The media can influence the behavior of women depending on the messages sent. One of the biggest influences is the advertisement of prescription medications on television. The frequent phrase at the end of the ad: "Ask your doctor if this medication is right for you" creates a powerful suggestion for the woman to request that specific medication when she visits her health care provider if her symptoms seem to match those portrayed in the ad.

Issues related to health promotion, contagion, disease diffusion, and general well-being are classic epidemiologic concerns that are addressed by social networks and mass media. Frequently, mass media depict a world in which unhealthy behaviors such as physical aggression, unprotected sex, smoking, and drinking are glamorous and risk free. These unrealistic messages can be detrimental to the health choices of young women. It is essential that nurses address these myths to dispel them.

POVERTY

Poverty is a measurement based on the specific monetary income of a family. The poverty threshold is the dollar amount that the United States Census Bureau uses to determine whether a family is living in poverty. If the individual's or family's income is below the threshold, then that person or family is said to be living in poverty.

Despite the many global economic gains that have been made during the past century, poverty continues to grow and the gap between rich and poor is widening. Major gaps continue to arise between the economic opportunities and status afforded to women and those offered to men. A disproportionate share of the burden of poverty rests on women's shoulders, and undermines their health. However, poverty, particularly for women, is more than monetary deficiency. Women continue to lag behind men in control of cash, credit, and collateral. Other forms of impoverishment may include deficiencies in literacy, education, skills, employment opportunities, mobility, and political representation, as well as pressures on time and energy linked to their responsibilities. These poverty factors may affect a woman's health (WHO, 2015c).

GLOBAL HEALTH FOR WOMEN

The struggle to ensure women's health worldwide is ongoing since a nation's health is directly related to maternal and child health. The poor state of maternal health in developing countries continues to go virtually unnoticed. Women throughout the world, particularly in Asia and Africa, continue to face enormous obstacles in their attempts to receive reproductive health services, including contraception, emergency obstetrical care, and safe abortion services (McFarlane, 2015).

Globally, an estimated 600,000 women die each year from pregnancy-related causes (United Nations International Children's Emergency Fund [UNICEF], 2015), but focusing only on pregnancy-related health issues provides an incomplete understanding of women's health within the global community. Approximately 800 women die every day from preventable causes related to pregnancy and childbirth, with 99% of these women dying in developing countries. Today, more than 50% of maternal deaths occur in just six countries: India, Nigeria, Pakistan, Afghanistan, Ethiopia, and Democratic Republic of the Congo (WHO, 2015d). In developing countries, the five major direct causes of maternal death are hemorrhage, sepsis, gestational hypertension, unsafe abortion, and obstructed labor. The four major direct causes of maternal death in the United States are hypertension (preeclampsia and eclampsia), hemorrhage, placenta previa, and abortions (WHO, 2015d). Women's health and well-being depend on many broader issues that are economic, political, and social in nature. These important factors are often ignored, but adverse effects of women's ill health cut across the economic layers of all societies, rich and poor.

Skewed perceptions, attitudes, and practices toward women persist around the world. They are not limited to the underdeveloped and developing worlds. Regrettably, women in developed countries also suffer from gender bias. A great variance in women's salaries compared with those of men and a reluctance to politically empower women are some of the examples. All over the world, major disparities remain between female and male access to education, employment, and salaries. Although women are the world's main food producers and their working hours are longer than those of men, women earn only 10% of the world's income and own less than 1% of property worldwide. Women comprise nearly two thirds of the world's 800 million illiterate adults. Even in regions with high rates of female literacy, women's wages continue to be lower than those of men, even for work of equal value. These discrepancies are not based on the issue of competence, but on bias (United Nations, 2016).

The world leaders who attend the Global Summit of Women in 2015 will agree to continue to promote gender equality and eliminate still-prevalent gender discrimination. They agreed to explore ways women can (1) reshape the business world, (2) reengineer communities, (3) redefine global leadership, (4) guarantee the free and equal right of women to own and inherit property, (5) recreate sustainable futures, (6) expand women's economic opportunities globally, and (7) restore peace worldwide (GlobeWomen, 2015).

Dramatic improvements in health have been achieved worldwide since the early 1990s. Moving forward will require collective global action—a daunting task given the current climate of global reproductive health politics and international economic insecurity. Even so, women have never shied away from a challenge. Global collaboration, policy action, resources, leadership, research, and evidence are needed to move forward to improve health for all women and their families.

Current successes could be explained by scientific advances delivered by health systems, economic growth, and expanded access to education and health services. However, ongoing poverty, low educational opportunities for girls, and poor public health decisions still prevent about a billion people in low-income and middle-income countries from fully sharing in these health gains.

Nevertheless, progress for women verses men has been slow. An example is the poor state of girls' health in India and China, the only two countries in the world where girls are more likely than boys to die before the age of 5. The poor progress in these countries can be explained by female infanticide and discrimination against girls when it comes to receiving vaccinations, medical care for acute illnesses, and adequate nutrition (WHO, 2015e).

Healthy People 2020's goal is to "improve public health and strengthen United States national security through global disease detection, response, prevention, and control strategies (USDHHS, 2015a)." The health of the United States population can be affected by public health threats or events around the world. As the world and its economies become increasingly globalized, including extensive international travel and commerce, it is essential to think about health in a global context. Rarely a week goes by without a headline about the emergence of an infectious disease or other health threat somewhere in the world. Globally, the rates of mortality from "lifestyle" conditions such as diabetes, obesity, heart disease, mental illness, substance abuse, and injuries are growing. The world community needs to work together to develop strategies to confront major health threats.

Improving women's health globally must be grounded in the principles of human rights and gender equality. Applied in a culturally sensitive manner, nurses must promote the empowerment of women in making their own health-related decisions to improve their overall health. A key to changing women's lifestyle behaviors and allowing them to make informed choices is for nurses to facilitate and partner with all women to access health information and increase their knowledge. Recognizing that all women are vital and equal members of society may finally lead to a long overdue reduction in worldwide maternal morbidity and mortality, decreased rates of human immunodeficiency virus/acquired immunodeficiency syndrome (HIV/AIDS) transmission, and an end to violence against women on a truly global scale.

HOMELESSNESS

Families with children are the fastest-growing segment of the homeless population. Homeless families commonly are victims of violence and may have mental health challenges. Homelessness occurs in large urban areas and midsize cities as well as suburban and rural areas.

Homelessness can have a negative impact on health and well-being in numerous ways, including:

• Mental health issues such as anxiety, depression, or aggressive behavior

• Chronic health problems and injuries

• Premature death and disability

• Nutritional deficiencies, affecting fetal growth and development

• Behaviors such as illegal substance use or unprotected sex with multiple partners

• Limited access to health care services such as preventive care, prenatal care, or dental care

Violence

Violence can occur in any setting and can involve anyone. Violence against women is a major public health concern with long-term health and social consequences–it affects thousands of lives and costs the health care system millions of dollars. Globally, 603 million women live in countries where intimate partner violence is not yet considered a crime. Up to 70% of women in the world report having experienced physical and/or sexual violence at some point in their

lifetime (United Nations, 2016a). Violence affects families, women, and children of all ages, ethnic backgrounds, races, educational levels, and socioeconomic levels. Pregnancy is often a time when physical abuse starts or escalates, resulting in poor outcomes for the mother and the baby. The nurse is responsible for assessing for and following up on any abuse.

Violence in the home environment, known as intimate partner violence, affects many lives in the United States. The U.S. Bureau of Justice Office on Violence against Women (2015) estimates that over 1 million violent crimes are committed by former spouses, boyfriends, or girlfriends each year; about 85% of the victims are women. This violence is known as intimate partner abuse, family violence, wife beating, battering, marital abuse, or partner abuse, but regardless of the term used, its effects are widespread. Violence against women of any type can lead to a multitude of health consequences, including physical, reproductive, and psychological (Davies et al., 2015).

Nurses serve their clients best not by trying to rescue them, but by helping them build on their strengths and providing support, thereby empowering them to help themselves. All nurses need to include a screening tool like "RADAR" in every client visit (Bartlett Regional Hospital, n.d.; U.S. Prevention Services Task Force [USPSTF], 2015; Box 1.3).

Community

Community encompasses a broad range of concepts, from the nation where a person lives down to a particular neighborhood or group. The surrounding community affects many aspects of a person's health and general welfare. The quality of life within the community has a great influence on an individual's ability to develop and become a functional member of society. Community influences include the school, which is a community by itself, and peer groups. The support and assistance offered to women and their families from other areas of the community, such as school programs and community centers, can improve the individual's overall health and well-being.

BOX 1.3

RADAR

R—Routinely screen every client for abuse.

A—Affirm feelings and assess abuse.

D—Document your findings.

A—Assess for your client's safety.

R—Review options and make referrals.

Culture

Culture is a view of the world and a set of traditions that are used by a specific social group and are transmitted to the next generation. It plays a critical role with women and their families. A person's culture influences not only socialization but also his or her experiences related to health and specific health practices (Aggleton, Parker, & Thomas, 2015). Culture is a complex phenomenon involving many components, such as beliefs, values, language, time, personal space, and view of the world, all of which shape a person's actions and behavior. Individuals learn these patterns of cultural behaviors from their family and community through a process called *enculturation*, which involves acquiring knowledge and internalizing values. Culture is learned first in the family, then in school, and then in the community and other social organizations. Culture influences every aspect of development and is reflected in childbearing and child-rearing beliefs and practices designed to promote healthy adaptation (Galanti, 2015).

With today's changing demographic patterns, nurses must be able to assimilate cultural knowledge into their interventions, so they can care for culturally diverse women, children, and families. Nurses must be aware of the wide range of cultural traditions, values, and ethics. **Cultural competence** is the ability to apply knowledge about a client's culture so that the health care provided can be adapted to meet his or her needs. Cultural competence refers to the process by which individuals and systems respond respectfully and effectively to people of all cultures, languages, classes, races, ethnic backgrounds, disabilities, religions, genders, sexual orientation, and other diversity factors in a manner that recognizes, affirms, and values the worth of individuals, families, and communities, and protects and preserves the dignity of each. Nurses need to attain the knowledge, skills, and attitudes to provide effective care for diverse populations (Blanchet Garneau & Pepin, 2015). Nurses need to learn about general cultural groups, ethnicity, and health practices; how they affect women and their health; and the changing demographics of the population. This will help them view culture as a point of congruence rather than as a potential source of conflict with clients.

Cultural Groups

A society typically includes dominant and minority groups. The dominant group, often the largest group, is the group that has the greatest authority to control values and sanctions of the society (Phillips et al., 2015). As a result, the dominant or majority culture may have the largest impact on health. The minority cultural groups may remain in their own communities and maintain some of their traditions and values while mainstreaming into American society. A culture may contain many subcultures, and geographic differences also can occur; for example, Hispanics living in New York may be quite different from Hispanics living in Florida. Being aware of these differences is essential in providing culturally competent care. The more knowledge a nurse has about a specific culture, the more accurate and complete the cultural assessment will be. For example, if nurses are not aware that many Hispanics use traditional healers such as *curandros, masjistas, sobodoes, y(j)erberos,* and *esperititas,* they will not know how to ask specific and appropriate questions about the individual's use of these alternative practitioners and their therapies (Taber, Leyva, & Persoskie, 2015).

Nurses need to be aware of the health care values and practices that are passed along from one generation to the next. For example, a belief in folk healers relates to how the culture interprets illness and health. Some of these parts of the culture may have major influences on an individual's health. Table 1.2 highlights some major cultural groups and their common health beliefs and practices.

Take Note!

Nurses can have a lifelong influence on an individual's perceptions of health and use of health services. By understanding how a woman's and her family's culture influences their health practices, nurses can enhance the family's traditional practices, and different cultural practices can become sources of strength rather than areas of conflict.

Take Note!

The health status of a newborn may affect his or her long-term health and development.

Nutrition

Nutrition provides the body with the calories and nutrients required to sustain life and promote growth, as well as the essentials required to maintain health and prevent illness. Nutritional deficiencies or excesses are common problems in the United States, as evidenced by the persistent problem of iron-deficiency anemia and the increasing incidence of obesity (DeBruyne, Pinna, & Whitney, 2015). Inadequate food intake, social and cultural food practices or habits that may be nutritionally unsound, the availability of processed and nutritionally inadequate foods, lack of nutrition education in homes and schools, and the presence of illness that interferes with the ingestion, digestion, and absorption of food are factors that can affect an individual's nutrition.

At no other time of life is nutrition more important than during fetal development and infancy. Adequate nutrition is essential for tissue formation, neurologic development, bone growth, and overall long-term health. During pregnancy, a woman needs additional calories to support fetal growth and development as well as to support her own needs, and an adequate intake of folic acid is important to prevent neural tube defects (Fig. 1.4). Nutrition and its effects on health status are integrated throughout this text; see Chapter 11.

Lifestyle Choices

Lifestyle choices that affect an individual's health include eating; exercise; use of tobacco, drugs, or alcohol; and methods of coping with stress. Most health problems that arise today are due to an individual's lifestyle. Poor lifestyle choices made early in life can affect the quality of life as an individual ages. Also these poor choices affect the increasing incidence of chronic disease. The same concept of making poor choices can be applied to pregnant women and the health and well-being of the infant. Maintaining a healthy level of activity through exercise and hobbies is important for adults and children.

Environmental Exposure

Pregnant women are exposed to many and varied environmental chemicals. Scientific evidence documents that widespread exposure to environmental chemicals at levels that are encountered in daily life can have an adverse impact on reproductive and developmental health across the lifespan (Yin-Hsiu et al., 2015).

In utero, the fetus can be affected by the lack of maternal nutrition, environmental chemical exposures, maternal infections, or maternal use of alcohol, tobacco, and drugs. Nurses caring for pregnant women should be aware of the risks to the fetus posed by certain drugs, chemicals, and dietary agents, as well as maternal illnesses. These agents, known as teratogens, may be linked to preterm births and birth defects in children. Not all drugs or agents have fetal effects, however, and research is necessary to identify the correlations between teratogens and other variables.

Stress and Coping

Disasters such as the terrorist attacks of September 11, 2001, the killings at Columbine High School, Super Storm Sandy in New Jersey, or Hurricane Katrina in New Orleans can have a significant impact on the well-being of women, children, and families. Stressors such as war, terrorism, violence, and natural disasters may decrease a person's coping ability. Exposure to traumatic events and violence may have long-term effects on an individual's psychosocial development and status.

Exposure to stress is not limited to disasters or traumatic events, however. Stress can also include areas such as inadequate finances, family crises, inadequate support systems, or domestic violence. Like disasters and traumatic events, the effects of these stressors can dramatically affect the health status of a woman or family.

TABLE 1.2 BELIEFS AND PRACTICES OF SELECTED CULTURAL GROUPS

Cultural Group	Beliefs and Practices Affecting Maternal and Children's Health
African Americans	View of health as harmony with nature, illness as disruption in harmony Use of folk healing and home remedies common View of pregnancy as a state of wellness Emotional support during labor commonly from other women, primarily the woman's own mother Liberal use of oil on newborn's and infant's scalp and skin Belief in illnesses as natural (due to natural forces person hasn't protected self against) and unnatural (due to person or spirit) Illness commonly associated with pain Postpartum practices for the infant may include the use of a bellyband or a coin placed on top of the infant's umbilicus to prevent umbilical hernias Pain and suffering inevitable; relief achieved through prayers and laying on of hands
Asian Americans	Use of complementary modalities along with Western health care practices View of life as a cycle with everything connected to health Usually attended by a female relative and tend to be quiet and sedate during labor and birth Health viewed as a balance between the forces of yang and yin Illness is the disharmony of yin and yang Yang—energy outside of body where matter is dynamic, external, upward, ascending, and brilliant Yin—energy inside of body where matter is static, internal, downward, descending, dull, regressive, and hypoactive During postpartum, women don't expose themselves to cold air or bathe themselves for the first month to avoid exposure to illness Respect for authority emphasized Women are very modest and may insist on a female health care provider for maternity care View of pregnancy as a natural process and happy time for woman Little involvement of the father during labor; quiet, stoic appearance of woman during labor
Arab Americans	Women subordinate to men; young individuals subordinate to older persons Family loyalty is primary. Women value modesty and want their bodies covered during examinations. Procreation is regarded as the purpose of marriage, thus high fertility rates are favored. During labor, women openly express pain through facial expressions, verbalizations, and body movements. Mothers may be reluctant to bathe after childbirth because of beliefs that air gets into the mother and causes illness. Good health associated with eating properly, consuming nutritious foods, and fasting to cure disease Illness is due to inadequate diet, shifts in hot and cold, exposure of stomach while sleeping, emotional or spiritual distress, and "evil eye." Little emphasis on preventive care Breast-feeding often delayed for 2 to 3 days after birth. Cleanliness important for prayer
Hispanic Americans	Family is important: father is the source of strength, wisdom, and self-confidence; mother is the caretaker and decision-maker for health; children are persons who will continue the family and culture. During the period of *la cuerentena* (first 40 days after childbirth) women are thought to be susceptible to cold, so many will avoid taking showers, sitz baths, tub baths, washing their hair, or being exposed to cold air. Likely to be very vocal during labor by crying or frequently making loud screams Newborn protection from the "evil eye" Health as God's will, maintainable with a balance of hot and cold food intake Freedom from pain indicative of good health; pain tolerated stoically due to belief that it is God's will Folk medicine practices and prayers, herbal teas, and poultices for illness treatment

Native Americans	Place high value on family and tribe; respect for elders
	Family as an extended network providing care for newborns and children
	View of pregnancy as a normal and natural process; entire family may be present at birth
	Use of food to celebrate life events and in healing and religious ceremonies
	Health as harmony with nature; illness due to disharmony, evil spirits
	Restoration of physical, mental, and spiritual balance through healing ceremonies

FIGURE 1.4 A pregnant client is eating a healthy meal to ensure adequate nutrition.

Recall Sophia, the 38-year-old pregnant woman who has come to the prenatal clinic for a visit. While talking with the nurse, Sophia mentions that her children are very involved in activities. She says, "My husband is busy at work, so I do most of the running around. Sometimes I feel like the people at the drive-through know me by name! My husband helps out on the weekends, but during the week, it's all me." What factors may be influencing Sophia's health? How might these factors be influencing the health of her family?

Health Care Cost Containment

The health care system functions within a market setting, offering goods and services that carry a cost to health care consumers and clients. There is no disagreement that health care costs have inflated beyond the pocketbooks of most Americans. The increase in costs has been attributed to such factors as technological advances, inflation, increased needs of a growing older adult population, longer life spans, and the cost of medical liability. The advent of managed care has led to a trend of attempting to reduce health care costs, but has not been very effective (Hall et al., 2015). The purpose of managed care is to achieve cost control by assigning set fees for services, monitoring the need for procedures such as tests and surgical operations, and stressing preventive care. One such mechanism is utilization review, which is employed to limit reimbursement of medical care that is determined to be medically necessary. These efforts have led to shorter hospital stays and increased awareness on the part of nurses about the costs of supplies and services. The overall challenge is to maintain the quality of care while reducing its cost. For example, if a pregnant woman with diabetes needs to go to an endocrinologist, she has very little choice except to purchase the services needed or go without care. In today's managed care environment, the woman will need to go through her primary health care provider or "gatekeeper" to receive a referral to a specialist. Often she must trust her primary provider to make that choice for her instead of making that decision on her own.

Although cost containment is important to restrain health care spending, such efforts should not reduce the quality or safety of care delivered. Preventive care (remember the old saying "an ounce of prevention is worth a pound of cure") has been shown to lower costs significantly. Mammograms, cervical cancer screenings, prenatal care, smoking cessation programs, and immunizations are a few examples of preventive care that yield positive outcomes and reduce overall health care costs. Using technological advances to diagnose and treat diseases early saves lives as well as money. Although the ACA expands insurance coverage to cover preventive screenings, there are still differences in availability of this coverage across many states (Sabik, Tarazi, & Bradley, 2015).

Nurses can be leaders in providing quality care within a limited-resource environment by emphasizing to their clients the importance of making healthy lifestyle and food choices, seeking early interventions for minor problems before

they become major ones, and learning about health-related issues that affect them. Thus, they can select the best option for themselves and their families. Prevention services and health education are the cornerstones of delivering quality maternal, newborn, and women's health care.

Access to Health Care

The health care system continues to change. In the United States, changes in the health care system result from pressures coming from many directions. These changes reflect shifts in social and economic realities and the results of the biomedical and technological progress that has been made over the past several decades. The effects are felt by everyone who seeks health care in any form. The system of providing medical care in a high-tech environment has changed to providing health care in an environment with limited resources and access to services. Ways to allocate our limited health care resources continue to be the focus.

A major factor that affects access to care is health insurance. People without health insurance typically cannot afford to seek health care for maintenance and prevention interventions. The "working poor" may not earn enough money to afford health insurance or medical care, and part-time workers do not always receive health insurance benefits. In most states, a man and a woman of the same age and health status will be charged different rates for exactly the same individual health insurance policy, a practice called *gender rating*. Women pay a much higher health insurance rate for the same coverage than do men in the United States—an inequality that has lessened with the full enactment of the ACA in 2014 (Starrs, 2015).

The ACA, which began fully in 2014, aims to make health insurance accessible to many Americans previously without health insurance. It obligates health insurance agencies to cover a wide range of preventive health services at no cost to the person. Ideally, in the future, people will start to look at their health care providers as partners in wellness, rather than providers who treat disease.

Preventive Care Focus

The emphasis on cost reduction has also led to an emphasis on preventive care and services. The ACA of 2014 has added preventive services for women. Research suggests that better access to preventive services can be maintained at

a reasonable cost to the health care system, and that some services can lower the health care costs. For the ACA to be truly transformational for women's health, its promise to remove cost barriers to well-woman visits must be realized fully (Fitzgerald et al., 2015). Anticipatory guidance is vital during each health contact with women and their families. Education of the family includes everything from keeping the home safe to ways to prevent illness.

The Continuum of Care Emphasis

A *continuum of care* strategy is cost effective and provides efficient and effective services. This continuum extends from acute care settings such as hospitals to outpatient settings such as ambulatory care clinics, primary care offices, rehabilitative units, community care settings, long-term facilities, and homes. For example, a hospital stay is now integrated into a continuum that allows the client to complete therapy at home or at other community settings, while reentering the hospital for short periods for specific treatments or illnesses (Stanhope & Lancaster, 2014). The ACA offers provisions that the health care delivery system be person-centered with individual control; improves quality, and integrates care across settings and providers. It stresses expansion of community-based services and coordination of care while the person transitions from one setting to another to meet changing health care needs (Mansur & Thompson, 2015).

Improvements in Diagnosis and Treatments

Because of the tremendous improvements that have been made in technology and biomedicine, disorders and diseases are being diagnosed and treated earlier. The 1990s witnessed the establishment of a remarkable and productive connection between genetics and various pathophysiologic processes. For example, female fetuses with congenital adrenal hyperplasia, a genetic disorder resulting in a steroid enzyme deficiency that can lead to disfiguring anatomic abnormalities, are beginning to receive treatment before birth. In addition, many genetic defects are being identified so counseling and treatment may occur early. With these improved diagnoses and treatments, nurses may now be caring for individuals who have survived situations that once would have been fatal, who are living well beyond their life expectancy for a specific illness, or who are functioning with chronic disabilities (Dumas & Turner, 2015). For example, at one time, women with congenital heart disease did not live long enough to become pregnant. However, with new surgical techniques to correct the defects, many of these women survive and become pregnant, progressing through their pregnancy without significant problems.

Although positive and exciting, these advances and trends also pose new challenges for the health care community. For example, as health care for premature newborns improves and survival rates increase, the incidence of long-term chronic conditions such as respiratory airway dysfunction or developmental delays has also increased. As a result, nurses are faced with caring for clients at all stages along the health–illness continuum.

Empowerment of Health Care Consumers

As a result of the influence of managed care, the focus on prevention, a more educated population, and technological advances, individuals and families have taken on increased responsibility for their own health. Health care consumerism adds an important voice to the current United States health care system reform, as people become informed, proactive, and demand choices in the delivery of their health care. Health care consumers want to play a greater role in managing health and illness. Families want information about illnesses and they want to participate in making decisions about treatment options. As client advocates who value family-centered care, nurses are instrumental in promoting this empowerment. To do this, the nurse should respect the family's views and concerns, address all issues and concerns, consider the family members to be important participants, and always include the woman and her family in the decision-making process.

BARRIERS TO HEALTH CARE

Women are major consumers of health care services, in many cases arranging not only their own care but also that of family members. Compared with men, women have more health problems, longer life spans, and more significant reproductive health needs (McFarlane, 2015). Access to care can be jeopardized by lower incomes and greater responsibilities (juggling work and family). Lack of finances or transportation, geographic misdistribution of health care providers, no babysitters, language or cultural barriers, inconvenient clinic hours, and the poor attitudes of health care workers often discourage clients from seeking health care (Tucker Edmonds, Mogul, & Shea, 2015).

Finances

The existence of financial barriers is one of the most important factors that limit care. Childbirth is the leading reason for hospitalization in the United States. For both private insurers and Medicaid, hospital maternity and newborn charges exceed those for any other condition. In United States hospitals, vaginal and cesarean births are costly. Many women have limited or no health insurance and cannot afford to pay for maternity care. Compared with other racial and ethnic groups, African American women tend to be younger, more likely to have a surgical birth, experience preterm births, to stay longer in the hospital, and to incur higher Medicaid costs. African American women experience a higher rate of adverse pregnancy outcomes than White or Hispanic women. Racial disparities in adverse pregnancy outcomes not only represent potential preventable human suffering, but also avoidable economic costs (Catov et al., 2015). Although Medicaid covers prenatal care in most states, the paperwork and enrollment process can be so overwhelming that many women do not register. Many families do not have health insurance, do not have enough insurance to cover the services they need, or cannot pay for services.

Transportation

Getting to and from appointments can be challenging for clients who do not drive or own a car or cannot use public transportation (if there is public transportation in the area). Prenatal care has the potential to improve perinatal outcomes and decrease health disparities, yet many women struggle with access to care. It can be difficult for these clients to attend all recommended prenatal health care visits, especially if they have other small children who must be taken along on a visit. These challenges can reduce the adherence to scheduled appointments and follow-up.

Language and Culture

Language is how people communicate with each other to increase their understanding or knowledge. If a health care worker cannot speak the same language as the client or does not have a trained interpreter available, a barrier is created. The client's complaints can be misinterpreted or ignored or their significance can be misconstrued. The language barrier might prevent the client from accessing the necessary care, such as prenatal care or preventive care.

Knowledge barriers (e.g., lack of understanding of the importance of prenatal care or child health promotion), low health literacy, gender attitudes, health beliefs, retention of information, and spiritual barriers (e.g., some forms of treatment are proscribed by religions) also pose barriers to receiving health care.

Low Health Literacy

Health literacy is defined as the degree to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions (Health and Medicine Division (HMD), 2016). It also includes the ability to understand instructions on prescription drug bottles, appointment slips, education brochures, health care provider's directions, consent forms, and the ability to negotiate complex health care systems.

Vulnerable populations for low health literacy include older adults, immigrants, minorities, and low income populations. Low health literacy is a major source of economic inefficiency in the U.S. health system. It is estimated that the cost of it to the U.S. economy is approximately $106–238 billion annually (CDC, 2015f).

Low health literacy is associated with poor health outcomes, increased emergency room visits, higher morbidity and mortality rates, and less use of preventive health services. Nurses have the potential to impact and change these outcomes. Nurses can use screening tools to assess a client's health literacy in addition to identifying characteristics that indicate low health literacy. Having clients repeat the instructions verbally and having them demonstrate the specific treatment procedure needed for their continued care is essential. Simply handing a client a piece of paper with written instructions for a vital medication or treatment procedure is not advocating for that client (French, 2015).

Health Care Delivery System

The health care delivery system itself can create barriers. Fifty-eight percent of employed families with insurance are covered by some type of managed health care plan or health maintenance organization, but millions of Americans remain uninsured (Holden, Chen, & Dagher, 2015). This prospective payment system based on diagnosis-related groups limits the amounts of health care the family may receive. This also includes Medicaid reimbursements. As a result of cost-containment efforts, the trend is to discharge clients as soon as possible from the hospital and to deliver care in the home or through community-based services. Postpartum hospital stays are often shorter than 48 hours following a vaginal birth; thus, most postpartum care takes place in the home and the community. Home visits by nurses to provide support at home for mothers and infants is needed for high risk families to prevent health problems from becoming chronic with long-term effects (Aston et al., 2015). Although overall insurance plans may improve access to preventive services, they may limit access to specialty care, which greatly affects clients with chronic or long-term illnesses.

Clinic hours must meet the needs of the clients, not the health care providers who work there. Evening or weekend hours might be needed to meet the schedules of working clients. Clinic personnel should evaluate the availability and accessibility of the services they offer.

Unfortunately, some health care workers exhibit negative attitudes toward poor or culturally diverse families, and this could deter these clients from seeking health care. Long delays, hurried examinations, and rude comments by staff discourage clients from returning.

Consider This

I was a 17-year-old pregnant migrant worker needing prenatal care. Although my English wasn't good, I was able to show the receptionist my "big belly" and ask for services. All the receptionist seemed interested in was a Social Security number and health insurance—neither of which I had. She proceeded to ask me personal questions concerning who the father was and commented

on how young I looked. The receptionist then "ordered" me in a loud voice to sit down and wait for an answer by someone in the back, but never contacted anyone that I could see. It seemed to me like all eyes were on me while I found an empty seat in the waiting room. After sitting there quietly for over an hour without any attention or answer, I left.

Thoughts: *Why did she leave before receiving any health care service? What must she have been feeling during her wait? Would you come back to this clinic again? Why or why not?*

LEGAL AND ETHICAL ISSUES IN MATERNAL, NEWBORN, AND WOMEN'S HEALTH CARE

Law and ethics are interrelated and affect all of nursing. Professional nurses must understand their scope of practice, standards of care, institutional or agency policies, and state laws. All nurses are responsible for knowing current information regarding ethics and laws related to their practice.

The AWHONN (2009) publishes their *Standards for Professional Nursing Practice in the Care of Women and Newborns,* which are summarized below:

- *Standard I: Assessment*—The RN collects health data about women and newborns in the context of women-centered and family-centered care.

- *Standard II: Diagnosis*—The RN formulates nursing diagnoses by analyzing assessment data to identify and differentiate normal physiologic and developmental transitions from pathophysiologic variations and other clinical issues.

- *Standard III: Outcomes Identification*—The RN individualizes expected outcomes for women and newborns.

- *Standard IV: Planning*—The RN develops a plan of care that includes interventions and alternatives to attain expected outcomes for women and newborns.

- *Standard V: Implementation*—The RN implements the interventions identified in the women's or newborn's plan of care.

- *Standard VI: Evaluation*—The RN evaluates the progress of women and newborns toward attainment of expected outcomes.

- *Standard VII: Quality of Practice*—The RN systematically evaluates and implements measures to improve the quality, safety, and effectiveness of nursing practice.

- *Standard VIII: Education*—The RN acquires and maintains knowledge and competencies that reflect current EBP.

- *Standard IX: Professional Practice Evaluation*—The RN evaluates his or her own nursing practice in relation to current evidence-based care information, professional standards and guidelines, statues, rules, and regulations.

- *Standard X: Ethics*—The RN's decisions and actions on behalf of women, fetuses, and newborns are determined in an ethical manner and guided by an ethical decision-making process.
- *Standard XI: Collegiality*—The RN interacts with and contributes to the professional development of peers, colleagues, and other health care providers.
- *Standard XII: Collaboration and Communication*—The RN collaborates and communicates with women, their families, the community, and other health care providers in providing safe care.
- *Standard XIII: Research*—The RN generates and/or integrates evidence to validate interprofessional knowledge in providing care to women and newborns.
- *Standard XIV: Resources and Technology*—The RN considers factors related to safety, effectiveness, technology, and expense in providing care to women and newborns.
- *Standard XV: Leadership*—The RN should serve as a role model, change agent, consultant, and mentor to all women, their families, and other health care professionals.

Several areas are of particular importance to the health care of women and their families. These include abortion, substance abuse, intrauterine therapy, maternal–fetal conflict, stem cell research, umbilical cord blood banking, informed consent, and confidentiality.

Abortion

Abortion has been a legal medical procedure in the United States for more than three decades, yet it continues to be a hotly debated and volatile legal, social, and political issue. It was an issue even before *Roe v. Wade*, the 1973 Supreme Court decision that legalized abortion. The Supreme Court ruled that a woman, in consultation with her health care provider, has a constitutionally protected right to have an abortion in early stages of pregnancy—that is, before viability—free from government interference. Nearly half of pregnancies among American women are unintended, and about 4 in 10 of these are terminated by abortion. Twenty-two percent of all pregnancies (excluding miscarriages) end in abortion (Guttmacher Institute, 2015).

Every time abortion is debated on the national level, the Hyde Amendment is cited. Named after its author, Rep Henry Hyde (R-Illinois), the Hyde Amendment places limits on federally funded abortions. By denying abortion coverage to low-income women on Medicaid, the Hyde Amendment has limited choices of low-income women regarding their reproductive rights.

Medical and surgical modalities are available to terminate a pregnancy, depending on how far the pregnancy has developed. A medical abortion by taking mifepristone and prostaglandins is well established and safe when performed as per guidelines with a success rate of up to 97%. A surgical intervention can be performed up to 14 weeks' gestation; a medical intervention can be performed up to 9 weeks' gestation (Hickey & Moore, 2015).

In September, 2000, the United States Food and Drug Administration approved mifepristone to be marketed in the United States as an alternative to surgical abortion. Medication abortion using mifepristone or a similar medication accounted for 38% of all nonhospital abortions, and about one quarter of abortions before 9 weeks' gestation (Guttmacher Institute, 2015). All women undergoing abortion need emotional support, a stable environment in which to recover, and nonjudgmental care throughout the process.

The issue of abortion separates people into two camps: pro-choice and pro-life. The pro-choice group supports the right of any woman to make decisions about her reproductive functions based on her own moral and ethical beliefs. The pro-life group feels strongly that abortion is murder and deprives the fetus of the basic right to life. Both sides will continue to debate this very emotional issue for years to come.

Abortion is a complex issue, and the controversy is not only in the public arena: many nurses struggle with the conflict between their personal convictions and their professional duty. Nurses are taught to be supportive client advocates and to interact with a nonjudgmental attitude under all circumstances even when personal and political views differ from those of their clients. With all the advances in abortion care, this points toward greater nursing involvement. Although this bodes well for woman-centered care, the burden on nurses is likely to increase incrementally. This may have an adverse effect on the affective attributes or emotions that those nurses possess (McLemore, Levi, & James, 2015).

Nurses need to clarify their personal values and beliefs on this issue and must be able to provide unbiased care before assuming responsibility for clients who might be in a position to consider abortion. Their decision to care for or refuse to care for such clients affects staff unity, influences staffing decisions, and challenges the ethical concept of duty (King et al., 2015).

The ANA's Code of Ethics for Nurses upholds the nurse's right to refuse to care for a client undergoing an abortion if the nurse ethically opposes the procedure (Fowler & Lachman, 2015). Nurses need to make their values and beliefs known to their managers before the situation occurs so that alternative staffing arrangements can be made. Open communication and acceptance of the personal beliefs of others can promote a comfortable working environment.

Substance Abuse

Substance abuse for any person is a problem, but when it involves a pregnant woman, substance abuse can cause preterm birth, placenta abruption, poor weight gain, low birth weight, stillbirth, spontaneous abortion, a variety of behavioral and cognitive problems in exposed children, and fetal injury, and thus has legal and ethical implications. Many state laws require evidence of prenatal drug exposure to be reported, which may lead to charges of negligence and child endangerment against the pregnant woman. It has been found that incarceration or threat of it has no effect in reducing cases of alcohol or drug abuse. Laws that criminalize drug use during pregnancy usually deter women from seeking prenatal care that can provide them access to appropriate counseling, referral, and monitoring (AWHONN, 2015). This punitive approach to fetal injury raises ethical and legal questions about the degree of government control that is appropriate in the interests of child safety. All pregnant women and women of childbearing age should be screened periodically for alcohol, tobacco, and prescription and illicit drug use. Nurses should employ a flexible approach to the care of women who have substance use problems, and they should encourage the use of all available community resources. Women should be counseled about the risks of preconception, antepartum, and postpartum substance abuse in a calm, nonjudgmental manner by nurses (AWHONN, 2015). Pregnant women who abuse substances should be afforded access to preventive, supportive, and recovery services that meet their special needs. The nurse can be instrumental in facilitation referral to community programs for both pregnant and postpartum women who can help ensure their full recovery and better lives for them and their children.

Intrauterine Therapy

Progress in prenatal diagnosis can lead to the diagnosis of severe fetal abnormalities, which previously would have resulted in a fatal outcome or the development of severe disability despite optimal postnatal care. Intrauterine therapy can now be offered in these selected cases and also in the treatment of fetal obstructive uropathy, intrauterine transfusions for fetal anemia, spina bifida repair, and stem cell transplantation. Intrauterine therapy is a procedure that involves opening the uterus during pregnancy, performing a surgery, and replacing the fetus in the uterus. Although the risks to the fetus and the mother are both great, fetal therapy may be used to correct anatomic lesions (Mathis, Raio, & Baud, 2015). Some argue that medical technology should not interfere with nature, and thus this intervention should not take place. Others argue that the surgical intervention improves the child's quality of life. For many people, these are the subjects of debate and intellectual discussion, but for nurses, these procedures may be part of their daily routine.

Nurses play an important supportive role in caring and advocating for clients and their families. As the use of technology grows, situations will surface more frequently that test a nurse's belief system. Encouraging open discussions to address emotional issues and differences of opinion among staff members is healthy and increases tolerance for differing points of view.

Maternal–Fetal Conflict

In maternity nursing, the ethical principles of beneficence and autonomy provide the fundamental framework that guides the management of all pregnant women. Because the fetus also needs to be considered, autonomy can become a complex issue giving rise to what is sometimes called *maternal–fetal conflict*.

Fetal care becomes problematic when what is required to benefit one member of the dyad will cause unacceptable harm to the other. Even when a fetal condition poses no health threat to the mother, caring for the fetal client will always carry some degree of risk to the mother, without direct therapeutic benefit for her. The ethical principles of beneficence (be of benefit) and nonmaleficence (do no harm) can come into conflict.

Because the clients are biologically linked, both, or neither, must be treated alike. It would be unethical to recommend fetal therapy as if it were medically indicated for both clients. Still, given a recommendation for fetal therapy, pregnant women, in most cases, will consent to treatment that promotes fetal health. When pregnant women refuse therapy, health care providers must remember that the ethical injunction against harming one client in order to benefit another is virtually absolute.

The use of court orders to force treatment on pregnant women raises many ethical concerns. Court orders force pregnant women to forfeit their autonomy in ways not required of competent men or nonpregnant women. There is an inconsistency in allowing competent adults to refuse therapy in all cases but pregnancy. The American Congress of Obstetricians and Gynecologists (ACOG) advocates counseling and education to convince a mother to follow her doctor's advice and condemns the use of coercion on a pregnant woman, because this violates the intent of the informed consent process. Faced with a continuing disagreement with a pregnant woman, a physician should turn to an institutional ethics committee. Resorting to the legal system is almost never justified (Campbell, 2015).

Stem Cell Research

The goal of stem cell research is the relief of human suffering, which ethically is good. Benefits of stem cell research include providing therapies for Parkinson's disease, regenerating diseased body tissues, repairing spinal cord injuries, and growing needed organs for transplant.

   The therapeutic needs of sick clients, along with the potential benefits of that therapy must be balanced with ensuring rigorous scientific standards and effective consent procedures related to stem cell research. The ethical concerns surrounding stem cell research vary depending on the origin of the stem cells. Adult stem cells are cells found in adults and can replace old cells by reproducing new ones such as blood and liver cells. Bone marrow transplants are examples of the use of adult stem cells in medical therapy. Embryonic stem cells are derived from the inner cell mass of an early embryo. Stem cells, which can grow into any cell type in the body, have been touted as a potential cure for everything from type 1 diabetes to stroke. They are not without controversy, however; embryonic stem cells come from discarded human embryos, but they hold huge promise, too. The controversy is not about whether stem cells should be used, but rather what source of stem cells should be used, and how they are obtained (Devolder, 2015).

   The controversy focuses on the use of embryonic stem cells, because the process of obtaining these cells results in the destruction of the embryo. Some people feel that the destruction of the human embryo constitutes the killing of a human being and reject this practice on religious grounds. Views about when life begins and whether the early embryo is considered a person with moral status are at the heart of the ethical deliberations related to the use of embryonic stem cells. Everyone has to decide on the basis of personal values and ethical background.

Umbilical Cord Blood Banking

Umbilical cord blood, the blood remaining in the umbilical cord at birth, can be collected at birth and be a source of stem cells for an individual in need of a bone marrow transplant later in life. The extraordinary scientific and technological advances of contemporary medicine constantly lead toward the introduction of new treatments. Umbilical cord blood is a potential vast source of primitive hematopoietic stem and progenitor cells available for clinical applications. Cord blood can be used as an alternative source for bone marrow transplantation and its use is developing into a new field of treatment for pediatric and adult clients presenting with hematologic disorders, immunologic defects, and specific genetic diseases (Meierrhenry et al., 2015).

Private banks were initially developed to store cord blood stem cells from newborns, for a fee, for potential future use by the same child or a family member if he or she developed disease later in life. Today, public cord blood banks store, for free, stem cells that can be used by anyone needing them, in a manner similar to the way public blood banks work. Umbilical cord banks are a central component, as the providers of umbilical cord tissue, in both medical treatment and scientific research with stem cells. But, whereas the creation of umbilical cord banks is seen as a successful practice, it is perceived as ethically risky by others.

Pregnant women should be aware that stem cells from cord blood cannot currently be used to treat inborn errors of metabolism or other genetic diseases in the same individual from which they were collected because the cord blood would have the same genetic mutation. Cord blood collected from a newborn who later develops childhood leukemia cannot be used to treat that leukemia for much the same reason.

The fact that private cord banks offer their services as "biologic insurance" in order to obtain informed consent from parents (by ensuring that the tissue that will be made available if their child needs it in the future) raises the issue of whether the consent is freely given or given under coercion. Another consideration that must be made in relation to privately owned cord banks has to do with the ownership of the stored umbilical cord. Conflicts between moral principles and economic interests (many physicians own private blood banks) cause dilemmas in the clinical practice of umbilical cord blood storage and use especially in privately owned banks (Guilcher, Fernandez, & Joffe, 2015).

Both ACOG (2012) and the American Academy of Pediatrics (AAP, 2010) have issued statements opposing the use of for-profit banks and criticizing their marketing tactics. Instead, they recommended that parents donate cord blood to public banks, which make it available for free to anyone who needs it. Globally, other organizations have done the same. Private umbilical cord blood banking raises a question of special legal regulation. This practice promises the safe storage of biologic material on the assumption that it may be useful, at a certain moment in future, for its own donor (or for a donor's close family member) for curing serious blood diseases (Elmoazzen & Holovati, 2015). Currently, it is recommended that delaying the clamping and cutting of the umbilical cord constitutes the best EBP. So, cord blood stem cell collection should not alter the timing of umbilical cord clamping. Nurses providing prenatal care to pregnant women need increased awareness and knowledge about options for storage, or "banking," of cord blood and tissue in order to present information to expectant parents that is accurate, evidence-based, and without bias.

Informed Consent

The purpose of **informed consent** in health care is to ensure that client autonomy is respected in decisions about their health care. It is an agreement by a client to undergo an operation or medical treatment or take part in a clinical trial after being informed of and understanding the risks involved. It is a legal document in all 50 states, and stems from the legal and ethical right an individual has to decide what is done to his or her body, and from the physician's ethical duty to make sure that individuals are involved in decisions about their own health care (Boyd, 2015).

The doctrine of informed consent protects clients' rights to voluntary consent or refusal of any medical treatment, procedure, or intervention based on information regarding the risks, benefits, and alternatives of care. This includes the provision of sufficient, evidence-based information to make a decision that reflects self-determination, autonomy, and control. Client consent or refusal is more than a legal doctrine to obtain a client's signature; it is a process of information exchange and involvement of clients in decision making (Grady, 2015).

Making informed choices during childbirth can be complex and multilayered. The process involves the integration of evidence-based information with individual health care needs, values, beliefs, and preferences. Thus, health care providers are obligated to adequately inform clients of planned procedures and to be assured of client permission prior to their performance. Client rights and autonomy need consideration because uninformed clients cannot make thoughtful decisions.

Four Key Components of Informed Consent

Informed consent has four key components: disclosure, comprehension, competency, and voluntariness (Cornock, 2015). It occurs prior to initiation of the procedure or specific care and addresses the legal and ethical requirements of informing the client about the procedure. The physician or the advanced practice nurse or the midwife is responsible for informing the client about the procedure and obtaining consent by providing a detailed description of the procedure or treatment, its potential risks and benefits, and alternative methods available. The nurse's responsibilities related to informed consent include the following:

1. Ensuring that the consent form is completed with signatures from the client

2. Serving as a witness to the signature process

3. Determining whether the client understands what she is signing by asking her pertinent questions

4. In certain states, mature minors and emancipated minors may consent to their own health care and certain health care may be provided to adolescents without parental notification, including contraception, pregnancy counseling, prenatal care, testing and treatment of STIs and communicable diseases (including HIV), substance abuse and mental illness counseling and treatment, and health care required as a result of a crime-related injury (Dickens & Cook, 2015).

Although laws vary from state to state, certain key elements are associated with informed consent (Box 1.4). Nurses need to be familiar with their specific state laws as well as the policies and procedures of the health care agencies where they work. Treating clients without obtaining proper consent may result in charges of assault, and the health care provider and/or facility may be held liable for any damages. Generally, only people over the age of majority (18 years of age) can legally provide consent for health care, except in the case of an emancipated minor (a person who is no longer subject to parental control, e.g., one who marries) (Arnold & Boggs, 2016).

BOX 1.4

KEY ELEMENTS OF INFORMED CONSENT

- The decision maker must be of legal age in that state, with full civil rights, and must be competent (have the ability to make the decision).
- Information is presented in a manner that is simple, concise, and appropriate to the level of education and language of the individual responsible for making the decision.
- The decision must be voluntary, without coercion or force or under duress.
- There must be a witness to the process of informed consent.
- The witness must sign the consent form.

Most care rendered in a health care setting is covered by the initial consent for treatment that is signed when the individual becomes a client at that office or clinic or by the consent to treatment signed on admission to a hospital or other inpatient facility. Certain procedures, however, may require a specific process of informed consent: major or minor surgery; invasive procedures such as amniocentesis or internal fetal monitoring; treatments placing the client at higher risk, such as chemotherapy or radiation therapy; procedures or treatments involving research; and photography involving the client.

Informed consent also rests on an assumption of competence (all adults are competent unless a court decides otherwise) and capacity (ability to understand alternatives and consequences of treatment and choose the best option). Nurses must use caution when determining the capacity of a client when the client has received medications that would alter his or her cognition ability to make decisions about care. Medications may need to be delayed or withheld temporarily to restore the client's capacity to make health care decisions.

If the client cannot provide consent, then the person closest to the client may

give consent for emergency treatment. In an emergency, a verbal consent, via the telephone, may be obtained. Two witnesses must also be listening simultaneously and must sign the consent form, indicating that consent was received via the telephone. The ideal informed consent process would be achieved if a health care provider and a knowledgeable nurse collaborate for the client's good (Cornock, 2015).

Refusal of Medical Treatment

All clients have the right to refuse medical treatment, based on the American Hospital Association's Patient Care Partnership. Ideally, medical care without informed consent should be used only when the client's life is in danger. Clients may refuse treatment if it conflicts with their religious or cultural beliefs (Khoury, 2015). An example would be a Jehovah's Witness. Individuals of this faith have strong beliefs based on passages from the Bible that are interpreted as prohibiting the "consumption" of blood. Their beliefs prevent them from accepting transfusions of whole blood or its primary components. With recent advances and the use of biologic hemostats that aid coagulation and reduce blood loss, major surgery can be performed safely on a Jehovah's Witness who refuses a blood transfusion by utilizing these hemostats, which decrease surgical blood loss (Carr, 2015). In these cases, it is important to educate the client and family about the importance of the recommended treatment without coercing or forcing the client to agree. Sometimes common ground may be reached between the family's religious or cultural beliefs and the health care team's recommendations. Communication and education are the keys in this situation.

Confidentiality

Nurses face particular challenge in respecting the confidentiality of clients in a world where information is quickly shared and where information about illness can be sensitive. Nurses have a duty of care toward clients. That duty includes maintaining privacy and confidentiality. With the establishment of the Health Insurance Portability and Accountability Act (HIPAA) of 1996, the confidentiality of health care information is now mandated by law. The primary intent of the law is to protect health insurance coverage for workers and their families when they change or lose jobs. Another aspect of the law requires the USDHHS to establish national standards for electronic transmission of health information. The HIPAA regulations were instituted to protect the privacy of individuals by safeguarding individually identifiable health care records, including those housed in electronic media. Protection of individual medical records extends not only to clinical health care sites but also to all ancillary health care providers, such as pharmacies, laboratories, and third-party payers. Each health care provider dealing with client health care data must provide for secure and limited access to the information (Price, 2015). For example, no information that clearly identifies a client can be on public display, including information on a client's chart. In maternal and newborn health care, information is shared only with the client, legal partner, parents, legal guardians, or individuals as established in writing by the client or the child's parents. This law promotes the security and privacy of health care and health information for all clients. Client information should always be kept confidential in the context of the state law, as well as the institution's policies.

Today, social media provide a rich source for errors to expose confidential client information. "Friending" clients on Facebook™, communicating about client care with identifiers, and posting inappropriate photos all lead to violations of HIPAA and/or employer policies resulting in discipline or termination of employment (Scruth et al., 2015).

Exceptions to confidentiality exist. For example, suspicion of physical or sexual abuse and injuries caused by a weapon or criminal act must be reported to the proper authorities. Abuse cases are reported to the appropriate welfare authorities, whereas criminal acts are reported to the police. The health care provider must also follow public health laws related to reporting certain infectious diseases to the local health department (e.g., tuberculosis, hepatitis,

HIV, and other STIs). Finally, there is a duty to warn third parties when there is a specific threat to an identifiable person. There must be a balance between confidentiality and required disclosure. If health care information must be disclosed by law, the client must be informed that this will occur (Price, 2015).

IMPLICATIONS FOR NURSES

The health care system is intricately woven into the political and social structure of our society, and nurses should understand social, legal, and ethical health care issues so they can play an active role in meeting the health care needs of women and their families. Nurses are in a unique position because they are often the first contact clients have within health care systems. Nurses need to take a proactive role in advocating for and empowering their clients. For example, nurses can help women to increase control over the factors that affect health, thereby improving their health status. A woman may become empowered by developing skills not only to cope with her environment, but also to change it. Nurses can also assume this mentoring role with families, thus helping them to improve their overall health status and health outcomes.

Nurses must have a solid knowledge base about the factors affecting maternal, newborn, and women's health and barriers to health care. They can use this information to provide anticipatory guidance, health counseling, and teaching for women and their families. It also is useful in identifying high-risk groups so that interventions can be initiated early on, before problems occur.

When caring for women and their families, the nurse operates within the framework of the nursing process, which is applicable to all health care settings. Maternal, newborn, and women's health nursing is ever changing as globalization and its accompanying exchange of information expand. Nurses must remain up to date about new technologies and treatments and integrate high-quality, evidence-based interventions into the care they provide.

KEY CONCEPTS

- Maternal, newborn, and women's health nurses provide care using a philosophy that focuses on the family and the use of EBP in a case management environment to provide quality, cost-effective care.

- *Healthy People 2020* presents a national set of health goals and objectives for adults and children that focus on health promotion and disease prevention.

- One method to establish the aggregate health status of women and infants is with statistical data, such as mortality and morbidity rates.

- The infant mortality rate is the lowest in the history of the United States, but it

is still higher than that of other industrialized countries. This high rate may be due to the number of low-birth-weight infants born in this country (CDC, 2015d).

- The family is considered the basic social unit of our society. The family greatly influences the development and health of its members because members learn health care activities, health beliefs, and health values from their family.

- Culture influences every aspect of development and is reflected in childbearing and child-rearing beliefs and practices designed to promote healthy adaptation.

- Other factors affecting the health of women and their families include health status and lifestyles, health care cost containment, improved diagnosis and treatment, and health care consumer empowerment. Finances, transportation, language, culture, and the health care delivery system can act as barriers to health care.

- Advances in science and technology have led to increased ethical dilemmas in health care.

- All clients have the right to refuse medical treatment based on the American Hospital Association's Patient Care Partnership.

- Nurses must be knowledgeable about the laws related to health care of women and their families in the state where they practice as well as the specific policies of their health care institution.

CHAPTER **WORKSHEET**

MULTIPLE-CHOICE QUESTIONS

1. When preparing a presentation for a local woman's group on women's health problems, what would the nurse include as the number one cause of mortality for women in the United States?

   a. Breast cancer

   b. Childbirth complications

   c. Injury resulting from violence

   d. Heart disease

2. Which factor would most likely be responsible for a pregnant women's failure to receive adequate prenatal care in the United States?

   a. Belief that it is not necessary in a normal pregnancy

   b. Use of denial to cope with pregnancy

   c. Lack of health insurance to cover expenses

   d. Inability to trust traditional medical practices

3. When caring for an adolescent, in which instance must the nurse share information with the parents, no matter which state care is provided in?

   a. Pregnancy counseling

   b. Depression

c. Contraception

d. Tuberculosis

4. Client advocacy, utilization management, and coordination of care describe which of the following?

a. Primary nursing care

b. Case management

c. Family-centered care

d. Patient-focused care

5. Nurses in the United States working in maternity services need to have knowledge of a variety of cultures and be culturally competent in caring for women and their families because:

a. All members of a specific culture are homogenous.

b. Physiological differences exist among different cultures.

c. Care can be individualized for different cultural preferences.

d. Nondominant cultural groups are made up of new immigrants.

6. The nurse is preparing a class about homelessness. Which factors contribute to homelessness? Select all that apply.

a. Decrease in the number of people living in poverty

b. Unemployment

c. Exposure to abuse or neglect

d. Cutbacks in public welfare programs

e. Establishment of community crisis centers

CRITICAL THINKING EXERCISES

1. As a nurse working in a federally funded low-income clinic offering women's health services, the nurse is becoming increasingly frustrated with the number of "no-shows" or appointments missed in your maternity clinic. Some clients come for their initial prenatal intake appointment and never come back. The nurse realizes that some just forget their appointments, but most don't even call to notify the clinic. Many of the clients are high risk and thus are

jeopardizing their health and the health of their future child.

    a. What changes might be helpful to address this situation?

    b. Outline what the nurse might say at the next staff meeting to address the issue of clients making one clinic visit and then never returning.

    c. What strategies might the nurse use to improve attendance and notification?

    d. Describe what cultural and customer service techniques might be needed.

STUDY ACTIVITIES

1. Research a current policy, bill, or issue being debated on the community, state, or national level that pertains to the health and welfare of women or their families. Summarize the major facts and supporting and opposing arguments and prepare an oral report on your findings.

2. Within your clinical group, debate the following statement: should access to health care be a right or a privilege? Be able to back up your response.

3. Visit a local community health center that offers services to women from various cultures and their families. Interview the staff about any barriers to health care that they have identified. Investigate what the staff has done to minimize these barriers.

BRINGING IT ALL TOGETHER: CASE STUDY

Maize, a 64 year old Hispanic woman, presented to the Women's Clinic complaining about a vaginal discharge that was itchy and uncomfortable. Maize hadn't been to the clinic for years, since she had her last child decades ago. She never finished high school and was working locally as a motel housekeeper. She didn't have any health insurance, so tended to use home remedies to treat any health issue. Prior to her visit today, she had douched to attempt to treat this problem.

    The health care provider examined Maize and prescribed vaginal suppositories for a yeast infection. Instructions were given to her verbally and in writing before she left. Maize shook her head in agreement that she understood the treatment regimen. A few days later the clinic nurse received a phone call from Maize stating that she would "just have to live with this condition because

that medicine she got was "rank-tasting," it was making her gag when she attempted to swallow it, and she didn't think it was working!"

Go to thePoint **to find questions to consider about this case.**

Family-Centered Community-Based Care

secondary prevention
tertiary prevention

Learning Objectives

Upon completion of the chapter, you will be able to:

1. Define the key terms used in this chapter.
2. Examine the major components and key elements of family-centered community health care.
3. Explain the reasons for the increased emphasis on community-based care.
4. Differentiate community-based nursing from nursing in acute care settings.
5. Integrate the different levels of prevention in community-based nursing, providing examples of each.
6. Cite examples of cultural issues that may be faced when providing community-based nursing.
7. Describe the dynamic forces contributing to cultural diversity to adapt delivery of culturally competent care to women and their families.
8. Construct strategies for integrating elements of alternative/complementary therapies and scientific health care practice.
9. Identify the variety of settings where community-based care can be provided to women and their families.
10. Outline the various roles and functions assumed by the community health nurse.
11. Demonstrate the ability to use therapeutic communication skills when interacting with women and their families.
12. Evaluate the process of health teaching as it relates to women and their families.
13. Determine the importance of discharge planning and case management in providing community-based care.

Maria was home a few days after giving birth to her first child. She had just changed her newborn son and placed him on his stomach for a nap when the community health nurse arrived for a postpartum visit. Because the nurse did

not speak Spanish and Maria did not speak English, a great deal of gesturing followed. After examining Maria, the nurse picked up Maria's son and placed him on his back in the crib. How might the nurse have prepared for this home visit? What message did the nurse convey in changing the newborn's position? What actions did the nurse take to decrease trust? What actions should she take to increase trust with this mother?

Words of Wisdom

To recognize diversity in others and respect it, nurses must first have some awareness of who they are.

INTRODUCTION

Women and their families receive most of their health care, both well and ill care, in the community setting. During the past several years, the health care delivery system has changed dramatically. Medicare's prospective payment system for hospitals, introduced in the United States in 1983, replaced cost reimbursement with a system of fixed rates that created incentives for hospitals to control costs. This focus on cost containment has meant that people are spending less time in the hospital. Clients are being discharged "sicker and quicker" from their hospital beds (Hansen, 2015). The health care system has responded by moving from reactive treatment strategies in hospitals to a proactive approach in the community. This has resulted in an increasing emphasis on health promotion and illness prevention within the community.

Nurses play an important role in the health and wellness of a community. They not only meet the health care needs of the individual but also go beyond that to implement interventions that affect the community as a whole. Nurses practice in a variety of settings within a community, such as clinics and physician offices, shelters, churches, health departments, community health centers, and homes. They promote the health of individuals, families, groups, communities, and populations and promote an environment that supports health.

This chapter describes the concepts of community and community-based nursing, addressing the varied settings where such care is provided to women and their families. The chapter also highlights the major roles and functions of community-based nurses, emphasizing their role as educators in health promotion and maintenance.

FAMILY-CENTERED CARE

Family-centered care refers to the collaborative partnership among the individual, family, and caregivers that exist to determine goals, share information, offer support, and formulate plans for health care. It is generally understood to be an approach in which clients and their families are considered integral components of the health care decision-making and delivery processes (McGurk, 2015; Pate & Andrews, 2015). Nursing support of the family can take many forms. For example, *informational support* is designed to provide supportive communication by making available understandable information to the family about their member's condition, treatment, development, and care; about their behavioral and emotional responses and needs; and about what to expect regarding their condition. *Emotional support* includes listening, exhibiting caring behaviors, and being concerned in ways that help the family cope with their member's illness and the other aspects of their lives that are affected by the illness. *Appraisal support*, also called *esteem support*, is conceptualized as enhancing, reinforcing, and supporting the family role. Finally, *instrumental support* includes providing assistance of any kind, such as financial, time, labor, or environmental modifications. In short, nursing support to families includes providing a supportive relationship and ongoing information; helping maintain the family role by offering encouragement, affirmative comment, and appraisal; giving emotional support; and providing competent nursing care. To provide good-quality, family-centered care, nurses need adequate resources and appropriate education, as well as support from managers and other health care disciplines (Roberts, 2015).

The philosophy of family-centered care recognizes the family as the constant: the health of all the family members and their functional abilities influence the health of the client and other members of the family. The core concepts of family-centered care include:

• Providing dignity and respect for the client and family choices

• Sharing health care information that is meaningful and accurate

• Encouraging clients and their families to participate in decisions about their care

• Collaborating with clients, families, and other health care providers in the

delivery of care (Nichols, Crow, & Balakas, 2015).

Family-centered care works well in all arenas of health care from preventive care to long-term care. Family-centered care enhances the confidence of all those involved about their skills and helps to prepare individuals for assuming responsibility for their own health care needs. It is vital for the nurse to assess how much knowledge the family already has about the client's health or illness. At the heart of family-centered care is a commitment to working with clients as partners, which is a shift from a "doing to and doing for" which was the mantra of the past.

Using a family-centered approach is associated with positive outcomes such as decreased anxiety, improved pain management, shorter recovery times, and enhanced confidence and problem-solving skills. Communication between the health care team and the family is also improved, leading to greater satisfaction for both health care providers and health care consumers (families). Parents should be involved in the care of and decision making for their newborn, and separations should be minimized. Their needs should be anticipated, respected, and addressed in the obstetrical unit. Open, clear, consistent information and communication should be maintained (Flagg, 2015). It is important for nurses to remain neutral to all they hear and see in order to enhance trust and maintain open communication lines with all family members. Nurses need to remember that the client is an expert about his or her own health; thus, nurses should work within the client's framework when planning health promotion interventions. Practicing true family-centered care may empower the family, strengthen family resources, and help the woman or child feel more secure throughout the process.

COMMUNITY-BASED CARE

Community may be defined as a specific group of people, often living in a defined geographic area, who share common interests, interact with each other, and function collectively within a defined social structure to address common concerns (Stanhope & Lancaster, 2014). The common features of a community may be common rights and privileges as members of a certain city or common ties of identity, values, norms, culture, language, or social support. Women are caregivers to children, parents, spouses, and neighbors and provide important social support in these roles.

A person can be a part of many communities during the course of daily life. Examples might include area of residence (home, apartment, shelter), gender, place of employment (organization or home), language spoken (Spanish, Chinese, English), educational background or student status, culture (Italian, African American, Indian), career (nurse, businesswoman, housewife), place of worship (church or synagogue), and community memberships (garden club, YMCA, support group, school PTA, youth organizations, athletic teams).

A **population** is a group of individuals who share personal or environmental characteristics. Typically the most common characteristic is geographic location. Populations are made up of human beings within complex social and physical environments. The betterment of human populations remains the goal of community-based nursing care. Examples of populations include nurses who work the night shift, older mothers having their first pregnancy, high risk infants, or Native Americans.

In community-based care, the community is the unit of service. The providers of care are concerned not only with the clients who present for service but also with the larger population of potential or at-risk clients.

Community Health Nursing

Community health nursing focuses on preventing illness and improving the health of populations and communities. Community health nurses work in geographically and culturally diverse settings. They address the current and potential health needs of a population or community. They promote and preserve the health of a population and are not limited to particular age groups or diagnoses. **Public health nursing** is a specialized area of community health nursing.

   Epidemiology (the study of the causes, distribution, and control of disease in populations) can help determine the health and health needs of a population and assist in planning health services. Community health nurses perform epidemiologic investigations to help analyze and develop health policy and community health initiatives. Community health initiatives can be focused on the community as a whole or a specific target population with specific needs. *Healthy People 2020: Improving the Health of Americans* is an example of a national health initiative that was developed using the epidemiologic process. *Healthy People* provides science-based, 10-year national objectives for improving the health of all Americans. *Healthy People 2020* ensures that health care professionals evaluate the individual as well as the community. It emphasizes the ever-present link between the individual's health and the health of the community (Lundy & Janes, 2016). *Healthy People 2020* identifies two major goals: to increase the quality of life and the life expectancy of individuals of all ages and to decrease health disparities among different populations. Relevant *Healthy People 2020* objectives are highlighted throughout this text, and *Healthy People 2020* is available online at http://www.healthypeople.gov. These objectives provide a tool for all health care providers to move from a focus on illness and cure to a focus on health promotion and illness prevention for entire populations.

   The focus of health care initiatives today is on people and their needs, strengthening their abilities to shape their own lives. The emphasis has shifted away from dependence on health professionals toward personal involvement and personal responsibility, and this gives nurses the opportunity to interact with individuals in a variety of self-help roles. Nurses in the community can be the primary force in identifying the challenges and implementing changes in women's and newborn's health for the future.

Community-Based Nursing

In the past, the only community-based roles for nurses were community health nurses or public health nurses. This is now a subset of what is considered community-based nursing. The health needs of the society and consumer demand brought about community-based and community-focused services. The movement from an illness-oriented "cure" perspective in hospitals to a focus on health promotion and primary health care in community-based settings has dramatically changed employment opportunities for today's nurses. This shift in emphasis to primary care and outpatient treatment and management will likely continue. As a result, employment growth in a variety of community-based settings can be expected for properly educated nurses. With the worldwide strategic shift of health care delivery from secondary to primary care settings, more newly qualified nurses are working in primary care, making exposure to the variety of roles available to nurses essential for future workforce development (Clark & Paraska, 2015).

The Bureau of Labor Statistics, U.S. Department of Labor, Occupational Employment Statistics (2015) found the following trends in registered nurse (RN) employment settings:

• Fifty-seven percent of RNs work in the hospital setting.

• Thirty-four percent work outside the hospital setting in community-based settings.

• The number of RNs employed in community-based settings has continued to grow largely due to an increase in nurses working in home health care and managed care organizations.

Community-based nursing settings include ambulatory care, home health care, occupational health, school health, and hospice settings (Table 2.1). Clinical practice within the community may also include case management, research, quality improvement, and discharge planning. Nurses with advanced practice and experience may be employed in areas of staff development, program development, and community education.

TABLE 2.1 Community-Based Practice Settings

Setting	Description
Ambulatory care settings	Physician's offices Health maintenance organizations (HMOs) Day surgery centers Freestanding urgent care centers Family planning clinics Mobile mammography centers
Health department services	Maternal/child health clinics Family planning clinics Sexually transmitted infection programs Immunization clinics Substance-abuse programs Jails and prisons
Home health care services	High-risk pregnancy/neonate care Maternal/child newborn care Skilled nursing care Hospice care
Long-term care	Skilled nursing facilities Nursing homes Hospices Assisted living
Other community-based settings	Parish nursing programs Summer camps Community-sponsored education programs School health programs Occupational health programs

Community-Based Nursing Interventions

Nursing interventions involve any treatment that the nurse performs to enhance the client's outcome. Nursing practice in the community uses the nursing process and is similar to that in the acute care setting because assessing, performing procedures, administering medications, coordinating services and equipment, counseling clients and their families, and teaching about care are all part of the care administered by nurses in the community. Box 2.1 highlights the most common nursing interventions used in community-based nursing practice.

Community-Based Nursing Challenges

Despite the benefits achieved by caring for families in their own homes and communities, challenges also exist. Clients are being discharged from acute care facilities very early in their recovery course and present with more health care needs than in the past. As a result, nursing care and procedures in the home and community are becoming more complex and time consuming. Consider the example of a woman who develops a systemic infection, a pelvic abscess, and deep vein thrombosis in one leg after a cesarean birth and who is now being discharged from the hospital. The nurse's primary focus of care in this situation

would be to administer heparin and antibiotics intravenously rather than educating her about child care and follow-up appointments. In the past, this woman would have remained hospitalized for treatment, but home infusion therapy is now less costly and allows the client to be discharged sooner.

BOX 2.1

COMMUNITY-BASED NURSING INTERVENTIONS

- *Health screening*—Detecting unrecognized or preclinical illness among individuals so they can be referred for definitive diagnosis and treatment (e.g., mammogram or Pap smear, vision, and hearing checks).
- *Health education programs*—Assisting clients in making health-related decisions about self-care, use of health resources, and social health issues such as smoking bans and motorcycle helmet laws (e.g., childbirth education or breast self-examination, drug awareness programs).
- *Medication administration*—Preparing, giving, and evaluating the effectiveness of prescription and over-the-counter drugs (e.g., hormone therapy in menopausal women)
- *Telephone consultation*—Identifying the problem to be addressed; listening and providing support, information, or instruction; documenting advice/instructions given to concerns raised by caller (e.g., consultation for a mother with a newborn with colic, interaction with a parent whose child has a fever or is vomiting).
- *Health system referral*—Passing along information about the location, services offered, and ways to contact agencies (e.g., referring a woman for a breast prosthesis after a mastectomy).
- *Instructional*—Teaching an individual or a group about a medication, disease process, lifestyle changes, community resources, or research findings concerning their environment (e.g., childbirth education class, basic life support classes for parents).
- *Nutritional counseling*—Demonstrating the direct relationship between nutrition and illness while focusing on the need for diet modification to promote wellness (e.g., Women, Infants, and Children [WIC] program; counselor interviewing a pregnant woman who has anemia).
- *Risk identification*—Recognizing personal or group characteristics that predispose people to develop a specific health problem, and modifying or eliminating them (e.g., genetic counseling of an older pregnant woman at risk for a Down syndrome infant; genetic screening of family members for

cystic fibrosis or Huntington's disease).

Adapted from Murphy, J. W. (2015). *Community-based interventions.* New York, NY: Springer; and Lundy, K. S., & Janes, S. (2016). *Community health nursing: Caring for the public's health* (3rd ed.). Burlington, MA: Jones & Bartlett Learning.

This demand on the nurse's time may limit the amount of time spent on prevention measures, education, and the family's psychosocial issues. More time may be needed to help families deal with these issues and concerns. With large client caseloads, nurses may find it difficult to spend the time needed while meeting the time restrictions dictated by their health care agencies. Nurses need to plan the tasks to be accomplished (Box 2.2).

Nurses working in the community have fewer resources available to them compared with the acute care setting. Decisions often have to be made in isolation. The nurse must possess excellent assessment skills and the ability to communicate effectively with the family to be successful in carrying out the appropriate plan of care. Nurses interested in working in community-based settings must be able to apply the nursing process in an environment that is less structured or controlled than that in acute care facilities. Nurses must be able to assimilate information well beyond the immediate physical and psychosocial needs of the client in a controlled acute care setting and deal with environmental threats, lifestyle choices, family issues, different cultural patterns, financial burdens, transportation problems, employment hazards, communication barriers, limited resources, and client acceptance and adherence to care regimens.

Although opportunities for employment in community-based settings are plentiful, many positions require a baccalaureate degree. Previous medical-surgical experience in an acute care setting is typically required by home health agencies because these nurses must function fairly independently within the home environment.

The nurse must also be familiar with and respectful of many different cultures and socioeconomic levels, remaining objective in dealing with such diversity and demonstrating an understanding of and appreciation for cultural differences. Interventions must be individualized to address the cultural, social, and economic diversity among clients in their own environment (Lundy & Janes, 2016).

The mission for all nurses is profound but simple: to treat with dignity and compassion every person who is in their care. Imagine for a moment what it

would be like to be sick and not be able to communicate with your caregivers—to not understand what they are saying or to become greatly alarmed when you hear information in terms that are offensive or inappropriate in your culture. Quality care depends on quality communication, thus utilizing language interpreters can make a major difference in all situations (Purnell, 2015).

Shift in Responsibilities from Hospital-Based to Community-Based Nursing

Community care, especially home care, is a rapidly growing service in the United States (Adams, 2015). Community-based care has been shown to be a cost-effective method for providing care. An increase in disposable income and the increased longevity of individuals with chronic and debilitating health conditions have also contributed to the continued shift of health care to the community and home setting. Technology has advanced, allowing for improved monitoring of clients in community settings and at home and also allowing complicated procedures to be done at home, such as intravenous administration of antibiotics and renal dialysis. There is a need to facilitate effective community-based care by extending the hospital and health care providers into the community by providing mobile access to information via a secure Internet. The design of future technologies to support complex health care in the home environment continues on the fast-track (Vizard, 2015).

BOX 2.2

HOME CARE VISITATION PLANNING

- Review previous interventions to eliminate unsuccessful ones.
- Check previous home visit narrative to validate interventions.
- Communicate with previous nurse to ask questions and clarify.
- Formulate plan of interventions based on data received (e.g., client preference of IV placement or order of fluids).
- Prioritize client needs based on their potential to threaten the client's health status.
- Use Maslow's hierarchy of needs to set forth a plan of care.
- Address life-threatening physiologic issues first (e.g., an infectious process would take precedence over anorexia).
- Develop goals that reflect primary, secondary, and tertiary prevention levels.
- *Primary prevention*—Have the client consume adequate fluid intake to prevent dehydration.
- *Secondary prevention*—Administer drug therapy as prescribed to contain and treat an existing infectious process.
- *Tertiary prevention*—Instruct the stroke client how to exercise to minimize disability.
- Bear in mind the client's readiness to accept intervention and education.
- Ascertain the client's focus and how she sees her needs.
- Address client issues that might interfere with intervention (e.g., if the client is in pain, attempting to teach her about her care will be lost; her pain must be addressed first before she is ready to learn).
- Consider the timing of the visit to prevent interfering with other client activities.
- Schedule all visits at convenient times for the client if possible (e.g., if the client has a favorite soap opera to watch, attempt to schedule around that event if at all possible).
- Reschedule a home visit if a client event comes up suddenly.

- Be aware of nurse's safety in neighborhoods and take precautions to secure it.
- Outline nursing activities to be completed during the scheduled visit.
- Know the health care agency's policy and procedures for home visits.
- Consider the time line and other visits scheduled that day.
- Research evidence-based best practices to use in the home to validate your intervention decisions.
- Obtain necessary materials/supplies before making the visit.
- Assemble all equipment needed for any procedure in advance.
- Secure any equipment that might be needed if a problem occurs (e.g., bring additional IV tubing and a catheter to make sure the procedure can be carried out without delay).
- Determine criteria to be used to evaluate the effectiveness of the home visit.
- Revisit outcome goals to determine the effectiveness of the intervention.
- Assess the client's health status to validate improvement.
- Monitor changes in the client's behavior toward health promotion activities and disease prevention (e.g., verify/observe that the client demonstrates correct handwashing technique after instruction and reinforcement during the home care visit).

Adapted from de Chesnay, M., & Anderson, B. (2015). *Caring for the vulnerable* (4th ed.). Burlington, MA: Jones & Bartlett Learning; Lundy, K. S., & Janes, S. (2016). *Community health nursing: Caring for the public's health* (3rd ed.). Burlington, MA: Jones & Bartlett Learning; and Denham, S. A., Eggenberger, S., Young, P., & Krumwiede, N. (2015). *Family-focused nursing care*. Philadelphia, PA: F. A. Davis Company.

Levels of Prevention in Community-Based Nursing

The concept of prevention is a key part of community-based nursing practice. The emphasis on health care delivery in community-based settings has moved beyond primary preventive health care (e.g., well-child checkups, routine physical examinations, prenatal care, and treatment of common acute illnesses) and now encompasses secondary and tertiary care.

PRIMARY PREVENTION

The concept of **primary prevention** involves preventing the disease or condition before it occurs through health promotion activities, environmental protection, and specific protection against disease or injury. Its focus is on **health promotion** to reduce the person's vulnerability to any illness by strengthening the person's capacity to withstand physical, emotional, and environmental stressors (Lundy & Janes, 2016).

Primary prevention encompasses a vast array of areas, including nutrition, good hygiene, sanitation, immunizations, protection from ultraviolet rays, genetic counseling, bicycle helmets, handrails on bathtubs, drug education for schoolchildren, adequate shelter, smoking cessation, family planning, and the use of seat belts (Stanhope & Lancaster, 2014). Prevention of disease is often difficult to put into practice. Among the challenges, the success of prevention is invisible in many cases, lacks drama, often requires persistent behavior change, and does not produce immediate results. The nurse's role is to help people change their lifestyle to move toward a state of optimal health and avoid illness. Nurses can address this by using evidence-based health promotion; identifying effective interventions built on research findings and applying them to improve the health and well-being of individuals, aggregates, and communities (Fig. 2.1).

Approximately 1/1,000 children in the United States are born each year with defects of the neural tube—the part of a growing fetus that will become the brain and spinal cord—which can cause severe mental and physical disability or death. It is the second most common major congenital anomaly worldwide (cardiac malformations are first). Neural tube defects (NTDs) are more common in Whites and Hispanics than African Americans (National Coalition for Health Professional Education in Genetics [NCHPEG], 2015). The prevention of NTDs is an example of primary prevention. The use of folic acid supplementation daily for 3 months before and 3 months after conception reduces the risk of first occurrence of NTD. American College of Obstetricians & Gynecologists [ACOG] (2013) recommends that all women be on a baseline dose of 400 µg of folic acid daily to prevent NTDs. Mandatory folic acid fortification for all pregnant women remains an effective public health intervention (Williams et al., 2015). Giving anticipatory guidance to parents with toddlers about poison prevention and safety during play is another example of primary prevention.

SECONDARY PREVENTION

Secondary prevention is the early detection and treatment of adverse health

conditions. This level of prevention is aimed at halting the disease, thus shortening its duration and severity to get the person back to a normal state of functioning. Health screenings are the mainstay of secondary prevention. Pregnancy testing, blood pressure evaluations, cholesterol monitoring, fecal occult blood testing, breast examinations, mammography screening, hearing and vision examinations, and Papanicolaou (Pap) smears are examples of this level of prevention. Such interventions do not prevent the health problem but are intended for early detection and prompt treatment to prevent complications (Clark & Paraska, 2015).

A good example is osteoporosis, a common disease of the bones where one's body loses too much bone, makes too little bone, or both. Osteoporosis causes significant morbidity and mortality in women. Its prevalence and costs to society are huge and its incidence is rising as the population ages. Although osteoporosis is preventable, it is a silent disease that does not become apparent until a fracture occurs. Screening to identify women at risk and instituting secondary prevention pharmacotherapy will assist to reduce the incidence of fractures and reduce mortality and morbidity. If the health condition cannot be cured and further complications and disability arise, then the tertiary level of prevention is needed.

FIGURE 2.1 Levels of prevention in community-based nursing. **A.** At the primary prevention level, the nurse provides a woman with teaching about breast self-examination if high risk. **B.** At the secondary level of prevention, a woman undergoes a mammogram for early detection of breast problems. **C.** At the tertiary level of prevention, mastectomy after surgery, a nurse assists a client with her strength exercises.

TERTIARY PREVENTION

Tertiary prevention is designed to reduce or limit the progression of a permanent, irreversible disease or disability. The purpose of tertiary prevention is to restore individuals to their maximum potential (Prince et al., 2015). Tertiary intervention takes place only if the condition results in a permanent disability. Tertiary prevention measures are supportive and restorative. For example, tertiary prevention efforts would focus on minimizing and managing the effects of a chronic illness such as cerebrovascular disease or the chronic effects of sexually transmitted infections (STIs), e.g., herpes, human immunodeficiency virus (HIV), and untreated syphilis. Another example would involve working with women who have suffered long-term consequences of violence. Client education is the cornerstone of all disease management programs. The focus of the nurse would be to maximize the woman's strengths through education, to help her recover from the trauma and loss and to build support systems.

The Nurse's Role in Community-Based Preventive Care

All health professionals have a special role in health promotion, health protection, and disease prevention. Much of community nursing involves prevention, early identification, and prompt treatment of health problems and monitoring for emerging threats that might lead to health problems. Community-based nurses provide health care for women and their families at all three levels of prevention. This care often involves advocating for services to meet their needs.

Cultural Issues in Community-Based Nursing

The United States contains an ever-changing mix of numerous, diverse cultural groups of people who arrive daily from every corner of the world. The United States has more immigrants than any other nation. The U.S. Census Bureau (2015a) projects that the United States foreign-born population will reach 78 million by 2060, making up 19% of the total population.

 Take Note!

More than one million immigrants come to the United States each year, and more than half are of childbearing age. Latin America accounts for more than 50% of immigrants to the United States. By the year 2050, people of African, Asian, and Latino backgrounds will make up one half of our population (U.S. Census Bureau, 2015b).

This growing diversity has significant implications for the health care system. For years nurses have struggled with the issues of providing optimal health care that meets the needs of women and their families from various cultures and ethnic groups. In addition to displaying competence in technical skills, nurses must also become competent in caring for clients from diverse ethnic and racial backgrounds. Adapting to different cultural beliefs and practices requires flexibility and acceptance of others' viewpoints. Nurses must listen to clients and learn about their beliefs about health and wellness. To provide culturally appropriate care to diverse populations, nurses need to know, understand, and respect culturally influenced health behaviors. Chapter 1 provides a more detailed discussion of the impact of culture on the health of women, children, and families.

Nurses must research and understand the cultural characteristics, values, and beliefs of the various people to whom they deliver care so that false assumptions and stereotyping do not lead to insensitive care. Time orientation, personal space, family orientation (patriarchal, matriarchal, or egalitarian), and language are important cultural concepts. Although the location might be different in community-based care, these principles apply to both inpatient and outpatient settings. Cultural competence and cultural adaptation are considered important

components of providing quality health care in multicultural societies. These include not only treatment of disease, but also primary, secondary, and tertiary prevention measures by health care professionals, as well as health promotion to all diverse cultures.

Culturally Competent Nursing Care

Cultural competence is defined as the knowledge, willingness, and ability to adapt health care to enhance its acceptability to and effectiveness with clients from diverse cultures. Nurses need to possess an understanding of the perspectives, traditions, values, practices, and family systems of culturally diverse individuals, families, communities, and populations for whom they provide care, as well as knowledge of the complex variables that affect the achievement of health and well-being (Martin et al., 2016). Cultural competence is a dynamic process during which nurses obtain and then apply cultural information. Nurses must look at clients through their own eyes and the eyes of clients and family members. Nurses must develop nonjudgmental acceptance of cultural differences in clients, using diversity as a strength that empowers them to achieve mutually acceptable health care goals. Nurses must integrate their client's cultural beliefs and practices into health prescriptions to eliminate or mitigate health disparities and provide client satisfaction. Cultural competence is a dynamic, lifelong learning process. Understanding the process for assessing cultural patterns and factors that influence individual and group differences is critical in preventing overgeneralization and stereotyping (Purnell, 2015). This cultural awareness allows nurses to see the entire picture and improves the quality of care and health outcomes. Cultural competence does not appear suddenly; it must be developed through a series of steps (Box 2.3).

A level of cultural competence is needed by all nurses to increase their knowledge of diverse cultures, to change attitudes and values when working with clients of different cultures.

Cultural competence does not mean replacing one's own cultural identity with another, ignoring the variability within cultural groups, or even appreciating the cultures being served. Instead, nurses who are culturally competent show a respect for differences, an eagerness to learn, and a willingness to accept multiple views of the world. Much of the process of developing cultural competence involves a reexamination of nurses' values and the influence of these values on their beliefs, which affect attitudes and actions. At the core of

both client centeredness and cultural competence is the importance of seeing the client as a unique person (Beard et al., 2015). It is important for all nurses to incorporate the client's traditional healing and health practices with conventional medicine by asking such questions as "Do you have treatment preferences you would like me to include in your care plan?" Some clients may prefer certain foods and/or drinks when they are ill. In addition, during fasting and religious seasons, diets may be different and need to be considered during the process of determining the appropriate course of treatment. Some clients may have a different idea about what is causing the illness. Spirituality, culture, and experience may have a significant role in the client's understanding and treatment of the illness.

Barriers to Cultural Competence

Barriers to cultural competence can be grouped into two categories: those related to providers and those related to systems. Illness is culturally shaped in the sense that how we perceive, experience, and cope with disease is based on our individual explanations of sickness. Awareness and appreciation of how this might be of influence—instead of mere knowledge about the cultural practices or beliefs of specific ethnic groups—help nurses deal effectively with cultural issues (Lundy & Janes, 2016). When a health care provider lacks knowledge of a client's cultural practices and beliefs or when the provider's beliefs differ from those of the client, the provider may be unprepared to respond when the client makes unexpected health care decisions. System-related barriers can occur if agencies that have not been designed for cultural diversity want all clients to conform to the established rules and regulations and attempt to fit everyone into the same mold.

BOX 2.3

STEPS TO DEVELOPING CULTURAL COMPETENCE

Cultural Awareness

- Become aware of, appreciate, and become sensitive to the values, beliefs, customs, and behaviors that have shaped one's own culture.
- Examine your own sociocultural heritage to gain personal insight.
- Recognize the influence of clients' cultures on their health status.
- Examine personal biases and prejudices toward other cultures.
- Become aware of differences in personal and clients' backgrounds.

Cultural Knowledge

- Apply knowledge of social and cultural factors across multiple backgrounds.

- Seek resources that increase your understanding of different sociocultural groups.

- Become familiar with culturally/ethnically diverse groups, worldviews, beliefs, practices, lifestyles, and problem-solving strategies.

Cultural Skills

- Apply relevant best evidence-based practices in providing culturally competent care.

- Learn how to perform a competent cultural assessment.

- Assess each client's unique cultural values, beliefs, and practices without depending solely on written facts about specific cultural groups.

- Advocate for social justice to eliminate health disparities in diverse populations.

Cultural Encounter

- Promote safe and quality outcomes of care for all diverse individuals.
- Adapt care practices and therapies to be consistent with client values and beliefs.
- Respect clients' sociocultural identity in a nonjudgmental manner when interacting.
- Learn key words or phases of clients' language to improve communication.
- Engage in cross-cultural interactions with people from culturally diverse backgrounds, such as attending religious services or ceremonies and participating in important family events.
- Participate in as many cultural encounters as possible to avoid cultural stereotyping.

Consider This

Our medical mission took a team of nurse practitioners into the rural mountains of Guatemala to offer medical services to people who had never had any. One day, a distraught mother brought her 10-year-old daughter to the mission clinic, asking me if there was anything I could do about her daughter's right wrist. She had sustained a fracture a year ago and it had not healed properly. As I looked at the girl's malformed wrist, I asked if it had been splinted to help with alignment, knowing what the answer was going to be. The interpreter enlightened me by saying that this young girl would never marry and have children because of this injury. I appeared puzzled at the

interpreter's prediction of this girl's future. It was later explained to me that if the girl could not make tortes from corn meal for her husband because of her wrist disability, she would not be worthy of becoming someone's wife and thus would probably live with her parents the rest of her life.

I reminded myself during the week of the medical mission not to impose my cultural values on the women for whom I was caring and to accept their cultural mores without judgment. These silent self-reminders served me well throughout the week, for I was open to learning about their lifestyles and customs.

Thoughts: *What must the young girl be feeling at the age of 10, being rejected for a disability that was not her fault? What might have happened if I had imposed my value system on this client? How effective would I have been in helping her if she did not feel accepted? This incident ripped my heart out, for this young girl will be deprived of a fulfilling family life based on a wrist disability. This is just another example of female suppression that happens all over the world—such a tragedy—and yet a part of their culture, on which nurses should not pass judgment.*

Use of Complementary and Alternative Medicine

The federal government formed the National Center for Complementary and Alternative Medicine (NCCAM) to conduct and support research and provide education and information on complementary and alternative medicine (CAM) to health care providers and the public.

The use of CAM is not unique to a specific ethnic or cultural group; interest in CAM therapies continues to grow nationwide and will affect care of many clients. People from all walks of life and in all areas of the community use CAM. Overall, CAM use is seen more in women than men, and in people with higher educational levels. In the United States, approximately 40% of adults (about 4 in 10) and approximately 12% of children (about 1 in 9) are using some form of CAM. Prayer specifically for health reasons is the most commonly used CAM therapy (National Center for Complementary and Alternative Medicine [NCCAM], 2015). It is well known that CAM, including homeopathy, acupuncture, phytotherapy, and hydrotherapy, is also being used increasingly by midwives for childbirth (Hall, Griffiths, & McKenna, 2015).

Types of CAM

CAM includes diverse practices, products, and health care systems that are not currently considered to be part of conventional medicine (NCCAM, 2015). *Complementary* medicine is used together with conventional medicine, such as using aromatherapy to reduce discomfort after surgery or to reduce pain during a procedure or during early labor. *Alternative* medicine is used in place of conventional medicine, such as eating a special natural diet to control nausea and vomiting or to treat cancer instead of undergoing surgery, chemotherapy, or radiation that has been recommended by a conventional doctor. *Integrative* medicine combines mainstream medical therapies and CAM therapies for which there is some scientific evidence of safety and effectiveness (NCCAM, 2015).

INTEGRATIVE MEDICINE

Integrative medicine includes acupuncture, reflexology, therapeutic touch, meditation, yoga, massage, herbal therapies, nutritional supplements, homeopathy, naturopathic medicine, and many more used for the promotion of health and well-being (Treister-Goltzman & Peleg, 2015).

The philosophy of integrative medicine focuses on treating the whole person, not just the disease, and combines conventional Western medicine with complementary treatments. The goal is to treat the mind, body, and spirit all at the same time. History has taught us that in science, application of the results is never determined by a single study but, rather, by the weight of the evidence. Medicine rests on a foundation that begins with good clinical observations, case reports, and careful interpretations. Replication of these results by other scientists, which is the true hallmark of valid science, establishes whether those clinical observations are important and perhaps applicable. Although some of the therapies used are nonconventional, a guiding principle within integrative medicine is to use therapies that have some high-quality evidence to support them (King et al., 2015). The nurse should avoid judgment and encourage the family to research all evidence-based approaches that support healthy outcomes. Table 2.2 describes selected CAM therapies and treatments.

TABLE 2.2 Selected Complementary and Alternative Therapies

Therapy	Description
Aromatherapy	Use of essential oils to stimulate the sense of smell for balancing mind, body, and spirit
Homeopathy	Based on the theory of "like treats like"; helps restore the body's natural balance
Acupressure	Restoration of balance by pressing an appropriate point so self-healing capacities can take over
Feng shui (pronounced *fung shway*)	The Chinese art of placement. Objects are positioned in the environment to induce harmony with chi
Guided imagery	Use of consciously chosen positive and healing images along with deep relaxation to reduce stress and to help people cope
Reflexology	Use of deep massage on identified points of the foot or hand to scan and rebalance body parts that correspond with each point
Therapeutic touch	Balancing of energy by centering, invoking an intention to heal, and moving the hands from the head to the feet several inches from the skin
Herbal medicine	The therapeutic use of plants for healing and treating diseases and conditions
Spiritual healing	Praying, chanting, presence, laying on of hands, rituals, and meditation to assist in healing
Chiropractic therapy	Aimed at removing irritants to the nervous system to restore proper function (e.g., spinal manipulation done for musculoskeletal complaints)
Massage therapy	Therapeutic stroking or kneading of the body to decrease pain, produce relaxation, and/or to improve circulation to that body part

Theories of CAM

The theoretic underpinnings of complementary and alternative health practices propose that health and illness are complex interactions of the mind, body, and spirit. It is then surmised that many aspects of clients' health experiences are not subject to traditional scientific methods. This field does not lend itself readily to scientific study or to investigation and therefore is not easily embraced by many hard-core scientists (Jaiswal et al., 2015). Much of what is considered to be alternative medicine comes from the Eastern world, folk medicine, and religious and spiritual practices. There is no unifying basic theory for the numerous treatments or modalities, except (as noted previously) that health and illness are considered to be complex interactions among the body, mind, and spirit.

Nursing Implications of CAM

Because of heightened interest in CAM and its widening use, anecdotal efficacy, and growing supporting research evidence, nurses need to be sensitive to and knowledgeable enough to answer many of the questions clients ask and to guide them in a safe, objective way (Ernst, 2015). Nurses have a unique opportunity to provide services that facilitate wholeness. They need to understand all aspects of CAM, including costs, client knowledge, and drug interactions, if they are to promote holistic strategies for clients and families.

The growing use of CAM during pregnancy and childbirth could be interpreted as a response by women regarding a need for autonomy and active participation in their health care. Studies have shown that massage, acupuncture, vitamins, and herbs are the most frequently applied CAM methods during pregnancy (Nursing & Midwifery Council, 2015).

Many clients who use CAM do not reveal this fact to their health care provider. Therefore, one of the nurse's most important roles during the assessment phase of the nursing process is to encourage clients to communicate their use of these therapies to eliminate the possibility of harmful interactions and contraindications with current medical therapies. When assessing clients, ask specific questions about any nonprescription medications they may be taking, including vitamins, minerals, or herbs. Clients should also be asked about any therapies they are taking that have not been ordered by their primary health care provider.

When caring for clients and their families who practice CAM, nurses need to:

• Be culturally sensitive to nontraditional treatments

• Acknowledge and respect different beliefs, attitudes, and lifestyles

• Keep an open mind, remembering that standard medical treatments do not work for all clients

• Accept CAM and integrate it if it brings comfort without harm

• Provide accurate information, not unsubstantiated opinions

• Advise clients how they can best monitor their condition using CAM

• Discourage practices only if they are harmful to the client's health

• Instruct the client to weigh the risks and benefits of CAM use

• Avoid confrontation when asking clients about CAM

• Be reflective, nonjudgmental, and open minded about CAM

The use of CAM is widespread, especially by women desiring to alleviate the nausea and vomiting of early pregnancy. Ginger lollipops or tea, Sea-Bands, and vitamin B_6 are frequently used to treat morning sickness (Brucker & King, 2016). Although these may not cause any ill effects during the pregnancy, most substances ingested cross the placenta and have the potential to reach the fetus, so nurses should stress to all pregnant women that they should be cautious when using CAM.

Women at risk for osteoporosis are seeking alternatives to hormone replacement therapy since the Women's Health Initiative study raised doubts about the benefit of estrogen. Some of the alternative therapies for osteoporosis include soy isoflavones, epimedium koreanum Nakai (herb) progesterone cream, magnet therapy, tai chi, and hip protectors (Mukhtar & Jackson, 2015). In addition, menopausal women may seek CAM therapies for hot flashes. Once again, despite many claims, most of these therapies have not undergone scientific testing and thus could place the woman at risk.

If clients are considering the use of or are using CAM therapies, suggest they check with their health care provider before taking any "natural" substance. Offer clients the following instructions:

• Keep in mind that "natural" does not necessarily mean "safe."

• Seek medical care when ill.

• Always inform the health care provider if you are taking herbs or other therapies.

• Be sure that any product package contains a list of all ingredients and amounts

of each.

- Be aware that frequent or continual use of large doses of a CAM preparation is not advisable, and harm may result if therapies are mixed (e.g., vitamin E, garlic, and aspirin all have anticoagulant properties).
- Research CAM through resources such as books, websites, and articles (NCCAM, 2015).

All nurses, especially nurses working in the community, must educate themselves about the pros and cons of CAM and be prepared to discuss and help their clients make sense of it all. Expanding our consciousness by understanding and respecting diverse cultures and CAM will enable nurses to provide the best treatment for clients and their families receiving community-based care.

COMMUNITY-BASED NURSING CARE SETTINGS

Community-based nursing takes place in a variety of settings, including physicians' offices, clinics, health departments, urgent care centers, hospital outpatient centers, churches, shelters, and clients' homes. Nurses provide well care, episodic ill care, and chronic care. They work to promote, preserve, and improve the health of the women and their families in these settings.

Due to technological advances, cost containment, and shortened hospital stays, the home is a common care setting for women and families today. Home care is geared toward the needs of the client and family. Private-duty nursing care is used when more extensive care is needed; it may be delivered hourly (several hours per day) or on a full-time, live-in basis. Periodic nursing visits may be used for intermittent interventions, such as intravenous antibiotic administration, follow-up client teaching, and monitoring. The goals of nursing care in the home setting include promoting, restoring, and maintaining the health of the client.

Home care focuses on minimizing the effects of the illness or disability along with providing the client with the means to care for the illness or disability at home. Nurses in the home care setting are direct care providers, educators, advocates, and case managers.

Prenatal Care

Early, adequate prenatal care has long been associated with improved pregnancy outcomes (March of Dimes, 2015). Adequate prenatal care is a comprehensive process in which any problems associated with pregnancy are identified and treated. Basic components of prenatal care include early and continuing risk assessment, health promotion, medical and psychosocial interventions, and follow-up. Within the community setting, several services are available to provide health care for pregnant women (Box 2.4).

MATERNAL COMMUNITY HEALTH CARE SERVICES

- State public health prenatal clinics provide access to care based on a sliding-scale payment schedule is used or services may be paid for by Medicaid.

- Federally funded community clinics typically offer a variety of services, which may include prenatal, pediatric, adult health, and dental services. A sliding-scale payment schedule is used or Medicaid may cover costs.

- Hospital outpatient health care services offer maternal–child health services. Frequently they are associated with a teaching hospital in which medical school students, interns, and OB/GYN residents rotate through the clinic services to care for clients during their education process.

- Private OB/GYN offices are available for women with health insurance seeking care during their pregnancies. Some physicians in private practice will accept Medicaid clients as well as private clients.

- Community free clinics offer maternal–child services in some communities for women with limited economic resources (homeless, unemployed).

- Freestanding birth centers offer prenatal care for low-risk mothers as well as childbirth classes to educate couples regarding the birthing process. Most centers accept private insurance and Medicaid for reimbursement services.

- Midwifery services are available in many communities where midwives provide women's health services. They usually accept a multitude of payment plans ranging from private pay to health insurance to Medicaid for reimbursement purposes.

- WIC provides food, nutrition counseling, and access to health services for low-income women, infants, and children. WIC is a federally funded program and is administered by each state. All persons receiving Aid to Families with Dependent Children (AFDC), food stamps, or Medicaid are automatically eligible for WIC. An estimated 10 million people get WIC benefits monthly. WIC serves 53% of all infants born in the United States (USDA Food and Nutrition Service, 2015).

- Childbirth classes offer pregnant women and their partners a series of educational classes on childbirth preparation. Women attend them during

their last trimester of pregnancy. Some classes are free and some have a fee.

• Local La Leche League groups provide mother-to-mother support for breast-feeding, nutrition, and infant care problem-solving strategies. All women who have an interest in breast-feeding are welcome to participate in the meetings, which are typically held in the home of a La Leche member.

Adapted from Community Health Network. (2015). *Maternity services*. Retrieved from http://www.ecommunity.com/ob; La Leche League. (2015). *Breastfeeding resources*. Retrieved from http://www.llli.org/resources.html; and USDA Food and Nutrition Service. (2015). *WIC fact sheet*. Retrieved from http://www.fns.usda.gov/wic/factsheets.htm

Not all women are aware of the community resources available to them. Most public health services are available for consultation, local hospitals have "hotlines" for questions, and public libraries have pregnancy-related resources as well as Internet access. Nurses can be a very helpful link to resources for all women regardless of their economic status.

Technologically advanced care has been shown to improve maternal and infant outcomes. Regionalized high-risk care, recommended by the American Academy of Pediatrics in the late 1970s, aimed to promote uniformity nationwide, covering the prenatal care of high-risk pregnancies and high-risk newborns. The advanced technology found in level III perinatal regional centers and community-based prenatal surveillance programs has resulted in better risk-adjusted mortality rates. Regionalized systems of perinatal care, along with telemedicine, are recommended to ensure that each mother and newborn achieves optimal outcomes. Telemedicine is when a health care provider uses interactive real-time audio and video telecommunications to deliver health services to a client at a site distant to the health care provider for the purpose of assessment, diagnosis, and treatment (Ivey et al., 2015). For example, fetal monitoring and ultrasound technology have traditionally been used in acute care settings to monitor the progress of many high-risk pregnancies. However, with the increased cost of hospital stays, many services were moved to outpatient facilities and into the home. The intent was to reduce health care costs and to monitor women with complications of pregnancy in the home rather than in the hospital. Examples of services offered in the home setting might include:

• Infusion therapy to treat infections or combat dehydration

• Hypertension monitoring for women with gestational hypertension

• Uterine monitoring for mothers who are at high risk for preterm labor

• Fetal monitoring to evaluate fetal well-being

• Portable ultrasound to perform a biophysical profile to assess fetal well-being

As a result, home care has the potential to produce cost savings compared with inpatient care.

Labor and Birth Care

Pregnancy involves numerous choices: cloth or disposable diapers, breast-feeding or bottle feeding, doctor or midwife, and where to give birth (at a birthing center, at home, or at a hospital). Deciding where to give birth depends on the woman's pregnancy risk status. For the pregnant woman who is at high risk as a result of medical or social factors, the hospital is considered the safest place for birth. Potential complications can be addressed because medical technology, skilled professionals, and neonatal services are available. For low-risk women, a freestanding birthing center or a home birth is an option.

The choice between a birthing center, home birth, or hospital depends on the woman's preferences, her risk status, her financial status, and her distance from a hospital. Some women choose an all-natural birth with no medications and no medical intervention, whereas others would feel more comfortable in a setting in which medications and trained staff are available if needed. Presenting the facts to women and allowing them to choose in collaboration with their health care provider is the nurse's role. Client safety is paramount, but at the same time nurses must protect the woman's right to select birth options. Nurses should promote family-centered care in all maternity settings (see Evidence-Based Practice 2.1).

Birthing Center

A birthing/childbirth center is a cross between a home birth setting and a hospital. Birthing centers offer a home-like setting but with proximity to a hospital in case of complications. Midwives often are the sole care providers in freestanding birthing centers, with obstetricians as backups in case of emergencies. Birthing centers usually have fewer restrictions and guidelines for families to follow and allow for more freedom in making decisions about labor. The rates of cesarean birth and the costs are much lower than those of a hospital. A study shows that midwife-led comprehensive care in a birthing center using the same medical guidelines as in standard care in hospitals reduced medical interventions without jeopardizing maternal and infant health (Arcia, 2015). The normal discharge time in birthing centers after childbirth is usually measured in hours (4 to 24 hours), not 24 to 48 hours, as is the case in hospitals.

Childbirth centers aim to provide a relaxing home environment and promote a

"culture of normalcy." Pregnancy and childbirth are healthy, normal life events for most women. In birth centers, midwives and staff hold to the wellness model of birth, which means they provide continuous, supportive care during which interventions are used only when medically necessary. Currently, the number of birth centers being established is on the rise. It is in these birth centers that midwives will learn about normalcy, building the skills needed to support women through labor, rather than managing labor. The current economic climate may result in more efficient use of resources, possibly normalizing birth (ACOG, 2015). The range of services for the expectant family often includes prenatal care, childbirth education, intrapartum care, and postpartum care, including home follow-up and family planning (Fig. 2.2). One of the hallmarks of the freestanding birthing center is that it can provide truly family-centered care by approaching pregnancy and birth as a natural family event and encouraging all family members to participate. Education is often provided by such centers, encouraging families to become informed and self-reliant in the care of themselves and their families (Sporek, 2015).

EVIDENCE-BASED PRACTICE 2.1 HOME BIRTH AFTER HOSPITAL BIRTH: WOMEN'S CHOICES AND REFLECTIONS

Women have been giving birth to newborns in the home setting since the beginning of time; giving birth in an institution has been the norm only since the early 20th century. The number of women in the United States choosing home birth is increasing. Little is known about women who choose home birth after having experienced hospital birth; therefore, the purpose of this research was to explore reasons why these women chose a home birth and their perceptions regarding both of their birth experiences.

STUDY

The research design was a qualitative description, whereby focus groups were conducted with women who had hospital births and subsequently choose a home birth and their perceptions regarding both birth experiences. Five focus groups were conducted ($N = 20$), recorded, and transcribed verbatim. Qualitative content analyses were applied to the women's narratives.

Findings

Five themes emerged from the focus group's narratives. (1) *Choices and empowerment*: With home birth, women felt they were given real choices rather than perceived choices, providing them feelings of power and control over their bodies. (2) *Interventions and interruptions*: Women believed interventions were done in the hospital setting that were not beneficial to the birthing process, and there were numerous interruptions with their hospital births. (3) *Disrespect and dismissal*: Women believed during their hospital birth, providers were more focused on the laboring uterus than themselves; others were dismissed from their providers when choosing a home birth. (4) *Birth space*: Home birth provided a peaceful and calm environment surrounded by friends and family. (5) *Connection*: Women felt connected to their providers and family at home. Most women felt dissatisfied with their hospital birth that influenced their subsequent decision to choose a home birth for their next pregnancy.

Nursing Implications

This study brings forth several themes that influenced women to select a home birth verses a hospital birth. Many of the themes focus on the women's control of her own birth experience in the home setting verses the hospital setting that included unnecessary interventions and multiple interruptions that impacted the women's birth experience negatively. Nurses, working in labor and birth suites within hospitals, need to be aware of these five themes and work toward changing their birthing environments to make it a more positive experience. This study's findings can act as a catalyst toward change with additional focus group's comments done upon discharge. Collecting consumer's feedback is needed to continually meet their needs.

Adapted from Bernhard, C., Zielinski, R., Ackerson, K., & English, J. (2014). Home birth after hospital birth: Women's choices and reflections. *Journal of Midwifery & Women's Health*, 59(2), 160–166.

Birthing centers provide an alternative for women who are uncomfortable with a home birth but who do not want to give birth in a hospital. Advantages of birthing centers include a noninterventional approach to obstetric care, freedom to eat and move around during labor, ability to give birth in any position, and the right to have any number of family and friends attend the birth. Disadvantages are that some centers have rigid screening criteria, which may eliminate healthy mothers from using birth centers; many have rigid rules concerning transporting the mother to the hospital (e.g., prolonged labor and ruptured membranes); and many have no pediatrician on staff if the newborn has special needs after birth (Gardner, 2015).

Home Birth

Home births continue to constitute only a small percentage of all childbirths in the United States, in part because of the concerns about safety. The literature is mixed regarding the safety of home births, but health care professionals should respect a woman's choice of birth settings, her right to choose, and her autonomy. Many women choose to have a home birth so it can be a family event. Feeling safe and in control can assist the birthing process because the woman

feels more comfortable in her own surroundings and confident in her coping ability (Jokinen & Johnson, 2015).

FIGURE 2.2 Birthing centers aim to provide a relaxing home-like environment and promote a culture of normality while offering a full range of health care services to the expectant family. (Photos by Gus Freedman.)

For centuries women have been giving birth to babies in their home. Many women feel more comfortable and relaxed when giving birth in their own environment. Women who want no medical interventions and a very family-

centered birth often choose to have a home birth. Home births are recommended for pregnant women who are considered to be at low risk for complications during labor and birth (ACOG, 2015). Home birth is advantageous because it:

• Is the least expensive

• Allows the woman to experience labor and birth in the privacy, comfort, and familiarity of home while surrounded by loved ones

• Permits the woman to maintain control over every aspect affecting her labor (e.g., positions, attire, and support people)

• Minimizes interference and unnecessary interventions, allowing labor to progress normally

• Provides continuous one-on-one care by the midwife throughout the childbirth process

• Promotes the development of a trusting relationship with the nurse midwife (American Pregnancy Association [APA], 2015)

A home birth does have some disadvantages, including the limited availability of pain medication and danger to the mother and baby if an emergency arises (e.g., placental abruption, uterine rupture, cord prolapse, or a distressed fetus). Delay in getting to the hospital could jeopardize the life of the child or the mother. A backup plan for a health care provider and nearby hospital on standby must be established should an emergency occur. The available evidence suggests that planned home birth is safe for women who are at low risk of complications and are cared for by appropriately qualified and AMCB-certified midwives with access to timely transfer to hospital if required (Grunebaum et al., 2015).

Postpartum and Newborn Care

Recent reforms in health care financing have reduced hospital stays significantly for new mothers. As a result, community-based nurses play a major role in extending care beyond the hospital setting. When new mothers are discharged from the hospital, most are still experiencing perineal discomfort and uterine cramping. They may still have pain from an episiotomy. They are fatigued and may be constipated. They may feel uncertain about feeding and caring for their newborn. The prevalence of early postpartum mental health conditions is high also. Nurses are in prime position to identify mothers at risk. A recent study found that excessive infant crying problems, older age, lower educational levels, breastfeeding problems, and single first-time mothers with no partner support were predictors of maternal distress in the postpartum period (Aston et al., 2015). These new mothers need to be made aware of community resources such as telephone consultation by nurses, outpatient clinics, home visits, neighborhood mother's support groups, and online new parent forums.

Telephone Consultation

Many hospitals offer telephone consultation services by their maternity nurses. The discharged mother is given the phone number of the nursing unit on the day of discharge and is instructed to call if she has any questions or concerns. Because the nurses on the unit are familiar with her birth history and the newborn, they are in a good position to assist her in adjusting to her new role. Although this service is usually free, not all families recognize a problem early or use this valuable informational resource.

Outpatient Clinics

Outpatient clinics offer another community-based site where the childbearing family can obtain services. Usually the mother has received prenatal care before giving birth and thus has established some rapport with the nursing staff there. The clinic staff is usually willing to answer any questions she may have about her health or that of her newborn. Appointments usually include an examination of the mother and newborn and instructions about umbilical cord care, postpartum and infant care, and nutrition for both mother and infant.

Postpartum Home Visits

Home visits offer services similar to those offered at a scheduled clinic visit, but they also give the nurse an opportunity to assess the family's adaptation and dynamics and the home environment. During the past decade, hospital stays have averaged 24 to 48 hours or less for vaginal births and 72 to 96 hours for cesarean births (Centers for Disease Control and Prevention [CDC], 2015a). Federal legislation went into effect in 1998 that prohibited insurers from restricting hospital stays for mothers and newborns to less than 2 days for vaginal births or 4 days for cesarean births (CDC, 2015a). These shortened stays have reduced the time available for educating mothers about caring for themselves and their newborns. Home visiting programs in general seek to promote child health/development, prevent child abuse/neglect, improve maternal well-being, and improve the parental capacity of mothers.

FIGURE 2.3 The nurse makes a postpartum home visit to assess the woman and her newborn. During the visit, the nurse assists the mother with breast-feeding.

Postpartum care in the home environment usually includes:

• Monitoring the physical and emotional well-being of the family members (Fig. 2.3)

• Identifying potential or developing complications for the mother and newborn

- Assessing behaviors characteristic of postpartum depression
- Linking the family, as needed, to community social services and housing and governmental programs
- Reviewing of role adjustments and available community supports
- Contraception education and community locations to obtain it
- Bridging the gap between discharge and ambulatory follow-up for mothers and their newborns (Lundy & Janes, 2016)

The use of technology to complement home-based nursing care may enhance care. Technology in its many forms can help empower clients while they remain in the comfort of their own homes. Technology examples may include telephone conversations between clients and nurses to triage symptoms, provide advice, monitor vital signs, and provide guidance on use of medications; phone texting on health promotion; video conferencing; or local Internet-based support groups for sharing information with other new mothers (Vo et al., 2015).

Support Groups for New Mothers

Support groups for new mothers are typically local groups led by a facilitator with previous experience in motherhood, breast-feeding, and infant care. Usually they are composed of 6 to 12 mothers who share information on breast-feeding techniques, infant sleeping patterns, child care issues, body image issues, and how to integrate the new baby into the family unit. Support groups usually meet weekly and provide an avenue of support that encourages disclosure and provides contact with other new mothers experiencing the same journey and challenges.

Online Motherhood Forums and Blogs

Support groups in online communities provide an anonymous place to exchange information and advice. Previous research has suggested that these groups offer a safe, nonjudgmental forum for new mothers to share experiences and interact anonymously. They are seen as a safe, supportive space in which new mothers can better understand their new role of parenting. They offer a viable form of education for new parents, along with laughs, memories, deep thoughts and recollections of pre-motherhood days. Reasons for new mothers to seek out online blogs and forums include feelings of community or acceptance, the desire

to be a good mother, for emotional support and the need for practical advice about parenting (Johnson, 2015).

High-Risk Newborn Home Care

With the reduced lengths of hospital stays, high-risk newborns are also being cared for in community settings. High-tech care once was provided only in the hospital. Now, however, the increasing cost of complex care and the influences of managed care have brought high-tech care into the home. Families have become health care systems by providing physical, emotional, social, and developmental home care for their technology-dependent infants. Suitable candidates for home care may include preterm infants who continue to need oxygen, low-birth-weight infants who need nutritional or hypercaloric formulas or adjunct feeding methods (e.g., tube feedings), or infants with hydrocephalus or cerebral palsy. Home care with prepared caregivers might contribute to earlier detection of significant residual/recurrent problems amenable to therapy. Studies suggest that improving home care for the high risk infant in the early months after discharge, a critical period for growth, has the potential to reduce incidences and burdens of their health care needs over the lifespan (Cheng et al., 2015). A wide range of equipment may be used, including mechanical ventilation, electronic apnea monitors, home oxygen equipment, intravenous infusion equipment, respiratory nebulizers, phototherapy, and suction equipment.

All family members must work together to provide 24-hour care. The parents must negotiate with insurers for reimbursement for durable medical equipment, must be able to troubleshoot equipment problems, and must be able to manage inventories of supplies and equipment. In addition, they must be able to assess the infant for problems; determine the problem; decide when to call the nurse, pharmacist, or physical therapist; and interpret and implement prescriptions. The use of technology in the home requires nurses to focus on the family home care system to provide total care to the infant.

Nurses can play a key role in assisting families by preparing them for and increasing their confidence in caring for their infants at home. This adaptation begins before discharge from the hospital. Family members are active participants in the transition-to-home plan. Recognition of parental needs and addressing each area in the discharge plan will ease the transition to home.

Assessment of the family's preparedness is essential. The following areas should be explored:

- *Parenting education*: Assess the family's knowledge of positioning and handling of their infant, nutrition, hygiene, elimination, growth and development, immunizations needed, and recognition of illnesses. Asking questions in a sensitive manner will assist the nurse in identifying knowledge deficiencies, so they can be reinforced in the nurse's teaching plan.

- *Postpartum care*: Determine the mother's concerns in areas of body image, weight loss, sleep/rest needs, discomfort, fatigue, and adjustment to her new role. Asking open-ended questions concerning these areas will help the nurse extract more information to include in the teaching plan. Targeting the mother's areas of concern will help the nurse focus on needed education to facilitate the mother's transition into her new role as a parent.

- *Support systems*: Assess physical and emotional support for the new mother by asking questions about the availability of her immediate family, other relatives, and significant others to provide help. If lacking, referrals may need to be made to community parenting programs, cooperative daycare, or other community resources needed to assist this family. Exploring these vital areas through sensitive questioning hopefully will convey the nurse's concern for the infant and family while obtaining a thorough assessment of the family's learning needs.

Once preparedness has been assessed, the nurse can intervene as necessary. For example, if the caretakers do not think they are prepared to maintain machinery, technology, medication, or developmental therapy, then the nurse can demonstrate the care to the family. The nurse provides instructions and hands-on experience in a supportive environment until the family's confidence increases. The nurse can also assist the family to anticipate the common problems that might occur (e.g., advising them to avoid running out of supplies, to have enough medication or special formula mixture to last throughout the weekend, and to keep backup batteries for powering machines or portable oxygen). The outcome of the preparedness assessment and intervention is that the safety of the infant is established and maintained.

Nursing for families who are using complex home care equipment requires caring for the infant and family members' physical and emotional well-being as well as providing solutions to problems they may encounter. Home health nurses need to identify, mobilize, and adapt a myriad of community resources to support the family in giving the best possible care in the home setting. Preparing families before hospital discharge, with home health nurses continuing and

reinforcing that focus, will ease the burden of managing high-tech equipment in the home.

Women's Health Care

A woman's reproductive years span half her lifetime, on average. This is not a static period, but rather one that encompasses several significant stages. As her reproductive goals change, so do a woman's health care needs. Because of these changing needs, comprehensive community-centered care is critical.

Community-based women's health services have received increased emphasis during the past few decades simply because of economics. Women use more health care services than men, they make as many as 90% of health care decisions, and they represent the majority of the population (CDC, 2015b). Women spend 66 cents of every health care dollar, and seven of the ten most frequently performed surgeries in the United States are specific to women (Alexander et al., 2014). Examples of community-based women's health care services that can be freestanding or hospital based include:

• Screening centers that offer mammograms, Pap smears, bone density assessments, genetic counseling, ultrasound imaging, breast examinations, complete health risk appraisals, laboratory studies (complete blood count, cholesterol testing, thyroid testing, glucose testing for diabetes, follicle-stimulating hormone levels), and electrocardiograms

• Educational centers that provide women's health lectures, instruction on breast self-examinations and Pap smears, and computers for research

• Counseling centers that offer various support groups: genetics, psychotherapy, substance abuse, sexual assault, and domestic violence

• Wellness centers that offer stress reduction techniques, massage therapy, guided imagery, hypnosis, smoking cessation, weight reduction, tai chi, yoga, and women's fitness/exercise classes

• Alternative/wholeness healing centers that provide acupuncture, aromatherapy, biofeedback, therapeutic touch, facials, reflexology, and herbal remedies

• Retail centers that offer specialty equipment for rental and purchase, such as breast prostheses

Women have multiple choices regarding services, settings, and health care providers. In the past, most women received health care services from physicians such as obstetricians, gynecologists, and family physicians, but today nurse midwives and nurse practitioners are becoming more prevalent in providing

well-woman care.

Nurses who work in community-based settings need to be familiar with the many health issues commonly encountered by women within their communities. All nurses who work with women of any age in community-based settings, including the workplace, schools, practitioners' offices, and clinics, should possess a thorough understanding of the scope of women's health care and should be prepared to intervene appropriately to prevent problems and to promote health.

ROLES AND FUNCTIONS OF THE COMMUNITY-BASED NURSE

Many nurses find the shift from acute care to community settings a challenge. With the shift in responsibilities from hospital care to community care, changes in nursing care have resulted. Nurses working in community-based settings share many of the same roles and responsibilities as their colleagues in acute care settings, but there are some differences. For example, in the community or home care setting the nurse will provide direct client care but will spend more time in the role of educator, communicator, and manager than the nurse in the acute care setting. In home care, the nurse will spend a significant amount of time in the supervisory or management role. Regardless of which setting (inpatient or outpatient) a nurse works in, principles of holistic care still apply universally.

Communicator

Effective therapeutic communication with women, children, and families is critical to the provision of quality nursing care. Client- and family-centered communication increases satisfaction with nursing care and aids in improving knowledge and health care skills (Arnold & Boggs, 2015). The significance of communication revolves around its effectiveness and the climate in which communication occurs. Trust, respect, and empathy are three factors needed to create and foster effective therapeutic communication among people.

Verbal and Nonverbal Communication

Nurses use verbal communication continuously throughout the day when interacting with their clients. Good verbal communication skills are necessary for excellent nursing assessment and teaching. Nonverbal communication, also referred to as body language, is composed of affective or expressive behavior, which can be demonstrated by attending to others and active listening. When clients and families feel they are being heard, trust and rapport are established.

> *Recall Maria, who recently was discharged from the hospital with her newborn son. How did the nurse communicate with Maria? Did the nurse's actions during the visit promote the development of trust between Maria and the nurse? What might have been done differently to foster trust?*

 Take Note!

People of all ages desire to be listened to without interruption (Bloomfield, 2015).

Active listening is critical to the communication process. Listening may uncover fears or concerns that the nurse may not have discovered through questioning. By not listening, critical information may be missed. Active listening is important in providing comprehensive nursing care. Research shows that exposure to an empathetic and active listening nurse has a calming and

healing effect on clients (Arnold & Boggs, 2015). If the client or family senses that the nurse is not listening, they may be reluctant to share further information. During the interaction, determine whether the client's verbal communication is congruent with his or her nonverbal communication.

Communication With Families

When communicating with families, be honest. Families desire to be valued and should be equal partners in the health care team. Allow family members to verbalize concerns and questions. Explain the use of equipment and the correct sequence of procedures. Help the members understand the long-term as well as short-term effects of a health treatment.

Working With an Interpreter

Attempting to communicate with a family whose members do not speak English can be a highly frustrating situation for health care providers. Timely identification of a client's language needs at the first point of contact can facilitate the provision of language-appropriate services and contribute to quality of care, better outcomes, and client satisfaction (Kamimura et al., 2015). Interpreters are an invaluable aid and an essential component of client and family education. Working with an interpreter, whether in person or over the phone, requires coordination of efforts by both parties. This coordination is important so that both the family and the interpreter understand the information to be communicated. Working as a team, the nurse questions or informs and the interpreter conveys the information completely and accurately. *Healthy People 2020* also addresses the topic of language differences (see *Healthy People 2020*). In addition, many health care facilities subscribe to Language Line Services which is an on-demand interpretation company that provides telephone access to interpretation of 170 languages. Numerous other interpreters, translators, and language resources are available online.

HEALTHY PEOPLE 2020 • 2.1

Objective ECBP-11 Increase the proportion of local health departments that have established culturally appropriate and linguistically competent

community health promotion and disease prevention programs.

Nursing Significance

Work with professionals and individuals from various cultures to develop materials and programs for health promotion that are culturally competent. Ensure teaching materials are provided in the appropriate language.

Objective ECBP-10 Increase the number of community-based organizations (including local health departments, tribal health services, nongovernmental organizations, and state agencies) providing population-based primary prevention services in the following areas: injury, mental illness, tobacco use, substance abuse, unintended pregnancy, nutrition, and physical activity.

Nursing Significance

Educational and community-based programs play a key role in preventing disease and injury, improving and enhancing the quality of life. Education and community-based programs and strategies are designed to reach people outside of traditional health care settings. These settings may include schools, work sites, and health care agencies. Community health promotion activities are initiated by a health department or organization; organizers have a responsibility to engage the community. Realizing the vision of healthy people in healthy communities is possible only if the community, in its full cultural, social, and economic diversity, is an authentic partner in changing the conditions for health.

Healthy People objectives based on data from http://www.healthypeople.gov

HEALTHY PEOPLE 2020 • 2.2

Objective HC/HIT-1 (Developmental) Improve the health literacy of the population.

Nursing Significance

Ideas about health and behaviors are shaped by communication, information, and technology. Health literacy is central to health care, public health, and the way our society views health. These processes make up the context and the ways professionals and the public search for, understand, and use health information, significantly impacting their health decisions and actions. Disparities in access to health information, services, and technology can result in lower usage rates of preventive services, less knowledge of chronic disease management, higher rates of hospitalization, and poorer reported health status. Thus, providing accurate, accessible, and actionable health information that is targeted or tailored to the individual client is essential.

Objective HC/HIT-2 Increase the proportion of persons who report that their health care providers have satisfactory communication skills.

Nursing Significance

Support shared decision making between clients and providers so that everyone buys into the treatment plan. Provide sound principles in the design of programs and interventions that result in healthier behaviors of the client and the family. Link the continuity of care within the community and at home to foster the best health outcomes.

Healthy People objectives based on data from http://www.healthypeople.gov.

Recall Maria, the woman with the newborn who is receiving home care. On the second visit to Maria's home, the nurse brought a Spanish-speaking interpreter who explained the reason for the "back to sleep" position and demonstrated to Maria several other useful positions for feeding and holding. Maria was smiling when the nurse left and asking when she would be back. What made the difference in their relationship during the second visit? What interventions demonstrate culturally competent care?

Communicating With Deaf Clients and Their Families

Nearly one in six Americans has hearing loss, and for those over the age of 65, the ratio climbs to one in three. By the end of this century, there will be approximately 360 million people around the world with some hearing disability.

Studies show that deaf people have poorer health than those that hear normally, which is attributed to problems accessing health care and communicating with health care providers (Emond et al., 2015). Health care providers are under a duty to provide auxiliary aids and services to establish effective communication with their clients. Providing assistance to people with hearing impairments in health care settings is critically important because, without assistance through auxiliary aids and services, health service providers run the risk of not understanding the client's symptoms, misdiagnosing the client's health problem, and prescribing inadequate or even harmful treatment (Alselai & Alrashed, 2015).

Pregnant women who have hearing impairments are often neglected mostly because of a lack of understanding of how best to care for women with different communication needs. Nurses have a key role in exchanging information and taking the time to understand the needs of women with hearing impairments in order to act as an advocate and to help overcome the barriers that can be created by deafness. To fulfill this role, nurses need to have an understanding of the problems faced by women with hearing impairments and their partners when accessing maternity services (Velonaki et al., 2015).

For clients with hearing impairments, nurses should determine their desired method of communication: lip reading, American Sign Language (ASL), another method such as CART (Communication Access Real-time Translation) which can be viewed on a tablet, laptop, or smart phone, or some combination. If the nurse is not proficient in ASL and the client or family uses it, then an ASL interpreter must be available if another adult family member is not present for translation. According to federal law, deaf clients and deaf family members must be given the ability to communicate effectively with health care providers (Oliveira et al., 2015).

Direct Care Provider

The community-based nurse typically performs less direct physical care than the nurse in the acute care setting. Many times the nurse may observe the client or caregiver performing physical care tasks. Excellent assessment skills are especially important in the community care setting. The nurse often is functioning in an autonomous role, and after data collection, the community-based nurse will often decide whether to initiate, continue, alter, or end physical nursing care. Assessment extends beyond physical assessment of the client to include the environment and the community.

The nurse provides direct care to the perinatal client, beginning with the woman's first visit to the health care provider and extending through the pregnancy and birth. In addition, the nurse provides direct care involving the following areas:

• Contraception

• Abortion

• Infertility

• Screening for STIs

• Preconceptual risk assessment and care

Educator

As a result of shortened hospital stays and decreased admissions, providing client and family education is a key role for nurses in the community. Many times teaching begins in the community setting, especially the home. In the community-based setting, client teaching is often focused on assisting the client and family to achieve independence.

Regardless of the type of setting, nurses are in a unique position to help clients and families manage their own health care. Clients and families need to be knowledgeable about areas such as their condition, the health care management plan, and when and how to contact health care providers. With the limited time available in all health care arenas, nurses must focus on teaching goals and begin teaching at the earliest opportunity (Peter et al., 2015).

 Take Note!

There is no prescription more valuable than knowledge (C. Everett Koop, MD, Former Surgeon General of the United States).

Client education occurs when nurses share information, knowledge, and skills with clients and families, thus empowering them to take responsibility for their health care. Through client education, clients and families can overcome feelings of powerlessness and helplessness and gain the confidence and capability to be active members in their plan of care.

Overall, client and family education allows clients and families to make informed decisions, ensures the presence of basic health care skills, promotes recognition of problem situations, promotes appropriate responses to problems, and allows for questions to be answered. When thorough and structured education begins in the hospital setting, it can carry over into the home setting, which can decrease hospital readmissions. An evidence-based discharge checklist describes the processes needed for a safe and optimal discharge and a recommended timeline of when to complete each step, starting on the first day of admission. A check list includes (1) indication for admission to the hospital; (2) primary care in the home; (3) medication safety; (4) follow-up plans; (5) home care referrals; (6) communication with community providers; and (7) client

education (Coleman et al., 2015). It can play an important role in aiding bedside nurses to provide early formal education for clients and families being discharged home with a new device so that safe care can be achieved in the home setting (Ulin et al., 2015). Client and family education is a priority and is addressed in *Healthy People 2020*.

Take Note!

To cope effectively with illness, to understand and participate in decisions about treatment plans, and to maintain and improve health after treatment, clients and their families must have knowledge and skills relevant to their conditions (Joint Commission, 2015).

Steps of Client and Family Education

Client education is an integral component of nursing care. The steps of client and family education are similar to the steps of the nursing process: the nurse must assess, plan, implement, evaluate, and finally document education. Once the nurse achieves a level of comfort and experience with each of these steps, they blend together and become a harmonious daily part of nursing practice. Client education begins with the first client encounter and proceeds through discharge and beyond. Reassessment after each step or change in the process is critical to ensuring success.

INTERVENING TO ENHANCE LEARNING

Nurses are in an excellent position to foster an environment that is conducive to learning. For example, it is entirely appropriate to say to the client, "Many people have a problem reading and remembering the information on this paper (booklet, manual). Is this ever a problem for you?" Once a problem is acknowledged, the nurse is free to adjust verbal communication techniques and written materials to assist with learning and to communicate this need to the entire interdisciplinary health care team.

Nurses implement individualized teaching techniques based on the assessment information and identified goals. In general, the following techniques can facilitate learning:

• Slow down and repeat information often.

• Speak in conversational style using plain, nonmedical language.

• Break the information down and teach it in small, digestible bits using logical steps.

• Prioritize information and teach survival skills first.

• Use visuals, such as pictures, videos, and models.

• Teach using an interactive, hands-on approach.

If the client or family has poor health literacy skills, learning can be fostered by the use of pictures or illustrations, videos or audio tapes, or color coding (such as medication bottles or steps of a procedure). In addition, teaching can include a "backup" family member.

DOCUMENTING TEACHING AND LEARNING

Documenting client care and education is an imperative part of every nurse's professional practice and is the only means available to ensure that the educational plan and objectives have been completed. Documentation serves four main purposes:

1. First and foremost, the client's medical record serves as a communication tool that the entire interdisciplinary team can use to keep track of what the client and family have learned already and what learning still needs to occur.

2. Second, it serves to testify to the education the family has received if legal matters arise.

3. Third, it verifies standards set by the Joint Commission, Centers for Medicare and Medicaid Services, and other accrediting bodies that hold health care providers accountable for client education activities.

4. Finally, it informs third-party payers of the goods and services that were provided for reimbursement purposes.

Client and family education plays an essential role in promoting safe self-management practice. To ensure that clients and their families attain the required abilities, client and family education needs to be competency based. When developing and applying a competency-based education lesson/program, each nurse must identify essential competencies to be taught, optimal teaching methods, best method to evaluate achievement, and documentation of evidence that learning has taken place (Embo et al., 2015).

Discharge Planner and Case Manager

Because of the short length of stays in acute settings and the shift to community settings for clients with complex health needs, discharge planning and case management have become an important nursing role in the community (Stanhope & Lancaster, 2014). Discharge planning involves the development and implementation of a comprehensive plan for the safe discharge of a client from a health care facility and for continuing safe and effective care in the community and at home. Case management focuses on coordinating health care services while balancing quality and cost outcomes. Often clients requiring community-based care, especially home care, have complex medical needs that require an interdisciplinary team to meet their physical, psychosocial, medical, nursing, developmental, and education needs. The nurse plays an important role in initiating and maintaining the link between team members and the client to ensure that the client and family are receiving comprehensive, coordinated care.

Advocate and Resource Manager

Client advocate is another important role of the community-based nurse to ensure that the client's and family's needs are being met. Advocacy also helps ensure that the client and family have available to them appropriate resources and health care services. For example, the pregnant woman on bed rest at home may need help in caring for her other children, maintaining the household, or getting to her appointments. Women with complex medical needs may require financial assistance through Medicaid or Medicaid waivers (state-run programs that use federal and state money to pay for the health care of individuals with certain medical conditions). They may also need assistance in obtaining needed equipment, additional services, and transportation. Community-based nurses need a basic understanding of community, state, and federal resources to ensure that clients and their families have access to needed resources.

KEY CONCEPTS

- Family-centered care recognizes the concept of the family as the constant. The health and functional abilities of the family affect the health of the client and other members of the family. Family-centered care recognizes and respects family strengths and individuality, encourages referrals for family support, and facilitates collaboration. It ensures flexible, accessible, and responsive health care delivery while incorporating developmental needs and implementing policies to provide emotional and financial support to women and their families.

- Health care delivery has moved from acute care settings out into the community, with an emphasis on health promotion and illness prevention (Lundy & Janes, 2016). Community health nursing focuses on preventing health problems and improving the health of populations and communities, addressing the current and potential health needs of the population or community, and promoting and preserving the health of a population regardless of age or diagnosis. Community health nurses perform epidemiologic investigations to help analyze and develop health policy and community health initiatives.

- Community-based nurses focus on providing personal care to individuals and families in the community. They focus on promoting and preserving health as

well as preventing disease or injury. They help women and their families cope with illness and disease. They focus on minimizing barriers to allow the client to develop to his or her full potential.

- Community-based nursing uses the nursing process in caring for clients in community settings and involves primary, secondary, and tertiary prevention levels. Nursing interventions in community-based settings include health screening, education, medication administration, telephone consultation, health system referral, instruction, nutritional counseling, and risk identification.

- Nurses working in the community need to develop cultural competence. Steps to gaining cultural competence include cultural self-awareness, cultural knowledge, cultural skills, and cultural encounters.

- Settings for community-based nursing including physicians' offices, clinics, health departments, urgent care centers, clients' homes, churches, and shelters (e.g., domestic violence shelters, homeless shelters, and disaster shelters). Nurses provide wellness care, episodic ill care, and chronic care to women and their families.

- Home health care situations have increased due to shorter hospital stays and cost containment measures along with an increase in the income and longevity of individuals with chronic and debilitating health conditions. Technology also has improved, which allows clients to be monitored and to undergo complicated procedures at home (Vizard, 2015).

- The roles and functions of the community-based nurse include communicator, direct care provider, educator, discharge planner and case manager, and advocate and resource manager.

- Open, honest communication is essential for community-based nurses. The use of an interpreter may be necessary to ensure effective communication. Maintaining confidentiality and providing privacy are key.

- A family's knowledge related to the client's health or illness is vital. Nurses working in the community play a major role in educating women and their families.

- Discharge planning provides a comprehensive plan for the safe discharge of a client from a health care facility and for continuing safe and effective care in the community. Case management focuses on coordinating health care services while balancing quality and costs. Discharge planning and case

management contribute to improved transitions from the hospital to the community for women, their families, and the health care team.

- Community-based nurses act as resource managers to help ensure that the client and family have the necessary resources and appropriate health care services available to them.

CHAPTER **WORKSHEET**

MULTIPLE-CHOICE QUESTIONS

1. A community-based nurse is involved in secondary prevention activities. Which activities might be included? Select all that apply.
   a. Fecal occult blood testing
   b. Hearing screening

c. Smoking cessation program

d. Cholesterol testing

e. Hygiene program

f. Pregnancy testing

2. A woman is to undergo a colonoscopy at a freestanding outpatient surgery center. Which would the nurse identify as a major disadvantage associated with this community-based setting?

a. Increased risk for infection verses a hospital

b. Increased health care costs verses a hospital

c. Need to be transferred if complications arise

d. Increased disruption of family functioning

3. When developing a teaching plan for a pregnant client with preterm labor who is to be discharged, what would the nurse do first?

a. Decide which procedures and medications the client will need at home.

b. Determine the client's learning needs and styles.

c. Ask the client if she has ever had preterm labor before.

d. Tell the client what the goals of the teaching session are.

4. Which action by a nurse would best demonstrate cultural competence?

a. Being well versed in the customs and beliefs of his or her own culture

b. Demonstrating an openness to the values and beliefs of other cultures

c. Applying knowledge about various cultures in the practice setting

d. Playing a role in establishing policies to address diverse cultures

5. Nurses working with an interpreter should emphasize the need for the interpreter to:

a. Elaborate on the content being interpreted

b. Clarify misinformation in their own words

c. Paraphrase statements to reduce time

d. Maintain confidentiality of content interpreted

6. Which factor would the nurse identify as being least likely to contribute to the rise in community-based care?

a. Focus on illness-oriented curative care

b. Rise in consumer disposable income

c. Technological advances for home care

d. Emphasis on primary care and treatment

CRITICAL THINKING EXERCISE

1. A 63-year-old woman from Saudi Arabia has become seriously ill while on a visit to the United States. It is projected that she will require a lengthy hospitalization. Describe the steps the nurse should take to communicate with and provide extensive health care teaching to this woman and her family.

2. A pregnant woman is discharged home from the hospital after admission due to preterm labor. The woman is to be on complete bed rest and will receive home health care through a local agency to assist her and her family and to monitor her health status. As the home health nurse assigned to this woman, what should your nursing assessment include?

STUDY ACTIVITIES

1. Shadow a nurse working in a community setting, such as a women's health clinic, birthing center, home care, or health department. Identify the role the nurse plays in the health of women and families in the setting and in the community.

2. Arrange for a visit to a community health center that offers services to various cultural groups. Interview the staff about the strategies used to overcome communication barriers and different health care practices for the women and their families in these groups.

3. Identify at least three community-based practice settings in which the nurse may practice family-centered care.

BRINGING IT ALL TOGETHER: CASE STUDY

The school nurse is becoming very distressed because of the high numbers of students she is seeing in the high school health clinic with sexually transmitted infections (STIs) recently. Just today, she saw a 14-year-old student experiencing pelvic pain secondary to an untreated gonorrhea infection. The nurse wants to initiate primary, secondary, and tertiary care interventions to address this problem.

Go to thePoint to find questions to consider about this case.

penis
progesterone
testes
uterus
vagina
vulva

Learning Objectives

Upon completion of the chapter, you will be able to:

1. Contrast the structure and function of the major external and internal female genital organs.
2. Outline the phases of the menstrual cycle, the dominant hormones involved, and the changes taking place in each phase.
3. Classify external and internal male reproductive structures and the function of each in hormonal regulation.

> ***Linda,*** *49, started menstruating when she was 12 years old. Her menstrual periods have always been regular, but now she is experiencing irregular, heavier, and longer ones. She wonders if there is something wrong or if this is normal.*

Words of Wisdom

All nurses should take care of and respect the human body, for it is a wondrous precision machine.

INTRODUCTION

The reproductive system is a collection of organs that function in the production of offspring. Scientists argue that the reproductive system is among the most important systems in the entire body. Without the ability to reproduce, a species dies. The female reproductive system produces the female reproductive cells (the eggs, or ova) and contains an organ (**uterus**) in which development of the fetus takes place; the male reproductive system produces the male reproductive cells (the sperm) and contains an organ (**penis**) that deposits the sperm within the female. Nurses need to have a thorough understanding of the anatomy and physiology of the male and female reproductive systems to be able to assess the health of these systems, to promote reproductive system health, to care for conditions that might affect the reproductive organs, and to provide client teaching concerning the reproductive system. This chapter reviews the female and male reproductive systems and the menstrual cycle as it relates to reproduction.

FEMALE REPRODUCTIVE ANATOMY AND PHYSIOLOGY

The female reproductive system is composed of both external and internal reproductive organs. It consists of the paired ovaries and oviducts, the uterus, the vagina, the external genitalia, and the mammary glands. All of these structures have evolved for the important functions of ovulation, fertilization of an ovum by a sperm, support of the developing embryo and fetus, and the birth and care of a newborn.

External Female Reproductive Organs

The external female reproductive organs collectively are called the **vulva** (which means "covering" in Latin). The vulva serves to protect the urethral and vaginal openings and is highly sensitive to touch to increase the female's pleasure during sexual arousal (Patton & Thibodeau, 2016). The structures that make up the vulva include the mons pubis, the labia majora and minora, the clitoris and prepuce, the structures within the vestibule, and the perineum (Fig. 3.1).

Mons Pubis

The mons pubis is the elevated, rounded, fleshy prominence made up of fatty tissue that overlays the symphysis pubis. The skin of this fatty tissue is covered with coarse, curly pubic hair after puberty. The mons pubis protects the symphysis pubis during sexual intercourse.

FIGURE 3.1 A. The external female reproductive organs. **B.** Normal appearance of external structures. (Photo by B. Proud.)

Labia

The labia majora (large lips), which are relatively large and fleshy, are comparable to the scrotum in males. The labia majora contain sweat and sebaceous (oil-secreting) glands; after puberty, they are covered with hair. Their function is to protect the vaginal opening and provide cushioning during sexual activity. The labia minora (small lips) are the delicate hairless inner folds of skin; they can be very small or up to 2 in wide. They lie just inside the labia majora and surround the openings to the vagina and urethra. The labia minora grow down from the anterior inner part of the labia majora on each side. These lips surround the vaginal opening and extend upward to form protection around both

the clitoris and urethra. They are highly vascular and abundant in nerve supply. They lubricate the vulva, swell in response to stimulation, and are highly sensitive.

Clitoris and Prepuce

The clitoris is a small, cylindrical mass of erectile tissue and nerves. It is highly sensitive and is analogous to the head of the male's penis. Unlike the penis, however, the function of the clitoris is purely erogenous. Most of the components of the clitoris are buried under the skin and connective tissue of the vulva. It is located at the anterior junction of the labia minora. There are folds above and below the clitoris. The joining of the folds above the clitoris forms the prepuce, a hood-like covering over the clitoris; the junction below the clitoris forms the frenulum.

 Take Note!

The hood-like covering over the clitoris is the site for female genital mutilation or cutting, which is a cultural ritual still practiced in some countries, including in the United States. It is internationally recognized as a human rights violation against women.

A rich supply of blood vessels gives the clitoris a pink color. Like the penis, the clitoris is very sensitive to touch, stimulation, and temperature and can become erect. For its small size, 9 to 11 cm, it has a generous blood and nerve supply. There are more free nerve endings of sensory reception located on the clitoris than on any other part of the body, and it is, unsurprisingly, the most erotically sensitive part of the genitalia for most females. Its function is sexual stimulation (Pauls, 2015).

 Take Note!

The word clitoris is from the Greek word for "key"; in ancient times the clitoris was thought to be the key to a woman's sexuality.

Vestibule

The vestibule is an oval area enclosed by the labia minora laterally. It is inside the labia minora and outside of the hymen and is perforated by six openings. Opening into the vestibule are the urethra from the urinary bladder, the vagina, and two sets of glands. The opening to the vagina is called the introitus, and the half-moon–shaped area behind the opening is called the fourchette. Through tiny ducts beside the introitus, Bartholin's glands, when stimulated, secrete mucus that supplies lubrication for intercourse. Skene's glands are located on either side of the opening to the urethra. They secrete a small amount of mucus to keep the opening moist and lubricated for the passage of urine (Velkey et al., 2015).

The vaginal opening is surrounded by the hymen (maidenhead). The hymen is a tough, elastic, perforated, mucosa-covered tissue across the vaginal introitus. In a virgin, the hymen may completely cover the opening, but it usually encircles the opening like a tight ring. Because the degree of tightness varies among women, the hymen may tear at the first attempt at intercourse, or it may be so soft and pliable that no tearing occurs. In a woman who is not a virgin, the hymen usually appears as small tags of tissue surrounding the vaginal opening, but the presence or absence of the hymen can neither confirm nor rule out sexual experience (Acien & Acien, 2015).

Take Note!

Heavy physical exertion, use of tampons, or injury to the area can alter the appearance of the hymen in girls and women who have not been sexually active.

Perineum

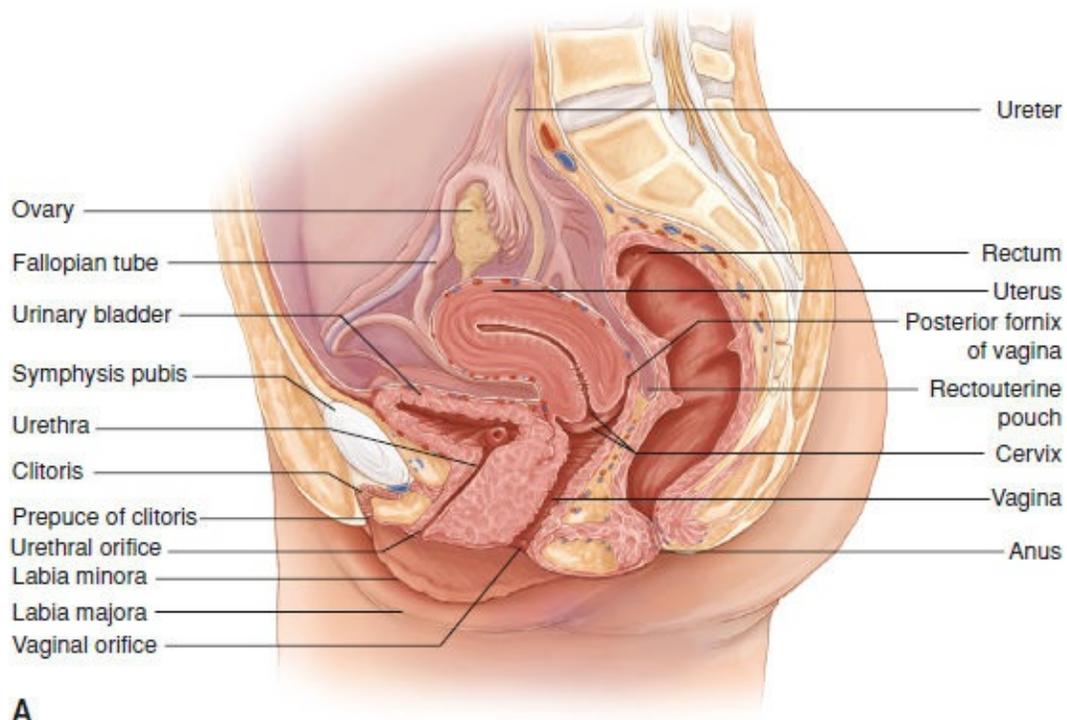
The perineum is the most posterior part of the external female reproductive organs. This external region is located between the vulva and the anus. It is made up of skin, muscle, and fascia. The perineum can become lacerated or incised during childbirth and may need to be repaired with sutures. Incising the perineum area to provide more space for the presenting part is called an episiotomy. Although still a common obstetric procedure, the use of episiotomy has decreased during the past 25 years. The procedure should be applied selectively rather than routinely. An episiotomy can add to postpartum discomfort and perineal trauma and can lead to fecal incontinence (King et al.,

2015).

Internal Female Reproductive Organs

The internal female reproductive organs consist of the vagina, uterus, fallopian tubes, and ovaries (Fig. 3.2). These structures develop and function according to specific hormonal influences that affect fertility and childbearing.

Vagina

The **vagina** is a highly distensible canal situated in front of the rectum and behind the bladder. It is a tubular, fibromuscular organ lined with mucous membrane that lies in a series of transverse folds called rugae. The rugae allow for extreme dilation of the canal during labor and birth. The vagina is a canal that connects the external genitals (vulva) to the cervix. It receives the penis and the sperm ejaculated during sexual intercourse, and it serves as an exit passageway for menstrual blood and for the fetus during childbirth. The front and back walls normally touch each other so that there is no space in the vagina except when it is opened (e.g., during a pelvic examination or intercourse). In the adult, the vaginal cavity is 3 to 4 in long. Muscles that control its diameter surround the lower third of the vagina. The upper two thirds of the vagina lies above these muscles and can be stretched easily. During a woman's reproductive years, the mucosal lining of the vagina has a corrugated appearance and is resistant to bacterial colonization. Before puberty and after menopause (if the woman is not taking estrogen), the mucosa is smooth due to lower levels of estrogen (Farage, Miller, & Maibach, 2015).


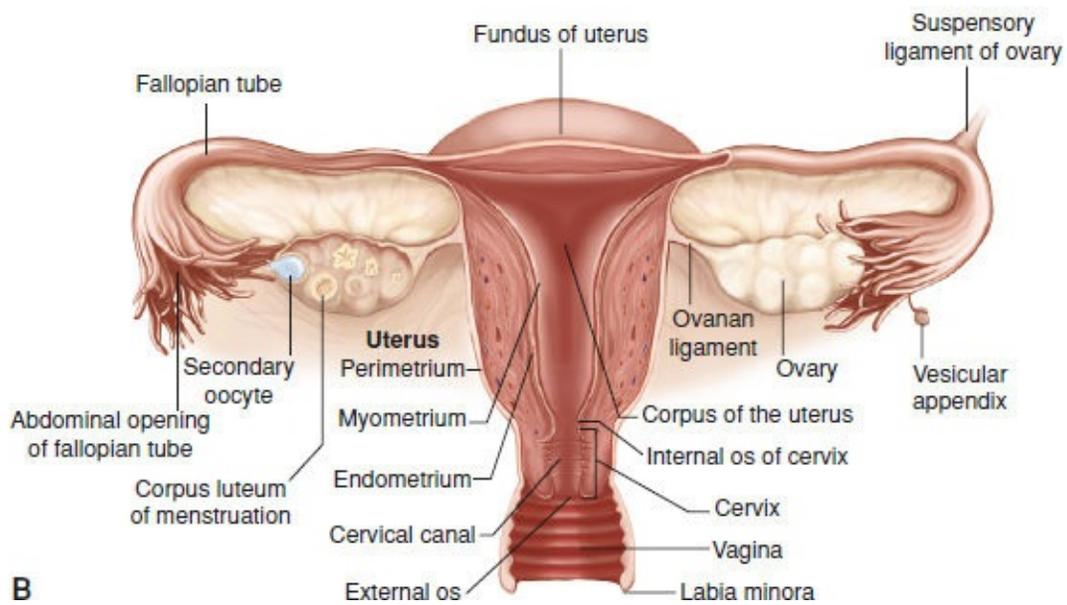


FIGURE 3.2 The internal female reproductive organs. **A.** Lateral view. **B.** Anterior view. (Source: Anatomical Chart Company. [2001]. *Atlas of human anatomy*. Springhouse, PA: Springhouse.)

The vagina has an acidic environment, which protects it against ascending infections. Antibiotic therapy, douching, perineal hygiene sprays, and deodorants upset the acid balance within the vaginal environment and can predispose women to infections.

Uterus

The uterus is an inverted, pear-shaped muscular organ at the top of the vagina. It lies behind the bladder and in front of the rectum and is anchored in position by eight ligaments, although it is not firmly attached or adherent to any part of the skeleton. A full bladder tilts the uterus backward; a distended rectum tilts it forward. The uterus alters its position by gravity or with change of posture, and is the size and shape of an inverted pear. It is the site of menstruation, receiving a fertilized ovum, development of the fetus during pregnancy, and contracting to help in the expulsion of the fetus and placenta. Before the first pregnancy, it measures approximately 3 in long, 2 in wide and 1 in thick. After a pregnancy, the uterus remains larger than before the pregnancy. After menopause, it becomes smaller and atrophies.

The uterine wall is relatively thick and composed of three layers: the **endometrium** (innermost layer), the myometrium (muscular middle layer), and the perimetrium (outer serosal layer that covers the body of the uterus). The endometrium is the mucosal layer that lines the uterine cavity in nonpregnant women. It varies in thickness from 0.5 to 5 mm and has an abundant supply of glands and blood vessels (Tambouret & Wilbur, 2015). The myometrium makes up the major portion of the uterus and is composed of smooth muscle linked by connective tissue with numerous elastic fibers. During pregnancy, the upper myometrium undergoes marked hypertrophy, but there is limited change in the cervical muscle content.

Anatomic subdivisions of the uterus include the convex portion above the uterine tubes (the fundus), the central portion (the corpus or body) between the fundus and the cervix, and the cervix, or neck, which opens into the vagina.

CERVIX

The **cervix,** the lower part of the uterus, is sometimes called the neck of the uterus. It opens into the vagina and has a channel that allows sperm to enter the uterus and menstrual discharge to exit. It is composed of fibrous connective tissue. During a pelvic examination, the part of the cervix that protrudes into the upper end of the vagina can be visualized. Like the vagina, this part of the cervix is covered by mucosa, which is smooth, firm, and doughnut shaped, with a visible central opening called the external os (Fig. 3.3). Before childbirth, the external cervical os is a small, regular, oval opening. After childbirth, the opening is converted into a transverse slit that resembles lips (Fig. 3.4). Except

during menstruation or ovulation, the cervix is usually a good barrier against bacteria. The cervix has an alkaline environment, which protects the sperm from the acidic environment in the vagina.

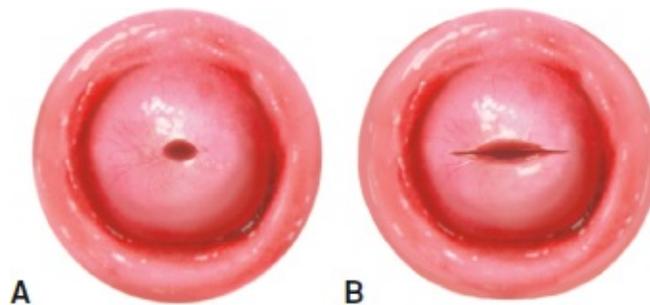
FIGURE 3.3 Appearance of normal cervix. Note: This is the cervix of a multipara female. (Photo by B. Proud.)


FIGURE 3.4 **A.** Nulliparous cervical os. **B.** Parous cervical os.

The canal or channel of the cervix is lined with mucus-secreting glands. This mucus is thick and impenetrable to sperm until just before the ovaries release an egg (ovulation). At ovulation, the consistency of the mucus changes so that sperm can swim through it, allowing fertilization. At the same time, the mucus-secreting glands of the cervix actually become able to store live sperm for 2 or 3

days. These sperm can later move up through the corpus and into the fallopian tubes to fertilize the egg; thus, intercourse 1 or 2 days before ovulation can lead to pregnancy. Because some women do not ovulate consistently, pregnancy can occur at varying times after the last menstrual period. During pregnancy the cervix is the vital mechanical barrier which resists compressive and tensile loads generated from a growing fetus. The channel in the cervix is too narrow for the fetus to pass through during pregnancy, but during labor it stretches to let the newborn through.

CORPUS

The corpus, or the main body of the uterus, is a highly muscular organ that enlarges to hold the fetus during pregnancy. The inner lining of the corpus (endometrium) undergoes cyclic changes as a result of the changing levels of hormones secreted by the ovaries: it is thickest during the part of the menstrual cycle in which a fertilized egg would be expected to enter the uterus and is thinnest just after menstruation. If fertilization does not take place during this cycle, most of the endometrium is shed and bleeding occurs, resulting in the monthly period. If fertilization does take place, the embryo attaches to the wall of the uterus, where it becomes embedded in the endometrium (about 1 week after fertilization); this process is called implantation (Patton & Thibodeau, 2015). Menstruation then ceases during the 40 weeks (280 days) of pregnancy. During labor, the muscular walls of the corpus contract to push the baby through the cervix and into the vagina.

Fallopian Tubes

The **fallopian tubes**, also known as oviducts, are hollow, cylindrical structures that extend 2 to 3 in from the upper edges of the uterus toward the ovaries. Each tube is about 7 to 10 cm long (4 in) and approximately 0.7 cm in diameter. The end of each tube flares into a funnel shape, providing a large opening for the egg to fall into when it is released from the ovary. Cilia (beating, hair-like extensions on cells) line the fallopian tube and the muscles in the tube's wall. The fallopian tubes convey the ovum from the ovary to the uterus and sperm from the uterus toward the ovary. This movement is accomplished via ciliary action and peristaltic contraction. If sperm are present in the fallopian tube as a result of sexual intercourse or artificial insemination, fertilization of the ovum can occur in the distal portion of the tube. If the egg is fertilized, it will divide over a

period of 4 days while it moves slowly down the fallopian tube and into the uterus, where it implants into the uterine lining.

Ovaries

The **ovaries** are a set of paired glands resembling unshelled almonds that are the organs of gamete production in the female. They are set in the pelvic cavity below and to either side of the umbilicus. They are usually pearl colored, oblong, and have a lumpy surface. They are homologous to the testes. Each mature ovary weighs from 2 to 5 g and is about 4 cm long, 2 cm wide, and 1 cm thick (Jones & Lopez, 2014). The ovaries are not attached to the fallopian tubes but are suspended nearby from several ligaments, which help hold them in position. The development and the release of the ovum and the secretion of the hormones **estrogen** and **progesterone** are the two primary functions of the ovary. The ovaries link the reproductive system to the body's system of endocrine glands, as they produce the ova (eggs) and secrete, in cyclic fashion, the female sex hormones estrogen and progesterone. After an ovum matures, it passes into the fallopian tubes.

Breasts

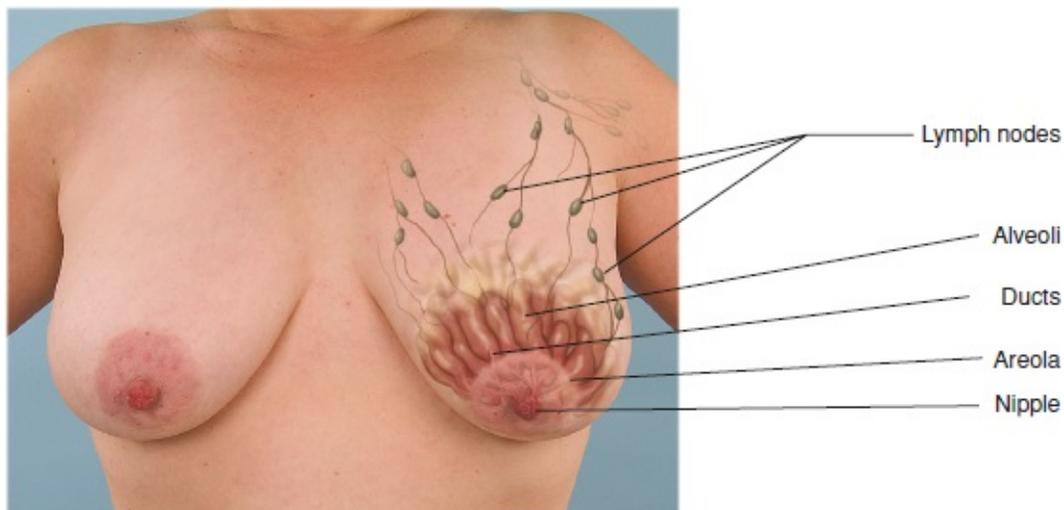
The two mammary glands, or **breasts**, are accessory organs of the female reproductive system that are specialized to secrete milk following pregnancy. They overlie the pectoralis major muscles and extend from the second to the sixth ribs and from the sternum to the axilla. Each breast has a nipple located near the tip, which is surrounded by a circular area of pigmented skin called the areola. Each breast is composed of approximately 9 lobes (the number can range between 4 and 18), which contain glands (alveolar) and a duct (lactiferous) that leads to the nipple and opens to the outside (Fig. 3.5). The lobes are separated by dense connective and adipose tissues, which also help support the weight of the breasts (Kandeel, 2014).


FIGURE 3.5 Anatomy of the breasts. (Photo by B. Proud.)

During pregnancy, placental estrogen and progesterone stimulate the development of the mammary glands. Because of this hormonal activity, the breasts may double in size during pregnancy. At the same time, glandular tissue replaces the adipose tissue of the breasts.

Following childbirth and the expulsion of the placenta, levels of placental hormones (progesterone and lactogen) fall rapidly, and the action of prolactin (milk-producing hormone) is no longer inhibited. Prolactin stimulates the production of milk within a few days after childbirth, but in the interim, dark yellow fluid called colostrum is secreted. Colostrum contains more minerals and

protein, but less sugar and fat, than mature breast milk. Colostrum secretion may continue for approximately a week after childbirth, with gradual conversion to mature milk. Colostrum is rich in maternal antibodies, especially immunoglobulin A (IgA), which offers protection for the newborn against enteric pathogens.

Female Sexual Response

The sexual response in both females and males is governed primarily by the nervous system rather than by hormones. The sexual response starts in a state of sexual neutrality, and the person's sexual desire is more of a reciprocal response than a spontaneous one (Housman & Odum 2016). The sexual cycle is usually thought of as having five phases: desire, excitement, plateau, orgasm, and resolution:

1. *Desire:* Starts with a desire for sexual intimacy, also known as *libido.*

2. *Excitement:* Both men and women have a heightened sexual awareness. When a female is sexually aroused, her brain coordinates a patterned sexual response cycle consisting of increased heart rate, respiratory rate, blood pressure, and general level of excitement (Sherwood, 2016). With sexual stimulation, tissues in the clitoris and breasts and around the vaginal orifice fill with blood and the erectile tissues swell. At the same time, the vagina begins to expand and elongate to accommodate the penis. As part of the whole vasocongestive reaction, the labia majora and minor swell and darken. As sexual stimulation intensifies, the vestibular glands secrete mucus to moisten and lubricate the tissues to facilitate insertion of the penis. Hormones play an integral role in the female sexual response as well. Adequate estrogen and testosterone must be available for the brain to sense incoming arousal stimuli. Research indicates that estrogen preserves the vascular function of female sex organs and affects genital sensation. It also is believed to promote blood flow to these areas during stimulation. Testosterone is needed to stimulate sexual desire in women. Recent research findings also suggest that testosterone therapy improves sexual desire, arousal, orgasm frequency, and satisfaction in women (Davis, 2013).

3. *Plateau:* The heart rate, blood pressure, level of muscle tension, and respiration rate all increase. During this phase, the penile erection intensifies and the vagina constricts around the penis. Continued stimulation of the clitoris and penis with movement leads to the next phase of the sexual response—*orgasmic phase.*

4. *Orgasm:* Women experience rhythmic contractions of the pelvic muscles and vaginal walls. In men, ejaculation occurs during the *orgasmic phase* and both sexes experience a peak of sexual pleasure at orgasm. Typically the woman

feels warm and relaxed after an orgasm. Within a short time after orgasm, the two physiologic mechanisms that created the sexual response, vasocongestion and muscle contraction, rapidly dissipate. The orgasmic experience varies from person to person and from time to time in the same person. Orgasm is an intense sensation of pleasure achieved by stimulation of erogenous zones. Women do not have a refractory period after each orgasm and can, therefore, experience multiple orgasms. Clitoral sexual response and the female orgasm are not affected by aging (Minkin, 2016). Some orgasms are intense, some are quiet, and some are gentle (Wheatley & Puts, 2015). At the completion of the sexual episode, the brain and body return to an unaroused state, which is termed *sexual resolution*. During this phase, the heart rate, blood pressure, and respirations slow; the muscles relax. Frequently, fatigue sets in for both people.

THE FEMALE REPRODUCTIVE CYCLE

The female reproductive cycle is a complex process that encompasses an intricate series of chemical secretions and reactions to produce the ultimate potential for fertility and birth. The female reproductive cycle is a general term that includes the ovarian cycle, the endometrial (uterine) cycle, the hormonal changes that regulate them, and the cyclical changes in the breasts. The endometrium, ovaries, pituitary gland, and hypothalamus are all involved in the cyclic changes that help to prepare the body for fertilization. Absence of fertilization results in menstruation, the monthly shedding of the uterine lining. **Menstruation** (shedding of the endometrium) marks the beginning and end of the monthly cycle. Menopause is the naturally occurring cessation of menstrual cycles.

The menstrual cycle results from a functional hypothalamic–pituitary–ovarian axis and a precise sequencing of hormones that lead to ovulation. The ovarian cycle, during which ovulation occurs, and the endometrial cycle, during which menstruation occurs, are divided at midcycle by ovulation. **Ovulation** occurs when the ovum is released from its follicle; after leaving the ovary, the ovum enters the fallopian tube and journeys toward the uterus. If sperm fertilize the ovum during its journey, pregnancy occurs (Fig. 3.6).

Ovarian Cycle

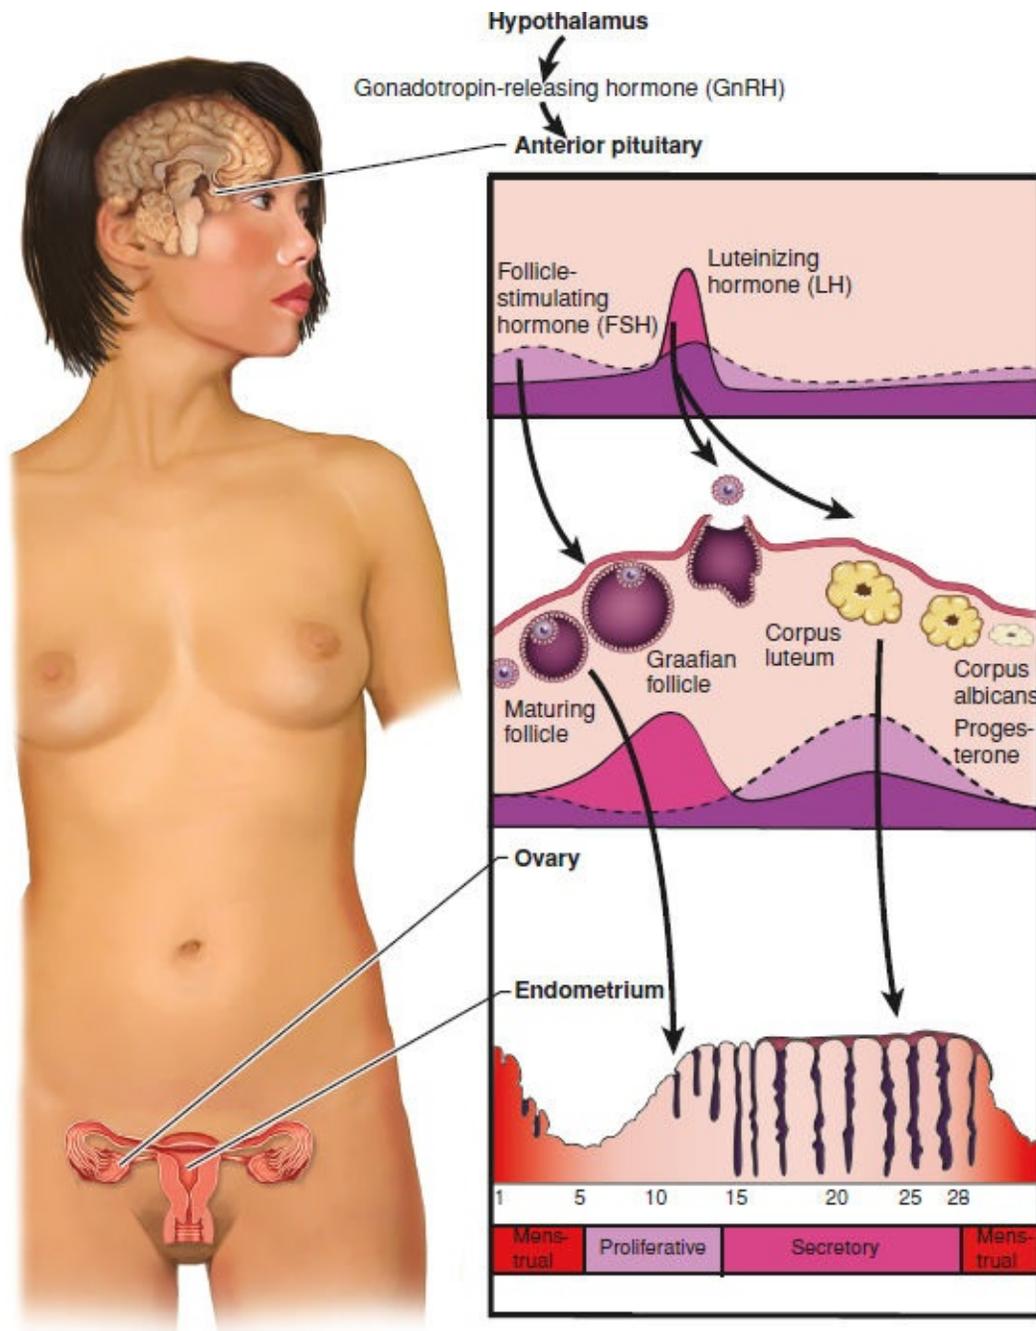
The ovarian cycle is the series of events associated with a developing oocyte (ovum or egg) within the ovaries. Whereas men manufacture sperm daily, often into advanced age, women are born with a single lifetime supply of ova that are released from the ovaries gradually throughout the childbearing years. In the female ovary, 1 million oocytes are present at birth, and about 200,000 to 400,000 follicles are still present at puberty. Typically, a woman ovulates one oocyte per month over an approximately 40-year reproductive lifespan. This accounts for the loss of 400 to 500 follicles. By age 35 she will have fewer than 100,000 follicles, and, by menopause, her follicular supply will be nearly depleted (Jones & Lopez, 2014). The ovarian cycle begins when the follicular cells (ovum and surrounding cells) swell and the maturation process starts. The maturing follicle at this stage is called a graafian follicle. The ovary raises many follicles monthly, but usually only one follicle matures to reach ovulation. The ovarian cycle consists of three phases: the follicular phase, ovulation, and the luteal phase.


FIGURE 3.6 Menstrual cycle summary based on a 28-day (average) menstrual cycle.

Follicular Phase

This phase is so named because it is when the follicles in the ovary grow and form a mature egg. The goal of this phase is to produce an ovum for fertilization. This phase starts on day 1 of the menstrual cycle and continues until ovulation, approximately 10 to 14 days later. The follicular phase is not consistent in

duration because of the time variations in follicular development. These variations account for the differences in menstrual cycle lengths (Sherwood, 2016). The hypothalamus is the initiator of this phase. Increasing levels of estrogen secreted from the maturing follicular cells and the continued growth of the dominant follicle cell induce proliferation of the endometrium and myometrium. This thickening of the uterine lining supports an implanted ovum if pregnancy occurs.

Prompted by the hypothalamus, the pituitary gland releases **follicle-stimulating hormone** (FSH), which stimulates the ovary to produce 5 to 20 immature follicles. Each follicle houses an immature oocyte or egg. The follicle that is targeted to mature fully will soon rupture and expel a mature oocyte in the process of ovulation. A surge in **luteinizing hormone** (LH) from the anterior pituitary gland is actually responsible for affecting the final development and subsequent rupture of the mature follicle.

Ovulation

At ovulation, a mature follicle ruptures in response to a surge of LH, releasing a mature oocyte (ovum). No one single event causes ovulation. This usually occurs on day 14 in a 28-day cycle. When ovulation occurs, there is a drop in estrogen. Typically ovulation takes place approximately 10 to 12 hours after the LH peak and 24 to 36 hours after estrogen levels peak (King et al., 2015). The distal ends of the fallopian tubes become active near the time of ovulation and create currents that help carry the ovum into the uterus. The life span of the ovum is only about 24 hours; unless it meets a sperm on its journey within that time, it will die.

During ovulation, the cervix produces thin, clear, stretchy, slippery mucus that is designed to capture the man's sperm, nourish it, and help the sperm travel up through the cervix to meet the ovum for fertilization. Ovulation symptoms also include vaginal spotting, an increase in vaginal discharge giving the woman a "feeling of wetness," an increased libido leading to more desire to be intimate, a slight rise in basal body temperature, and lower abdominal cramping.

The one constant, whether a women's cycle is 28 days or 120 days, is that ovulation takes place 14 days before menstruation (Housman & Odum, 2016).

Take Note!

About one in five women can feel a pain on one side of the abdomen around the time the egg is released. This midcycle pain is called mittelschmerz.

Luteal Phase

The luteal phase begins at ovulation and lasts until the menstrual phase of the next cycle. It typically occurs on days 15 through 28 of a 28-day cycle. After the follicle ruptures as it releases the egg, it closes and forms a corpus luteum. The corpus luteum secretes increasing amounts of the hormone progesterone, which interacts with the endometrium to prepare it for implantation. At the beginning of the luteal phase, progesterone induces the endometrial glands to secrete glycogen, mucus, and other substances. These glands become tortuous and have large lumens due to increased secretory activity. The progesterone secreted by the corpus luteum causes the temperature of the body to rise slightly until the start of the next period. A significant increase in temperature, usually 0.5° to 1°F, is generally seen within a day or two after ovulation has occurred; the temperature remains elevated until 3 days before the onset on the next menstruation (Housman & Odum, 2016). This rise in temperature can be plotted on a graph and gives an indication of when ovulation has occurred. In the absence of fertilization, the corpus luteum begins to degenerate and consequently ovarian hormone levels decrease. As estrogen and progesterone levels decrease, the endometrium undergoes involution. In a 28-day cycle, menstruation then begins approximately 14 days after ovulation in the absence of pregnancy. FSH and LH are generally at their lowest levels during the luteal phase and highest during the follicular phase.

Endometrial (Uterine) Cycle

The endometrial (uterine) cycle occurs in response to cyclic hormonal changes. The four phases of the endometrial cycle are the proliferative phase, secretory phase, ischemic phase, and menstrual phase.

Proliferative Phase

The proliferative phase of the endometrial cycle corresponds to the follicular phase of the ovarian cycle. It starts with enlargement of the endometrial glands in response to increasing amounts of estrogen. The blood vessels become dilated and the endometrium increases in thickness dramatically from 0.5 to 5 mm in height and increases eightfold in thickness in preparation for implantation of the fertilized ovum (Oyelowo & Johnson, 2016). Cervical mucus becomes thin, clear, stretchy, and more alkaline, making it more favorable to sperm to enhance the opportunity for fertilization. The proliferative phase starts on about day 5 of the menstrual cycle and lasts to the time of ovulation. This phase depends on estrogen stimulation resulting from ovarian follicles, and this phase coincides with the follicular phase of the ovarian cycle.

Secretory Phase

The secretory phase begins at ovulation to about 3 days before the next menstrual period. Under the influence of progesterone released by the corpus luteum after ovulation, the endometrium becomes thickened and more vascular (growth of the spiral arteries) and glandular (secretion of more glycogen and lipids). These dramatic changes are all in preparation for implantation, if it were to occur. This phase typically lasts from day 15 (after ovulation) to day 28 and coincides with the luteal phase of the ovarian cycle. In the absence of fertilization by day 23 of the menstrual cycle, the corpus luteum begins to degenerate and consequently ovarian hormone levels decrease. As estrogen and progesterone levels decrease, the endometrium undergoes involution.

Concept Mastery Alert

Proliferative Versus Secretory Phases of the Uterine Cycle

During the proliferative phase, the ovarian follicles are producing increased amounts of estrogen, and the endometrium prepares for possible fertilization with pronounced growth. The secretory phase begins at time of ovulation. If the ovum is not fertilized, then the corpus luteum degenerates and hormone levels fall, ultimately resulting in menstruation.

Ischemic Phase

If fertilization does not occur, the ischemic phase begins. Estrogen and progesterone levels drop sharply during this phase as the corpus luteum starts to degenerate. Changes in the endometrium occur with spasm of the arterioles, resulting in ischemia of the basal layer. The ischemia leads to shedding of the endometrium down to the basal layer, and menstrual flow begins.

Menstrual Phase

The menstrual phase begins as the spiral arteries rupture secondary to ischemia, releasing blood into the uterus, and the sloughing of the endometrial lining begins. If fertilization does not take place, the corpus luteum degenerates. As a result, both estrogen and progesterone levels fall and the thickened endometrial lining sloughs away from the uterine wall and passes out via the vagina. The beginning of the menstrual flow marks the end of one menstrual cycle and the start of a new one. Most women report menstrual bleeding for an average of 3 to 7 days. The amount of menstrual flow varies, but averages 1 ounce or a range of approximately 2/3 to 2 2/3 ounces in volume per cycle (Thornhill & Gangestad, 2015).

Menstruation

Menstruation is a term derived from the Latin word *mensis*, meaning "month." It is the normal, predictable physiologic process whereby the inner lining of the uterus (endometrium) is expelled by the body. Typically, this occurs monthly. Menstruation has many effects on girls and women, including emotional and self-image issues. In the United States, the average age at **menarche** (the start of menstruation in females) is 12.8 years, with a range between 8 and 18. Genetics is the most important factor in determining the age at which menarche starts, but geographic location, nutrition, weight, general health, nutrition, cultural and social practices, the girl's educational level, attitude, family environment, and beliefs are also important (Krieger et al., 2015).

Pubertal events preceding the first menses have an orderly progression: Thelarche, the development of breast buds; adrenarche, the appearance of pubic and then axillary hair, followed by a growth spurt; and menarche (occurring about 2 years after the start of breast development). In healthy pubertal girls, the menstrual period varies in flow heaviness and may remain irregular in occurrence for up to 2 years following menarche. After that time, the regular menstrual cycle should be established. Most women will experience 300 to 400 menstrual cycles within their lifetime (King et al., 2015). Normal, regular menstrual cycles vary in frequency and blood loss (Kandeel, 2014). Irregular menses can be associated with irregular ovulation, polycystic ovary syndrome, type 2 diabetes, weather conditions, stress, disease, and hormonal imbalances (Senie, 2014).

> *Think back to Linda, who was introduced at the beginning of the chapter. What questions might need to be asked to assess her condition? What laboratory work might be anticipated to validate her heavier flow?*

Although menstruation is a normal process, various world cultures have taken a wide variety of attitudes toward it, seeing it as everything from a sacred time to an unclean time. Folk culture surrounding menstrual-related matters has considerable implications for symptom expression and treatment-seeking behavior. Recent research findings imply the need for education to help adolescent girls manage menstrual symptoms and increase awareness of the

benefit of treating them. Given that menstrual-related information comes from mothers, family, and social culture, negative attitudes toward their monthly cycles can be formed in young impressionable girls. Nurses, through formal instruction, can help young girls in shaping good menstrual attitudes and a more positive image of this natural physiologic process (Clark & Paraska, 2014).

Take Note!

Knowledge about menstruation has increased significantly and attitudes have changed. What was once discussed only behind closed doors is discussed openly today.

Consider This

We had been married for 2 years when my husband and I decided to start a family. I began thinking back to my high school biology class and tried to remember about ovulation and what to look for. I also used the Internet to find the answers I was seeking. As I was reading, it all started to come into place. During ovulation, a woman's cervical mucus increases and she experiences a wet sensation for several days midcycle. The mucus also becomes stretchable during this time. In addition, body temperature rises slightly and then falls if no conception takes place. Armed with this knowledge, I began to check my temperature daily before arising and began to monitor the consistency of my cervical mucus. I figured that monitoring these two signs of ovulation could help me discover the best time to conceive. After 6 months of trying without results, I wondered what I was doing wrong. Did I really understand my body's reproductive activity?

Thoughts: What additional suggestions might the nurse offer this woman in her journey to conception? What community resources might be available to assist this couple? How does knowledge of the reproductive system help nurses take care of couples who are trying to become pregnant?

BOX 3.1

SUMMARY OF MENSTRUAL CYCLE HORMONES

• LH rises and stimulates the follicle to produce estrogen.

• As estrogen is produced by the follicle, estrogen levels rise, inhibiting the output of LH.

• Ovulation occurs after an LH surge damages the estrogen-producing cells, resulting in a decline in estrogen.

• The LH surge results in establishment of the corpus luteum, which produces estrogen and progesterone.

• Estrogen and progesterone levels rise, suppressing LH output.

• Lack of LH promotes degeneration of the corpus luteum.

• Cessation of the corpus luteum means a decline in estrogen and progesterone output.

• The decline of the ovarian hormones ends their negative effect on the secretion of LH.

• LH is secreted, and the menstrual cycle begins again.

Menstrual Cycle Hormones

The menstrual cycle involves a complex interaction of hormones. The predominant hormones include gonadotropin-releasing hormone, FSH, LH, estrogen, progesterone, and prostaglandins. Box 3.1 summarizes menstrual cycle hormones.

Gonadotropin-Releasing Hormone

Gonadotropin-releasing hormone (GnRH) is secreted from the hypothalamus in a pulsatile manner throughout the reproductive cycle. It pulsates slowly during the follicular phase and increases during the luteal phase. GnRH induces the release of FSH and LH to assist with ovulation.

Follicle-Stimulating Hormone

FSH is secreted by the anterior pituitary gland and is primarily responsible for the maturation of the ovarian follicle. FSH secretion is highest and most important during the first week of the follicular phase of the reproductive cycle.

Luteinizing Hormone

LH is secreted by the anterior pituitary gland and is required for both the final maturation of preovulatory follicles and luteinization of the ruptured follicle. As a result, estrogen production declines and progesterone secretion continues. Thus, estrogen levels fall a day before ovulation, and progesterone levels begin to rise.

Estrogen

Estrogen is secreted by the ovaries and is crucial for the development and maturation of the follicle. Estrogen is predominant at the end of the proliferative phase, directly preceding ovulation. After ovulation, estrogen levels drop sharply as progesterone dominates. In the endometrial cycle, estrogen induces proliferation of the endometrial glands. Estrogen also causes the uterus to increase in size and weight because of increased glycogen, amino acids, electrolytes, and water. Blood supply is expanded as well.

Progesterone

Progesterone is secreted by the corpus luteum. Progesterone levels increase just before ovulation and peak 5 to 7 days after ovulation. During the luteal phase, progesterone induces swelling and increased secretion of the endometrium. This hormone is often called the hormone of pregnancy because of its calming effect (reduces uterine contractions) on the uterus, allowing pregnancy to be maintained.

Prostaglandins

Prostaglandins are primary mediators of the body's inflammatory processes and are essential for the normal physiologic function of the female reproductive system. They are a closely related group of oxygenated fatty acids that are produced by the endometrium, with a variety of effects throughout the body. Although they have regulatory effects and are sometimes called hormones, prostaglandins are not technically hormones because they are produced by all tissues rather than by special glands (Jones & Lopez, 2014). Prostaglandins increase during follicular maturation and play a key role in ovulation by freeing the ovum inside the graafian follicle. Large amounts of prostaglandins are found in menstrual blood. Current research suggests that the pathogenesis of menstrual cramps/pain is due to prostaglandin F2a (PGF2a), a potent myometrial stimulant and vasoconstrictor, in the secretory endometrium. Elevated prostaglandin levels are found in the endometrial fluid of women with dysmenorrhea (painful menses) and correlates well with their degree of pain. Nonsteroidal anti-inflammatory drugs have been introduced as the primary choice of treatment for menstrual cramps (Nguyen et al., 2015).

Perimenopause

Perimenopause or menopausal transition and menopause are biologic markers of the transition from young adulthood to middle age. Neither of these is a symptom or disease, but rather a natural maturing of the reproductive system.

During the perimenopausal years (2 to 8 years prior to menopause), women may experience physical changes associated with decreasing estrogen levels, which may include vasomotor symptoms of hot flashes, irregular menstrual cycles, sleep disruptions, forgetfulness, irritability, mood disturbances, weight gain and bloating, irregular menses, headaches, decreased vaginal lubrication, night sweats, fatigue, vaginal atrophy, and depression (McNamara, Batur, & DeSapri, 2015). Vasomotor symptoms (hot flashes and night sweats) are the most common complaints for which women seek treatment. Several therapies can be considered to help manage these complaints. Choosing an appropriate treatment approach for the management of these symptoms requires careful assessment of the risk/benefit ratio of each alternative, as well as individual client preference (Schuiling & Likis, 2016).

Menopause

Menopause is a universal and irreversible part of the overall aging process involving a woman's reproductive system, after which she no longer menstruates. This naturally occurring phase of every woman's life marks the end of her childbearing capacity. The average age of natural menopause—defined as 1 year without a menstrual period—is 50 to 51 years old (Alexander et al., 2014). This period is frequently termed the *climacteric* or *perimenopause*, but mostly recently the *menopausal transition* has been used (Hoyt & Falconi, 2015). As the average life expectancy for women increases, the number of women reaching and living in menopause has escalated. Most women can expect to spend more than one third of their lives beyond menopause. It is usually marked by atrophy of the breasts, uterus, fallopian tubes, and ovaries (Crawford, 2015).

Many women pass through menopause without untoward symptoms. These women remain active and in good health with little interruption of their daily routines. Other women experience vasomotor symptoms, which give rise to sensations of heat, cold, sweating, headache, insomnia, and irritability. A recent study found that women experiencing menopausal symptoms reported significantly lower health-related quality of life and significantly high work impairment when compared to women without menopausal symptoms (Coney, 2015).

Until recently, hormone therapy was the mainstay of menopause pharmacotherapy, but with the recent results of the Women's Health Initiative trial and the Heart and Estrogen Replacement Study (HERS), the use of hormone therapy has become controversial. Many women have turned to nontraditional remedies to manage their menopausal symptoms. Common complementary and alternative medicine (CAM) remedies used for the treatment of menopausal symptoms include black cohosh, dong quai, St John's wort, hops, wild yam, ginseng, evening primrose oil, exercise, and acupuncture. Evidence supporting the efficacy and safety of most CAM for relief of menopausal symptoms is limited and most of the reports of efficacy do not support use of them (Wicks & Mahady, 2015). Nurses can play a major role in assisting menopausal women by educating and counseling them about the multitude of options available for disease prevention and treatments for menopausal symptoms during this time of change in their lives. Menopause should be an opportunity for women to strive

for a healthy, long life, and nurses can help to make this opportunity a reality. (See Chapter 4 for more information about menopause.)

> *Recall Linda, who was experiencing changes in her menstrual patterns. Which hormones might be changing, and which systems might they affect? What approach should the nurse take to enlighten Linda about what is happening to her?*

MALE REPRODUCTIVE ANATOMY AND PHYSIOLOGY

The male reproductive system, like that of the female, consists of those organs that facilitate reproduction. The male organs are specialized to produce and maintain the male sex cells, or sperm; to transport them, along with supporting fluids, to the female reproductive system; and to secrete the male hormone testosterone. The organs of the male reproductive system include the penis, scrotum, two **testes** (where sperm cells and testosterone are made), and accessory organs (epididymis, vas deferens, seminal vesicles, ejaculatory duct, urethra, bulbourethral glands, and prostate gland).

External Male Reproductive Organs

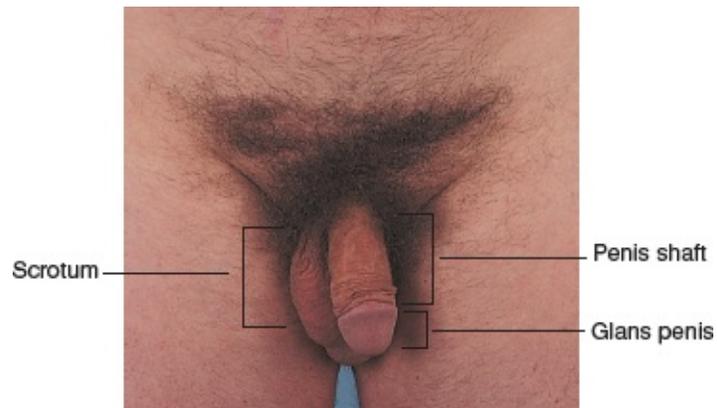
The penis and the scrotum form the external genitalia in the male (Fig. 3.7).


FIGURE 3.7 The external male reproductive organs. (Photo by B. Proud.)

FIGURE 3.8 The urinary meatus. (Photo by B. Proud.)

Penis

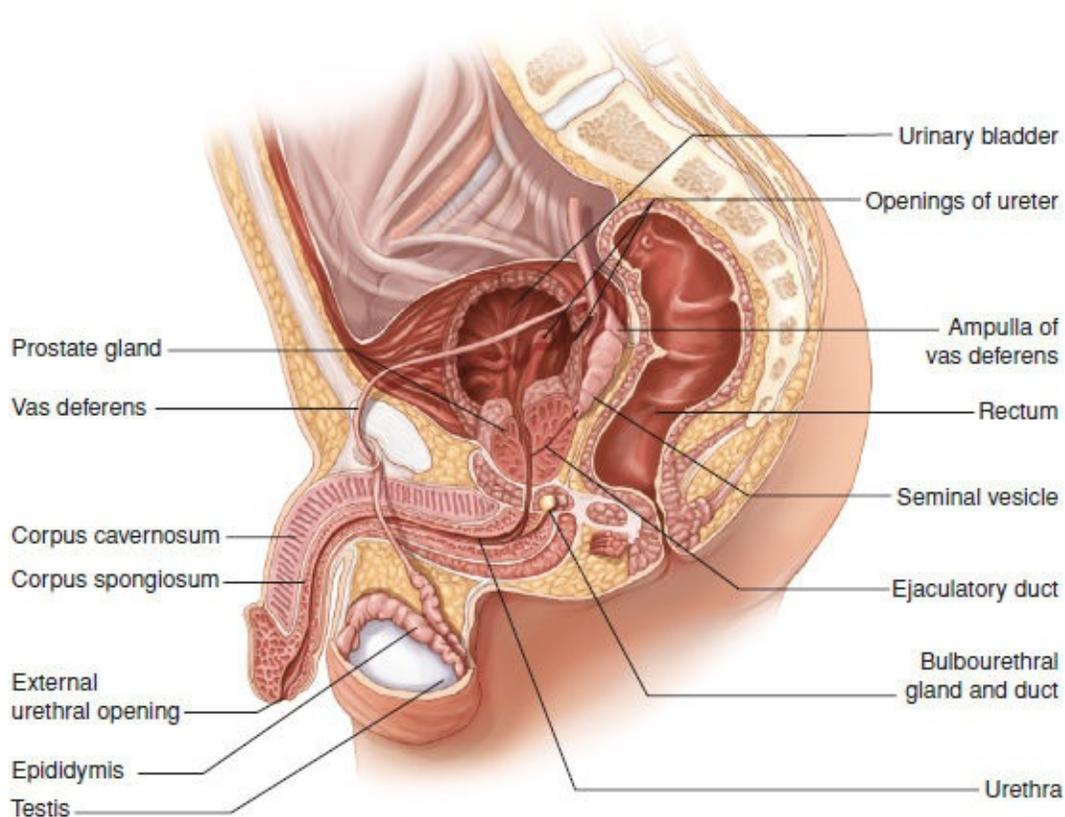
The penis is the organ for copulation and serves as the outlet for both sperm and urine. The penis becomes engorged with blood during sexual arousal and is inserted into the female vagina during intercourse. The skin of the penis is thin, with no hairs. The prepuce (foreskin) is a circular fold of skin that extends over the glans unless it is removed by circumcision shortly after birth. The urinary

meatus, located at the tip of the penis, serves as the external opening to the urethra (Fig. 3.8). The penis is composed mostly of erectile tissue. Most of the body of the penis consists of three cylindrical spaces (sinuses) of erectile tissue. The two larger ones, the corpora cavernosa, are side by side. The third sinus, the corpus spongiosum, surrounds the urethra. Erection results when nerve impulses from the autonomic nervous system dilate the arteries of the penis, allowing arterial blood to flow into the erectile tissues of the organ.

Scrotum

The scrotum is the thin-skinned sac that surrounds and protects the testes. The scrotum also acts as a climate-control system for the testes, because they need to be slightly cooler than body temperature to allow normal sperm development. The scrotum is covered with hair starting in puberty. The cremaster muscles in the scrotal wall relax or contract to allow the testes to hang farther from the body to cool or to be pulled closer to the body for warmth or protection (Patton & Thibodeau, 2015). A medial septum divides the scrotum into two chambers, each of which encloses a testis.

Internal Male Reproductive Organs

The internal structures include the testes, the ductal system, and accessory glands (Fig. 3.9).


Testes

The testes are oval bodies in the size of large olives that lie in the scrotum; usually the left testis hangs a little lower than the right one. These two nut-like structures are analogous to ovaries in the female and two testes are present in males. The testes have two functions: producing sperm and synthesizing testosterone (the primary male sex hormone). Sperm is produced in the seminiferous tubules of the testes. Similar to the female reproductive system, the anterior pituitary releases the gonadotropins, FSH and LH. These hormones stimulate the testes to produce testosterone, which assists in maintaining

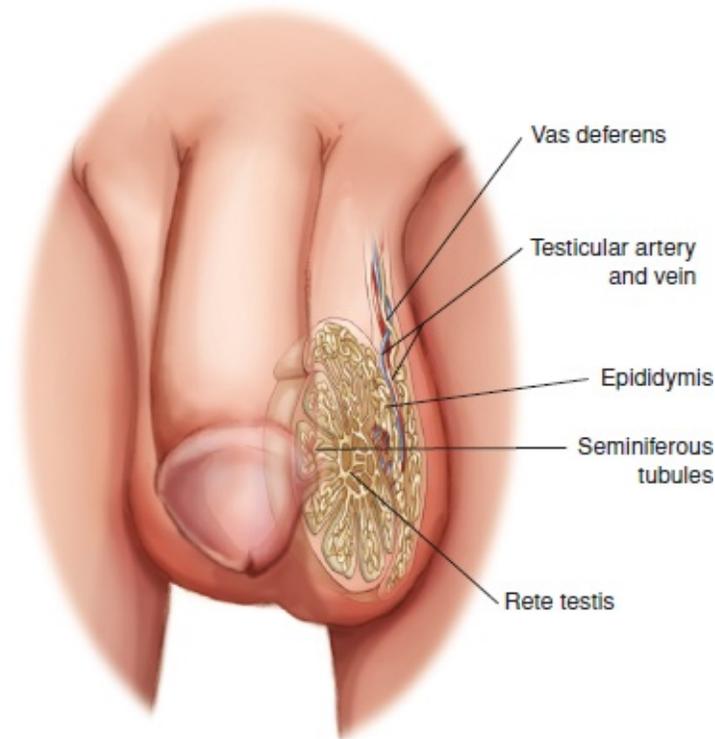
spermatogenesis, increases sperm production by the seminiferous tubules, and stimulates production of seminal fluid (Jones & Lopez, 2014). The epididymis, which lies against the testes, is a coiled tube almost 20 ft long. It collects sperm from the testes and provides the space and environment for sperm to mature (Fig. 3.10).


FIGURE 3.10 Internal structures of a testis.

The Ductal System

The vas deferens is a cord-like duct that transports sperm from the epididymis. One such duct travels from each testis up to the back of the prostate and enters the urethra to form the ejaculatory ducts. Other structures, such as blood vessels and nerves, also travel along with each vas deferens and together form the spermatic cord. The urethra is the terminal duct of the reproductive and urinary systems, serving as a passageway for semen (fluid containing sperm) and urine. It passes through the prostate gland and the penis and opens to the outside.

Accessory Glands

The seminal vesicles, which produce nutrient seminal fluid, and the prostate

gland, which produces alkaline prostatic fluid, are both connected to the ejaculatory duct leading into the urethra. The paired seminal vesicles are convoluted pouch-like structures lying posterior to, and at the base of, the urinary bladder in front of the rectum. They secrete an alkaline fluid that contains fructose and prostaglandins. The fructose supplies energy to the sperm on its journey to meet the ovum, and the prostaglandins assist in sperm mobility.

The prostate gland lies just under the bladder in the pelvis and surrounds the middle portion of the urethra. Usually the size of a walnut, this gland enlarges with age. The prostate and the seminal vesicles above it produce fluid that nourishes the sperm. This fluid provides most of the volume of semen, the secretion in which sperm are expelled during ejaculation. Other fluid that makes up the semen comes from the vas deferens and from mucous glands in the head of the penis.

The bulbourethral glands (Cowper's glands) are two small structures about the size of peas, located inferior to the prostate gland. They are composed of several tubes whose epithelial linings secrete a mucus-like fluid. It is released in response to sexual stimulation and lubricates the head of the penis in preparation for sexual intercourse, in addition, neutralizes the acidity of the urethra to protect sperm during their journey out of the body during ejaculation. Their existence is said to be constant, but they gradually diminish in size with advancing age.

Male Sexual Response

Regardless of the type of sexual stimulation, the physiologic response in both men and women is similar and usually follows a five-phase pattern, as described earlier:

1. *Desire:*Starts with a desire for sexual intimacy. This can also be termed libido.

2. *Excitement:* The man experiences sexual arousal with either thoughts or physical sexual stimuli which cause specific changes such as the heart beating faster, blood pressure rising, the testicles enlarging and more blood flowing into the penis, creating an erection.

3. *Plateau:* It is the phase between excitement and orgasm in which the head of the penis enlarges and becomes more purplish in color; the glands secrete semen into the urethra; and it is challenging to stop from having an orgasm.

4. *Orgasm:* It is a total body response. The tension that built up during the previous two phases is released. It triggers a series of muscle spasms in the legs, stomach, arms, back, and penis. The feelings are intense and pleasurable. Ejaculation of semen occurs at this time.

5. *Resolution:* The body returns to the physiologic nonstimulated state. The blood flows out of the penis and erection ceases; an overall feeling of relaxation ensues, and the testes and scrotum return to their normal size (Housman & Odum, 2016).

Sexual behavior involves the participation of autonomic and somatic nerves and the integration of numerous spinal sites in the central nervous system (CNS). The penile portion of the process that leads to erections represents only a single component. Penile erections are an integration of complex physiologic processes involving the CNS, peripheral nervous system, and hormonal and vascular systems (Sherwood, 2016). With sexual stimulation, the arteries leading to the penis dilate and increase blood flow into erectile tissues. At the same time, the erectile tissue compresses the veins of the penis, reducing blood flow away from the penis. Blood accumulates, causing the penis to swell and elongate and producing an erection. As in women, the culmination of sexual stimulation is an orgasm, a pleasurable feeling of physiologic and psychological release.

Orgasm is accompanied by emission (movement of sperm from the testes and fluids from the accessory glands) into the urethra, where the sperm and fluids are

mixed to form semen. As the urethra fills with semen, the base of the erect penis contracts, this increases pressure. This pressure forces the semen through the urethra to the outside (ejaculation). During ejaculation, the ducts of the testes, epididymis, and vas deferens contract and cause expulsion of sperm into the urethra, where the sperm mixes with the seminal and prostatic fluids. These substances, together with mucus secreted by accessory glands, form the semen, which is discharged from the urethra.

KEY CONCEPTS

- The female reproductive system produces the female reproductive cells (the eggs, or ova) and contains an organ (uterus) where the fetus develops. The male reproductive system produces the male reproductive cells (the sperm) and contains an organ (penis) that deposits the sperm within the female.

- The internal female reproductive organs consist of the vagina, the uterus, the fallopian tubes, and the ovaries. The external female reproductive organs make up the vulva. These include the mons pubis, the labia majora and minora, the clitoris and prepuce, structures within the vestibule, and the perineum.

- The breasts are accessory organs of the female reproductive system that are specialized to secrete milk following pregnancy.

- The main function of the reproductive cycle is to stimulate growth of a follicle to release an egg and prepare a site for implantation if fertilization occurs.

- Menstruation, the monthly shedding of the uterine lining, marks the beginning and end of the cycle if fertilization does not occur.

- The ovarian cycle is the series of events associated with a developing oocyte (ovum or egg) within the ovaries.

- At ovulation, a mature follicle ruptures in response to a surge of LH, releasing a mature oocyte (ovum).

- The endometrial cycle is divided into four phases: the follicular or proliferative phase, the luteal or secretory phase, the ischemic phase, and the menstrual phase.

- The menstrual cycle involves a complex interaction of hormones. The predominant hormones are gonadotropin-releasing hormone (GnRH), FSH, LH, estrogen, progesterone, and prostaglandins.

- The organs of the male reproductive system include the penis, scrotum, two testes (where sperm cells and testosterone are made), and accessory organs (epididymis, vas deferens, seminal vesicles, ejaculatory ducts, urethra, bulbourethral glands, and prostate gland).

CHAPTER **WORKSHEET**

MULTIPLE-CHOICE QUESTIONS

1. The predominant anterior pituitary hormones that orchestrate the menstrual cycle include:

    a. Thyroid-stimulating hormone (TSH)

    b. Follicle-stimulating hormone (FSH)

    c. Corticotropin-releasing hormone (CRH)

    d. Gonadotropin-releasing hormone (GnRH)

2. Which glands are located on either side of the female urethra and secrete mucus to keep the opening moist and lubricated for urination?

a. Cowper's

b. Bartholin's

c. Skene's

d. Seminal

3. What event occurs during the proliferative phase of the menstrual cycle?

a. Menstrual flow starts

b. Endometrium thickens

c. Ovulation occurs

d. Progesterone secretion peaks

4. Which hormone is produced in high levels to prepare the endometrium for implantation just after ovulation by the corpus luteum?

a. Estrogen

b. Prostaglandins

c. Prolactin

d. Progesterone

5. Sperm maturation and storage in the male reproductive system occur in the:

a. Testes

b. Vas deferens

c. Epididymis

d. Seminal vesicles

6. The nurse is preparing to teach a class to a group of middle-aged women regarding the most common vasomotor symptoms experienced during menopause and possible modalities of treatment available. Common vasomotor symptoms would include which of the following?

a. Chronic fatigue and confusion

b. Forgetfulness and irritability

c. Night sweats and hot flashes

d. Decrease in sexual response and appetite

CRITICAL THINKING EXERCISE

1. The school nurse was asked to speak to a 10th-grade biology class about menstruation. The teacher felt that the students did not understand this monthly event and wanted to dispel some myths about it. After the nurse explains the factors influencing the menses, one girl asks, "Could someone get pregnant if she had sex during her period?"

   a. How should the nurse respond to this question?

   b. What factor regarding the menstrual cycle was not clarified?

   c. What additional topics might this question lead to that might be discussed?

STUDY ACTIVITIES

1. Should sex education be taught in public schools, and if so, what topics should be addressed? Debate the pros and cons of teaching this and then outline which topics should be covered.

2. Respond to the following as a topic sentence: "When I was growing up, talking about sexual matters with my parents was … because…. Now the situation is …?"

3. List the predominant hormones and their function in the menstrual cycle.

4. The ovarian cycle describes the series of events associated with the development of the _____ within the ovaries.

5. Sperm cells and the male hormone testosterone are made in which of the following structures? Select all that apply.

   a. Vas deferens

   b. Penis

   c. Scrotum

   d. Ejaculatory ducts

   e. Prostate gland

   f. Testes

   g. Seminiferous tubules

h. Bulbourethral glands

BRINGING IT ALL TOGETHER: CASE STUDY

A 53-year-old woman came to see her women's health nurse practitioner for her annual examination. She had a hysterectomy 20 years ago for a prolapsed uterus and has been healthy up until now. She had a long list of symptoms that had been bothering her, but until recently just chalked them up to the aging process. She told the nurse practitioner that she was experiencing insomnia, weight gain around her middle despite not consuming additional calories, painful intercourse, and hot flashes that were increasing in frequency throughout the day and night. She had been taking black cohosh for these distressing symptoms for the past several months, but was not getting any relief. She was concerned that something awful was wrong with her since this natural herb was not reducing her symptoms and they seemed to be getting worse.

Go to thePoint to find questions to consider about this case.

oral contraceptives (OCs)

osteoporosis

premenstrual syndrome (PMS)

sexual abstinence

Standard Days Method (SDM)

sterilization

symptothermal method

transdermal patch

tubal ligation

vaginal ring

vasectomy

Learning Objectives

Upon completion of the chapter, you will be able to:

1. Examine common reproductive concerns in terms of symptoms, diagnostic tests, and appropriate interventions.
2. Identify risk factors and outline appropriate client education needed in common reproductive disorders.
3. Compare and contrast the various contraceptive methods available and their overall effectiveness.
4. Analyze the physiologic and psychological aspects of menopausal transition.
5. Delineate the nursing management needed for women experiencing common reproductive disorders.

***Izzy,** a 27-year-old, presents to her health care provider complaining of progressive severe pelvic pain associated with her monthly periods. She has to take off work and "dope up" with pills to endure the pain. In addition, she has been trying to conceive for over a year without any luck.*

Words of Wisdom

When women bare their souls to us, we must respond without judgment.

INTRODUCTION

Good health throughout the life cycle begins with the individual. Women today can expect to live well into their 80s and need to be proactive in maintaining their own quality of life. Women need to take steps to reduce their risk of disease and need to become active partners with their health care professional to identify problems early, when treatment may be most successful (Teaching Guidelines 4.1). Nurses can assist women in maintaining their quality of life by helping them to become more attuned to their body and its clues and can use the assessment period as an opportunity for teaching and counseling. Nurses are in a prime position to offer information that provides women with the tools needed to maintain a healthy lifestyle and assist in altering behaviors that may cause harm or illness.

Teaching Guidelines 4.1

TIPS FOR BEING AN ACTIVE PARTNER IN MANAGING YOUR HEALTH

• Become an informed consumer. Read, ask, and search.

• Know your family history and know factors that put you at high risk.

• Maintain a healthy lifestyle and let moderation be your guide.

• Schedule regular medical checkups and screenings for early detection.

• Ask your health care provider for a full explanation of any treatment.

• Seek a second medical opinion if you feel you need more information.

• Know when to seek medical care by being aware of disease symptoms.

Common reproductive issues addressed in this chapter that nurses might encounter in caring for women include menstrual disorders, infertility, contraception, abortion, and the menopausal transition.

MENSTRUAL DISORDERS

Many women sail through their monthly menstrual cycles with little or no concern. With few symptoms to worry about, their menses are like clockwork, starting and stopping at nearly the same times every month. For others, the menstrual cycle causes physical and emotional symptoms that initiate visits to their health care provider for consultation. The following menstruation-related conditions will be discussed in this section: amenorrhea, dysmenorrhea, abnormal uterine bleeding (AUB), premenstrual syndrome (PMS), premenstrual dysphoric disorder (PMDD), and endometriosis. To gain an understanding of menstrual disorders, nurses should know the terms used to describe them (Box 4.1).

BOX 4.1

MENSTRUAL DISORDER VOCABULARY

- *meno* = menstrual related
- *metro* = time
- *oligo* = few
- *a* = without, none or lack of
- *rhagia* = excess or abnormal
- *dys* = not or pain
- *rhea* = flow

Amenorrhea

Amenorrhea simply means absence of menses. Amenorrhea is normal in prepubertal, pregnant, postpartum, and postmenopausal females. The uterus, endometrial lining, ovaries, pituitary, and hypothalamus must function properly and in harmony for a menstrual cycle to occur. The two categories of amenorrhea are primary and secondary amenorrhea. Primary amenorrhea is defined as either the:

1. absence of menses by age 14, with absence of growth and development of secondary sexual characteristics; or

2. absence of menses by age 16, with normal development of secondary sexual characteristics (Schuiling & Likis, 2016).

Ninety-eight percent of girls living in the United States menstruate by age 15 (Krieger et al., 2015). Findings of recent studies indicate that age at menarche has overall declined since the twentieth century (King et al., 2015). Once menarche has occurred, cycles may take up to 2 years to become regular, ovulatory cycles. Secondary amenorrhea is the absence of regular menses for three cycles or irregular menses for 6 months in women who have previously menstruated regularly.

Nurses need to consider the causes of amenorrhea as occurring in one of the four anatomical areas: outflow area of the uterus and vagina, the ovaries, the pituitary gland, or the central nervous system. Outflow area problems are obstructive in nature and can be found on physical exam, whereas ovarian, pituitary, and central nervous system problems involve disruptions in the hypothalamic–pituitary–ovarian axis that controls the neuroendocrine processes required for a normal menstrual cycle and are generally found through laboratory analysis (King et al., 2015).

Etiology

Primary amenorrhea has multiple causes:

• Extreme weight gain or loss

• Congenital abnormalities of the reproductive system

• Stress from a major life event

- Excessive exercise
- Eating disorders (anorexia nervosa or bulimia)
- Cushing disease
- Polycystic ovary syndrome
- Hypothyroidism
- Turner syndrome—defective development of the gonads (ovary or testes)
- Imperforate hymen
- Chronic illness—diabetes, thyroid disease, depression
- Pregnancy
- Cystic fibrosis
- Congenital heart disease (cyanotic)
- Ovarian or adrenal tumors
- Causes of secondary amenorrhea can include:
- Pregnancy
- Breast-feeding
- Emotional stress
- Pituitary, ovarian, or adrenal tumors
- Depression
- Hyperthyroid or hypothyroid conditions
- Malnutrition
- Hyperprolactinemia
- Rapid weight gain or loss
- Chemotherapy or radiation therapy to the pelvic area
- Vigorous exercise, such as long-distance running
- Kidney failure
- Colitis
- Chemotherapy, irradiation
- Use of tranquilizers or antidepressants
- Postpartum pituitary necrosis (Sheehan syndrome)
- Early menopause (Kovanci & Schutt, 2015).

Therapeutic Management

Therapeutic intervention depends on the cause of the amenorrhea. The treatment of primary amenorrhea involves the correction of any underlying disorders and estrogen replacement therapy to stimulate the development of secondary sexual characteristics (Moses, 2015a). If a pituitary tumor is the cause, it might be treated with drug therapy, surgical resection, or radiation therapy. Surgery might be needed to correct any structural abnormalities of the genital tract. Dopamine agonists are effective in treating hyperprolactinemia. In most cases, this treatment restores normal ovarian endocrine function and ovulation (Goswami, 2015). Therapeutic interventions for secondary amenorrhea can include:

• cyclic progesterone, when the cause is anovulation, or **oral contraceptives** (OCs);

• bromocriptine to treat hyperprolactinemia;

• nutritional counseling to address anorexia, bulimia, or obesity;

• gonadotropin-releasing hormone (GnRH), when the cause is hypothalamic failure;

• thyroid hormone replacement, when the cause is hypothyroidism (Creatsas & Creatsa, 2015).

Nursing Assessment

Nursing assessment for the young girl or woman experiencing amenorrhea includes a thorough health history, physical examination, and several laboratory and diagnostic tests of selected hormone levels to help to identify an underlying cause.

HEALTH HISTORY AND PHYSICAL EXAMINATION

A thorough history and physical examination are needed to determine the etiology. The history should include questions about the women's menstrual history; past illnesses; hospitalizations and surgeries; obstetric history; use of prescription and over-the-counter drugs; recent or past lifestyle changes; and history of present illness, with an assessment of any body changes.

The physical examination should begin with an overall assessment of the woman's nutritional status and general health. A sensitive and gentle approach to the pelvic examination is critical in young women. Height, weight, and body

mass index (BMI) should be taken, along with vital signs. Hypothermia, bradycardia, hypotension, and reduced subcutaneous fat may be observed in women with anorexia nervosa. Facial hair and acne might be evidence of androgen excess secondary to a tumor. The presence or absence of axillary and pubic hair may indicate adrenal and ovarian hyposecretion or delayed puberty. A general physical examination may uncover unexpected findings that are indirectly related to amenorrhea. For example, hepatosplenomegaly, which may suggest a chronic systemic disease or an enlarged thyroid gland, might point to a thyroid disorder as well as a reason for amenorrhea (Tharpe, Farley, & Jordan, 2016). Examination of the breasts also deserves careful attention because breast development is a reliable indicator of estrogen production. The Tanner stages of breast development should be noted also. The Tanner stages include:

• Stage I—Papilla elevation only

• Stage II—Breast buds palpable and areolae enlarge ∼11 years old

• Stage III—Elevation of breast contour; areolae enlarge ∼12 years old

• Stage IV—Areolae forms secondary mound on the breast ∼13 years old

• Stage V—Adult breast contour; areola recesses to breast contour (Moses, 2015b)

Information gained from the history and physical exam clearly can exclude certain diagnostic possibilities, but first impressions also can be deceiving and lead to errors in judgment. A methodical, systematic approach to identify the etiology of amenorrhea is the best.

LABORATORY AND DIAGNOSTIC TESTS

Common laboratory tests that might be ordered to determine the cause of amenorrhea include:

• karyotype (might be positive for Turner syndrome);

• ultrasound to detect ovarian cysts;

• quantitative human chorionic gonadotropin (hCG) test to rule out pregnancy;

• thyroid function studies to determine thyroid disorder;

• prolactin level (an elevated level might indicate a pituitary tumor);

• follicle-stimulating hormone (FSH) level (an elevated level might indicate ovarian failure);

- luteinizing hormone (LH) level (an elevated level might indicate gonadal dysfunction);
- 17-ketosteroids (an elevated level might indicate an adrenal tumor) (Pagana, Pagana, & Pagana, 2015).

Nursing Management

Counseling and education are primary interventions and appropriate nursing roles. Address the diverse causes of amenorrhea, the relationship to sexual identity, possible infertility, and the possibility of a tumor or a life-threatening disease. Evidence is mounting that loss of menstrual regularity is a risk factor for later development of osteoporosis and hip fractures, so treatment to restore regular menstrual cycles is essential (Carlson, 2015). In addition, inform the woman about the purpose of each diagnostic test, how it is performed, and when the results will be available to discuss with her. Listening sensitively, interviewing, and presenting treatment options are paramount to gain the woman's cooperation and understanding.

Nutritional counseling is also vital in managing this disorder, especially if the woman has findings suggestive of an eating disorder. The relation between eating disorders and menstrual dysfunction has been identified in research studies. Careful evaluation of menstrual status is warranted for all women with eating disorders. Timely intervention is important because shorter duration of illness is associated with improved outcomes (Golden et al., 2015). Although not all causes can be addressed by making lifestyle changes, emphasize maintaining a healthy lifestyle (Teaching Guidelines 4.2).

Teaching Guidelines 4.2

TIPS FOR MAINTAINING A HEALTHY LIFESTYLE

- Balance energy expenditure with energy intake to maintain ideal weight range.
- Modify your diet to maintain ideal weight to avoid becoming over weight.
- Avoid excessive use of alcohol and mood-altering or sedative drugs.
- Avoid cigarette smoking to prevent cardiovascular disease and lung cancer.

- Identify areas of emotional stress and seek assistance to resolve them.
- Balance work, recreation, and rest to reduce anxiety and stress in life.
- Maintain a positive outlook regarding the diagnosis and prognosis.
- Participate in ongoing care to monitor any medical conditions.
- Maintain bone density through:
  - Calcium intake (1,200 to 1,600 mg daily)
  - Vitamin D (600 to 1,000 International Units/daily)
  - Weight-bearing exercise (30 min or more daily)
  - Hormone therapy (HT) for low risk women

Adapted from Centers for Disease Control and Prevention. (2015a). *Healthy eating for a healthy weight*. Retrieved from http://www.cdc.gov/healthyweight/healthy_eating/; and Housman, J., & Odum, M. (2016). *Alters & Schiff's essential concepts for healthy living* (7th ed.). Burlington, MA: Jones & Bartlett Learning.

Dysmenorrhea

Dysmenorrhea refers to painful menstruation and is a common problem in adolescence. This condition has also been termed *cyclic perimenstrual pain.* Usually pain starts along with the start of bleeding and lasts for 48 to 72 hours (Creatsas & Creatsa, 2015). The term *dysmenorrhea* is derived from the Greek words *dys*, meaning "difficult, painful, or abnormal," and *rrhea*, meaning "flow." Based on results of large epidemiologic studies, it is estimated that it may affect more than half of menstruating women. It is the leading cause of absenteeism of work and school, and has adverse effects on the quality of life of young women (Joshi et al.*,* 2015). Another recent research study linked early smoking (<13 years old) to an increased risk for developing chronic dysmenorrhea (Weinberger, Smith, Allen, et al., 2015). Uterine contractions occur during all periods, but in some women these cramps can be frequent and very intense. It has a major impact on women's quality of life, work productivity, and health care utilization. Dysmenorrhea is classified as primary (spasmodic) or secondary (congestive) (Calis et al., 2015).

Etiology

Primary dysmenorrhea refers to painful menstrual bleedings in the absence of any detectable underlying pathology. It is caused by increased prostaglandin production by the endometrium in an ovulatory cycle. This hormone causes contraction of the uterus, and levels tend to be higher in women with severe menstrual pain than women who experience mild or no menstrual pain. Dysmenorrhea is caused by an excess of prostaglandin production. These levels are highest during the first 2 days of menses, when symptoms peak (Maurice & Rosenzweig, 2015). This results in increased rhythmic uterine contractions from vasoconstriction of the small vessels of the uterine wall. This condition usually begins within a few years of the onset of ovulatory cycles at menarche.

Secondary dysmenorrhea is painful menstruation due to pelvic or uterine pathology. It may be caused by endometriosis, adenomyosis, fibroids, pelvic infection, an intrauterine system, cervical stenosis, or congenital uterine or vaginal abnormalities. Adenomyosis involves the ingrowth of the endometrium into the uterine musculature. Endometriosis involves ectopic implantation of endometrial tissue in other parts of the pelvis. It occurs most commonly in the

third or fourth decade of life and affects 10% of women of reproductive age. The pain tends to get worse, rather than better, over time (American College of Obstetricians & Gynecologists [ACOG], 2015a). **Endometriosis** is the most common cause of secondary dysmenorrhea and is associated with pain beyond menstruation, dyspareunia, low back pain, heavy or irregular bleeding, bloating, nausea and vomiting, and infertility (ACOG, 2015a). Treatment is directed toward removing the underlying pathology.

> *Think back to Izzy from the chapter opener. Is her pelvic pain complaint a common one with women?*

Therapeutic Management

The goal of treatment is to provide adequate pain relief to allow the woman to perform her usual activities. Current treatment is mainly based on surgery and ovarian suppressive agents (OCs, progestins, GnRh antagonist, levonorgestrel-releasing intrauterine system, and androgenic agents). Hormonal treatment is often associated with unwanted side effects and recurrence of symptoms when stopped. Severe dysmenorrhea can be distressing, adversely affecting social and occupational activities. Treatments vary from over-the-counter remedies to hormonal control. However, for some women satisfactory pain relief is difficult to achieve, and increasingly they seek alternative options. Complementary therapies such as acupuncture (needles are used to stimulate certain points of the body to balance the flow of energy within the body) and acupressure (the use of fingers and hands to stimulate acupoints and maintains the balance of energy) are gaining popularity and the evidence base for their use is growing (Wicks & Mahady, 2015).

Therapeutic intervention is directed toward pain relief and building coping strategies that will promote a productive lifestyle. General measures for management include client education and reassurance. Treatment is supportive and should be guided by individual needs. Treatment measures usually include treating infections if present; suppressing the endometrium if endometriosis is suspected by administering low-dose OCs; administering prostaglandin inhibitors to reduce the pain; administering Depo-Provera to suppress ovulation, which thins the endometrial lining of the uterus with subsequent reduction of fluid contents of the uterus during menses; and initiating lifestyle changes

(Schuiling & Likis, 2016). Table 4.1 lists selected treatment options for dysmenorrhea.

Nursing Assessment

As with any gynecologic complaint, a thorough focused history and physical examination are needed to make the diagnosis of primary or secondary dysmenorrhea. In primary dysmenorrhea, the history usually reveals the typical cramping pain with menstruation, and the physical examination is completely normal. In secondary dysmenorrhea, the history discloses cramping pain starting after 25 years old with a pelvic abnormality, a history of infertility, heavy menstrual flow, irregular cycles, and little response to nonsteroidal anti-inflammatory drugs (NSAIDs), OCs, or both (Elnashar, 2015).

HEALTH HISTORY AND CLINICAL MANIFESTATIONS

Note the past medical history, including any chronic illnesses and family history of gynecologic concerns. Determine medication and substance use, such as prescription medications, contraceptives, anabolic steroids, tobacco, and marijuana, cocaine, or other illegal drugs. A detailed sexual history is essential to assess for inflammation and scarring (adhesions) secondary to pelvic inflammatory disease (PID). Women with a previous history of PID, sexually transmitted infections (STIs), low consumption of fruits and vegetables, depression, high stress level, multiple sexual partners, or unprotected sex are at increased risk (Tharpe et al., 2016).

During the initial interview, the nurse might ask some of the following questions to assess the woman's history of dysmenorrhea:

• At what age did your menstrual cycles start?

• Have your cycles always been painful, or did the pain start recently?

• When in your cycle do you experience the pain?

• How would you describe the pain you feel?

• Are you sexually active?

• What impact does your cycle have on your physical and social activity?

• When was the first day of your last menstrual cycle?

• Was the flow of your last menstrual cycle a normal amount for you?

• Do your cycles tend to be heavy or last longer than 5 days?

- Are your cycles generally regular and predictable?
- What have you done to relieve your discomfort? Is it effective?
- Has there been a progression of symptom severity?
- Do you have any other symptoms?

Assess for clinical manifestations of dysmenorrhea. Affected women experience sharp, intermittent spasms of pain, usually in the suprapubic area. Pain may radiate to the back of the legs or the lower back. Pain usually develops within hours of the start of menstruation and peaks as the flow becomes heaviest during the first day or two of the cycle (King et al., 2015). Systemic symptoms of nausea, vomiting, diarrhea, fatigue, fever, headache, or dizziness are fairly common. Explore the history for physical symptoms of bloating, water retention, weight gain, headache, muscle aches, abdominal pain, food cravings, or breast tenderness.

TABLE 4.1 TREATMENT OPTIONS FOR DYSMENORRHEA

Therapy Options	Dosage	Comments
Nonsteroidal anti-inflammatory agents (NSAIDs)		NSAIDS prevent prostaglandin synthesis by inhibiting COX-1 and COX-2 conversion, reducing cramping.
Ibuprofen (Advil, Motrin, Midol)	400–800 mg TID	Take with meals. Do not take with aspirin.
Naproxen (Anaprox, Naprelan, Naprosyn, Aleve)	250–500 mg TID	Avoid alcohol. Watch for signs of GI bleeding. Same as above.
Hormonal contraceptives		Decrease prostaglandin synthesis; second-line treatment.
Low-dose oral contraceptives	Taken daily—extended cycle formulas (84 d on, 7 d off)	Take active pills for an extended time to reduce number of monthly cycles.
Depo-medroxyprogesterone (DMPA), Depo-Provera	150 mg IM every 12 wks	Within 9–12 mo of DMPA therapy, 75% of women will experience amenorrhea.
Levonorgestrel-releasing IUS (Mirena)	Inserted into uterine cavity and may remain for up to 5 yrs	Inhibits ovulation and decreases thickness of endometrium. Inhibits uterine contractions and reduces pain from menstrual cramps.
Selective estrogen receptor modulators (SERMS)	Used for women not responding to NSAIDS and oral contraceptives; dosage is individualized	Adverse effects include hot flashes, nausea and vomiting, and risk of thromboembolism.
Raloxifene hydrochloride (Evista); tamoxifen citrate (Nolvadex)		Research is needed to validate effectiveness, doses, side effects, and contradictions.
Complementary therapies Thiamine (vitamin B) Vitamin E (tocopherols) Magnesium Omega-3 fatty acids (fish oil)		Gives sense of control over life.
Lifestyle changes Daily exercise Limited salty foods Weight loss Smoking cessation Relaxation techniques		

Adapted from Calis, K. A., Popat, V., Dang, D. K., & Kalantaridou, S. N. (2015). Dysmenorrhea. eMedicine. Retrieved from http://emedicine.medscape.com/article/253812-overview; King, T. L., Brucker, M. C., Kriebs, J. M., Fahey, J. O., Gegor, C. L., & Varney, H. (2015). *Varney's midwifery* (5th ed.). Burlington, MA: Jones and Bartlett Learning; Schuiling, K. D., & Likis, F. E. (2016). *Women's gynecologic health* (3rd ed.). Burlington, MA: Jones & Bartlett Learning.

PHYSICAL EXAMINATION

The physical examination performed by the health care provider centers on the bimanual pelvic examination. This examination is done during the nonmenstrual phase of the cycle. Explain to the woman how it is to be performed, especially if

it is her first pelvic examination. Prepare the woman in the examining room by offering her a cover gown to put on and covering her lap with a privacy sheet on the examination table. Remain in the examining room throughout the examination to assist the health care provider with any procedures or specimens and to offer the woman reassurance.

LABORATORY AND DIAGNOSTIC TESTS

Common diagnostic tests that may be ordered to determine the cause of dysmenorrhea can include:

• complete blood count to rule out anemia;

• urinalysis to rule out a bladder infection;

• pregnancy test (hCG level) to rule out pregnancy;

• cervical culture to exclude STI;

• erythrocyte sedimentation rate to detect an inflammatory process;

• stool guaiac test to exclude gastrointestinal bleeding or disorders;

• pelvic and/or vaginal ultrasound to detect pelvic masses or cysts;

• diagnostic laparoscopy and/or laparotomy to visualize pathology that may account for the symptoms (Tharpe et al., 2016).

> *What diagnostic tests might be ordered to diagnose Izzy's pelvic pain?*

Nursing Management

Educating the client about the normal events of the menstrual cycle and the etiology of her pain is paramount in achieving a successful outcome. Explaining the normal menstrual cycle will teach the woman the correct terms to use, so she can communicate her symptoms more accurately and will help dispel myths. Provide the woman with monthly graphs or charts to record menses, the onset of pain, the timing of medication, relief afforded, and coping strategies used. This involves the woman in her care and provides objective information so that therapy can be modified if necessary.

The nurse should explain in detail the dosing regimen and the side effects of the medication therapy selected. Commonly prescribed drugs include NSAIDs such as ibuprofen (Motrin, Advil) or naproxen (Naprosyn). These drugs alleviate

dysmenorrhea symptoms by decreasing intrauterine pressure and inhibiting prostaglandin synthesis, thus reducing pain (Skidmore-Roth, 2015). The primary goal of NSAID therapy of dysmenorrhea is to preempt the production of prostaglandins; thus starting the medication prophylactically and using sufficient doses to maximally suppress prostaglandin production are essential. If pain relief is not achieved in two to four cycles, a low-dose combination OC may be initiated. Client teaching and counseling should include information about how to take pills, side effects, and danger signs to watch for.

Encourage the woman to apply a heating pad or warm compress to alleviate menstrual cramps. Additional lifestyle changes that the woman can make to restore some sense of control and active participation in her care are listed in Teaching Guidelines 4.3.

Teaching Guidelines 4.3

TIPS FOR MANAGING DYSMENORRHEA

- Exercise to increase endorphins and suppress prostaglandin release.
- Limit salty foods to prevent fluid retention.
- Increase water consumption to serve as a natural diuretic.
- Increase fiber intake with fruits and vegetables to prevent constipation.
- Use heating pads or warm baths to increase comfort.
- Take warm showers to promote relaxation.
- Sip on warm beverages, such as decaffeinated green tea.
- Keep legs elevated while lying down or lie on side with knees bent.
- Use stress management techniques to reduce emotional stress.
- Practice relaxation techniques to enhance ability to cope with pain.
- Stop smoking and decrease alcohol use which causes vasoconstriction.

Abnormal Uterine Bleeding

Disturbances of menstrual bleeding manifest in a wide range of presentations. *AUB* is the umbrella term used to describe any deviation from normal menstruation or from a normal menstrual cycle pattern. It can occur in women of any age. The key characteristics are regularity, frequency, volume or heaviness of flow, and duration of flow, but each of these may exhibit considerable variability.

AUB is a disorder that occurs most frequently in women at the beginning and end of their reproductive years. AUB is defined as a painless endometrial bleeding that is prolonged, excessive, and irregular, and not attributed to any underlying structural or systemic disease (Creatsas & Creatsa, 2015). It is frequently associated with anovulatory cycles, which are common for the first year after menarche and is associated with immaturity of the hypothalamic–pituitary–ovarian axis. It also occurs later in life as women approach menopause and experience irregular menstrual cycles.

The pathophysiology of AUB is related to a hormone disturbance. With anovulation, estrogen levels rise as usual in the early phase of the menstrual cycle. In the absence of ovulation, a corpus luteum never forms and progesterone is not produced. The endometrium moves into a hyperproliferative state, ultimately outgrowing its estrogen supply. This leads to irregular sloughing of the endometrium and excessive bleeding (King et al., 2015). If the bleeding is heavy enough and frequent enough, anemia can result. AUB is similar to several other types of uterine bleeding disorders and sometimes overlaps these conditions. They include:

• menorrhagia (abnormally long, heavy periods, prolonged bleeding);

• oligomenorrhea (bleeding occurs at intervals of more than 35 days);

• metrorrhagia (bleeding between periods, irregular bleeding);

• menometrorrhagia (excessive uterine bleeding at and between menstrual periods);

• polymenorrhea (too frequent periods).

Etiology

The possible causes of AUB may include:

• Adenomyosis

• Pregnancy

• Hormonal imbalance

• Fibroid tumors (see Chapter 7)

• Endometrial polyps or cancer

• Endometriosis

• Intrauterine systems (IUS)

• Polycystic ovary syndrome

• Morbid obesity

• Adnomyosis

• Steroid therapy

• Hypothyroidism

• Blood dyscrasias/clotting disorder

• Malignancy and hyperplasia

• Uterine polyps

Therapeutic Management

Treatment of AUB depends on the cause of the bleeding, the age of the client, and whether or not she desires future fertility. When known, the underlying cause of the disorder is treated. Otherwise, the goal of treatment is to normalize the bleeding, correct the anemia, prevent or diagnose early cancer, and restore quality of life (Schuiling & Likis, 2016).

Treatment options for AUB include combined OCs, progestogens, NSAIDS, tranexamic acid (antifibrinolytic), GnRH analogs, Danazol, and Levonorgestrel = releasing intrauterine system (LNG IUS) (Bitzer et al., 2015).

Management of AUB might include medical care with pharmacotherapy or insertion of a hormone-secreting intrauterine system. OCs are used for cycle regulation as well as for contraception. They help prevent the risks associated with prolonged, unopposed estrogen stimulation of the endometrium. NSAIDS and progestin therapy (progesterone-releasing IUS [Mirena] or Depo-Provera) decrease menstrual blood loss significantly (Skidmore-Roth, 2015). The drug categories used in the treatment of AUB are the following:

• *Estrogens*: cause vasospasm of the uterine arteries to decrease bleeding

- *Progestins*: used to stabilize an estrogen-primed endometrium
- *OCs*: regulate the cycle and suppress the endometrium
- *NSAIDs:* inhibit prostaglandins in ovulatory menstrual cycles
- *Progesterone-releasing IUSs*: suppress endometrial growth
- *Androgens*: create a high-androgen/low-estrogen environment that inhibits endometrial growth
- *Antifibrinolytic drugs*: (tranexamic acid) prevent fibrin degradation to reduce bleeding
- *Iron replacement therapy*: replenish iron stores lost during heavy bleeding

If the client does not respond to medical therapy, surgical intervention might include dilation and curettage (D&C), endometrial ablation, uterine artery embolization, or hysterectomy. Surgery should be considered in women for whom medical treatment has failed, cannot be tolerated, or is contraindicated (Kho & Mathur, 2015). Endometrial ablation is an alternative to hysterectomy, but both would be for the woman no longer desiring fertility as both procedures can cause infertility. Techniques used for ablation include laser, electrosurgery excision procedure, freezing, heated fluid infusion, or thermal balloon ablation. Most women will have reduced menstrual flow following endometrial ablation, and up to half will stop having periods. Younger women are less likely than older women to respond to endometrial ablation. Recent scientific evidence supports that up to one quarter of clients treated with endometrial ablation require repeat ablation or subsequent hysterectomy to stop AUB. Hysterectomy should be considered a last resort for AUB (ACOG, 2015b).

Nursing Assessment

A thorough history should be taken to differentiate between AUB and other conditions that might cause vaginal bleeding, such as pregnancy and pregnancy-related conditions (abruptio placentae, ectopic pregnancy, abortion, or placenta previa); systemic conditions such as Cushing disease, blood dyscrasias, liver disease, renal disease, or thyroid disease; and genital tract pathology such as infections, tumors, or trauma (Schuiling & Likis, 2016).

Assess for clinical manifestations of AUB, which commonly include vaginal bleeding between periods, irregular menstrual cycles (usually less than 28 days between cycles), infertility, mood swings, hot flashes, vaginal tenderness,

variable menstrual flow ranging from scanty to profuse, obesity, acne, stress, anorexia, thyroid disease, and diabetes. Signs of polycystic ovary syndrome might be present, because it is associated with unopposed estrogen stimulation, elevated androgen levels, and insulin resistance, and is a common cause of anovulation (Tharpe et al., 2016).

Measure orthostatic blood pressure and orthostatic pulse; a drop in pressure or pulse rate may occur with anemia. The health care provider, with the nurse assisting, performs a pelvic examination to identify any structural abnormalities.

Common diagnostic/lab tests that may be ordered to determine the cause of AUB include:

• Complete blood count to detect anemia

• Prothrombin time to detect blood dyscrasias

• Pregnancy test to rule out a spontaneous abortion or ectopic pregnancy

• Thyroid-stimulating hormone level to screen for hypothyroidism

• Transvaginal ultrasound to measure endometrium

• Pelvic ultrasound to view any structural abnormalities

• Endometrial biopsy to check for intrauterine pathology

• D&C for diagnostic evaluation

Nursing Management

Educate the client about normal menstrual cycles and the possible reasons for her abnormal pattern. Inform the woman about treatment options. Do not simply encourage the woman to "live with it." Instruct the client about any prescribed medications and potential side effects. For example, if high-dose estrogens are prescribed, the woman may experience nausea. Teach her to take antiemetics as prescribed and encourage her to eat small, frequent meals to alleviate nausea. Adequate follow-up and evaluation are essential for women who do not respond to medical management. See Nursing Care Plan 4.1: Overview of a Woman With Abnormal Uterine Bleeding.

Concept Mastery Alert

Treatments for Premenstrual Syndrome

Possible treatment options for PMS include reduction of caffeine intake, vitamin and mineral supplements, diuretic therapy, and NSAIDs. Medication therapy that has been found to be helpful for clients with PMS are antidepressants and anxiolytics. Other medications that are used are diuretics and NSAIDs.

 Take Note!

Complications such as infertility can result from lack of ovulation, severe anemia can result secondary to prolonged or heavy menses, depression and embarrassment may be secondary to the irregular and heavy bleeding, and endometrial cancer can occur associated with prolonged buildup of the endometrial lining without menstrual bleeding (Hoyt & Falconi, 2015).

Premenstrual Syndrome

PMS describes a constellation of recurrent symptoms that occur during the luteal phase or last half of the menstrual cycle and resolve with the onset of menstruation. A majority of women in their reproductive years' experience a variety of premenstrual symptoms that can alter their behavior and well-being. Women have between 400 and 500 menstrual cycles over their reproductive years, and since premenstrual distress symptoms peak during 4 to 7 days prior to menses, consistently symptomatic women may spend up to 10 years of their lives in a state of compromised physical functioning and/or psychological well-being; thus it would constitute a major health problem for women (Tacani et al., 2015). The American College of Obstetricians and Gynecologists (ACOG) defines PMS as "the cyclic occurrence of symptoms that are sufficiently severe to interfere with some aspects of life, and that appear with consistent and predictable relationship to menses" (ACOG, 2015c). A woman experiencing PMS may have a wide variety of seemingly unrelated symptoms; for that reason, it is difficult to define and more challenging to diagnose. PMS affects millions of women during their reproductive years. Approximately 80% of women will experience cyclic fluctuations in mood, sleep, and sense of well-being, related to their menstrual cycles (King et al., 2015). The exact cause of PMS is not known. It is thought to be related to the interaction between hormonal events and neurotransmitter function, specifically serotonin. Not all women respond to serotonin reuptake inhibitors (SSRIs; Prozac, Paxil, Zoloft), however, which implies that other mechanisms may be involved (Skidmore-Roth, 2015).

As defined by the American Psychiatric Association, PMDD is a more severe variant of PMS affecting 5% to 8% of premenopausal women. Experts compare the difference between PMS and PMDD to the difference between a mild tension headache and a migraine. Risk factors identified that predispose to PMS/PMDD are age between 25 and 35 years, a psychiatric history, a family history of PMDD, unhealthy living habits, and stressful life events (Santamaria & Lago, 2015). PMDD markedly interferes with work, school, social activities, and relationships with others.

Therapeutic Management

Treatment of PMS is often frustrating for both clients and health care providers.

Clinical outcomes can be expected to improve as a result of recent consensus on the diagnostic criteria for PMS and PMDD, data from clinical trials, and the availability of evidence-based clinical guidelines.

NURSING CARE PLAN 4.1

Overview of a Woman with Abnormal Uterine Bleeding

Stacy, a 52-year-old obese woman, comes to her gynecologist with the complaint of heavy erratic bleeding. Her periods were fairly regular until about 4 months ago, and since that time they have been unpredictable, excessive, and prolonged. Stacy reports she is tired all the time, can't sleep, and feels "out of sorts" and anxious. She is fearful she has cancer.

NURSING DIAGNOSIS: Fear related to current signs and symptoms possibly indicating a life-threatening condition

Outcome Identification and Evaluation
The client will acknowledge her fears as evidenced by statements made that fear and anxiety have been lessened after explanation of diagnosis.

Interventions: *Reducing Fear and Anxiety*
• Distinguish between anxiety and fear to determine appropriate interventions.
• Check complete blood count and assess for possible anemia secondary to excessive bleeding to determine if fatigue is contributing to anxiety and fear. Fatigue occurs because the oxygen-carrying capacity of the blood is reduced.
• Reassure client that symptoms can be managed to help address her current concerns.
• Provide client with factual information and explain what to expect to assist client with identifying fears and help her to cope with her condition.
• Provide symptom management to reduce concerns associated with the cause of bleeding.
• Teach client about early manifestations of fear and anxiety to aid in prompt recognition and to minimize escalation of anxiety.
• Assess client's use of coping strategies in the past and reinforce use of effective ones to help control anxiety and fear.
• Instruct client in relaxation methods, such as deep-breathing exercises and imagery, to provide her with additional methods for controlling anxiety and fear.

NURSING DIAGNOSIS: Deficient knowledge related to menopausal transition and its management

Outcome Identification and Evaluation
The client will demonstrate understanding of her symptoms as evidenced by making health-promoting lifestyle choices, verbalizing appropriate health care practices, and adhering to measures and complying with therapy.

Interventions: *Providing Client Education*
• Assess client's understanding of menopausal transition and its treatment to provide a baseline for teaching and developing a plan of care.
• Review instructions about prescribed procedures and recommendations for self-care, frequently obtaining feedback from the client to validate adequate understanding of information.
• Outline link between anovulatory cycles and excessive buildup of uterine lining in menopausal transition women to assist client in understanding the etiology of her bleeding.
• Provide written material with pictures to promote learning and help client visualize what is occurring to her body during menopausal transition.
• Inform client about the availability of community resources and make appropriate referrals as needed to provide additional education and support.
• Document details of teaching and learning to allow for continuity of care and further education, if needed.

The management of PMS or PMDD requires a multidimensional approach because these conditions are not likely to have a single cause, and they appear to affect multiple systems within a woman's body; therefore, they are not likely to be amenable to treatment with a single therapy (Naeimi, 2015). To reduce the negative impact of premenstrual disorders on a woman's life education, along with reassurance and anticipatory guidance, is needed for women to feel they have some control over their condition.

Take Note!

Because there are no diagnostic tests that can reliably determine the existence of

PMS or PMDD, the woman herself must decide that she needs help during this time of the month. The woman must embrace multiple therapies and become an active participant in her treatment plan to find the best level of symptom relief.

Therapeutic interventions for PMS and PMDD address the symptoms because the exact cause of this condition is still unknown. Treatments may include vitamin supplements, diet changes, exercise, lifestyle changes, and medications (Box 4.2). Medications used in treating PMDD may include antidepressant and antianxiety drugs, diuretics, anti-inflammatory medications, analgesics, synthetic androgen agents, OCs, or GnRH agonists to regulate menses. Unlike the approach to the treatment of depression, antidepressants need not be given daily but can be effective when used cyclically, only in the luteal phase, or even limited to the duration of the monthly symptoms.

COMPLEMENTARY AND ALTERNATIVE THERAPIES

No single treatment is universally recognized as effective, and many clients often turn to therapeutic approaches outside of conventional medicine. Many women use dietary supplements and herbal remedies for their menstrual health and treating their bleeding disorders, although there has been little research to demonstrate their efficacy. Alternative treatments for treating PMDD include calcium supplementation, vitex agnus castus (chaste tree berry), hypericum perforatum (St. John's wort), and cognitive/behavioral/relaxation therapies (Wicks & Mahady, 2015). Some other alternative therapies include the use of yoga, magnesium, vitamin B_6, evening primrose oil, vitex agnus castus, ginkgo biloba, viburnum, dandelion, stinging nettle, burdock, raspberry leaf, and skullcap (Tremellen & Pearce, 2015). Although research has not validated the efficacy of these alternative therapies, it is important for the nurse to be aware of the alternative products that many women choose to use.

BOX 4.2

TREATMENT OPTIONS FOR PMS AND PMDD

• Lifestyle changes
• Reduce stress
• Exercise three to five times each week
• Eat a balanced diet and increase water intake
• Decrease caffeine intake
• Stop smoking and limit the intake of alcohol
• Attend a PMS/women's support group
• Vitamin and mineral supplements
• Multivitamin daily
• Vitamin E, 400 units daily
• Calcium, 1,200 to 1,600 mg daily
• Magnesium, 200 to 400 mg daily
• Medications
• NSAIDs taken a week prior to menses
• OCs (low dose)
• Antidepressants (SSRIs)
• Anxiolytics (taken during luteal phase)
• Diuretics to remove excess fluid
• Progestins
• GnRH agonists
• Danazol (androgen hormone inhibits estrogen production)

T., & Aung, K. (2015). Premenstrual dysphoric disorder. *eMedicine*. Retrieved from

Nursing Assessment

Although little consensus exists in the medical literature and among researchers about what constitutes PMS and PMDD, the physical and psychological symptoms are very real. The extent to which the symptoms debilitate or incapacitate a woman is highly variable.

More than 150 symptoms are assigned to PMS, but irritability, food cravings, mood swings, tearfulness, depression, sleep disturbances, headache, back pain, fatigue, bloating, edema of the face, abdominal area, and extremities, tension, and dysphoria (a profound state of unease and anxiety) are the most prominent and consistently described (Tacani et al., 2015). To establish the diagnosis of PMS, elicit a description of cyclic symptoms occurring before the woman's menstrual period. The woman should chart her symptoms daily for two cycles. These data will help demonstrate symptoms clustering around the luteal phase of ovulation, with resolution after bleeding starts. Ask the woman to bring her list of symptoms to the next appointment. Symptoms can be categorized using the following:

• **A**—*anxiety*: difficulty sleeping, tenseness, mood swings, and clumsiness

• **C**—craving: cravings for sweets, salty foods, chocolate

• **D**—depression: feelings of low self-esteem, anger, easily upset

• **H**—hydration: weight gain, abdominal bloating, breast tenderness

• **O**—other: hot flashes or cold sweats, nausea, change in bowel habits, aches or pains, dysmenorrhea, acne breakout (Naeimi, 2015).

The ACOG diagnostic criteria for PMS consist of having at least one of the following affective and somatic symptoms during the 5 days before menses in each of the three previous cycles:

• Affective symptoms: depression, angry outbursts, irritability, anxiety

• Somatic symptoms: breast tenderness, abdominal bloating, edema, headache

• Symptoms relieved from days 4 to 13 of the menstrual cycle (ACOG, 2015c).

In PMDD, the main symptoms are mood disorders such as depression, anxiety, tension, and persistent anger or irritability. Physical symptoms such as

headache, joint and muscle pain, lack of energy, bloating, and breast tenderness are also present (Htay, 2015). It is estimated that up to 75% of reproductive-age women experience premenstrual symptoms that meet the ACOG criteria for PMS and up to 5% meet the diagnostic criteria for PMDD (Pearlstein, 2015).

According to the American Psychiatric Association, a woman must have at least five of the typical symptoms to be diagnosed with PMDD (Pearlstein, 2015). These must occur during the week before and a few days after the onset of menstruation and must include one or more of the first four symptoms:

• Affective lability: sadness, tearfulness, irritability

• Anxiety and tension

• Persistent or marked anger or irritability

• Depressed mood, feelings of hopelessness

• Difficulty concentrating

• Sleep difficulties

• Increased or decreased appetite

• Increased or decreased sexual desire

• Chronic fatigue

• Headache

• Constipation or diarrhea

• Breast swelling and tenderness (Htay, 2015).

Nursing Management

Educate the client about the management of PMS or PMDD. Advise her that lifestyle changes often result in significant symptom improvement without pharmacotherapy. Encourage women to eat a balanced diet that includes nutrient-rich foods to avoid hypoglycemia and associated mood swings. Encourage all women to participate in aerobic exercise three times a week to promote a sense of well-being, decrease fatigue, and reduce stress. Administer calcium (1,200 to 1,600 mg/day), magnesium (400 to 800 mg/day), and vitamin B$_6$ (50 to 100 mg/day) as prescribed. In some studies, these nutrients have been shown to decrease the intensity of PMS symptoms. NSAIDs may be useful for painful physical symptoms and spironolactone (Aldactone) may help with bloating and water retention. Herbs such as vitex agnus castus (chaste tree

berry), evening primrose, and SAM-e (a dietary supplement used to enhance mood) may be recommended; although not harmful, not all herbs have enough clinical or research evidence to document their safety or efficacy. Nutritional treatments include a diet low in salt, alcohol, caffeine, and sugar (Schuiling & Likis, 2016).

A recent research study proposes calcium (1,600 mg/day) and vitamin D (400 International Units/day) supplementation in adolescents and women in an effort to prevent PMS, but further research using a larger population needs to be conducted to validate this (Santamaria & Lago, 2015).

Explain to your client the relationship between cyclic estrogen fluctuation and changes in levels of serotonin levels, and how the different management strategies help maintains serotonin levels, thus improving symptoms. It is important to rule out other conditions that might cause erratic or dysphoric behavior. If the initial treatment regimen does not work, explain to the woman that she should return for further testing. Behavioral counseling and stress management might help women regain control during these stressful periods. Reassuring the woman that support and help are available through many community resources/support groups can be instrumental in her acceptance of this monthly disorder. Nurses can be a very calming force for many women experiencing PMS or PMDD. A holistic approach, including lifestyle modifications, pharmacotherapy, herbal therapies, and cognitive behavioral therapy, is most beneficial for symptom reduction, improvement in daily functioning, and quality of life. See Evidence-Based Practice 4.1.

Take Note!

Adolescents and women who experience more extensive emotional symptoms with PMS should be evaluated for PMDD, because they may require antidepressant therapy.

Endometriosis

Endometriosis is one of the most common gynecologic diseases, affecting more than 6 million women in the United States, about 10% of the adult women population (Kapoor et al., 2015). In this condition, for unknown reasons bits of functioning endometrial tissue are located outside of their normal site, the uterine cavity. This endometrial tissue is commonly found attached to the ovaries, fallopian tubes, the outer surface of the uterus, the bowels, the area between the vagina and the rectum (rectovaginal septum), and the pelvic side wall (Fig. 4.1). The places where the tissue attaches are called implants, or lesions. Endometrial tissue found outside the uterus responds to hormones released during the menstrual cycle in the same way as endometrial lining within the uterus.

EVIDENCE-BASED PRACTICE 4.1 THE EFFECT OF WHEAT GERM EXTRACT ON PREMENSTRUAL SYNDROME SYMPTOMS

STUDY

PMS is one of the most common disorders in women and impairs work and social relationships. Several treatment modalities have been proposed including herbal medicines. Herbal medicines are among the most common treatments because they are economical, safe, noninvasive, and have fewer side effects than do traditional medicines. Wheat germ contains magnesium, zinc, calcium, selenium, potassium, phosphorus, chromium, and vitamins A, E, C, B12, B6, Niacin, folic acid. Considering the properties of wheat germ, this study aimed to determine the effects of wheat germ extract on the symptoms of PMS.

Findings

This triple-blind clinical trial was conducted on 84 women that completed daily records regarding their symptoms for two consecutive months while taking 400 mg capsules of wheat germ extract or placebo three times a day from day 16 until day 5 of the next menstrual cycle. The study found that wheat germ significantly reduced the severity of physical symptoms (64%), psychological symptoms (66%), and general symptoms (65%) when compared to the placebo group within the first month of treatment. No complications were observed in either group.

Nursing Implications

Based on the study results, it seems that using wheat germ extract reduces the severity of general, psychological and physical symptoms of PMS in women that take it during their mid-cycle. Given the positive effects of taking B6 and E, calcium, and magnesium in previous studies to reduce the symptoms of PMS, it makes sense that wheat germ which contains all of the compounds listed would help relieve PMS symptoms. Nurses can suggest using nontraditional modalities to women that request them and cite this study's results to validate them.

Adapted from Ataollahi, M., Akbari, S. A. A., Mojab, F., & Alavi Majd, H. (2015). The effect of wheat germ extract on premenstrual syndrome symptoms. *Iranian Journal of Pharmaceutical Research: IJPR*, 14(1), 159–166.

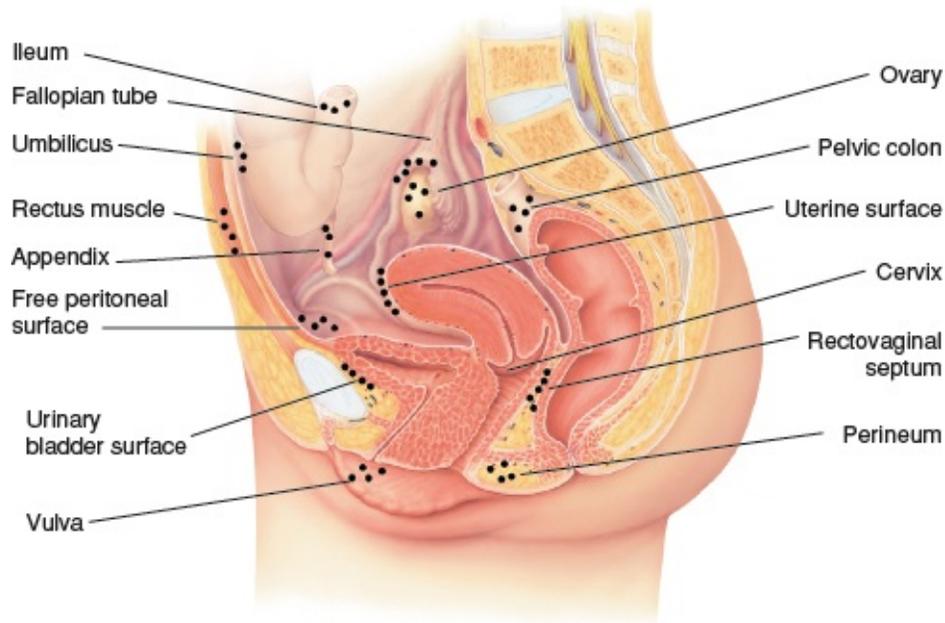
At the beginning of the menstrual cycle, when the lining of the uterus is shed and menstrual bleeding begins, these abnormally located implants swell and bleed also. In short, the woman with endometriosis experiences several "mini-periods" throughout her abdomen, wherever this endometrial tissue exists. In addition to cyclic bleeding outside the uterus, scarring, and adhesion formation throughout the pelvis occurs. Symptoms begin as early as adolescence and typically settle after menopause.


FIGURE 4.1 Common sites of endometriosis formation. (Asset provided by Anatomical Chart Co.)

Think back to Izzy, with her progressive pelvic pain and infertility concerns. After a pelvic examination, her health care provider suspects she has endometriosis.

Etiology and Risk Factors

It is not currently known why endometrial tissue becomes transplanted and grows in other parts of the body. Several theories exist, but to date none has been scientifically proven. However, several factors that increase a woman's risk of developing endometriosis have been identified:

• The aging process

• Family history of endometriosis in a first-degree relative

• Short menstrual cycle (less than 28 days)

• Long menstrual flow (more than 1 week)

• High dietary fat consumption

• Young age of menarche (younger than 12)

• Few (one or two) or no pregnancies (Johnson, Reid, & Hunter, 2015).

Therapeutic Management

Therapeutic management of the client with endometriosis needs to take into consideration the following factors: severity of symptoms, desire for fertility, degree of disease, and the client's therapy goals. The aim of therapy is to suppress levels of estrogen and progesterone, which cause the endometrium to grow. Current treatment of endometriosis is mainly based on surgery and ovarian suppressive agents (OCs, progestins, GnRh agonist and androgenic agents). Approximately only half of women with endometriosis experience pain relief from existing medial or surgical treatments (NICHD, 2015). Treatment can include surgical removal of ectopic endometrial tissue or medications such as NSAIDs, OCs, Depo-Provera, synthetic testosterone, GnRH agonists, etc. Also, alternative therapies may be used, including acupuncture and supplements of vitamins, minerals, and fish oil (Elnashar, 2015). These interventions may control symptoms initially, but many have significant adverse effects and limits on duration of therapy (Table 4.2).

Nursing Assessment

Nurses encounter women with endometriosis in a variety of settings: community health settings, schools, clinics, day surgical centers, and hospitals. Health care professionals must not trivialize or dismiss the concerns of these women, because early recognition is essential to preserve fertility. The diversity of presenting symptoms and a low index of suspicion contribute to women with endometriosis falling through the cracks and not being diagnosed promptly.

TABLE 4.2 TREATMENT OPTIONS FOR ENDOMETRIOSIS

Therapy Options	Comment
Surgical intervention	
Conservative surgery	Removal of implants/lesions using laser, cautery, or small surgical instruments. This intervention will reduce pain and allows pregnancy to occur in the future.
Definitive surgery	Abdominal hysterectomy, with or without bilateral salpingo-oophorectomy. Will eliminate pain but will leave a woman unable to become pregnant in the future.
Medication therapy	
NSAIDs	First-line treatment to reduce pain; taken early when premenstrual symptoms are first felt
Oral contraceptives	Suppresses cyclic hormonal response of the endometrial tissue
Progestogens	Used to cast off the endometrial cells and thus destroy them
Antiestrogens	Suppresses a woman's production of estrogen, thus stopping the menstrual cycle and preventing further growth of endometrium
Gonadotropin-releasing hormone analogues (GnRH-a)	Suppresses endometriosis by creating a temporary pseudomenopause

Adapted from Kapoor, D. W., Alderman, E., Hiraoka, M. K., & Davila, G. W. (2015). Endometriosis. eMedicine. Retrieved from http://emedicine.medscape.com/article/271899-overview; Elnashar, A. (2015). (2015). *Varney's midwifery* (5th ed.). Burlington, MA: Jones and Bartlett Learning.

HEALTH HISTORY

Obtain a health history and elicit a description of signs and symptoms to determine risk factors. Endometriosis is often asymptomatic, but it can be a severe and debilitating condition. It typically is chronic and progressive. Ask specifically about menarche, history of menstrual problems, details of pregnancies, and difficulties with conception. Assess the client for clinical manifestations, which include:

• Infertility

• Back pain

• Pain before and during menstrual periods

• Pain during or after sexual intercourse

• Painful urination

• Depression

• Fatigue

• Painful bowel movements

• Chronic pelvic pain

• Hypermenorrhea (heavy menses)

• Pelvic adhesions

• Irregular and more frequent menses

• Premenstrual vaginal spotting (Schuiling & Likis, 2016)

The two most common symptoms are infertility and pelvic pain. Endometriosis occurs in 38% of infertile women and in 71% to 87% of women with chronic pelvic pain (Kapoor et al., 2015). About 30% to 40% of women with this condition are infertile, making it one of the top three causes of female infertility (Brown & Farquhar, 2015).

What are the two most common symptoms experienced by women with endometriosis? Is Izzy's profile typical? As a nurse, what would be your role in Izzy's continued workup?

PHYSICAL EXAMINATION AND LABORATORY AND DIAGNOSTIC TESTS

The pelvic examination typically correlates with the extent of the endometriosis. The usual finding is nonspecific pelvic tenderness. The hallmark finding is the presence of tender nodular masses on the uterosacral ligaments, the posterior uterus, or the posterior cul-de-sac. The only definitive diagnosis is the one made during surgery (Signorile & Baldi, 2015).

After a thorough history and a pelvic examination, the health care provider may suspect endometriosis, but the only certain method of diagnosing it is by seeing it. Pelvic or transvaginal ultrasound is used to assess pelvic organ structures. However, a laparoscopy is needed to diagnose endometriosis. Laparoscopy is the direct visualization of the internal organs with a lighted instrument inserted through an abdominal incision. A tissue biopsy of the suspected implant taken at the same time and examined microscopically confirms the diagnosis.

Nurses can play a role by offering a thorough explanation of the condition and explaining why tests are needed to diagnose endometriosis. The nurse can set up appointments for imaging studies and laparoscopy.

Nursing Management

In addition to the interventions outlined above, the nurse should encourage the client to adopt healthy lifestyle habits with respect to diet, exercise, sleep, and stress management. Referrals to support groups and Internet resources can help the woman to understand this condition and to cope with chronic pain. A number of organizations provide information about the diagnosis and treatment of endometriosis and offer support to women and their families. Nurses are uniquely situated to improve client outcomes by assisting women to make informed treatment decisions. A prompt diagnosis ensures appropriate care (Box 4.3).

INFERTILITY

Infertility is defined as the inability to conceive a child after 1 year of regular sexual intercourse unprotected by contraception (RESOLVE, 2015). Secondary infertility is the inability to conceive after a previous pregnancy. Many people take the ability to conceive and produce a child for granted, but infertility affects more than 6 million Americans, or up to 20% of the reproductive-age population and as many 186 million people worldwide, according to the American Society for Reproductive Medicine (ASRM, 2015). Infertility is a widespread problem that has an emotional, social, and economic impact on couples. Although male infertility contributes to more than half of all causes, infertility remains a woman's social burden. It affects relationships, leads to tension and anger between partners, and can result in severe sexual dysfunction and breakdown of the relationship. Nurses must recognize infertility and understand its causes and treatment options so that they can help couples understand the possibilities as well as the limitations of current therapies. Nurses have a central role in supporting couples through these stressful treatments. Couples will frequently confide in their nurse and can gain great benefit from a sympathetic and sensible discussion. Recent studies have found that women wish to be treated with respect and dignity and given appropriate information and support. Infertility was once considered a disorder of inconvenience, but it is now classified as a disease in the United States Regulatory Americans with Disabilities Act (Turchi, 2015). Women want their distress recognized and they want to feel cared for and to have confidence in health care providers in situations where outcomes are uncertain. The caring aspect of professional nursing is an essential component of meeting the special needs of these couples (Whitman, 2015). Prevention of infertility through education should also be incorporated into any client–nurse interaction.

> *After completing several diagnostic tests, Izzy is diagnosed with endometriosis. She asks you about her chances of becoming pregnant and becoming pain-free. What treatment options would you explain to Izzy? What information can you give about her future childbearing ability?*

Cultural Considerations

Infertility is not only a physiologic problem, but is one that can initiate a life crisis that is experienced with psychological, familial, social, and cultural consequences. Cross-culturally, the expectation for couples to reproduce is an accepted norm and the inability to conceive may be considered a violation of this cultural norm. In this context, infertility represents a crisis for the couple. The manner in which different cultures, ethnic groups, and religious groups perceive and manage infertility may be very different. For example, many African Americans believe that assisted reproductive techniques are unnatural and that they remove the spiritual or divine nature of creation from conception. For this reason, they may seek spiritual rather than medical assistance when trying to conceive. The Hispanic culture believes that children validate the marriage, so families are typically large. Like the African-American culture, Hispanics are very spiritual and may consider infertility a test of faith and seek spiritual counseling. Disappointing one's spouse is of greater concern to African-American women, whereas avoiding the stigmatization of infertility is of greatest concern to Asian-American women (Inhorn & Patrizio, 2015).

Religion often influences cultural factors and for this reason may also be considered when pursuing treatment for infertility. In the Orthodox Jewish religion, procreation is considered to be a "mitzvah," a commandment to have children. However, even Orthodox Jews accept the use of contraceptives to prevent conception when it is not desired. Conservative and Reform Jews put no restrictions on contraception. Roman Catholics have a very restrictive view on the use of assisted reproductive technologies since in their view procreation cannot be separated from the relationship between parents. Thus, God wants human life to begin through the "conjugal act" and not artificially. Most religious teachings speak to the significance of procreation, thus infertility can impact the self and relational identities of the couple wishing to become parents. Therefore, the risk is present for both a crisis of identity and of faith (Dombo & Flood, 2015). Nurses must be cognizant of the client's cultural and religious background and how it may dictate which, if any, reproductive treatment options are chosen. Nurses need to include this awareness in their counseling of infertile couples.

Consider This

We had been married for 3 years and wanted to start a family, but much to our dismay nothing happened after a year of trying. I had some irregular periods and was finally diagnosed with endometriosis and put on Clomid for three cycles. After that time without achieving a pregnancy, I went to a fertility expert. The doctor lasered the misplaced endometriosis tissue, sent carbon dioxide through my tubes to make sure they were patent, and put me back on Clomid, but still with no luck. Finally, 2 years later, we were put on an in vitro fertilization (IVF) waiting list and prayed we would have the money for the procedure when we were chosen. By then I felt a failure as a woman. We then decided that it was more important for us to be parents than it was for me to be pregnant, so we considered adoption. We tried for another year without any results.

We went to the adoption agency to fill out the paperwork for the process to begin. Our blood was taken and we waited for an hour, wondering the whole time why it was taking so long for the results. The nurse finally appeared and handed a piece of paper to me with the word "positive" written on it. I started to cry tears of joy, for a pregnancy had started and our long journey of infertility was finally ending.

***Thoughts:** For many women the dream of having a child is not easily realized. Infertility can affect self-esteem, disrupt relationships, and result in depression. This couple experienced many years of frustration in trying to have a family. What help can be offered to couples during this time? What can be said to comfort the woman who feels she is a failure?*

Etiology and Risk Factors

Reproduction requires the interaction of the female and the male reproductive tracts, which involves (1) the release of a normal preovulatory oocyte, (2) the production of adequate spermatozoa, (3) the normal transport of the gametes to the ampullary portion of the fallopian tube (where fertilization takes place), and (4) the subsequent transport of the cleaving embryo into the endometrial cavity for implantation and development (Puscheck & Woodward, 2015).

Multiple known and unknown factors affect fertility. Female-factor infertility is detected in about 40% of cases, and male-factor infertility in about 40% of cases. The remaining 20% fall into a category of combined (both male and female factors) or unexplained infertility. In women, ovarian dysfunction (40%) and tubal/pelvic pathology (40%) are the primary contributing factors to infertility (ASRM, 2015).

Risk factors for infertility in women include:

• Overweight or underweight (can disrupt hormone function)

• Hormonal imbalances leading to irregular ovulation

• Uterine fibroids

• Tubal blockages

• Cervical stenosis

• Reduced oocyte quality

• Chromosomal abnormalities

• Congenital anomalies of the uterus

• Immune system disorders

• Chronic illnesses such as diabetes, thyroid disease, asthma

• STIs

• Ectopic pregnancy

• Age older than 27

• Endometriosis

• Turner syndrome

• Eating disorders

• History of PID

- Smoking and alcohol consumption

- Multiple miscarriages

- Menstrual abnormalities

- Exposure to chemotherapeutic agents

- Psychological stress (Senie, 2014)

   Risk factors for infertility in men include:

- Exposure to toxic substances (lead, mercury, x-rays, chemotherapy)

- Cigarette or marijuana smoke

- Heavy alcohol consumption

- Use of prescription drugs for ulcers or psoriasis

- Exposure of the genitals to high temperatures (hot tubs or saunas)

- Hernia repair

- Obesity is associated with decreased sperm quality

- Cushing syndrome

- Frequent long-distance cycling or running

- STIs

- Undescended testicles (cryptorchidism)

- Mumps after puberty (Puscheck & Woodward, 2015)

Therapeutic Management

As noted earlier, the main causes of infertility are female factor (anovulation, tubal damage, endometriosis, and ovarian failure), male factor (low or absent numbers of motile sperm in the ejaculate, and erectile dysfunction), or unexplained infertility (Jin, 2015). The test results are presented to the couple and different treatment options are suggested. The majority of infertility cases are treated with drugs or surgery. Treatment options include lifestyle changes, such as weight loss, and smoking cessation; taking clomiphene to promote ovulation; hormone injections to promote ovulation; intrauterine insemination; and *in vitro* fertilization. Various ovulation-enhancement drugs and timed intercourse might be used for the woman with ovulation problems. The woman should understand a drug's benefits and side effects before consenting to take it. Depending on the type of drug used and the dosage, some women may experience multiple births. If the woman's reproductive organs are damaged, surgery can be done to repair them. Still other couples might opt for the hi-tech approaches of artificial insemination (Fig. 4.2), IVF (Fig. 4.3), and egg donation, or they may contract for a gestational carrier or surrogate (Jin, 2015). Table 4.3 lists selected treatment options for infertility.

Nursing Assessment

Infertile couples are under tremendous pressure and often keep the problem a secret, considering it to be very personal. Couples are often beset by feelings of inadequacy and guilt, and many are subject to pressures from both family and friends. As the problem becomes more chronic, they may begin to blame one another, with consequent marital discord. Seeking help is often a very difficult step for them, and it may take a lot of courage to discuss something about which they feel deeply embarrassed or upset. The nurse working in this specialty setting must be aware of the conflict and problems couples present with and must be very sensitive to their needs.

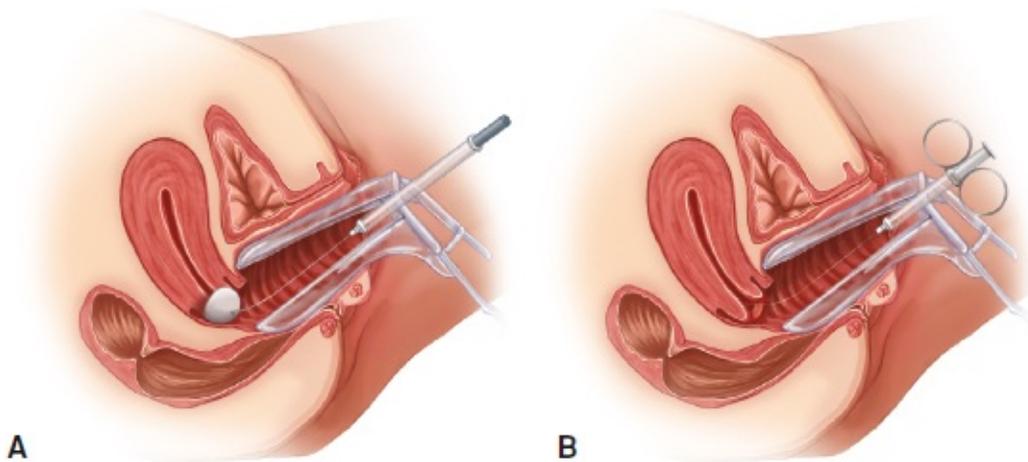
A full medical history should be taken from both partners, along with a physical examination. The data needed for the infertility evaluation are very sensitive and of a personal nature, so the nurse must use very professional interviewing skills.


FIGURE 4.2 Artificial insemination. Sperm are deposited next to the cervix (**A**) or injected directly into the uterine cavity (**B**).

Infertility has numerous causes and contributing factors, so it is important to use the process of elimination, determining what problems do not exist to better comprehend the problems that do exist. At the first visit, a plan of investigation is outlined and a complete health history is taken. This first visit forces many couples to confront the reality that their desired pregnancy may not occur naturally. Alleviate some of the anxiety associated with diagnostic testing by

explaining the timing and reasons for each test.

Assessing Male Factors

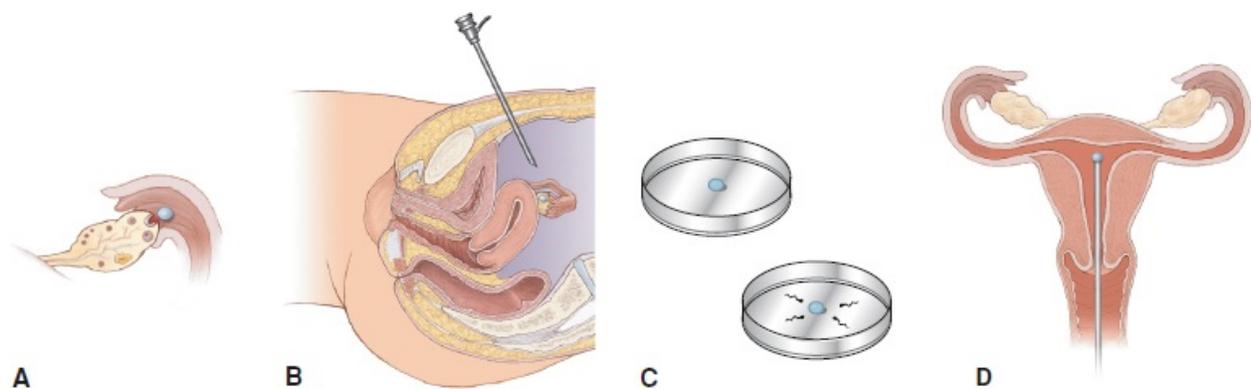
The initial screening evaluation for the male partner should include a reproductive history and a semen analysis. From the male perspective, three things must happen for conception to take place: the number of sperm must be adequate; those sperm must be healthy and mature; and the sperm must be able to penetrate and fertilize the egg. Normal males have more than 20 million sperm per milliliter with greater than 50% motility (World Health Organization [WHO], 2015). Semen analysis is the most important indicator of male fertility. The man should abstain from sexual activity for 24 to 48 hours before giving the sample. For a semen examination, the man is asked to produce a specimen by ejaculating into a specimen container and delivering it to the laboratory for analysis within 1 to 2 hours. When the specimen is brought to the laboratory, it is analyzed for volume, viscosity, number of sperm, sperm viability, motility, and sperm shape. If semen parameters are normal, no further male evaluation is necessary (Puscheck & Woodward, 2015).


FIGURE 4.3 Steps involved in vitro fertilization. **A.** Ovulation. **B.** Capture of the ova (done here intra-abdominally). **C.** Fertilization of ova and growth in culture medium. **D.** Insertion of fertilized ova into uterus.

TABLE 4.3 SELECTED TREATMENT OPTIONS FOR INFERTILITY

Procedure	Comments	Nursing Considerations
Fertility drugs		
Clomiphene citrate (Clomid)	A nonsteroidal synthetic antiestrogen used to induce ovulation. Clomid is typically discontinued after three cycles of use.	Nurse can advise the couple to have intercourse every other day for 1 wk starting after day 5 of medication.
Human menopausal gonadotropin (HMG); Pergonal	Induces ovulation by direct stimulation of ovarian follicle	Same as above
Artificial insemination	The insertion of a prepared semen sample into the cervical os or intrauterine cavityEnables sperm to be deposited closer to improve chances of conception.Husband or donor sperm can be used.	Nurse needs to advise couple that the procedure might need to be repeated if not successful the first time.
*Assisted reproductive technologies**		
In vitro fertilization (IVF)	Oocytes are fertilized in the lab and transferred to the uterus. Usually indicated for tubal obstruction, endometriosis, pelvic adhesions, and low sperm counts	Nurse advises woman to take medication to stimulate ovulation so the mature ovum can be retrieved by needle aspiration.
Gamete intrafallopian transfer (GIFT)	Oocytes and sperm are combined and immediately placed in the fallopian tube so fertilization can occur naturally. Requires laparoscopy and general anesthesia, which increases risk	Nurse needs to inform couple of risks and have consent signed.
Intracytoplasmic sperm injection (ICSI)	One sperm is injected into the cytoplasm of the oocyte to fertilize it. Indicated for male factor infertility.	Nurse needs to inform the male that sperm will be aspirated by a needle through the skin into the epididymis.
Donor oocytes or sperm	Eggs or sperm are retrieved from a donor and the eggs are inseminated; resulting embryos are transferred via IVF. Recommended for women older than 40 yrs and those with poor-quality eggs.	Nurse needs to support couple in their ethical/religious discussions prior to deciding.
Preimplantation genetic diagnosis (PGD)	Used to identify genetic defects in embryos created through IVF before pregnancy. This is done specifically when one or both genetic parents have a known genetic abnormality and testing is performed on an embryo to see if it also carries a genetic abnormality.	Nurse should inform couple about this option and support them until test results return.
Gestational carrier (surrogacy)	Laboratory fertilization takes place and embryos are transferred to the uterus of another woman, who will carry the pregnancy. Or intrauterine insemination can be done with the male sperm. Medical-legal issues have resulted over the "true ownership" of the resulting infant.	Nurse should encourage an open discussion regarding implications of this method with the couple.

*When other options have been exhausted, these are considered.

Adapted from American Society for Reproductive Medicine. (2015). Frequently asked questions about infertility. Retrieved from http://www.asrm.org/detail.aspx?id=2322; Jin, J. (2015). Treatments for infertility. *JAMA*, 313(5), 520–320; Puscheck, E. E., & Woodward, T. L. (2015). Infertility. eMedicine. Retrieved from http://emedicine.medscape.com/article/274143-overview

A recent study shows that social strain and stress are highest among couples without a clear etiology for their infertility. These findings highlight the clinically significant negative sexual, personal, and social strains of a perceived

infertility diagnosis for men (Cavallini, 2015). Nurses need to be very cognizant of this impact on males and address it.

The physical examination routinely includes:

• assessment for appropriate male sexual characteristics, such as body hair distribution, development of the Adam's apple, and muscle development;

• examination of the penis, scrotum, testicles, epididymis, and vas deferens for abnormalities (e.g., nodules, irregularities, varicocele);

• assessment for normal development of external genitalia (small testicles);

• performance of a digital internal examination of the prostate to check for tenderness or swelling (Dohle, 2015).

Assessing Female Factors

The initial assessment of the woman should include a thorough history of factors associated with ovulation and the pelvic organs. Diagnostic tests to determine female infertility may include:

• Assessment of ovarian function

• Ovulation predictor kits used midcycle

• Urinary LH level

• Clomiphene citrate challenge test

• Assessment of pelvic organs

• Papanicolaou (Pap) smear to rule out cervical cancer or inflammation

• Cervical culture to rule out any STIs

• Ultrasound to assess pelvic structures

• Hysterosalpingography to visualize structural defects

• Laparoscopy to visualize pelvic structures and diagnose endometriosis (Dadhich, Ramasamy, & Lipshultz, 2015)

Laboratory and Diagnostic Testing

The diagnostic procedures that should be done during an infertility workup should be guided by the couple's history. They generally proceed from less to more invasive tests.

HOME OVULATION PREDICTOR KITS

Home ovulation predictor kits contain monoclonal antibodies specific for LH and use the ELISA test to determine the amount of LH present in the urine. A significant color change from baseline indicates the LH surge and presumably the most fertile day of the month for the woman.

CLOMIPHENE CITRATE CHALLENGE TEST

The clomiphene citrate challenge test is used to assess a woman's ovarian reserve (ability of her eggs to become fertilized). FSH levels are drawn on cycle day 3 and on cycle day 10 after the woman has taken 100 mg clomiphene citrate on cycle days 5 through 9. If the FSH level is greater than 15, the result is considered abnormal and the likelihood of conception with her own eggs is very low (Schuiling & Likis, 2016).

HYSTEROSALPINGOGRAPHY

Hystersalpingography is the gold standard in assessing patency (being open and unobstructed) of the fallopian tubes. Fallopian tube obstruction is among the most common causes of female factor infertility. Ultrasonography and magnetic resonance imaging (MRI) are used in this assessment. In hysterosalpingography, 3 to 10 mL of an opaque contrast medium is slowly injected through a catheter into the endocervical canal so that the uterus and tubes can be visualized during fluoroscopy and radiography. If the fallopian tubes are patent, the dye will ascend upward to distend the uterus and the tubes and will spill out into the peritoneal cavity (Fig. 4.4) (Hemingway & Trew, 2015).

LAPAROSCOPY

A laparoscopy is usually performed early in the menstrual cycle. It is not part of the routine infertility evaluation. It is used when abnormalities are found on the ultrasound or the hysterosalpingogram. Because of the added risks of surgery, the need for anesthesia, and operative costs, it is only used when clearly indicated. During the procedure, an endoscope is inserted through a small incision in the anterior abdominal wall. Visualization of the peritoneal cavity in an infertile woman may reveal endometriosis, pelvic adhesions, tubal occlusion, fibroids, or polycystic ovaries (Kodaman, 2015).

Nursing Management

Nurses play an important role in the care of infertile couples. They are pivotal educators about preventive health care. A number of potentially modifiable risk factors are associated with the development of impaired fertility in women, and women need to be aware of these risks to institute change. The nurse is most effective when he or she offers care and treatment in a professional manner and regards the couple as valued and respected individuals. The nurse must be respectful of and mindful that many women may seek spiritual help for their infertility issues in addition to traditional medical modalities (King et al., 2015). The nurse's focus must encompass the whole person, not just the results of the various infertility studies. Throughout the entire process, the nurse's role is to provide information, anticipatory guidance, stress management, and counseling. The couple's emotional distress is usually very high, and the nurse must be able to recognize that anxiety and provide emotional support. The nurse may need to refer couples to a reproductive endocrinologist or surgeon, depending on the problem identified.

FIGURE 4.4 Insertion of a dye for a hysterosalpingogram. The contrast dye outlines the uterus and fallopian tubes on an x-ray to demonstrate patency.

There is no absolute way to prevent infertility per se because so many factors are involved in conception. Nurses can be instrumental in educating men and women about the factors that contribute to infertility. The nurse can also outline the risks and benefits of treatments so that the couple can make an informed decision. As couples struggle with infertility, they frequently turn to nurses for empathy, counseling, and support. By understanding the struggles and lived experiences of women and couples experiencing infertility, the nurse can tailor

his/her approach to better meet their needs so that the pregnancy and birth experience of these women are healing, transformative, and positive.

With advances in genetics and reproductive medicine also come a myriad of ethical, social, and cultural issues that will affect the couple's decisions. With this in mind, provide an opportunity for the couple to make informed decisions in a nondirective, nonjudgmental environment. It is important to encourage couples to remain optimistic throughout investigation and treatment. Through the use of advocacy and anticipatory guidance, assist and support couples through the diagnosis and treatment of infertility (Ying & Loke, 2015).

Finances and insurance coverage often dictate the choice of treatment. Help couples decipher their insurance coverage and help them weigh the costs of various procedures by explaining what each will provide in terms of their infertility problems. Assisting them to make a priority list of diagnostic tests and potential treatment options will help the couple plan their financial strategy.

Many infertile couples are not prepared for the emotional roller coaster of grief and loss that accompanies infertility treatments. Financial concerns and coping as a couple are two major areas of stress when treatment is undertaken. During the course of what may be months or even years of infertility care, it is essential to develop a holistic approach to nursing care. Stress management and anxiety reduction need to be addressed, and referral to a peer support group such as RESOLVE might be in order (Box 4.4).

BOX 4.4

ORGANIZATIONS AND WEB RESOURCES TO ASSIST THE CLIENT WITH INFERTILITY

• RESOLVE: a nationwide network of chapters dedicated to providing education, advocacy, and support for men and women facing infertility. They provide a helpline, medical referral services, and a member-to-member contact system (http://www.resolve.org).

• American Society of Reproductive Medicine (ASRM): provides fact sheets and other resources on infertility, treatments, insurance, and other issues (http://www.asrm.org).

• International Counsel on Infertility (INCIID): provides information about infertility, support forums, and a directory of infertility specialists (http://www.inciid.org).

• American Fertility Association: offers education, referrals, research, support, and advocacy for couples dealing with infertility (http://www.americaninfertility.org).

• Bertarelli Foundation—The Human Face of Infertility: aims to promote and improve understanding of infertility by offering resources (ihttp://www.bertarelli.edu).

• International Consumer Support for Infertility: an international network engaged in advocacy on behalf of infertile couples via fact sheets and information (http://www.icsi.ws).

CONTRACEPTION

Contraception is any method that prevents conception or childbirth, including OCs, sterilization of the female, and the male condom, which are the most popular methods in the United States (Alan Guttmacher Institute, 2015a). Additional types of contraceptives are discussed later in this chapter.

In the United States, there are approximately 68 million women in their childbearing years (between the ages of 15 and 44), and throughout those years a variety of contraceptive methods may be used. Studies have shown that 98% of sexually active women in the United States admit to having used at least one form of contraception; however, despite the widespread use of contraceptives, almost half of all pregnancies in the United States are unintended, accounting for a higher unintended pregnancy rate than any other Western county (Centers for Disease Control and Prevention [CDC], 2015b). As outlined in the United Nations Population Fund (UNFPA) *State of the World Population 2014 Report*, over 7 billion people inhabit the earth now and over 80 million people are added to the world each year, more than half of whom are unintended.

In addition to unwanted pregnancies, which can result in abortion, some contraceptives also help prevent transmission of STIs and human immune deficiency virus (HIV). The UNFPA report also shows that about 50,000 people in the United States become infected with HIV every year. Much of this suffering could be prevented by access to and consistent use of safe, efficient, appropriate, modern contraception for everyone who wants it, as well as proper education regarding benefits and instructions for use (UNFPA, 2015). In addition, climate change (extreme temperature changes and rising ocean levels) will interact with population growth in ways that put additional stress on already weak health systems and will exacerbate vulnerability to the adverse health effects of climate change. The damage done to the environment by modern society is perhaps one of the most inequitable health risks of our time (UNFPA 2015).

Today, the voluntary control of fertility is of vital importance to modern society. From a global perspective, countries currently face a crisis of rapid population growth that has begun to threaten human survival. At the present rate, the population of the world will double in 40 years; in several of the more socioeconomically disadvantaged countries, populations will double in less than

20 years (UNFPA 2015).

HEALTHY PEOPLE *2020* • *4.1*

Objective	Nursing Significance
FP-1 Increase the proportion of pregnancies that are intended.	Would reduce number of unplanned pregnancies and girls not finishing their education. This would in turn reduce the number of single parents on state financial assistance.
FP-2 Reduce the proportion of females experiencing pregnancy despite use of a reversible contraceptive method.	Awareness of contraceptive methods and accessibility brings about better compliance and prevention of unintended pregnancies.
FP-3 Increase the proportion of publicly funded family planning clinics that offer the full range of FDA-approved methods of contraception, including emergency contraception, on site.	Would increase accessibility to contraception and prevent unintended pregnancies.
FP-7 Increase the proportion of sexually active persons who received reproductive health services.	Accessibility of reproductive resources can offer pregnancy prevention and preventive education.

Healthy People objectives based on data from http://www.healthypeople.gov

Types of Contraceptive Methods

Contraceptive methods can be divided into four types: behavioral methods, barrier methods, hormonal methods, and permanent methods. Women must decide which method is appropriate for them to meet their changing contraceptive needs throughout their life cycles. Nurses can educate and assist women during this selection process. This part of the chapter will outline the most common birth control methods available.

In an era when many women wish to delay pregnancy and avoid STIs, choices are difficult. Numerous methods of contraception are available today, and many more will be offered in the near future. The ideal contraceptive method for many women would have the following characteristics: ease of use, safety, effectiveness, minimal side effects, "naturalness," nonhormonal method, and immediate reversibility (Samra-Latif & Wood, 2015). Currently, no one contraceptive method offers everything. Box 4.5 outlines the contraceptive methods available today. Table 4.4 provides a detailed summary of each type, including information on failure rates, advantages, disadvantages, STI protection, and danger signs.

BOX 4.5

OUTLINE OF CONTRACEPTIVE METHODS

Reversible Methods

- Behavioral
  - Abstinence
  - Fertility awareness–based methods (FAMs)
  - Withdrawal (coitus interruptus)
  - Lactational amenorrhea method (LAM)
- Barrier
  - Condom (male and female)
  - Diaphragm
  - Cervical cap
  - Sponge
- Hormonal
  - OC
  - Injectable contraceptive
  - Transdermal patch
  - Vaginal ring
  - Implantable contraceptive
  - Intrauterine contraceptive
  - Emergency contraceptive

<div style="border:1px solid green;">

Permanent Methods

• Tubal ligation or Essure for women

• Vasectomy for men

</div>

TABLE 4.4 E SUMMARY OF CONTRACEPTIVE METHODS

Type	Description	Failure Rate	Pros	Cons	STI Protection	Danger Signs	Comments
Abstinence	Refrain from sexual activity	None	Costs nothing	Difficult to maintain	100%	None	Must be joint couple decision.
Fertility awareness–based methods	Refrain from sex during fertile period	25%	No side effects; acceptable to most religious groups	High failure rate with incorrect use	None	None	Requires high level of couple commitment.
Withdrawal (coitus interruptus)	Man withdraws before ejaculation	27%	Involves no devices and is always available	Requires considerable self-control by the man	None	None	Places woman in trusting and dependent role.
Lactational amenorrhea method (LAM)	Uses lactational infertility for protection from pregnancy	1%–2% chance of pregnancy in first 6 mo	No cost; not coitus linked	Temporary method; effective for only 6 mo after giving birth	None	None	Mother must breast-feed infant on demand without supplementation for 6 mo.
Male condom	Thin sheath placed over an erect penis, blocking sperm	15%	Widely available; low cost; physiologically safe	Decreased sensation for man; interferes with sexual spontaneity; breakage risk	Provides protection against STIs	Latex allergy	Couple must be instructed on proper use of condom.
Female condom	Polyurethane sheath inserted vaginally to block sperm	21%	Use controlled by woman; eliminates postcoital drainage of semen	Expensive for frequent use; cumbersome; noisy during sex act; for single use only	Provides protection against STIs	Allergy to polyurethane	Couple must be instructed on proper use of condom.
Diaphragm with spermicide	Shallow latex cup with spring mechanism in its rim to hold it in place in the vagina	16%	Does not use hormone; considered medically safe; provides some protection against cervical cancer	Requires accurate fitting by health care professional; increase in UTIs	None	Allergy to latex, rubber, polyurethane, or spermicide Report symptoms of toxic shock syndrome May become dislodged in female superior position	Woman must be taught to insert and remove diaphragm correctly.

Cervical cap with spermicide	Soft cup-shaped latex device that fits over base of cervix	24%	No use of hormones; provides continuous protection while in place	Requires accurate fitting by health care professional; odor may occur if left in too long	None	Irritation, allergic reaction; abnormal Pap test; risk of toxic shock syndrome	Instructions on insertion and removal must be understood by client.
Sponge with spermicide	Disk-shaped polyurethane device containing a spermicide that is activated by wetting it with water	25%	Offers immediate and continuous protection for 24 hr; OTC	Can fall out of vagina with voiding; is not form fitting in the vagina	None	Irritation, allergic reactions; toxic shock syndrome can occur if sponge left in too long	Caution woman not to leave sponge in beyond 24 hr.
Oral contraceptives (combination)	A pill that suppresses ovulation by combined action of estrogen and progestin	8%	Easy to use; high rate of effectiveness; protection against ovarian and endometrial cancer	User must remember to take pill daily; possible undesirable side effects; high cost for some women; prescription needed	None	Dizziness, nausea, mood changes, high blood pressure, blood clots, heart attacks, strokes	Each woman must be assessed thoroughly to make sure she is not a smoker and does not have a history of thromboembolic disease.
Oral contraceptives (progestin-only minipills)	A pill containing only progestin that thickens cervical mucus to prevent sperm from penetrating	8%	No estrogen-related side effects; may be used by lactating women; may be used by women with history of thrombophlebitis	Must be taken with meticulous accuracy; may cause irregular bleeding; less effective than combination pills	None	Irregular bleeding, weight gain, increased incidence of ectopic pregnancy	Women should be screened for history of functional ovarian cysts, previous ectopic pregnancy, and hyperlipidemia prior to giving prescription.
Patch (Ortho Evra)	Transdermal patch that releases estrogen and progestin into circulation	8%	Easy system to remember; very effective	May cause skin irritation where it is placed; may fall off and not be noticed and thus provide no protection	None	Less effective in women weighing more than 200 pounds	Instruct woman to apply patch every week for 3 wks and then not to wear one during week 4.

Ring (NuvaRing)	Vaginal contraceptive ring about 2 inches in diameter that is inserted into the vagina; releases estrogen and progestin	8%	Easy system to remember; very effective	May cause a vaginal discharge; can be expelled without noticing and not offer protection	None	Similar to oral contraceptives	Instruct woman to use a backup method if ring is expelled and remains out for more than 3 hr.
Depo-Provera injection	An injectable progestin that inhibits ovulation	3%	Long duration of action (3 mo); highly effective; estrogen-free; may be used by smokers; can be used by lactating women	Menstrual irregularities; return visit needed every 12 wks; weight gain, headaches, depression; return to fertility delayed up to 12 mo	None	If depression is a problem, this method may increase the depression.	Inform woman that fertility is delayed after stopping the injections.
Implant (Nexplanon)	A time-release implant (one rod) of levonorgestrel for 3 yrs	0.05%	Long duration of action; low dose of hormones; reversible; estrogen-free	Irregular bleeding; weight gain; breast tenderness; headaches; difficulty in removal	None	If bleeding is heavy, anemia may occur.	Before insertion, assess woman to make sure she is aware that this method will produce about 3 years of infertility.
Intrauterine contraceptives (IUCs)	A T-shaped device inserted into the uterus that releases copper or progesterone or levonorgestrel	1%	It is immediately and highly effective; allows for sexual spontaneity; can be used during lactation; return to fertility not impaired; requires no motivation by the user after insertion	Insertion requires a skilled professional; menstrual irregularities; prolonged amenorrhea; can be unknowingly expelled; may increase the risk of pelvic infection; user must regularly check string for placement; no protection against STIs; delay of fertility after discontinuing for possibly 6–12 mo	None	Cramps, bleeding, pelvic inflammatory disease; infertility; perforation of the uterus	Instruct woman how to locate string to check monthly for placement.

Postcoital emergency contraceptives (ECs)	Combination of levonorgestrel-only pills; combined estrogen and progestin pills; or the copper IUS inserted within 72 hr after unprotected intercourse	80%	Provides a last chance to prevent a pregnancy	Risk of ectopic pregnancy if EC fails	None	Nausea, vomiting, abdominal pain, fatigue, headache	Inform woman that ECs do not interrupt an established pregnancy, and the sooner they are taken the more effective they are.
Permanent sterilization							
Male	Sealing, tying, or cutting the vas deferens	<1%	One-time decision provides permanent sterility; short recovery time; low long-term risks	Procedures are difficult to reverse; initial cost may be high; chance of regret; some pain/discomfort after procedures	None for both	Postoperative complications: pain, bleeding, infection	Counsel both as to permanence of procedure and urge them to think it through prior to signing consent.
Female	Fallopian tubes are blocked to prevent conception	<1%

E. (2016). *Women's gynecologic health* (3rd ed.). Burlington, MA: Jones & Bartlett Learning.

Sexual Abstinence

Sexual abstinence (not having vaginal or anal intercourse) is one of the least

expensive forms of contraception and has been used for thousands of years. Basically, pregnancy cannot occur if sperm is kept out of the vagina. It also reduces the risk of contracting HIV/AIDS and other STIs, unless body fluids are exchanged through oral sex; however, some infections, like herpes and human papilloma virus (HPV), can be passed by skin-to-skin contact. Dental dams can be used to prevent transmission, however. There are many pleasurable options for sex play without intercourse ("outercourse"), such as kissing, masturbation, erotic massage, sexual fantasy, sex toys such as vibrators, and oral sex.

Many people have strong feelings about abstinence based on religious and moral beliefs. There are many good and personal reasons to choose abstinence. For some it is a way of life, whereas for others it is a temporary choice. Some people choose sexual abstinence because they want to:

• wait until they are older;

• wait for a long-term relationship;

• avoid pregnancy or STIs;

• relieve feelings of depression or anxiety;

• follow religious or cultural expectations.

Fertility Awareness–Based Methods

Fertility awareness refers to any natural contraceptive method that does not require hormones, pharmaceutical compounds, physical barriers, or surgery to prevent pregnancy. FAMs use physical signs and symptoms that change with hormone fluctuations throughout a woman's menstrual cycle to predict a woman's fertility. Ovulation occurs on one day during each menstrual cycle, and the several days preceding ovulation are when intercourse is most likely to result in pregnancy. Collectively, the potentially fertile days up to and including the day of ovulation are called the "fertile window." Awareness of fertility is a better fertility-producing method than contraceptives. Less than 1% of women in the United States who use contraception employ these methods (King et al., 2015). The unifying theme of FAMs is that a woman can reduce her chance of pregnancy by abstaining from coitus or using barrier methods during times of fertility. These methods require couples to take an active role in preventing pregnancy through their sexual behaviors and women need to have regular menstrual cycles for it to be effective. Couples agree to practice certain techniques, use calculations, and be observant of the "fertile" and the "safe"

periods in a monthly menstrual cycle. Using these methods for birth control requires a strong commitment from both partners. The normal physiologic changes caused by hormonal fluctuations during the menstrual cycle can be observed and charted. This information can then be used to avoid or promote pregnancy. Fertility awareness methods rely on the following assumptions:

- A single ovum is released from the ovary 14 days before the next menstrual period. It lives approximately 24 hours.
- Women using this method must have regular menstrual cycles for it to be effective.
- Sperm can live up to 5 days after intercourse. The "unsafe period" during the menstrual cycle is thus approximately 6 days: 3 days before and 3 days after ovulation. Because body changes start to occur before ovulation, the woman can become aware of them and not have intercourse on these days or use another method to prevent pregnancy.
- The exact time of ovulation cannot be determined, so 2 to 3 days are added to the beginning and end to avoid pregnancy.

Techniques used to determine fertility include the cervical mucus ovulation method, the basal body temperature (BBT) method, the symptothermal method, standard day's method, and two-day method (Everett, 2014). Fertility awareness methods are moderately effective but are very unforgiving if not carried out as prescribed. Fertility awareness can be used in combination with coital abstinence or barrier methods during fertile days if pregnancy is not desired.

CERVICAL MUCUS OVULATION METHOD

Cervical mucus is a jellylike vaginal discharge that comes from the cervix. The **cervical mucus ovulation method** is used to assess the character of the cervical mucus. Cervical mucus changes in consistency during the menstrual cycle and plays a vital role in fertilization of the egg. Studies conducted by the WHO indicate that 93% of women, regardless of their education level, are capable of identifying and distinguishing fertile and infertile cervical secretions (Planned Parenthood, 2015a). In the days preceding ovulation, fertile cervical mucus helps draw sperm up and into the fallopian tubes, where fertilization usually takes place. It also helps maintain the survival of sperm. As ovulation approaches, the mucus becomes more abundant, clear, slippery, and smooth; it can be stretched between two fingers without breaking. Under the influence of estrogen, this

mucus looks like egg whites. It is called *spinnbarkeit* mucus (Fig. 4.5). After ovulation, the cervical mucus becomes thick and dry under the influence of progesterone.

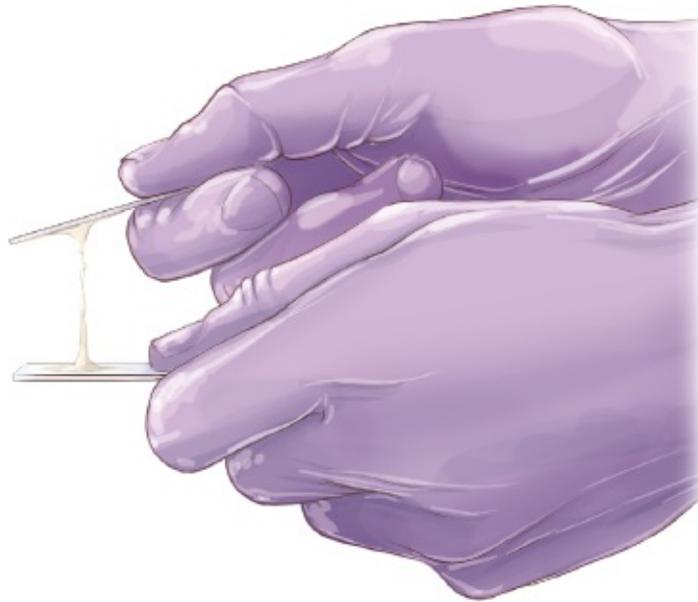
The cervical position can also be assessed to confirm changes in the cervical mucus at ovulation. Near ovulation, the cervix feels soft and is high/deep in the vagina, the os is slightly open, and the cervical mucus is copious and slippery (Bieber et al, 2015). This method works because the woman becomes aware of her body changes that accompany ovulation. When she notices them, she abstains from sexual intercourse or uses another method to prevent pregnancy. Each woman is an individual, so each woman's unsafe time of the month is unique and thus must be individually assessed and determined.


FIGURE 4.5 Spinnbarkeit mucus is cervical mucus that can stretch a distance before breaking.

BASAL BODY TEMPERATURE METHOD

The **BBT** refers to the lowest temperature reached on awakening. The woman takes her temperature orally before rising and records it on a chart. Preovulation temperatures are suppressed by estrogen, whereas postovulation temperatures are increased under the influence of heat-inducing progesterone. Temperatures typically rise within a day or two after ovulation and remain elevated for approximately 2 weeks (at which point bleeding usually begins). If using this method by itself, the woman should avoid unprotected intercourse until the BBT has been elevated for 3 days. Nurses should instruct women using the BBT

method that it is important to keep in mind that illness and any drugs, including alcohol, can raise their body temperature and give a false reading. Other fertility awareness methods should be used along with BBT for better results (Fig. 4.6).

SYMPTOTHERMAL METHOD

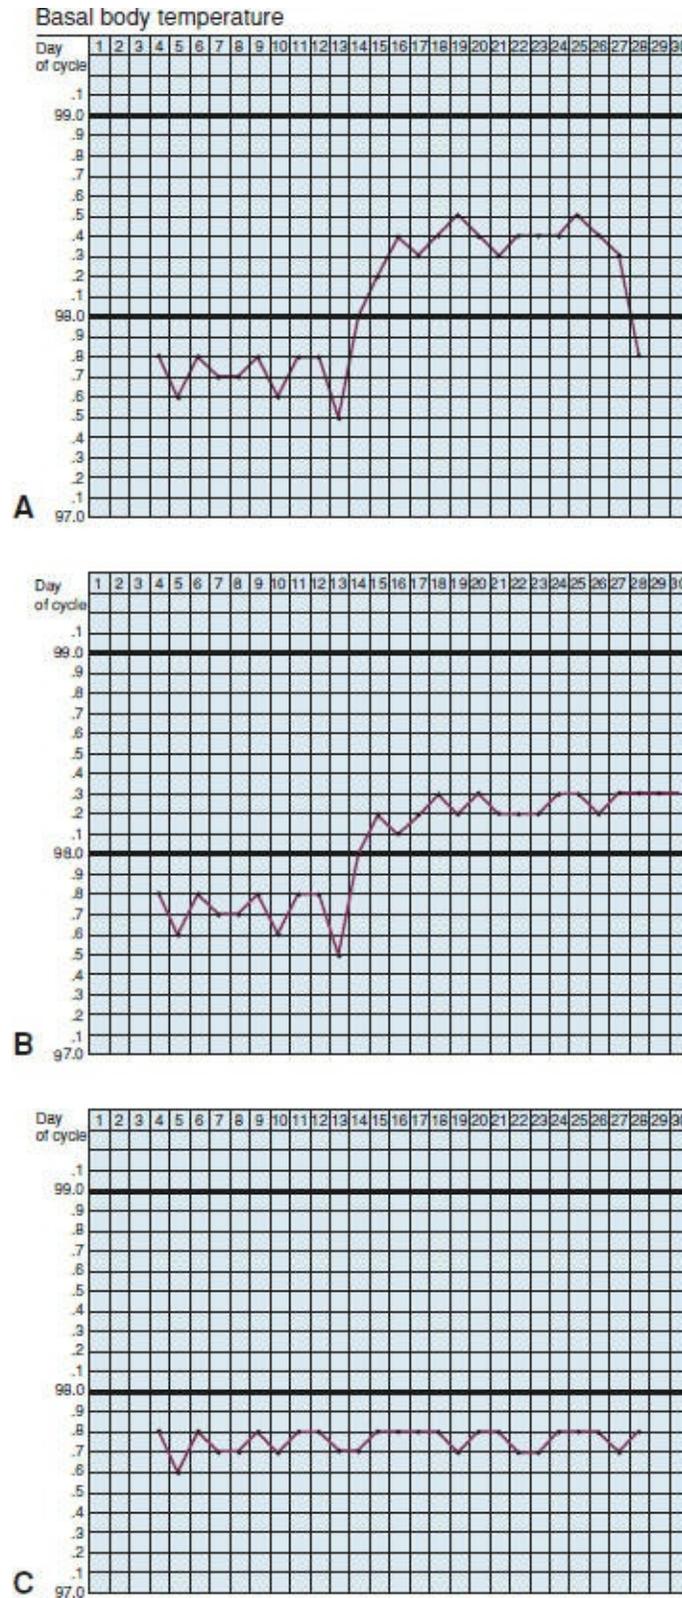
The **symptothermal method** relies on a combination of techniques to recognize ovulation, including BBT, cervical mucus changes, alterations in the position and firmness of the cervix, and other symptoms of ovulation, such as increased libido, *mittelschmerz* (midcycle, lower abdominal pain at ovulation), pelvic fullness or tenderness, and breast tenderness (Planned Parenthood, 2015a). Combining all these predictors increases the awareness of when ovulation occurs and increases the effectiveness of this method. A home predictor test for ovulation is also available in most pharmacies. It measures LH levels to pinpoint the day before or the day of ovulation. These tests are widely used for fertility and infertility regimens.


FIGURE 4.6 Basal body temperature graph. **A.** The woman's temperature dips slightly at midpoint in the menstrual cycle, then rises sharply, an indication of ovulation. Toward the end of the cycle (the 24th day),

her temperature begins to decline, indicating that progesterone levels are falling and that she did not conceive. **B.** The woman's temperature rises at the midpoint in the cycle and remains at that elevated level past the time of her normal menstrual flow, suggesting that pregnancy has occurred. **C.** There is no preovulatory dip and no rise of temperature anywhere during the cycle. This is the typical pattern of a woman who does not ovulate.

THE STANDARD DAYS METHOD AND THE TWO-DAY METHOD

The **Standard Days Method** (SDM) and the Two-Day Method are both natural methods of contraception developed by Georgetown University Medical Center's Institute for Reproductive Health. Both methods provide women with simple, clear instructions for identifying fertile days. Women with menstrual cycles between 26 and 32 days long can use the SDM to prevent pregnancy by avoiding unprotected intercourse on days 8 through 19 of their cycles. Most SDM users utilize a visual aid—CycleBeads—to assist their correct use of SDM. An international clinical trial of the SDM showed that the method is more than 95% effective when used correctly (Wright, Iqteit, & Hardee, 2015). SDM identifies the 12-day "fertile window" of a woman's menstrual cycle. These 12 days takes into account the life span of the women's egg (about 24 hours) and the viability of the sperm (about 5 days) as well as the variation in the actual timing of ovulation from one cycle to another. For the Two-Day Method, women observe the presence or absence of cervical secretions by examining toilet paper or underwear or by monitoring their physical sensations. Every day, the woman asks two simple questions: "Did I note any secretions yesterday?" and "Did I note any secretions today?" If the answer to either question is yes, she considers herself fertile and avoids unprotected intercourse. If the answers are no, she is unlikely to become pregnant from unprotected intercourse on that day (King et al., 2015).

To help women keep track of the days on which they should avoid unprotected intercourse, a string of 32 color-coded beads (CycleBeads) is used, with each bead representing a day of the menstrual cycle. Starting with the red bead, which represents the first day of her menstrual period, the woman moves a small rubber ring one bead each day. The brown beads are the days when pregnancy is unlikely, and the white beads represent her fertile days (Stanford, 2015). This method has been used in underdeveloped countries for women with limited educational resources (Fig. 4.7).

Withdrawal (Coitus Interruptus)

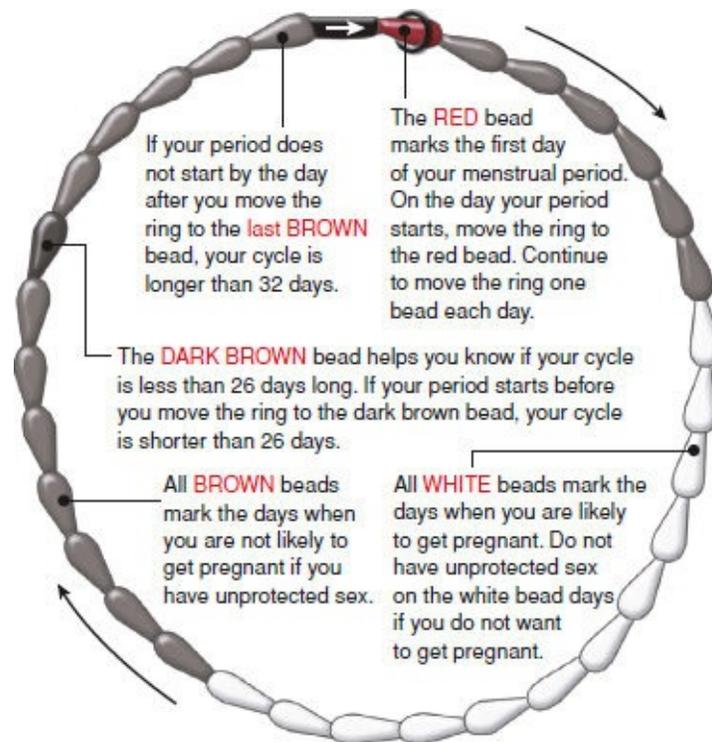
In **coitus interruptus**, also known as withdrawal, a man controls his ejaculation during sexual intercourse and ejaculates outside the vagina. It is better known colloquially as "pulling out in time" or "being careful." It is one of the oldest and most widely used means of preventing pregnancy in the world and also one of the least effective methods in preventing pregnancy (Creatsas, 2015). The problem with this method is that the first few drops of the true ejaculate contain the greatest concentration of sperm, and if some pre-ejaculatory fluid escapes from the urethra before orgasm, conception may result. This method requires that the woman rely solely on the cooperation and judgment of the man. Nurses might wish to discuss emergency contraceptives be available with this couple or use a more effective method of contraception.


FIGURE 4.7 CycleBeads help women use the Standard Days Method.

Lactational Amenorrhea Method

The **LAM** is an effective temporary method of contraception used by breast-feeding mothers. It relies on physiologic changes associated with breast-feeding for contraception. Continuous breast-feeding usually can postpone ovulation and thus prevent pregnancy. Breast-feeding stimulates the hormone prolactin, which is necessary for milk production, and also inhibits the release of another

hormone, gonadotropin, which is necessary for ovulation.

Breast-feeding as a contraceptive method can be fairly effective for up to 6 months after giving birth only if:

• a woman has not had a period since she gave birth;

• infant is younger than 6 months of age;

• the woman breast-feeds her baby at least six times daily on both breasts;

• she breast-feeds her baby "on demand" at least every 4 hours;

• a woman does not substitute other foods for a breast-milk meal;

• nighttime feedings are provided at least every 6 hours.

Also, pumping or manual expression of milk may reduce effectiveness. Do not rely on this method after 6 months (Planned Parenthood, 2015a).

Nurses can help couples to make a decision about family planning options available in the postpartum period by discussing the advantages and disadvantages of each, taking into consideration the demands of the postpartum period. The options they may consider include lactational amenorrhea, combined oral contraception, implants, intrauterine systems, injectable methods, barrier methods, emergency contraception, and sterilization (Hughes, 2015).

Barrier Methods

Barrier contraceptives are forms of birth control that prevent pregnancy by preventing the sperm from reaching the ovum. Mechanical barriers include condoms, diaphragms, cervical caps, and sponges. These devices are placed over the penis or cervix to physically obstruct the passage of sperm through the cervix. Chemical barriers called spermicides may be used along with mechanical barrier devices. They come in creams, jellies, foam, suppositories, and vaginal films. They chemically destroy the sperm in the vagina. These contraceptives are called barrier methods because they not only provide a physical barrier for sperm, but also protect against STIs. Since the HIV/AIDS epidemic started in the early 1980s, these methods have become extremely popular. Progress has been made in society's reaction to condom use as a disease prevention device now and not just as a contraceptive (Haddad, Philpott-Jones, & Schonfeld, 2015).

Many of these barrier methods contain latex. Allergy to latex was first recognized in the late 1970s, and since then it has become a major health concern, with increasing numbers of people affected. According to the American

Academy of Allergy, Asthma and Immunology (AAAAI) (2015), 6% of the general population, 10% of health care workers, and 50% of spina bifida clients are sensitive to natural rubber latex. Health care workers in both the medical and dental environments, as well as specific groups of individuals including those with spina bifida, myelodysplasia, and food allergies (banana, kiwi, avocado, and others), are at increased risk of sensitization (Kim, 2015). Teaching Guidelines 4.4 provides tips for individuals with latex allergy.

 Teaching Guidelines 4.4

TIPS FOR INDIVIDUALS ALLERGIC TO LATEX

Symptoms of latex allergy include:

• Skin rash, itching, hives.

• Itching or burning eyes.

• Swollen mucous membranes in the genitals.

• Shortness of breath, difficulty breathing, wheezing.

• Anaphylactic shock.

• Use of or contact with latex condoms, cervical caps, and diaphragms is contraindicated for men and women with a latex allergy.

• If the female partner is allergic to latex, have the male partner apply a natural condom over the latex one.

• If the male partner experiences penile irritation after condom use, try different brands or place the latex condom over a natural condom.

• Use polyurethane condoms rather than latex ones.

• Use female condoms; they are made of polyurethane.

• Switch to another birth control method that isn't made with latex, such as OCs, intrauterine systems, Depo-Provera, fertility awareness, and other nonbarrier methods. However, these methods do not protect against STIs.

CONDOMS

Condoms are barrier methods of contraceptives made for both males and females. The male condom is made from latex or polyurethane or natural membrane and may be coated with spermicide. Male condoms are available in many colors, textures, sizes, shapes, and thicknesses. When used correctly, the male condom is put on over an erect penis before it enters the vagina and is worn throughout sexual intercourse (Fig. 4.8). It serves as a barrier to pregnancy by trapping seminal fluid and sperm and offers protection against STIs. Condoms are not perfect barriers, however, because breakage and slippage can occur. Emergency postcoital contraception may need to be sought to prevent a pregnancy. In addition, the nonlatex condoms have a higher risk of pregnancy and STIs than latex condoms (Everett, 2014).

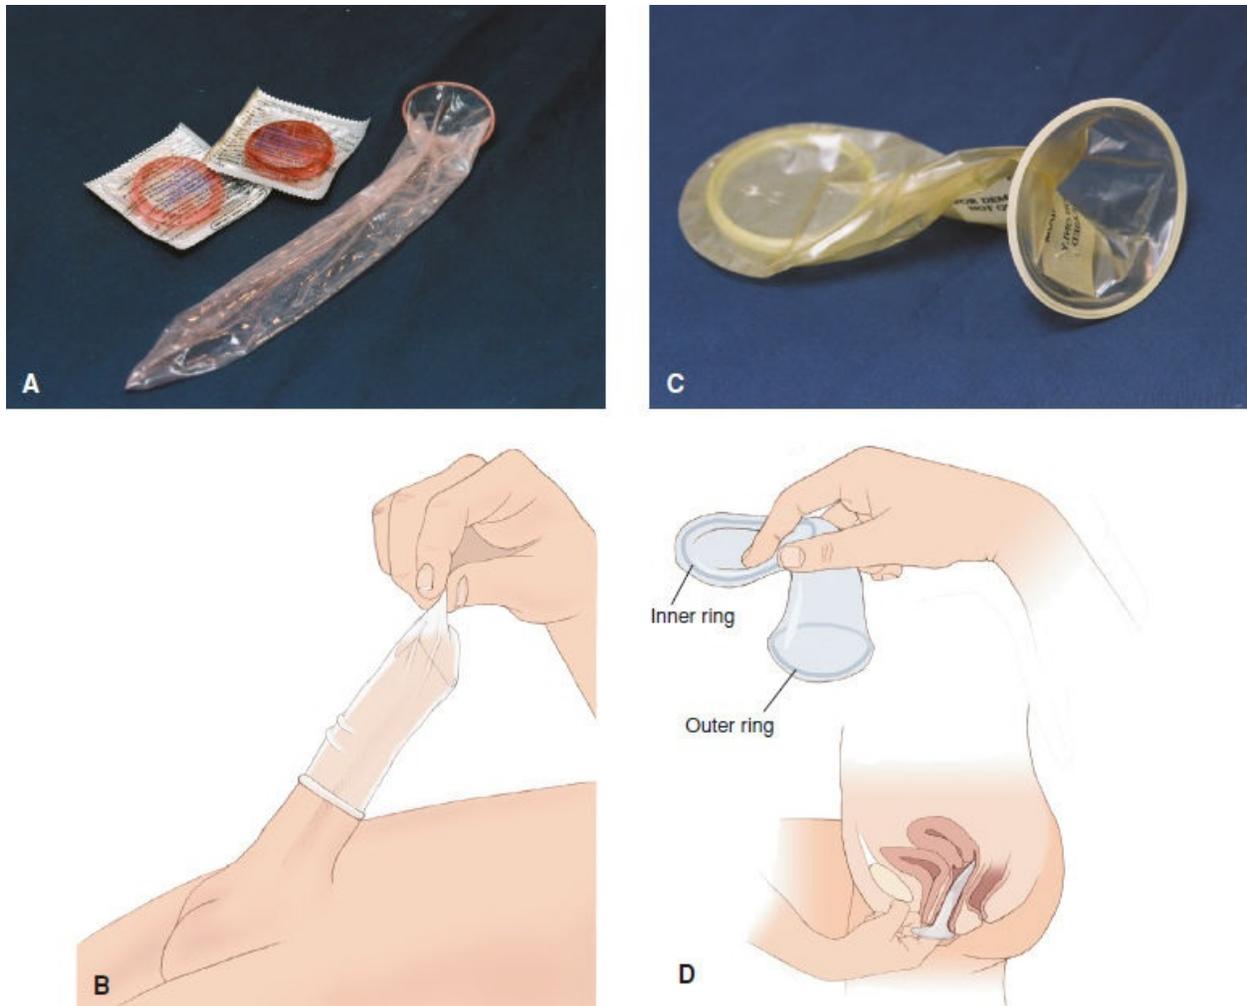
The female condom is a polyurethane pouch inserted into the vagina. It consists of an outer and inner ring that is inserted vaginally and held in place by the pubic bone. Some women complain that the female condom is cumbersome to use and makes noise during intercourse. Female condoms are readily available, are inexpensive, and can be carried inconspicuously by the woman. The female condom was the first woman-controlled method that offered protection against pregnancy and some STIs. Nurses can play a key role in educating clients on how to initiate and maintain use of the female condom, an underused method for HIV/STI and pregnancy prevention in the United States. Providing a brief education session along with free samples would go a long way to promote increased use of this device to prevent STIs transmission as well as pregnancy (Boyd et al., 2015).


FIGURE 4.8 A. Male condom. **B.** Applying a male condom. Leaving space at the tip helps to ensure the condom will not break with ejaculation. **C.** The female condom. **D.** Insertion technique.

DIAPHRAGM

The **diaphragm** is a soft latex dome surrounded by a metal spring. Used in conjunction with a spermicidal jelly or cream, it is inserted into the vagina to cover the cervix (Fig. 4.9). The diaphragm may be inserted up to 4 hours before intercourse but must be left in place for at least 6 hours afterwards. Diaphragms are available in a range of sizes and styles. The diaphragm is available only by prescription and must be professionally fitted by a health care provider. Women may need to be refitted with a different-sized diaphragm after pregnancy, abdominal or pelvic surgery, or weight loss or gain of 10 pounds or more. As a general rule, diaphragms should be replaced every 1 to 2 years. Recently, a single-size diaphragm used with contraceptive jelly was introduced and studied

for its effectiveness. The single-size diaphragm was deemed safe and as effective as a standard individually fitted one based on a population sample of >400 women that participated in the research study (Schwartz et al., 2015). The diaphragm provides both a physical and chemical barrier to sperm (Tharpe et al., 2016).

FIGURE 4.9 Sample diaphragm used for measuring.

Diaphragms are user-controlled, nonhormonal methods that are needed only at the time of intercourse, but they are not effective unless used correctly. Women need to receive thorough instruction about diaphragm use and should practice putting one in and taking it out before they leave the health care office (Fig. 4.10).

Results of a two-year multisite study indicate that the effectiveness rates of the SILCS single-size, contoured diaphragm are similar to those of traditional diaphragms, but they also provide a long-term controlled release of the lead

candidate anti-HIV microbicide dapivirine. This would make it a new multipurpose prevention device (Schwartz et al., 2015). The biggest difference with this new device is that since it is a single size, a pelvic exam to assess size is not required, and it also releases an anti-HIV microbicide that potentially is capable of preventing HIV transmission. Most women in the study were able to correctly insert, remove, and check correct position of the device by simply using the instructions (Schwartz et al., 2015).

CERVICAL CAP

The **cervical cap** is smaller than the diaphragm and covers only the cervix; it is held in place by suction. Caps are made from silicone or latex and are used with spermicide (Fig. 4.11). The FemCap is the only cervical cap device currently available in the United States and comes in three sizes (Planned Parenthood, 2016). The cap may be inserted up to 36 hours before intercourse and provides protection for 48 hours. The cap must be kept in the vagina for 6 hours after the final act of intercourse and should be replaced every year of use. A refitting may also be necessary when a woman experiences pregnancy, abortion, or weight changes. The dome of the cap is filled about one third full with spermicide. Spermicide should not be applied to the rim because it might interfere with the seal that must form around the cervix. The cap is available only by prescription and must be fitted by a health care provider. Contraindications to use of a cervical cap include cervical cancer, recent urinary tract infection, latex allergy, pelvic-organ prolapse, and history of toxic shock syndrome. Using the cervical cap during menstruation may increase the risk of toxic shock syndrome and, therefore, should be avoided (Schuiling & Likis, 2016).

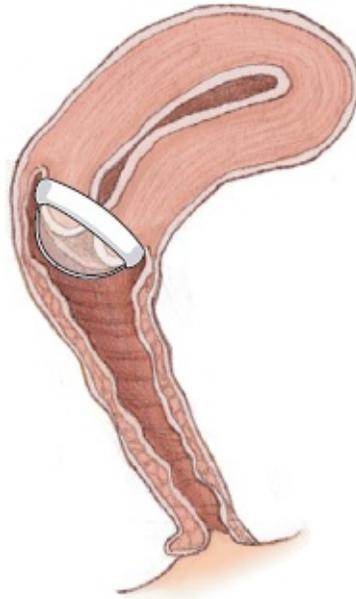

FIGURE 4.11 A cervical cap is placed over the cervix and used with a spermicidal jelly, the same as a diaphragm.

CONTRACEPTIVE SPONGE

The **contraceptive sponge** is a nonhormonal, nonprescription device that includes both a barrier and a spermicide. When it was removed from the market in 1995, it was the most popular OTC female contraceptive in America (Everett, 2014). The manufacturer, Wyeth, stopped making the sponge rather than upgrade its manufacturing plant after the Food and Drug Administration (FDA) found deficiencies, but the device's effectiveness and safety were never questioned. After receiving reapproval from the FDA in 2009, the contraceptive sponge is once again being marketed to women.

The contraceptive sponge is a soft concave device that prevents pregnancy by covering the cervix and releasing spermicide. The sponge, made of polyurethane saturated with nonoxynol-9 (1,000 mg), releases 125 mg of the spermicide over 24 hours of use. Unlike the diaphragm, the sponge can be used for more than one coital act within 24 hours without the insertion of additional spermicide, and the sponge does not require fitting or a prescription from a health care provider

(Zieman, 2015). While it was less effective than several other methods and does not offer protection against STIs, the sponge achieved a wide following among women who appreciated the spontaneity with which it could be used and its easy availability. When compared with the diaphragm in a recent study, the sponge was found to be less effective than the diaphragm in preventing pregnancy. Discontinuation rates were higher at 12 months as well (Sharma & Walmsley, 2015).

To use the sponge, the woman first wets it with water, and then inserts it into the vagina with a finger, using a cord loop attachment. It can be inserted up to 24 hours before intercourse and should be left in place for at least 6 hours following intercourse. The sponge provides protection for up to 12 hours, but should not be left in for more than 30 hours after insertion to avoid the risk of toxic shock syndrome (Moses, 2015c).

Hormonal Methods

Several options are available to women who want long-term but not permanent protection against pregnancy. These methods of contraception work by altering the hormones within a woman's body. They rely on estrogen and progestin or progestin alone to prevent ovulation. When used consistently, these methods are a reliable way to prevent pregnancy. Hormonal methods include OCs, injectables, implants, vaginal rings, and transdermal patches.

ORAL CONTRACEPTIVES

As early as 1937, scientists recognized that the injection of progesterone inhibited ovulation in rabbits and provided contraception. The first hormonal pill, called *Enovid*, was approved by the FDA in May 1960. It contained high levels of estrogen to prevent ovulation. Since that time, it has evolved through gradual lowering of estrogen and is now combined with many different progestins. Breakthrough bleeding was reported in early clinical trials in women, and the role of estrogen in cycle control was launched. This established the rationale for modern-combination OCs that contains both estrogen and progesterone (Stewart & Black, 2015).

Development of hormonal contraception marked a revolutionary step in social change that has improved the lives of women and families worldwide. Since the first OC was introduced, hormonal contraception has undergone various stages of advancement. Today, OC regimens are safer and more tolerable, with equal or

improved efficacy, than the early formulations. Incremental decreases in the estrogen dosage helped to alleviate some of the unwanted side effects of the pill (Craik & Melvin, 2015). Today, over 30-combination OCs are available in the United States. The most notable change in over 50 years of OC improvement has been the lowering of the estrogen dose to as low as 10 mcg and the introduction of new progestins.

FIGURE 4.12 Oral contraceptive.

Oral contraception is the most popular method of nonsurgical contraception, used by approximately 25 million women in the United States (Fig. 4.12) (Samra-Latif & Wood, 2015). Unlike the original OCs that women took decades ago, the new low-dose forms carry fewer health risks.

OC, although most commonly prescribed for contraception, has long been used in the management of a wide range of conditions and has many health benefits, such as:

• reduced incidence of ovarian and endometrial cancer;

• prevention and treatment of endometriosis;

• decreased incidence of acne and hirsutism;

• decreased incidence of ectopic pregnancy;

• decreased incidence of acute PID and possible protection against PID;

• reduced incidence of fibrocystic breast disease;

• decreased perimenopausal symptoms;

• reduced risk of developing uterine fibroids;

- maintenance of bone mineral density;
- improvement in asthmatic symptoms;
- delayed onset of multiple sclerosis and arthritis;
- increased menstrual cycle regularity;
- lower incidence of colorectal cancer;
- decreased number of pregnancy-related deaths by preventing pregnancy;
- reduced iron-deficiency anemia by treating menorrhagia;
- reduced incidence of dysmenorrhea (Evans & Sutton, 2015).

OCs work primarily by suppressing ovulation by adding estrogen and progesterone to a woman's body, thus mimicking pregnancy. This hormonal level stifles GnRH, which in turn suppresses FSH and LH and thus inhibits ovulation. Cervical mucus also thickens, which hinders sperm transport into the uterus. Implantation is inhibited by suppression of the maturation of the endometrium and alterations of uterine secretions (Everett, 2014).

The combination pills are prescribed as monophasic pills, which deliver fixed dosages of estrogen and progestin, or as multiphasic ones. Multiphasic pills (e.g., biphasic and triphasic OCs) alter the amount of progestin and estrogen within each cycle. To maintain adequate hormonal levels for contraception and enhance adherence to the regimen, OCs should be taken at the same time daily.

OCs that contain progestin are sometimes called mini-pills. Progestin-only pills (POPs) have both advantages and disadvantages when compared with combined pills. The pill-taking regimen is simple and fixed; no pill color changes or days without pill-taking occur. These pills are appropriate for women who cannot take estrogen in combined OCs, for example, a woman older than 35 years who smokes cigarettes. They are prescribed for women who cannot take estrogen at all. These OCs work primarily by thickening the cervical mucus to prevent penetration of the sperm and make the endometrium unfavorable for implantation. POPs must be taken at a certain time every 24 hours. Breakthrough bleeding and a higher risk of pregnancy have made these OCs less popular than combination OCs (Craik & Melvin, 2015).

Extended OC regimens have been used for the management of menstrual disorders and endometriosis for years but now are attracting wider attention. Surveys asking women about their willingness to reduce their menstrual cycles from 12 to 4 annually were returned with a resounding "yes!" (Zorbas,

Economopoulos, & Vlahos, 2015). Research has confirmed that the extended use of active OC pills carries the same safety profile as the conventional 28-day regimens. OCs taken continuously or in long cycles offer benefits with regard to menstrual symptoms and the recurrence of symptoms related to endometriosis (Zieman, 2015). The extended regimen consists of 84 consecutive days of active combination pills, followed by 7 days of placebos. The woman has four withdrawal-bleeding episodes a year. Seasonale and Seasonique, a combination OC, is on the market for women who choose to reduce the number of periods that they have. In 2009, the makers of Seasonique came out with LoSeasonique. LoSeasonique consists of 84 orange tablets containing 0.1 mg levonorgestrel and 0.02 mg ethinyl estradiol and 7 yellow tablets containing 0.01 mg ethinyl estradiol. The risk profile is similar to those of its sister products, Seasonale and Seasonique; however, the risk of unplanned breakthrough bleeding is increased (Samra-Latif & Wood, 2015).

Lybrel was the first FDA-approved OC with 365-day combination dosing. It contains a low combined daily dose of the hormones levonorgestrel and ethinyl estradiol (90 and 20 mcg, respectively). It provides women with more hormonal exposure on a yearly basis (13 additional weeks of hormone intake per year) than conventional cyclic OCs that contain the same strength of synthetic estrogens and similar strength of progestins (Samra-Latif & Wood, 2015). There is no physiologic requirement for cyclic hormonal withdrawal bleeds while taking OCs (Skidmore-Roth, 2015).

A growing body of evidence indicates that over-the-counter access to OC pills is safe and effective and that women are interested in obtaining pills this way. With half of all pregnancies being unintended—a figure that has remained unchanged for decades—innovation is needed to address this statistic. Although an over-the-counter contraceptive pill may sound revolutionary in the United States, over-the-counter access is already a reality in more than 100 countries and has been for decades. ACOG supports over-the-counter access to contraceptive pills, but numerous social and professional groups oppose it (Foster et al., 2015). Even after ACOG's support, women will probably not be seeing an over-the-counter OC product on the local pharmacy shelf any time soon, despite its cost-effectiveness and impact on reduction in unintended pregnancies.

The balance between the benefits and the risks of OCs must be determined for each woman when she is being assessed for this type of contraceptive. It is a highly effective contraceptive when taken properly but can aggravate many

medical conditions, especially in women who smoke. Comparison Chart 4.1 lists advantages and disadvantages of OCs. A thorough history and pelvic examination, including a Pap smear, are not required before the medication is prescribed, but a regular medical follow-up is advised. Women should also be counseled that the effectiveness of OCs is decreased when the woman is taking antibiotics; thus, the woman will need to use an alternative or secondary method during this period to prevent pregnancy.

Nurses need to provide OC users with a great deal of education before they leave the health care facility. They need to be able to identify early signs and symptoms that might indicate a problem.

Take Note!

The mnemonic "ACHES" can help women remember the early warning signs that necessitate a return to the health care provider (Box 4.6).

COMPARISON CHART 4.1 ADVANTAGES AND DISADVANTAGES OF ORAL CONTRACEPTIVES

Advantages	Disadvantages
Regulate and shorten menstrual cycle	Offer no protection against STIs
Decrease severe cramping and bleeding	Pose slightly increased risk of breast cancer
Reduce anemia	
Reduce ovarian and colorectal cancer risk	Modest risk for venous thrombosis and pulmonary emboli
Decrease benign breast disease	Increased risk for migraine headaches
Reduce risk of endometrial cancer, colorectal cancer, and ovarian cancer	
Improve acne and reduces incidence of menstrual headaches	Increased risk for myocardial infarction, stroke, and hypertension for women who smoke
Minimize perimenopausal symptoms	May increase risk of depression
Decrease incidence of rheumatoid arthritis	User must remember to take pill daily
Improve PMS symptoms	High cost for some women
Protect against loss of bone density and reduces risk of osteoporosis	

Adapted from Jick, S. (2015). Oral contraceptives and the risk of venous thromboembolism. In *Medicines for Women* (pp. 181–201). Springer International Publishing; Zieman, M. (2015). *Managing contraception on the go* (13th ed.). New York: Ardnet Media; and Everett, S. (2014). *Handbook of contraception and sexual health* (3rd ed.). New York: Routledge.

INJECTABLE CONTRACEPTIVE

Injectable contraception includes progestin-only and combination estrogen and progestin agents that provide safe and highly effective birth control for up to three months. Injectable agents are widely available and play an important role in family planning worldwide. They offer a discrete, convenient, reversible, and noncoital-dependent method of birth control.

Depo-Provera is the trade name for an intramuscular injectable of a progesterone-only contraceptive given every 12 weeks which contains 150 mg/1 mL. Depo-subQ Pronera is a lower-dose injectable given subcutaneously delivering 104 mg/0.65 mL every 12 weeks. They are the only injectable agents available in the United States. Depo-Provera works by suppressing ovulation and the production of FSH and LH by the pituitary gland, by increasing the viscosity of cervical mucus and causing endometrial atrophy. A single injection of 150 mg into the buttocks acts like other progestin-only products to prevent pregnancy for 3 months at a time (Fig. 4.13). The primary side effect of Depo-Provera is menstrual cycle disturbance.

Recent clinical studies have raised concerns about whether Depo-Provera reduces bone mineral density. This evidence has prompted the manufacturer and the FDA to issue a warning about the long-term use (>2 years) of Depo-Provera and bone loss (Wolfe & Cansino, 2015). It is not entirely clear if this loss in bone mineral density (BMD) is reversible because there have not been any long-term prospective studies in current and past users. It is highly recommended that bone density scans be done while on Depo-Provera (Curtis, 2014).

TRANSDERMAL PATCHES

Transdermal delivery of contraceptive hormones avoids hepatic first-pass metabolism, allowing a lower total hormone dose when compared to that of oral products that are metabolized in the liver. A **transdermal patch**, Ortho Evra, is available in the United States. It is a matchbox-sized patch containing hormones that are absorbed through the skin when placed on the lower abdomen, upper outer arm, buttocks, or upper torso (avoiding the breasts). The patch is applied weekly for 3 weeks, followed by a patch-free week during which withdrawal bleeding occurs. The patch delivers continuous levels of progesterone and estrogen. Transdermal absorption allows the drug to enter the bloodstream directly, avoiding rapid inactivation in the liver known as first-pass metabolism. Because estrogen and progesterone are metabolized by liver enzymes, avoiding first-pass metabolism was thought to reduce adverse effects. However, recent evidence suggests that the risk of venous thrombosis and embolism is increased with the patch and the risk of skin burns occurring if undergoing an MRI, but still less than the risk of venous thromboembolism during pregnancy (Nelson,

2015). Additional studies are under way to understand the clinical significance of these latest findings, but in the interim nurses need to focus on ongoing risk assessment and should be prepared to discuss current research findings with clients.

Adherence to the regimen of combination contraceptive patch use has been shown to be significantly greater than adherence with OCs. In addition, research suggests that overweight and obese women with weights exceeding 198 pounds should be advised of the potentially decreased effectiveness of the patch and increase incidence of venous thromboembolism and weight gain (Pocius & Dutton, 2015). The patch provides combination HT with a side-effect profile similar to that of OCs (Fig. 4.14).

VAGINAL RINGS

Approved in 2001 by the FDA, the **vaginal ring** contains both estrogen and progesterone hormones. The contraceptive vaginal ring, NuvaRing, is a flexible, soft, transparent ring that is inserted by the user for a 3-week period of continuous use followed by a ring-free week to allow withdrawal bleeding (Fig. 4.15). Ethinyl estradiol and etonogestrel are rapidly absorbed through the vaginal epithelium and result in a steady serum concentration. Because the hormones are released directly into the vagina, a lower daily dose of hormones is required in comparison with OC doses. Studies have demonstrated that the efficacy and safety of the ring are equivalent to those of OCs. Clients report being highly satisfied with the vaginal ring and report fewer systemic side effects than do OC users. The ring provides effective cycle control as well as symptom relief for women with menorrhagia, dysmenorrhea, and polycystic ovarian syndrome. Reported problems associated with the use of vaginal rings include erosion of vaginal wall, ring expulsion, interference with coitus, unpleasant ring odor, and premature discontinuation due to vaginal discomfort (Khan & Krupanidhi, 2015). The ring can be inserted by the woman and does not have to be fitted. The woman compresses the ring and inserts it into the vagina, behind the pubic bone, as far back as possible, but precise placement is not critical. The hormones are absorbed through the vaginal mucosa. It is left in place for 3 weeks and then removed and discarded. Effectiveness and adverse events are similar to those seen with combination OCs. Clients need to be counseled regarding timely insertion of the ring and what to do in case of accidental expulsion. Recent studies suggest that a vaginal ring containing etonogestrel and ethinyl estradiol used in an extended regimen is a safe contraceptive method that offers good

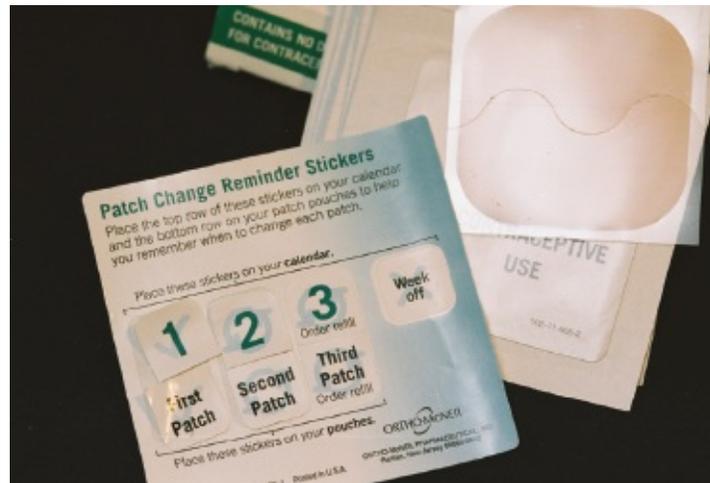
cycle control and can be an option for women who have gastric intolerance or other side effects when using oral hormonal contraceptives (King et al., 2015).


FIGURE 4.14 Transdermal patch.

**FIGURE 4.15** Vaginal ring.

IMPLANTABLE CONTRACEPTIVES

The **implant** is a subdermal time-release method that delivers synthetic progestin that inhibits ovulation. Once in place, it delivers 3 years of continuous, highly effective contraception. Like POPs, implants act by inhibiting ovulation and thickening cervical mucus, so sperm cannot penetrate. A single-rod progestin implant (Nexplanon) is currently available in the United States. Nexplanon is 4 cm long and 2 mm in diameter, and contains 68 mg of the hormone progestin. The implant is radio-opaque and is over 99% effective (King

et al., 2015). The side effects are also similar to those of POPs: irregular bleeding, headaches, weight gain, breast tenderness, and depression. Fertility is restored quickly after it is removed. Implants require a minor surgical procedure for both insertion and removal. The implants do not offer any protection against STIs.

Hormonal side effects are not exclusive to implants but tend to be a problem with all hormonal contraceptives. Preinsertion counseling by the nurse is essential to prepare the woman for any such side effects. Expert counseling should cover the one side effect most likely to cause discontinuation: initial irregular bleeding and the possibility of amenorrhea with longer use (Craik & Rowlands, 2015).

INTRAUTERINE CONTRACEPTIVES

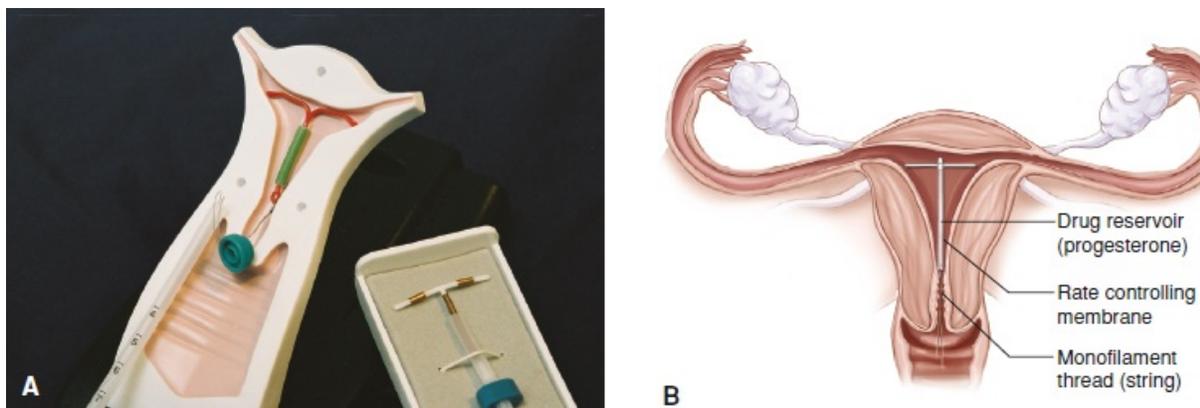
Intrauterine contraceptives are classified as either hormonal or nonhormonal. Both types prevent pregnancy via inhibition of sperm mobility and sperm viability and change the speed of transport of the ovum in the fallopian tube. An intrauterine contraceptive (IUC) is a small plastic T-shaped object that is placed inside the uterus to provide contraception (Fig. 4.16). It prevents pregnancy by making the endometrium of the uterus hostile to implantation of a fertilized ovum by causing a nonspecific inflammatory reaction and inhibiting sperm and ovum from meeting (Wildemeersch & Jandi, 2015). The hormonal IUC will make monthly periods lighter, shorter, and less painful, making this a useful method for women with heavy, painful periods. The implants contain either copper or progesterone to enhance their effectiveness. One or two attached strings protrude into the vagina so that the user can check for placement.


FIGURE 4.16 A. Intrauterine contraceptive. **B.** An IUC in place in the uterus.

Currently three IUCs are available in the United States: the copper ParaGard-TCu-380A, the levonorgestrel-releasing intrauterine system (LNG-IUS) marketed as Mirena, and another LNG-IUD marketed as Skyla. The ParaGard-TCu-380A is approved for 10 years of use and is nonhormonal. Its mechanism of action is based on the release of copper ions, which alone are spermicidal. Additionally, the device causes an inflammatory action leading to a hostile uterine environment. The TCu-380A is also approved for use as emergency contraception. Mirena provides intrauterine conception for 5 years, but has been shown to be effective for as long as 7 years. Skyla has been approved for 3 years of pregnancy prevention. Both devices release a low dose of progestin causing thinning of the endometrium and thickening of cervical mucus, which inhibits sperm entry into the upper genital tract. Their use results in a major reduction in menstrual flow and dysmenorrhea, suggesting that they are viable alternative to hysterectomy and endometrial ablation in women with menorrhagia (Atkin et al., 2015). An advantage of these hormonally impregnated intrauterine systems is that they are relatively maintenance-free: users must consciously discontinue using them to become pregnant rather than making a daily decision to avoid conception (Alan Guttmacher Institute, 2015a).

The IUCs provide a safe, highly effective, long-lasting, yet reversible method of contraception. Expanding access to intrauterine contraception is an important measure to reduce the rate of unintended pregnancy in the United States. Nurses should consider including them in their discussion to appropriate candidates, including women who are nulliparous, adolescent, immediately postpartum, or postabortion, and those who desire emergency contraception, and as an alternative to permanent sterilization. Limitations barriers to obtaining intrauterine contraception such as requiring cervical cancer screening before insertion, routine testing for gonorrhea and chlamydial infection in low-risk women, or scheduling insertion only during menses are unnecessary. IUC insertion can take place on any day of the menstrual cycle, if absence of pregnancy is confirmed (Cheng & Van Leuven, 2015). Box 4.7 highlights the warning signs of the potential complications of IUCs.

EMERGENCY CONTRACEPTION

Unplanned pregnancy is a major health, economic, and social issue for women. Approximately one third of all unplanned pregnancies end in abortion (CDC, 2015b). Using an emergency contraceptive provides a woman a second chance to prevent an unintended pregnancy. **Emergency contraception** (EC) reduces

the risk of pregnancy after unprotected intercourse or contraceptive failure such as condom breakage (Raymond & Cleland, 2015). It is used within 72 hours of unprotected intercourse to prevent pregnancy. The sooner ECs are taken, the more effective they are. They reduce the risk of pregnancy for a single act of unprotected sex by almost 80% (Samra-Latif & Wood, 2015). The methods available in the United States are POPs, Plan B One-Step (Fig. 4.17), Next Choice, Next Choice One Dose; combined estrogen and progestin pills, or insertion of a copper-releasing intrauterine system up to 7 days after unprotected intercourse. Ulipristal acetate (marketed as Ella) is a selective progesterone receptor modulator that, when taken as a single 30-mg dose, is a new, safe, and effective emergency contraceptive that can be used from the first day and up to 5 days following unprotected intercourse. The older progesterone-only emergency contraceptive, levonorgestrel, is taken as two 0.75-mg pills 12 hours apart (Next Choice®; Watson Pharmaceuticals Inc., Morristown, NJ, USA) or as a single 1.5-mg pill (Plan B One-Step™; Watson Pharmaceuticals Inc.), and is approved for only 72 hours after unprotected intercourse (Mulligan, 2015).

FIGURE 4.17 Emergency contraceptive kit.

Access to emergency contraceptives has been controversial for minors. Prior to 2013, the pills were available by prescription only, and even when approved for nonprescription status, access was restricted based on age. In 2013, several judicial courts and the FDA ruled in favor of nonprescription access to EC by all women regardless of age. At this time, the federal government has not appealed these rulings, but many states have placed restrictions on access of EC (Casey & Isaacs, 2015). The only contraindication to the use of any of the four EC

methods is a known pregnancy as defined as implantation.

Although access to EC has increased with nonprescription status and approval of Plan B One-Step without age restrictions, many barriers remain in public awareness and unintended pregnancies continue to rise. Because of the lack of awareness of EC and the politics surrounding it, EC is not used as widely as would be warranted by the incidence of unprotected coitus. Nurses need to educate their female clients to bring about increased awareness of this second chance method. Table 4.5 lists recommended oral medication and intrauterine regimens.

Prime points to stress concerning ECs are the following:

• ECs do not offer any protection against STIs or future pregnancies.

• ECs should not be used in place of a regular birth control method, because they are less effective.

• ECs may delay the next menses, so evaluation for pregnancy is needed if menses does not occur within three weeks after EC use

• Report any severe abdominal pain to health care provider immediately.

• ECs are regular birth control pills given at a higher dose.

• ECs are contraindicated during pregnancy (Ilic, 2015).

Take Note!

Contrary to popular belief, ECs do not induce abortion and are not related to mifepristone or RU-486, the so-called abortion pill approved by the FDA in 2000.

Mifepristone chemically induces abortion by blocking the body's progesterone receptors, which are necessary for pregnancy maintenance. ECs simply prevent embryo creation and uterine implantation from occurring in the first place. There is no evidence that ECs have any effect on an already implanted ovum. The side effects are nausea and vomiting.

TABLE 4.5 EMERGENCY POSTCOITAL CONTRACEPTION OPTIONS

Product	Dosage (Within 72 Hr)	Comments
Combined estrogen and progestin pills (Yuzpe regimen)	OCSs are taken in various formulations to prevent conception.	Interfere with the cascade of events that result in ovulation and fertilization
Plan B One-Step	1.5 mg pill taken	Can cause nausea and vomiting
Intrauterine		
Copper-bearing IUS (ParaGard-TCu-380A)	Inserted within 5 d after unprotected sexual episode	Can be left in for long-term contraception (10 yrs)

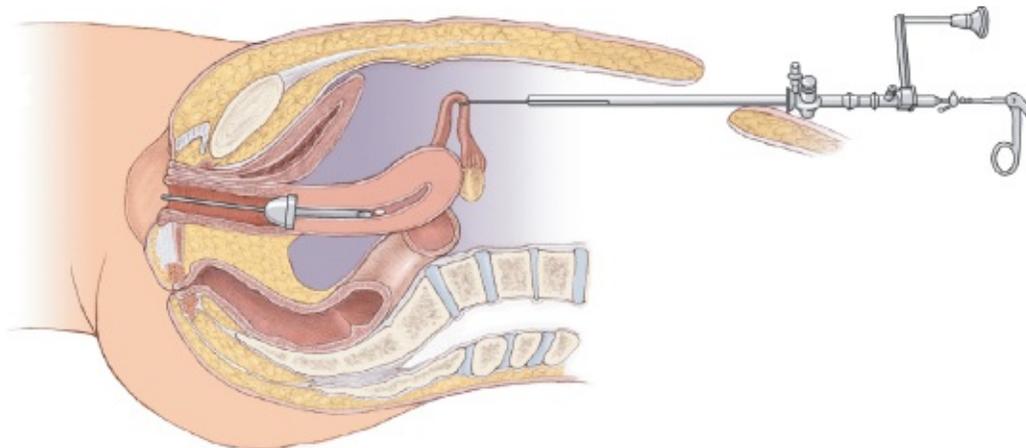

FIGURE 4.18 Laparoscopy for tubal sterilization.

Sterilization

Sterilization is a permanent, safe, and highly effective method of contraception for those who are certain they do not want any or any more children. Vasectomy is the only highly reliable form of male contraception. Approximately 600,000 tubal occlusions and 200,000 vasectomies are performed in the United States annually and over 220 million worldwide (ACOG, 2013). It is the most widely used method of family planning in the world in both developed and developing countries. Sterilization refers to surgical procedures intended to render the person infertile. Laparoscopic, abdominal, and hysteroscopic methods of female sterilization are available in the United States, with most of these procedures performed outside the hospital. Sterilization is a safe and effective form of permanent birth control. In the United States, it is still the second most commonly used form of contraception overall and is the most frequently used method among married women and among women over 30 years of age (McKay

& Schunmann, 2015). More women than men undergo surgical sterilization. According to the CDC (2015b), approximately 18% of women undergo female sterilization in comparison with 7% of men in the United States. Sterilization should be considered a permanent end to fertility because reversal surgery is difficult, expensive, and not always successful. Because these methods are intended to be irreversible, all couples should be appropriately counseled about the permanency of sterilization and the availability of highly effective, long-acting, reversible methods of contraception before their decision is made.

TUBAL LIGATION

Tubal ligation, the sterilization procedure for women, can be performed postpartum, after an abortion, or as an interval procedure unrelated to pregnancy. Mini-laparotomies and laparoscopies are the two most common techniques. In the laparoscopy procedure, the abdomen is filled with carbon dioxide gas so that the abdominal wall balloons away from the tubes to provide a view of the fallopian tubes. They are grasped and sealed with a cauterizing instrument or with rings, bands, or clips, or cut and tied (Fig. 4.18).

ESSURE

Essure is a nonsurgical, nonhormonal, permanent birth control method that is 99% effective. This method is for women who desire no more children as it is a permanent method of birth control. It offers several advantages over a conventional tubal ligation: general anesthesia and incisions are not needed, thereby increasing safety, lowering costs, and improving access to sterilization. A tiny coil (Essure) is introduced and released into the fallopian tubes through the cervix. The coil promotes tissue growth in the fallopian tubes, and over a period of 3 months, this growth blocks the tubes. The build-up of tissue creates a barrier that keeps sperm from the reaching the ovum, thus preventing conception (Thurkow, 2015). This less-invasive technique uses a hysteroscopy under local anesthesia in an office setting. Sterilization does not occur immediately after this procedure, so women must be educated to use additional contraception for 3 months until permanent tubal occlusion is verified.

VASECTOMY

Male sterilization is accomplished with a surgical procedure known as a **vasectomy**. More than 500,000 men have a vasectomy performed in the United

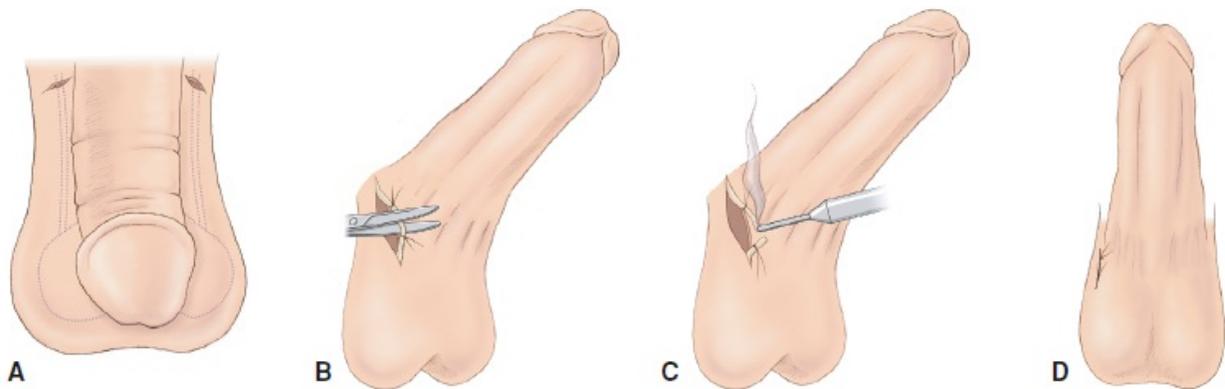
States each year (Mcfarlane, 2015). It is usually performed under local anesthesia in a urologist's office, and most men can return to work and normal activities in a day or two. The procedure involves making a small incision into the scrotum and cutting the vas deferens, which carries sperm from the testes to the penis (Fig. 4.19). Complications from vasectomy are rare and minor in nature. Immediate risks include infection, hematoma, and pain. After vasectomy, semen no longer contains sperm. This is not immediate, though, and the man must submit semen specimens for analysis 8 to 16 weeks after a vasectomy until two specimens show that no sperm is present. When the specimen shows azoospermia, the man's sterility is confirmed (Whitaker, 2015).


FIGURE 4.19 Vasectomy. **A.** Site of vasectomy incisions. **B.** The vas deferens is cut with surgical scissors. **C.** Cut ends of the vas deferens are cauterized to ensure blockage of the passage of sperm. **D.** Final skin suture.

Nursing Management of the Woman Choosing a Contraceptive Method

The choice of a contraceptive method is a very personal one involving many factors. What makes a woman choose one contraceptive method over another? In making contraceptive choices, couples must balance their sexual lives, their reproductive goals, and each partner's health and safety. The search for a choice that satisfies all three objectives is challenging. A method that works for a sexually active teenage girl may not meet her needs later in life. Several considerations influence a person's choice of contraceptives:

• Motivation

• Cost

• Cultural and religious beliefs (Box 4.8)

• Convenience

• Effectiveness

• Side effects

• Desire for children in the future

• Safety of the method

• Comfort level with sexuality

• Protection from STIs

• Interference with spontaneity

If a contraceptive is to be effective, the woman must understand how it works, must be able to use it correctly and consistently, and must be comfortable and confident with it. If a client cannot adhere to taking a pill daily, consider a method used once a week (transdermal patches), once every 3 weeks (transvaginal ring), or once every 3 months (Depo-Provera injection). Another option may be a progesterone IUC that lasts 3 to 5 years and reduces menstrual flow significantly.

Regardless of which method is chosen, the client's needs should be paramount in the discussion. The nurse can educate clients about which methods are available and their advantages and disadvantages, efficacy, cost, and safety. Knowledge of contraceptive effectiveness is crucial to making an informed

choice. The couple has to comprehend the pros and cons of the contraceptive methods being considered. Choice may be influenced by understanding the likelihood of pregnancy with each method and factors that influence effectiveness. Counseling can help the woman choose a contraceptive method that is efficacious and fits her preferences and lifestyle.

BOX 4.8

SELECTED RELIGIOUS CHOICES FOR FAMILY PLANNING AND ABORTION

• Roman Catholic—Abstinence and natural family planning; no abortion

• Judaism (Orthodox)—Family planning and abortion accepted in first trimester. Conservative and Reform Judaism accept both family planning and abortion.

• Islam—Family planning accepted; abortion only for serious reasons

• Protestant Christianity—Firmly in favor of family planning; mixed on abortion

• Buddhism—Long experience with family planning and abortion

• Hinduism—Accept both family planning and abortion

• Native American religions—Accept both family planning and abortion

• Chinese religions—Taoism and Confucianism accept both

Adapted from McFarland, M. R., & Wehbe-Alamah, H. B. (2015). *Leininger's cultural care diversity and universality: A worldwide nursing theory* (3rd ed.). Burlington, MA: Jones & Bartlett Learning; and McFarlane, D. R. (2015). *Global population and reproductive health.* Burlington, MA: Jones & Bartlett Learning.

Nursing Assessment

When assessing which contraceptive method might meet the client's needs, the nurse might ask the following:

• Do your religious beliefs interfere with any methods?

• Will this method interfere with your sexual pleasure?

• Are you aware of the various methods currently available?

• Is cost a major consideration, or does your insurance cover it?

• Does your partner influence which method you choose?

• Are you in a stable, monogamous relationship?

• Have you heard anything troubling about any of the methods?

• How comfortable are you touching your own body?

• What are your future plans for having children?

  Although deciding on a contraceptive is a very personal decision between a woman and her partner, nurses can assist in this process by performing a complete health history and physical examination, and by educating the woman and her partner about necessary laboratory and diagnostic testing. Areas of focus during the nursing assessment are as follows:

• Medical history: smoking status, cancer of reproductive tract, diabetes mellitus, migraines, hypertension, thromboembolic disorder, allergies, risk factors for cardiovascular disease (CVD)

• Family history: cancer, CVD, hypertension, stroke, diabetes

• OB/GYN history: menstrual disorders, current contraceptive, previous STIs, PID, vaginitis, sexual activity

• Personal history: use of tampons and female hygiene products, plans for childbearing, comfort with touching herself, number of sexual partners and their involvement in the decision

• Physical examination: height, weight, blood pressure, breast examination, thyroid palpation, pelvic examination

• Diagnostic testing: urinalysis, complete blood count, Pap smear, wet mount to check for STIs, HIV/AIDS tests, lipid profile, glucose level

Figure 4.20 shows an example of a family planning flow record that can be used during the assessment. After collecting the assessment data above, consider the medical factors to help decide if the woman is a candidate for all methods or whether some should be eliminated. For example, if she reports she has multiple sex partners and a history of pelvic infections, she would not be a good candidate for an intrauterine contraceptive. Barrier methods (male or female condoms) of contraception might be recommended to this client to offer protection against STIs.

Nursing Diagnoses

A few nursing diagnoses that might be appropriate based on the nurse's assessment during the decision-making process include:

• Deficient knowledge related to:
  • methods available
  • side effects/safety
  • correct use of method chosen
  • previous myths believed
• Risk for infection related to:

  • unprotected sexual intercourse
  • past history of STIs
  • methods offering protection
    Nursing diagnoses applicable to the contraceptive would be:
• Health-seeking behaviors related to:
  • perceived need for limiting number of children
  • overall health relative to contraceptives
• Risk for ineffective health maintenance related to:
  • not being familiar with the various contraceptive methods
  • being unaware of high-risk sexual behavior leading to STIs
• Fear related to:
  • not understanding the correct procedure to use
  • unintended pregnancy occurring if not used correctly
  • general health concerning the long-term side effects

Nursing Interventions

Contraception is an important issue for all couples, and the method used should be decided by the woman and her partner jointly. Facilitate this process by establishing a trusting relationship with the client and by providing unbiased, accurate information about all methods available. As a nurse, reflect honestly on your feelings about contraceptives while allowing the client's feelings to be paramount. Be aware of the practical issues involved in contraceptive use, and avoid making assumptions, making decisions on the woman's behalf, and making judgments about her and her situation. To do so, it is important to keep up to date on the latest methods available and convey this information to clients. Encourage female clients to take control of their lives by sharing information that allows them to plan their futures.

The following guidelines are helpful in counseling and educating the client or couple about contraceptives:

• Encourage the client/couple to participate in choosing a method.

• Provide client education. The client/couple must become informed users before the method is chosen. Education should be targeted to the client's level so it is understood. Provide step-by-step teaching and an opportunity for practice for certain methods (cervical caps, diaphragms, vaginal rings, and condoms). See Teaching Guidelines 4.5 and Figure 4.21.

FIGURE 4.20 Family planning flow (visit) record.

FIGURE 4.21 The nurse demonstrates insertion of a vaginal ring during client teaching.

• Obtain written informed consents, which are needed for intrauterine contraceptives, implants, abortion, or sterilization. Informed consent implies that the client is making a knowledgeable, voluntary choice; has received complete information about the method, including the risks; and is free to change her mind before using the method or having the procedure (Schuiling & Likis, 2016).

• Discuss contraindications for all selected contraceptives.

• Consider the client's cultural and religious beliefs when providing care.

• Address myths and misperceptions about the methods under consideration in your initial discussion of contraceptives.

Teaching Guidelines 4.5

TIPS FOR THE USE OF CERVICAL CAPS, DIAPHRAGMS, VAGINAL RINGS, AND CONDOMS

Cervical Cap Insertion/Removal Technique

• It is important to be involved in the fitting process.

• To insert the cap, pinch the sides together, compress the cap dome, insert into the vagina, and place over the cervix.

- Use one finger to feel around the entire circumference to make sure there are no gaps between the cap rim and the cervix.
- After a minute or two, pinch the dome and tug gently to check for evidence of suction. The cap should resist the tug and not slide off easily.
- To remove the cap, press the index finger against the rim and tip the cap slightly to break the suction. Gently pull out the cap.
- The woman should practice inserting and removing the cervical cap three times to validate her proficiency with this device.

Client Teaching and Counseling Regarding the Cervical Cap

- Fill the dome of the cap up about one third full with spermicide cream or jelly. Do not apply spermicide to the rim, since it may interfere with the seal.
- Wait approximately 30 minutes after insertion before engaging in sexual intercourse to be sure that a seal has formed between the rim and the cervix.
- Leave the cervical cap in place for a minimum of 6 hours after sexual intercourse. It can be left in place for up to 48 hours without additional spermicide being added.
- Do not use during menses due to the potential for toxic shock syndrome. Use an alternative method such as condoms during this time.
- Replace the cervical cap after each year of use.
- Inspect the cervical cap prior to insertion for cracks, holes, or tears.
- After using the cervical cap, wash it with soap and water, dry thoroughly, and store in its container.

Diaphragm Insertion/Removal Technique

- Always empty the bladder prior to inserting the diaphragm.
- Inspect diaphragm for holes or tears by holding it up to a light source, or fill it with water and check for a leak.
- Place approximately a tablespoon of spermicidal jelly or cream in the dome and around the rim of the diaphragm.
- The diaphragm can be inserted up to 6 hours prior to intercourse.
- Select the position that is most comfortable for insertion:
  - Squatting

- Leg up, raising the nondominant leg up on a low stool
- Reclining position, lying on back in bed
- Sitting forward on the edge of a chair
- Hold the diaphragm between the thumb and fingers and compress it to form a "figure-eight" shape.
- Insert the diaphragm into the vagina, directing it downward as far as it will go.
- Tuck the front rim of the diaphragm behind the pubic bone so that the rubber hugs the front wall of the vagina.
- Feel for the cervix through the diaphragm to make sure it is properly placed.
- To remove the diaphragm, insert the finger up and over the top side and move slightly to the side, breaking the suction.
- Pull the diaphragm down and out of the vagina.

Client Teaching and Counseling Regarding the Diaphragm
- Avoid the use of oil-based products, such as baby oil, because they may weaken the rubber.
- Wash the diaphragm with soap and water after use and dry thoroughly.
- Place the diaphragm back into the storage case.
- The diaphragm may need to be refitted after weight loss or gain or childbirth.
- Diaphragms should not be used by women with latex allergies.

Vaginal Ring Insertion/Removal Technique and Counseling
- Each ring is used for one menstrual cycle, which consists of 3 weeks of continuous use followed by a ring-free week to allow for menses.
- No fitting is necessary—one size fits all.
- The ring is compressed and inserted into the vagina, behind the pubic bone, as far back as possible.
- Precision placement is not essential.
- Backup contraception is needed for 7 days if the ring is expelled for more than 3 hours during the 3-week period of continuous use.
- The vaginal ring is left in place for 3 weeks, then removed and discarded.

- The vaginal ring is not recommended for women with uterine prolapse or lack of vaginal muscle tone (Schuiling & Likis, 2016).

Male Condom Insertion/Removal Technique and Counseling

- Always keep the condom in its original package until ready to use.
- Store in a cool, dry place.
- Spermicidal condoms should be used if available.
- Check expiration date before using.
- Use a new condom for each sexual act.
- Condom is placed over the erect penis prior to insertion.
- Place condom on the head of the penis and unroll it down the shaft.
- Leave a half-inch of empty space at the end to collect ejaculate.
- Avoid use of oil-based products, because they may cause breakage.
- After intercourse, remove the condom while the penis is still erect.
- Discard condom after use.

Female Condom Insertion/Removal Technique and Counseling

- Practice wearing and inserting prior to first use with sexual intercourse.
- Condom can be inserted up to 8 hours before intercourse.
- Condom is intended for one-time use.
- It can be purchased over the counter—one size fits all.
- Avoid wearing rings to prevent tears; long fingernails can also cause tears.
- Spermicidal lubricant can be used if desired.
- Insert the inner ring high in the vagina, against the cervix.
- Place the outer ring on the outside of the vagina.
- Make sure the erect penis is placed inside the female condom.
- Remove the condom after intercourse. Avoid spilling the ejaculate.

Education and Counseling of women using Injectable Contraceptives

- Consume a diet high in calcium and vitamin D to prevent bone mineral loss.
- Know the conditions that need to be reported to the health care provider:
  - Significant headaches
  - Menorrhagia

- Depression
- Severe abdominal pain
- Awareness of any infection present at injection site.

It is also important to clear up common misconceptions about contraception and pregnancy. Clearing up misconceptions will permit new learning to take hold and a better client response to whichever methods are explored and ultimately selected. Some common misconceptions include:

- Breast-feeding protects against pregnancy.
- Pregnancy can be avoided if the male partner "pulls out" before he ejaculates.
- Pregnancy cannot occur during menses.
- Douching after sex will prevent pregnancy.
- Pregnancy will not happen during the first sexual experience.
- Taking birth control pills protects against STIs.
- The woman is too old to get pregnant.
- If female orgasm is not reached, conception is not likely.
- Irregular menstruation prevents pregnancy.

When discussing in detail each method of birth control, focus on specific information for each method outlined. Include information such as how this particular method works to prevent pregnancy under normal circumstances of use; the noncontraceptive benefits to overall health; advantages and disadvantages of all methods; the cost involved for each particular method; danger signs that need to be reported to the health care provider; and the required frequency of office visits needed for the particular method.

In addition, outline factors that place the client at risk for method failure. Contraceptives can fail for any of many reasons. Use Table 4.6 to provide client education concerning a few of the reasons for contraceptive failure. Help clients who have chosen abstinence or fertility awareness methods to define the sexual activities in which they do or do not want to participate. This helps them set sexual limits or boundaries. Help them to develop communication and negotiation skills that will allow them to be successful. Supporting, encouraging, and respecting a couple's choice of abstinence is vital for nurses.

TABLE 4.6 CONTRACEPTIVE PROBLEMS AND EDUCATIONAL NEEDS

Contraceptive Failure	
Problem	**Client Education Needed**
Not following instructions for use of contraceptive correctly	Take pill the same time every day. Use condoms properly and check condition before using. Make sure diaphragm or cervical cap covers cervix completely. Check IUD for placement monthly.
Inconsistent use of contraceptive	Contraceptives must be used regularly to achieve maximum effectiveness. All it takes is one unprotected act of sexual intercourse to become pregnant. Two to 5% of condoms will break or tear during use.
Condom broke during sex	Check expiration date. Store condoms properly. Use only a water-based lubricant. Watch for tears caused by long fingernails. Use spermicides to decrease possibility of pregnancy. Seek emergency postcoital conception.
Use of antibiotics or other herbs taken with OCs	Use alternative methods during the antibiotic therapy, plus 7 additional days. Implement on day 1 of taking antibiotics.
Belief that you can't get pregnant during menses or that it is safe "just this one-time"	It may be possible to become pregnant on almost any day of the menstrual cycle.

After clients have chosen a method of contraception, it is important to address the following:

• Emphasize that a second method to use as a backup is always needed.

• Provide both oral and written instructions on the method chosen.

• Discuss the need for STI protection if not using a barrier method.

• Inform the client about the availability of ECs.

Steady progress in contraception research has been achieved over the past several years. Hormonal and nonhormonal contraceptives have improved women's lives by reducing different health conditions that contribute to morbidity. However, the contraceptives available today are not suitable to all users, and the need to expand contraceptive choices still exists. It is hoped that the introduction of newer methods in the near future with additional health benefits will continue to help women and couples meet their family planning needs.

ABORTION

Abortion is defined as the expulsion of an embryo or fetus before it is viable (Alexander et al., 2014). Abortion can be a medical or surgical procedure. The purpose of abortion is to terminate a pregnancy. More than 40% of all women will end a pregnancy by abortion at some time in their reproductive lives. Both in the United States and globally, more than one fifth of all known pregnancies end in abortion (McFarlane, 2015). Surgical abortion is the most common procedure performed in the United States (approximately 1.3 million annually) and might be the most common surgical procedure in the world (Alan Guttmacher Institute, 2015b). Both medical and surgical abortions are safe and legal in the United States; an abortion is considered a woman's constitutional right based on the fundamental right to privacy. Eighty-nine percent of abortions occur in the first 12 weeks of pregnancy (Alan Guttmacher Institute, 2015b).

Since the landmark U.S. Supreme Court decision *Roe v. Wade* legalized abortion in 1973, debate has continued over how and when abortions are provided. Every state has laws regulating some aspects of the provision of abortion, and many have passed restrictions such as parental consent or notification requirements, mandated counseling and waiting periods, and limits on funding for abortion. Each state addresses these matters independently, and the laws that are passed or enforced are legislative decisions and a function of the political system. Although opponents of abortion continue to be very much a part of the current debates, recently they have refocused their attention on "regulation legislation" among the states to reduce the number of abortions not medically necessary (Kreitzer, 2015).

Surgical Abortion

Two types of surgical abortion are available: vacuum aspiration or dilation, and evacuation (D&C). Method selection is based on gestational age. It is an ambulatory procedure done under local anesthesia. The cervix is dilated prior to surgery and then the products of conception are removed by suction evacuation. The uterus may gently be scraped by curettage to make sure that it is empty. The entire procedure lasts about 10 minutes. The overall risk of complications is less than 1% for surgical termination (Upadhyay et al., 2015).The major risks and complications in the first trimester are infection, retained tissue or hemorrhage, uterine perforation, retained products of conception, or cervical tear (Udoh et al., 2015). For women whose blood is Rh negative, *RhoGAM* is indicated prior to start of either medical or surgical termination.

Medical Abortion

Medical abortions are achieved through administration of medication either vaginally or orally. The administration of medication occurs in the clinic or doctor's office, may require two to four office visits, and costs between $300 and $800 (Planned Parenthood, 2015b). Three drugs are currently used to terminate a pregnancy during the first trimester. The first drug is methotrexate (an antineoplastic agent; Rheumatrex) followed by misoprostol (a prostaglandin agent; Cytotec) given as a vaginal suppository or in oral form 3 to 7 days later. Methotrexate induces abortion because of its toxicity to trophoblastic tissue, the growing embryo. Misoprostol works by causing uterine contractions, which helps to expel the products of conception. This method is 90% to 98% successful in completing an abortion (Patil & Edelman, 2015).

The second drug used to induce first-trimester abortions involves using mifepristone (a progesterone antagonist; Mifeprex, RU-486) followed 48 hours later by misoprostol (a prostaglandin agent), which causes contractions of the uterus and expulsion of the uterine contents. Currently, the most widely used method of medication abortion in the United States is the administration of mifepristone in conjunction with misoprostol. Another frequent method used includes the combination of methotrexate with misoprostol (Schuiling & Likis, 2016). Mifepristone, the generic name for RU-486, is sold under the brand names Mifeprex and Early Option. Mifepristone is an antiprogestin and blocks the action of progesterone, which is necessary for the maintenance of the pregnancy. This method is 95% effective when used within 49 days after the last menstrual cycle (Patil & Edelman, 2015).

Another drug frequently used is misoprostol (Cytotec), which is a prostaglandin analog that softens the cervix and causes uterine contractions, which results in the expulsion of uterine contents. There is no standard protocol for use of misoprostol (Cytotec) alone for termination of early pregnancy, and it is not FDA-approved for this purpose (King et al., 2015). Complications of medical abortions include incomplete expulsion of uterine contents, uterine infection, and heavy bleeding (Ganatra, Guest, & Berer, 2015).

The assessment of the woman with an unintended pregnancy should be performed with cautious sensitivity. It is essential to explore the women's feelings about pregnancy before congratulating or consoling her. The encounter should be guided by the feelings of the client, not by the assumptions and values

of the nurse.

Abortion is a very emotional, deeply personal issue. Give support and accurate information. If for personal, religious, or ethical reasons you feel unable to actively participate in the care of a woman undergoing an abortion, you still have the professional responsibility to ensure that the woman receives the nursing care and help she requires. This may necessitate a transfer to another area or a staffing reassignment. Nurses must keep in mind that all women have the right to have access to unbiased, factual information about available reproductive health choices, whether they seek to end or start a pregnancy, from which they can then make informed decisions about their own reproductive health.

MENOPAUSAL TRANSITION

Menopause is a natural process that occurs in all women's lives as part of normal aging. *Meno* is derived from the Greek word for "month," and *pause* is derived from the Greek word for "pause" or "halt." Menopause is the technical term for a point in time at which menses and fertility cease (King et al., 2015). The change of life. The end of fertility. The beginning of freedom. Whatever people call it, menopause is a unique and personal experience for every woman. The term **menopausal transition** refers to the transition from a woman's reproductive phase of her life to her final menstrual period. This period is also referred to as *perimenopause.* It is the end of her menstruation and childbearing capacity. The average age of natural menopause—defined as 1 year without a menstrual period—is 51.4 years old. The average age of natural menopause has remained constant for the last several hundred years despite improvements in nutrition and health care (Alexander et al., 2014). With current female life expectancy at 84 years, this event comes in the middle of a woman's adult life. Many women go through the menopausal transition with few or no symptoms, while some have significant or even disabling symptoms.

Take Note!

Humans are virtually the only species to outlive their reproductive capacities.

Menopause signals the end of an era for many women. It concludes their ability to reproduce, and some women find advancing age, altered roles, and these physiologic changes to be overwhelming events that may precipitate depression and anxiety (Woods & Mitchell, 2015). Menopause does not happen in isolation. Midlife is often experienced as a time of change and reflection. Change happens in many arenas: children are leaving or returning home, employment pressures intensify as career moves or decisions are required, older adult parents require more care or the death of a parent may have a major impact, and partners are retrenching or undergoing their own midlife crises. Women must negotiate all these changes in addition to menopause. Managing these stressful changes can be very challenging for many women as they make

the transition into midlife.

A woman is born with approximately 2 million ova, but only about 400 ever mature fully to be released during the menstrual cycle. The absolute number of ova in the ovary is a major determinant of fertility. Over the course of her premenopausal life there is a steady decline in the number of immature ova (Wood, 2015). No one understands this depletion, but it does not occur in isolation. Maturing ova are surrounded by follicles that produce two major hormones: estrogen, in the form of estradiol, and progesterone. The cyclic maturation of the ovum is directed by the hypothalamus. The hypothalamus triggers a cascade of neurohormones, which act through the pituitary and the ovaries as a pulse generator for reproduction. This hypothalamic–pituitary–ovarian axis begins to break down long before there is any sign that menopause is imminent. Some scientists believe that the pulse generator in the hypothalamus simply degenerates; others speculate that the ovary becomes more resistant to the pituitary hormone FSH and simply shuts down (Schuiling & Likis, 2016). The final act in this well-orchestrated process is amenorrhea.

As menopause approaches, more and more of the menstrual cycles become anovulatory. This period of time, usually 2 to 8 years before cessation of menstruation, is termed *perimenopause* (McNamara, Batur, & DeSapri, 2015). In perimenopause, the ovaries begin to fail, producing irregular and missed periods and an occasional hot flash. When menopause finally appears, viable ova are gone. Estrogen levels plummet by 90%, and estrone, produced in fat cells, replaces estradiol as the body's main form of estrogen. The major hormone produced by the ovaries during the reproductive years is estradiol; the estrogen found in postmenopausal women is estrone. Estradiol is much more biologically active than estrone (Hoyt & Falconi, 2015). In addition, testosterone levels decrease with menopause.

Menopausal transition, with its dramatic decline in estrogen, affects not only the reproductive organs, but also other body systems:

• Brain: hot flashes, disturbed sleep, mood and memory problems

• Cardiovascular: lower levels of high-density lipoprotein (HDL) and increased risk of CVD

• Skeletal: rapid loss of bone density that increases the risk of osteoporosis

• Breasts: replacement of duct and glandular tissues by fat

• Genitourinary: vaginal dryness, stress incontinence, cystitis

• Gastrointestinal: less absorption of calcium from food, increasing the risk for

fractures
- Integumentary: dry, thin skin and decreased collagen levels
- Body shape: more abdominal fat; waist size that swells relative to hips

Therapeutic Management

Menopausal transition should be managed individually. In the past, despite the wide diversity of symptoms and risks, the traditional reaction was to reach for the one-size-fits-all therapy: HT. Today the medical community is changing its thinking in light of the Women's Health Initiative (WHI) study and the Heart and Estrogen/Progestin Replacement Study Follow-Up (HERS II), which reported that long-term HT increased the risks of heart attacks, strokes, and breast cancer; in short, the overall health risks of HT exceeded the benefits (Kyvernitakis et al., 2015). In addition, HT did not protect against the development of coronary artery disease (CAD), nor did it prevent the progression of CAD, as it was previously touted to do.

A recent research finding examined the timing of HT in relation to CAD in women and it found that the earlier initiation of HT was associated with less CAD in women with natural but not surgical menopause. A Cochrane Review study found that HT in postmenopausal women overall, had little benefit in CAD prevention, but caused an increase in the risk of stroke and venous thromboembolic events (Boardman et al., 2015). As expected, the fallout from this study and others forced practitioners to re-evaluate their usual therapies and tailor treatment to each client's history, needs, and risk factors. A current study, however, shows that the incidence of fractures among menopausal transition and postmenopausal women increased significantly in the 3 years after publication of the WHI and HERS II results. This trend followed a decline in the use of HT, concurrent with an increase in the use of other bone-modifying agents (Bakour & Williamson, 2015). There is considerable evidence that estrogen or HT reduces the risk of postmenopausal osteoporotic fracture of both the spine and hip (Mirkin et al., 2015).

A number of treatment options are available, but factors in the client's history should be the driving force when determining therapy. Women need to educate themselves about the latest research findings and collaborate with their health care provider on the right menopause therapy. The following factors should be considered in management:

• The risk/benefit ratio is highest in younger women who begin HT not long after menopause.

• HT is approved for two indications: relief of vasomotor symptoms and

prevention of osteoporosis.

- Research suggests that HT may be beneficial for preventing diabetes, improving mood, or avoiding urinary tract problems.
- Using HT long beyond menopause carries increased risks, which, for some women, may be outweighed by the benefits (Bakour & Williamson, 2015).

Many women consider nonhormonal therapies such as bisphosphonates and selective estrogen receptor modulators (SERMs). Consider weight-bearing exercises, calcium, vitamin D, smoking cessation, and avoidance of alcohol to treat or prevent osteoporosis. Annual breast examinations and mammograms are essential. Local estrogen creams can be used for vaginal atrophy. Consider herbal therapies for symptoms, although none have been validated by rigorous research studies (Ismail et al., 2015).

ACOG recently revised guidelines on treating menopausal symptoms. Their recommendations include systemic HT, with estrogen or estrogen plus progestin, is the most effective approach for treating vasomotor symptoms; the lowest effective dose for the shortest duration is the best regimen; thromboembolic disease and breast cancer are risks for combined systemic HT; and local estrogen therapy is advised for isolated atrophic vaginal symptoms (2014).

Although numerous symptoms have been attributed to menopause (Box 4.9), some of them are more closely related to the aging process than to estrogen deficiency. A few of the more common menopausal conditions and their management are discussed next.

Managing Hot Flashes and Night Sweats

The emergence of hot flashes and night sweats (also known as vasomotor symptoms) coincides with a period in life that is also marked by dynamic changes in hormone and reproductive function that interconnect with the aging process, changes in metabolism, lifestyle behaviors, and overall health (Wood, 2015). Hot flashes and night sweats are classic signs of estrogen deficiency and the predominant complaint of perimenopausal women. A hot flash is a transient and sudden sensation of warmth that spreads over the body, particularly the neck, face, and chest. Hot flashes are caused by vasomotor instability. This instability causes inappropriate peripheral vasodilation of superficial blood vessels, which gives the sensation of heat. Nearly 85% of menopausal women experience them (Alexander et al., 2014). Hot flashes are an early and acute sign

of estrogen deficiency. These flashes can be mild or extreme and can last from 2 to 30 minutes and may occur as frequently as every hour to several times per week. On average, women experience hot flashes for a period of 6 months to 2 years, but the symptoms may last up to 10 years or more. Severe vasomotor symptoms can have a significant and detrimental effect on quality of life. Factors that trigger vasomotor symptoms include caffeine and alcohol consumption, intake of hot drinks and spicy foods, hot environment, depression, stress, and anxiety (Avis et al., 2015).

COMMON SYMPTOMS OF MENOPAUSE

• Hot flashes or flushes of the head and neck

• Dryness in the eyes and vagina

• Personality changes

• Anxiety and/or depression

• Loss of libido

• Decreased lubrication

• Weight gain and water retention

• Night sweats

• Atrophic changes—loss of elasticity of vaginal tissues

• Fatigue

• Irritability

• Poor self-esteem

• Insomnia

• Stress incontinence

• Heart palpitations

Adapted from Coney, P. (2015). Menopause. *Emedicine*. Retrieved from http://emedicine.medscape.com/article/264088-overview; Kessenich, C. R. (2015). Inevitable menopause. *Nursing Spectrum*. Retrieved from http://ce.nurse.com/ce232-60/Inevitable-Menopause; and Schuiling, K. D. & Likis, F. E. (2016). *Women's gynecologic health* (3rd ed.). Burlington, MA: Jones & Bartlett Learning.

Many options are available for treating hot flashes. Treatment must be based on symptom severity, the client's medical history, and the client's values and concerns. Although the gold standard in the treatment of hot flashes is estrogen, this is not recommended for all women who have high risk factors in their history.

TRADITIONAL THERAPIES FOR THE MANAGEMENT OF HOT FLASHES

The following are traditional therapies for the management of hot flashes:

• Pharmacologic options

• HT unless contraindicated

• Androgen therapy (potentiates estrogen)

• Estrogen and androgen combinations

• Progestin therapy (Depo-Provera injection every 3 months)

• Clonidine (central alpha-adrenergic agonist) weekly patch

• Neurontin (antiseizure) decreased hot flashes

• Propranolol (beta-adrenergic blocker)

• Brisdelle: FDA approved nonhormonal medication

• Short-term sleep aids: Ambien, Dalmane

• Gabapentin (Neurontin): antiseizure drug

• SSRIs: venlafaxine (Effexor) and paroxetine (Paxil) have shown promise (King & Brucker, 2016)

COMPLEMENTARY AND ALTERNATIVE THERAPIES FOR MANAGEMENT OF HOT FLASHES

Many women are choosing alternative treatments for managing menopausal symptoms. Bioidentical hormones have the ability to bind to receptors in the human body and function in the same way as a woman's natural hormones. They simulate three estrogens (estradiol, estriol, and estrone), as well as progesterone, testosterone, dehydroepiandrosterone (DHEA), thyroxine, and cortisol. Bioidentical hormones are not, however, natural hormones. The estrogens are derived via a chemical process from soybeans (*Glycine max*) and progesterone from Mexican yam (*dioscorea villosa*). As with conventional hormones, however, bioidentical hormones are available only with a physician's prescription and through a pharmacy. Because of their natural origin, women perceive that alternative treatments are safer. The interest in phytoestrogens came about because of the low prevalence of hot flashes in Asian women, which was attributed to their diet being rich in phytoestrogens. Recent studies have found that black cohosh, multibotanical herbs, and increased soy intake do not reduce the frequency or severity of menopausal hot flashes or night sweats.

Other remedies for easing menopausal symptoms might include red clover, motherwort, ginseng, sarsaparilla root, valerian root, L-tryptophan, calcium-magnesium, and kelp tablets (Ismail et al., 2015). Again, research thus far has been skeptical about their efficacy, but many women report they ease their symptoms and their use has skyrocketed. Although some benefits may accrue from their use, evidence of the efficacy of alternative products in menopause is largely anecdotal. Small, preliminary clinical trials might demonstrate the safety of some of the nonpharmacologic products. Nurses should be aware of the purported action of these agents as well as any adverse effects or drug interactions.

The following are lifestyle changes and CAM therapies for the treatment of hot flashes:

• Lifestyle changes

• Lower room temperature; use fans

• Wear clothing in layers for easy removal

• Limit caffeine and alcohol intake

• Drink 8 to 10 glasses of water daily

• Stop smoking or cut back

• Avoid hot drinks and spicy food

• Take calcium (1,200 to 1,600 mg) and vitamin D (400 to 600 International Units)

• Exercise daily, but not just before bedtime

• Maintain a healthy weight

• Identify stressors and learn to manage them

• Keep a diary to identify triggers of hot flashes

• Phytoestrogens: isoflavones, ligands, coumetrols

• Black cohosh

• Chamomile: mild sedative to alleviate insomnia

• Unopposed transdermal progesterone

• Compounded bioidentical hormones

• Try relaxation techniques, deep breathing, and meditation

• Acupuncture may reduce the frequency of hot flashes

- Vitamin E: 100 mg daily
- Dehydroepiandrosterone (DHEA)
- Chaste tree berry (vitex): balances progesterone and estrogen
- Dong quai: acts as a form of phytoestrogen
- Ginseng: purported to improve memory
- St. John's wort: reduces depression and fatigue
- Wild yam: treats menopausal symptoms
- Valerian root: induces sleep and relaxation (Wood, 2015)

Managing Urogenital Changes

Menopausal transition can be a physically and emotionally challenging time for women. In addition to the psychological burden of leaving behind the reproductive phase of life and the stigma of an aging body, sexual difficulties resulting from urogenital changes plague most women but are frequently not addressed. Sexual desire is affected by endocrine and psychosocial factors. Menopausal hormonal changes are relevant to the causes of sexual dysfunction during reproductive aging. The frequency of sexual intercourse declines as women enter midlife. Whereas partner availability and function probably play a role, menopausal symptoms, such as vaginal dryness, are also present (Comhaire & Depypere, 2015).

Vaginal atrophy occurs during menopause because of declining estrogen levels. These changes include thinning of the vaginal walls, an increase in pH, irritation, increased susceptibility to infection, **dyspareunia** (difficult or painful sexual intercourse), loss of lubrication with intercourse, vaginal dryness, and a decrease in sexual desire related to these changes. Decreased estrogen levels can also influence a woman's sexual function as well. Delayed clitoral reaction, decreased vaginal lubrication, diminished circulatory response during sexual stimulation, and reduced contractions during orgasm have all been linked to low estrogen levels (Coney, 2015).

Management of these changes might include the use of estrogen vaginal tablets (Vagifem) or Premarin cream; Estring, an estrogen-releasing vaginal ring that lasts for months; testosterone patches; and over-the-counter moisturizers and lubricants (Astroglide) (King et al., 2015). A positive outlook on sexuality and a supportive partner are also needed to make the sexual experience enjoyable and fulfilling. Nurses can improve the sexual health and quality of life in menopausal

women by educating them about their symptoms and offering them choices about managing them.

![Take Note icon] *Take Note!*

Sexual health is an important aspect of the human experience. By keeping an open mind, listening to women, and providing evidence-based treatment options, the nurse can help improve quality of life for menopausal women.

Preventing and Managing Osteoporosis

Osteoporosis has been recognized as a significant worldwide public health problem. As the world's population ages, both in the United States and internationally, the prevalence of osteoporosis is expected to increase significantly. **Osteoporosis** is the state of diminished bone density. This disorder is a systemic skeletal disease characterized by low bone mass and microarchitectural deterioration of bone tissue with a consequent increase in bone fragility and susceptibility to fracture (National Osteoporosis Foundation [(NOF], 2015a).

According to recent information from NOF (2015a), osteoporosis is a major medical problem that affects 10 million women and 2 million men in the United States. An additional 34 million Americans have low bone mass. Each year, an estimated 1.5 million individuals in the United States experience a fragility fracture secondary to osteoporosis, resulting in an annual cost of ∃18 billion. By 2025, experts predict that osteoporosis will be responsible for approximately 3 million fractures and ∃26 billion in costs each year (NOF, 2015a). With the rapidly aging population, the problem of osteoporosis is now reaching epidemic proportions. Seventy-five million baby boomers are entering the stage in their lives when they are most at risk for osteoporosis. One half of all women and one third of all men will sustain a fragility fracture during their lifetimes. Osteoporosis continues to be underdiagnosed and undertreated because it is often not recognized until the first fracture occurs.

Women are greatly affected by osteoporosis after menopause. Osteoporosis is a condition in which bone mass declines to such an extent that fractures occur with minimal trauma. Bone loss begins in the third or fourth decade of a woman's life and accelerates rapidly after menopause (Alexander et al., 2014).

This condition puts many women into long-term care, with a resulting loss of independence. Figure 4.22 shows the skeletal changes associated with osteoporosis.

FIGURE 4.22 Skeletal changes associated with osteoporosis. (John Radcliffe Hospital/Photo Researcher Inc.)

Most women with osteoporosis do not know they have the disease until they sustain a fracture, usually of the wrist or hip. Risk factors include:

• Increasing age
• Postmenopausal status without hormone replacement
• Small, thin-boned frame
• Low bone mineral density
• White or Asian with small bone frame
• Impaired eyesight that would increase risk of falling
• Rheumatoid arthritis
• Family history of osteoporosis
• Sedentary lifestyle
• History of treatment with:

- Antacids with aluminum
- Heparin
- Long-term use of steroids > 3 months
- Thyroid replacement drugs
- Smoking and consuming alcohol
- Low calcium and vitamin D intake
- Excessive amounts of caffeine
- Personal history of nontraumatic fracture
- Anorexia nervosa or bulimia (NOF, 2015a)

Currently, no method exists for directly measuring bone mass. Instead a BMD measurement is used. BMD is a two-dimensional measurement of the average content of mineral in a section of bone. BMD evaluations are made at the hip, femoral neck, and spine. There is a significant relationship between BMD and fracture: as BMD is reduced, the risk of fracture increases (Sullivan et al., 2015). Screening tests to measure bone density are not good predictors for young women who might be at risk for developing this condition. Dual-energy x-ray absorptiometry (DXA or DEXA) is a screening test that calculates the mineral content of the bone at the spine and hip. It is highly accurate, fast, and relatively inexpensive. The dual energy x-ray absorptiometry scan (DEXA scan) is the gold standard radiologic method for identifying osteoporosis through measuring BMD (U.S. Preventive Services Task Force, 2015).

Hip fracture is the most devastating of the fragility fractures secondary to osteoporosis. A number of medical, social, and economic consequences follow a hip fracture. Of women older than 50 years, on average, 24% die within the first year after hip fracture (Wang et al., 2015). The concern surrounding osteoporosis is not the rate of fracture alone but also the potential for lifelong disability secondary to fracture. The incidence of hip fracture is estimated to double by the year 2025 and nearly double again by 2050. For women, this is a projected 240% increase (NOF, 2015a).

The best management for this painful, crippling, and potentially fatal disease is prevention.

Women can modify many risk factors by doing the following:

- Engage in daily weight-bearing exercise, such as walking to increase osteoblast activity.

• Increase calcium and vitamin D intake.

• Avoid smoking and excessive alcohol (more than two drinks per day).

• Discuss bone health with a health care provider.

• When appropriate, have a bone density test and take medication if needed (NOF, 2015b).

Medications that can help in preventing and managing osteoporosis include:

• HT (Premarin)

• SERMs (raloxifene [Evista])

• Calcium and vitamin D supplements (Tums)

• Estrogen agonist/antagonist [SERM] (Evista)

• Bisphosphonates (Actonel, Fosamax, Boniva, or Reclast)

• Parathyroid hormone (Forteo)

• Calcitonin (Miacalcin) (King & Brucker, 2016)

Preventing and Managing Cardiovascular Disease

Despite the dramatic decrease in annual CVD mortality and total cardiovascular mortality for American women each year since 2000, CVD remains the number-one killer of women, accounting for one in three deaths in the United States. This is likely due to increased rates of obesity, sedentary lifestyle, diabetes, and high cholesterol levels (Chomistek et al., 2015). More women die from heart disease and stroke than the next five causes of death combined, including breast cancer. Half a million women die annually in the United States of CVD, with strokes accounting for about 20% of the deaths (Alexander et al., 2014). This translates into approximately one death every minute. While men's mortality from CVD has decreased since the 1980s, women's mortality from CVD has climbed. This has resulted in a sex-related CVD mortality gap, with women having higher mortality than men since 1984. Contributing to this female-majority CVD mortality gap is a lack of awareness among women and their physicians of the risk for CVD. Awareness campaigns, such as the Heart Truth and the Red Dress symbol, appear to have improved recognition of CVD risk in women. Further, female-specific guidelines have been developed to prevent and reduce CVD in women. Though the current understanding of the role of menopause in CVD is controversial, studies suggest that menopause does not

exacerbate CVD independent of aging, and HT is not effective for secondary prevention of CVD (Hale & Shufelt, 2015).

For the first half of a woman's life, estrogen seems to be a protective substance for the cardiovascular system by smoothing, relaxing, and dilating blood vessels. It even helps boost HDL and lower low-density lipoprotein (LDL) levels, helping to keep the arteries clean from plaque accumulation. But when estrogen levels plummet as women age and experience menopause, the incidence of CVD increases dramatically. Women are more likely to have atypical cardiovascular symptoms compared with men. This may lead to a delayed or misdiagnosis of CAD and suboptimal treatment. These symptoms may include:

• A – Angina (chest pain)

• B – Breathlessness

• C – Chronic fatigue

• D – Dizziness

• E – Edema of hands and feet

• F – Fluttering of the heart

• G – Gastric upset

• H – Heavy pain in back and shoulders

Menopause is not the only factor that increases a woman's risk for CVD. Lifestyle and medical history factors such as the following play a major role:

• Smoking

• Obesity

• High-fat diet

• Sedentary lifestyle

• High cholesterol levels

• Family history of CVD

• Hypertension

• Apple-shaped body

• Diabetes

Two of the major risk factors for coronary heart disease are hypertension and

dyslipidemia. Both are modifiable and can be prevented by lifestyle changes and, if needed, controlled by medication. This is why prevention is essential. In addition, women who experience early menopause lose the protection afforded by endogenous estrogen to the cardiac system and are at greater risk for more extensive atherosclerosis. Major preventive strategies include a healthy diet, increased activity, exercise, smoking cessation, decreased alcohol intake, and weight reduction.

Nurses, particularly those caring for women during their reproductive years, are uniquely positioned to provide education and support for women's long-term cardiovascular health. Raising awareness of heart disease in women is an essential role for nurses. The good news is that CVD is largely preventable. Because CVD is a chronic disease that develops over time, primary prevention lifestyle modification interventions are most effective if initiated before the development of overt disease. Stressing the importance of lifestyle modifications must begin early in life and should be reinforced from the beginning of a young woman's reproductive years through menopause. Nurses are in an ideal position to teach the importance of good nutrition, healthy weight, and daily exercise before CVD becomes clinically evident.

Nursing Assessment

Menopausal transition is a universal and irreversible part of the overall aging process involving a woman's reproductive system. Although not a disease state, menopausal transition does place women at greater risk for the development of many conditions of aging. Nurses can help the woman become aware of her risk for postmenopausal diseases, as well as strategies to prevent them. The nurse can be instrumental in assessing risk factors and planning interventions in collaboration with the client. These might include:

• Screening for osteoporosis, CVD, and cancer risk

• Assessment of blood pressure to identify hypertension

• Blood cholesterol test to identify hyperlipidemia risk

• Mammogram to find a cancerous lesion

• Pap smear to identify cervical cancer

• Pelvic examination to identify endometrial cancer or masses

• Digital rectal examination to assess for colon cancer

• Bone density testing as a baseline at menopause to identify osteopenia (low bone mass), which might lead to osteoporosis

• Assessing lifestyle to plan strategies to prevent chronic conditions:

• Dietary intake of fat, cholesterol, and sodium

• Weight management

• Calcium intake

• Use of tobacco, alcohol, and caffeine

• Amount and type of daily exercise routines

Nursing Management

There is no "magic bullet" in managing menopause. Nurses can counsel women about their risks and help them to prevent disease and debilitating conditions with specific health maintenance education. Women should make their own decisions, but the nurse should make sure they are armed with the facts to do so intelligently. Nurses can offer a thorough explanation of the menopausal process, including the latest research findings, to help women understand and make decisions about this inevitable event.

If the woman decides to use HT to control her menopausal symptoms, after being thoroughly educated, she will need frequent reassessment. There are no hard-and-fast rules that apply to meeting a woman's individual needs. The nurse can provide realistic expectations of the therapy to reduce the woman's anxiety and concern.

It is also useful to emphasize the value of friends to gain support and share information and resources. Often just talking about emotional difficulties such as the death of a parent or problematic relationships helps solve problems. It also shows the woman that her emotional responses are valid.

Healthy lifestyles and stress management techniques are vital to health and longevity, and it is important to keep these on the client's agenda when discussing menopause (North American Menopause Society, 2015). Evidence-based interventions include lifestyle modifications, risk management therapies, and preventive drug interventions, such as the following:

• Participate actively in maintaining health.

• Exercise regularly to prevent CVD and osteoporosis.

• Take supplemental calcium and eat appropriately to prevent osteoporosis.

• Stop smoking to prevent lung and heart disease.

• Reduce caffeine and alcohol intake to prevent osteoporosis.

• Monitor blood pressure, lipids, and diabetes (drug therapy management).

• Use low-dose aspirin to prevent blood clots.

• Reduce dietary intake of fat, cholesterol, and sodium to prevent CVD.

• Maintain a healthy weight for body frame.

• Perform breast self-examinations for breast awareness.

• Control stress to prevent depression (Worel & Hayman, 2015).

    These life approaches may seem low-tech, but they can stave off menopause-related complications such as CVD, osteoporosis, and depression. These tips for healthy living work well, but the client needs to be motivated to stick with them.

KEY CONCEPTS

- Establishing good health habits and avoiding risky behaviors early in life will prevent chronic conditions later in life.
- PMS has more than 150 symptoms, and at least 2 different syndromes have been recognized: PMS and PMDD.
- Endometriosis is a condition in which bits of functioning endometrial tissue are located outside their normal site, the uterine cavity.
- Infertility is a widespread problem that has an emotional, social, and economic impact on couples.
- More than half of all unintended pregnancies occur in women who report using some method of birth control during the month of conception.
- Hormonal methods include OCs, injectables, implants, vaginal rings, and transdermal patches.
- Recent studies have shown that the extension of active extended cycle OC pills carries the same safety profile as the conventional 28-day regimens (Zieman, 2015).
- Currently three intrauterine contraceptives are available in the United States: the copper ParaGard-TCu-380A, the levonorgestrel-releasing intrauterine system (LNG-IUS) marketed as Mirena and another LNG-IUD marketed as Skyla (King et al., 2015).
- OCs, sterilization, and male condoms are the most popular methods of contraception in the United States and worldwide (Alan Guttmacher Institute, 2015a).
- Menopause, with a dramatic decline in estrogen levels, affects not only the reproductive organs but also other body systems.
- Most women with osteoporosis do not know they have the disease until they sustain a fracture, usually of the wrist or hip (NOF, 2015a).
- Half a million women die annually in the United States of CVDs, with strokes

accounting for about 20% of the deaths (Alexander et al., 2014).

- Nurses should aim to have a holistic approach to the sexual health of women from menarche through menopause.

CHAPTER **WORKSHEET**

MULTIPLE-CHOICE QUESTIONS

1. A couple is considered infertile after how many months of trying to conceive?
   a. 6 months
   b. 12 months
   c. 18 months
   d. 24 months

2. A couple reports that their condom broke while they were having sexual intercourse last night. What would you advise to prevent pregnancy?
   a. Inject a spermicidal agent into the woman's vagina immediately.
   b. Obtain emergency contraceptives and take them immediately.
   c. Douche with a solution of vinegar and hot water tonight.
   d. Take a strong laxative now and again at bedtime.

3. Which of the following combination contraceptives has been approved for extended continuous use?
   a. Seasonale
   b. Triphasil
   c. Ortho Evra
   d. Mirena

4. Which of the following measures helps prevent osteoporosis?
   a. Supplementing with iron

b. Sleeping 8 hours nightly

c. Eating lean meats only

d. Walking daily

5. Which of the following activities will increase a woman's risk of cardiovascular disease if she is taking oral contraceptives?

a. Eating a high-fiber diet

b. Smoking cigarettes

c. Taking daily multivitamins

d. Drinking alcohol

6. The nurse is preparing to teach a class to a group of middle aged women regarding the most common vasomotor symptoms experienced during menopause and possible modalities of treatment available. Which of the following would be a vasomotor symptom experienced by menopausal women?

a. Weight gain

b. Bone density

c. Hot flashes

d. Heart disease

7. Throughout life, a woman's most proactive activity to promote her health would be to engage in:

a. consistent exercise

b. socialization with friends

c. quality quiet time with herself

d. consuming water

8. What comment by a woman would indicate that a diaphragm is not the best contraceptive device for her?

a. "My husband says it is my job to keep from getting pregnant."

b. "I have a hard time remembering to take my vitamins daily."

c. "Hormones cause cancer and I don't want to take them."

d. "I am not comfortable touching myself down there."

9. The most common cause of menstrual abnormality in a reproductive-age woman is:

a. ectopic pregnancy

b. coagulopathy

c. carcinoma

d. anovulation

CRITICAL THINKING EXERCISE

1. Ms. London, age 25, comes to your family planning clinic requesting to have an IUC inserted because "birth control pills give you cancer." In reviewing her history, you note she has been into the STI clinic three times in the past year with vaginal infections and was hospitalized for PID last month. When you question her about her sexual history, she reports having sex with multiple partners and not always using protection.

a. Is an IUC the most appropriate method for her? Why or why not?

b. What myths/misperceptions will you address in your counseling session?

c. Outline the safer sex discussion you plan to have with her.

STUDY ACTIVITIES

1. Develop a teaching plan for an adolescent with PMS and dysmenorrhea.

2. Arrange to shadow a nurse working in family planning for the morning. What questions does the nurse ask to ascertain the kind of family planning method that is right for each woman? What teaching goes along with each method? What follow-up care is needed? Share your findings with your classmates during a clinical conference.

3. Surf the Internet and locate three resources for infertile couples to consult that provide support and resources.

4. Sterilization is the most prevalent method of contraception used by married couples in the United States. Contact a local urologist and gynecologist to

learn about the procedure involved and the cost of a male and female sterilization. Which procedure poses less risk to the person and costs less?

5. Take a field trip to a local drugstore to check out the variety and costs of male and female condoms. How many different brands did you find? What was the range of costs?

6. Noncontraceptive benefits of combined oral contraceptives include which of the following? Select all that apply.

a. Protection against ovarian cancer

b. Protection against endometrial cancer

c. Protection against breast cancer

d. Reduction in incidence of ectopic pregnancy

e. Prevention of functional ovarian cysts

f. Reduction in deep venous thrombosis

g. Reduction in the risk of colorectal cancer

BRINGING IT ALL TOGETHER: CASE STUDY

L. H. is a 66-year-old White female who presents to the Women's Health Primary Care Clinic for her annual gynecologic examination. She states that she is fairly healthy with no active medical conditions other than hypertension controlled with medication. She is postmenopausal and feels she is doing well, but has a few questions and concerns. Her primary concern is that she is bothered by vaginal dryness and pain with sexual intercourse. Over-the-counter lubricants and moisturizers have not been useful. She never took HT since her hot flashes were not severe, but asks if she should start taking it now to reduce her vaginal dryness.

Go to thePoint **to find questions to consider about this case.**

5

Sexually Transmitted Infections

bacterial vaginosis
genital/vulvovaginal candidiasis
gonorrhea
pelvic inflammatory disease (PID)
sexually transmitted infection (STI)
syphilis
trichomoniasis

Learning Objectives

Upon completion of the chapter, you will be able to:

1. Evaluate the spread and control of sexually transmitted infections.
2. Identify risk factors and outline appropriate client education needed in common sexually transmitted infections.
3. Describe how contraceptives can play a role in the prevention of sexually transmitted infections.
4. Analyze the physiologic and psychological aspects of sexually transmitted infections.
5. Outline the nursing management needed for women with sexually transmitted infections.

> ***Sandy,*** *a 19-year-old girl, couldn't imagine what these "things" were that appeared "down there" in her genital area last week. She was too embarrassed to tell anyone, so she stopped by the college health service today to find out what they were.*

Words of Wisdom

Unconditional self-acceptance in clients is the core to reducing risky behavior and fostering peace of mind.

INTRODUCTION

Sexually transmitted infections (STIs) are infections of the reproductive tract caused by microorganisms transmitted through vaginal, anal, or oral sexual intercourse (Centers for Disease Control and Prevention [CDC], 2015a). STIs are a significant health challenge globally which pose a serious threat not only to women's sexual health but also to the general health and well-being of millions of people worldwide (see Box 5.1 for STI classification). STIs constitute an epidemic of tremendous magnitude. An estimated 65 million people live with an incurable STI, 18,000 die from acquired immune deficiency syndrome (AIDS) annually, and another 20 million are newly infected each year (CDC, 2015a). The incidence of STIs continues to rise and costs the United States over $18 billion annually (CDC, 2015a).

STIs are biologically sexist, presenting greater risk and causing more complications among women than among men. Women are diagnosed with two thirds of the estimated 20 million new cases of STIs annually in the United States. After only a single exposure, women are twice as likely as men to acquire infections from pathogens that cause gonorrhea, chlamydial infection, hepatitis B, and syphilis. Every day, more than one million people are newly infected with STIs that can lead to morbidity, mortality, and an increased risk of human immunodeficiency virus (HIV) acquisition (Fernández-Romero et al., 2015). STIs may contribute to cervical cancer, infertility, ectopic pregnancy, chronic pelvic pain, and death. Certain infections can be transmitted in utero to the fetus or during childbirth to the newborn (Table 5.1).

Additional information on therapeutic management of STIs can be found in Chapter 20.

CULTURAL AND PSYCHOLOGICAL COMPONENTS OF SEXUALLY TRANSMITTED INFECTIONS

Nurses should always address a woman's psychosocial well-being whenever a diagnosis of any STI is given. The woman may be afraid or embarrassed to tell her partner and ask him or her to seek treatment. In some instances, the woman may be afraid that telling her partner may place her in danger of escalating abuse. The nurse can empathize with the woman's feelings and suggest specific ways of talking with partners that will help decrease her anxiety and assist in efforts to control infection (Reidy et al., 2016). Nurses implementing STI prevention strategies must also acknowledge the possible role of violence in increasing women's risk as a barrier to practicing safer sex. Research suggests a strong association between intimate partner violence and STIs. Both need to be addressed to reduce the spread of STIs. Even brief interventions in the health care settings are not only feasible but also potentially lifesaving for women experiencing violence in their lives (Durevall & Lindskog, 2015).

TABLE 5.1 SEXUALLY TRANSMITTED INFECTIONS AND EFFECTS ON THE FETUS OR NEWBORN

STI	Effects on Fetus or Newborn
Chlamydia	Can be infected during delivery Eye infections (neonatal conjunctivitis), pneumonia, low birth weight, preterm birth, stillbirth
Gonorrhea	Can be infected during delivery Rhinitis, vaginitis, urethritis, inflammation of sites of fetal monitoring, chorioamnionitis, preterm birth, IUGR Ophthalmia neonatorum can lead to blindness and sepsis (including arthritis and meningitis).
Genital herpes	Contamination can occur during birth. Intellectual disability, blindness, seizures, premature birth, low birth weight, death
HIV/AIDS	Preterm birth, low birth weight, HIV positive status, intrauterine fetal death, miscarriage
Syphilis	Can be passed in utero Can result in fetal or infant death Congenital syphilis symptoms include skin ulcers, rashes, fever, weakened or hoarse cry, swollen liver and spleen, jaundice and anemia, various deformations.
Trichomoniasis	Premature rupture of membranes, preterm birth, low birth weight
Genital warts	May develop warts in throat (laryngeal papillomatosis); uncommon but life threatening

CDC CLASSIFICATION OF SEXUALLY TRANSMITTED INFECTIONS

• Infections characterized by vaginal discharge

  • Vulvovaginal candidiasis

  • Trichomoniasis

  • Bacterial vaginosis

• Infections characterized by cervicitis

  • Chlamydia

  • Gonorrhea

• Infections characterized by genital ulcers

  • Genital herpes simplex

  • Syphilis

• Vaccine-preventable STIs

  • Hepatitis A

  • Hepatitis B

  • Human papillomavirus (HPV)

• Ectoparasitic infections

  • Pediculosis pubis

  • Scabies

Adapted from Centers for Disease Control and Prevention [CDC]. (2015k). *STD treatment guidelines*. Retrieved from http://www.cdc.gov/std/treatment/2010/default.htm.

STIs know no gender, class, racial, ethnic, or social barriers—all individuals are vulnerable if exposed to the infectious organism. The problem of STIs has still not been tackled adequately on a global scale, and until this is done, numbers worldwide will continue to increase. Nurses working with women from diverse cultures need to be cognizant of effective methods of STI prevention (Box 5.2).

Given the high value some cultures place on virginity and fidelity, a diagnosis of an STI can be devastating to the woman and her family. Even to suggest a test for STIs can appear inappropriate or offensive. When a client must be screened for STIs, explaining the need carefully and not revealing to other family members that testing has occurred are essential. By adopting a multicultural approach to the control of STIs, nurses can address specific cultural and religious attitudes and behaviors that influence exposure to STIs (Thomas et al., 2015). To maximize the impact of behavioral interventions and risk reduction programs, the nurse must adjust for social and cultural differences within all diverse populations. Nurses play a crucial role in supporting women from diverse cultures within sexual health services and as trusted health care providers in a range of settings.

BOX 5.2

SEXUALLY TRANSMITTED INFECTIONS IN DIVERSE CULTURES

Cultural adaptation is an important step in the process of implementing health promotion interventions that, having been proven to be effective in one culture, are being applied in another. Nurses working with women from diverse cultures need to be cognizant of effective methods of STI prevention.

In a recent CDC study, greater prevention intervention efficacy was observed in studies that specifically targeted females of different cultures that used gender- or culture-specific materials, used female deliverers, addressed empowerment issues, provided skills training in condom use and negotiation of safer sex, and used role-playing to teach negotiation skills. The incidence of STIs was reduced significantly (Thomas et al., 2015). To truly maximize the impact of behavioral interventions and risk reduction programs, nurses must adjust for social and cultural differences within any diverse population group for which they care.

Racial minorities continue to face severe disparities in all reportable STIs, but African Americans are the group most affected. Gonorrhea rates among African Americans are higher than those for any other racial or ethnic group and 15 times higher than that of Whites (Kraft et al., 2015). Nurses cannot ignore the glaring racial disparities in rates of STIs. Research has shown that socioeconomic barriers to quality health care and higher overall prevalence of STIs within minority communities contribute to this pervasive threat. It is imperative that the health care team work together to improve access to effective STI prevention and treatment services in local communities for those who need it the most. By adopting a multicultural approach to the control of STIs, nurses can address specific cultural attitudes and behaviors that may impact exposure to STIs and intervene to reduce them.

SEXUALLY TRANSMITTED INFECTIONS AND ADOLESCENTS

STIs occur disproportionately in adolescents. An estimated two thirds of all STIs occur among persons under the age of 25. Forty-seven percent of high school students report having been sexually active. These data reinforce existing recommendations for sexual health education and STI prevention targeting adolescents before sexual debut (Liu et al., 2015).

Risk Factors

Because of biologic and behavioral factors, adolescents are at particularly high risk for acquiring STIs and for the serious, long-term, potentially life-altering sequelae that can develop from undiagnosed, untreated infections. Each year 5 million cases of STIs occur among teenagers (CDC, 2015a). In the United States, teens who are sexually active experience high rates of STIs, and some groups are at higher risk, including African American youths, abused youths, homeless youths, young men having sex with men, and lesbian, gay, bisexual, and transgendered (LGBT) youths. High-risk factors in adolescents include having multiple or new sexual partners and not using condoms for any number of reasons. Inexperience with condoms also can lead to more condom accidents, such as breakage caused by storage in a hot environment, opening packages with teeth, using long fingernails to put condoms on, slippage if the wrong size condom is used, or failure to hold the condom while withdrawing. Furthermore, some adolescents are unwilling to disclose their sexual activity. If symptoms of an STI develop, they may misperceive them as normal, consequently delaying medical treatment. Untreated STIs can cause pelvic inflammatory disease (PID, which can lead to infertility), adverse pregnancy outcomes, and anogenital and cervical cancers. In addition, the presence of other STIs increases the likelihood of both transmitting and acquiring HIV (Smith, 2015).

Take Note!

It is estimated that before graduating from high school, 25% of adolescents will contract an STI (CDC, 2015a).

Biologic and behavioral factors place teenagers at high risk. Female adolescents are more susceptible to STIs than males due to their anatomy. During adolescence and young adulthood, women's columnar epithelial cells are especially sensitive to invasion by sexually transmitted organisms, such as chlamydia and gonococci, because they extend out over the vaginal surface of the cervix, where they are unprotected by cervical mucus; these cells recede to a more protected location as women age. Behaviorally, adolescents and young adults tend to think they are invincible and deny the risks of their behavior. This

risky behavior exposes them to STIs and HIV/AIDS. Adolescents frequently have unprotected intercourse, they engage in partnerships of limited duration, and they face many obstacles that prevent them from using the health care system.

Healthy People 2020 Objective

Healthy People 2020 (U.S. Department of Health & Human Services [USDHHS], 2010) provides science-based, 10-year national objectives for improving the health of all people in the United States. For three decades, *Healthy People* has established benchmarks and monitored progress over time. One specific *Healthy People 2020* goal that applies to this chapter is to promote healthy sexual behaviors, strengthen community capacity, and increase access to quality services to prevent STIs and their complications.

An important feature of *Healthy People 2020* is its emphasis on responsibility. People need to accept responsibility for their lifestyle choices and behaviors. This personal responsibility is especially important for sexually active adolescents because they contract the highest rate of STIs as a result of making poor choices. Chlamydial and gonorrheal infections are the two most commonly reported bacterial STIs in the United States, and their prevalence is highest among females aged 15 to 24. Human papillomavirus (HPV) infection, trichomoniasis, and herpes simplex virus (HSV) infections are also common in adolescents (Jones, 2015). The *Healthy People 2020* objective, "Increase the proportion of sexually active persons aged 15 to 19 years who use condoms to both effectively prevent pregnancy and provide barrier protection against disease," addresses this personal responsibility focus (USDHHS, 2010).

Healthy People 2020's emphasis on personal responsibility gives adolescents a role in the quality of their lives and the length of healthy life they may have by making the right choices and engaging in nonrisky behaviors.

Nursing Assessment

Many health care providers fail to assess adolescent sexual behavior and STI risks, to screen for asymptomatic infection during clinic visits, or to counsel adolescents on STI risk reduction. Nurses need to remember that they play a key role in the detection, prevention, and treatment of STIs in adolescents. All states allow adolescents to give consent to confidential STI testing and treatment. Table 5.2 discusses the clinical manifestations of common STIs in adolescents.

Nursing Management

Prevention of STIs among adolescents is critical. Health care providers have a unique opportunity to provide counseling and education to their clients. Adolescents are less willing to be open to nurses and less likely to return for care if they are uncertain about confidentiality. Nurses working with adolescents need to convey their willingness to discuss sexual habits, and any interactions with clients need to be direct and nonjudgmental.

Nurses can provide effective guidance and promote sexual health so that primary or repeat infections can be avoided. Adolescents bear disproportionate burdens when it comes to STIs, so education is needed to help them protect their reproductive futures. Specific actions to take include the following:

• Encourage the client to complete antibiotic prescriptions (specific management for each type of STI is discussed below).

• Adapt the style and content of any message to the client's developmental level.

• Identify risk factors and risk behaviors and guide the client to develop specific individualized actions of prevention.

• Teach adolescents about their sexual development to foster understanding of their bodily changes—the role of hormones and the emotions they are experiencing.

• Encourage adolescents to postpone initiation of sexual intercourse for as long as possible, but if they choose to have sexual intercourse, explain the necessity of using barrier methods, such as male and female condoms (Teaching Guidelines 5.1). For teens who have already had sexual intercourse, the clinician can encourage abstinence at this point. If adolescents are sexually active, they should be directed to teen clinics, and contraceptive options should be explained. In areas where specialized teen clinics are not available, nurses should feel comfortable discussing sexuality, safety, and contraception with teens. Encourage adolescents to minimize their lifetime number of sexual partners, to use barrier methods consistently and correctly, and to be aware of the connection between drug and alcohol use and the incorrect use of barrier methods. Table 5.3 discusses barriers to condom use and means to overcome them.

TABLE 5.2 COMMON SEXUALLY TRANSMITTED INFECTIONS

Disease	Causative Organism	Transmission Mode	Diagnostic Testing	Female Symptoms	Male Symptoms	Treatment
Chlamydia Curable STI Seen frequently among sexually active adolescents and young adults Sexually active adolescents should be screened at least annually.	*Chlamydia trachomatis* (bacteria)	Vaginal, anal, oral sex, and by childbirth	Culture fluid from urethral swabs in males or endocervical swabs for females and conjunctival secretions in neonates	May be asymptomatic Dysuria Vaginal discharge (mucus or pus) Endocervicitis May lead to pelvic inflammatory disease, ectopic pregnancy, and infertility Can cause inflammation of the rectum and lining of the eye (conjunctivitis) Can infect the throat from oral sexual contact with an infected partner	May be asymptomatic Dysuria Penile discharge (mucus or pus) Urethral tingling May lead to epididymitis (inflammation of the epididymis, the tubular structure that connects the testicle with the vas deferens) and sterility Can cause inflammation of the rectum and lining of the eye (conjunctivitis) Can infect the throat from oral sexual contact with an infected partner	Azithromycin (Zithromax) Doxycycline (Vibramycin) Erythromycin (EES) Ofloxacin (Floxin) Sexual partners need evaluation, testing, and treatment also.
Gonorrhea Curable STI Client is often co-infected with *Chlamydia trachomatis*	*Neisseria gonorrhoeae* (bacteria)	Vaginal, anal, oral sex, and by childbirth	Staining samples directly for the bacterium, detection of bacterial genes or DNA in urine, and growing the bacteria in laboratory cultures More than one test may be used	May be asymptomatic or no recognizable symptoms until serious complications such as pelvic inflammatory disease Dysuria Urinary frequency Vaginal discharge (yellow, foul) Dyspareunia Endocervicitis Arthritis	Most produce symptoms but can be asymptomatic Dysuria Penile discharge (pus) Arthritis May lead to epididymitis and sterility Symptoms of rectal infection include discharge, anal itching, and occasional painful bowel movements with fresh blood.	Usually a single dose of one of the following: Cefixime (Suprax) Ciprofloxacin (Cipro) Ceftriaxone (Rocephin) Ofloxacin (Floxin) Levofloxacin (Levaquin) **No Floxin or Cipro if <18 years or pregnant!**
				May lead to pelvic inflammatory disease, ectopic pregnancy, and infertility Symptoms of rectal infection include discharge, anal itching, and occasional painful bowel movements with fresh blood.		Azithromycin (Zithromax) Doxycycline (Vibramycin) Usually will be treated for co-infection with chlamydia, so a combination is given (e.g., ceftriaxone and doxycycline). Sexual partners need evaluation, testing, and treatment also.
Genital herpes Lifelong recurrent viral disease Most people have not been diagnosed. There is no cure.	Herpes simplex virus II (HSV II)	Having sexual contact (vaginal, oral, or anal) with someone who is shedding the herpes virus either during an outbreak or during a period with no symptoms Can be transmitted through close skin-to-skin contact	Visual inspection and symptoms or culture Virologic and type-specific serologic tests can tell if herpes simplex virus II is present but does not confirm genital herpes, though most providers will assume a positive HSV II means genital herpes. IgG/IgM antibody testing is also done.	Blister-like genital lesions Dysuria Fever, headache, muscle aches	Blister-like genital lesions Dysuria Fever, headache, muscle aches	Acyclovir (Zovirax) Other antivirals DOES NOT CURE, just controls symptoms Sexual partners benefit from evaluation and counseling. If symptomatic, they need treatment. If asymptomatic, offer testing and education.
Syphilis	*Treponema pallidum* (spirochete bacteria)	Sexual contact with an infected person	Blood tests Venereal Disease Research Laboratory (VDRL), Rapid Plasma Reagin (RPR), and treponemal tests (e.g.,	Disease is divided into four stages: *Primary infection* • Chancre on place of entrance of bacteria (usually vulva or vagina but can develop in other parts of the body)	Disease is divided into four stages: *Primary infection* • Chancre on place of entrance of bacteria (usually on penis but can develop in other parts of the body)	Penicillin G inj. (if penicillin allergy, doxycycline or erythromycin) Azithromycin; Rocephin, Cipro Sexual partners need evaluation and testing.

			fluorescent treponemal antibody absorbed [FTA-ABS]) can lead to a presumptive diagnosis. Dark-field examination and direct fluorescent antibody tests of lesion exudate or tissue provide definitive diagnosis of early syphilis.	*Secondary infection* • Maculopapular rash (hands & feet) • Sore throat • Lymphadenopathy • Flu-like symptoms *Latent infection* • No symptoms • No longer contagious • Many people if not treated will suffer no further signs and symptoms. Some people will go on to develop tertiary or late syphilis. *Tertiary infections* • Tumors of skin, bones & liver • CNS symptoms • CV symptoms • Usually not reversible at this stage	*Secondary, latent, and tertiary infections* All similar to female symptoms	
Trichomoniasis	*Trichomonas vaginalis* (protozoan)	Vaginal intercourse with an infected partner	Microscopic evaluation of vaginal secretions or culture	Many women have symptoms but some may be asymptomatic.	Most infected men are asymptomatic. Dysuria Penile discharge (watery, white)	Metronidazole (Flagyl) Sexual partners need evaluation, testing, and treatment also.
		May be picked up from direct genital contact with damp or moist objects, such as towels, wet clothing, or a toilet seat		Dysuria Urinary frequency Vaginal discharge (yellow, green, or gray & foul odor) Dyspareunia Irritation or itching of genital area		

Genital Warts (condylomata acuminata) One of the most common STIs in the United States Could lead to cancers of the cervix, vulva, vagina, anus, or penis No cure; warts can be removed but virus remains	Human papill-omavirus	Vaginal, anal, or oral sex with an infected partner	Visual inspection Abnormal Pap smear may indicate cervical infection of HPV.	Wart-like lesions that are soft, moist, or flesh colored and appear on the vulva and cervix and inside and surrounding the vagina and anus Sometimes appear in clusters that resemble cauliflower-like bumps, and are either raised or flat, small or large	Wart-like lesions that are soft, moist, or flesh colored and appear on the scrotum or penis Sometimes appear in clusters that resemble cauliflower-like bumps, and are either raised or flat, small or large	May disappear without treatment Treatment is aimed at removing the lesions rather than HPV itself No optimal treatment has been identified, but there are several ways to treat them depending on size and location. Most methods rely on chemical or physical destruction of the lesion: Imiquimod cream 20% Podophyllin antimitotic solution 0.5% Podofilox solution 5% 5-Fluorouracil cream Trichloroacetic acid (TCA) Small warts can be removed by: • Freezing (cryosurgery) • Burning (electrocautery) • Laser treatment Large warts that have not responded to treatment may be removed surgically.

HEALTHY PEOPLE 2020 • 5.1

Healthy People 2020 STI Objectives	Nursing Significance
STD-1 Reduce the proportion of young adults with *Chlamydia trachomatis* infections.	Provide confidential care to all young females.
STD-3 Increase the proportion of sexually active females aged 21 to 24 years enrolled in Medicaid plans that are screened for genital *Chlamydia* infections during the measurement year.	Assess for sexual behaviors and STI risks during clinic visits; take every opportunity to educate on risks of STIs and risk reduction.
STD-4 Increase the proportion of sexually active females aged 21 to 24 years and under enrolled in commercial health insurance plans that are screened for genital *Chlamydia* infections during the measurement year.	Be direct and nonjudgmental and tailor your approach to the client.
STD-6 Reduce gonorrhea rates.	Encourage women to minimize their lifetime number of sexual partners.
STD-7 Reduce sustained domestic transmission of primary and secondary syphilis.	Educate about the importance of correct and consistent condom use.
STD-9 (Developmental) Reduce the proportion of females with human papillomavirus (HPV) infection.	
STD-10 Reduce the proportion of young adults with genital herpes infection due to herpes simplex type 2.	

Healthy People objectives based on data from http://www.healthypeople.gov.

HEALTHY PEOPLE 2020 • 5.2

Healthy People 2020 STIs & Adolescents	Nursing Significance
STD-1 Reduce the proportion of adolescents with *Chlamydia trachomatis* infections.	Educate adolescents that abstinence is the only way to completely avoid contracting sexually transmitted infections.
STD-3 Increase the proportion of sexually active adolescents enrolled in Medicaid plans that are screened for genital *Chlamydia* infections during the measurement year.	Encourage adolescents to postpone initiation of sexual intercourse for as long as possible. For teens who have already had sexual intercourse, encourage abstinence at this point.
STD-4 Increase the proportion of adolescents enrolled in commercial health insurance plans that are screened for genital *Chlamydia* infections during the measurement year.	Encourage adolescents to minimize their lifetime number of sexual partners.
STD-5 Reduce the proportion of adolescents who have ever required treatment for pelvic inflammatory disease (PID).	Encourage adolescents always to use condoms if participating in any sexual act.
	Provide an open and confidential environment so that adolescents will report symptoms and seek treatment earlier.

Healthy People objectives based on data from http://www.healthypeople.gov.

TABLE 5.3 CANADIAN GUIDELINES: BARRIERS TO CONDOM USE AND MEANS TO OVERCOME THEM

Perceived Barrier	Intervention Strategy
Decreases sexual pleasure (sensation) Note: Often perceived by those who have never used a condom	• Encourage client to try. • Put a drop of water-based lubricant or saliva inside the tip of the condom or on the glans of the penis before putting on the condom. • Try a thinner latex condom or a different brand or more lubrication.
Decreases spontaneity of sexual activity	• Incorporate condom use into foreplay. • Remind client that peace of mind may enhance pleasure for self and partner.
Embarrassing, juvenile, "unmanly"	• Remind client that it is "manly" to protect himself and others.
Poor fit (too small or too big, slips off, uncomfortable)	• Smaller and larger condoms are available.
Requires prompt withdrawal after ejaculation	• Reinforce the protective nature of prompt withdrawal and suggest substituting other postcoital sexual activities.
Fear of breakage may lead to less vigorous sexual activity.	• With prolonged intercourse, lubricant wears off and the condom begins to rub. Have a water-soluble lubricant available to reapply.
Nonpenetrative sexual activity	• Condoms have been advocated for use during fellatio; unlubricated condoms may prove best for this purpose due to the taste of the lubricant. • Other barriers, such as dental dams or an unlubricated condom, can be cut down the middle to form a barrier; these have been advocated for use during certain forms of nonpenetrative sexual activity (e.g., cunnilingus and anolingual sex).
Allergy to latex	• Polyurethane male and female condoms are available. • A natural skin condom can be used together with a latex condom to protect the man or woman from contact with latex.

Adapted from Public Health Agency of Canada. (2015). *Canadian guidelines on sexually transmitted infections.* Retrieved from http://www.phac-aspc.gc.ca/std-mts/sti-its/pdf/401mts-prisencharge-eng.pdf.

 Teaching Guidelines 5.1

PROPER CONDOM USE

• Use latex condoms to create a mechanical barrier for STIs and pregnancy

• Use a new condom with each act of sexual intercourse. Never reuse a condom.

• Handle condoms with care to prevent damage from sharp objects such as fingernails and teeth.

• Ensure condom has been stored in a cool, dry place away from direct sunlight. Do not store condoms in wallet or automobile or anywhere they would be exposed to extreme temperatures.

• Do not use a condom if it appears brittle, sticky, or discolored. These are signs of aging.

• Put condom on before any genital contact because sperm is present in

preejactulate fluid.

- Put condom on when penis is erect. Ensure it is placed so it will readily unroll.

- Hold the tip of the condom while unrolling. Ensure there is a space at the tip for semen to collect, but make sure no air is trapped in the tip.

- Ensure adequate lubrication during intercourse. If external lubricants are used, use only water-based lubricants such as K-Y jelly with latex condoms. Oil-based or petroleum-based lubricants, such as body lotion, massage oil, or cooking oil, can weaken latex condoms.

- Withdraw while penis is still erect, and hold condom firmly against base of penis.

Think back to Sandy, who was introduced at the beginning of the chapter. How should the nurse handle Sandy's anxious state? What specific questions should the nurse ask Sandy to determine the source of the possible infection in her genital area?

INFECTIONS CHARACTERIZED BY VAGINAL DISCHARGE

Vaginitis is a generic term that means inflammation and infection of the vagina. Vaginitis has hundreds of causes, but more often than not the cause is infection by one of three organisms:

• *Candida,* a fungus

• *Trichomonas,* a protozoan

• *Gardnerella,* a bacterium

The complex balance of microbiologic organisms in the vagina is a key element in the maintenance of health. Subtle shifts in the vaginal environment may allow organisms with pathologic potential to proliferate, causing infectious symptoms.

The nurse's role in managing vaginitis is one of primary prevention and education to limit recurrences of these infections. Primary prevention begins with changing the sexual behaviors that place women at risk for infection. In addition to assessing women for the common signs and symptoms and risk factors, the nurse can help women to avoid vaginitis or to prevent a recurrence by teaching them to take the precautions highlighted in Teaching Guidelines 5.2.

 Teaching Guidelines 5.2

PREVENTING VAGINITIS

• Avoid douching to prevent altering the vaginal environment.

• Use condoms to avoid spreading the organism.

• Avoid tights, nylon underpants, and tight clothes.

• Wipe from front to back after using the toilet.

• Wash only with hypoallergenic bar soaps; avoid using liquid soaps or body washes.

- Avoid powders, bubble baths, and perfumed vaginal sprays.
- Wear clean cotton underpants.
- Change out of wet bathing suits as soon as possible.
- Become familiar with the signs and symptoms of vaginitis.
- Choose to lead a healthy lifestyle.

Genital/Vulvovaginal Candidiasis

Genital/vulvovaginal candidiasis (VVC) is one of the most common causes of vaginal discharge. It is also referred to as yeast, monilia, and a fungal infection. It is not considered an STI because *Candida* is a normal constituent in the vagina and becomes pathologic only when the vaginal environment becomes altered. An estimated 75% of women will have at least one episode of VVC, and 40% to 50% will have two or more episodes in their lifetime (CDC, 2015b).

Therapeutic Management

Treatment of candidiasis includes one of the following medications:
• Miconazole (Monistat) cream or suppository
• Clotrimazole (Mycelex) tablet or cream
• Terconazole (Terazol) cream or intravaginal suppository
• Fluconazole (Diflucan) oral tablet (Prabhu & Gardella, 2015).

   Most of the above medications are used intravaginally in the form of a cream, tablet, or suppositories for 3 to 7 days. If fluconazole (Diflucan) is prescribed, a 150-mg oral tablet is taken as a single dose.
   Topical azole preparations are effective in the treatment of VVC, relieving symptoms and producing negative cultures in 80% to 90% of women who complete therapy (CDC, 2015b). If VVC is not treated effectively during pregnancy, the newborn can develop an oral infection known as thrush during the birth process; that infection must be treated with a local azole preparation after birth.

Nursing Assessment

Assess the client's health history for predisposing factors for VVC, which include:
• Pregnancy
• Use of oral contraceptives with high estrogen content
• Use of broad-spectrum antibiotics
• Diabetes mellitus

• Obesity

• Use of steroid and immunosuppressive drugs

• HIV infection

• Wearing tight, restrictive clothes and nylon underpants

• Trauma to vaginal mucosa from chemical irritants or douching

Assess the client for clinical manifestations of genital/vulvovaginal candidiasis. Typical symptoms, which can worsen just before menses, include:

• Pruritus

• Vaginal discharge (thick, white, curd-like)

• Vaginal soreness

• Vulvar burning

• Erythema in the vulvovaginal area

• Dyspareunia

• External dysuria

Figure 5.1 shows the typical appearance of VVC.

Speculum examination will reveal white plaques on the vaginal walls. The vaginal pH remains within normal range. Definitive diagnosis is made by a wet smear, which reveals the filamentous hyphae and spores characteristic of a fungus when viewed under a microscope.

Candida infection

Hyphae

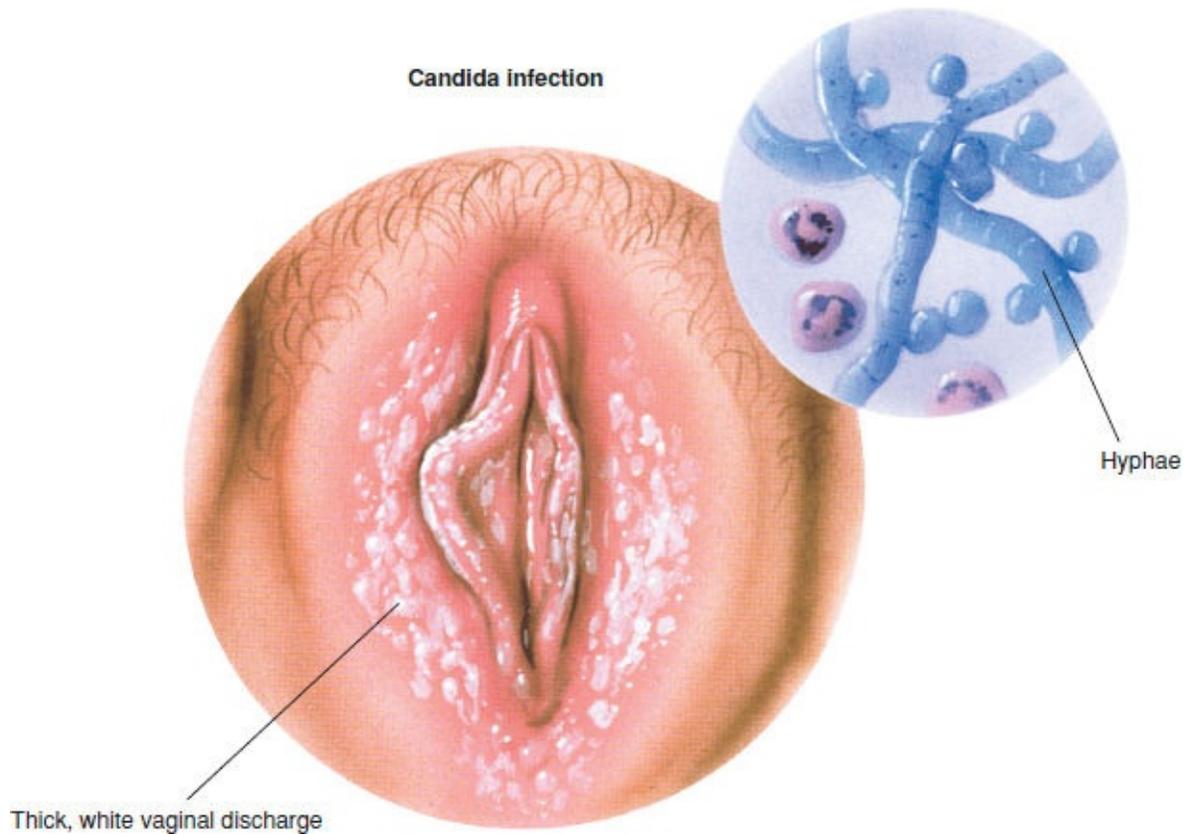
Thick, white vaginal discharge


FIGURE 5.1 Vulvovaginal candidiasis. (Asset provided by Anatomical Chart Co.)

Nursing Management

Teach the following preventive measures to women with frequent VVC infections:

• Reduce dietary intake of simple sugars and soda.

• Wear white, 100% cotton underpants.

• Avoid wearing tight pants or exercise clothes with spandex.

• Shower rather than taking tub baths.

• Wash with a mild, unscented soap and dry the genitals gently.

• Avoid the use of bubble baths or scented bath products.

• Wash underwear in unscented laundry detergent and hot water.

• Dry underwear in a hot dryer to kill the yeast that clings to the fabric.

• Remove wet bathing suits promptly.

• Practice good body hygiene.

- Avoid vaginal sprays/deodorants.
- Avoid wearing pantyhose (or cut out the crotch to allow air circulation).
- Use white, unscented toilet paper and wipe from front to back.
- Avoid douching (which washes away protective vaginal mucus).
- Avoid the use of superabsorbent tampons (use pads instead).

Trichomoniasis

Trichomoniasis is another common vaginal infection that causes a discharge, but is not always sexually transmitted. The organism can live on damp/wet surfaces and poorly cleaned/maintained hot tubs and drains. The woman may be markedly symptomatic or asymptomatic. Men are asymptomatic carriers. Although this infection is localized, there is increasing evidence of preterm birth, premature rupture of membranes, low-birth-weight infants, postpartum endometritis, and infertility in women with this vaginitis. The high prevalence of this infection worldwide and frequency of co-infection with other STIs make trichomoniasis a compelling public health concern. Notably, research has shown that infection with trichomoniasis increases the risk of HIV transmission in both men and women (Smith & Ramos, 2015). *Trichomonas vaginalis* is an ovoid, single-cell protozoan parasite that can be observed under the microscope making a jerky swaying motion. In the United States, an estimated 3.7 million people have the infection, but only about 30% develop any symptoms of trichomoniasis. Infection is more common in women than in men, and older women are more likely than younger women to have been infected (CDC, 2015c).

Therapeutic Management

A single 2-g dose of oral metronidazole (Flagyl) or tinidazole (Tindamax) for both partners is a common treatment for this infection. Sex partners of women with trichomoniasis should be treated to avoid recurrence of infection.

Nursing Assessment

Assess the client for clinical manifestations of trichomoniasis, which include:
• A heavy yellow/green or gray frothy or bubbly discharge
• Vaginal pruritus and vulvar soreness
• Dyspareunia
• A cervix that may bleed on contact
• Dysuria
  • Vaginal odor, described as foul
  • Vaginal or vulvar erythema

• Petechiae on the cervix

Figure 5.2 shows the typical appearance of trichomoniasis.

The diagnosis is confirmed when a motile flagellated trichomonad is visualized under the microscope. In addition, a vaginal pH of greater than 4.5 is a typical finding. U.S. Food and Drug Administration (FDA)-approved tests for trichomoniasis in women include the OSOM Trichomonas Rapid Test (Genzyme Diagnostics, Cambridge, MA), an immunochromatographic capillary flow dipstick technology, and the Affirm VPIII (Becton Dickinson, San Jose, CA), a nucleic acid probe test that evaluates for *T. vaginalis*, *Gardnerella vaginalis*, and *Candida albicans*. Each of these tests, which are performed on vaginal secretions, has a sensitivity of >83% and a specificity of >97%. Both tests are considered point-of-care diagnostics (CDC, 2015c).

Nursing Management

Instruct clients to avoid sex until they and their sex partners are cured (i.e., when therapy has been completed and both partners are symptom-free) and also to avoid consuming alcohol during treatment because mixing the medications and alcohol causes severe nausea and vomiting (CDC, 2015c). In addition, it is important to provide information regarding infection cause and transmission, effects on reproductive organs and future fertility, and the need for partner notification and treatment. Follow-up testing is not indicated if symptoms resolve with treatment. See Evidence-Based Practice 5.1 for interventions for trichomoniasis in pregnancy.

Bacterial Vaginosis

A third common infection of the vagina is bacterial vaginosis (BV) caused by the gram-negative bacillus *G. vaginalis.* It is the most prevalent cause of vaginal discharge or malodor, but up to 50% of women are asymptomatic. BV is a sexually associated infection characterized by alterations in vaginal flora in which lactobacilli in the vagina are replaced with high concentrations of anaerobic bacteria. BV was named so because bacteria are the etiologic agents and an associated inflammatory response is lacking. The bacterial imbalance is associated with sexual contact, but is not usually spread through sex. The cause of the microbial alteration is not fully understood but is associated with having multiple sex partners, douching, and lack of vaginal lactobacilli (CDC, 2015d). Research suggests that BV is associated with preterm labor, premature rupture of membranes, chorioamnionitis, postpartum endometritis, and PID (CDC, 2015d).

EVIDENCE-BASED PRACTICE 5.1 ADOLESCENT PATIENT PREFERENCES SURROUNDING PARTNER NOTIFICATION FOR SEXUALLY TRANSMITTED INFECTIONS

STUDY

A sexually transmitted epidemic exists among adolescents. Important barriers to addressing the sexually transmitted infection (STI) epidemic among adolescents are the inadequate partner notification of positive STI results and insufficient rates of partner testing and treatment. However, adolescent attitudes regarding partner notification and treatment are not well understood. The objective of this study was to qualitatively explore the barriers to and preferences for partner notification and treatment among adolescent males and females tested for STIs in an emergency department (ED) setting and to explore the acceptability of ED personnel notifying their sexual partners. This was a descriptive, qualitative study in which a convenience sample of 40 adolescents (18 females, 22 males) 14 to 21 years of age who presented to either adult or pediatric EDs with STI-related complaints participated. Data were analyzed using framework analysis.

Findings

Barriers to partner notification included fear of retaliation or loss of the relationship, lack of understanding of or concern for the consequences associated with an STI, and social stigma and embarrassment. Participants reported two primary barriers to their partners obtaining STI testing and treatment: lack of transportation to the health care site and the partner's fear of STI-positive test results. Most participants were agreeable with a health care provider notifying their sexual partners of the STI exposure by phone.

Therapeutic Management

Treatment for BV includes oral metronidazole (Flagyl) or clindamycin (Cleocin) cream. Treatment of the male partner has not been beneficial in preventing recurrence because sexual transmission of BV has not been proven (CDC, 2015d).

Nursing Assessment

Assess the client for clinical manifestations of BV. Primary symptoms are a thin, white homogeneous vaginal discharge and a characteristic "stale fish" odor, often recognized only after sexual intercourse. Figure 5.3 shows the typical appearance of BV.

   To diagnose BV, three of the following four criteria must be met:

• Thin, grayish white homogeneous vaginal discharge which adheres to the vaginal mucosa

• Vaginal pH > 4.5

• Positive "whiff test" (secretion is mixed with a drop of 10% potassium hydroxide on a slide, producing a characteristic stale fishy odor)

• A pH greater than 4.5

• The presence of clue cells on wet-mount examination (CDC, 2015d).

Nursing Management

The nurse's role is one of primary prevention and education to limit recurrences of these infections. Primary prevention begins with changing hygiene behaviors that place women at risk for infection. In addition to assessing women for common signs, symptoms, and risk factors (recent antibiotic use, decreased estrogen production, douching, and sexual activity with a new partner), the nurse can help women to avoid vaginitis or to prevent a recurrence by teaching them to take the precautions highlighted in Teaching Guidelines 5.2.

Clue cell seen in bacterial vaginosis caused by Gardnerella vaginalis

Discharge with fishy odor

INFECTIONS CHARACTERIZED BY CERVICITIS

Cervicitis is a catchall term that implies the presence of inflammation or infection of the cervix. It is used to describe everything from symptomless erosions to an inflamed cervix that bleeds on contact and produces quantities of purulent discharge containing organisms not ordinarily found in the vagina. Cervicitis is usually caused by gonorrhea or chlamydia, as well as almost any pathogenic bacterial agent and a number of viruses. The treatment of cervicitis involves the appropriate therapy for the specific organism that has caused it.

Chlamydia

Chlamydia is the most commonly reported bacterial STI in the United States. The CDC (2015e) estimates that over 3 million new cases occur each year; the highest predictor for the infection is age. The highest rates of infection are among those aged 15 to 19, mainly because their sexual relations are often unplanned and are sometimes the result of rape, and typically happen before they have the experience and skills to protect themselves. The rates are highest among this group regardless of demographics or location (CDC, 2015e). The young have the most to lose from acquiring STIs, because they will suffer the consequences the longest and might not reach their full reproductive potential. The most common risk factors associated with chlamydia are age >25 years, recent change in sexual partner or multiple sexual partners, poor socioeconomic conditions, exchange of sex for money, non-White race, single status, and lack of use of barrier contraception (Qureshi, 2015).

Asymptomatic infection is common among both men (50%) and women (70%). Men primarily develop urethritis. In women, chlamydia is linked with cervicitis, acute urethral syndrome, salpingitis, chronic pelvic pain, dysuria, stillbirth, ectopic pregnancy, PID, and infertility (Simmons, 2015). Chlamydia causes half of the 1 million recognized cases of PID in the United States each year, and treatment costs run over $800 million yearly. The CDC recommends yearly chlamydia testing of all sexually active women aged 25 or younger, older women with risk factors for chlamydial infections (those who have a new sex partner or multiple sex partners), and all pregnant women (CDC, 2015e).

Chlamydia trachomatis is the bacterium that causes chlamydia. It is an intracellular parasite that cannot produce its own energy and depends on the host for survival. It is often difficult to detect, and this can pose problems for women due to the long-term consequences of untreated infection. Untreated chlamydia has been linked to increased incidence and severity of sequelae, such as PID and infertility in women. After a single chlamydial infection, the risk of developing PID is estimated to be approximately 20% to 50% %, and the risk of developing tubal infertility is estimated to be approximately 10% to 20% (Amoako & Balen, 2015). Moreover, lack of treatment provides more opportunity for the infection to be transmitted to sexual partners. An estimated 100,000 pregnant women are affected by this STI. When untreated, chlamydia is associated with premature rupture of membranes, preterm labor, and postpartum endometritis (Collins,

2015). Newborns delivered to infected mothers may develop conjunctivitis, which occurs in 1% to 12% of all newborns. Ophthalmia neonatorum is an acute mucopurulent conjunctivitis occurring in the first month of birth. It is essentially an infection acquired during vaginal delivery. The most frequent infectious agents involved in are *C. trachomatis* and *Neisseria gonorrhoeae* (Moore & MacDonald, 2015).

Therapeutic Management

Antibiotics are usually used in treating this STI. The CDC treatment options for chlamydia include doxycycline (Vibramycin) 100 mg orally twice a day for 7 days or azithromycin (Zithromax) 1 g orally in a single dose. Because of the common co-infection of chlamydia and gonorrhea, a combination regimen of ceftriaxone (Rocephin) with doxycycline or azithromycin is prescribed frequently (CDC, 2015e). Additional CDC guidelines for client management include annual screening of all sexually active women aged 20 to 25 years, screening of all high-risk people, and treatment with antibiotics effective against both gonorrhea and chlamydia for anyone diagnosed with a gonococcal infection (CDC, 2015e).

Except in pregnant women, test-of-cure (repeat testing 3 to 4 weeks after completing therapy) is not recommended for women treated with the recommended or alterative regimens, unless therapeutic adherence is in question, symptoms persist, or reinfection is suspected. Pregnant women should be retested in 3 to 6 months after the initial infection, preferably in the third trimester, because of an increased risk for reinfection (King et al., 2015).

Nursing Assessment

Assess the health history for significant risk factors for chlamydia, which may include:
• Being an adolescent
• Having multiple sex partners
• Having a new sex partner
• Engaging in sex without using a barrier contraceptive (condom)
• Using oral contraceptives
• Being pregnant

• Having a history of another STI (Schuiling & Likis, 2016).

Assess the client for clinical manifestations of chlamydia. The majority of women (70%) are asymptomatic (CDC, 2015e). If the client is symptomatic, clinical manifestations include:

• Mucopurulent vaginal discharge

• Urethritis

• Bartholinitis

• Endometritis

• Salpingitis

• Dysfunctional uterine bleeding

The diagnosis can be made by urine testing or swab specimens collected from the endocervix or vagina. Culture, direct immunofluorescence, enzyme immunoassay, or nucleic acid amplification methods by polymerase chain reaction or ligase chain reaction (DNA probe, such as GenProbe or Pace2) are highly sensitive and specific when used on urethral and cervicovaginal swabs. They can also be used with good sensitivity and specificity on first-void urine specimens (King et al., 2015). The chain reaction tests are the most sensitive and cost-effective. Because the majority of chlamydia cases are asymptomatic, the CDC recommends screening of all women with a new sex partner and annual screening for women 25 years and younger (CDC, 2015e).

Chlamydia is an important preventable cause of infertility and other adverse reproductive health outcomes. Effective prevention interventions are available to reduce the burden of chlamydia and its sequelae, but they are underutilized. Although many prevention programs are available, improvements can be made in raising awareness about chlamydia, increasing screening coverage, and enhancing partner services. In addition, nurses can focus their efforts on reaching disproportionately affected racial/ethnic groups. To break the cycle of chlamydia transmission in the United States, health care providers should encourage annual chlamydia screening for all sexually active females less than 25 years old, maximize use of effective partner treatment services, and rescreen infected females and males 3 months after treatment (CDC, 2015e).

Gonorrhea

Gonorrhea is a serious and potentially very severe bacterial infection. It is the second most commonly reported infection in the United States and globally is an urgent problem because it is now capable of rapidly developing resistance to multiple antibiotic classes. Gonorrhea is highly contagious and is a reportable infection to the health department authorities. Gonorrhea increases the risk for PID, infertility, ectopic pregnancy, and HIV acquisition and transmission (CDC, 2015f). It is rapidly becoming more and more resistant to cure. In the United States, over 820,000 new gonorrhea infections occur annually, with 570,000 of them occurring among young people 15 to 24 years old (CDC, 2015f). In common with all other STIs, it is an equal-opportunity infection—no one is immune to it, regardless of race, creed, gender, age, or sexual preference.

The cause of gonorrhea is an aerobic gram-negative intracellular diplococcus, *N. gonorrhoeae*. The site of infection is the columnar epithelium of the endocervix. Gonorrhea is almost exclusively transmitted by sexual activity. In pregnant women, gonorrhea is associated with chorioamnionitis, premature labor, premature rupture of membranes, and postpartum endometritis (Piszczek, Jean, & Khaliq, 2015). It can also be transmitted to the newborn in the form of ophthalmia neonatorum during birth by direct contact with gonococcal organisms in the cervix. Ophthalmia neonatorum is highly contagious and, if untreated, leads to blindness in the newborn.

Therapeutic Management

Gonorrhea can be cured with the right treatment. CDC now recommends dual therapy (i.e., using two drugs) as the treatment for gonorrhea. Dual drug therapy is recommended to prevent drug resistance, and is also effective against chlamydia. The treatment of choice for uncomplicated gonococcal infections is a single intramuscular dose of ceftriaxone (Rocephin) 250 mg plus a single dose of azithromycin 1 g orally or doxycycline 100 mg orally twice a day for 7 days (Kohlhoff & Hammerschlag, 2015; Wong, 2015). Pregnant women should not be treated with quinolones or tetracyclines. Pregnant women with a positive test for gonorrhea should be treated with the same recommended dual therapy as above (CDC, 2015f). To prevent gonococcal ophthalmia neonatorum, a prophylactic agent should be instilled into the eyes of all newborns; this procedure is required

by law in most states. Erythromycin or tetracycline ophthalmic ointment in a single application is recommended (CDC, 2015f). With use of recommended treatment, follow-up testing to document eradication of gonorrhea is no longer recommended. Instead, rescreening in 3 months to identify reinfection is suggested (CDC, 2015f).

Nursing Assessment

Assess the client's health history for risk factors, which may include low socioeconomic status, living in an urban area, single status, inconsistent use of barrier contraceptives, age under 25 years old, and multiple sex partners. Assess the client for clinical manifestations of gonorrhea, keeping in mind that 70% of women infected with gonorrhea are totally symptom-free (Wong, 2015). Because women are so frequently asymptomatic, they are regarded as a major factor in the spread of gonorrhea. If symptoms are present, they might include:

• Abnormal vaginal discharge

• Dysuria

• Cervicitis

• Abnormal vaginal bleeding

• Bartholin's abscess

• Enlarged lymph nodes locally

• PID

• Neonatal conjunctivitis in newborns

• Mild sore throat (for pharyngeal gonorrhea)

• Rectal infection (itching, soreness, bleeding, discharge)

• Perihepatitis (King et al., 2015).

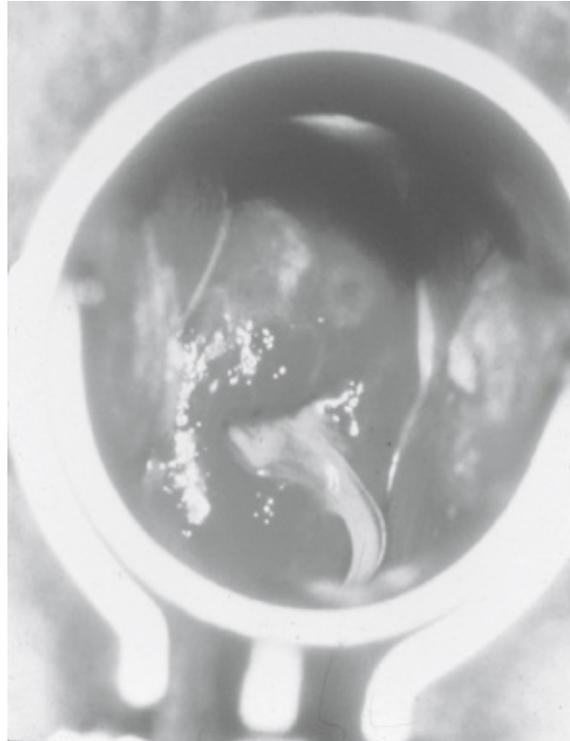
Sometimes a local gonorrheal infection is self-limiting (there is no further spread), but usually the organism ascends upward through the endocervical canal to the endometrium of the uterus, further on to the fallopian tubes, and out into the peritoneal cavity. When the peritoneum and the ovaries become involved, the condition is known as PID (discussed later in this chapter). The scarring to the fallopian tubes is permanent. This damage is a major cause of infertility and is a possible contributing factor in ectopic pregnancy (Heller, 2015).


FIGURE 5.4 Gonorrhea. (From Gorbach, S. L., et al. [2004]. *Infectious diseases*. Philadelphia, PA: Lippincott Williams & Wilkins.)

If gonorrhea remains untreated, it can enter the bloodstream and produce a disseminated gonococcal infection. This severe form of infection can invade the joints (arthritis), the heart (endocarditis), the brain (meningitis), and the liver (toxic hepatitis). Figure 5.4 shows the typical appearance of gonorrhea.

The CDC recommends screening for all women at risk for gonorrhea. Pregnant women should be screened at the first prenatal visit and again at 36 weeks of gestation. Nucleic acid hybridization tests (GenProbe) are used for diagnosis. Any woman suspected of having gonorrhea should be tested for chlamydia also because co-infection (45%) is extremely common (CDC, 2015f).

Nursing Management of Chlamydia and Gonorrhea

The prevalence of chlamydia and gonorrhea is increasing dramatically, and these infections can have long-term effects on people's lives. Sexual health is an important part of a person's physical and mental health, and nurses have a professional obligation to address it. Be particularly sensitive when addressing STIs because women are often embarrassed, feel guilty or angry, or may even be fearful of outcomes related to telling partners about the diagnosis (see earlier

section on the cultural and psychological impacts of STI diagnosis). There is still a social stigma attached to STIs, so women need to be reassured about confidentiality.

The nurse's knowledge about chlamydia and gonorrhea should include treatment strategies, referral sources, and preventive measures. The nurse should be skilled at client education and counseling and be comfortable talking with, and advising, women diagnosed with these infections. Provide education about risk factors for these infections. High-risk groups include single women, women younger than 25 years old, African American women, women with a history of STIs, those with new or multiple sex partners, those with inconsistent use of barrier contraception, and women living in communities with high infection rates (Comkornruecha, 2013). Assessment involves taking a health history that includes a comprehensive sexual history. Ask about the number of sex partners and the use of safer sex techniques. Review previous and current symptoms. Emphasize the importance of seeking treatment and informing sex partners. The four-level P-LI-SS-IT model (Box 5.3) can be used to determine interventions for various women because it can be adapted to the nurse's level of knowledge, skill, and experience. Of utmost importance is the willingness to listen and show interest and respect in a nonjudgmental manner.

In addition to meeting the health needs of women with chlamydia and gonorrhea, the nurse is responsible for educating the public about the increasing incidence of these infections. This information should include high-risk behaviors associated with these infections, signs and symptoms, and the treatment modalities available. Stress that both of these STIs can lead to infertility and long-term sequelae. Teach safer sex practices to people in nonmonogamous relationships. Know the physical and psychosocial responses to these STIs to prevent transmission and the disabling consequences. Nurses must also inform their pregnant clients that they should avoid quinolones or tetracyclines to prevent risks associated with irreversible tooth discoloration and enamel hypoplasia in the newborn (Kohlhoff & Hammerschlag, 2015).

THE P-LI-SS-IT MODEL

P Permission—gives the woman permission to talk about her experience

LI Limited Information—information given to the woman about STIs

• Factual information to dispel myths about STIs

• Specific measures to prevent transmission

• Ways to reveal information to her partners

• Physical consequences if the infections are untreated

SS Specific Suggestions—an attempt to help women change their behavior to prevent recurrence and prevent further transmission of the STI

IT Intensive Therapy—involves referring the woman or couple for appropriate treatment elsewhere based on their life circumstances

Adapted from Annon, J. S. (1976). The PLISSIT model: A proposed conceptual scheme for the behavioral treatment of sexual problems. *Journal of Sex Education Therapy*, 2, 1–15.

Take Note!

If the epidemic of chlamydia and gonorrhea is to be halted, nurses must take a major front-line role now.

INFECTIONS CHARACTERIZED BY GENITAL ULCERS

In the United States, the majority of young, sexually active clients who have genital ulcers have genital herpes, syphilis, or chancroid. The frequency of each condition differs by geographic area and client population; however, genital herpes is the most prevalent of these diseases (CDC, 2015g). More than one of these diseases can be present in a client who has genital ulcers. All three of these diseases have been associated with an increased risk for HIV infection. Not all genital ulcers are caused by STIs.

Genital Herpes Simplex

Genital herpes is a recurrent, lifelong viral infection that has the potential for transmission throughout the lifespan. The CDC (2015h) estimates that one out of six people in the United States have genital HSV infection, with 776,000 people getting new cases annually. About 22% of pregnant women are infected with HSV. The most devastating consequence of maternal genital herpes is neonatal herpes disease, which occurs in approximately 1 in 3,200 births in the US and has a high mortality rate (James & Kimberlin, 2015).

Genital herpes is more common among females (1 out of 5) than males (1 out of 9) in part due to prolonged contact with semen during vaginal intercourse. Two serotypes of HSV have been identified: HSV-1 and HSV-2. HSV-1 is associated mainly with oral herpes (commonly called cold sores and fever blisters) and HSV-2 is mainly associated with genital herpes, both types can cause outbreaks in either location. Approximately 80% of individuals infected with genital herpes are asymptomatic and unaware of being infected with the virus (Leone, 2015).

HSV is transmitted by contact of mucous membranes or breaks in the skin with visible or nonvisible lesions. Most genital herpes infections are transmitted by individuals unaware that they have an infection. Many have mild or unrecognized infections but still shed the herpes virus intermittently. HSV is transmitted primarily by direct contact with an infected individual who is shedding the virus. Kissing, sexual contact (including oral sex), and vaginal delivery are means of transmission.

Having sex with an infected partner places the individual at risk for contracting HSV. After the primary outbreak, the virus remains dormant in the nerve cells for a lifetime, resulting in periodic recurrent outbreaks. Recurrent genital herpes outbreaks are triggered by precipitating factors such as emotional stress, menses, ultraviolet light exposure, illness, surgery, fatigue, genital trauma, immunosuppression, and sexual intercourse, but more than half of recurrences occur without a precipitating cause. Immunocompromised women have more frequent and more severe recurrent outbreaks than normal hosts. A genital herpes infection during pregnancy can cause a spontaneous abortion, preterm labor, microcephaly, low-birth-weight infant, microophthalmia, chorioretinitis, and/or neonatal HSV infection (Silasi et al., 2015).

Living with genital herpes can be difficult due to the erratic, recurrent nature

of the infection, the location of the lesions, the unknown causes of the recurrences, and the lack of a cure. Upon diagnosis, clients have important concerns related not to the physical nature of the disease but to the social consequences, including transmission and the impact on their sex life. Furthermore, the stigma associated with this infection may affect the individual's feelings about herself and her interaction with partners. Potential psychosocial consequences may include emotional distress, isolation, fear of rejection by a partner, fear of transmission of the disease, loss of confidence, and altered interpersonal relationships (Alexander et al., 2014).

Along with the increase in the incidence of genital herpes has been an increase in neonatal HSV infections, which are associated with a high incidence of mortality and morbidity. The risk of neonatal infection with a primary maternal outbreak is between 30% and 50%; it is less than 1% with a recurrent maternal infection (CDC, 2015h).

Therapeutic Management

No cure exists, but antiviral drug therapy helps to reduce or suppress symptoms, shedding, and recurrent episodes. Advances in treatment with acyclovir (Zovirax) 400 mg orally three times daily for 7 to 10 days, famciclovir (Famvir) 250 mg orally three times daily for 7 to 10 days, or valacyclovir (Valtrex) 1 g orally twice daily for 7 to 10 days have resulted in an improved quality of life for those infected with HSV. However, these drugs neither eradicate latent virus nor affect the risk, frequency, or severity of recurrences after the drug is discontinued (CDC, 2015h). Suppressive therapy is recommended for individuals with six or more recurrences per year. The natural course of the disease is for recurrences to be less frequent over time. The safety of antiviral therapy has not been established during pregnancy.

Therapeutic management also includes counseling regarding the natural history of the disease, the risk of sexual and perinatal transmission, and the use of methods to prevent further spread. The following guidelines can help the nurse when delivering information in a time-limited environment: (1) Use all available client reading materials; (2) have another knowledgeable staff member in the office who can spend extra time with women who need it; (3) refer clients to good and accurate websites such as the American Social Health Association website (refer to for additional information); (4) know the phone numbers of herpes support groups in your area; (5) educate the client to abstain from all

sexual activity until HSV lesions resolve; (6) use good hand hygiene to prevent spread; (7) educate that there is no cure, and that practicing safer sex (using condoms and dental dams) with every sex act is essential to prevent transmission; and (8) encourage all clients to inform their current sex partners that they have genital herpes and to inform future partners before initiating a sexual relationship. Finally, many experts recommend a sympathetic, nonjudgmental approach. The nurse can state in clear terms that having herpes does not change the core of the person or make the person less worthwhile (Myers et al., 2015).

Nursing Assessment

Assess the woman for risk factors, which may include having unprotected sexual intercourse, multiple sexual partners, lower socioeconomic status, a history of STIs, and increasing age (Moses, 2015). Assess the client for clinical manifestations of HSV. Clinical manifestations can be divided into the primary episode and recurrent infections. The first or primary episode is usually the most severe, with a prolonged period of viral shedding. Primary HSV is a systemic disease characterized by multiple painful vesicular lesions, mucopurulent discharge, superinfection with candida, fever, chills, malaise, dysuria, headache, genital irritation, inguinal tenderness, and lymphadenopathy. The lesions in the primary herpes episode are frequently located on the vulva, vagina, and perineal areas. The vesicles will open and weep and finally crust over, dry, and disappear without scar formation (Fig. 5.5). This viral shedding process usually takes up to 2 weeks to complete.

Recurrent infection episodes may occur five to eight times per year and are usually much milder with fewer lesions and shorter in duration than the primary one. Tingling, itching, pain, unilateral genital lesions, and a more rapid resolution of lesions are characteristics of recurrent infections. Recurrent herpes is a localized disease characterized by typical HSV lesions at the site of initial viral entry. Recurrent herpes lesions are fewer in number and less painful and resolve more rapidly (King et al., 2015).

Herpetic lesions on labia majora

FIGURE 5.5 Genital herpes simplex. (Illustration provided by Anatomical Chart Co. Photograph courtesy of Stephen Ludwig, MD.)

Diagnosis of HSV is often based on clinical signs and symptoms and is confirmed by viral culture of fluid from the vesicles. The IgG/IgM antibody testing is frequently done for screening purposes. Papanicolaou (Pap) smears are an insensitive and nonspecific diagnostic test for HSV and should not be relied on for diagnosis. The women should be tested for all common STIs, especially if she has a new sexual partner. Ideally, the woman will initiate an open conversation with her sexual partner about the risk of transmission and the need for safer sexual practices.

Syphilis

Syphilis is a complex, curable bacterial infection caused by the spirochete *Treponema pallidum*. It is often thought to be a disease of the past, largely eradicated in modern America, but its incidence is on the rise in certain populations (gay men, bisexual men, men having sex with men, and women of color living in the South). It is estimated that 12 million people globally are infected annually (Ramsey, 2015). It is a serious systemic disease that can lead to disability and death if untreated. Syphilis has a complex life cycle during which episodes of active clinical disease are punctuated with periods of latency. About 2.1 million pregnant women have active syphilis every year. Congenital syphilis can occur when an infected mother directly infects her fetus. Without screening and treatment, 69% of these women will have an adverse outcome to their pregnancy (Angoori, 2015). Rates of syphilis in the United States are increasing, especially among young adults and African Americans in urban areas and in the South (CDC, 2015i). The World Health Organization (WHO, 2015d) estimates that the rates of maternal syphilis and subsequent neonatal mortality and morbidity easily exceed that of other neonatal infections, especially among lower socioeconomic classes, aboriginal and African American cultures, and sex trade workers. It continues to be one of the most important STIs both because of its biologic effect on HIV acquisition and transmission and because of its impact on infant health (Tipple & Taylor, 2015). All pregnant women should be screened for syphilis infection at their first prenatal visit and repeated in the third trimester For women in high-risk groups, repeat serology testing may be necessary in the third trimester and at birth (CDC, 2015j).

The syphilis spirochete rapidly penetrates intact mucous membranes or microscopic lesions in the skin and within hours enters the lymphatic system and bloodstream to produce a systemic infection long before the appearance of a primary lesion. The site of entry may be vaginal, rectal, or oral (Klein, McLaud, & Rogers, 2015). The syphilis spirochete can cross the placenta after 9 weeks of gestation. One out of every 10,000 infants born in the United States has congenital syphilis (CDC, 2015i). Maternal infection consequences for the newborn include spontaneous abortion, low birth weight, prematurity, stillbirth, intrauterine growth restriction, and multisystem failure of the heart, lungs, spleen, liver, and pancreas, as well as structural bone damage, nervous system involvement, and intellectual disability (Chen et al., 2015).

Therapeutic Management

Fortunately, an effective treatment is available for syphilis. Single-dose therapy is preferred for ease of use of azithromycin (Zithromax, Z-Pak) 1 g orally once, or ceftriaxone (Rocephin) 250 mg IM once or ciprofloxacin (Cipro) 500 mg orally twice a day for three days, or erythromycin base 500 mg orally three times a day for seven days can be prescribed. Ciprofloxacin is contraindicated for pregnant and lactating women. Penicillin G benzathine 2.4 million units IM weekly for 3 weeks can also be used for treatment, but client adherence can be challenging (King et al., 2015). The preparations used, the dosage, and the length of treatment depend on the stage and clinical manifestations of disease (CDC, 2015j). Other medications, such as doxycycline, are available if the client is allergic to penicillin.

Women should be reevaluated at 6 and 12 months after treatment for primary or secondary syphilis with additional serologic testing. Women with latent syphilis should be followed clinically and serologically at 6, 12, and 24 months (Lawrence et al., 2015).

Concept Mastery Alert

Syphilis Transmission in Pregnancy

Although some sexually transmitted infections such as gonorrhea and the herpes virus are transmitted to the newborn by the birth canal, syphilis is transmitted through the placenta at any time during the pregnancy. This means the fetus is at risk during the entire pregnancy, unless the mother is diagnosed and properly treated.

Nursing Assessment

Syphilis has many nonspecific signs and symptoms that may be overlooked by the health care provider, or may simply be indistinguishable from other more common diseases. Regrettably, undiagnosed and untreated syphilis may lead to life-threatening complications such as hepatitis, stroke, and nervous system damage (Klein et al., 2015). Assess the client for any clinical manifestations of syphilis. If untreated, syphilis is a lifelong infection progressing in orderly

staging. The five stages of syphilis infection are (1) primary, (2) secondary, (3) early latent, (4) late latent, and (5) tertiary. The primary, secondary, and early latent stages are considered the most infectious: the estimated risk of per person transmission is 60%. Furthermore, in these stages, the fetus is at higher risk of acquiring maternal infections Klein et al., 2015).

FIGURE 5.6 Chancre of primary syphilis. (From Sweet, R. L., & Gibbs, R. S. [2005]. *Atlas of infectious diseases of the female genital tract*. Philadelphia, PA: Lippincott Williams & Wilkins.)

Primary syphilis is characterized by a chancre (painless ulcer) at the site of bacterial entry that will disappear within 1 to 6 weeks without intervention (Fig. 5.6). Motile spirochetes are present on dark-field examination of ulcer exudate. In addition, painless bilateral adenopathy is present during this highly infectious period. The client is highly infectious whenever chancres are present. If left untreated, the infection progresses to the secondary stage.

Secondary syphilis appears 2 to 6 months after the initial exposure and is manifested by flu-like symptoms and a maculopapular rash of the trunk, palms, and soles. Alopecia and adenopathy are both common during this stage. In addition to rashes, secondary syphilis may present with symptoms of fever, pharyngitis, weight loss, and fatigue (Peterman et al., 2015). The secondary stage of syphilis lasts about 2 years. Once the secondary stage subsides, the latency periods (early and late) begin. These stages are characterized by the absence of any clinical manifestations of disease, although the serology is positive. This stage can last as long as 20 years. If not treated, *tertiary* or *late syphilis* occurs, with life-threatening heart disease and neurologic disease that slowly destroys the heart, with inflammation of the aorta, eyes, brain, central

nervous system, and skin.

Clients with a diagnosis of HIV or another STI should be screened for syphilis, and all pregnant women should be screened at their first prenatal visit. Serologic testing for syphilis is evaluated by using both nontreponemal and treponemal tests. Nontreponemal tests measure immunoglobulin M (IgM) and immunoglobulin G (IgG). Although these tests are less specific, they are commonly used for primary screening because they are rapid to perform and inexpensive. The most commonly used nontreponemal tests are the rapid plasma regain (RPR) and the Venereal Disease Research Laboratory (VDRL) tests. Treponemal tests detect treponema-specific immunoglobulin A (IgA), IgM, and IgG antibodies, giving these tests a greater accuracy. Current treponemal tests include the EIA, fluorescent treponemal antibody absorption (FTA-ABS), *T. pallidum* agglutination assay (TPPA), and *T. pallidum* hemagglutination assay (TPHA) (Schuiling & Likis, 2016).

A presumptive diagnosis can be made by using two serologic tests:

• Nontreponemal tests (VDRL and RPR)

• Treponemal tests (FTA-ABS and TP-PA). Dark-field microscopic examinations and direct fluorescent antibody tests of lesion exudate or tissue are the definitive methods for diagnosing early syphilis (CDC, 2015k).

Nursing Management of Herpes and Syphilis

Genital ulcers from either herpes or syphilis can be devastating to women, and the nurse can be instrumental in helping her through this difficult time. Referral to a support group may be helpful. Address the psychosocial aspects of these STIs with women by discussing appropriate coping skills, acceptance of the lifelong nature of the condition (herpes), and options for treatment and rehabilitation. Nurses can help to ameliorate the misery, morbidity, and mortality associated with STIs through safe, accurate, sensitive, and supportive care. Teaching Guidelines 5.3 highlights appropriate teaching points for the client with genital ulcers.

Teaching Guidelines 5.3

CARING FOR GENITAL ULCERS

- Abstain from intercourse during the prodromal period and when lesions are present.
- Wash hands with soap and water after touching lesions to avoid autoinoculation.
- Use comfort measures such as wearing nonconstricting clothes, wearing cotton underwear, urinating in water if urination is painful, taking lukewarm sitz baths, and air-drying lesions with a hair dryer on low heat.
- Avoid extremes of temperature such as ice packs or hot pads to the genital area as well as application of steroid creams, sprays, or gels.
- Use condoms with all new or noninfected partners.
- Inform health care professionals of your condition.

Pelvic Inflammatory Disease

PID is a common and serious reproductive health disorder in which rates remain unacceptably high among adolescent girls and young adult women in the United States. It refers to an inflammatory state of the upper female genital tract and nearby structures. The fallopian tubes, ovaries, or peritoneum may be involved and endometriosis may also be present. PID results from an ascending polymicrobial infection of the upper female reproductive tract, frequently caused by untreated chlamydia or gonorrhea (Fig. 5.7). Annually, in the United States, the CDC (2015l) estimates that more than one million women experience an episode of acute PID. Up to 10% to 15% of these women may become infertile as a result of PID. A large proportion of the ectopic pregnancies, pelvic abscess formations, and chronic pelvic pain that occur every year is due to the consequences of PID (CDC, 2015l). It is a serious health problem in the United States, costing an estimated ∃10 billion annually in terms of hospitalizations and surgical procedures (Gilbert, 2015). All sexually active women are at risk for PID, but common risk factors include age less than 25 years, residence in an inner city, multiple sexual partners, sex with a new partner, insertion of an intrauterine contraceptive (IUC) within the past 6 weeks, vaginal douching, history of STI in the woman or her partner, lack of barrier contraceptive use, and a previous episode of PID. Women of African or African Caribbean ethnicity also have a higher reported prevalence of the condition (Simmons, 2015). Complications include fibrosis, scarring, loss of tubal function, ectopic pregnancy, pelvic abscess, infertility, recurrent or chronic episodes of the disease, chronic abdominal pain, pelvic adhesions, and depression (Simmons, 2015). Because of the seriousness of the complications of PID, an accurate diagnosis is critical.

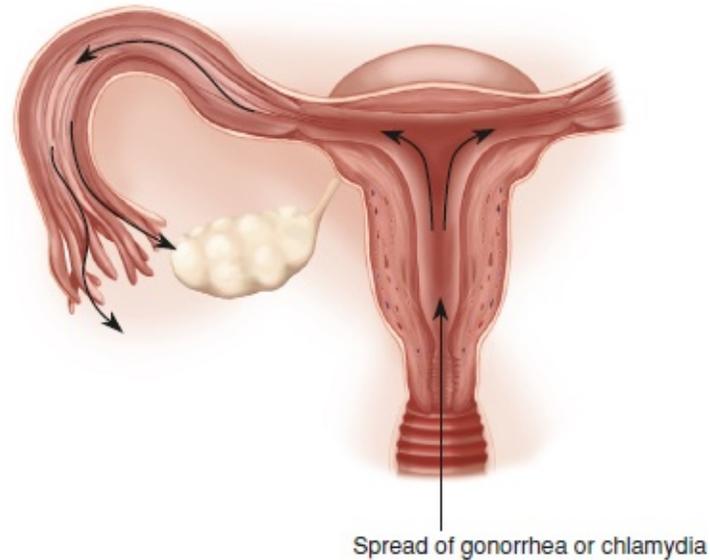
Spread of gonorrhea or chlamydia


FIGURE 5.7 Pelvic inflammatory disease. Chlamydia or gonorrhea spreads up the vagina into the uterus and then to the fallopian tubes and ovaries.

Therapeutic Management

Broad-spectrum antibiotic therapy is generally required to cover chlamydia, gonorrhea, and/or any anaerobic infection. The current CDC recommendation (Blank, 2015) is: ceftriaxone 250 mg in a single injection plus doxycycline 100 mg twice a day for 14 days with or without metronidazole 500 mg orally, twice a day for 14 days, or cefoxitin 2 g intramuscularly in a single dose and probenecid 1 g orally administered concurrently in a single dose plus doxycycline 100 mg orally twice a day for 14 days with or without metronidazole 500 mg orally twice a day for 14 days. PID in pregnancy is uncommon, but a combination of cefotaxime, azithromycin, and metronidazole for 14 days may be used. Tetracyclines and quinolones should be avoided during pregnancy (King et al., 2015). The client is treated on an ambulatory basis with a single-dose injectable antibiotic or is hospitalized and given antibiotics intravenously. The decision to hospitalize a woman is based on clinical judgment and the severity of her symptoms (e.g., severely ill with high fever, a tubo-ovarian abscess is suspected, the woman is immunocompromised or presents with protracted vomiting). Treatment then includes intravenous antibiotics, increased oral fluids to improve hydration, bed rest, and pain management. Follow-up is needed to validate that the infectious process has disappeared to prevent the development of chronic pelvic pain.

Nursing Assessment

Nursing assessment of the woman with PID involves a complete health history and assessment of clinical manifestations, physical examination, and laboratory and diagnostic testing.

HEALTH HISTORY AND CLINICAL MANIFESTATIONS

Explore the client's current and past medical health history for risk factors for PID, which may include:

• Adolescence or young adulthood

• Non-White female

• Having multiple sex partners

• Early onset of sexual activity

• History of PID or STI

• Sexual intercourse at an early age

• Alcohol or drug use

• Having intercourse with a partner who has untreated urethritis

• Recent insertion of an IUC

• Nulliparity

• Cigarette smoking

• Recent termination of pregnancy

• Lack of consistent condom use

• Lack of contraceptive use

• Douching

• Prostitution

   Assess the client for clinical manifestations of PID, keeping in mind that, because of the wide variety of clinical manifestations of PID, clinical diagnosis can be challenging. To reduce the risk of missed diagnosis, the CDC has established criteria for the diagnosis of PID. Minimal criteria (all must be present) are lower abdominal tenderness, adnexal tenderness, and cervical motion tenderness. Additional supportive criteria that support a diagnosis of PID are:

- Abnormal cervical or vaginal mucopurulent discharge
- Oral temperature above 101°F (38.3°C)
- Cervical motion tenderness
- Elevated erythrocyte sedimentation rate (inflammatory process)
- Elevated C-reactive protein level (inflammatory process)
- *N. gonorrhoeae* or *C. trachomatis* infection documented (causative bacterial organism)
- White blood cells on saline vaginal smear
- Prolonged or increased menstrual bleeding
- Dysmenorrhea
- Dysuria
- Acute lower abdominal pain
- Painful sexual intercourse
- Nausea
- Vomiting (CDC, 2015l).

PHYSICAL EXAMINATION AND LABORATORY AND DIAGNOSTIC TESTS

Inspect the client for presence of fever (usually over 101°F [38.3°C]) or vaginal discharge. Palpate the abdomen, noting tenderness over the uterus or ovaries. Laparoscopy is the current criterion standard for the diagnosis of PID. No single test is highly specific or sensitive for the disease, but certain laboratory studies that can be used to support the diagnosis include the erythrocyte sedimentation rate, C-reactive protein, and chlamydial and gonococcal DNA probes and cultures (Simmons, 2015).

Nursing Management

If the woman with PID is hospitalized, maintain hydration via intravenous fluids if necessary and administer analgesics as needed for pain. Semi-Fowler's positioning facilitates pelvic drainage. A key element to treatment of PID is education to prevent recurrence. Depending on the clinical setting (hospital or community clinic) where the nurse encounters the woman diagnosed with PID, a risk assessment should be done to ascertain what interventions are appropriate to

prevent a recurrence. To gain the woman's cooperation, explain the various diagnostic tests needed. Discuss the implications of PID and the risk factors for the infection; her sexual partner should be included if possible. Sexual counseling should include practicing safer sex, limiting the number of sexual partners, using barrier contraceptives consistently, avoiding vaginal douching, considering another contraceptive method if she has an IUC and has multiple sexual partners, and completing the course of antibiotics prescribed (Shepherd, 2015). Explain the serious sequelae that may occur if the condition is not treated or if the woman does not adhere to the treatment plan. Ask the woman to have her partner go for evaluation and treatment to prevent a repeat infection. Provide nonjudgmental support while stressing the importance of barrier contraceptive methods and follow-up care. Teaching Guidelines 5.4 gives further information related to PID prevention.

Teaching Guidelines 5.4

PREVENTING PELVIC INFLAMMATORY DISEASE

• Advise sexually active girls and women to insist their partners use condoms.

• Discourage routine vaginal douching, as this may lead to bacterial overgrowth.

• Encourage regular STI screening.

• Emphasize the importance of having each sexual partner receive antibiotic treatment.

VACCINE-PREVENTABLE STIs

Some STIs can be effectively prevented through preexposure vaccination. Vaccines are under development or are undergoing clinical trials for certain STIs, including HIV and HSV. However, the only vaccines currently available are for prevention of hepatitis A, hepatitis B, and HPV infection. Vaccination efforts focus largely on integrating the use of these available vaccines into STI prevention and treatment activities (CDC, 2015g).

Human Papillomavirus

HPV is the most common viral infection in the United States. HPV is so common that nearly all sexually active men and women will get at least one type of HPV at some point in their lives (CDC, 2015m). Genital warts or condylomata (Greek for "warts") are caused by HPV. Conservative estimates suggest that in the United States, approximately 79 million people have productive HPV infection, and 14 million Americans acquire it annually (CDC, 2015m). Clinical studies have confirmed that HPV is the cause of essentially all cases of cervical cancer, which is the fourth most common cancer in women in the United States, following lung, breast, and colorectal cancer. Every year in the United States, over 12,000 women are diagnosed with cervical cancer, and about 4,000 women die from this disease. About 1% of sexually active men and women in the United States have genital warts at any given time (American Cancer Society [ACS], 2015). HPV-mediated oncogenesis is responsible for up to 95% of cervical squamous cell carcinomas and nearly all preinvasive cervical neoplasms (CDC, 2015m). More than 40 types of HPV can infect the genital tract. Types 16, 18, 31, 35, 39, 45, 51, 52, 58, 59, and 68 are associated with cervical dysplasia and may contribute to the development of anal, cervical, penile, and cancers (ACS, 2015). HPV is most prevalent in young women between the ages of 20 and 24 years, followed closely by the 15- to 19-year-old age group (Gearhart, Randall, Buckley, & Buckley, 2016).

 Take Note!

The lifetime risk of HPV infection is estimated to be as high as 50% in sexually active individuals.

Nursing Assessment

Nursing assessment of the woman with HPV involves a complete health history and assessment of clinical manifestations, physical examination, and laboratory and diagnostic testing. A woman with HPV lesions may have symptoms such as profuse, irritating vaginal discharge, itching, dyspareunia, or bleeding after intercourse. She may also report 'bumps' on her labia. Physical inspection of the

external genitalia is important whenever HPV lesions are suspected or seen.

HEALTH HISTORY AND CLINICAL MANIFESTATIONS

Assess the client's health history for risk factors for HPV, which include having multiple sex partners, age (15 to 25 years), sex with a male who has had multiple sexual partners, and first intercourse at age 16 or younger (Mohanty & Ghosh, 2015). Risk factors contributing to the development of cervical cancer include smoking, few or no screenings for cervical cancer, multiple sex partners, immunosuppressed state, long-term contraceptive use (more than 2 years), co-infection with another STI, pregnancy, nutritional deficiencies, and early onset of sexual activity (Gearhart, Higgins, Randall, & Buckley, 2016).

Assess the client for clinical manifestations of HPV. Most HPV infections are asymptomatic, unrecognized, or subclinical. Visible genital warts usually are caused by HPV types 6 or 11. In addition to the external genitalia, genital warts can occur on the cervix and in the vagina, urethra, anus, and mouth. Depending on the size and location, genital warts can be painful, friable (easily pulverized or crumbled), and pruritic (itching), although most are typically asymptomatic (Fig. 5.8). The strains of HPV associated with genital warts are considered low risk for development of cervical cancer, but other HPV types (16, 18, 31, 33, and 35) have been strongly associated with cervical cancer (CDC, 2015m).

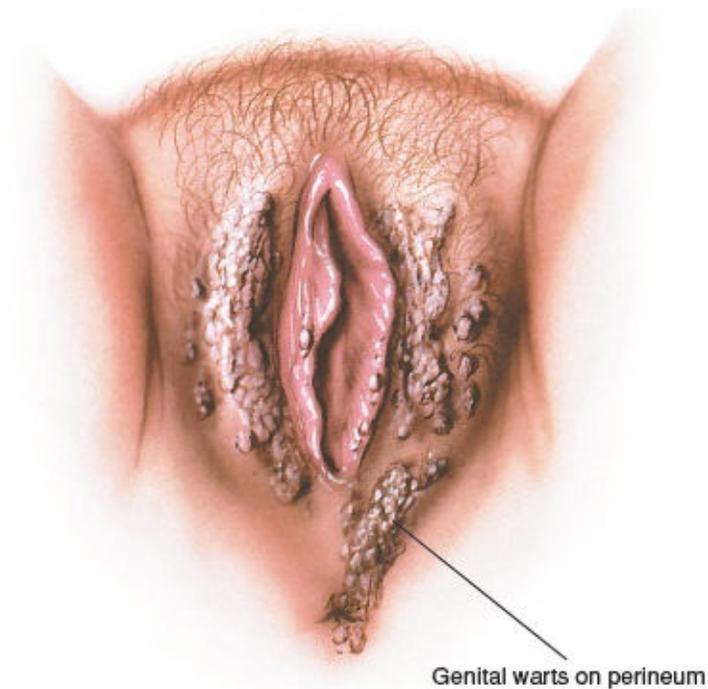
Genital warts on perineum


FIGURE 5.8 Genital warts. (Illustration provided by Anatomical Chart Co. Photograph from Gorbach, S. L., et al. [2004]. *Infectious diseases*. Philadelphia, PA: Lippincott Williams & Wilkins.)

PHYSICAL EXAMINATION AND LABORATORY AND DIAGNOSTIC TESTS

Clinically, visible warts are diagnosed by inspection. The warts are fleshy papules with a warty, granular surface. Lesions can grow very large during pregnancy, affecting urination, defecation, mobility, and descent of the fetus

(CDC, 2015m). Large lesions, which may resemble cauliflowers, exist in coalesced clusters and bleed easily.

Pap smears now are performed every 3 to 5 years for low-risk women. This current standard of care, calling for less frequent cervical cancer screening than in the past, makes it critical for women to understand when they are to have them and follow through to get them. These regular Pap smears will detect the cellular changes associated with HPV. The FDA has recently approved an HPV test as a follow-up for women who have an ambiguous Pap test. In addition, this HPV test may be a helpful addition to the Pap test for general screening of women aged 30 and over. The HPV test is a diagnostic test that can determine the specific HPV strain, which is useful in discriminating between low-risk and high-risk HPV types. A specimen for testing can be obtained with a fluid-phase collection system such as Thin Prep. The HPV test can identify 13 of the high-risk types of HPV associated with the development of cervical cancer and can detect high-risk types of HPV even before there are any conclusive visible changes to the cervical cells. If the test is positive for the high-risk types of HPV, the woman should be referred for colposcopy, which is a visual examination of the cervix using magnification and simple staining solutions such as acetic acid and Lugol's solution. It is sometimes accompanied by a biopsy to confirm a cervical abnormality (Decker, McLachlin, & Lotocki, 2015).

> *Upon physical examination, it is determined that Sandy has genital warts. The nurse finds out that Sandy engaged in high-risk behavior with a stranger she "hooked up" with recently at college. She couldn't imagine that he would give her an STI because "he looked so clean-cut." She wonders how she could possibly have genital warts. What information should be given to Sandy about STIs in general? What specific information about HPV should be stressed?*

Therapeutic Management

There is currently no medical treatment or cure for HPV. Instead, therapeutic management focuses heavily on prevention through the use of the HPV vaccine and education and on the treatment of lesions and warts caused by HPV. The FDA has approved three HPV vaccines to prevent cervical cancer: Cervarix, Gardasil, and Gardasil 9.

The CDC's Advisory Committee on Immunization Practices (ACIP) has recommended the vaccine for routine administration to 11- and 12-year-old girls and boys. This recommendation has created a firestorm from many parents feeling that such a vaccine would give young women a false sense of security and lead to promiscuity. Nurses may encounter parental resistance and will need to present the facts to parents about the effectiveness of the vaccines and prevention of cervical cancer. The ACIP also endorses the use of a HPV vaccine for girls and boys as young as age 9 and recommends that women between the ages of 13 and 26 receive the vaccination series, which consists of three injections over 6 months. All three are prophylactic HPV vaccines designed primarily for cervical cancer prevention. Cervarix is effective against HPV-16, -18, -31, -33, and -45, the five most common cancer-causing types, including most causes of adenocarcinoma for which we cannot screen adequately. Gardasil is effective against HPV-16, -18, and -31, three common squamous cell cancer-causing types. In addition, Gardasil is effective against HPV-6 and -11, causes of genital warts and respiratory papillomatosis. The most important determinant of vaccine impact to reduce cervical cancer is its duration of efficacy. To date, Cervarix's efficacy is proven for 6.4 years and Gardasil's for 5 years (CDC, 2015n). Gardasil 9 is effective against HPV types 6, 11, 16, 18, 31, 33, 45, 52, and 58. According to the FDA, the new vaccine (Gardasil 9) can potentially prevent about 90% of cervical, vulvar, vaginal, and anal cancers (Gearhart, Higgins, Randall, & Buckley, 2016). Prophylactic HPV vaccines are safe, well tolerated, and highly efficacious in preventing persistent infections and cervical diseases associated with vaccine-HPV types among young females. However, long-term efficacy and safety need to be addressed in the future (Castle & Schmeler, 2015).

The vaccine is administered intramuscularly in three separate 0.5-mL doses. The first dose may be given to any individual 9 to 26 years old prior to infection with HPV. The second dose is administered 2 months after the first, and the third dose is given 6 months after the initial dose. The deltoid region of the upper arm or anterolateral area of the thigh may be used. The most common vaccine side effects include pain, fainting, redness, and swelling at the injection site; fatigue; headache; muscle and joint aches; and gastrointestinal distress. Serious adverse events reported to the CDC include blood clots occurring in the heart, lungs, or legs, Guillain–Barré syndrome, and less than 30 deaths (CDC, 2015n). Most client profiles had risk factors that may have attributed to these adverse events and not to the vaccine alone (CDC, 2015n).

If the woman does not receive primary prevention with the vaccine, then secondary prevention would focus on education about the importance of receiving regular Pap smears and, for women over age 30, including an HPV test to determine whether the woman has a latent high-risk virus that could lead to precancerous cervical changes. Finally, treatment options for precancerous cervical lesions or genital warts caused by HPV are numerous and may include:

• Topical trichloroacetic acid (TCA) 80% to 90%

• Liquid nitrogen cryotherapy

• Topical imiquimod 5% cream (Aldara)

• Topical podophyllin 10% to 25%

• Laser carbon dioxide vaporization

• Client-applied Podofilox 0.5% solution or gel

• Simple surgical excision

• Loop electrosurgical excisional procedure (LEEP)

• Intralesional interferon therapy (King et al., 2015)

The goal of treating genital warts is to remove the warts and induce wart-free periods for the client. Treatment of genital warts should be guided by the preference of the client and available resources. No single treatment has been found to be ideal for all clients, and most treatment modalities appear to have comparable efficacy. Because genital warts can proliferate and become friable during pregnancy, they should be removed using a local agent. A cesarean birth is not indicated solely to prevent transmission of HPV infection to the newborn, unless the pelvic outlet is obstructed by warts (Gearhart, Higgins, Randall, & Buckley, 2016).

Nursing Management

An HPV infection has many implications for the woman's health, but most women are unaware of HPV and its role in cervical cancer. The average age of sexual debut is in early adolescence; therefore, it is important to target this population for use of the HPV/cervical cancer vaccine.

Key nursing roles are teaching about prevention of HPV infection and promotion of vaccines and screening tests in order to reduce the morbidity and mortality associated with cervical cancer caused by HPV infection. Teach all

women that the only way to prevent HPV is to refrain from any genital contact with another individual. Although the effect of condoms in preventing HPV infection is unknown, latex condom use has been associated with a lower rate of cervical cancer. Teach women about the link between HPV and cervical cancer. Explain that, in most cases, there are no signs or symptoms of infection with HPV. Strongly encourage all young women between the ages of 9 and 26 (and in the case of young girls between 9 and 18, their parents) to consider receiving the vaccine against HPV. For all women, promote the importance of obtaining regular Pap smears and, for women over age 30, suggest an HPV test to rule out the presence of a latent high-risk strain of HPV.

Education and counseling are important aspects of managing women who have genital warts. Teach the woman that:

• Even after genital warts are removed, HPV still remains and viral shedding will continue.

• The likelihood of transmission to future partners and the duration of infectivity after treatment for genital warts are unknown.

• The recurrence of genital warts within the first few months after treatment is common and usually indicates recurrence rather than reinfection (CDC, 2015m).

In the absence of major national health policy mandates, a multilevel, multifaceted approach will be needed to achieve high rates of HPV vaccination in the United States. Nurses need to focus on the education of their clients regarding indications of HPV vaccination and work on approaches to communicating most effectively with parents about the safety and benefits of vaccination and the risks associated with not vaccinating their children.

Sandy is being treated for HPV and is anxious for her "things" to disappear and never return. What education is needed to prevent further transmission from Sandy to any future sexual partners?

Hepatitis A and B

Hepatitis is an acute, systemic, viral infection that can be transmitted sexually. The viruses associated with hepatitis or inflammation of the liver are hepatitis A, B, C, D, E, and G. Hepatitis A is an inflammation of the liver caused by infection with the hepatitis A virus (HAV). Hepatitis A is highly contagious and spreads primarily through the fecal–oral route from person-to-person or by ingesting contaminated food or water. Hepatitis A can also be transmitted through sexual intercourse. Person-to-person transmission through the fecal–oral route (i.e., ingestion of something that has been contaminated with the feces of an infected person) is the primary means of HAV transmission in the United States (CDC, 2015o). Most infections result from close personal contact with an infected household member or sex partner. A HAV infection produces a self-limited disease that does not result in chronic infection or chronic liver disease, but it can be easily passed on to others within the same household.

The hepatitis B virus (HBV) is transmitted by infected body fluids through saliva, blood serum, semen, menstrual blood, and vaginal secretions, and through activities that involve percutaneous (i.e., puncture through the skin) or mucosal contact with infectious blood or body fluids (e.g., semen, saliva). Transmission also occurs via having sex with an infected partner; injection-drug use that involves sharing needles, syringes, or drug-preparation equipment; birth to an infected mother; contact with the blood or open sores of an infected person; needle sticks or sharp instrument exposures; or sharing items such as razors or sharing toothbrushes with an infected person. HBV is not spread through food or water, sharing eating utensils, breast-feeding, skin-to-skin contact, coughing, or sneezing (CDC, 2015p).

The WHO estimates that globally about 2 billion people have been infected with HBV and that more than 240 million have chronic (long-term) liver infections as a result. Worldwide, hepatitis B has the highest death rate (780,000 annually) of any STI except HIV (WHO, 2015a). Risk factors for infection include having multiple sex partners, engaging in unprotected receptive anal intercourse, and having a history of other STIs (CDC, 2015p). The most effective means to prevent the transmission of hepatitis A or B is preexposure immunization. Vaccines are available for the prevention of HAV and HBV, both of which can be transmitted sexually. Every person seeking treatment for an STI should be considered a candidate for HBV vaccination, and some individuals

(e.g., men who have sex with men, and injection-drug users) should be considered for HAV vaccination (CDC, 2015p).

Therapeutic Management

Unlike other STIs, HAV and HBV are preventable through immunization. HAV is usually self-limiting and does not result in chronic infection. HBV can result in serious, permanent liver damage. Treatment is generally supportive. No specific treatment for acute HBV infection exists.

Nursing Assessment

Assess the client for clinical manifestations of hepatitis A and B. Hepatitis A produces flu-like symptoms with malaise, fatigue, anorexia, nausea, pruritus, fever, and upper right quadrant pain. Symptoms of hepatitis B are similar to those of hepatitis A, but with less fever and skin involvement. The diagnosis of hepatitis A cannot be made based on clinical manifestations alone and requires serologic testing. The presence of IgM antibody to HAV is diagnostic of acute HAV infection. Hepatitis B is detected by a blood test that looks for antibodies and proteins produced by the virus and are positively diagnosed by the presence of hepatitis B surface antigen (HBsAg) (Pyrsopoulos & Reddy, 2015).

Nursing Management

Nurses should encourage all women to be screened for hepatitis when they have their annual Pap smear, or sooner if high-risk behavior is identified. Nurses should also encourage women to undergo HBV screening at their first prenatal visit and repeat screening in the last trimester for women with high-risk behaviors to comply with USPSTF (2015) recommendations. Nurses can also explain that hepatitis B vaccine is given to all infants after birth in most hospitals. The vaccination consists of a series of three injections given within 6 months. The vaccine has been shown to be safe and well tolerated by most recipients (CDC, 2015p). Hepatitis A vaccine is strongly encouraged for children between 12 and 23 months of age; persons 1 year of age and older traveling to countries with a high prevalence of hepatitis A, such as Central or South America, Mexico, Asia, Africa, and eastern Europe; men who have sex with men; persons who use street drugs; and persons with chronic liver disease (CDC, 2015o). For others, hepatitis A vaccine series (two doses 6 months apart) may be

started whenever a person is at risk for infection.

Hepatitis C

Hepatitis C is an infection caused by the hepatitis C virus (HCV) that attacks the liver and leads to inflammation. It is estimated that about 3% of the world's population has been infected with HCV and that there are more than 170 million chronic carriers who are at risk for developing liver cirrhosis and/or liver cancer (WHO, 2015e). Although HCV is not usually transmitted sexually, it deserves a brief mention here because injection-drug use by women places them at risk for it. HCV-infected pregnant women have a 2% to 8% risk of viral transmission to their newborn, but the mechanism and timing of mother-to-fetus transmission are not fully understood. Although the typical transmission of HCV is not sexual, it can be transmitted sexually. Those with the virus are instructed to refrain from unprotected sexual activity. Women at high risk include those with a history of injection-drug use, health care workers, and those with a history of blood transfusion before 1992 (Dhawan, 2015). The prevalence of HCV infection in pregnant women is approximately 1%. The majority of infected women are not aware they have HCV because they are not clinically ill. Perinatal transmission of HCV is relatively rare, except in women who are immunocompromised (e.g., have HIV/AIDS). A timely diagnosis of HIV and HCV is needed to start treatment, with the best option is to treat HCV before pregnancy (Snijdewind et al., 2015).

Hepatitis infections continue to be an important public health challenge. These viruses impact the entire age spectrum from newborns to the older population. Nurses from all disciplines may, therefore, encounter hepatitis-infected clients. As such, all nurses have a unique opportunity to prevent new infections through client education and improve health outcomes for those already infected.

ZIKA VIRUS DISEASE

Zika virus is transmitted to humans primarily through the bite of an infected *Aedes* species mosquito during the daytime. The most common symptoms of Zika are fever, rash, headaches, bone pains, joint tenderness, and conjunctivitis. The illness is typically mild with symptoms lasting for several days to a week after being bitten. Up to 80% of people infected with the virus have no symptoms (CDC, 2016). The virus is in the Caribbean as well as parts of Central and South America. The virus has been reported to be spread through blood transfusions, sexual contact and can also be passed from a pregnant woman to her fetus and has been linked to a serious birth defect of the brain termed microcephaly. The CDC, WHO, and other scientific organizations are working to understand this possible link.

In 2016 the World Health Organization declared Zika virus a public health emergency of international concern. The CDC recommends abstaining from oral, anal, or vaginal sexual contact with anyone who has traveled to areas with active infections. Pregnant women are also discouraged from traveling to regions with active infections (2016). At this time, there is no vaccine given to prevent Zika, or anti-viral medication to treat the infection. Prevention measures would include better housing construction, use insect repellents, wear long-sleeved shirts and pants, regular use of air conditioning, use of window screens, avoid traveling to mosquito-infested areas, and state and local mosquito control efforts.

ECTOPARASITIC INFECTIONS

Ectoparasites are a common cause of skin rash and pruritus throughout the world, affecting persons of all ages, races, and socioeconomic groups. Overcrowding, global traveling, immigration, delayed diagnosis and treatment, and poor public education contribute to the prevalence of ectoparasites in both industrial and nonindustrial nations. Approximately 300 million ectoparasitic cases are reported worldwide each year (CDC, 2015g). These infections include infestations of scabies and pubic lice. Because these parasites are easily passed from one person to another during sexual intimacy, clients should be assessed for them when receiving care for other STIs.

Scabies is an intensely pruritic dermatitis caused by a mite. The worldwide prevalence has been estimated at about 100 million cases annually (Monsel & Chosidow, 2015). In general, transmission occurs by direct skin-to-skin contact. The female mite burrows under the skin and deposits eggs, which hatch. The lesions start as a small papule that reddens, erodes, and sometimes crusts. Diagnosis is based on history and appearance of linear burrows in the webs of the fingers, on the elbows, in the axillae, buttocks, and the genitalia (Mutasim, 2015). Aggressive infestation can occur in immunodeficient, debilitated, or malnourished people, but healthy people do not usually suffer sequelae. Scabies treatment includes topical administration of a scabicidal agent (e.g., permethrin, crotamiton, or ivermectin), as well as an antibiotic if a secondary infection is present.

Lice are parasitic insects that can be found on people's head, body or pubic areas. Clients with pediculosis pubis (pubic louse) usually seek treatment because of the pruritus, because of a rash brought on by skin irritation from scratching, or because they notice lice or nits in their pubic hair, axillary hair, abdominal and thigh hair, and sometimes in the eyebrows, eyelashes, and beards. Infestation is usually asymptomatic until after a week or so, when bites cause pruritus and secondary infections from scratching (Fig. 5.9). Diagnosis is based on history and the presence of nits (small, shiny, yellow, oval, dewdrop-like eggs) affixed to hair shafts or lice (a yellowish, oval, wingless insect) (Guenther & Maguiness, 2015).

Treatment has two aspects: medication and environmental control measures. Medications used include topical anti-louse agents such as permethrin shampoos,

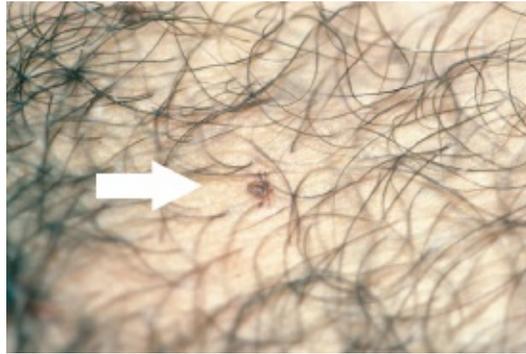
malathion, spinosad, or ivermectin. Bedding and clothing should be washed in hot water and dried using a hot setting on the dryer; dry cleaning or sealing clothes in plastic bags for 2 weeks to decontaminate them. Sexual partners should also be treated, as well as family members who live in close contact with the infected person.


FIGURE 5.9 Pubic lice. A small brown living crab louse is seen at the base of hairs (*arrow*). (From Goodheart, H. [2009]. *Goodheart's photoguide of common skin disorders*. Philadelphia, PA: Lippincott Williams & Wilkins.)

Nursing care of a woman infested with lice or scabies involves a three-tiered approach: eradicating the infestation with medication, removing nits, and preventing spread or recurrence by managing the environment. The CDC recommends regimens using pyrethrins and permethrins. Frequently, a combination of malathion or ivermectin is also added. Nurses should provide education about these products (Teaching Guidelines 5.5). The nurse can follow these same guidelines to prevent the health care facility from becoming infested.

Teaching Guidelines 5.5

TREATING AND MINIMIZING THE SPREAD OF SCABIES AND PUBIC LICE

• Use the medication according to the manufacturer's instructions.

• Remove nits with a fine-toothed nit comb.

• Do not share any personal items with others or accept items from others.

- Treat objects, clothing, and bedding and wash them in hot water.
- Meticulously vacuum carpets to prevent a recurrence of infestation.

HUMAN IMMUNODEFICIENCY VIRUS

Many advances have been made in the prevention of HIV transmission and management of HIV/AIDS since the virus was discovered in the early 1980s. Since that time, AIDS has claimed more than 40 million lives (WHO, 2015b). One of the most important discoveries has been antiretroviral treatment, which can halt the replication of the virus and ease symptoms, turning AIDS into a chronic condition instead of a rapidly terminal illness. Despite advances, HIV remains a major public health challenge today.

Globally, an estimated 35 million people are infected or living with HIV, of which 22.5 million are in sub-Saharan Africa. In addition, of the 2.5 million children in the world estimated to be living with HIV, 2.3 million are in sub-Saharan Africa (WHO, 2015b).

In the United States, an estimated 1.2 million people currently live with HIV, with almost one in six unaware of their infections. An estimated 50,000 new HIV infections occur annually; typically, every 10 minutes a person in the United States becomes infected with HIV (CDC, 2015q). In terms of epidemiology, fatality rate, and its social, legal, ethical, and political aspects, HIV/AIDS is a public health crisis and has generated more concern than any other infectious disease in modern medical history. The course of HIV infection is characterized primarily by latency. Unfortunately, profound immune suppression eventually develops and the illness is lethal. More than 650,000 people have died of AIDS in the United States since the 1980s (CDC, 2015q).

HIV/AIDS continues to outpace the science, financing, prevention, and treatment efforts of the past quarter century. The economic impact of HIV/AIDS presents huge challenges. While the causality between poverty and HIV is not clear, it is certain that HIV pushes households and individuals into poverty. While many illnesses create catastrophic expenditures that can result in poverty, HIV/AIDS is among the worst because its victims are ill for a prolonged period of time before they die, and many are the chief household income earners. According to the WHO, the lower a person's socioeconomic status is, the worse the health outcomes for them. An intervention to address this issue is to help women's vocational development and economic empowerment since the illness exists for years (Conyers et al., 2015). To date, there is no cure for this fatal viral infection.

The HIV virus is transmitted by intimate sexual contact; by sharing needles for intravenous drug use; from mother to fetus during pregnancy or breast-feeding; and by transfusion of blood or blood products. Men who have sex with men represent the largest proportion of new infections, followed by men and women infected through heterosexual sex (CDC, 2015q). Among racial/ethnic groups in the United States, African Americans are at the highest risk of acquiring HIV/AIDS, and account for 45% of new HIV infections. The African American community continues to be ravaged by HIV/AIDS infection, despite the marked expenditures utilized to reduce incidence among this cohort. Efforts to produce culturally appropriate programs that work continue to elude officials, and HIV/AIDS has become pandemic within this racial/ethnic group. More awareness of HIV/AIDS using media campaigns is needed to reduce risky behaviors (Nunn et al., 2015).

The number of women with HIV infection and AIDS has been increasing steadily worldwide. Today, women account for one in four (25%) new HIV infections in the United States. Women of color have been especially hard hit and represent the majority of women living with the disease and newly infected ones. Most women are infected through heterosexual sex (Kaiser Family Foundation, 2015). The WHO estimates that over 25 million women are living with HIV/AIDS worldwide, accounting for approximately 50% of the 40 million adults living with HIV/AIDS (CDC, 2015r). HIV disproportionately affects African American and Hispanic women: together they represent less than 25% of all women in the United States; yet they account for more than 82% of AIDS cases among women (CDC, 2015r). African American women in this country suffer disproportionately from the HIV/AIDS epidemic, as they acquire new HIV infections at nearly 15 times the rate of White women (CDC, 2015r). Women are particularly vulnerable to heterosexual transmission of HIV as a result of substantial mucosal exposure to seminal fluids. This biologic fact amplifies the risk of HIV transmission when coupled with the high prevalence of nonconsensual sex, sex without condoms, and the unknown and/or high-risk behaviors of their partners (CDC, 2015r). Therefore, the face of HIV/AIDS is becoming the face of young women. That shift will ultimately exacerbate the incidence of HIV because women spread it not only through sex, but also through nursing and childbirth.

AIDS is a breakdown in the immune function caused by HIV, a retrovirus. A sufficient quantity of viruses must be transferred to infect a person. The virus cannot live long outside the human body; it cannot be transmitted via tears or

sweat. The HIV infection is associated with continued activation of immune system and is the driving force behind CD4 T cell depletion and progression to AIDS. The infected person develops opportunistic infections or malignancies that become fatal. Progression from HIV infection to AIDS occurs at a median of 11 years after infection (Bharaj & Chahar, 2015). HIV transmission modalities include the following:

• Sexual intercourse with an infected partner unprotected by condoms

• Blood transfusions from infected donors or organ transplants from infected donors

• Needle sticks from contaminated sharps or sharing needles with infected people

• Mother-to-infant during pregnancy, childbirth or breastfeeding

More than 30 years have passed since HIV/AIDS began to affect our society. Since then, 50 million people have been infected by the virus, with AIDS being the fourth leading cause of death globally (CDC, 2015q). The morbidity and mortality of HIV continue to hold the attention of the medical community. While there has been a dramatic improvement in both morbidity and mortality with the use of highly active antiretroviral therapy, the incidence of HIV infection continues to rise.

Take Note!

More than 90% of individuals infected with HIV worldwide do not know they are infected and, thus, are at risk of spreading it sexually to others (CDC, 2015q).

The fetal and neonatal effects of acquiring HIV through perinatal transmission are devastating and eventually fatal. An infected mother can transmit HIV infection to her newborn before or during birth and through breast-feeding. Most cases of mother-to-child HIV transmission, the cause of more than 90% of pediatric-acquired infections worldwide, occur late in pregnancy or during delivery. Transmission rates vary from 25% in untreated non–breast-feeding populations in industrialized countries to about 40% among untreated breast-feeding populations in developing countries (Castel, Magnus, & Greenberg,

2015). Despite the dramatic reduction in perinatal transmission, hundreds of infants will be born infected with HIV.

HIV and Adolescents

The effects of HIV and AIDS on adolescents and young adults is of increasing concern, but it is difficult to get accurate data because of the varying ways in which this population seeks health care services. Some adolescents continue to receive care through pediatricians and adult services, but many do not have access to health care. HIV infections are increasing in adolescents and young adults aged 13 to 24 years. Approximately 25% of cases of STIs reported in the United States each year are among teenagers. More than two million adolescents between the ages of ten and nineteen are living with HIV, and many do not receive the care and support they need to stay in good health. This is particularly significant because the risk of HIV transmission increases substantially if either partner is infected with an STI (WHO, 2015c). At least one adolescent in the United States is infected with HIV each hour. Since it takes an average of 11 years for AIDS symptoms to appear when HIV is left untreated, it is obvious that many adults with AIDS were infected as adolescents.

Nurses can play a key role in preventing and controlling HIV infection by promoting risk reduction counseling and offering routine HIV testing to adolescents. Most sexually active youth do not feel that they are at risk for contracting HIV and have never been tested. Obtaining a sexual history and creating an atmosphere that promotes nonjudgmental risk counseling is a key component of the adolescent visit. In light of increasing numbers of people with HIV/AIDS and missed opportunities for HIV testing, the CDC (2015q) recommends universal and routine HIV testing for all clients seen in health care settings who are 13 to 64 years of age.

Clinical Manifestations

HIV infection undergoes three distinct phases: acute seroconversion, asymptomatic infection, and then progression to AIDS. When a person is initially infected with HIV, he or she goes through an acute primary infection period for about 3 weeks. The HIV viral load drops rapidly because the host's immune system works well to fight this initial infection. The onset of the acute primary infection occurs 2 to 6 weeks after exposure. Symptoms include fever, pharyngitis, rash, and myalgia. Most people do not associate this flu-like condition with HIV infection. After initial exposure, there is a period of 3 to 12 months before seroconversion. The person is considered infectious during this time.

After the acute phase, the infected person becomes asymptomatic, but the HIV virus begins to replicate. Even though there are no symptoms, the immune system runs down. A normal person has a CD4 T-cell count of 450 to 1,200 cells per microliter. When the CD4 T-cell count reaches 200 or less, the person is considered to have AIDS. The immune system begins a constant battle to fight this viral invasion, but over time it falls behind. A viral reservoir occurs in T cells that can store various stages of the virus. The onset and severity of the disease correlate directly with the viral load: the more HIV virus that is present, the worse the person will feel. As profound immunosuppression begins to occur, an opportunistic infection will occur, qualifying the person for the diagnosis of AIDS. As of now, AIDS will eventually develop in everyone who is HIV positive.

The WHO now recommends earlier initiation of antiretroviral therapy (ART) for adults and adolescents, the delivery of more client-friendly ART drugs, and prolonged use of ART drugs to reduce the risk of mother-to-child transmission of HIV. ART should be started when the CD4 counts are below 350 cells/microliter. Further recommendations include initiation of ART irrespective of CD4 cell count or clinical stage for people co-infected with active tuberculosis or hepatitis B with severe liver disease, pregnant women in serodiscordant partnerships, and children under 5 years of age (Bennett & Gilroy, 2015).

Diagnosis

Several types of tests are approved to detect HIV. These tests are designed to detect antigens, antibodies, or RNA. The enzyme-linked immunosorbent assay (ELISA) is used as the initial screening test to determine presence of the HIV virus. When ELISA generates a positive result, a confirmation test (Western blot test) is then performed. In addition, several point-of-care or rapid antibody tests are available. Two categories of screening methods are currently used: rapid HIV tests and confirmatory tests. The rapid tests allow for screening at the point-of-care and quick results. Five rapid HIV tests that are FDA approved include: (1) OraQuick Advance HIV tests (whole blood used); (2) Uni-Gold Recombigen HIV test (whole blood used); (3) Reveal G-3 Rapid HIV Antibody test (serum or plasma used); (4) Multispot (serum or plasma used); and (5) Clearview Stat-Pak and complete (whole blood used). A positive result is followed up with one of two confirmatory tests: Western blot (WB) or immunofluorescence (IFA) (Shafiee et al., 2015).

Quick tests for HIV produce results in 10 to 20 minutes and also lower the health care worker's risk of occupational exposure by eliminating the need to draw blood. The CDC's Advancing HIV Prevention initiative, launched in 2003, has made increased testing a national priority. The CDC recommends HIV screening of all US residents aged 13 to 64 years in all health care settings (CDC, 2015r).

Fewer than half of adults between the ages of 18 and 64 have ever had an HIV test, according to the CDC. The agency estimates that one fourth of the million HIV-infected people in the United States do not know they are infected. This means they are not receiving treatment that can prolong their lives, and they may be unknowingly infecting others. In addition, even when people do get tested, one in three fails to return to the testing site to learn their results when there is a 2-week wait. The CDC hopes that the new "one-stop" approach to HIV testing will change that pattern.

People who are infected with HIV but not aware of it are not able to take advantage of the therapies that can keep them healthy and extend their lives, nor do they have the knowledge to protect their sex or drug-use partners from becoming infected. Knowing whether one is positive or negative for HIV confers great benefits in healthy decision-making.

Rapid point-of-service HIV tests are becoming powerful screening tools in

various health care settings because they offer the opportunity to not only screen for HIV, but also to educate the person regarding risk factors, and discuss their test results—all in one clinical visit. Most use a fingerstick drop of blood or a swab of saliva taken from the mouth. Results are typically ready within 10 to 20 minutes. If the confirmation test (WB or IFA) is positive, the person is infected with HIV and is capable of transmitting the virus to others. HIV antibody is detectable in at least 95% of people within 3 months after infection (CDC, 2015q).

Therapeutic Management

The goals of HIV drug therapy are as follows:

• Decrease the HIV viral load below the level of detection.

• Restore the body's ability to fight off pathogens.

• Improve the client's quality of life.

• Reduce HIV morbidity and mortality (Bennett & Gilroy, 2015).

Highly active antiretroviral therapy (HAART), which combines at least three antiretroviral drugs, has dramatically improved the prognosis of HIV/AIDS. Often treatment begins with combination HAART at the time of the first infection, when the person's immune system is still intact. The current HAART standard is a triple combination therapy, but some clients may be given a fourth or fifth agent.

Current therapy to prevent the transmission of HIV to the newborn includes a three-part regimen:

1. The mother takes an oral antiretroviral agent at 14 to 34 weeks of gestation; it is continued throughout pregnancy.

2. During labor, an antiretroviral agent is administered intravenously until delivery.

3. An antiretroviral syrup is administered to the infant within 12 hours after birth.

Dramatic new treatment advances with antiretroviral medications have turned a disease that used to be a death sentence into a chronic, manageable one for individuals who live in countries where ART is available. Despite these advances in treatment, however, only a minority of HIV-positive people in the United States who take antiretroviral medications are receiving the full benefits because they are not adhering to the prescribed regimen. Successful ART requires nearly perfect adherence to a complex medication regimen; less-than-perfect adherence leads to drug resistance (King et al., 2015).

Adherence is difficult because of the complexity of the regimen and the lifelong duration of treatment. A typical antiretroviral regimen may consist of three or more medications taken twice daily. Adherence is made even more

difficult because of the unpleasant side effects, such as nausea and diarrhea. Women in early pregnancy already experience these, and the antiretroviral medication only exacerbates them.

Nursing Management

Nurses can play a major role in caring for the HIV-positive woman by helping her accept the possibility of a shortened life span, cope with others' reactions to a stigmatizing illness, and develop strategies to maintain her physical and emotional health. Educate the woman about changes she can make in her behavior to prevent spreading HIV to others, and refer her to appropriate community resources such as HIV medical care services, substance abuse services, mental health services, and social services. See Nursing Care Plan 5.1: Overview of the Woman Who Is HIV Positive.

Providing Education About Drug Therapy

The goal of antiretroviral therapy is to suppress viral replication so that the viral load becomes undetectable by diagnostic tests. This is done to preserve immune function and delay disease progression but is a challenge because of the side effects of nausea and vomiting, diarrhea, altered taste, anorexia, flatulence, constipation, headaches, anemia, and fatigue. Although not everyone experiences all of the side effects, the majority do have some of them. Current research has not documented the long-term safety of exposure of the fetus to antiretroviral agents during pregnancy, but collection of data is ongoing.

   Help to reduce the development of drug resistance and thus treatment failure by identifying the barriers to adherence; identifying these barriers can help the woman to overcome them. Some of the common barriers exist because the woman:

• Does not understand the link between drug resistance and nonadherence

• Fears revealing her HIV status by being seen taking medication

• Has not adjusted emotionally to the HIV diagnosis

• Does not understand the dosing regimen or schedule

• Experiences unpleasant side effects frequently

• Feels anxious or depressed (Dubin, 2015)

   Educate the woman about the prescribed drug therapy and stress that it is very important to take the regimen as prescribed. Offer suggestions about how to cope with anorexia, nausea, and vomiting by:

• Separating the intake of food and fluids

• Eating dry crackers upon arising

• Eating six small meals daily

• Using high-protein supplements (Boost, Ensure) to provide quick and easy protein and calories

• Eating "comfort foods," which may appeal when other foods do not

Promoting Adherence to Therapy

Remaining adherent to drug therapy is a huge challenge for many HIV-infected

people. Adherence becomes difficult when the same pills that are supposed to thwart the disease are making the person sick. Nausea and diarrhea are just two of the possible side effects. It is often difficult to increase the client's quality of life when so much oral medication is required. The combination medication therapy is challenging for many people, and staying compliant over a period of years is extremely difficult. Stress the importance of taking the prescribed antiretroviral drug therapies by explaining that they help prevent replication of the retroviruses and subsequent progression of the disease and also decrease the risk of perinatal transmission of HIV. In addition, provide written materials describing diet, exercise, medications, and signs and symptoms of complications and opportunistic infections. Reinforce this information at each visit.

Preventing HIV Infection

Despite the available information about HIV infection and AIDS, it causes great anxiety and fear of the unknown. It is vital to take a leadership role in educating the public about risky behaviors in the fight to control this disease. The core of HIV prevention is to reduce the number of sexual contacts and to use condoms. This is all good advice for many women, but some simply do not have the economic and social power or choices or control over their lives to put that advice into practice. Recognize that fact, and address the factors that will give women more control over their lives by providing anticipatory guidance, giving ample opportunities to practice negotiation techniques and refusal skills in a safe environment, and encouraging the use of female condoms to protect against this deadly virus. Prevention is the key to reversing the current infection trends.

NURSING CARE PLAN 5.1

Overview of the Woman Who is HIV Positive

Annie, a 28-year-old African American woman, is HIV-positive. She acquired HIV through unprotected sexual contact. She has been inconsistent in taking her antiretroviral medications and presents today stating she is tired and does not feel well.

NURSING DIAGNOSIS: Risk for infection related to positive HIV status and inconsistent adherence to antiretroviral therapy regimen

Outcome Identification and Evaluation
The client will remain free of opportunistic infections as evidenced by temperature within acceptable parameters and absence of signs and symptoms of opportunistic infections.

Interventions: *Minimizing the Risk of Opportunistic Infections*
• Assess CD4 count and viral loads *to determine disease progression* (CD4 counts <500/L and viral loads >10,000 copies/L = increased risk for opportunistic infections).
• Assess complete blood count *to identify presence of infection* (>10,000 cells/mm^3 may indicate infection).
• Assess oral cavity and mucous membranes for painful white patches in mouth *to evaluate for possible fungal infection*.
• Teach client to monitor for general signs and symptoms of infections, such as fever, weakness, and fatigue, *to ensure early identification*.
• Provide information explaining the importance of avoiding people with infections when possible *to minimize risk of exposure to infections*.
• Teach importance of keeping appointments so her CD4 count and viral load can be monitored *to alert the health care provider about her immune system status*.
• Instruct her to reduce her exposure to infections via:
  • Meticulous hand hygiene
  • Thorough cooking of meats, eggs, and vegetables

- • Wearing shoes at all times, especially when outdoors
- Encourage a balance of rest with activity throughout the day *to prevent overexertion.*
- Stress importance of maintaining prescribed antiretroviral drug therapies *to prevent disease progression and resistance.*
- If necessary, refer Annie to a nutritionist to help her understand what constitutes a well-balanced diet with supplements *to promote health and ward off infection.*

NURSING DIAGNOSIS: Deficient knowledge related to HIV infection and possible complications

Outcome Identification and Evaluation
The client will demonstrate increased understanding of HIV infection as evidenced by verbalizing appropriate health care practices and adhering to therapy and reduce her risk of further exposure and reduce risk of disease progression.

Interventions: *Providing Client Education*
- Assess her understanding of HIV and its treatment *to provide a baseline for teaching.*
- Establish trust and be honest with Annie; encourage her to talk about her fears and the impact of the disease *to provide an outlet for her concerns.* Encourage her to discuss reasons for her nonadherence to therapy.
- Provide a nonjudgmental, accessible, confidential, and culturally sensitive approach *to promote Annie's self-esteem and allow her to feel that she is a priority.*
- Explain measures, including safer sex practices and birth control options, to prevent disease transmission; determine her willingness to practice safer sex to protect others *to determine further teaching needs.*
- Discuss the signs and symptoms of disease progression and potential opportunistic infections *to promote early detection for prompt intervention.*
- Outline with the client the availability of community resources and make appropriate referrals as needed *to provide additional education and support.*
- Encourage Annie to keep scheduled appointments *to ensure follow-up and allow early detection of potential problems.*

Providing Care During Pregnancy and Childbirth

Voluntary counseling and HIV testing should be offered to all pregnant women as early in the pregnancy as possible to identify HIV-infected women so that treatment can be initiated early. Once a pregnant woman is identified as being HIV positive, she should be informed about the risk for perinatal infection. Current evidence indicates that in the absence of antiretroviral medications, 25% of infants born to HIV-infected mothers will become infected with HIV (CDC, 2015q). If women do receive a combination of antiretroviral therapies during pregnancy, however, the risk of HIV transmission to the newborn drops below 2% (Castel, Magnus, & Greenberg, 2015). In addition, HIV can be spread to the infant through breast-feeding, and thus all HIV-infected pregnant women should be counseled to avoid breast-feeding and use formula instead. A recent maternal infection with HIV may raise the risk of transmission through breast-feeding to twice that of a woman with earlier established infection, probably as a result of the high viral load associated with recent infection (Koletzko, 2015).

In addition, the woman needs instructions on ways to enhance her immune system by following these guidelines during pregnancy:

• Getting adequate sleep each night (7 to 9 hours)

• Avoiding infections (e.g., staying out of crowds, good hand hygiene)

• Decreasing stress in her life

• Consuming adequate protein and vitamins

• Increasing her fluid intake to 2 liters daily to stay hydrated

• Planning rest periods throughout the day to prevent fatigue

As said earlier, despite the dramatic reduction in perinatal transmission, hundreds of infants will be born infected with HIV. The birth of each infected infant is a missed prevention opportunity. To minimize perinatal HIV transmission, identify HIV infection in women, preferably before pregnancy; provide information about disease prevention; and encourage HIV-infected women to follow the prescribed drug therapy.

Providing Appropriate Referrals

The HIV-infected woman may have difficulty coping with the normal activities of daily living because she has less energy and decreased physical endurance. She may be overwhelmed by the financial burdens of medical and drug therapies, the emotional responses to a life-threatening condition, and, if she is pregnant, concern about her infant's future. A case management approach is needed to deal with the complexity of her needs during this time. Be an empathetic listener and make appropriate referrals for nutritional services, counseling, homemaker services, spiritual care, and local support groups. Many community-based organizations have developed programs to address the numerous issues regarding HIV/AIDS. The national AIDS hotline (1-800-342-AIDS) is a good resource. Table 5.4 provides a summary of the perinatal effects of STIs during pregnancy.

PREVENTING SEXUALLY TRANSMITTED INFECTIONS

Education about safer sex practices—and the resulting increase in the use of condoms—can play a vital role in reducing STI rates all over the world. Clearly, knowledge and prevention are the best defenses against STIs. The prevention and control of STIs is based on the following concepts (American College of Obstetricians & Gynecologists [ACOG], 2015; U.S. FDA, 2015):

1. Education and counseling of persons at risk about safer sexual behavior
2. Recommending immunizations that prevent Hepatitis B and HPV preexposure
3. Educating people that latex condoms offer some protection and reduce risk of transmission
4. Identifying asymptomatic infected individuals and symptomatic individuals unlikely to seek diagnosis and treatment
5. Effectively diagnosing and treating infected individuals
6. Evaluating, treating, and counseling sex partners of people who are infected with an STI

Nurses play an integral role in identifying and preventing STIs. They have a unique opportunity to educate the public about this serious public health issue by communicating the methods of transmission and symptoms associated with each condition, tracking the updated CDC treatment guidelines, and offering clients strategic preventive measures to reduce the spread of STIs. Nurses have a huge role to play to ensure all women are well educated about STIs by informing them how these infections are transmitted, symptoms, risk factors, potential for adverse effects, screening, and treatment recommendations. Armed with this knowledge, women can make fully informed decisions about accepting screening and adhering to treatment and follow-up advice.

It is not easy to discuss STI prevention when globally we are failing at it. Knowledge exists on how to prevent every single route of transmission, but the incidence of STIs continues to climb. Challenges to prevention of STIs include lack of resources and difficulty in changing the behaviors that contribute to their spread. Regardless of the challenging factors involved, nurses must continue to educate and to meet the needs of all women to promote their sexual health.

Successful treatment and prevention of STIs is impossible without education. Successful teaching approaches include giving clear, accurate messages that are age appropriate and culturally sensitive.

TABLE 5.4 MATERNAL AND FETAL EFFECTS FROM SEXUALLY TRANSMITTED INFECTIONS

STI	Maternal Effects	Fetal Effects
Candidiasis	Resistant to treatment during pregnancy; uncomfortable localized genital itching and discharge	Can acquire thrush in the mouth during birthing process if mother infected
Trichomoniasis	Has been implicated in causing the premature rupture of membranes (PROM) and preterm births	Risk of prematurity
Bacterial vaginosis	Increases risk for spontaneous abortion, PROM, chorioamnionitis, postpartum endometritis, and preterm labor	Risk of neonatal sepsis
Chlamydia	Postpartum endometritis, PROM, and preterm birth	Conjunctivitis, which can lead to blindness; low birth weight; and pneumonitis
Gonorrhea	Chorioamnionitis, preterm birth, PROM, intrauterine growth restriction (IUGR), and postpartum sepsis	Eye infection (*gonococcal ophthalmia*), which can cause blindness
Genital herpes	Spontaneous abortion, intrauterine infection, preterm labor, PROM, and IUGR	Birth anomalies and transplacental infection
Syphilis	Spontaneous abortion, preterm birth, and stillbirth	Congenital syphilis, leading to multisystem organ failure and structural damage, and intellectual disability
Human papillomavirus (HPV)	May cause dystocia if large lesions	None known
Hepatitis B	May cause preterm birth; can be transmitted to fetus if active in last trimester	Can become chronic carrier of hepatitis B, which may lead to liver cancer or cirrhosis
HIV	Fatigue, nausea, and weight loss	Transmission can occur transplacentally, during childbirth or through breast milk

(2016). *Women's gynecologic health* (3rd ed.). Burlington, MA: Jones & Bartlett Learning.

Primary prevention strategies include educating all women, especially adolescents, regarding the risk of early sexual activity, the number of sexual partners, and STIs. Sexual abstinence is ideal but often not practiced; therefore, the use of barrier contraception (condoms) should be encouraged (see Teaching Guidelines 5.1).

Secondary prevention involves the need for annual pelvic examinations with Pap smears for all sexually active women, regardless of age. Many women with

STIs are asymptomatic, so regular screening examinations are paramount for early detection. Understanding the relationship between poor socioeconomic conditions and poor patterns of sexual and reproductive self-care is significant in disease prevention and health promotion strategies.

Every successful form of prevention requires a change in behavior. The nursing role in teaching and rendering quality health care is invaluable evidence that the key to reducing the spread of STIs is through behavioral change. Nurses working in these specialty areas have a responsibility to educate themselves, their clients, their families, and the community about STIs and to provide compassionate and supportive care to clients. Some strategies nurses can use to prevent the spread of STIs are detailed in Box 5.4.

Behavior Modification

Research validates that changing behaviors does result in a decrease in new STI infections, but it must encompass all levels—governments, community organizations, schools, churches, parents, and individuals (WHO, 2015d). Education must address the following: ways to prevent becoming infected; condom promotion; target vulnerable populations such as adolescents, sex workers, men who have sex with men, and people who inject drugs; ways to prevent transmitting infection; symptoms of STIs; and treatment. At this point in the STI epidemic, nurses do not have time to debate the relative merits of prevention versus treatment: both are underused and underfunded, and one leads to the other. But being serious about prevention and focusing on the strategies outlined above will bring about a positive change on everyone's part.

BOX 5.4

SELECTED NURSING STRATEGIES TO PREVENT THE SPREAD OF SEXUALLY TRANSMITTED INFECTIONS

• Provide basic information about STI transmission.

• Outline safer sexual behaviors for people at risk for STIs.

• Refer clients to appropriate community resources to reduce risk.

• Screen asymptomatic persons with STIs.

• Identify barriers to STI testing and remove them.

• Offer pre-exposure immunizations for vaccine-preventable STIs.

• Respond honestly about testing results and options available.

• Counsel and treat sexual partners of persons with STIs.

• Educate school administrators, parents, and teens about STIs.

• Support youth development activities to reduce sexual risk-taking.

• Promote the use of barrier methods (condoms, diaphragms) to prevent the spread of STIs.

• Assist clients to gain skills in negotiating safer sex.

• Discuss reducing the number of sexual partners to reduce risk.

Contraception

The spread of STIs could be prevented by access to safe, efficient, appropriate barrier contraceptives. The consistent and correct use of condoms plays an important role in preventing the spread of STIs. Nurses can play an important role in helping women to identify their risk of STIs and to adopt preventive measures through the dual protection that contraceptives offer. Traditionally, family planning and STI services have been separate entities. Family planning services have addressed a woman's need for contraception without considering her or her partner's risk of STIs; meanwhile, STI services have been heavily slanted toward men while ignoring their contraceptive needs.

Many women are at significant risk for unintended pregnancy and STIs; yet with this separation of services, there is limited evaluation of whether they need dual protection—that is, concurrent protection from STIs and unintended pregnancy. This lack of integration of services represents a missed opportunity to identify many at-risk women and to offer them counseling on dual protection. Nurses can play a key role in influencing clients to initiate and maintain use of the female condom, an underused method for STI and pregnancy prevention (Alexander et al., 2015).

Consider This

I was thinking of my carefree college days, when the most important thing was having an active sorority life and meeting guys. I had been raised by very strict parents and was never allowed to date under their watch. Since I attended an out-of-state college, I figured that my parents' outdated advice and rules no longer applied. Abruptly, my thoughts of the past were interrupted by the HIV counselor asking about my feelings concerning my positive diagnosis. What was there to say at this point? I had a lot of fun but never dreamed it would haunt me for the rest of my life, which was going to be shortened considerably now. I only wish I could turn back the hands of time and listen to my parents' advice, which somehow doesn't seem so outdated now.

> *Thoughts:* *All of us have thought back on our lives to better times and wondered how our lives would have changed if we had made better choices or gone down another path. It is a pity that we have only one chance to make good, sound decisions at times. What would you have changed in your life if given a second chance? Can you still make a change for the better now?*

Nurses can expand their scopes in either setting by discussing dual protection by use of a male or female condom alone or by use of a condom along with a nonbarrier contraceptive. Because barrier methods are not the most effective means of fertility control, they have not been typically recommended as a method alone for dual protection. Unfortunately, the most effective pregnancy prevention methods—sterilization, hormonal methods, and intrauterine systems —do not protect against STIs. Dual-method use protects against STIs and pregnancy.

KEY CONCEPTS

- Avoiding risky sexual behaviors may preserve fertility and prevent chronic conditions later in life.
- An estimated 65 million people live with an incurable sexually transmitted infection (STI), and another 15 million are infected each year (CDC, 2015a).
- The most reliable way to avoid transmission of STIs is to abstain from sexual intercourse (i.e., oral, vaginal, or anal sex) or to be in a long-term, mutually monogamous relationship with an uninfected partner.
- Barrier methods of contraception are recommended because they increase protection from contact with urethral discharge, mucosal secretions, and lesions of the cervix or penis.
- The high rate of asymptomatic transmission of STIs calls for teaching high-risk women the nature of transmission and how to recognize infections.
- Nurses should practice good hand hygiene and follow standard precautions to protect themselves and their clients from STIs.
- Nurses are in an important position to promote the sexual health of all women. Nurses should make their clients and the community aware of the perinatal implications and lifelong sequelae of STIs.

CHAPTER **WORKSHEET**

MULTIPLE CHOICE QUESTIONS

1. The nurse's primary role related to sexually transmitted infections is:

    a. Case reporting of partners

    b. Detection and education

    c. Sexual counseling

    d. Diagnosis and treatment

2. A 16-year-old teen comes to the clinic for routine care and is diagnosed with gonorrhea. The teen asks the nurse why she needs treatment for this since she has no symptoms. The nurse should explain that possible complications of lack of treatment could result in:

a. Sterility, birth defects, and miscarriage

b. The need for future births by cesarean section

c. Skin rashes and hearing loss

d. Disseminated systemic infections

3. Which of the following contraceptive methods offers protection against sexually transmitted infections (STIs)?

a. Oral contraceptives

b. Withdrawal

c. Latex condom

d. Intrauterine contraceptive (IUC)

4. In teaching about human immunodeficiency virus (HIV) transmission, the nurse explains that the virus cannot be transmitted by:

a. Shaking hands

b. Sharing drug needles

c. Sexual intercourse

d. Breast-feeding

5. A woman with human papilloma virus (HPV) is likely to present with which nursing assessment finding?

a. Profuse, pus-filled vaginal discharge

b. Clusters of genital warts

c. Single painless ulcer

d. Multiple vesicles on genitalia

6. The nurse's discharge teaching plan for the woman with pelvic inflammatory disease (PID) should reinforce which of the following potentially life-threatening complications?

a. Involuntary infertility

b. Chronic pelvic pain

c. Depression

d. Ectopic pregnancy

7. To confirm a finding of primary syphilis, the nurse would observe which of the following on the external genitalia?

a. A highly variable skin rash

b. A yellow–green vaginal discharge

c. A nontender, indurated ulcer

d. A localized gumma formation

CRITICAL THINKING EXERCISES

1. Sally, age 17, comes to the teen clinic saying that she is in pain and has some "crud" between her legs. The nurse takes her into the examining room and questions her about her symptoms. Sally states she had numerous genital bumps that had been filled with fluid, then ruptured and turned into ulcers with crusts. In addition, she has pain on urination and overall body pain. Sally says she had unprotected sex with several men when she was drunk at a party a few weeks back, but she thought they were "clean."

a. What STI would the nurse suspect?

b. The nurse should give immediate consideration to which of Sally's complaints?

c. What should be the goal of the nurse in teaching Sally about STIs?

STUDY ACTIVITIES

1. Go to the CDC web site and select a specific STI of interest. Educate yourself about one specific STI thoroughly and share your expertise with your clinical group.

2. Contact your local health department and request current statistics regarding three STIs. Ask them to compare the current number of cases reported to last year's report. Has the number of STIs increased or decreased? What may be

some of the reasons for the change in the number of cases reported?

3. Request permission to attend a local STI clinic to shadow a nurse for a few hours. Describe the nurse's counseling role with clients and what specific information is emphasized to clients.

4. Two common STIs that appear together and are commonly treated together regardless of identification of the secondary one are _____ and _____.

5. Genital warts can be treated with which of the following? Select all that apply.
   a. Penicillin
   b. Podophyllin
   c. Imiquimod
   d. Cryotherapy
   e. Antiretroviral therapy
   f. Acyclovir

BRINGING IT ALL TOGETHER: CASE STUDY

Grace, a 25-year-old college student, came back upset from her annual gynecologic appointment at the college health center. The results from her pap smear were "abnormal" and she would need further testing to rule out cervical cancer. She had heard about cervical cancer but did not think it could happen to someone of her age, so she looked for some information on the Internet. What she found surprised and worried her. She learned that each year approximately 13,000 new cases of cervical cancer are found and that over 4,000 women die of the disease. This is twice as many as die of HIV/AIDS. She also learned that 93% of cervical cancers are caused by a virus.

Go to thePoint to find questions to consider about this case.

6

Disorders of the Breasts

benign breast disorder
breast augmentation
breast cancer
breast-conserving surgery
breast implants
breast self-examination (BSE)
carcinoma
chemotherapy
duct ectasia
endocrine therapy
fibroadenomas

fibrocystic breast changes
mammography
mastitis
modified radical mastectomy
simple mastectomy

Learning Objectives

Upon completion of the chapter, you will be able to:

1. Identify the incidence, risk factors, screening methods, and treatment modalities for benign breast conditions.
2. Appraise reasons behind breast augmentation including the potential benefits and risks.
3. Outline preventive strategies for breast cancer through lifestyle changes and health screening.
4. Analyze the incidence, risk factors, treatment modalities, and nursing considerations related to breast cancer.
5. Develop an educational plan to teach BSE to a group of high-risk women.

> *Nancy hasn't been able to sleep well since she felt the lump in her left breast over a month ago, just after her 60th birthday. She knows she is at high risk because her mother died of breast cancer, but she can't bring herself to have it checked out.*

Words of Wisdom

Focus on reducing fear, anxiety, pain, and loneliness in all women diagnosed with a breast disorder.

INTRODUCTION

The breasts are modified sweat glands, lying over the pectoralis major muscles of the chest wall. Physiologically, the breast is an organ specialized for milk formation to nourish their offspring. Each breast extends approximately from the second to the sixth rib. The female breasts are closely linked to womanhood in American culture. Women's breasts act as physical markers for transitions from one stage of life to another, and although the primary function of the breasts is lactation, they are perceived as a symbol of beauty and sexuality.

This chapter discusses assessments, screening procedures, and management of specific benign and malignant breast disorders. Nurses play a key role in helping women maintain breast health by providing education and screening. A good working knowledge of early detection techniques, diagnosis, and treatment options is essential.

BENIGN BREAST DISORDERS

A benign breast disorder is any noncancerous breast abnormality. Though not life-threatening, benign disorders can cause pain and discomfort, and they account for a large number of visits to primary care providers. Fully understanding benign breast disorders should enable the nurse to appropriately evaluate symptoms, determine which breast lesions require treatment, and identify women who are at increased risk for breast cancer.

Depending on the type of benign breast disorder, treatment might or might not be necessary. Although these disorders are benign, the emotional trauma women experience is phenomenal. Fear, anxiety, disbelief, helplessness, and depression are just a few of the reactions that a woman may have when she discovers a lump in her breast. Many women believe that all lumps are cancerous, but actually more than 80% of the lumps discovered are benign and need no treatment (Alexander et al., 2014). Patience, support, and education are essential components of nursing care.

The most commonly encountered benign breast disorders in women include fibrocystic changes of the breasts, fibroadenomas, and mastitis. Although these breast disorders are considered benign, fibrocystic changes of the breasts carry a cancer risk, with prolific masses and hyperplastic changes occurring within the breasts. Generally speaking, fibroadenomas and mastitis carry little cancer risk (Seetharam & Rodrigues, 2015). Table 6.1 summarizes benign breast conditions.

Fibrocystic Breast Changes

Fibrocystic breast changes, also known as *benign breast disease* (BBD), represent a variety of changes in the glandular and structural tissues of the breast. Because this condition affects 50% to 60% of all women at some point, it is more accurately defined as a "change" rather than a "disease." Fibrocystic changes are caused by an overgrowth of fibrous tissues in the connective tissues supporting the breasts. This is frequently accompanied by the presence of fluid-filled cysts, which contribute to the lumpy feeling experienced by women. In contrast to malignant breast lesions, the cysts that develop move freely when palpated and symptoms decline after menopause when levels of estrogen and progesterone drop (Sabel, 2015). Fibrocystic changes do not increase the risk of breast cancer for most women except when the breast biopsy shows "atypia" or abnormal breast cells. The cause for concern for many women with fibrocystic changes is that breast examinations and mammography become more difficult to interpret with multiple cysts present, and early cancerous lesions may occasionally be overlooked (American Cancer Society [ACS], 2015a).

TABLE 6.1 SUMMARY OF BENIGN BREAST DISORDERS

Breast Condition	Nipple Discharge	Site	Characteristics/ Age of Client	Tenderness	Diagnosis and Treatment
Fibrocystic breast changes	+ or −	Bilateral; upper outer quadrant	Round, smooth Several lesions Cyclic, palpable 30–50 yrs old	+	Aspiration and biopsy; Limit caffeine; ibuprofen; supportive bra
Fibroadenomas	−	Unilateral; nipple area or upper outer quadrant	Round, firm, movable Palpable, rubbery Well delineated Single lesion 15–30 yrs old	−	Mammogram; "Watchful waiting" Aspiration and biopsy; Surgical excision
Mastitis	−	Unilateral; outer quadrant	Wedge shaped Warmth, redness Swelling Nipple cracked Breast engorged	+	Antibiotics; Warm shower; Supportive bra; Breast-feeding; Increase fluids

(2015a). *Non-cancerous breast conditions*. Retrieved from http://www.cancer.org/Healthy/FindCancerEarly/WomensHealth/Non-CancerousBreastConditions/non-cancerous-breast-conditions-fibrocystic-changes; and Bope, E. T., & Kellerman, R. D. (2015). *Conn's current therapy 2015*. Philadelphia, PA: Saunders Elsevier.

Fibrocystic breast changes are most common in women between the ages of 20 and 50. The condition is rare in postmenopausal women not taking hormone

replacement therapy (HRT). According to the ACS (2015a), fibrocystic breast changes affect at least half of all women at some point in their lives and are the most common breast disorder today.

Therapeutic Management

Management of the symptoms of fibrocystic breast changes begins with self-care. For some women, diet and lifestyle changes help to reduce discomfort. Other options include wearing a supportive bra, taking over-the-counter pain relievers, and limiting salt consumption which can cause fluid retention (Files, Allen, & Pruthi, 2015). In severe cases drugs, including bromocriptine, tamoxifen, or danazol, can be used to reduce the influence of estrogen on breast tissue. However, several undesirable side effects, including masculinization, have been documented. Aspiration or surgical removal of breast lumps will reduce pain and swelling by removing the space-occupying mass.

Nursing Assessment

Nursing assessment consists of a health history, physical examination, and laboratory and diagnostic tests.

HEALTH HISTORY

Ask the woman about common clinical manifestations, which include lumpy, tender breasts, particularly during the week before menses. Changes in breast tissue produce pain by nerve irritation from edema in connective tissue and by fibrosis from nerve pinching. The pain is cyclic and frequently dissipates after the onset of menses. The pain is described as a dull, aching feeling of fullness. Masses or nodularities usually appear in both breasts and are often found in the upper outer quadrants. Some women also experience spontaneous clear to yellow nipple discharge when the breast is squeezed or manipulated.

PHYSICAL EXAMINATION

It is best to examine a woman's breast a week after menses, when swelling has subsided. The breast exam is performed using the Triple Touch Method in which the health care provider uses the pads of the middle three fingers and makes dime-sized overlapping circles to feel the breast tissue with three levels of pressure: light, medium, and firm (Jarvis, 2015). Observe the breasts for fibrosis,

or thickening of the normal breast tissues, which occurs in the early stages. Cysts form in the later stages and feel like multiple, smooth, well-delineated tiny pebbles or bumpy oatmeal under the skin (Fig. 6.1). On physical examination of the breasts, a few characteristics might be helpful in differentiating a cyst from a cancerous lesion. Cancerous lesions typically are fixed and painless and may cause skin retraction (pulling). Cysts tend to be mobile and tender and do not cause skin retraction in the surrounding tissue.

LABORATORY AND DIAGNOSTIC TESTS

Mammography can be helpful in distinguishing fibrocystic changes from breast cancer. Ultrasound is a useful adjunct to mammography for breast evaluation because it helps to differentiate a cystic mass from a solid one (Dixon & Macaskill, 2015). Ultrasound produces images of the breasts by sending sound waves through a gel applied to the breasts. Fine-needle aspiration biopsy can also be done to differentiate a solid tumor, cyst, or malignancy. A fine-needle aspiration biopsy uses a thin needle guided by ultrasound to the mass. In a method called stereotactic needle biopsy, a computer maps the exact location of the mass using mammograms taken from two angles, and the map is used to guide the needle.

Nursing Management

A nurse caring for a woman with fibrocystic breast changes can teach her about the condition, provide tips for self-care (Teaching Guidelines 6.1), suggest lifestyle changes, and demonstrate how to perform monthly breast self-examination (BSE) after her menses to monitor the changes. Nursing Care Plan 6.1 presents a plan of care for a woman with fibrocystic breast changes.

Teaching Guidelines 6.1

RELIEVING SYMPTOMS OF FIBROCYSTIC BREAST CHANGES

• Wear an extra-supportive bra to prevent undue strain on the ligaments of the breasts to reduce discomfort.

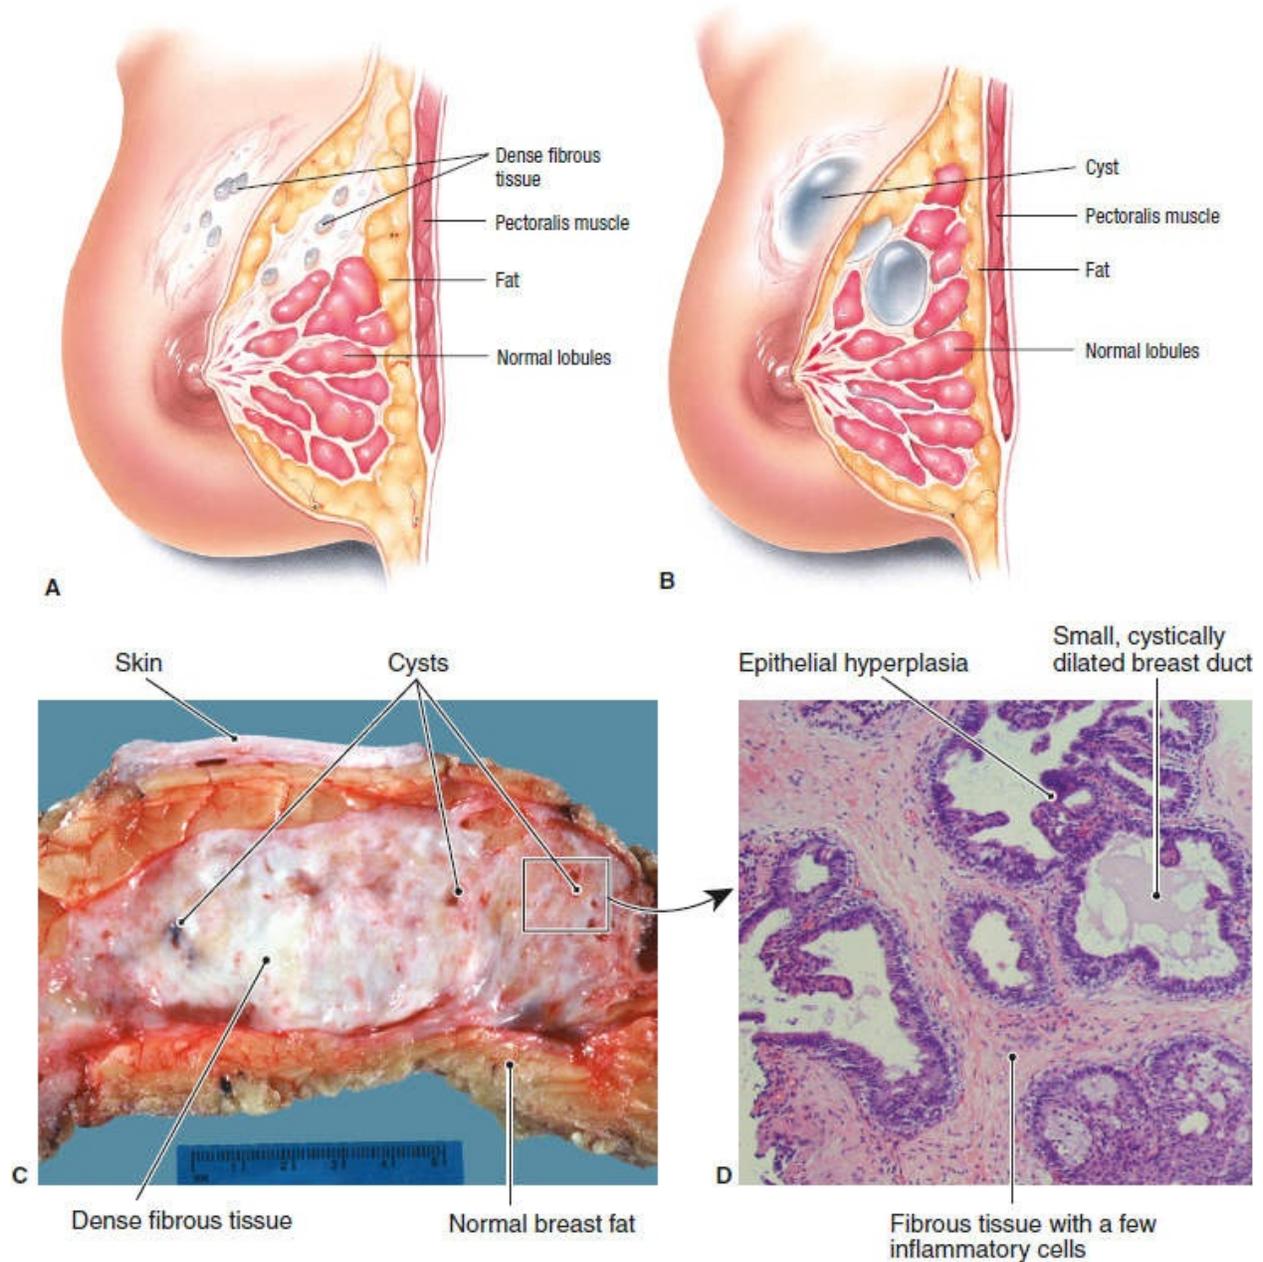
- Take oral contraceptives, as recommended by a health care practitioner, to stabilize the monthly hormonal levels.
- Eat a low-fat diet rich in fruits, vegetables, and grains to maintain a healthy nutritional lifestyle and ideal weight.
- Apply heat to the breasts to help reduce pain via vasodilation of vessels.
- Take diuretics, as recommended by a health care practitioner, to counteract fluid retention and swelling of the breasts.
- Reduce salt intake to reduce fluid retention and swelling in the breasts.
- Take over-the-counter medications, such as acetylsalicylic acid (Aspirin) or ibuprofen (Motrin, Advil, Nuprin), to reduce inflammation and discomfort.
- Use thiamine and vitamin E therapy. This has been found helpful for some women, but research has failed to demonstrate a direct benefit from either therapy.
- Take medications as prescribed (e.g., bromocriptine, tamoxifen, or danazol).
- Discuss the possibility of aspiration or surgical removal of breast lumps with a health care practitioner.
- Avoid caffeinated drinks (coffee, tea, soda) which tend to trigger breast discomfort.


FIGURE 6.1 A. Fibrocystic breast changes. **B.** Breast cysts. **C.** This gross study shows that most of the abnormal tissue is fibrous. Cysts are relatively inconspicuous in this example. **D.** The microscopic study shows dense fibrous tissue containing dilated ducts lined by hyperplastic epithelium. [2014]. *The Nature of Disease Pathology for the Health Professions*, 2nd edition. Philadelphia, PA: Lippincott Williams & Wilkins.)

NURSING CARE PLAN 6.1

Overview of the Woman with Fibrocystic Breast Changes

Sheree Rollins is a 37-year-old woman who comes to the clinic for her routine checkup. During the examination, she says, "Sometimes my breasts feel so heavy and they ache a lot. I noticed a couple of lumpy areas in my breast last week just before I got my period. Is this normal? Now they feel like they're almost gone. Should I be worried?" Clinical breast examination reveals two small (pea-sized), mobile, slightly tender nodules in each breast bilaterally. No skin retraction noted. Previous mammogram revealed fibrocystic breast changes.

NURSING DIAGNOSIS: Pain related to changes in breast tissue

Outcome Identification and Evaluation
The client will demonstrate a decrease in breast pain as evidenced by a pain rating of 1 or 2 on a pain rating scale of 0 to 10 and statements that pain is lessened.

Interventions: *Relieving Pain*
• Ask client to rate her pain using a numeric pain rating scale to establish a baseline.
• Discuss with client any measures used to relieve pain to determine effectiveness of the measures.
• Encourage use of a supportive bra to aid in reducing discomfort.
• Instruct client in use of over-the-counter analgesics to promote pain relief.
• Advise the client to apply warm compresses or allow warm water from the shower to flow over her breasts to promote vasodilation and subsequent pain relief.
• Tell client to reduce her intake of salt to reduce risk of fluid retention and swelling leading to increased pain.

NURSING DIAGNOSIS: Deficient knowledge related to fibrocystic breast changes and appropriate care measures

Outcome Identification and Evaluation
The client will verbalize understanding of condition as evidenced by statements about the cause of breast changes and appropriate choices for lifestyle changes, and demonstration of self-care measures.

Interventions: *Providing Client Education*
• Assess client's knowledge of fibrocystic breast changes to establish a baseline for teaching.
• Explain the role of monthly hormonal level changes and describe the signs and symptoms to promote understanding of this condition.
• Teach the client how to perform breast self-examination after her menstrual period to monitor for changes.
• Encourage client to report any changes promptly to ensure early detection of problems.
• Suggest client speak with her primary care provider about the use of oral contraceptives to help stabilize monthly hormonal levels.
• Review lifestyle choices, such as eating a low-fat diet rich in fruits, vegetables, and grains, and adhering to screening recommendations to promote health.
• Discuss measures for pain relief to minimize discomfort associated with breast changes.

Fibroadenomas

Fibroadenomas are common benign solid breast tumors that occur in about 25% of all women and account for up to half of all breast biopsies. They are the most common mass in women aged 15 to 25 years (Seetharam & Rodrigues, 2015). They are considered hyperplastic lesions associated with an aberration of normal development and involution rather than a neoplasm. Fibroadenomas can be stimulated by external estrogen, progesterone, lactation, and pregnancy (Schuiling & Likis, 2016). They are composed of both fibrous and glandular tissue that feels round or oval, firm, rubbery and smooth, and is mobile and may be tender. They are usually unilateral, but may present in both breasts (Alexander et al., 2014). Giant fibroadenomas account for approximately 4% of cases. These masses are frequently larger than 5 cm and occur most often in pregnant or lactating women. These large lesions may regress in size once hormonal stimulation subsides (Janardhan, Venkateshwar, & Rao, 2015). Fibroadenomas are rarely associated with cancer.

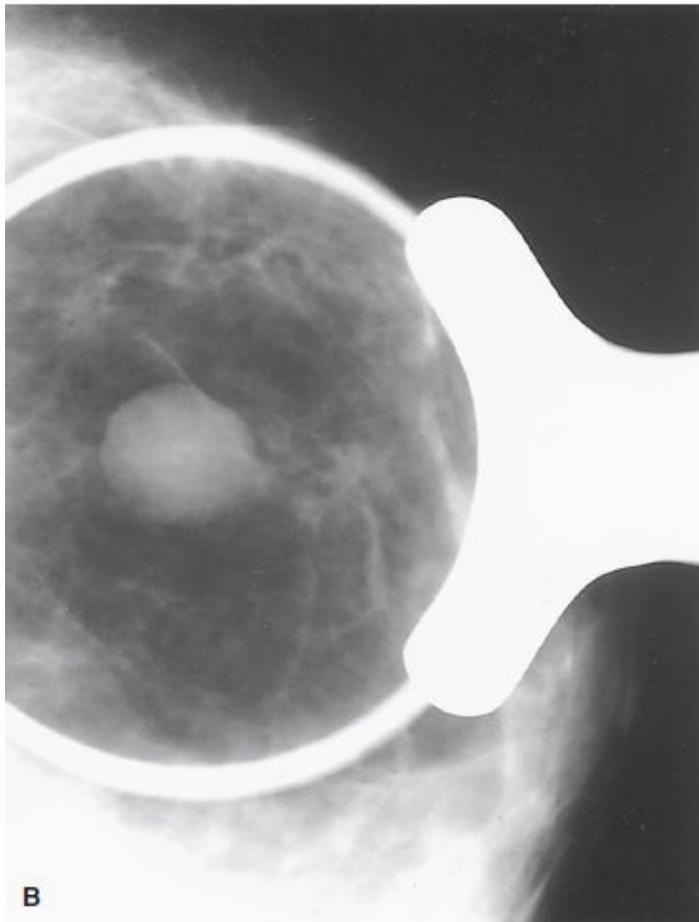
A

B


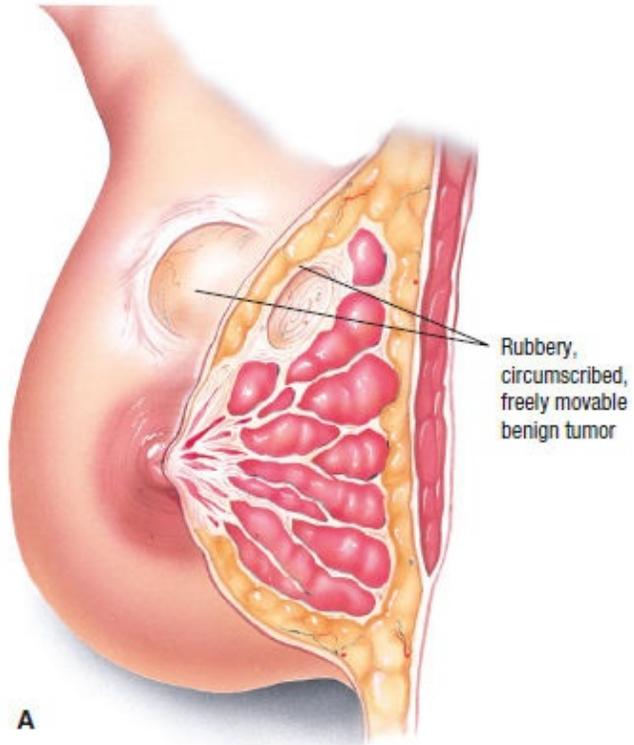


FIGURE 6.2 A. Fibroadenoma. (Asset provided by Anatomical Chart Co.) **B.** Spot compression view of a smoothly marinated mass proven to represent a fibroadenoma. Ultrasonography demonstrated a solid mass.

Therapeutic Management

Treatment may include a period of "watchful waiting" because many fibroadenomas stop growing or shrink on their own without any treatment. Other growths may need to be surgically removed if they do not regress or if they remain unchanged. Cryoablation, an alternative to surgery, can also be used to remove a tumor. In this procedure, extremely cold gas is piped into the tumor using ultrasound guidance. The tumor freezes and dies. The current trend is toward a more conservative approach to treatment after careful evaluation and continued monitoring.

Nursing Assessment

Ask the woman about clinical manifestations of fibroadenomas. These lumps are felt as firm, rubbery, well-circumscribed, freely mobile nodules that might or might not be tender when palpated.

Breast fibroadenomas are usually detected incidentally during clinical or self-examinations and are usually located in the upper outer quadrant of the breast; more than one may be present (Fig. 6.2). Several other breast lesions have similar characteristics, so every woman with a breast mass should be evaluated to exclude cancer. A clinical breast examination by a health care provider is critical. In addition, diagnostic studies include imaging studies (mammography, ultrasound, or both) and some form of biopsy, most often a fine-needle aspiration, core needle biopsy, or stereotactic needle biopsy. The core needle biopsy removes a small cylinder of tissue from the breast mass, more than the fine-needle aspiration biopsy. If additional tissue needs to be evaluated, the advanced breast biopsy instrument (ABBI) is used. This instrument removes a larger cylinder of tissue for examination by using a rotating circular knife. The ABBI procedure removes more tissue than any of the other methods except a surgical biopsy (ACS, 2015a).

Nursing Management

The nurse should urge the client to return for reevaluation in 6 months, perform monthly BSEs, and return annually for a clinical breast examination. Recent

studies suggest that women with high breast density and proliferative benign breast disease are at very high risk for future breast cancer. Women with low breast density are at low risk, regardless of their benign pathologic diagnosis (Slanetz, Freer, & Birdwell, 2015). This is all the more reason for women to have close monitoring over time.

Mastitis

Mastitis is an infection or inflammation of the connective tissue in the breast that occurs primarily in lactating or engorged women. The prevalence of it in breast-feeding women may be as high as 33% (Faguy, 2015). Mastitis is divided into lactational or nonlactational types. The usual causative organisms for lactational mastitis are *Staphylococcus aureus, Hemophilus influenzae,* and hemophilus and streptococcus species, the source of which is the baby's flora. Lactating mastitis typically occurs in the first two to three weeks of lactation, but can occur at any stage of lactation. One or more of the ducts drain poorly or become blocked, resulting in bacterial growth in the retained milk (Pluchinotta, 2015). The only evidence-based predisposing factor that may lead to mastitis is the development of milk stasis. However, other associated factors include damaged or cracked nipples, especially those colonized with *Staphylococcus aureus*; irregular or missed feedings; failing to allow the infant to empty one breast completely before moving on to the next breast; poor latch and transfer of milk; illness of mother or infant; oversupply; a tight bra; blocked nipple pore or duct; being primiparous women; and maternal stress and fatigue (Miller & Kennedy, 2015).

Nonlactational mastitis can be caused by duct ectasia, which occurs when the milk ducts become congested with secretions and debris, resulting in periductal inflammation. It may be divided into central (periareolar) and peripheral breast lesions. Periareolar infections consist of active inflammation around nondilated subareolar breast ducts—a condition termed periductal mastitis. Peripheral nonlactating breast abscesses are less common than periareolar abscesses and are often associated with an underlying condition such as diabetes, rheumatoid arthritis, steroid treatment, granulomatous lobular mastitis, and trauma (Faguy, 2015). Women with these types of abscesses present with greenish nipple discharge, nipple retraction, and noncyclical pain.

Therapeutic Management

Effective milk removal, pain medication, and antibiotic therapy have been the mainstays of treatment. Management of both types of mastitis involves the use of oral antibiotics (usually a penicillinase-resistant penicillin or cephalosporin), warm compresses to the inflamed area of the breast, continued breast-feeding, and acetaminophen (Tylenol) for pain and fever (King et al., 2015).

Nursing Assessment

Assess the client's health history for risk factors for mastitis, which include poor hand hygiene ductal abnormalities, nipple cracks and fissures, lowered maternal defenses due to fatigue, tight clothing, poor support of pendulous breasts, failure to empty the breasts properly while breast-feeding, or missing breast-feedings.

The diagnosis of mastitis is made clinically on the basis of a localized, unilateral area of erythema with associated fever. Assess the client for clinical manifestations of mastitis, which include flu-like symptoms of malaise, nausea, headache, leukocytosis, fever, fatigue, and chills. Physical examination of the breasts reveals increased warmth, swollen area of one breast, redness, tenderness, and swelling. The nipple is usually cracked or abraded and the breast is distended with milk (Fig. 6.3). In a lactating woman, severe engorgement can be differentiated from mastitis because engorgement is bilateral with general involvement of the whole breast. Ultrasound scans can be undertaken to differentiate between the types of mastitis or abscesses, but typically the diagnosis is made based on history and examination.

FIGURE 6.3 Mastitis. (From Sweet, R. L., & Gibbs, R. S. [2009]. *Infectious diseases of the female genital tract*. Philadelphia, PA: Lippincott Williams & Wilkins.)

Nursing Management

Teach the woman about the etiology of mastitis and encourage her to continue to breast-feed, emphasizing that it is safe for her infant to do so. Stress to all breast-feeding mothers to check for medication safety before taking it. Drugs administered to mothers can accumulate in the bodies of their infants and can

alter infant's bowel flora, causing diarrhea. Mothers should be warned about this to reduce their anxiety. Once it has been declared safe to do so, the nurse should urge them to take the medication as prescribed until completed. Continued emptying of the breast or pumping improves the outcome, decreases the duration of symptoms, and decreases the incidence of breast abscess. Thus, continued breast-feeding is recommended in the presence of mastitis (King et al., 2015).

Although 80% of breast biopsy results prove to be benign, increased surveillance is necessary because of the risk of cancer development. The recommended follow-up schedule is imaging (mammography or ultrasound) and a clinical breast exam by a surgeon at 6, 12, and 24 months after a benign breast biopsy finding (Tharpe, Farley, & Jordan, 2016). Instructions for the woman with mastitis are detailed in Teaching Guidelines 6.2.

Teaching Guidelines 6.2

CARING FOR MASTITIS

- Take medications as prescribed to reduce inflammation and infection.
- Continue breast-feeding, as tolerated to keep the milk flowing.
- Begin feeding on most affected breast to allow it to be emptied first.
- Massage the breasts before and during breast-feeding to encourage milk extraction.
- Wear a supportive bra 24 hours a day to support the breasts for comfort.
- Increase fluid intake to stay hydrated.
- Gentle massage toward nipple several times daily.
- Vary the infants breast-feeding position – cradle, side-lying, football and belly to belly
- Make sure infant is positioned correctly on the nipple to prevent discomfort.
- Practice good hand hygiene techniques to reduce risk of bacterial transfer.
- Apply warm compresses to the affected breast or take a warm shower before breast-feeding.
- Frequently change positions while nursing to improve milk flow.

- Get adequate rest and nutrition to support or improve the immune system.
- Instruct to contact their health care provider if fever returns, chills, or worsening symptoms.

MALIGNANT BREAST DISORDER

Breast cancer is a neoplastic disease in which normal body cells are transformed into malignant ones (National Cancer Institute ([NCI], 2015a). It is the most common cancer in women and the second leading cause of cancer deaths (lung cancer is first) among American women. Breast cancer accounts for one of every three cancers diagnosed in the United States (ACS, 2015a). A new case is discovered every 2 minutes. It is estimated that 1 out of every 8 women will develop the disease at some time during her life, and the mortality rate of those with breast cancer is 1 in 36 (NCI, 2015a).

Over 200,000 cases of invasive breast cancer are diagnosed in the United States each year (ACS, 2015a). Breast cancer can also affect men, but only 1% of all individuals diagnosed with breast cancer annually are men. About 2000 men are diagnosed with breast cancer annually, with about a 1 in 4 mortality rate (Khan, Allerton, & Petitt, 2015). Because men are not routinely screened for breast cancer, the diagnosis is often delayed. The most common clinical manifestation of male breast cancer is a painless, firm, subareolar breast mass. Any suspicious breast mass in a male should undergo diagnostic biopsy. If a malignancy is diagnosed, typical treatment is mastectomy with assessment of the axillary nodes.

 Consider This

It was pouring down rain and I was driving alone along dark wet streets to my 8 AM appointment for a breast ultrasound. I recently had my annual mammogram and the radiologist thought he saw something suspicious on my right breast. I was on my way to confirm or refute his suspicions, and I couldn't keep focused on the road ahead. For the past few days I had been a basket case, fearing the worst. I was playing in my mind, what I would do if…? What changes would I make in my life and how would I react when told? I have been through such personal turmoil since that doctor announced he wanted "more tests."

> **Thoughts**: *This woman is worrying and is emotionally devastated before she even has a conclusive diagnosis. Is this a typical reaction to a breast disorder? Why do women fear the worst? Many women use denial to mask their feelings and hope against hope the doctor made a mistake or misread their mammogram. How would you react if you or your sister, girlfriend, or mother were confronted with a breast disorder?*

The cause of breast cancer, while not well understood, is thought to be a complex interaction between environmental, genetic, and hormonal factors. Breast cancer is a progressive rather than a systemic disease, meaning that most cancers grow from small size with low metastatic potential to larger size and greater metastatic potential. Tumor stage, size, and lymph node involvement are major predictors of metastatic potential (Arora et al., 2015).

Pathophysiology

Cancer is not just one disease, but rather a group of diseases that result from unregulated cell growth. Without regulation, cells divide and grow uncontrollably until they eventually form a tumor. Extensive research has determined that all cancer is the result of changes in DNA or chromosome structure that cause the mutation of specific genes. Most genetic mutations that cause cancer are acquired sporadically, which means they occur by chance and are not necessarily due to inherited mutations (Shannon & Chittenden, 2015). Cancer development is thought to be clonal in nature, which means that each cell is derived from another cell. If one cell develops a mutation, any daughter cell derived from that cell will have that same mutation, and this process continues until a malignant tumor forms.

Breast cancer starts in the epithelial cells that line the mammary ducts within the breast. The growth rate depends on hormonal influences, mainly estrogen and progesterone. The two major categories of breast cancer are noninvasive and invasive. Noninvasive, or in situ, breast cancers are those that have not extended beyond their duct, lobule, or point of origin into the surrounding breast tissue. Conversely, invasive (infiltrating) breast cancers have extended into the surrounding breast tissue, with the potential to metastasize. Many researchers believe that most invasive cancers probably originate as noninvasive cancers (Cuzick & Thorat, 2015).

Breast cancer is considered to be a highly variable disease. While the process of metastasis is a complex and poorly understood phenomenon, there is evidence to suggest that new vascularization of the tumor plays an important role in the biologic aggressiveness of breast cancer (Toi et al., 2015). Breast cancer metastasizes widely and to almost all organs of the body, but primarily to the bone, lungs, lymph nodes, liver, and brain. The first sites of metastases are usually local or regional, involving the chest wall or axillary supraclavicular lymph nodes or bone (ACS, 2015a).

Invasive Ductal Carcinoma

By far the most common breast cancer is invasive ductal carcinoma, which represents 85% of all cases (ACS, 2015c). Carcinoma is a malignant tumor that occurs in epithelial tissue; it tends to infiltrate and give rise to metastases. The

incidence of this cancer peaks in the sixth decade of life (>60 years old). It spreads rapidly to axillary and other lymph nodes, even while small. Infiltrating ductal carcinoma may take various histologic forms—well differentiated and slow growing, poorly differentiated and infiltrating, or highly malignant and undifferentiated with numerous metastases. This common type of breast cancer starts in the ducts, breaks through the duct wall, and invades the fatty breast tissue. This type of cancer accounts for 75% of all breast cancers (Stopeck, Chalasani, & Thompson, 2015).

Invasive Lobular Carcinoma

Invasive lobular carcinomas, which originate in the terminal lobular units of breast ducts, account for 10% of all cases of breast cancer. The peak incidence is in women aged 40 to 50 years old. It presents as an area of ill-defined thickening rather than a palpable mass. The tumor is frequently located in the upper outer quadrant of the breast, and by the time it is discovered the prognosis is usually poor (Selvi, 2015).

Other Invasive Carcinomas

Other invasive types of cancer include tubular carcinoma (29%), which is fairly uncommon and typically occurs in women aged 55 and older. Colloid carcinoma (2% to 4%) occurs in women 60 to 70 years of age and is characterized by the presence of large pools of mucus interspersed with small islands of tumor cells. Medullary carcinoma accounts for 5% to 7% of malignant breast tumors; it occurs frequently in younger women (<50 years of age) and grows into large tumor masses. Inflammatory breast cancer (<4%) often presents with skin edema, redness, and warmth and is associated with a poor prognosis. Paget's disease (2% to 4%) originates in the nipple and typically occurs with invasive ductal carcinoma (Bope & Kellerman, 2015).

Staging of Breast Cancer

Breast cancers are classified into three stages based on:

1. Tumor size

2. Extent of lymph node involvement

3. Evidence of metastasis

The purposes of tumor staging are to determine the probability that the tumor has metastasized, to decide on an appropriate course of therapy, and to assess the client's prognosis. Table 6.2 gives details and characteristics of each stage (also Fig. 6.4). The overall 10-year survival rate for a woman with stage I breast cancer is 80% to 90%; for a woman with stage II, it is about 50%. The outlook is not as good for women with stage III or IV disease (Alexander et al., 2014).

TABLE 6.2 STAGING OF BREAST CANCER

Stage	Characteristics
0	In situ, early type of breast cancer
I	Localized tumor <1 inch in diameter
II	Tumor 1–2 inches in diameter; spread to axillary lymph nodes
III	Tumor 2 inches or larger; spread to other lymph nodes and tissues
IV	Cancer has metastasized to other body organs

Adapted from American Cancer Society [ACS]. (2015h). *How is breast cancer staged?* Retrieved from http://www.cancer.org/Cancer/BreastCancer/DetailedGuide/breast-cancer-staging.

There is no completely accurate way to know whether the cancer has micrometastasized to distant organs, but certain tests can help determine if the cancer has spread. A bone scan can be performed to assess the bones. Magnetic resonance imaging (MRI) can be used to detect metastases to the liver,

abdominal cavity, lungs, or brain.

Risk Factors

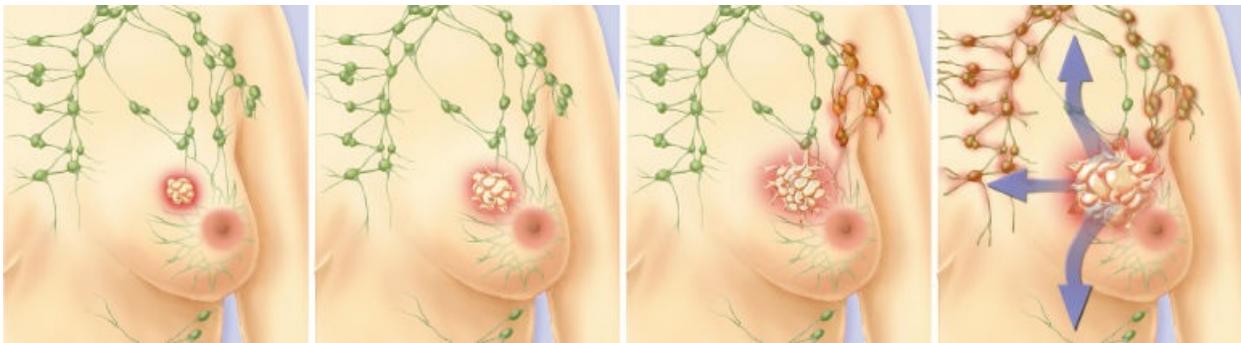
An estimated 80% of women in whom breast cancer develops have no documented risk factors (Bope & Kellerman, 2015). Breast cancer is thought to develop in response to a number of related factors: aging; gender (99% of cases occur in women, delayed childbearing or never bearing children, genetic influences); BRCA1 and BRCA2 genetic mutations; history of receiving ionizing radiation; high breast density; postmenopausal obesity; family history of cancer; hormonal factors such as early menarche <12 years, late menopause >50 years, first term pregnancy >30 to 35 years of age; HRT with estrogen plus progestin; and ingestion of two drinks or more alcohol each day (ACS, 2015b). Other factors might contribute to breast cancer but have not been scientifically proven.


FIGURE 6.4 Stages I to IV of breast cancer.

In 1970, the lifetime risk for developing breast cancer was 1 in 10; since then, the risk has gradually risen (NCI, 2015b). This slight increase in incidence might be explained in a variety of ways: better detection and screening tools are available, which have identified more cases; women are living to an older age, when their risk increases; and lifestyle changes in American women (having their first pregnancy at an older age, having fewer children, and using hormonal therapy to treat the symptoms of menopause) might have produced the higher numbers. Age is a significant risk factor. Because rates of breast cancer increase with age, estimates of risk at specific ages are more meaningful than estimates of lifetime risk. The estimated chances of a woman being diagnosed with breast cancer between the ages of 30 and 70 are detailed in Table 6.3.

Risk factors for breast cancer can be divided into those that cannot be changed

(nonmodifiable risk factors) and those that can be changed (modifiable risk factors). Nonmodifiable risk factors (ACS, 2015b) are:

• Gender (female)

• Aging (>50 years old)

• Genetic mutations (BRCA1 and BRCA2 genes)

• Personal history of ovarian or colon cancer

• Increased breast density increases the risk three- to fivefold

• Family history of breast cancer

• Personal history of breast cancer (three- to fourfold increase in risk for recurrence)

• Race/Ethnicity (higher in White women, but African-American women are more likely to die of it)

• Previous abnormal breast biopsy (atypical hyperplasia)

• Exposure to chest radiation (radiation damages DNA)

• Previous breast radiation (12 times normal risk)

• Early menarche (<12 years old) or late onset of menopause (>55 years old), which represents increased estrogen exposure over the lifetime

• Modifiable risk factors related to lifestyle choices (ACS, 2015b) include:

• Not having children at all or not having children until after age 30—this increases the risk of breast cancer by not reducing the number of menstrual cycles

• Postmenopausal use of estrogens and progestins—the Women's Health Initiative study (2002) reported increased risks with long-term (>5 years) use of HRT

• Failing to breast-feed for up to a year after pregnancy—increases the risk of breast cancer because it does not reduce the total number of lifetime menstrual cycles

• Alcohol consumption—boosts the level of estrogen in the bloodstream

• Smoking—exposure to carcinogenic agents found in cigarettes

• Obesity and consumption of high-fat diet—fat cells produce and store estrogen, so more fat cells create higher estrogen levels

• Sedentary lifestyle and lack of physical exercise—increases body fat, which

houses estrogen

TABLE 6.3 ESTIMATED RISK OF BREAST CANCER AT SPECIFIC AGES

Ages 30–39	1 out of 233
Ages 40–49	1 out of 69
Ages 50–59	1 out of 42
Ages 60–69	1 out of 29

Adapted from American Cancer Society [ACS]. (2015i). *How many women get breast cancer?* Retrieved from http://www.cancer.org/cancer/breastcancer/overviewguide/breast-cancer-overview-key-statistics.

Breast cancer incidence rates are higher in non-Hispanic White women compared with African-American women for most age groups. However, African-American women have a higher incidence rate before 40 years of age and are more likely to die from breast cancer at every age (ACS, 2015b). Some of that gap is because of social factors such as poverty and restricted access to health care. Some studies have also found genetic differences in the type of breast cancer that develops in African-American and White women. Little is known, however, about whether other risk factors have a different impact in women of different races. A new study's findings suggest that the risk factors are similar in both races (ACS, 2015b).

The presence of risk factors, especially several of them, calls for careful ongoing monitoring and evaluation to promote early detection. Even though risk factors are important considerations, many women with newly diagnosed breast cancer have no known risk factors. Although routine mammography and self-examination are prudent for high-risk women, these precautions may become lifesavers for early detection of cancerous lesions.

Consuming a low-fat diet with plenty of fruits, vegetables, legumes, and whole grains can provide all the vitamins and nutrients our bodies need and has been shown to significantly reduce the risk of developing many types of cancer. A plant-based diet can also reduce cancer recurrence: high-fiber, low-fat diets rich in fruits and vegetables, avoiding sugared beverages and calorie dense

foods, and processed meats reduces breast cancer recurrence (Catsburg et al., 2015). They studied the effectiveness of a high-vegetable, low-fat diet, aimed at markedly raising circulating carotenoid concentrations from food sources, in reducing additional breast cancer events and early death in women with early-stage invasive breast cancer. It is a prescription for cancer prevention that has only positive side effects—lower cholesterol, weight loss, and a lower risk of heart disease. Adherence to a plant-based diet that limits red meat intake may be associated with reduced risk of breast cancer, particularly in postmenopausal women (Catsburg et al., 2015).

Screening for breast cancer begins with a routine history and physical exam. Nurses should take every opportunity to educate and emphasize the goal of breast cancer screening: early detection reduces mortality. Screening also includes a BSE, clinical breast exam, and mammography.

Diagnosis

Many studies can be performed to make an accurate diagnosis of a malignant breast lump. Diagnostic tests include:

• Diagnostic mammography or digital mammography

• Magnetic resonance mammography (MRM)

• Fine-needle aspiration

• Stereotactic needle-guided biopsy

• Sentinel lymph node biopsy

• Hormone receptor status

• Infrared thermal imaging

• DNA ploidy status

• Cell proliferative indices

• HER-2/neu genetic marker (Han et al., 2015)

Mammography

Mammography has become an accepted screening procedure that is sanctioned by most cancer organizations and is paid for annually by most health insurance agencies. Mammography serves a twofold purpose: to screen and to diagnose. Mammography involves taking x-ray pictures of a bare breast while it is compressed between two plastic plates. This procedure is a screening tool used to identify and characterize a breast mass and to detect an early malignancy. It remains the gold standard screening method for women at average risk for breast cancer. It is relatively inexpensive, requires only a low dose of radiation, and reliably identifies malignant tumors, especially those that are too small to feel. It can also be used to investigate breast lumps and other symptoms. A screening mammogram typically consists of four views, two per breast (Fig. 6.5). It can detect lesions as small as 0.5 cm (the average size of a tumor detected by a woman practicing occasional BSE is approximately 2.5 cm) (Rifkin & Lazris, 2015).

A diagnostic mammogram is performed when a woman has suspicious clinical findings on a breast examination or an abnormality has been found on a screening mammogram. A diagnostic mammogram uses additional views of the

affected breast as well as magnification views. Diagnostic mammography provides the radiologist with additional detail to render a more specific diagnosis. Currently, digital mammography is being used to diagnose breast lesions.

FIGURE 6.5 Mammography. **A.** A top-to-bottom view of the breast. **B.** A side view of the breast.

Most women find the 10-minute mammography procedure uncomfortable but not painful. Teaching Guidelines 6.3 offers tips for a client to follow before she undergoes this procedure.

Teaching Guidelines 6.3

PREPARING FOR A SCREENING MAMMOGRAM

- Schedule the procedure just after menses, when breasts are less tender.
- Do not use deodorant or powder on the day of the procedure, because they can appear on the x-ray film as calcium spots.
- Acetaminophen (Tylenol) or acetylsalicylic acid (aspirin) can relieve any discomfort after the procedure.
- Remove all jewelry from around your neck, because the metal can cause distortions on the film image.
- Select a facility that is accredited by the American College of Radiology to ensure appropriate credentialed staff.

The U.S. Preventive Services Task Force (USPSTF) changed its recommendations for breast cancer screening in 2009, resulting in considerable controversy. The USPSTF now recommends biennial screening mammography for women aged 50 to 74 years. Previously, women 40 years and older were advised to start screening mammography. They stated that the decision to start regular, biennial screening mammography before the age of 50 years should be an individual one and take client context into account, including the client's values regarding specific benefits and harms. In addition, the USPSTF concluded that the current evidence is insufficient to assess the additional benefits and harms of screening mammography in women 75 years or older. Finally, the USPSTF recommended against teaching BSE because scientific evidence does not support this practice as a valid screening method for women since its sensitivity ranges from 12% to 41%, lower than that of the clinical breast exam done by a health care provider and mammography, and it is age-dependent. The USPSTF is currently updating their breast cancer screening recommendation guidelines and may return to every 1 to 2 years for women age 40 or older for diagnostic mammograms (USPSTF, 2015).

The American Cancer Society (ACS) has different guidelines for women with no symptoms or family history of breast cancer than the USPSTF. They still recommend annual mammograms and clinical breast exams for women starting at age 40 and do not recommend stopping them at any age. They also recommend a clinical breast exam about every three years for women in their 20s and 30s and every year for women >40. BSE is an option for women starting in their 20s (ACS, 2015d).

The American Congress of Obstetricians and Gynecologists (ACOG) recommends that mammography screening be offered annually to women beginning at age 40. Previous ACOG guidelines recommended mammograms every 1 to 2 years starting at age 40 and annually beginning at age 50. ACOG continues to recommend annual clinical breast exams (CBEs) for women aged 40 and older, and every 1 to 3 years for women aged 20 to 39. Additionally, it encourages breast self-awareness for women ages 20 and older (ACOG, 2015).

This conflicting information can be confusing to women trying to make decisions about breast cancer screening. Nurses can present the latest evidence-based research to help women make informed decisions based on their age, overall health status, and family history of cancer. (See Table 6.4 for a helpful outline.) There really isn't any clear direction given to women by the authoritative agencies; they in essence leave the decision up to the woman and her health care provider. The associated risk is delay in detecting a breast lesion early when it could be treated and her life saved.

Magnetic Resonance Mammography

MRM is a relatively new procedure that might allow for earlier detection because it can detect smaller lesions and provide finer detail. MRM is a highly accurate (>90% sensitivity for invasive carcinoma) but costly tool. Contrast infusion is used to evaluate the rate at which the dye initially enters the breast tissue. The basis of the high sensitivity of MRM is the tumor angiogenesis (vessel growth) that accompanies a majority of breast cancers, even early ones. Malignant lesions tend to exhibit increased enhancement within the first 2 minutes (Bhatti et al. 2015). Currently MRM is used as a complement to mammography and CBE because it is expensive, but recent research findings report that it is more accurate than mammography for size assessment of breast lesions (Poulos, 2015).

TABLE 6.4 SCREENING RECOMMENDATIONS FROM USPSTF, ACS, AND ACOG

The U.S. Preventive Services Task Force	In 2009, the USPSTF changed its recommendations for breast cancer screening for women with no symptoms or no family history of breast cancer. Previously they advised screening mammography for women aged 40 years and older. Updated recommendations include biennial screening mammography for women aged 50 to 74 years, and no breast self-examination (BSE) since scientific evidence does not support this practice as a valid screening method for women because its sensitivity ranges from 12% to 41%, which is lower than that of the clinical breast exam done by a health professional and mammography, and it is age dependent. The previous recommendations are now under review (2015). The USPSTF states that a woman's decision to start regular, biennial screening mammography before the age of 50 years should be an individual one and take client context into account, including the client's values regarding specific benefits and harms. The USPSTF also reports that current evidence is insufficient to assess the additional benefits and harmful aspects of screening mammography in women 75 years or older (USPSTF, 2015).
The American Cancer Society	Guidelines from the ACS differ from those of the USPSTF for women with no symptoms or no family history of breast cancer. The ACS still recommends annual mammograms and clinical breast exams for women starting at age 40 and do not recommend stopping them at any age. They suggest that BSEs can be optional for women from age 20 onward (ACS, 2015d).
The American Congress of Obstetricians and Gynecologists	The ACOG recommends screening mammograms be offered annually to women beginning at age 40. Previous guidelines recommended a mammogram every 1 to 2 years starting at age 40 and annually beginning at age 50. Clinical breast exams are still recommended every year, but BSEs are optional and not strongly recommended (ACOG, 2015).

Fine-Needle Aspiration Biopsy or Core Biopsy

Fine-needle aspiration biopsy is done to identify a solid tumor, cyst, or malignancy. It is a simple office procedure that can be performed with or without anesthesia. A small (23 to 27-gauge) needle connected to a 10-mL or larger syringe is inserted into the breast mass and suction is applied to withdraw the contents. The aspirate is then sent to the cytology laboratory to be evaluated for abnormal cells.

A core needle biopsy is much like a fine needle biopsy except that a larger needle is used to withdraw small cylinders or cores of tissue from the abnormal area of the breast. It takes longer than the fine needle biopsy, but more tissue is sampled to be tested.

Stereotactic Needle-Guided Biopsy

This diagnostic tool is used to target and identify mammographically detected nonpalpable lesions in the breast. This procedure is less expensive than an excisional biopsy. The procedure takes place in a specially equipped room and generally takes about an hour. Women are required to lie prone and must be able to remain still for approximately 20 minutes while the biopsy is taken. When proper placement of the breast mass is confirmed by digital mammograms, the breast is locally anesthetized and a spring-loaded biopsy gun is used to obtain

two or three core biopsy tissue samples. After the procedure is finished, the biopsy area is cleaned and a sterile dressing is applied.

Sentinel Lymph Node Biopsy

The status of the axillary lymph nodes is an important prognostic indicator in early-stage breast cancer. The presence or absence of malignant cells in lymph nodes is highly significant: the more lymph nodes involved and the more aggressive the cancer, the more powerful chemotherapy will have to be, both in terms of the toxicity of drugs and the duration of treatment (Tsujimoto, 2015). With a sentinel lymph node biopsy, the clinician can determine whether breast cancer has spread to the axillary lymph nodes without having to do a traditional axillary lymph node dissection. Experience has shown that the lymph ducts of the breast typically drain to one lymph node first before draining through the rest of the lymph nodes under the arm. The first lymph node is called the sentinel lymph node.

This procedure can be performed under local anesthesia. A radioactive blue dye is injected 2 hours before the biopsy to identify the afferent sentinel lymph node. The surgeon usually removes one to three nodes and sends them to the pathologist to determine whether cancer cells are present. The sentinel lymph node biopsy is usually performed before a lumpectomy to make sure the cancer has not spread. Removing only the sentinel lymph node can allow women with breast cancer to avoid many of the side effects (lymphedema) associated with a traditional axillary lymph node dissection. This procedure is associated with less morbidity compared to the axillary lymph node dissection, which results in more accurate staging, better axillary tumor control and improved survival. It is considered a standard of care for initial evaluation of metastatic spread to the axillary lymph node chain (Chatterjee, Serniak, & Czerniecki, 2015).

Hormone Receptor Status

Normal breast epithelium has hormone receptors and responds specifically to the stimulatory effects of estrogen and progesterone. Most breast cancers retain estrogen receptors, and for those tumors estrogen will retain proliferative control over the malignant cells. It is therefore, useful to know the hormone receptor status of the cancer to predict which women will respond to hormone manipulation. Hormone receptor status reveals whether the tumor is stimulated to grow by estrogen and progesterone. Postmenopausal women tend to be ER+;

premenopausal women tend to be ER− (Kalinsky et al., 2015). To determine hormone receptor status, a sample of breast cancer tissue obtained during a biopsy or a tumor removed surgically during a lumpectomy or mastectomy is examined by a cytologist.

Therapeutic Management

Women diagnosed with breast cancer have many treatments available to them. Generally, treatments fall into two categories: local and systemic. Local treatments are surgery and radiation therapy. Effective systemic treatments include chemotherapy, hormonal therapy, and immunotherapy (Evidence-Based Practice 6.1).

Treatment plans are based on multiple factors, with the primary factors being whether the cancer is invasive or noninvasive, the tumor's size and grade, the number of cancerous axillary lymph nodes, the hormone receptor status, and the ability to obtain clear surgical margins (ACS, 2015e). A combination of surgical options and adjunctive therapy is often recommended.

Another consideration in making decisions about a treatment plan is genetic testing for BRCA1 and BRCA2 genetic mutations. This genetic testing became available in 1995 and can pinpoint women who have a significantly increased risk for breast, ovarian cancer, and contralateral breast cancer: individuals with BRCA1 and BRCA2 mutations have a 75% lifetime risk of breast cancer and a 30% lifetime risk of ovarian cancer. Most cases of breast and ovarian cancer are sporadic in nature, but approximately 10% of breast and ovarian cancers are thought to result from genetic inheritance (Li et al., 2015). DNA (from a blood or saliva sample) is needed for mutation testing. The sample is sent to a laboratory for analysis. It usually takes about a month to get the results back. Testing positive for a BRCA1 or BRCA2 mutation can significantly alter health care decisions. In some cases, before genetic testing was available, lumpectomy with radiation, or mastectomy was the treatment most often recommended. However, if the woman is found to have a BRCA1 mutation, she is most likely to be offered the option of bilateral prophylactic mastectomy and possible bilateral oophorectomy. A recent study found that current evidence does not support worse breast cancer survival of BRCA1/2 mutation carriers in the adjuvant setting; differences if any are likely to be small when compared to non BRCA 1/2 mutation carriers (van den Broek et al., 2015).

Discovery of mutations in the breast and ovarian cancer susceptibility genes BRCA1 and BRCA2 can have emotional consequences for both the tested individual and his or her relatives.

EVIDENCE-BASED PRACTICE 6.1 COMBINATION (SEVERAL DRUGS AT A TIME) VERSUS SEQUENTIAL CHEMOTHERAPY (SAME DRUG GIVEN ONE AFTER THE OTHER) FOR METASTATIC BREAST CANCER

STUDY

Combination chemotherapy can cause greater tumor cell kill if the drug dose is not compromised, while sequential single agent chemotherapy may allow for greater dose intensity and treatment time, potentially meaning greater benefit from each single agent. In addition, sequentially using single agents might cause less toxicity and impairment of quality of life, but it is not known whether this might compromise survival time. The purpose of this study was to assess the effect of combination chemotherapy compared to the same drugs given sequentially in women with metastatic breast cancer.

Findings

Randomized controlled trials of combination chemotherapy compared to the same drugs used sequentially in women with metastatic breast cancer in the first-, second-, or third-line setting were selected. Twelve trials reporting on nine treatment comparisons (2317 patients randomized) were identified. The findings concluded that sequential single agent chemotherapy has a positive effect on progression-free survival, whereas combination chemotherapy has a higher response rate and a higher risk of febrile neutropenia in metastatic breast cancer. There was no difference in overall survival time between these treatment strategies, but when drugs were given one at a time, there was more time before the tumors grew back again. However, combination chemotherapy caused tumors to shrink more. Generally this study supports the recommendations by international guidelines to use sequential monotherapy unless there is rapid disease progression.

Severe psychological distress can occur as a result of genetic testing. Their distress relates to family cancer history, relationships, coping strategies, communication patterns, and mutation status (Wevers et al., 2015). Nurses might find it useful to explore these issues in order to prepare clients before BRCA1/BRCA2 testing and to support them through shifts in family dynamics after disclosure of results. Also, many women perceive their breasts as intrinsic to their femininity, self-esteem, and sexuality, and the risk of losing a breast can provoke extreme anxiety (Alexander et al., 2014). Nurses need to address the physical, emotional, and spiritual needs of the women they care for, as well as their families, since this mutation is inherited in an autosomal dominant fashion. Nurses should identify the woman's personal coping style which has an impact on her likelihood of experiencing distress after her diagnosis. Women who are emotionally expressive and/or have a "fighting spirit" usually experience lower levels of emotional distress. Based on Mendelian genetics, women with BRCA1 and BRCA2 mutations have a 5- to 20-fold increased risk of developing breast and ovarian cancer (Caple & Schub, 2015).

Surgical Options

Generally, the first treatment option for a woman diagnosed with breast cancer is surgery. A few women with tumors larger than 5 cm or inflammatory breast cancer may undergo neoadjuvant chemotherapy or radiotherapy to shrink the tumor before surgical removal is attempted (Debled et al., 2015). The surgical options depend on the type and extent of cancer. The choices are typically either breast-conserving surgery (lumpectomy with radiation) or mastectomy with or without reconstruction. The overall survival rate with lumpectomy and radiation is about the same as that with modified radical mastectomy (ACS, 2015f). Research has shown that the survival rates in women who have had mastectomies versus those who have undergone breast-conserving surgery followed by radiation are the same. However, lumpectomy may not be an option for some women, including those:

• Who have two or more cancer sites that cannot be removed through one incision

• Whose surgery will not result in a clean margin of tissue

• Who have active connective tissue conditions (lupus or scleroderma) that make body tissues especially sensitive to the side effects of radiation

• Who have had previous radiation to the affected breast

• Whose tumors are larger than 5 cm (2 inches) (National Comprehensive Cancer Network [NCCN], 2015).

These decisions are made jointly between the woman and her surgeon. If mastectomy is chosen, because of either tumor characteristics or client preference, then discussion needs to include breast reconstruction and regional lymph node biopsy versus sentinel lymph node biopsy. The mastectomy techniques are a simple mastectomy with sentinel node biopsy or a radical mastectomy with regional node biopsy. Removal of numerous lymph nodes places the client at high risk for lymphedema.

BREAST-CONSERVING SURGERY

Breast-conserving surgery, the least invasive procedure, is the wide local excision (or lumpectomy) of the tumor along with a 1-cm margin of normal tissue. A lumpectomy is often used for early-stage localized tumors. The goal of breast-conserving surgery is to remove the suspicious mass along with tissue free of malignant cells to prevent recurrence. The results are less drastic and emotionally less scarring than having a mastectomy to the woman. Women

undergoing breast-conserving therapy receive radiation after lumpectomy with the goal of eradicating residual microscopic cancer cells to limit locoregional recurrence. In women who do not require adjuvant chemotherapy, radiation therapy typically begins 2 to 4 weeks after surgery to allow healing of the lumpectomy incision site. Radiation is administered to the entire breast at daily doses over a period of several weeks (Corradini et al., 2015).

A sentinel lymph node biopsy may also be performed since the lymph nodes draining the breast are located primarily in the axilla. Theoretically, if breast cancer is to metastasize to other parts of the body, it will probably do so via the lymphatic system. If malignant cells are found in the nodes, more aggressive systemic treatment may be needed.

MASTECTOMY

A simple mastectomy is the removal of all breast tissue, the nipple, and the areola. The axillary nodes and pectoral muscles are spared. This procedure would be used for a large tumor or multiple tumors that have not metastasized to adjacent structures or the lymph system.

A modified radical mastectomy is another surgical option; conducive to breast reconstruction and results in greater mobility and less lymphedema (Alexander et al., 2014). This procedure involves removal of breast tissue, and a few positive axillary nodes. Breast-conserving surgeries do not increase the future risk of death from recurrent disease when compared mastectomy (Schuiling & Likis 2016).

In conjunction with the mastectomy, lymph node surgery (removal of underarm nodes) may need to be done to reduce the risk of distant metastasis and improve a woman's chance of long-term survival. For women with a positive sentinel node biopsy, 10 to 20 underarm lymph nodes may need to be removed. Complications associated with axillary lymph node surgery include nerve damage during surgery, causing temporary numbness down the upper aspect of the arm; seroma formation (fluid build-up) followed by wound infection; restrictions in arm mobility (some women need physiotherapy); and lymphedema (swelling related to the lymph glands). In many women lymphedema can be avoided by:

• Avoiding using the affected arm for drawing blood, inserting intravenous lines, or measuring blood pressure (can cause trauma and possible infection)

• Seeking medical care immediately if the affected arm swells

- Wearing gloves when engaging in activities such as gardening that might cause injury
- Wearing a well-fitted compression sleeve to promote drainage return

Women having mastectomies must decide whether to have further surgery to reconstruct the breast. If the woman decides to have reconstructive surgery, it ideally is performed immediately after the mastectomy. The woman must also determine whether she wants the surgeon to use saline implants or natural tissue from her abdomen (TRAM flap method) or back (LAT flap method).

If reconstructive surgery is desired, the ultimate decision regarding the method will be determined by the woman's anatomy (e.g., is there sufficient fat and muscle to permit natural reconstruction?) and her overall health status. Both procedures require a prolonged recovery period.

Some women opt for no reconstruction, and many of them choose to wear breast prostheses. Some prostheses are worn in the bra cup and others fit against the skin or into special pockets created into clothing.

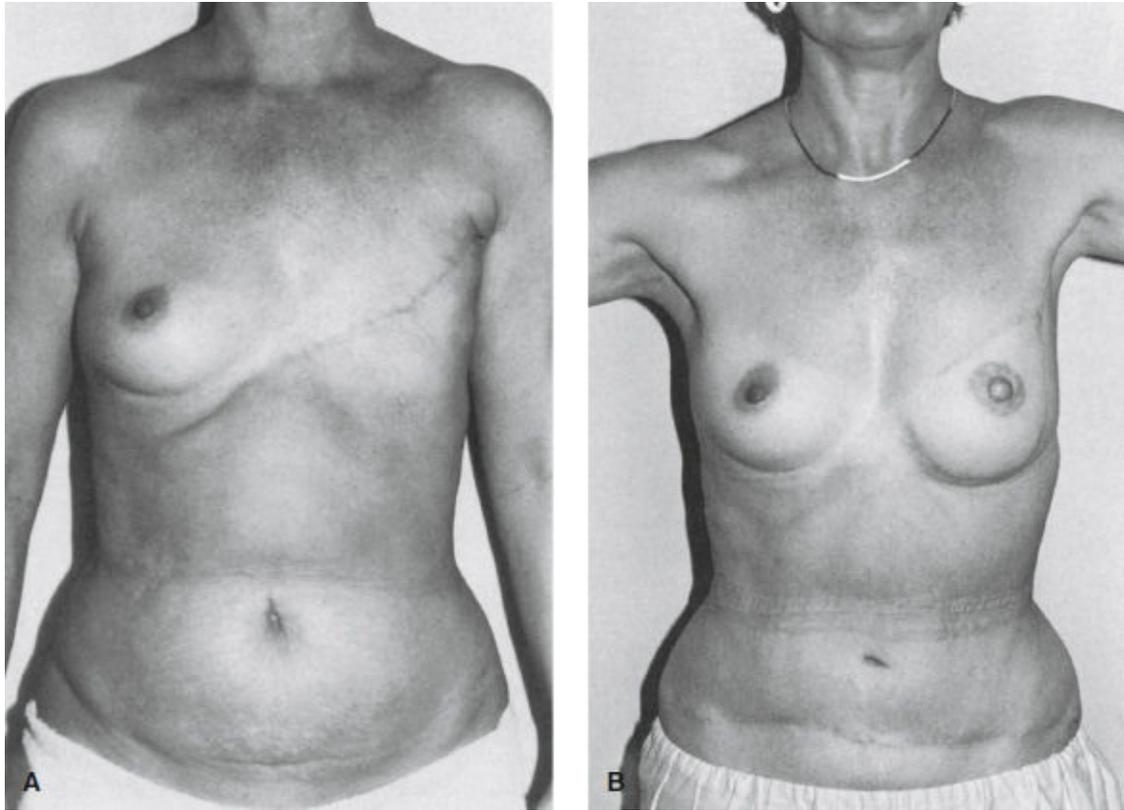
Whether to have reconstructive surgery is an individual and very complex decision. Each woman must be presented with all of the options and then allowed to decide. The nurse can play an important role here by presenting the facts to the woman so that she can make an intelligent decision to meet her unique situation. Breast reconstruction surgery can help restore the look and feel of the breast after a mastectomy. Performed by a plastic surgeon, breast reconstruction can be done immediately after the mastectomy or at a later date. Breast reconstruction can be done with breast implants (filled with saline or silicone); natural tissue flaps (using skin fat and muscle from your own body); or a combination of both. Side effects or complications include risk of rupture, hardening of the tissues around the implant, infection, and pain. Nurses need to educate the woman about these potential problems and make sure they understand before consenting to breast reconstruction. See Figure 6.6 for examples of pre- and postmastectomy and reconstruction.


FIGURE 6.6 Before and after photos of postmastectomy and reconstruction.

BREAST AUGMENTATION

Breast augmentation is a common surgical procedure with women undergoing it with implants for a variety of reasons ranging from aesthetic to reconstructive surgery following a mastectomy. Saline-filled or silicone-filled implants are used in cosmetic enhancement and reconstructive surgeries. The exact anatomical placement of breast implants can vary, but the location typically is subglandular (over the pectoral muscle) or subpectoral (under the muscle). Breast implants are not lifetime devices, but most are guaranteed for approximately 10 years in case of rupture. Breast augmentation with implants is not without risks. Potential complications include capsular contracture, rippling, implant rupture, infection, or hematoma. Capsular contraction occurs when scar tissue forms, contracts, and hardens around the implant. Rippling most often occurs when wrinkles form in the implant or as a complication of contracture (Mugea, 2015).

Breast examination in women with reconstructive surgery is done exactly the same way as for natural breasts. Breasts with implants in place usually feel firmer than normal breast tissue on palpation due to the formation of a fibrotic band or capsule around the implant. If implants are used, press firmly inward at

the edges of the implant to feel the ribs beneath.

Adjunctive Therapy

Adjunctive therapy is supportive or additional therapy that is recommended after surgery. Adjunctive therapies include local therapy such as radiation therapy and systemic therapies using chemotherapy, hormonal therapy, and immunotherapy.

RADIATION THERAPY

Radiation therapy (also called radiotherapy) uses high-energy rays to destroy cancer cells that might have been left behind in the breast, chest wall, or underarm area after a tumor has been removed surgically. Usually serial radiation doses are given 5 days a week to the tumor site for 6 to 8 weeks postoperatively. Each treatment takes only a few minutes, but the dose is cumulative. Women undergoing breast-conserving therapy receive radiation to the entire breast after lumpectomy with the goal of eradicating residual microscopic cancer cells to reduce the chance of recurrence (Chu et al., 2015).

Side Effects. Side effects of traditional radiation therapy include inflammation, local edema, anorexia, swelling, and heaviness in the breast; sunburn-like skin changes in the treated area; and fatigue. Changes to the breast tissue and skin usually resolve in about a year in most women (Lara et al., 2015). This type of therapy can be given several ways: external beam radiation, which delivers a carefully focused dose of radiation from a machine outside the body, or internal radiation, in which tiny pellets that contain radioactive material are placed into the tumor.

Several advances have taken place in the field of radiation oncology for the treatment of women with early-stage breast cancer that assist in reducing the side effects. The treatment position for external radiation has changed from supine to prone, with the arm on the affected side raised above the head, so that the treated breast hangs dependently through the opening of the treatment board. Treatment in the prone position improves dose distribution within the breast and allows for a decrease in the dose delivered to the heart, lung, chest wall, and other breast (NCCN, 2015).

High-dose brachytherapy is another advance that is an alternative to traditional radiation treatment. A balloon catheter is used to insert radioactive seeds into the breast after the tumor has been removed surgically. The seeds

deliver a concentrated dose directly to the operative site; this is important because most cancer recurrences in the breast occur at or near the lumpectomy site (Chang et al., 2015). This allows a high dose of radiation to be delivered to a small target volume with a minimal dose to the surrounding normal tissue. This procedure takes 4 to 5 days as opposed to the 4 to 6 weeks that traditional radiation therapy takes; it also eliminates the need to delay radiation therapy to allow for wound healing. Brachytherapy is now used as a primary radiation treatment after breast-conserving surgery in selected women as an alternative to whole breast irradiation (Guinot et al., 2015). Side effects of brachytherapy include redness or discharge around catheters, fever, and infection. Daily cleansing of the catheter insertion site with a mild soap and application of an antibiotic ointment will minimize the risk of infection.

Intensity-modulated radiation therapy (IMRT) offers still another new approach to the delivery of treatment to reduce the dose within the target area while sparing surrounding normal structures. A computed tomography scan is used to create a three-dimensional model of the breast. Based on this model, a series of intensity-modulated beams is produced to the desired dose distribution to reduce radiation exposure to underlying structures. Acute toxicity is thus minimized (Muralidhar, Soubhagya, & Ahmed, 2015). Research is ongoing to evaluate the impact of all of these advances in radiation therapy.

CHEMOTHERAPY

Chemotherapy refers to the use of drugs that are toxic to all cells and interfere with a cell's ability to reproduce. They are particularly effective against malignant cells but affect all rapidly dividing cells, especially those of the skin, the hair follicles, the mouth, the gastrointestinal tract, and the bone marrow. Breast cancer is a systemic disease in which micrometastases are already present in other organs by the time the breast cancer is diagnosed. Chemotherapeutic agents perform a systemic "sweep" of the body to reduce the chances that distant tumors will start growing.

Chemotherapy may be indicated for women with tumors larger than 1 cm, positive lymph nodes, or cancer of an aggressive type. Chemotherapy is prescribed in cycles, with each period of treatment followed by a rest period. Treatment typically lasts 3 to 6 months, depending on the dose used and the woman's health status.

Different classes of drugs affect different aspects of cell division and are used in combinations or "cocktails." The most active and commonly used

chemotherapeutic agents for breast cancer include alkylating agents, anthracyclines, antimetabolites, and vinca alkaloids. Fifty or more chemotherapeutic agents can be used to treat breast cancer; however, a combination drug approach appears to be more effective than a single drug treatment (ACS, 2015g). Refer to Evidence-Based Practice 6.1.

Side Effects. Side effects of chemotherapy depend on the agents used, the intensity of dosage, the dosage schedule, the type and extent of cancer, and the client's physical and emotional status. Nurses need to remain current in order to accommodate new treatments and the side effect profiles. This knowledge is vital to providing evidence-based care for breast cancer women receiving these treatments (Bourdeanu & Lui, 2015). However, typical side effects include nausea and vomiting, diarrhea or constipation, hair loss, weight loss, stomatitis, fatigue, and immunosuppression. The most serious is bone marrow suppression (myelosuppression). This causes an increased risk of infection, bleeding, and a reduced red blood cell count, which can lead to anemia. Treatment of the side effects can generally be addressed through appropriate support medications such as antinausea drugs. In addition, growth-stimulating factors, such as epoetin alfa (Procrit) and filgrastim (Neupogen), help keep blood counts from dropping too low. Counts that are too low would stop or delay the use of chemotherapy.

An aggressive systemic option, when other treatments have failed or when there is a strong possibility of relapse or metastatic disease, is high-dose chemotherapy with bone marrow and/or stem cell transplant. This therapy involves the withdrawal of bone marrow before the administration of toxic levels of chemotherapeutic agents. The marrow is frozen and then returned to the client after the high-dose chemotherapy is finished. Clinical trials are still researching this experimental therapy (King et al., 2015).

HORMONAL THERAPY

One of estrogen's normal functions is to stimulate the growth and division of healthy cells in the breasts. However, in some women with breast cancer, this normal function contributes to the growth and division of cancer cells.

The objective of endocrine therapy is to block or counter the effect of estrogen. Estrogen plays a central role in the pathogenesis of cancer, and treatment with estrogen deprivation has proven to be effective. Approximately two-thirds of women diagnosed with early-stage breast cancer have hormone-sensitive disease (estrogen receptor positive and/or progesterone receptor

positive), and adjuvant hormone therapy play an essential role in reducing the risk of recurrence and improving survival (Gradishar, 2015). Several different drug classes are used to interfere or block estrogen receptors. They include selective estrogen receptor modulators (SERMs), estrogen receptor down-regulators, aromatase inhibitors, luteinizing hormone-releasing hormone, progestin, and biologic response modifiers (King et al., 2015). Current recommendations for most women with ER+ breast cancer are to take a hormone-like medication—known as a SERM antiestrogenic agent—daily for up to 5 years after initial treatment. Certain areas in the female body (breasts, uterus, ovaries, skin, vagina, and brain) contain specialized cells called hormone receptors that allow estrogen to enter the cell and stimulate it to divide. SERMs enter these same receptors and act like keys, turning off the signal for growth inside the cell (King et al., 2015). The best-known SERM is tamoxifen (Nolvadex, 20 mg daily for 5 years). Although it works well in preventing further spread of cancer, it is also associated with an increased incidence of endometrial cancer, pulmonary embolus, deep vein thrombosis, hot flashes, vaginal discharge and bleeding, stroke, and cataract formation (Jager et al., 2015).

Another SERM is the anti-osteoporosis drug raloxifene (Evista), which has shown promising results. It has antiestrogen effects on the breast and uterus. In recent studies involving postmenopausal women at high risk for breast cancer, raloxifene worked as well as tamoxifen in preventing breast cancer, but with fewer serious adverse effects. Both drugs cut the cancer risk in half (Bevers, 2015). It was originally marketed solely for the prevention and treatment of osteoporosis but is now used as adjunctive breast cancer therapy.

Another class of endocrine agents, aromatase inhibitors, works by inhibiting the conversion of androgens to estrogens. Aromatase inhibitors include letrozole (Femara, 2.5 mg daily), exemestane (Aromasin, 25 mg daily), and anastrozole (Arimidex, 1 mg daily for 5 years), all of which are taken orally. These are usually given to women with advanced breast cancer. In recent clinical studies in postmenopausal women with breast cancer, third-generation aromatase inhibitors were shown to be superior to tamoxifen for the treatment of metastatic disease (Bevers, 2015).

Side Effects. The side effects associated with these endocrine therapies include hot flashes, bone pain, bone thinning, insomnia, weight gain, depression, fatigue, nausea, cough, dyspnea, and headache (Breast Cancer Organization, 2015).

Women with hormone-sensitive cancers can live for long periods without any intervention other than hormonal manipulation, but quality-of-life issues need to be addressed in the balance between treatment and side effects.

IMMUNOTHERAPY

Immunotherapy, used as an adjunct to surgery, represents an attempt to stimulate the body's natural defenses to recognize and attack cancer cells. Trastuzumab (Herceptin, 2- to 4-mg/kg intravenous infusion) is the first monoclonal antibody approved for breast cancer (NCCN, 2015). Some tumors produce excessive amounts of HER-2/neu protein, which regulates cancer cell growth. Breast cancers that overexpress the HER-2/neu protein are associated with a more aggressive form of disease and a poorer prognosis. Trastuzumab blocks the effect of this protein to inhibit the growth of cancer cells. It can be used alone or in combination with other chemotherapy to treat clients with metastatic breast disease. Although immunotherapy has shown some promise against the fight against cancer, recent data suggests that greater success will be achieved by combining it with other therapies, such as radiation (Leavy, 2015).

Concept Mastery Alert

Tamoxifen Versus Trastuzumab in Breast Cancer Treatment

Tamoxifen is a selective estrogen receptor modulator used to prevent further spread of breast cancer in women with ER-positive breast cancer. Trastuzumab is a monoclonal antibody used in the treatment of breast cancer and is considered immunotherapy.

Side Effects. Adverse effects of trastuzumab include cardiac toxicity, vascular thrombosis, hepatic failure, fever, chills, nausea, vomiting, and pain with first infusion (Skidmore-Roth, 2015).

Although the goal of treatment remains improved survival, increasing emphasis is being focused on prevention. Breast cancer prevention measures focus on evaluating and reducing risk factors. Approaches for reducing breast cancer risk include lifestyle modifications (diet and physical exercise), chemoprevention (SERMs & AIs), and prophylactic surgery (bilateral salpingoopjorectomy & bilateral prophylactic mastectomy) (Euhus & Diaz, 2015). Nurses can have an impact on early detection of breast disorders, treatment, and symptom management. Women with a cancer diagnosis often experience negative emotions and nurses' empathic response can help alleviate their distress (Alexander et al., 2014). A nurse who is involved in the woman's treatment plan from the beginning can effectively offer support throughout the whole experience.

Teamwork is important in breast screening and caring for women with breast disorders. Treatment is often fragmented between the hospital and community treatment centers, which can be emotionally traumatic for the woman and her family. The advances being made in the diagnosis and treatment of breast disorders mean that guidelines are constantly changing, requiring all health care providers to keep up to date. Informed nurses can provide support and information and, most importantly, continuity of care for the woman undergoing treatment for a breast problem.

The nurse plays a particularly important role in providing psychological support and self-care teaching to clients with breast cancer. Nurses can influence both physical and emotional recovery, which are both important aspects of care

that help in improving the woman's quality of life and the ability to survive. The nurse's role should extend beyond helping clients; spreading the word in the community about screening and prevention is a big part in the ongoing fight against cancer. The community should see nurses as both educators and valued sources of credible information. This role will help improve clinical outcomes while achieving high levels of client satisfaction.

Despite the new guidelines issued by various governmental agencies regarding BSEs, a CBE done by a professional health care provider is essential for good breast health for all women. See Box 6.1 for additional information.

Remember Nancy from the chapter opener? Is her response typical of many women upon discovering a lump in their breast? Nancy confides her discovery of the lump and her worries to you. What advice would you give her?

ASSESSMENT

Early breast cancer has no symptoms. The earliest sign of breast cancer is often an abnormality seen on a screening mammogram before the woman or the health care provider feels it. A healthy, asymptomatic presentation is typical. However, symptoms may include a lump in the breast that is usually nontender, fixed, and hard with irregular borders. In the woman presenting with a breast disorder, take a thorough history of the problem and explore the woman's risk factors for breast cancer. Assess the woman for clinical manifestations of breast cancer, such as changes in breast appearance and contour, which become apparent with advancing breast cancer (ACS, 2015d). These changes include:

• Continued and persistent changes in the breast

• A lump or thickening in one breast

• Persistent nipple irritation

• Unusual breast swelling or asymmetry

• A lump or swelling in the axilla

• Changes in skin color or texture

• Nipple retraction, tenderness, or discharge

Complete a breast examination to validate the clinical manifestations and findings of the health history and risk factor assessment. The CBE involves both inspection and palpation (Box 6.1). Helpful characteristics in evaluating palpable breast masses are described in Table 6.5. If a lump can be palpated, the cancer has been there for quite some time.

Be cognizant of the impact that breast cancer has on a woman's emotional state, coping ability, and quality of life. Women may experience sadness, vulnerability, loss of control, alteration of body image and integrity, anger, the illness's impact on relationships, fear of mortality, the need to reprioritize her life, and guilt as a result of having breast cancer. However, despite potential negative outcomes, many women have a positive outlook for their future and adapt to treatment modalities with a good quality of life (Kleban & Glaser, 2015). Closely monitor clients for their psychosocial adjustment to diagnosis and treatment and be able to identify those who need further psychological intervention. By giving practical advice, the nurse can help the woman adjust to her altered body image and to accept the changes in her life.

Because family members play a significant role in supporting women through

breast cancer diagnosis and treatment, assess the emotional distress of both partners during the course of treatment and, if needed, make a referral for psychological counseling. By identifying interpersonal strains, negative psychosocial side effects of cancer treatment can be minimized.

NURSING DIAGNOSIS

Appropriate nursing diagnoses for a woman with a diagnosis of breast cancer might include:

• Disturbed body image related to:
  • Loss of body part (breast)
  • Loss of femininity
  • Loss of hair due to chemotherapy
• Fear related to:
  • Diagnosis of cancer
  • Prognosis of disease
• Deficient knowledge related to:
  • Cancer treatment options
  • Reconstructive surgery decisions
  • Breast self-examination

BOX 6.1

CLINICAL BREAST EXAMINATION BY HEALTH CARE PROVIDER

If the woman is deemed high risk, the nurse would then teach the woman to perform a BSE to enhance breast awareness.

Purpose: To Assess Breasts for Abnormal Findings

• Inspect the breast for size, symmetry, and skin texture and color. It is common for the left breast to be slightly larger than the right. Inspect the nipples and areola. Ask the client to sit at the edge of the examination table, with her arms resting at her sides.

• Inspect the breast for masses, retraction, dimpling, or ecchymosis.

• The client places her hands on her hips.

• She then raises her arms over her head so the axillae can also be inspected.

- The client then stands, places her hands on her hips, and leans forward.

- Palpate the breasts using the pads of your first three fingers and make a rotary motion on the breast. Assist the client into a supine position with her arms above her head. Place a pillow or towel under the client's head to help spread the breasts. Three patterns might be used to palpate the breasts:

  1. Spiral

2. Pie-shaped wedges

3. Vertical strip

• Compress the nipple gently between the thumb and index finger to evaluate for masses and squeeze to check for any discharge.

- Palpate the axillary area for any tenderness or lymph node enlargement. Have the client sit up and move to the edge of the examination table. While supporting the client's arm, palpate downward from the armpit, palpating toward the ribs just below the breast.

Adapted from Ball, J. W., Dains, J. E., Flynn, J. A., Soloman, B. S., & Stewart, R. W. (2015). *Seidel's guide to physical examination* (8th ed.). St. Louis, MO: Elsevier Saunders.

TABLE 6.5 CHARACTERISTICS OF BENIGN VERSUS MALIGNANT BREAST MASSES

Benign Breast Masses Are Described As	Malignant Breast Masses Are Described As
• Frequently painful	• Hard to palpation
• Firm, rubbery mass	• Painless
• Bilateral masses	• Irregularly shaped (poorly delineated)
• Induced nipple discharge	• Immobile, fixed to the chest wall
• Regular margins (clearly delineated)	• Skin dimpling
• No skin dimpling	• Nipple retraction
• No nipple retraction	• Unilateral mass
• Mobile, not affixed to the chest wall	• Bloody, serosanguineous, or serous nipple discharge
• No bloody discharge	• Spontaneous nipple discharge

NURSING INTERVENTIONS

Offer information, support, and perioperative care to women diagnosed with breast cancer who are undergoing treatment. Implement health promotion and disease prevention strategies to minimize the risk for developing breast cancer and to promote optimal outcomes.

Remember Nancy, who discovered a breast lump? You offer to go with her to the doctor. After a full examination and several diagnostic tests, the results come back positive for breast cancer. What treatment options does Nancy have, and what factors need to be considered in selecting those options?

Providing Client Education

Help the woman and her partner to prioritize the voluminous amount of information given to them so that they can make informed decisions. Explain all treatment options in detail so the client and her family understand them. By preparing an individualized packet of information and reviewing it with the woman and her partner (if applicable), the nurse can help the woman understand her specific type of cancer, the diagnostic studies and treatment options she may choose, and the goals of treatment. For example, nurses play an important role in educating women about the use of endocrine therapies, observing women's experiences with treatment, and communicating those observations to their primary health care providers to make dosage adjustments, in addition to contributing to the knowledge base of endocrine therapy in the treatment of breast cancer.

Providing information is a central role of the nurse in caring for the woman with a diagnosis of breast cancer. This information can be given via telephone counseling, one-to-one contact, and pamphlets. Telephone counseling with women and their partners may be an effective method to improve symptom management and quality of life. Educate women on living with risk, maintaining quality of life, and participating in support groups (Strayer & Schub, 2014).

Providing Emotional Support

The diagnosis of cancer affects all aspects of life for a woman and her family. The threatening nature of the disease and feelings of uncertainty about the future can lead to anxiety and stress. Address the woman's need for:

• Information about diagnosis and treatment

• Physical care while undergoing treatments

• Contact with supportive people

• Education about disease, options, and prevention measures

• Discussion and support by a caring, competent nurse

Reassure the client and her family that the diagnosis of breast cancer does not necessarily mean imminent death, a decrease in attractiveness, or diminished sexuality. Encourage the woman to express her fears and worries. Be available to listen and address the woman's concerns in an open manner to help her toward recovery. All aspects of care must include sensitivity to the client's personal efforts to cope and heal. Some women will become involved in organizations or charities that support cancer research; they may participate in breast cancer walks to raise awareness or become a *Reach to Recovery* volunteer to help others. Each woman copes in her own personal manner, and all of these efforts can be positive motivators for her own healing.

To help women cope with the diagnosis of breast cancer, the ACS launched *Reach to Recovery* more than 30 years ago. Specially trained breast cancer survivors give women and their families' opportunities to express their feelings, verbalize their fears, and get answers. Recovery volunteers can also, when appropriate, provide a temporary breast form and give information on types of permanent prostheses, as well as lists of where those items are available in the community. Most importantly, *Reach to Recovery* volunteers offer understanding, support, and hope through face-to-face visits or by telephone; they are proof that people can survive breast cancer and live productive lives. National contact information is 1-800-ACS-2345.

Providing Postoperative Care

For the woman who has had surgery to remove a malignant breast lump or an entire breast, excellent postoperative nursing care is crucial. Tell the woman what to expect in terms of symptoms and when they usually occur during treatment and after surgery. This allows women to anticipate these symptoms and proactively employ management strategies to improve their cancer experience. Postoperative care includes immediate postoperative care, pain management, care of the affected arm, wound care, mobility care, respiratory care, emotional care, referrals, and educational needs.

Immediate Postoperative Care

Assess the client's respiratory status by auscultating the lungs and observing the breathing pattern. Assess circulation; note vital signs, skin color, and skin temperature. Observe the client's neurologic status by evaluating the level of alertness and orientation. Monitor the wound for amount and color of drainage. Monitor the intravenous lines for patency, correct fluid, and rate. Assess the drainage tube for amount, color, and consistency of drainage.

Pain Management

Provide analgesics as needed. Reassure the woman that her pain will be controlled. Teach the woman how to communicate her pain intensity on a scale of 0 to 10, with 10 being the worst pain imaginable. Assess the client's pain level frequently and anticipate pain before assisting the woman to ambulate.

Affected Arm Care

Elevate the affected arm on a pillow to promote lymph drainage. Make sure that no treatments are performed on the affected arm, including laboratory draws, intravenous lines, blood pressures, and so on. Place a sign above the bed to warn others not to touch the affected arm.

Wound Care

Observe the wound often and empty drainage reservoirs as needed. Tell the client to report any evidence of infection early, such as fever, chills, or any area of redness or inflammation along the incision line. Also tell the client to report any increase in drainage, foul odor, or separation at the incision site.

Mobility Care

Perform active range-of-motion and arm exercises as ordered. Encourage self-care activities for successful rehabilitation. Perform dressing and drainage care; explain the care during the procedure.

Respiratory Care

Assist with turning, coughing, and deep breathing every 2 hours. Explain that this helps to expand collapsed alveoli in the lungs, promotes faster clearance of inhalation agents from the body, and prevents postoperative pneumonia and atelectasis.

Emotional Care and Referrals

Encourage the client to participate in her care. Assess her coping strategies preoperatively. Explain possible body image concerns after discharge. Promote the ACS web sites, which provide the latest cancer therapy news. Encourage the client to attend local support groups for breast cancer survivors, such as *Reach to Recovery.*

Educational Needs

Provide follow-up information about adjunctive therapy. Explain that radiation therapy may start within weeks postoperatively. Discuss chemotherapy, its side effects and cycles, home care during treatment, and future monitoring strategies. Explain hormonal therapy, including antiestrogens or aromatase inhibitors. Teach progressive arm exercises to minimize lymphedema. Explain that ongoing surveillance is needed to detect recurrence of cancer or a new primary site and that the client will typically see the health care provider every 6 months.

Nancy underwent a mastectomy with radiation and chemotherapy. What follow-up care is needed? How can the nurse assist Nancy to cope with her uncertain future? What community resources might help her?

IMPLEMENTING HEALTH PROMOTION AND DISEASE PREVENTION STRATEGIES

In the past, most women assumed that there was little they could do to reduce their risk of developing breast cancer, but since the 1970s significant advances have been made in the diagnosis and treatment of breast cancer. Mortality rates have decreased since 1990, particularly in women <50 years old. The declining incidence of breast cancer and lower mortality rates have been attributed to early detection, improved treatment, and research (Sestak & Cuzick, 2015). However, research has found that the choices women make concerning breast cancer screening, diet, exercise, and other health practices have a profound impact on cancer risk. In the fight against cancer, nurses often assume a variety of roles, such as educator, counselor, advocate, and role model. Nurses can offer education about the following:

• Prevention

• Early detection

• Screening

• Dispelling myths and fears

• Self-examination techniques if needed

• Individual risk status and strategies for risk reduction

It is important to be knowledgeable about the most current evidence-based practices and cognizant of how the media presents this information. Offer prevention strategies within the context of a woman's life. Factors such as lifestyle choices, economic status, and multiple roles need to be taken into consideration when counseling women. Advocate for healthy lifestyles and making sound choices to prevent cancer. Nurses, like all health care providers, should offer guidance from a comprehensive perspective that acknowledges the unique needs of each individual. Nurses need to not only be proficient in the postoperative physical care of clients who undergo mastectomy but also demonstrate advanced skills related to the educational needs of clients and their families and to ensure care is delivered in a manner that is client-centered and individualized. Nurses require advanced skills to meet the social and psychological care needs of the woman and her family during this major life event (Fallowfield & Jenkins, 2015).

Breast cancer is a frightening experience for all women but is particularly

burdensome on African-American women, ranking second among the cause of cancer deaths in them. Although the incidence of breast cancer is highest in White women, African-American women have a higher breast cancer mortality rate at every age and a lower survival rate than any other racial or ethnic group. Statistics indicate that the gap is widening (ACS, 2015e).

Like a black cloud hanging over their heads, with little regard for any victim, breast cancer stalks women everywhere they go. Many women are left with new health risks and lingering effects associated with treatment (e.g., limited mobility, memory problems, low social activity, and support). Many have a close friend or relative who is battling the disease; many have watched their mothers and sisters die of this dreaded disease. Those with risk factors live with even greater anxiety and fear. No woman wants to hear those chilling words: "The biopsy is positive. You have breast cancer." Provide women with information about detection and risk factors, inform them about the new ACS screening guidelines, instruct them on BSE, and outline dietary changes that might reduce their risk of breast cancer.

Awareness is the first step toward a change in habits. Raising the level of awareness about breast cancer is of paramount importance, and nurses can play an important role in health promotion, disease prevention, and education.

Breast Cancer Screening

The three components of early detection are BSE, CBE, and mammography. The ACS (2015d) has issued breast cancer screening guidelines that, for the first time, offer specific guidance for the women and greater clarification of the role of breast examinations (see Table 6.4). ACS screening guidelines are revised about every 5 years to include new scientific findings and developments.

Women are exposed to multiple sources of cancer prevention information, and much of it may not be sound. Discuss the benefits, risks, and potential limitations of BSE, CBE, and mammography with each woman and tailor the information to her specific risk factors (ACS, 2015b). Based on the new guidelines, make clinical judgments as to the appropriateness of recommending BSE, and reevaluate the need to teach the procedure to all women; the focus might instead be on encouraging regular mammograms (depending, of course, on the woman's individual risk factors).

Breast Self-Examination

BSE is a technique that enables a woman to detect any changes in her breasts. BSEs, once thought essential for early breast cancer detection, are now considered optional. Instead, breast awareness is stressed. Breast awareness refers to a woman being familiar with the normal consistency of both breasts and the underlying tissue. This emphasis is now on awareness of breast changes, not just discovery of cancer. Research has shown that BSE plays a small role in detecting breast cancer compared with self-awareness. However, doing BSE is one way for a woman to know how her breasts normally feel so that she can notice any changes that do occur (ACS, 2015d).

If appropriate, there are two steps to conducting a BSE: visual inspection and tactile palpation. The visual part should be done in three separate positions: with the arms up behind the head, with the arms down at the sides, and bending forward. Instruct the woman to look for:

• Changes in shape, size, contour, or symmetry

• Skin discoloration or dimpling, bumps/lumps

• Sores or scaly skin

• Discharge or puckering of the nipple

In the second part, the tactile examination, the health care provider feels the woman's breasts in one of three specific patterns: spiral, pie-shaped wedges, or a vertical strip (up and down). When using any of the three patterns, the woman should use a circular rubbing motion (in dime-sized circles) without lifting the fingers. The examiner checks not only the breasts but also between the breast and the axilla, the axilla itself, and the area above the breast up to the clavicle and across the shoulder. The pads of the three middle fingers on the right hand are used to assess the left breast; the pads of the three middle fingers on the left hand are used to assess the right breast. Instruct the woman to use three different degrees of pressure:

• Light (move the skin without moving the tissue underneath)

• Medium (midway into the tissue)

• Hard (down to the ribs)

Nutrition

Nutrition plays a critical role in health promotion and disease prevention. Cancer is considered to be a chronic disease that may be influenced at many stages by nutrition. These factors may affect prevention, progression, and treatment of the disease (Shrivastava, Shrivastava, & Ramasamy, 2015). Being overweight or obese is a risk factor for breast cancer in postmenopausal women. Excess body weight has been linked to an increased risk of postmenopausal breast cancer, and growing evidence also suggests that obesity is associated with poor prognosis in women diagnosed with early-stage breast cancer. Dozens of studies demonstrate that women who are overweight or obese at the time of breast cancer diagnosis are at increased risk of cancer recurrence and death compared with leaner women, and some evidence suggests that women who gain weight after breast cancer diagnosis may also be at increased risk of poor outcomes (Wright et al., 2015). *Healthy People 2020* identified being overweight or obese as one of the 10 leading health indicators and a major health concern (U.S. Department of Health and Human Services, 2010). Almost 65% of women over the age of 20 years are overweight; of these, 33.4% are obese (Carlson, 2015). A Mediterranean diet high in fruits, vegetables, and high-fiber carbohydrates and low in animal fat seems to offer protection against breast cancer as well as weight control. Women who followed these dietary guidelines decreased their risk of breast cancer. In addition, substantial evidence has shown that obesity, as measured by body mass index (BMI) is linked to breast cancer outcomes and greater mortality risks (Chan & Norat, 2015).

The Women's Health Initiative Dietary Modification Trial (Brasky et al., 2015) was designed to study a low-fat diet, a nutritional approach to prevention of chronic diseases. It found a marginally statistically significant reduction in breast cancer incidence among women in the low-fat dietary pattern group, and also disproved that 'heart healthy eating' prevented future cardiac events in women.

The American Institute for Cancer Research, which conducts extensive research, made the following recommendations to reduce a woman's risk for developing breast cancer:

• Engaging in daily moderate exercise and weekly vigorous physical activity

• Consuming at least five servings of fruits and vegetables daily

- Not smoking or using any tobacco products
- Keeping a maximum BMI of 25 and limiting weight gain to no more than 11 pounds since age 18
- Consuming seven or more daily portions of complex carbohydrates, such as whole grains and cereals
- Limiting intake of processed foods and refined sugar
- Limiting consumption of energy-dense foods and sugary drinks
- Avoiding use of dietary supplements which are unlikely to improve prognosis
- Restricting red meat intake to approximately 3 ounces daily
- Limiting intake of fatty foods, particularly those of animal origin
- Restricting intake of salted foods and use of salt in cooking (Swisher et al., 2015).

   The medical community is also starting to study the role of phytochemicals in health. The unique geographic variability of breast cancer around the world and the low rate of breast cancer in Asia compared with Western countries prompted this interest. This area of research appears hopeful for women seeking to prevent breast cancer as well as those recovering from it. Although the mechanism is not clear, certain foods demonstrate anticancer properties and boost the immune system. Phytochemical-rich foods include:

- Green tea and herbal teas
- Garlic
- Whole grains and legumes
- Onions and leeks
- Soybeans and soy products
- Tomato products (cooked tomatoes)
- Fruits (citrus, apricots, pumpkin, berries)
- Green leafy vegetables (spinach, collards, romaine)
- Colorful vegetables (carrots, squash, tomatoes)
- Cruciferous vegetables (broccoli, cabbage, cauliflower)
- Flax seeds (Bahadoran, Karimi, & Abedini, 2015).

   Adopt a holistic approach when addressing the nutritional needs of women

with breast cancer. Incorporate nutritional assessment into the general overall assessment of all women. Culturally sensitive nutritional assessment tools need to be developed and used to enhance this process. Providing examples of appropriate foods associated with the woman's current dietary habits, relating current health status to nutritional intake, and placing proposed modifications within a realistic personal framework may increase a woman's willingness to incorporate needed changes in her nutritional behavior. Be able to interpret research results and stay up to date on nutritional influences so that you can transmit this key information to the public.

KEY CONCEPTS

- Many women believe that all lumps are cancerous, but actually more than 80% of the lumps discovered are benign and need no treatment (Alexander et al., 2014).

- The most commonly encountered benign breast disorders in women include fibrocystic breasts, fibroadenomas, and mastitis (Bope & Kellerman, 2015).

- Current research suggests that women with fibrocystic breast disease or other benign breast conditions are more likely to develop breast cancer later only if a breast biopsy shows "atypia" or abnormal breast cells (ACS, 2015a).

- Fibroadenomas are common benign solid breast tumors that can be stimulated by external estrogen, progesterone, lactation, and pregnancy.

- Mastitis is an infection of the connective tissue in the breast that occurs primarily in lactating or engorged women; it is divided into lactational or nonlactational types.

- Management of both types of mastitis involves the use of oral antibiotics (usually a penicillinase-resistant penicillin or cephalosporin) and acetaminophen (Tylenol) for pain and fever (Miller & Kennedy, 2015).

- Breast cancer is the most common cancer in women and the second leading cause of cancer deaths (lung cancer is first) among American women (ACS, 2015a).

- Breast cancer metastasizes widely and to almost all organs of the body, but primarily to the bone, lungs, lymph nodes, liver, and brain.

- The etiology of breast cancer is unknown, but the disease is thought to develop in response to a number of related factors: aging, delayed childbearing or

never bearing children, high breast density, family history of cancer, late menopause, obesity, and hormonal factors.

○ Breast cancer treatments fall into two categories: local and systemic. Local treatments are surgery and radiation therapy. Effective systemic treatments include chemotherapy, hormonal therapy, and immunotherapy.

○ Women commonly perceive their breasts as intrinsic to their femininity, self-esteem, and sexuality, and the risk of losing a breast can provoke extreme anxiety.

○ Nurses can influence both physical and emotional recovery, which are both important aspects of care that help in improving the woman's quality of life and the ability to survive.

○ Providing up-to-date information and emotional support are central roles of the nurse in caring for the woman with a diagnosis of breast cancer.

CHAPTER **WORKSHEET**

MULTIPLE-CHOICE QUESTIONS

1. Breast self-examinations involve both touching of breast tissue and:
   a. Palpation of cervical lymph nodes
   b. Firm squeezing of both breast nipples
   c. Visualizing both breasts for any change
   d. A mammogram to evaluate breast tissue

2. Which of the following is the strongest risk factor for breast cancer?

a. Advancing age and being female

b. High number of children

c. Genetic mutations in BRCA1 and BRCA2 genes

d. Family history of colon cancer

3. A biopsy procedure that traces radioisotopes and blue dye from the tumor site through the lymphatic system into the axillary nodes is:

a. Stereotactic biopsy

b. Sentinel node biopsy

c. Axillary dissection biopsy

d. Advanced breast biopsy

4. The most serious potential adverse reaction from chemotherapy is:

a. Thrombocytopenia

b. Deep vein thrombosis

c. Alopecia

d. Myelosuppression

5. What suggestion would be helpful for the client experiencing painful fibrocystic breast changes?

a. Increase her caffeine intake.

b. Take a mild analgesic when needed.

c. Reduce her intake of leafy vegetables.

d. Wear a bra bigger than she needs.

6. A postoperative mastectomy client should be referred to which of the following organizations for assistance upon discharge from the hospital?

a. National Organization for Women (NOW)

b. Food and Drug Administration (FDA)

c. March of Dimes Foundation (MDF)

d. Reach to Recovery (RTR)

7. Breast cancer that is localized is referred to as

a. Primary

b. In situ

c. Metastasized

d. Localized

8. A 25-year-old woman presents with an asymptomatic breast mass. Which of the following is true concerning her diagnosis and treatment?

a. All breast masses should be considered pre-malignant

b. The breast mass should be surgically removed immediately

c. Ultrasound is typically used to determine the diagnosis

d. Since it is asymptomatic, just reassurance is needed now

CRITICAL THINKING EXERCISE

1. Mrs. Gordon, 48, presents to the women's community clinic where you work as a nurse. She is very upset and crying. She tells you that she found lumps in her breast: "I know that it's cancer and I will die." When you ask her about her problem, she says she does not check her breasts monthly and hasn't had a mammogram for years because "they're too expensive." She also describes the intermittent pain she experiences.

a. What specific questions would you ask this client to get a clearer picture?

b. What education is needed for this client regarding breast health?

c. What community referrals are needed to meet this client's future needs?

2. Ruth Davis, 51, stops in at the urgent care facility with an anxious look on her face. She tells the nurse practitioner that she has green discharge coming from her right breast and discomfort intermittently. She can't understand how this would happen since she hasn't previously had any nipple discharge or pain.

a. What benign breast condition might the nurse practitioner suspect based on her description?

b. What specific information should the nurse practitioner give Mrs. Davis about duct ectasia?

c. The typical treatment of this benign breast condition would include what?

STUDY ACTIVITIES

1. Discuss with a group of women what their breasts symbolize to them and to society. Do they symbolize something different to each one?

2. When a woman experiences a breast disorder, what feelings might she be experiencing and how can a nurse help her sort them out?

3. Interview a woman who has fibrocystic breast changes and find out how she manages this condition.

4. An infection of the breast connective tissue that frequently occurs in the lactating woman is _____.

BRINGING IT ALL TOGETHER: CASE STUDY

A 67-year-old obese woman presents to her internist after several years' absence a right breast mass that she felt 4 weeks ago that seems to be getting larger. She also has recently noticed a 10-pound weight loss over the past 6 months and occasional right upper quadrant discomfort. She also states that she has been feeling tired over the last several months, but rationalized it as 'old age' catching up with her.

ASSESSMENT

She has a family history of breast and colon cancer in her immediate family and both of her parents died from these (mother from breast cancer and father from colon cancer). Her aunt also had breast cancer, but is in remission now after treatment. She can't remember when the last time she had a pap smear or mammogram. She admits that she does not keep up with her health checkups, since she babysits for her grandchildren and has difficulty scheduling them. She confesses that her diet hasn't been what it should be, since her grandchildren prefer fast food and sodas for meals, rather than home cooked ones. Thus, she gives into them and eats what they want.

Go to thePoint to find questions to consider about this case.

7

Benign Disorders of the Female Reproductive Tract

KEY TERMS

cystocele
enterocele
ovarian cyst
pelvic floor muscle exercises (Kegel exercises)
pelvic organ prolapse (POP)
pessary
polycystic ovary syndrome (PCOS)
polyps
rectocele

urinary incontinence (UI)
uterine fibroids
uterine prolapse

Learning Objectives

Upon completion of the chapter, you will be able to:

1. Characterize the major pelvic relaxation disorders in terms of etiology, management, and nursing interventions.
2. Outline the nursing management needed for the most common benign reproductive disorders in women.
3. Evaluate urinary incontinence in terms of pathology, clinical manifestations, treatment options, and effect on quality of life.
4. Compare the various benign growths in terms of their symptoms and management.
5. Analyze the emotional impact of polycystic ovarian syndrome and the nurse's role as a counselor, educator, and advocate.

Liz, a 26-year-old, overweight woman, presented to the clinic with hirsutism and facial acne and told the nurse that she was concerned about her irregular menstrual periods. She also said that recently the hair on top of her head seemed to be falling out. What diagnostic tests might the nurse anticipate with this client? How can the nurse prepare Liz for them?

WOW

Words of Wisdom

Women can influence their aging process by making wise lifestyle choices early on.

INTRODUCTION

The incidence of several benign pelvic disorders increases as women age. For instance, women may experience pelvic floor disorders related to pelvic relaxation or urinary incontinence. These disorders generally develop after years of wear and tear on the muscles and tissues that support the pelvic floor—such as that which occurs with childbearing, chronic coughing, straining, surgery, or simply aging. In addition to pelvic floor disorders, woman may also experience various benign neoplasms of the reproductive tract, such as cervical polyps, uterine leiomyomas (fibroids), ovarian cysts, genital fistulas, and Bartholin's cysts. This chapter provides an overview of various pelvic floor disorders and benign neoplasms, discussing the assessment, treatment, and prevention strategies for each. It also addresses female genital cutting in the context of it being a harmful practice that affects girls' and women's health.

PELVIC FLOOR DISORDERS

Pelvic floor disorders such as pelvic organ prolapse or genital prolapse and urinary and fecal incontinence are common in aging women. Researchers funded by the National Institutes of Health (NIH, 2015a) reported that more than one-third of women in the United States have a pelvic floor disorder, and nearly one-quarter of women in the United States have one or more pelvic floor disorders that cause symptoms. The study reported that the frequency of pelvic floor disorders increases with age, affecting more than 40% of women from 60 to 79 years of age, and about 50% of women 80 years and older. The NIH analysis is the first to document in a nationally representative sample the extent of pelvic floor disorders, a cluster of health problems that causes physical discomfort and limits activity.

Pelvic floor disorders cause significant physical and psychological morbidity and can diminish women's social interactions, emotional well-being, and overall quality of life. Because these disorders increase with age, the problem will grow worse as our population ages. The term "pelvic floor" refers to the group of muscles that form a sling or hammock across the pelvis. Together with their surrounding tissues, these muscles hold the pelvic organs (uterus, bladder, and bowel), in place so that they can function correctly. These disorders occur as a result of weakness of the connective tissue and muscular support of pelvic organs due to a number of factors: Pregnancy, vaginal childbirth, obesity, lifting, chronic cough from smoking, straining at defecation secondary to constipation, radiation to the pelvis for cancer, and estrogen deficiency (American College of Obstetricians and Gynecologists (ACOG, 2015a). The female anatomy is susceptible to the development of pelvic floor disorders because of its vertical structures placement. The bony pelvis has an exaggerated lumbar spinal curve and downward tilt to it. The bladder rests on the symphysis and the posterior organs rest on the sacrum and coccyx. The pelvis holds the organs, but a woman's erect posture causes a funneling effect and constant downward pressure.

Pelvic Organ Prolapse

Pelvic organ prolapse (POP) (from the Latin *prolapsus*, "a slipping forth") refers to the abnormal descent or herniation of the pelvic organs from their original attachment sites or their normal position in the pelvis. POP occurs when structures of the pelvis shift and protrude into or outside of the vaginal canal. This disorder affects a woman's micturition, defecation, and sexual activity. The Egyptians were the first to describe prolapse of the genital organs. Hippocrates in 400 BC made reference to placing a pomegranate half into the vagina to treat organ prolapse. A disorder exclusive to women, POP rarely results in severe morbidity or mortality but can affect a woman's daily activities and quality of life (Brown, 2015). It is difficult to determine the incidence of POP, because the disorder is often asymptomatic and many women do not seek treatment. It has been estimated, however, that up to 75% of all women who have had a vaginal birth have POP (ACOG, 2015a). Each year, over 250,000 women undergo surgery to repair the prolapse at a cost of over $1 billion for hospitalization and physician fees alone (Maher & Haya, 2015). As the older adult population is expected to double in number by 2030, POP and its associated symptoms will become more prevalent (Mukwege et al., 2015).

Obesity is associated with a high prevalence of pelvic floor disorders. Obesity can also aggravate symptoms of pelvic organ prolapse, fecal incontinence, sexual dysfunction, stress urinary incontinence, and increase the risk of endometrial polyps and symptomatic fibroids. Weight reduction enhances reproductive outcomes, diminishes symptoms of urinary incontinence, improves sexual dysfunction, and reduces morbidity following gynecologic surgery. Sustained and substantial weight loss, however, is difficult to achieve for many women with their current lifestyle and dietary choices (Ramalingam & Monga, 2015).

The treatment and diagnosis of POP is challenging and problematic.

Types of Pelvic Organ Prolapse

The four most common types of pelvic or genital prolapse are cystocele, rectocele, enterocele, and uterine prolapse (Fig. 7.1):

• **Cystocele** occurs when the posterior bladder wall protrudes downward through the anterior vaginal wall.

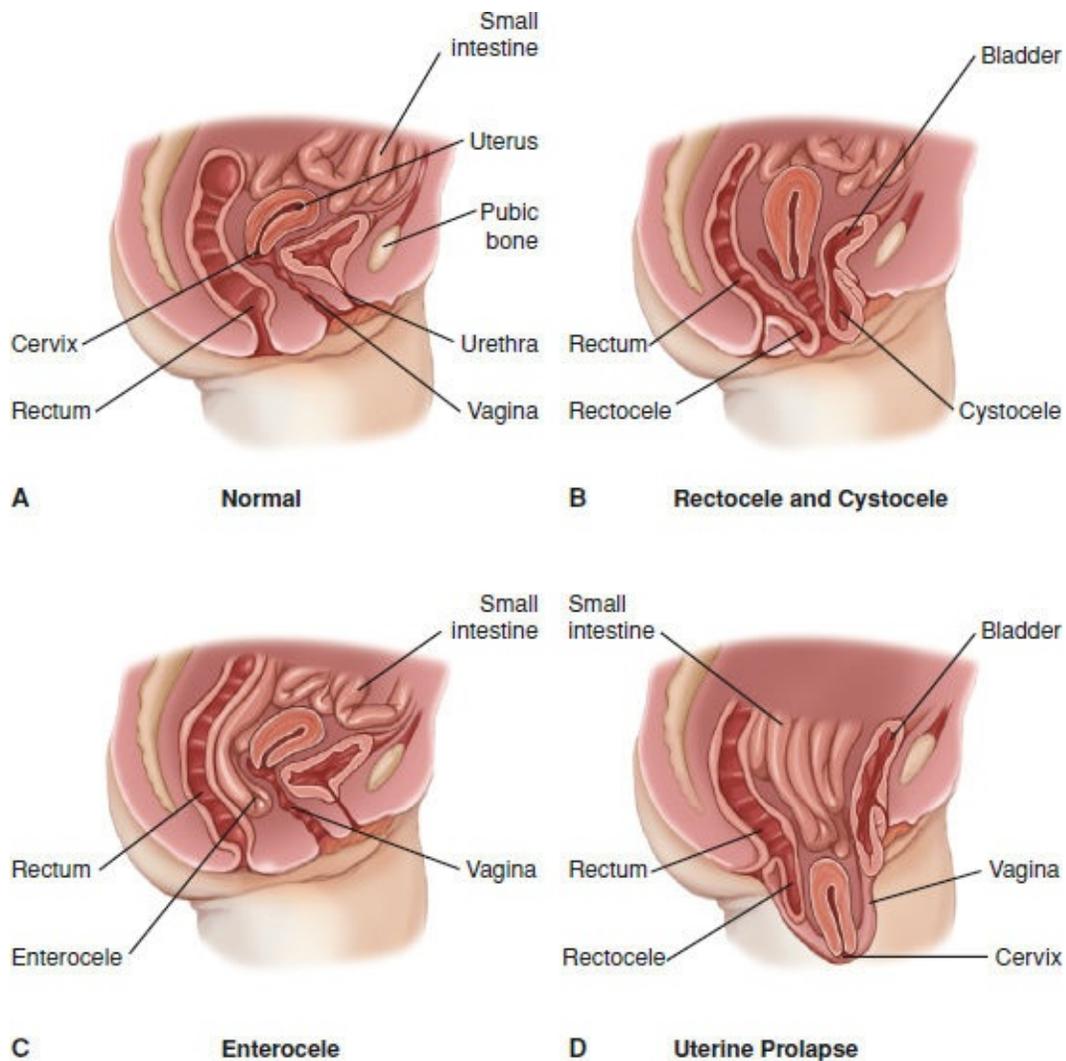
- **Rectocele** occurs when the rectum sags and pushes against or into the posterior vaginal wall.
- **Enterocele** occurs when the small intestine bulges through the posterior vaginal wall (especially common when straining).
- **Uterine prolapse** occurs when the uterus descends through the pelvic floor and into the vaginal canal. Multiparous women are at particular risk for uterine prolapse. The extent of uterine prolapse is classified in terms of stages:
  - *Stage 0:* No descent of pelvic structure during straining.
  - *Stage I:* The prolapsed descending organ is >1 cm above the hymenal ring.
  - *Stage II:* The prolapsed organ extends ~1 cm below the hymenal ring.
  - *Stage III:* The prolapsed organ extends 2 to 3 cm below the hymenal ring.
  - *Stage IV:* The vagina is completely everted or the prolapsed organ is >3 cm below the hymenal ring (Riss & Koch, 2015).


FIGURE 7.1 Types of pelvic prolapses. (**A**) Normal. (**B**) Rectocele and cystocele. (**C**) Enterocele. (**D**) Uterine prolapse.

Etiology

Anatomic support of the pelvic organs is mainly provided by the levator ani muscle complex and the connective tissue attachments of the pelvic organ fascia. Dysfunction of one or both of these components can lead to loss of support and eventually POP. Weakened pelvic floor muscles also prevent complete closure of the urethra, resulting in urine leakage during physical stress. This problem is not limited to older women: Urinary incontinence has been documented in women of varying ages, including young (<25 years old) women (Walters, 2015).

Many risk factors for POP have been suggested, but the true cause is likely to be multifactorial. Causes might include:

- Constant downward gravity because of erect human posture
- Atrophy of supporting tissues with aging and decline of estrogen levels
- Weakening of pelvic support related to childbirth trauma
- Reproductive surgery, including hysterectomy
- Instrumental childbirth
- Multiparity
- Uncontrolled rapid birth
- Family history of POP
- Young age at first birth
- Connective tissue disorders
- Infant birth weight of more than 4,500 g
- Pelvic radiation
- Increased abdominal pressure secondary to:
  - Lifting of children or heavy objects
  - Straining due to chronic constipation
  - Respiratory problems or chronic coughing
  - Obesity (Rodriguez-Mias et al., 2015).

Therapeutic Management

Treatment options for POP depend on the symptoms and their effect on the woman's quality of life. Important considerations when deciding on nonsurgical or surgical options include the severity of symptoms, the woman's preferences, the woman's health status, age, and suitability for surgery, and the presence of other pelvic conditions (urinary or fecal incontinence). Conservative measures such as pelvic floor muscle exercises (PFME) or Kegel exercises supplemented by lifestyle interventions such as weight loss, avoidance of straining (reducing lifting heavy weights, treatment of chronic cough and constipation) are recommended as first-line management. PFME is aimed to increase the strength and endurance of the pelvic floor supports, prevent or delay worsening of prolapse, and improve prolapse symptoms. PFME can help women delay or avert the need for surgery and pre and postoperatively have been found to improve outcomes after surgery.

When surgery is being considered, the nature of the procedure and the likely outcome must be fully explained and discussed with the woman and her partner. Treatment options for POP include pelvic floor muscle exercises, estrogen replacement therapy, dietary and lifestyle modifications, use of a pessary (a removable device placed into the vagina to support pelvic organs), and surgery (see Evidence-Based Practice 7.1).

PELVIC FLOOR MUSCLE EXERCISES OR KEGEL EXERCISES

Pelvic floor muscle exercises strengthen the pelvic floor muscles to support the inner organs and prevent further prolapse. Pelvic floor muscle exercises are generally accepted as first-line treatment for stress and urge urinary incontinence and they are also widely used for anal incontinence. Over the past 30 years a wealth of research has proven the benefits of pelvic floor muscle exercises in treating both urinary incontinence and pelvic organ prolapse (McClurg, Gerrard, & Hove, 2015). The purpose of pelvic floor exercises is to increase the muscle volume, which will result in a stronger muscular contraction. Pelvic floor muscle exercises might limit the progression of mild prolapse and alleviate mild prolapse symptoms, including low back pain and pelvic pressure. They will not, however, help severe uterine prolapse.

> **EVIDENCE-BASED PRACTICE 7.1 PELVIC FLOOR MUSCLE TRAINING VERSUS NO TREATMENT, OR INACTIVE CONTROL TREATMENTS, FOR URINARY INCONTINENCE IN WOMEN**

STUDY

Involuntary leakage of urine (urinary incontinence) affects women of all ages, particularly older women who live in residential care such as nursing homes. Some women leak urine during exercise or when they cough or sneeze (stress urinary incontinence) and this may occur as a result of weakness of the pelvic floor muscles such as damage during childbirth. Other women leak urine before going to the toilet when there is a sudden and compelling need to pass urine (urgency urinary incontinence). This may be caused by involuntary contraction of the bladder muscle. Mixed urinary incontinence is the combination of both stress and urgency urinary incontinence. Pelvic floor muscle training is a supervised physical therapy treatment and it involves muscle-clenching exercises to strengthen the pelvic floor muscles. It is a common treatment used by women to stop urine leakage. Other treatments are also available which can either be used alone or in combination with pelvic floor muscle training (PFMT).

PFMT is a conservative treatment for urinary incontinence in women. This systematic review evaluated the effects of PFMT when compared to no treatment, placebo, or other inactive control treatments for urinary incontinence in women.

This study was done to compare the effects PFMT to no treatment, placebo, or other inactive control treatments in the management of women with urinary incontinence.

Findings

Randomized or quasi-randomized trials were used. Twenty-one trials (1,281 women) met the eligibility criteria for inclusion, comprising women with stress urinary incontinence, urgency urinary incontinence or mixed urinary incontinence, and they compared PFMT added to no treatment, placebo or other inactive control treatments.

This systematic review found support for the widespread recommendation that PFMT should be included in first-line conservative management programs for women with stress and any type of urinary incontinence. In women with stress incontinence, there was high quality evidence that PFMT is associated with improvement or cure.

HORMONE REPLACEMENT THERAPY

Hormone replacement therapy, or HRT (orally, transdermally, low-dose vaginal ring or vaginal cream) may improve the tone, natural thickness, and vascularity of the supporting tissue in perimenopausal and menopausal women by increasing blood perfusion and the elasticity of the vaginal wall. HRT has many benefits, as well as risks. It is essential that the benefits are weighed out against the risks before this therapy is initiated.

Take Note!

Before hormone therapy is considered, a thorough medical history must be taken to assess a woman's risk for complications (e.g., endometrial cancer, myocardial infarction, stroke, breast cancer, pulmonary emboli, and deep vein thrombosis). Because of these risks, estrogens, with or without progestins, should be given at the lowest effective dose and for the shortest duration consistent with the treatment goals and risks for the individual woman (ACOG, 2015a).

DIETARY AND LIFESTYLE MODIFICATIONS

Dietary and lifestyle modifications may help prevent pelvic relaxation and

chronic problems later in life. Specific lifestyle changes would include avoiding constipation, bladder irritants, heavy lifting, high impact exercise, weight loss, and smoking cessation. Dietary habits can exacerbate the prolapse by causing constipation and consequently chronic straining. The stools of a constipated woman are hard and dry, and typically she must strain while bearing down to defecate. This straining to pass a hard stool increases intra-abdominal pressure, which over time causes the pelvic organs to prolapse. Dietary modifications can help to establish regular bowel movements without discomfort and eliminate flatus and bloating. A weight loss regimen might also need to be instituted if the woman is overweight.

PESSARIES

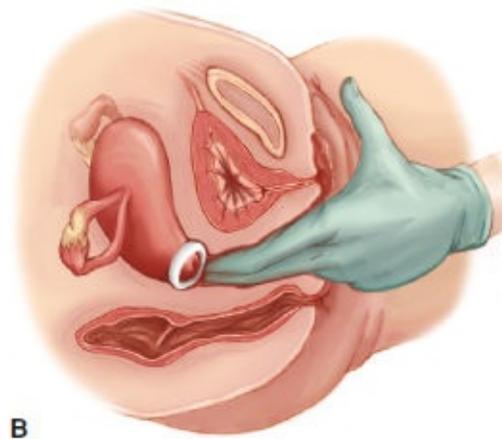
Vaginal **pessaries** are synthetic devices inserted in the vagina to provide support to the bladder and other pelvic organs as a corrective measure for urinary incontinence and/or pelvic organ prolapse (Fig. 7.2). Today almost all pessaries are made of medical-grade silicone, which provides many advantages. Silicone pessaries are pliable and have a long shelf life; lack odor and secretion absorption; are biologically inert, nonallergenic, and noncarcinogenic; and they can be boiled or autoclaved for sterilization. Because most pessaries are made of silicone, pessary style and size are the main considerations when selecting a pessary (Colyar, 2015). Although many types and shapes are available, the most commonly used pessary is a firm ring that presses against the wall of the vagina and urethra to help decrease leakage and support a prolapsed vagina or uterus. Pessaries are a low risk treatment option with the advantage of being cost effective and minimally invasive, and provide immediate relief of symptoms.


FIGURE 7.2 Examples of pessaries. **A.** Various shapes and sizes of pessaries available. **B.** Insertion of one type of pessary. A link to a web site for a picture of Colpexin Sphere is located on.

Indications for pessary use include uterine prolapse or cystocele, especially among elderly clients for whom surgery is contraindicated; younger women with prolapse who plan to have additional children; and women with marked prolapse who prefer to use a pessary rather than undergo surgery (Ralph & Tamussino, 2015). Many women use pessaries for only a short period of time and become free of symptoms. Long-term use can lead to pressure necrosis and the development of fistulas in some women; in this situation other methods of support should be explored. Pessaries are fitted by trial and error; the woman often needs to try several sizes or styles. The largest pessary that the woman can

wear comfortably is generally the most effective. The woman should be instructed to report any discomfort or difficulty with urination or defecation while wearing the pessary and also to attend follow-up care appointments to check positioning.

Nurses need to be aware of the personal isolation and embarrassment and social and cultural implications that urinary incontinence may cause as well as the subjective experiences of using a pessary. With appropriate support, vaginal pessaries can provide women with the freedom to lead active, engaged social lives.

SURGICAL INTERVENTIONS

Surgical interventions for pelvic or genital organ prolapse are designed to correct specific defects, with the goals being to restore normal anatomy and to preserve function. Approximately 260,000 stress incontinence surgical procedures are performed annually in the United States (Kirby, Tan-Kim, & Nager, 2015). Surgery is not an option for all women. Women who are at high risk of suffering recurrent prolapse after a surgical repair or who have morbid obesity, chronic obstructive pulmonary disease, or medical conditions in which general anesthesia would be risky are not good candidates for surgical repair (Alexander et al., 2015), and noninvasive treatment strategies should be discussed with them.

Surgical interventions might include anterior or posterior colporrhaphy (to repair a cystocele or rectocele) and vaginal hysterectomy (for uterine prolapse). This can be done laparoscopically whereby the uterus is removed through the vagina. An anterior and posterior colporrhaphy may be effective for a first-degree prolapse. This surgical procedure tightens the anterior and posterior vaginal wall, thus repairing a cystocele or rectocele. The pubocervical fascia (supportive tissue between the vagina and bladder) is folded and sutured to bring the bladder and urethra in proper position (Nilsson, 2015).

A vaginal hysterectomy is the treatment of choice for uterine prolapse because it removes the prolapsed organ that is bringing down the bladder and rectum with it. It can be combined with an anterior and posterior repair if a cystocele or rectocele is present.

Nursing Assessment

Nursing assessment for women with POP includes a thorough health history, a

physical examination, and several laboratory and diagnostic tests.

HEALTH HISTORY AND CLINICAL MANIFESTATIONS

A history and general assessment of the client is important to exclude pathology and evaluate various factors that may influence choice and success of management. Evaluation of systems such as bowel, urinary and sexual function, coexistent morbidities, medical and surgical history, any physical or mental impairment, and lifestyle are noticeably very important, particularly in older women. The client's social circumstances and support systems, desire for treatment, and expectations will have implications on the management options.

The cause of prolapse is multifactorial, with vaginal childbirth, advancing age, heavy work, poor nutrition, vaginal surgery, and increasing body mass index being the most consistent risk factors (Rodriguez-Mias et al., 2015). Assessment of risk factors (chronic straining, hysterectomy, normal aging, and abnormalities of connective tissue) in the woman's history will assist the health care provider in the diagnosis and treatment of POP. The history should include questions about:

• The woman's obstetrical history (number of pregnancies, weight of newborns, pregnancy spacing)
• Chronic respiratory condition (chronic coughing)
• Menopausal status
• Weight history (loss or gain)
• Constipation (frequency and chronicity)
• Age
• Work history (e.g., physical labor or light office work)
• Nutritional assessment
• Family history (family member with POP)
• Urinary incontinence
• Previous pelvic surgeries

Assess for clinical manifestations of POP. POP is often asymptomatic, but when symptoms do occur, they are often related to the site and type of prolapse. Symptoms common to all types of prolapses are a feeling of dragging, a lump in the vagina, or something "coming down." Women with POP can present either

with one symptom, such as vaginal bulging or pelvic pressure, or with several complaints, including many bladder, bowel, and pelvic symptoms. Symptoms associated with POP are summarized in Box 7.1.

Women present with varying degrees of uterine descent. Uterine prolapse is the most troubling type of pelvic relaxation because it is often associated with concomitant defects of the vagina in the anterior, posterior, and lateral compartments (Lazarou & Grigorescu, 2015).

PHYSICAL EXAMINATION

The pelvic examination performed by the health care provider includes an external genital inspection to visualize any obvious protrusion of the uterus, bladder, urethra, or vaginal wall occurring at the vaginal opening. Usually the woman is asked to perform the Valsalva maneuver (bearing down) while the examiner notes which organ prolapses first and the degree to which it occurs. Any urine leakage during the examination is important to note. The woman is asked to contract the pubococcygeal muscles (pelvic floor muscle exercise); the health care provider inserts two fingers into the vagina to assess the strength and symmetry of the contraction. Because pelvic or genital organ prolapse can cause urinary symptoms such as incontinence, bladder function should be assessed by determining postvoid residual with a catheter. If the woman has more than 100 mL of retained urine, she should be referred for further urodynamic evaluation and testing.

SYMPTOMS ASSOCIATED WITH PELVIC ORGAN PROLAPSE

- Urinary symptoms
- Stress incontinence
- Frequency (diurnal and nocturnal)
- Urgency and urge incontinence
- Hesitancy
- Poor or prolonged stream
- Feeling of incomplete emptying
- Bowel symptoms
- Difficulty with defecation
- Incontinence of flatus or liquid or solid stool
- Urgency of defecation
- Feeling of incomplete evacuation
- Rectal protrusion or prolapse after defecation
- Sexual symptoms
- Inability to have frequent intercourse
- Dyspareunia
- Lack of satisfaction or orgasm
- Incontinence during sexual activity
- Other local symptoms
- Pressure or heaviness in the vagina
- Pain in the vagina or perineum
- Low back pain after long periods of standing
- Palpable bulge in the vaginal vault
- Difficulty in walking due to a protrusion from the vagina
- Difficulty inserting or keeping a tampon in place
- Vaginal–cervical mucosa hypertrophy, excoriation, ulceration, and bleeding

• Abdominal pressure or pain

Adapted from American College of Obstetricians and Gynecologists [ACOG]. (2015a) Pelvic support problems. *ACOG Educational Pamphlet*. Retrieved from http://www.acog.org/~/media/For%20Patients/faq012.pdf?dmc=1&ts=20140128T1159591406; and Lazarou, G., & Grigorescu, B. A. (2015). Pelvic organ prolapse. *eMedicine*. Retrieved from http://emedicine.medscape.com/article/276259-overview

LABORATORY AND DIAGNOSTIC TESTS

Common laboratory tests that may be ordered to determine the cause of POP include a urinalysis to rule out a bacterial infection, urine culture to identify the specific organism if present, visualization of urine loss during the pelvic examination, and measurement of postvoid urine volume.

Nursing Management

Help the woman understand the nature of the condition, the treatment options, and the likely outcomes. Nursing considerations might include the following:

• Describe normal anatomy and causes of pelvic prolapse.

• Assess how this condition has affected the woman's life.

• Outline the options, with the advantages and disadvantages of each.

• Allow the client to make the decision that is right for her.

• Provide education.

• Schedule preoperative activities needed for surgery.

• Reassure the client that there is a solution for her symptoms.

• Provide community education about genital prolapse.

Nursing Care Plan 7.1 provides an overview of care for a woman with POP.

PROMOTE PREVENTION STRATEGIES

Limited data are available on ways to prevent POP, but a nurse needs first to understand its incidence, risk factors, prevalence, clinical implications, and treatment options to be an effective caretaker of the woman. The nurse's understanding will not only improve his or her ability to treat this growing client population, but will also help in developing preventive strategies to address a

woman's suffering from this condition.

Approaches include lifestyle changes that reduce modifiable risk factors, such as losing weight, avoiding heavy lifting, and relieving constipation. Explore with the woman what factors in her lifestyle might be modified to reduce her risk of developing POP (primary prevention) or to improve her quality of life after receiving treatment (secondary prevention).

ENCOURAGE PELVIC FLOOR MUSCLE TRAINING

Encourage the woman to perform pelvic floor muscle exercises daily (Teaching Guidelines 7.1). Discuss current research findings and educate the woman about estrogen therapy, allowing the woman to make her own decision on whether to use hormones. Controversy still exists regarding the benefits versus the risks of taking hormones, so the woman must weigh this option carefully (ACOG, 2015a).

Teaching Guidelines 7.1

PERFORMING PELVIC FLOOR EXERCISES

- Squeeze the muscles in your rectum as if you are trying to prevent passing flatus.
- Stop and start urinary flow to help identify the pubococcygeus muscle.
- Tighten the pubococcygeus muscle for a count of three, and then relax it.
- Contract and relax the pubococcygeus muscle rapidly 10 times.
- Try to bring up the entire pelvic floor and bear down 10 times.
- Repeat pelvic floor muscle exercises at least five times daily.

NURSING CARE PLAN 7.1

Overview of a Woman with Pelvic Organ Prolapse

Katherine, a 62-year-old multiparous woman, came to her gynecologist with complaints of a chronic dragging or heavy painful feeling in her pelvis, lower backache, constipation, and urine leakage. Her symptoms increase when she stands for long periods. She has not had menstrual cycles for at least a decade. She tells you, "I'm not taking any of those menopausal hormones." She also states that she is very self-conscious and embarrassed about her urine leakage and restricts her outside activities.

NURSING DIAGNOSIS: Body image changes related to relaxation of pelvic support and elimination difficulties.

Outcome Identification and Evaluation

The client will report an improved body image after management of pelvic organ prolapse and improved urinary control.

Interventions: *Providing Pain Management*

• Obtain a thorough history, including ongoing embarrassing experiences, methods of urine control used, what worked, what didn't, any changes in sexual practices related to this, and the effect of this condition on her activities of daily living *to provide a baseline and enable a systematic approach to address it.*

• Assess the frequency, severity, precipitating factors, and aggravating/alleviating factors *to identify characteristics of the client's abnormal urinary patterns to plan appropriate interventions.*

• Educate client about any medications prescribed (correct dosage, route, side effects, and precautions) *to increase the client's understanding of the therapy and promote compliance.*

• Assess problematic elimination patterns *to identify underlying factors from which to plan appropriate prevention strategies.*

• Encourage client to increase fluids and fiber in diet and increase physical activity daily *to promote peristalsis.*

• Assist client with establishing regular toileting patterns by setting aside time

daily for bowel elimination *to promote regular bowel function and evacuation.*
• Urge client to avoid the routine use of laxatives *to reduce risk of compounding constipation.*

NURSING DIAGNOSIS: Deficient knowledge related to causes of structural disorders and treatment options.

Outcome Identification and Evaluation
The client will demonstrate an understanding of current condition and treatments as evidenced by identifying treatment options, making health-promoting lifestyle choices, verbalizing appropriate health care practices, and adhering to treatment plan.

Interventions: Providing Client Education
• Assess client's understanding of pelvic organ prolapse and its treatment options *to provide a baseline for teaching.*
• Review information provided about surgical procedures and recommendations for healthy lifestyle, obtaining feedback frequently, *to validate client's understanding of instructions.*
• Discuss association between uterine, bladder, and rectal prolapse and symptoms *to help client understand the etiology of her symptoms and pain.*
• Have client verbalize and discuss information related to diagnosis, surgical procedure, preoperative routine, and postoperative regimen *to ensure adequate understanding and provide time for correcting or clarifying any misinformation or misconceptions.*
• Provide written material with pictures *to promote learning and help client visualize what has occurred to her body secondary to aging, weight gain, childbirth, and gravity.*
• Discuss pros and cons of hormone replacement therapy, osteoporosis prevention, and cardiovascular events common in postmenopausal women *to promote informed decision making by the client about available menopausal therapies.*
• Inform client about the availability of community resources and make appropriate referrals as needed *to provide additional education and support.*
• Document details of teaching and learning *to allow for continuity of care*

and further education, if needed.

ENCOURAGE DIETARY AND LIFESTYLE MODIFICATIONS

Instruct clients to increase dietary fiber and fluids to prevent constipation. A high-fiber diet with an increase in fluid intake alleviates constipation by increasing stool bulk and stimulating peristalsis. It is accomplished by replacing refined, low-fiber foods with high-fiber foods. The recommended daily intake of fiber for women is 25 g (Meyer, 2015). In addition to increasing the amount of fiber in her diet, also encourage the woman to drink eight 8-oz glasses of fluid daily and to engage in regular low-impact aerobic exercise, which promotes muscle tone and stimulates peristalsis.

Educate the client about other lifestyle changes that will assist with prolapse, such as:

- Achieve ideal weight to reduce intra-abdominal pressure and strain on pelvic organs, including pressure on the bladder.
- Wear a girdle or abdominal support to support the muscles surrounding the pelvic organs.
- Avoid lifting heavy objects to reduce the risk of increasing intra-abdominal pressure, which can push the pelvic organs downward.
- Avoid high-impact aerobics, jogging, or jumping repeatedly to minimize the risk of increasing intra-abdominal pressure, which places downward pressure on the organs.
- Give up smoking to minimize the risk for a chronic "smoker's cough," which increases intra-abdominal pressure and forces the pelvic organs downward.

PROVIDE TEACHING FOR PESSARY USE

Educate the woman about pessary use. Discuss complications as part of the instruction. Although the pessary is a safe device, it is still a foreign body in the vagina. Because of this, the most common side effects of the pessary are increased vaginal discharge, urinary tract infections, vaginitis, and odor. Odors can be reduced by douching with dilute vinegar or hydrogen peroxide. Postmenopausal women with thin vaginal mucosa are susceptible to vaginal ulceration with the use of a pessary. Advise the woman to use estrogen cream to make the vaginal mucosa more resistant to erosion and to strengthen the vaginal walls.

The woman must be capable of managing use of the pessary, either alone or with the help of a caretaker. The most common recommendations for pessary care include removing the pessary twice weekly and cleaning it with soap and water; using a lubricant for insertion; and having regular follow-up examinations every 6 to 12 months after an initial period of adjustment.

Besides cleaning, clients must properly reinsert the device into their vaginal cavity, and the woman must also be willing to participate in all aspects of care of the pessary for this treatment option to be successful. All women choosing this option must be instructed in the care of her pessary so that she feels comfortable with all aspects of it before leaving the health care facility. Health care visits should allow adequate time for women to share their concerns, anxieties, and fears surrounding the transition to life with a pessary.

PROVIDE PERIOPERATIVE CARE

Prepare the woman for surgery by reinforcing the risks and benefits of surgery and describing the postoperative course. Explain that a Foley catheter will be in place for up to one week, and that she might not be able to urinate due to the swelling after the catheter has been removed. Provide home care instructions for the Foley catheter. She should cleanse the perineal area daily with mild soap and water, especially around where the catheter enters the urinary meatus. If the woman is provided with a leg bag to be worn during waking hours, instruct her to empty it frequently and keep it below the level of the bladder to prevent backflow. The same principles are applied to the primary Foley bag when emptying it.

During the recovery period, instruct the client to avoid for several weeks activities that cause an increase in abdominal pressure, such as straining, sneezing, and coughing. In addition, advise her to avoid lifting anything heavy or straining to push anything. Explain to the woman that stool softeners and gentle laxatives might be prescribed to prevent constipation and straining with bowel movements. Avoiding vaginal intercourse will be recommended until the operative area is healed in six weeks.

Urinary Incontinence

Urinary incontinence (UI) is defined by the International Continence Society (2015) as the involuntary loss of urine that represents a hygienic or social problem to the individual. This disorder affects over 15 million women in the United States (Walters, 2015), but is underreported. It has been estimated that 50% of all women experience UT at some time in their life, varying in severity from mild to severe (Files, Mayer, & Chutka, 2015). The psychosocial costs and morbidities are even more difficult to quantify. Embarrassment and depression are common. The affected individual may experience a decrease in social interactions, excursions out of the home, and sexual activity (Su, Sun, & Jiann, 2015). It is more common than diabetes and Alzheimer's disease, both of which receive a great deal of press attention. Despite the considerable impact of incontinence on quality of life, many women are unlikely to bring up the subject of their lack of bladder control and very few women seek help or treatment for incontinence concerns. The following are several possible explanations for why clients do not talk about their bladder control issues. The client may:

• Feel that UI is inevitable and not amenable to treatment.

• Feel that UI is a "normal" part of aging.

• Believe that UI is part of being "female." Women tend to accept urinary symptoms such as UI more so than men.

• Feel embarrassment and try to deny that it is a real problem.

• Think that the only treatment option is surgical.

• The client may consider a UI a hygiene problem and not a medical condition.

 Take Note!

Incontinence is preventable, treatable, and often curable. However, many women believe that loss of bladder function is a normal and expected part of aging.

Incontinence can have far-reaching effects. Some women experience anxiety, depression, social isolation, embarrassment, insomnia, fear, feelings of uncleanliness, worry, vulnerability, shame, limit her ability to travel far from

home or have social engagements and disruptions in their self-esteem and dignity. UI can cause the woman to stop working, traveling, socializing, and enjoying sexual relationships. In addition, incontinence can create a tremendous burden for caretakers and is a common reason for admission to a long-term care facility. Depression and high levels of stress are typical in these women (Kwak, Kwon, & Kim, 2015).

Women often try to cope with UI through lifestyle modifications such as wearing protective pads, avoiding certain activities, emptying the bladder frequently, and modifying diet/fluid intake. Women who experience UI are generally most distressed by the social implications and many go to great efforts to hide their symptoms. In some cultures, UI is abhorred to the point where women are shunned by their communities. A sense of control, normality, and self-esteem are central issues in living with UI. Generally with time and a worsening of symptoms, women pursue medical evaluation and treatment (Waetjen et al., 2015).

The types of urinary incontinence are defined based on their presenting symptoms and signs. The three most common types of incontinence are urgency urinary incontinence (overactive bladder caused by detrusor muscle contractions), stress incontinence (inadequate urinary sphincter function), and mixed incontinence (involves both stress and urge incontinence) (King et al., 2015). Comparison Chart 7.1 details these types of UI.

Pathophysiology and Etiology

Urinary continence requires several factors, including effective functioning of the bladder, adequate pelvic floor muscles, neural control from the brain, and integrity of the neural connections that facilitate voluntary control. The bladder neck and proximal urethra function as a sphincter. During urination the sphincter relaxes and the bladder empties. The ability to control urination requires the integrated function of numerous components of the lower urinary tract, which must be structurally sound and functioning normally.

Incontinence can develop if the bladder muscles become overactive due to weakened sphincter muscles, if the bladder muscles become too weak to contract properly, or if signals from the nervous system to the urinary structures are interrupted. A major factor in women that contributes to urinary continence is the estrogen level, because this hormone helps maintain bladder sphincter tone. In perimenopausal or menopausal women, incontinence can be a problem as

estrogen levels begin to decline and genitourinary changes occur. In simple terms, the bladder is the reservoir, the urethra is the seal, and the levator ani muscle is the gate that holds pressure against the outflow of urine by supporting the urethra and bladder from below. When any of these three structures is not functioning normally, incontinence occurs.

COMPARISON CHART 7.1 **URGE INCONTINENCE VS. STRESS INCONTINENCE**

	Urge Incontinence	Stress Incontinence
Description	Precipitous loss of urine, preceded by a strong urge to void, with increased bladder pressure and detrusor contraction	Accidental leakage of urine that occurs with increased pressure on the bladder from coughing, sneezing, laughing, or physical exertion
Etiology	Causes might be neurologic, idiopathic, or infectious	Develops commonly in women in their 40s and 50s, usually as the result of weakened muscles and ligaments in the pelvis following childbirth
Signs and Symptoms	Urgency, frequency, nocturia, and a large amount of urine loss	Involuntary loss of a small amount of urine in response to physical activity that raises intra-abdominal pressure

Contributing factors in urinary incontinence include:

• Fluid intake, especially alcohol, carbonated drinks, and caffeinated beverages

• Constipation: alters the position of the pelvic organs and puts pressure on the bladder

• Habitual "preventive" emptying: may result in training the bladder to hold only small amounts of urine

• Menopause and depletion of estrogen

• Chronic disease such as stroke, multiple sclerosis or diabetes

• Smoking: nicotine increases detrusor muscle contractions

• Advancing age: age-related anatomic changes provide less pelvic support

• Pregnancy and childbirth: damage to pelvic structures during childbirth

• Obesity: increases abdominal pressure (Schuiling & Likis, 2016).

Therapeutic Management

Treatment options depend on the type of UI. In general, the least invasive procedure with the fewest risks is the first choice for treatment. Surgery is used only if other methods have failed. There is a widespread belief that UI is an inevitable problem of getting older and that little or nothing can be done to relieve symptoms or reverse it. Nothing is further from the truth, and attitudes must change so that women will feel comfortable seeking help for this embarrassing condition.

For many women with urge incontinence, simple reassurance and lifestyle interventions might help. The promotion of a healthy weight can help to reduce incontinence related to obesity. However, if more than simple lifestyle measures are needed, effective treatments might include:

• Bladder training to establish normal voiding intervals (every 3 to 5 hours)

• Pelvic floor muscle exercises to strengthen the pelvic floor musculature

• Pessary ring to support pelvic structures that have weakened

• Pharmacotherapy to reduce the urge to void. Anticholinergic agents such as oxybutynin (Ditropan) or tolterodine (Detrol) or oxybutynin (Oxytrol) might be prescribed. The most common side effects of anticholinergic agents are dry mouth, blurred vision, constipation, nausea, dizziness, and headaches (King et al., 2015).

For women with stress incontinence, treatment is not always a cure, but it can minimize the impact of this condition on the woman's quality of life. Some treatment options for stress incontinence might include:

• Weight loss if needed

• Avoidance of constipation

• Smoking cessation

• Pelvic floor muscle exercises to strengthen the pelvic floor

• Pessaries

• Weighted vaginal cones to improve the tone of pelvic floor muscles

• Periurethral injection (injecting a bulking agent [collagen] to form a bulge that brings the urethral walls closer together to achieve a better closure)

• Medications such as duloxetine (Cymbalta, Yentreve) to increase urethral sphincter contractions during the storage phase of the urination cycle

- Estrogen replacement therapy to improve bladder sphincter tone
- Surgery to correct genital prolapse and improve urethral and bladder tone.

Consider This

Life can be complicated and embarrassing at times when we least expect it. I met a man in church who seemed interested in me, and he asked me out for coffee after Sunday services. I have been alone for 10 years and this prospect seemed exciting to me. We talked for hours over coffee and seemed to have a great deal in common, especially since both of us had lost our spouses to cancer. He asked me to go square dancing with him, since that was an activity we both had enjoyed in the past with our spouses. I hadn't been out or physically active for ages and didn't realize how my body had changed with age.

It was during the first dance that I noticed a wet sensation between my legs, which I was unable to control. I managed to continue on and pretend that all was fine, but then realized what many of my friends were talking about—stress incontinence. Not being able to control one's urine is very embarrassing and it complicates your life, but I made up my mind that it wasn't going to control me!

Thoughts: *Gravity and childbirth take a toll on women's reproductive organs by pushing them downward. This woman is not going to let stress incontinence curtail her outside activity, which demonstrates a good attitude. What can be done about her embarrassing accidents? Were there any preventive strategies she could have used at an earlier age?*

Nursing Assessment

The assessment of the woman experiencing UI includes a history, physical examination, laboratory tests, and possibly urodynamic testing. The onset, frequency, severity, and pattern of incontinence should be determined, as well as any associated symptoms such as frequency, dysuria, urgency, and nocturia. Incontinence may be quantified by asking the woman if she wears a pad and how often the pad is changed. A review of the woman's current medications,

including over-the-counter medications, should be included in the history.

A complete physical examination should be carried out by the health care provider; it should include a neurologic assessment and pelvic and rectal examinations. The presence of associated POP should be noted because it can contribute to the woman's voiding problems and may have an impact on diagnosis and treatment. A rectal examination is done to evaluate sphincter tone and perineal sensation. A "cough stress test' can be performed by asking the woman to cough with a full bladder and subsequently observing for leakage of urine from the urethra can also help in assessing the client's ability to control voiding.

A urinalysis is performed to look for hematuria, pyuria, glucosuria, or proteinuria. A urine culture is done if there is pyuria or bacteriuria. Postvoid residual should be measured either with pelvic ultrasound or directly with a catheter. If the residual exceeds the limit set, urodynamic testing is then used to diagnose the incontinence.

Nursing Management

Incontinence can be devastating and can cause psychosocial concerns and isolation. Nurses can encourage women with troublesome symptoms to seek help. Discuss the treatment options with the client, including benefits and potential outcomes, and encourage her to select the continence treatment best for her lifestyle. Provide education about good bladder habits and strategies to reduce the incidence or severity of incontinence (Teaching Guidelines 7.2). Provide support and encouragement to ensure adherence to the guidelines. Remember that aging can increase the risk of incontinence, but incontinence is not an inevitable part of aging. Review the anatomy and physiology of the urinary system and offer simple explanations to help the woman cope with urinary alterations. Therapeutic listening is important. Be aware of the courage it takes for a woman to disclose an embarrassing condition.

Teaching Guidelines 7.2

MANAGING URINARY INCONTINENCE

• Avoid drinking too much fluid (i.e., 1.5 L total daily limit), but do not

decrease your intake of fluids.

- Reduce intake of fluids and foods that are bladder irritants and precipitate urgency, such as chocolate, caffeine, sodas, alcohol, artificial sweetener, hot spicy foods, orange juice, tomatoes, and watermelon.
- Increase fiber and fluids in your diet to reduce constipation.
- Control blood glucose levels to prevent polyuria.
- Treat chronic cough.
- Remove any barriers that delay you from reaching the toilet.
- Practice good perineal hygiene by using mild soap and water. Wipe from front to back to prevent urinary tract infections.
- Become aware of adverse drug effects.
- Take your medications as prescribed.
- Continue to do pelvic floor muscle exercises.

Adapted from Files, J. A., Mayer, A. P., & Chutka, D. S. (2015). Urinary incontinence: Not just a mid-laugh crisis. *Journal of Women's Health*, 24(1), 107–108; McClurg, D., Gerrard, J., & Hove, R. T. (2015). Reducing the incidence of incontinence. *British Journal of Midwifery*, 23(1), 17–20; and Vasavada, S. P., Carmel, M. E., & Rackley, R. (2015). Urinary incontinence. *eMedicine*. Retrieved from http://emedicine.medscape.com/article/452289-overview

Take Note!

Simple diet and lifestyle alterations, combined with a proper pelvic floor muscle strengthening program, can often produce significant improvements for women of all ages.

BENIGN GROWTHS

The most common benign growths of the reproductive tract include cervical, endocervical, and endometrial polyps; uterine fibroids (leiomyomas); genital fistulas; Bartholin's cysts; and ovarian cysts.

Polyps

Polyps are small, usually benign growths. The incidence of malignancy in cervical polyps is 1 in 1,000. Malignancy is more common in perimenopausal or postmenopausal women (Nelson, Papa, & Ritchie, 2015). The cause of polyp growth is not well understood, but they are frequently the result of infection. Polyps might be associated with chronic inflammation, an abnormal local response to increased levels of estrogen, or local congestion of the cervical vasculature (Stewart, 2016). Single or multiple polyps might occur. They are most common in multiparous women. Polyps can appear anywhere but are most common on the cervix and in the uterus (Fig. 7.3).

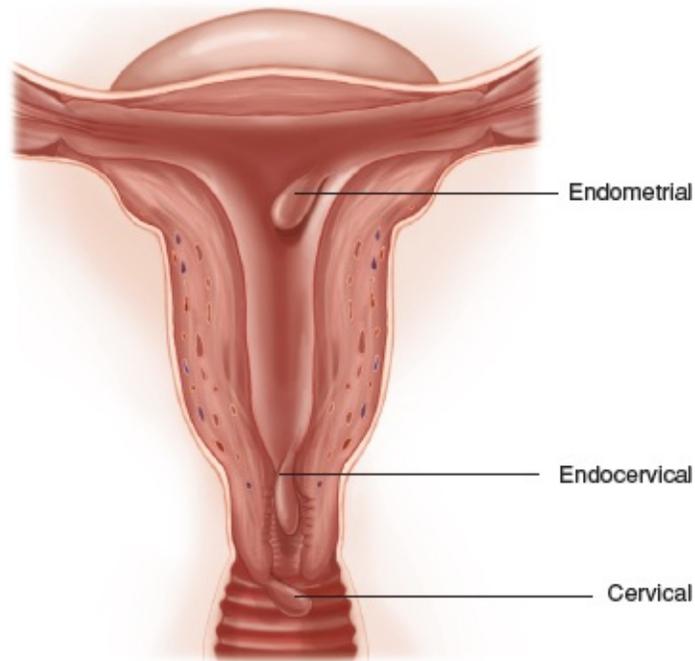
Cervical polyps often appear after menarche. They occur in 2% to 5% of women, and approximately 2% of these polyps have cancerous changes (Schuiling & Likis, 2016). Endocervical polyps are commonly found in multiparous women ages 40 to 60. Endocervical polyps are more common than cervical polyps, with a stalk of varied width and length. Endometrial polyps are benign tumors or localized overgrowths of the endometrium. Most endometrial polyps are solitary, and they rarely occur in women younger than 20 years of age. The incidence of these polyps rises steadily with increasing age, peaks in the fifth decade of life, and gradually declines after menopause. They are present in up to 25% of women being seen for abnormal bleeding (Lieng, 2015).


FIGURE 7.3 Cervical, endocervical, and endometrial polyps.

Therapeutic Management

Treatment of polyps usually consists of simple removal with small forceps done on an outpatient basis, removal during hysteroscopy, or dilation and curettage. The polyp base can be removed by laser vaporization. Because many polyps are infected, an antibiotic may be ordered after removal as a preventive measure or to treat early signs of infection.

Although polyps are rarely cancerous, a specimen should be sent after surgery to a pathology laboratory to exclude malignancy. A cervical biopsy typically reveals mildly atypical cells and signs of infection. Polyps rarely return after they are removed. Regularly scheduled Pap smears are suggested for women with cervical polyps to detect any future abnormal growths that may be malignant.

Nursing Assessment

Nursing assessment for a woman with polyps includes assisting with the physical examination and preparing the collected specimen to be sent to the cytologist.

CLINICAL MANIFESTATIONS

Assess for clinical manifestations of polyps. Most endocervical polyps are cherry red, whereas most cervical polyps are grayish-white (Heller, 2015). Cervical and endocervical polyps are often asymptomatic, but they can produce mild symptoms such as abnormal vaginal bleeding (after intercourse or douching, between menses) or discharge. The most common clinical manifestation of endometrial polyps is metrorrhagia (irregular, acyclic uterine bleeding).

PHYSICAL EXAMINATION AND LABORATORY AND DIAGNOSTIC STUDIES

Typically, cervical polyps are diagnosed when the cervix is visualized through a speculum during the woman's annual gynecologic examination (Nelson, Papa, & Ritchie, 2015). Endometrial polyps are not detected on physical examination, but rather with ultrasound or hysteroscopy (introduction of a small camera through the cervix to visualize the uterine cavity).

Nursing Management

Nursing management of polyps involves explaining the condition and the rationale for removal and giving follow-up care instructions. The nurse also assists the health care provider with the removal procedure.

Uterine Fibroids

Uterine fibroids, also known as myomas or leiomyomas, are benign tumors composed of smooth muscle and fibrous connective tissue in the uterus. Unlike cancerous tumors, fibroids usually grow slower responding to present estrogen levels and their cells do not break away and invade other parts of the body. Fibroids are classified according to their position in the uterus and on the uterine layer most involved (Fig. 7.4):

• *Subserosol fibroids:* lie underneath the outermost peritoneal layer of the uterus and grow outside the uterus. They are attached to the uterus by a stalk or peduncle.

• *Intramural fibroids:* grow within the wall of the uterus and are the most common type

• *Submucosal fibroids:* grow from immediately below the inner uterine surface (endometrium) into the uterine cavity (King et al., 2015).

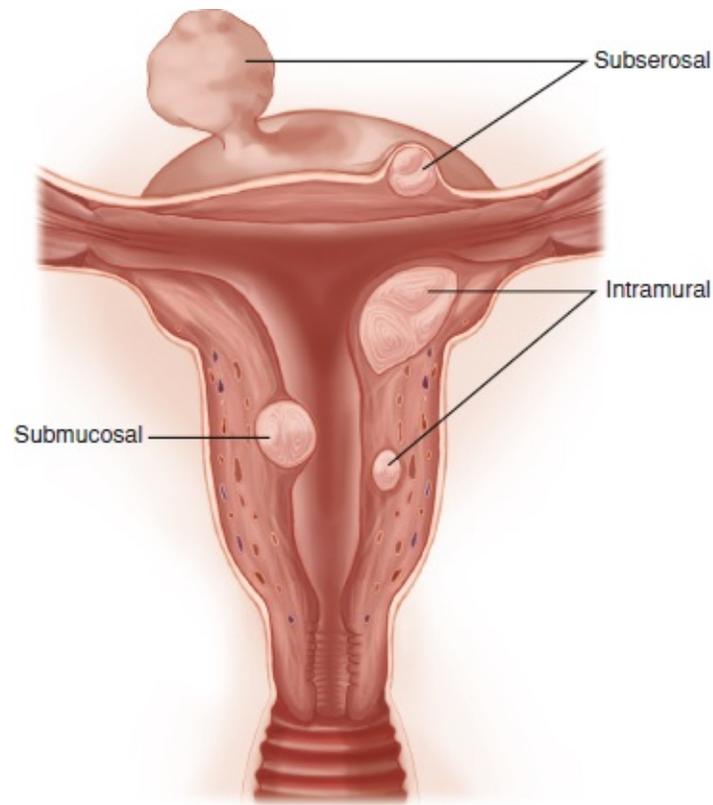
Fibroids are estrogen-dependent and thus grow rapidly during the childbearing years, when estrogen is plentiful, but they shrink during menopause, when estrogen levels decline. It is believed that these benign tumors develop in up to 70% of all women over 30 years of age, but up to 50% are asymptomatic (Stewart, 2015). It is difficult to be precise because fibroids may cause no symptoms, and thus many women do not know they have them.


FIGURE 7.4 Submucosal, intramural, and subserosal fibroids.

Fibroids are the most common indication for hysterectomy in the United States. The peak incidence occurs around age 45, and they are three times more prevalent in African American women than White women (Stewart, 2015).

Etiology

Although the cause of fibroids is unknown, several predisposing factors have been identified, including:

• Age (late reproductive years)

• Genetic predisposition

• African-American ethnicity

• Hypertension

• Nulliparity

• Obesity (Alexander et al., 2014).

Therapeutic Management

Treatment depends on the size of the fibroids and the woman's symptoms, which can include heavy or painful menses, feeling "full" in the lower pelvis, urinating frequently, pain during sexual relations, lower back pain, and infertility (NIH, 2015b). Several treatment options exist, ranging from watchful waiting to surgery.

MEDICAL MANAGEMENT

The goals of medical therapy are to reduce symptoms and/or to reduce the tumor size. This can be accomplished with pain medications to treat mild or occasional pain from fibroids; birth control pills to control heavy menses; or gonadotropin-releasing hormone (GnRH) agonists such as leuprolide (Lupron), nafarelin (Synarel), or goserelin (Zoladex), which stop ovulation and the production of estrogen, or low-dose mifepristone, a progestin antagonist. Both have produced regression and reduced the size of the tumors without surgery, but long-term therapy is expensive and not tolerated by most women. The side effects of GnRH medications include hot flashes, headaches, mood changes, vaginal dryness, musculoskeletal malaise, bone loss, and depression (King et al., 2015). Long-term mifepristone therapy can result in endometrial hyperplasia, which increases the risk of endometrial malignancy. Once either therapy is stopped, the fibroids typically recur.

Uterine artery embolization (UAE) is an option in which polyvinyl alcohol pellets are injected into selected blood vessels via a catheter to block circulation to the fibroid, causing it to shrink and producing symptom resolution. The procedure is carried out by an interventional radiologist who makes a tiny incision in the groin, introduces a fine catheter into the main artery leading to the uterus, and injects tiny particles of plastic or gelatin sponge into the artery that supplies blood to the fibroid. These particles stop the flow of blood, causing the fibroid to shrink or disappear completely over time. UAE has short-term advantages over surgery. Over the mid and long term, the benefits were similar, except for a higher re-intervention rate after UAE (Hehenkamp, Huirne, & Brolmann, 2015). There remains a need for a treatment that is noninvasive and that preserves fertility.

SURGICAL MANAGEMENT

For women with large fibroids or severe menorrhagia, surgery is preferred over medical treatment. Surgical management might involve myomectomy, laser surgery, or hysterectomy.

Myomectomy. Myomectomy involves removing the fibroid alone. A myomectomy is performed via laparoscopy, through an abdominal incision or through a vaginal approach. The advantage is that only the fibroid is removed; fertility is not jeopardized because this procedure leaves the uterine muscle walls intact. Myomectomy relieves symptoms but does not affect the underlying process; thus, fibroids grow back and further treatment will be needed in the future.

Laser Surgery. Laser surgery (or electrocauterization) involves destroying small fibroids with lasers. Laser therapy can be done using a vaginal approach or laparoscopically. The laser treatment preserves the uterus, but the process may cause scarring and adhesions, thus impairing fertility (Shigetomi et al., 2015). Fibroids can return after this procedure. Controversy remains as to whether laser treatment weakens the uterine wall and thus may contribute to uterine rupture in the future.

Hysterectomy. A hysterectomy is the surgical removal of the uterus. It is the most effective treatment for symptomatic fibroids with no recurrence. After cesarean section, it is the second most frequently performed surgical procedure for women in the United States. Approximately 600,000 hysterectomies are performed annually in the United States (Centers for Disease Control and Prevention [CDC], 2015). The top three conditions associated with hysterectomies are fibroids, endometriosis, and uterine prolapse (CDC, 2015). A hysterectomy to remove fibroids eliminates both the symptoms and the risk of recurrence, but it also terminates the woman's ability to bear children. Three types of hysterectomy surgeries are available: vaginal hysterectomy, laparoscopically assisted vaginal hysterectomy, and abdominal hysterectomy.

In a vaginal hysterectomy, the uterus is removed through an incision in the posterior vagina. Advantages include a shorter hospital stay and recovery time and no abdominal scars. Disadvantages include a limited operating space and poor visualization of other pelvic organs.

In a laparoscopically assisted vaginal hysterectomy, the uterus is removed through a laparoscope, through which structures within the abdomen and pelvis are visualized. Small incisions are made in the abdominal wall to permit the laparoscope to enter the surgical site. Advantages include a better surgical field, less pain, lower cost, and a shorter recovery time. Disadvantages include potential injury to the bladder and the inability to remove enlarged uteruses and

scar tissue.

In an abdominal hysterectomy, the uterus and other pelvic organs are removed through an incision in the abdomen. This procedure allows the surgeon to visualize all pelvic organs and is typically used when a malignancy is suspected or a very large uterus is present. Disadvantages include the need for general anesthesia, a longer hospital stay and recovery period, more pain, higher cost, and a visible scar on the abdomen.

Complications of hysterectomy vary based on route of surgery and technique. The most common complications include infection, venous thromboembolic, genitourinary and gastrointestinal injuries, and hemorrhage (Goldman et al., 2015). With astute nursing observations and assessments, these complications can be reduced or minimized. A summary of treatment options for uterine fibroids is presented in Table 7.1.

Nursing Assessment

Nursing assessment for the woman with uterine fibroids includes a thorough health history, physical examination, and laboratory and diagnostic studies.

HEALTH HISTORY AND CLINICAL MANIFESTATIONS

The history should include questions about the woman's menstrual cycle, including alterations in the menstrual pattern (e.g., pain or pressure, aggravating and alleviating factors), history of infertility, and any history of spontaneous abortion, which might indicate a space-occupying uterine lesion. Ask if any female relatives have had fibroids, because there is a familial predisposition. Assess for clinical manifestations of uterine fibroids. Symptoms of fibroids depend on their size and location and may include:

• Chronic pelvic pain

• Low back pain

• Iron-deficiency anemia secondary to bleeding

• Bloating

• Constipation

• Infertility (with large tumors)

• Dysmenorrhea

• Miscarriage

• Sciatica

• Dyspareunia

• Urinary frequency, urgency, incontinence

• Irregular vaginal bleeding (menorrhagia)

• Feeling of heaviness in the pelvic region

TABLE 7.1 SUMMARY OF TREATMENT OPTIONS FOR UTERINE FIBROIDS

Method	Advantages	Disadvantages
Hormones	Noninvasive Reduces size of fibroids Symptom improvement	Serious side effects with long-term use Fibroids regrow when meds stopped
Uterine artery embolization	Minimally invasive Dramatic decrease in symptoms Future fertility possible	Procedure frequently painful Requires radiation and contrast dye Permanently implanted material Possible negative fertility impact
Myomectomy	Performed as minor surgery Uterus is preserved	Requires general anesthesia New growth of fibroids occurs
Hysterectomy	Complete removal of fibroids Immediate symptom relief	Requires general anesthesia Major surgery with associated risks Fertility not preserved
Laser surgery	Can be done as an outpatient procedure to destroy small fibroids.	Vaporization process can cause scarring and adhesions, affecting future fertility.

PHYSICAL EXAMINATION AND LABORATORY AND DIAGNOSTIC STUDIES

The bimanual examination performed by the health care provider typically shows an enlarged, irregular uterus. The uterus may be palpable abdominally if the fibroid is very large. Ultrasound may be used to confirm the diagnosis.

Nursing Management

The level of support that nurses can provide women with fibroids depends on the type of treatment offered and her choice of them. Nurses should be able to explain any current treatment options and the implications of a diagnosis of fibroids. Many women have not heard of fibroids previously and need reassurance that they are both common and benign. If medication is prescribed, it is essential to explain the possible side effects and why medication can only be taken for a limited duration. If surgery is selected, verbal and written information

about it and the aftercare should be addressed (Box 7.2).

A woman undergoing a hysterectomy for the treatment of fibroids often needs special care and can benefit from presurgical and postsurgical support provided by nurses. Personalized nursing, tailored to the individual woman's needs, enhances the client's coping strategies and alleviates different adverse psychological sequelae following gynecologic surgery. Women must cope with a variety of psychological adjustment difficulties, related to the changes in self-image, self-esteem, loss of femininity or identity, and sexual dysfunction. The incidence of post-surgical problems can be reduced greatly with proper client-centered perioperative nursing care.

Genital Fistulas

Genital fistulas are an underestimated problem worldwide and have devastating consequences for women. Genital fistulas are abnormal openings between a genital tract organ and another organ, such as the urinary tract or the gastrointestinal tract. A fistula can result from a congenital anomaly, surgical complications, Bartholin's gland abscesses, radiation, or malignancy, but the majority of fistulas that occur worldwide are related to obstetric trauma and female genital cutting (Spurlock, 2015). During normal labor, the bladder is displaced upward into the abdomen, and the anterior vaginal wall, the base of the bladder, and the urethra are compressed between the fetal head and the posterior pubis. When labor is obstructed or prolonged, this unrelieved compression causes ischemia, which causes pressure necrosis and subsequent fistula formation.

Common types of fistulas include:

• *Vesicovaginal:* communication between the bladder and genital tract

• *Urethrovaginal:* communication between the urethra and the vagina

• *Rectovaginal:* communication between the rectum or sigmoid colon and the vagina

The direct consequences of this damage include urinary incontinence and fecal incontinence if the rectum is involved. This tragic condition has plagued women since the beginning of history (Taylor & Rakinic, 2015). Another major cause of genital trauma leading to the development of genital fistulas is female genital cutting. This cultural practice, primarily carried out in Africa and Asia, is receiving worldwide attention as part of the international public health agenda to move toward reducing its incidence. Reasons for continuing this practice include rite of passage, preserving chastity, ensuring marriageability, religion, hygiene, improving fertility, and enhancing sexual pleasure for men (Nour, 2015). Because of migration, health care providers are increasingly confronted with the range of negative urogynecological effects that result from this practice. Nurses need to have a deeper understanding of the history, cultural beliefs, medical complications, and methods of surgical reconstruction to provide culturally competent care to this unique group of women. This cultural practice will be addressed in detail in Chapter 9.

BOX 7.2

NURSING INTERVENTIONS FOR A WOMAN UNDERGOING A HYSTERECTOMY

Preoperative Care

• Instruct the client and her family about the procedure and aftercare.

• Provide interventions to reduce anxiety (due to perceived threats to the woman's self-concept and role functioning) and fear of alteration in body image, complications, and pain. Prepare the woman so that she knows what to expect throughout her perioperative experience. Explain postoperative pain management procedures that will be used. Identify the high-risk woman early to reduce her stress.

• Teach turning, deep breathing, and coughing before surgery to prevent postoperative atelectasis and respiratory complications such as pneumonia.

• Encourage the woman to discuss her feelings. Some women equate their femaleness with their reproductive capability, and loss of the uterus could evoke grieving.

• Complete all preoperative orders in a timely manner to allow for rest.

Postoperative Care

• Provide comfort measures.

• Administer analgesics promptly or use a patient-controlled anesthesia pump.

• Administer antiemetics to control nausea and vomiting per order.

• Change the client's linens and gown frequently to promote hygiene.

• Change the client's position frequently and use pillows for support to promote comfort and pain management.

• Assess the incision, the dressing, and vaginal bleeding and report if bleeding is excessive (soaking perineal pad within an hour).

• Monitor elimination and provide increased fluids and fiber to prevent constipation and straining.

• Encourage ambulation and active range-of-motion exercises when in bed to prevent thrombophlebitis and venous stasis.

• Monitor vital signs to detect early complications.

• Be comfortable discussing sexual concerns with the client.

Therapeutic Management

Many small fistulas will heal without treatment, but large fistulas often require surgical repair; surgery may be postponed until the edema or inflammation in the surrounding tissues has dissipated. Surgical repair of fistulas is associated with a high success rate if it is done in a timely manner, but larger fistulas and those of long duration have a poorer prognosis (Jellison & Raz, 2015).

Nursing Assessment

The history should include questions about any changes in the woman's urinary and bowel patterns. Assess for common signs and symptoms of fistulas, which

are related to the type of fistula. If the opening involves the rectum, feces and flatus will leak through the vagina. If it involves the bladder, urine will leak from the vagina. Depending on the location and size of the fistula, the woman may or may not experience discomfort. The health care provider can detect these abnormal openings through inspection and palpation during the pelvic examination. Diagnostic or laboratory tests are generally not ordered once this condition is found.

Nursing Management

Provide guidance and support. Offer information to help the woman learn about her condition and, with appropriate intervention, to improve her quality of life. Begin by making sure the woman understands her anatomy and why she is having such symptoms. Provide a thorough explanation of the treatment options so that she can make an informed decision. Be sensitive to the woman's feeling of shame and fear about her incontinence; these feelings may be why she delayed seeking treatment. Address all of the woman's needs, both physical and emotional.

Bartholin's Cysts

A Bartholin's cyst is a swollen, fluid-filled, sac-like structure that results when one of the ducts of the Bartholin's gland becomes blocked. The cyst may become infected and an abscess may develop in the gland. The Bartholin's glands are two mucus-secreting glandular structures with duct openings bilaterally at the base of the labia minora near the opening of the vagina that provide lubrication during sexual arousal. Normally these glands cannot be felt or seen unless they are infected. Bartholin's cysts are the most common cystic growths in the vulva, affecting approximately 2% of women at some time in their life (Reif et al., 2015).

Therapeutic Management

Treatment can be conservative or surgical depending on the symptoms, the size of the cyst, and whether it is infected or not. Small asymptomatic cysts do not require treatment. Sitz baths along with analgesics are used to reduce discomfort. Antibiotics are prescribed if the gland is infected. The aim of treatment for a cyst or abscess is to create a fistulous tract from the dilated duct to the outside vulva by incision and drainage. However, cysts or abscesses tend to return if this option is used.

Other treatment options beyond incision and drainage include placement of a Word catheter or a small loop of plastic tubing secured in place to prevent closure and to allow drainage. The use of a carbon dioxide laser to remove the cyst is also possible. After the Word catheter is inserted, the balloon tip is inflated and it is left in place for 4 to 6 weeks. The follow-up of the plastic tubing for removal is in approximately 3 weeks. Both procedures are safe and effective alternatives to surgery (Prabhu & Gardella, 2015). Treatment for a pregnant woman with a Bartholin's cyst depends on the severity of the symptoms and whether an infection is present. Surgery may be delayed until after the woman gives birth if there are no symptoms.

Nursing Assessment

Nursing assessment for the woman with a Bartholin's cyst includes a thorough health history, physical examination, and laboratory and diagnostic tests.

HEALTH HISTORY

The history should include questions about the woman's sexual practices and protective measures used. Assess for common signs and symptoms of Bartholin's cysts. The woman may be asymptomatic if the cyst is small (less than 5 cm) and not infected. If infection is present, symptoms include varying degrees of pain, especially when walking or sitting; unilateral edema; redness around the gland; and dyspareunia. Extensive inflammation may cause systemic symptoms. Abscess formation occurs when the cystic fluid becomes infected. An abscess usually develops rapidly over a 2- to 3-day period and may spontaneously rupture. A history of sudden relief of pain following profuse discharge is highly suggestive of spontaneous rupture (Schuiling & Likis, 2016).

PHYSICAL EXAMINATION AND LABORATORY AND DIAGNOSTIC STUDIES

The diagnosis of Bartholin's cysts or abscesses is primarily made during a physical examination when a protruding tender labial mass is located. In women over the age of 40, there is an increased risk of malignancy, typically sarcomas which account for 2% of all invasive vulvar malignancies. They are characterized by rapid growth, high metastatic potential, frequent recurrences, aggressive behavior, and high mortality rate (Chokoeva et al., 2015). Cultures of the purulent abscess fluid and of the cervix should be obtained for *Neisseria gonorrhoeae* and *Chlamydia trachomatis* to rule out a sexually transmitted infection.

Nursing Management

Nurses must be aware of and knowledgeable about vulvar cysts and treatment options. The woman may be aware of a vulvar cyst secondary to the pain or may be unaware of it if it is asymptomatic. A Bartholin's cyst may be an incidental finding during a routine pelvic examination. Explain the cause of the cyst and assist with cultures if needed. Provide reassurance and support.

Ovarian Cysts

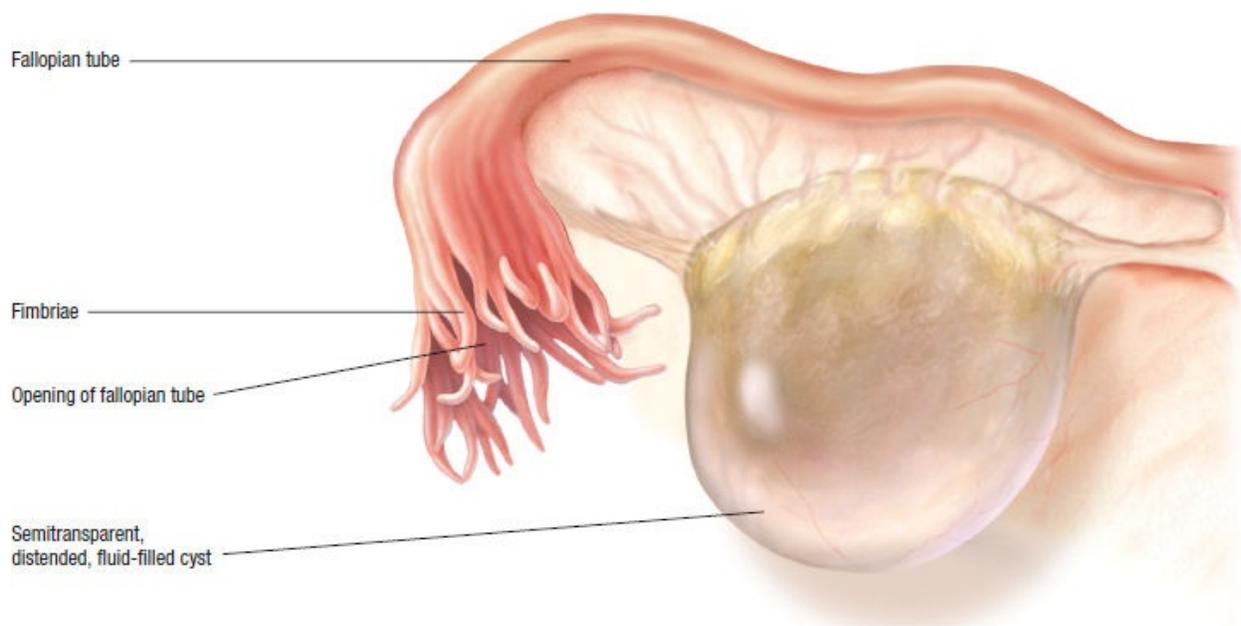
An **ovarian cyst** is a fluid-filled sac that forms on the ovary (Fig. 7.5). These very common growths are benign 90% of the time and are asymptomatic in many women. The cysts are discovered incidentally during an ultrasound or routine pelvic exam. Ovarian cysts occur in 30% of women with regular menses, 50% of women with irregular menses, and 7% of postmenopausal women (Templeman, 2015). When the cysts grow large and exert pressure on surrounding structures, women often seek medical help.


FIGURE 7.5 Ovarian cyst. (Asset provided by Anatomical Chart Co.)

Types of Ovarian Cysts

The most common benign ovarian cysts are follicular cysts, corpus luteum (lutein) cysts, theca-lutein cysts, and polycystic ovarian syndrome (PCOS).

FOLLICULAR CYSTS

Small follicular cysts are commonly found in the ovaries of prepubertal girls and women of reproductive age, and in most cases, they are of no clinical significance. They are usually self-limiting and resolve spontaneously. Follicular cysts are caused by the failure of the ovarian follicle to rupture at the time of

ovulation. Follicular cysts seldom grow larger than 5 cm in diameter; most regress and require no treatment. They can occur at any age and are rare after menopause. They are detected by vaginal ultrasound.

CORPUS LUTEUM (LUTEIN) CYSTS

A corpus luteum cyst forms when the corpus luteum becomes cystic or hemorrhagic and fails to degenerate after 14 days. These cysts might cause pain and delay the next menstrual period. A pelvic ultrasound helps to make this diagnosis. Typically these cysts appear after ovulation and resolve without intervention.

THECA-LUTEIN CYSTS

Prolonged abnormally high levels of human chorionic gonadotropin (hCG) stimulate the development of theca-lutein cysts. Although rare, these cysts are associated with hydatidiform mole, choriocarcinoma, polycystic ovary syndrome, and Clomid therapy.

POLYCYSTIC OVARY SYNDROME

Polycystic ovary syndrome is the most common endocrine condition in women of reproductive age. It is a heterogeneous condition that involves the presence of multiple inactive follicle cysts within the ovary that interfere with ovarian function. It is a multifaceted disorder, and central to its pathogenesis are hyperandrogenemia and hyperinsulinemia, which are targets for treatment (King et al., 2015). It is associated with obesity, hyperinsulinemia, elevated luteinizing hormone levels (linked to ovulation), elevated androgen levels (virilization), hirsutism (male-pattern hair growth), obstructive sleep apnea, follicular atresia (ovarian growth failure), ovarian growth and cyst formation, anovulation (failure to ovulate), infertility, type 2 diabetes, sleep apnea, amenorrhea (absence of menstruation or irregular periods), metabolic syndrome, which is characterized by abdominal obesity (waist circumference >35 in), dyslipidemia (triglyceride level >150 mg/dL, high-density lipoprotein cholesterol level <50 mg/dL), elevated blood pressure, a proinflammatory state characterized by an elevated C-reactive protein level, and a prothrombotic state characterized by elevated PAI-1 and fibrinogen levels. Recent studies also indicate that PCOS is associated with an increase in the risk of uterine fibroids, depression, adverse pregnancy outcomes and neonatal complications. A recent meta-analysis found that women

with PCOS demonstrated a significantly higher risk of developing gestational diabetes, gestational hypertension, preeclampsia, preterm birth, and had a higher cesarean section rate when compared to controls (Kyrou, Weickert, & Randeva, 2015). With an estimated prevalence of 5% to 10% of all females, PCOS is the most common cause of medically treatable infertility and is responsible for 70% of cases of anovulatory subfertility and up to 20% of couples' infertility cases (NIH, 2015c).

 Take Note!

Careful attention should be given to this condition because affected women are at increased risk for long-term health problems such as cardiovascular disease, hypertension, dyslipidemia, type 2 diabetes (half of all women), infertility, and cancer (endometrial, breast, and ovarian) (Moran, Norman, & Teede, 2015).

Initially PCOS was called Stein–Leventhal syndrome after its researchers, but it is now recognized to be an anabolic syndrome. Unfortunately, less than two-thirds of women are aware of their diagnosis or the concomitant high risk for developing type 2 diabetes mellitus and cardiovascular disease related to metabolic syndrome. Its etiology is not clearly understood, but studies suggest a genetic (autosomal-dominant) component. Women with PCOS have abnormalities in the metabolism of androgens and estrogen and in the control of androgen production. In addition, they have peripheral insulin resistance and hyperinsulinemia and obesity (Trikudanathan, 2015). All of these clinical manifestations must be addressed throughout the lifespan with an emphasis on prevention of cardiometabolic risks in the treatment plan.

Therapeutic Management

Treatment is centered on the clinical manifestations and should be initiated early to prevent/limit long-term complications such as metabolic syndrome, diabetes, endometrial carcinoma, and infertility (Ganie, Chakraborty, & Rehman, 2015). Oral contraceptives, antidiabetic agents, and statins are some of the common therapies used to address the symptoms of this complex hormonal condition. Weight loss and surgery may also be beneficial as non-drug options.

Treatment of ovarian cysts focuses on differentiating a benign cyst from a

solid ovarian malignancy. Transvaginal ultrasound is useful in distinguishing fluid-filled cysts from solid masses. Laparoscopy may be needed to remove the cyst if it is large and pressing on surrounding structures. For smaller cysts, monitoring with repeat ultrasounds every 3 to 6 months might be in order (Lucidi, 2015). Oral contraceptives are often prescribed to suppress gonadotropin levels, which may help resolve the cysts. Pain medication is also prescribed if needed.

Medical management of PCOS is aimed at the treatment of metabolic derangements, anovulation, hirsutism, and menstrual irregularity. This includes both drug and nondrug therapy, along with lifestyle modifications. Goals of therapy focus on reducing the production and circulating levels of androgens, protecting the endometrium against the effects of unopposed estrogens, supporting lifestyle changes to achieve ideal body weight, lowering the risk of cardiovascular disease, avoiding the effects of hyperinsulinemia on the risk of cardiovascular disease and diabetes, and inducing ovulation to achieve pregnancy if desired (Evidence-Based Practice 7.2). Treatment modalities for PCOS are highlighted in Box 7.3.

Nursing Assessment

Nursing assessment for the woman with PCOS includes a thorough health history, physical examination, and laboratory and diagnostic tests.

HEALTH HISTORY

The history should include questions about the woman's symptoms, including onset, location, frequency, quality, intensity, and aggravating and alleviating factors of her discomfort. Note the last menstrual period and whether or not her cycles are regular. Ask about her overall general health and any changes recently noticed, such as a change in abdominal girth without a concomitant weight gain. Assess for common signs and symptoms of ovarian cysts. Findings might include:

• Hirsutism (face and chin, upper lip, areola, lower abdomen, and perineum)

• Alopecia (frontal region and crown of head)

• Virilization (clitoral hypertrophy, deepening of voice, increased muscle mass, breast atrophy, male-pattern baldness)

• Menstrual irregularity and infertility (menorrhagia, anovulation)

- Polycystic ovaries (12 or more follicles on ovaries)
- Obesity (occurs in more than 50% of women with PCOS; occurs in abdominal region, with an increase in the waist–hip ratio)
- Insulin resistance (chronic hyperinsulinemia leads to type 2 diabetes)
- Metabolic syndrome (elevated cholesterol, triglycerides, low-density lipoprotein; risk of cardiovascular disease)
- Increased risk for endometrial cancer, ovarian cancer, breast cancer
- Psychological impact (depression, frustration, anxiety, eating disorders)
- Acne (face and shoulders) (Lucidi, 2015).

PHYSICAL EXAMINATION AND LABORATORY AND DIAGNOSTIC STUDIES

The physical examination includes inspection, auscultation, and palpation of the abdomen because large ovarian masses may cause visible changes in the abdomen. A complete pelvic examination is performed to assess the location, size, shape, texture, mobility, and tenderness of any palpable mass.

Diagnostic tests include a pregnancy test to rule out ectopic pregnancy. Gonorrhea and chlamydia testing is warranted if an ovarian abscess is suspected. An ultrasound may be ordered to differentiate between functional or simple ovarian cysts and a solid tumor. Additional tests may be performed depending on the findings.

EVIDENCE-BASED PRACTICE 7.2 IT'S NOT JUST PHYSICAL: THE ADVERSE PSYCHOSOCIAL EFFECTS OF POLYCYSTIC OVARY SYNDROME IN ADOLESCENTS

STUDY

The prevalence of depression and other psychological disorders in women with PCOS is high and varies in numerous studies. In particular, women with PCOS have been found to be at an increased risk of social phobia and suicide attempts. The reasons for a higher prevalence of psychological disorders in women with PCOS are likely to be complex. Some investigators suggest that physical symptoms experienced by women with PCOS are the likely cause of psychological distress. However, evidence is inconsistent. While acne, hirsutism and obesity have been linked to increased psychological distress in some studies, no link is demonstrated in others. It is likely that multiple factors contribute to the high prevalence of psychosocial disorders in women with PCOS.

This study sheds light on the fact that this gynecologic disorder of endocrine origin can be associated with a great number of psychological symptoms (e.g., depression, anxiety, body image dissatisfaction, eating and sexual disorders, and poor quality of life). The goal of the study was to address the prevalence of psychological disorders and determinants of well-being.

Findings

An overwhelming majority of scientific literature on PCOS has focused on the medical approach to analyze the disorder and only a few studies have investigated its predisposing psychological factors. The literature review revealed several psychological disorders that accompany this syndrome with limited attention given to them to help women cope. The symptoms typically associated with PCOS, including amenorrhea, oligomenorrhea, hirsutism, obesity, infertility, anovulation, and acne, can lead to symptoms of depression, withdrawal from society, emotional distress, embarrassment, lower self-esteem, anxiety, body image disturbances, eating disorders, marital and social maladjustment, and impaired sexual functioning.

Nursing Implications

PCOS is closely associated with psychological disorders with important implications that necessitate identification and treatment of the disorders. The high prevalence rate of these psychological disorders in this population suggests that initial evaluation of all women with PCOS should also include an assessment of their mental health. Psychological support by nurses should take on an important role in the management of the affected women with PCOS. This should not suggest that medical treatment of PCOS is not required, but a thorough cooperation between medical treatment and psychological support would improve the situation of PCOS affected women. The physical and psychosocial aspects of management of PCOS go hand in hand. Meeting physical management goals (e.g. weight loss, reduction in hyperandrogenism manifestations) can lessen some of the distressing psychosocial effects, and enhance self-esteem.

Adapted from Lee, J. S. (2015). It's not just physical: The adverse psychosocial effects of polycystic ovary syndrome in adolescents. *Women's Healthcare,* 3(1), 20–28.

Remember Liz, the client with irregular menses, facial hair, and acne? Her glucose level is elevated, multiple cysts were felt on her ovaries during the pelvic examination, and laboratory tests found elevated lipid and lipoprotein levels. What education should the nurse provide Liz regarding her PCOS diagnosis? What medications might be prescribed to address her abnormal laboratory values?

Nursing Management

Nursing care should include education about the condition, treatment options, diagnostic test arrangements, and referral for surgery if needed. Provide support and reassurance during the diagnostic period to allay anxiety in the client and her

family. Reassure the woman that the majority of ovarian cysts are benign, but regardless stress the importance of follow-up care. Listen to the woman's concerns about her appearance, infertility, and facial hair growth. Offer suggestions to help the woman feel better about herself and her health.

Nurses can have a positive impact on women with PCOS through counseling and education. Provide support for women dealing with negative self-image secondary to the physical manifestations of PCOS. Through education, help the woman understand the syndrome and its associated risk factors to prevent long-term health problems. Encourage the woman to make positive lifestyle changes. Make community referrals to local support groups to help the woman build her coping skills.

> *Liz returns to the clinic a month later for reevaluation of her PCOS. She has been taking metformin to reduce her insulin resistance and has followed her exercise regimen and reduced her caloric intake to lose weight, but she still complains about her facial hair and acne. What interventions might be helpful to address this problem? What medication might also be prescribed to regularize her menses and relieve the hirsutism?*

KEY CONCEPTS

- Pelvic floor disorders such as pelvic organ prolapse and urinary and fecal incontinence are prevalent conditions in aging women. They cause significant physical and psychological morbidity, with obvious detriment to women's social interactions, emotional well-being, and overall quality of life.

- The four most common types of genital prolapse are cystocele, rectocele, enterocele, and uterine prolapse.

- The purpose of pelvic floor muscle exercises is to increase the muscle volume, which will result in a stronger muscular contraction. These exercises might limit the progression of mild prolapse and alleviate mild prolapse symptoms, including low back pain and pelvic pressure.

- UI is the involuntary loss of urine sufficient enough to be a social or hygiene problem. It affects approximately 15 million women in the United States.

- The three most common types of incontinence are urge incontinence (overactive bladder caused by detrusor muscle contractions), stress

incontinence (inadequate urinary sphincter function), and mixed incontinence (involves both stress and urge incontinence).

- The most common benign growths of the reproductive tract include cervical, endocervical, and endometrial polyps; uterine fibroids (leiomyomas); genital fistulas; Bartholin's cysts; and ovarian cysts.

PCOS involves the presence of multiple inactive follicle cysts within the ovary that interfere with ovarian function. Hyperandrogenism, insulin resistance, and chronic anovulation characterize PCOS. Careful attention should be given to this condition because women with it are at increased risk for long-term health problems such as cardiovascular disease, hypertension, dyslipidemia, infertility, type 2 diabetes, and cancer (endometrial, breast, and ovarian).

CHAPTER **WORKSHEET**

MULTIPLE CHOICE QUESTIONS

1. When you are interviewing a client with uterine fibroids, what subjective data
   would you expect to find in her history?

   a. Cyclic migraine headaches

   b. Urinary tract infections

   c. Chronic pelvic pain

   d. Chronic constipation

2. Conservative treatment options available for women with pelvic organ
   prolapse are:

   a. Pessaries and PFM exercises

   b. External pelvic fixation devices

   c. Weight gain and yoga

   d. Firm panty-and-girdle garments

3. Which of the following dietary and lifestyle modifications might the nurse
   recommend to help prevent pelvic relaxation as women age?

   a. Eat a high-fiber diet to avoid constipation and straining.

   b. Avoid sitting for long periods; get up and walk around frequently.

   c. Limit the amount of exercise to prevent overdeveloping muscles.

   d. Space children a year apart to reduce wear and tear on the uterus.

4. Women with PCOS are at increased risk for developing which of the following long-term health problems?

   a. Osteoporosis

   b. Lupus

   c. Type 2 diabetes

   d. Migraine headaches

5. Side effects experienced by women taking GnRH agonists for the treatment of fibroids closely resemble those of:

   a. Anorexia nervosa

   b. Osteoarthritis

   c. Depression

   d. Menopause

6. In securing a health history of a 65-year-old woman, which clinical manifestation described by the client would the nurse suspect is related to pelvic organ prolapse?

   a. Chronic abdominal pain

   b. Heavy feeling or dragging in vagina

   c. Uterine cramping and backache

   d. Weight gain and edema of ankles

CRITICAL THINKING EXERCISE

1. Faith, a 42-year-old multiparous woman, presents to the women's health clinic complaining of pelvic pain, menorrhagia, and vaginal discharge. She says she has been having these problems for several months. On examination, her uterus is enlarged and irregular in shape. Her blood studies reveal anemia.

   a. What condition might Faith have, based on her symptoms?

   b. What treatment options are available to address this condition?

   c. What educational interventions should the nurse discuss with Faith?

STUDY ACTIVITIES

1. Prepare an educational session to teach women how to do Pelvic floor muscle exercises to prevent stress incontinence and pelvic floor relaxation.

2. In a small group, discuss the personal, social, and sexual issues that might affect a woman with pelvic organ prolapse. How might these issues affect her socialization? How might a support group help?

3. List the symptoms that a woman with uterine fibroids might have. Discuss how these symptoms might mimic a more frightening condition and why the woman might delay seeking treatment.

4. A bladder that herniates into the vagina is a _____.

5. A rectum that herniates into the vagina is a _____.

BRINGING IT ALL TOGETHER: CASE STUDY

Elizabeth, a 52-year-old woman presents to the gynecologic clinic to discuss a 'horrible personal problem' that is ruining her life. She appears very distressed and only wants to talk to the nurse in private about it. A few months ago when she was out walking her dog, she experienced a sudden rectal urgency that she thought was gas, but she expelled feces instead. Over the past few months, her fecal incontinence has increased in severity and frequency causing her extreme stress. To avoid embarrassment, she has had to cover and excuse herself from work situations and turn down social invitations. She now has to wear a protective pad and disposable pants.

ASSESSMENT

Elizabeth is otherwise healthy and takes no prescription medications presently. She has had five vaginal births with three episiotomies. She has a body mass index of 27, mild stress urinary incontinence, and a low-grade rectocele with slightly decreased anal sphincter tone. Her pelvic exam demonstrated pelvic organ prolapse. The digital rectal exam ruled out fecal impaction and any rectal mass. A detailed history of her incontinence episodes was also taken.

Go to thePoint to find questions to consider about this case.

8

Cancers of the Female Reproductive Tract

KEY TERMS

cervical cancer
cervical dysplasia
colposcopy
cone biopsy
cryotherapy
endometrial cancer
human papillomavirus
ovarian cancer
Papanicolaou (Pap) test

vaginal cancer
vulvar cancer

Learning Objectives

Upon completion of the chapter, you will be able to:

1. Evaluate the major modifiable risk factors for reproductive tract cancers.
2. Analyze the screening methods and treatment modalities for cancers of the female reproductive tract.
3. Outline the nursing management needed for the most common malignant reproductive tract cancers in women.
4. Examine lifestyle changes and health screenings that can reduce the risk of or prevent reproductive tract cancers.
5. Assess at least three web site resources available for a woman diagnosed with cancer of the reproductive tract.
6. Appraise the psychological distress felt by women diagnosed with cancer, and outline information that can help them to cope.

> *Carmella is an obese, 55-year-old woman who presents to her woman's health care provider with vaginal bleeding. She has been through menopause and wonders why she is having a period again. Her history includes infertility and hypertension. Three years ago she had a mastectomy for breast cancer, and she has been taking tamoxifen (Nolvadex) to prevent recurrent breast cancer since her surgery. What risk factors in Carmella's history might predispose her to a reproductive tract cancer? What additional information is needed to make a diagnosis?*

WOW

Words of Wisdom

The word "cancer" can strike fear into anyone who hears it. But when it involves a reproductive organ, this fear is often magnified.

INTRODUCTION

Cancer is the second leading cause of death for women in the United States, surpassed only by cardiovascular disease (Centers for Disease Control and Prevention [CDC], 2015a). Cardiovascular disease is, and should continue to be, a major focus of efforts in women's health. However, this should not overshadow the fact that many women between the ages of 35 and 74 are developing and dying of cancer (National Cancer Institute [NCI], 2015a). Women have a one-in-three lifetime risk of developing cancer, and one out of every four deaths is from cancer (Alexander et al., 2014). African American women have the highest death rates from both heart disease and cancer (CDC, 2015a). The American Cancer Society (ACS) (2015a) estimated that, in 2015, there were about 1,658,370 new cancer cases diagnosed and about 589,430 cancer deaths in the United States. Scientific evidence suggested that about one third of these cancer deaths expected to occur in 2015 were related to obesity, physical inactivity, and poor nutrition, and thus could have been prevented. Certain cancers are related to infectious agents, such as hepatitis B virus (HBV), human papillomavirus (HPV), human immunodeficiency virus (HIV), and *Helicobacter pylori* (*H. pylori*), and can be prevented through behavioral changes, vaccines, or antibiotics (Herrington, Coates, & Duprex, 2015). In addition, many of the more than 2 million skin cancers that are diagnosed annually could be prevented by protecting the skin from the sun's rays and avoiding indoor tanning. Sunburns, especially if they occur repetitively in childhood, may lead to melanoma. Most melanomas are treated successfully if discovered early, but metastatic melanoma has no good treatment (Balk, 2015).

It has been estimated that in the United States, half of all premature deaths, one third of acute disabilities, and one half of chronic disabilities are preventable, including some cancers (NCI, 2015b). Nurses need to focus their energies on screening, education, and early detection to reduce these numbers. Because cancer risk is strongly associated with lifestyle and behavior, screening programs are of particular importance for early detection. There is evidence that prevention and early detection have reduced cancer mortality rates and prevented reproductive cancers (CDC, 2015b).

This chapter begins with a nursing process overview of the care of women with reproductive cancer. It then describes selected cancers of the reproductive

system: ovarian, endometrial, cervical, vaginal, and vulvar cancer. The chapter discusses the nurse's role through diagnosis, intervention, and follow-up care. Cancer management requires a multidisciplinary approach, including specialists in surgical, medical, and radiation oncology. The nurse can provide guidance and support to the client as she finds her way through the health care maze.

NURSING PROCESS OVERVIEW FOR WOMEN WITH CANCER OF THE REPRODUCTIVE TRACT

The word *cancer* is laden with fear and dread. These feelings may worsen when the cancer involves a woman's reproductive tract. The diagnosis of a reproductive tract cancer can have a profound impact on a woman's sexuality because it affects the very core of her identity as a female. The loss of the reproductive body part as well as the possible loss of childbearing ability can have a significant effect on women and their partners. Nurses need to remember this when counseling women and their partners about cancer treatment and side effects and changes in gender roles and sexuality.

When a woman is first diagnosed with a reproductive tract cancer, two primary needs arise: information and emotional support. When the diagnosis is made, the woman typically has many questions, such as "What is going to happen to me?" "How will this change my life?" and "Will I survive?" Nurses can play a major role in helping women find the answers to their questions and directing them to the resources they need. Two reliable sources of general cancer information are the NCI and the American Cancer Society. They can be reached via the Internet or by phone.

The nurse also plays a key role in offering emotional support, determining appropriate sources of support, and helping the woman use effective coping strategies. A recent research study found that social support from the woman's family, friends, and coworkers is one of the strongest predictors of how well she will cope (Garner et al., 2015). Implications for nurses working with women following a cancer diagnosis include assessing women's definitions and availability of support; respecting varied needs for informational support; providing a supportive clinical environment; educating clinicians, family, and friends regarding unsupportive responses within the cultural context; and validating women's control and balancing of support needs. Nurses are well

positioned to provide women with anticipatory guidance from diagnosis to the end of treatment (Shirvani & Alhani, 2015). Women without a social support network may need a social work referral or may need to be guided toward support groups to receive the emotional support they need.

In addition, cancer clients have a strong need for hope. Strategies for inspiring hope may include active listening, touch, presence, and helping clients overcome communication barriers. Often it is not what nurses say or do but just their presence that counts.

Assessment

Assessment of a woman with cancer of the reproductive tract involves a thorough history and physical examination. In addition, various laboratory and diagnostic tests may be done to evaluate for a malignancy.

Health History and Physical Examination

Interview the woman carefully to determine any current or past factors that might increase her risk of cancer, such as early menarche, late menopause, sexually transmitted infections (STIs), use of hormonal agents, or infertility. Find out if the woman has a family history of cancer. Be thorough in obtaining the woman's past medical history, especially her reproductive, obstetric, and gynecologic history. Ask about her lifestyle and behaviors, including risky behaviors such as engaging in unprotected sexual intercourse or sexual intercourse with multiple partners. Find out if she has had routine or recommended screening procedures.

Ask if the woman has had any symptoms, such as abnormal vaginal bleeding or discharge or vaginal discomfort. Often the symptoms of cancer are vague and nonspecific and the woman may attribute them to another problem, such as aging, stress, or improper diet.

Perform a complete physical examination, including a review of body systems and a pelvic examination. Observe for lesions or masses in the perineal area. Note any masses when palpating the abdomen or when performing the pelvic examination.

Laboratory and Diagnostic Testing

Some of the laboratory and diagnostic tests used to help diagnose cancer of the reproductive tract are discussed in Common Laboratory and Diagnostic Tests 8.1.

COMMON LABORATORY AND DIAGNOSTIC TESTS 8.1

Test	Explanation	Indications	Nursing Implications
Clinical breast examination	Assessment of the breast for abnormal findings; client may discover lump herself; high-risk history for breast cancer	Identifies palpable mass, skin change, inverted nipple, or unresolved rash	• Educate client to perform breast self-examination and report any abnormalities of high risk. • Reinforce the need for frequent clinical breast examinations if risk factors are present.
Mammogra-phy	Screening modality for breast cancer or any distortion in breast tissue architecture	Detects calcifications, densi-ties, and nonpalpable cancer lesions	Stress the importance of annual mammo-grams for all women after the age of 40 or 50, depending on their risk history.
Pap smear	Cervical cytology screening to diag-nose cervical cancers	Aids in detecting abnormal cells of the cervix (from squamocolumnar junction of the cervix; most cervical cancers arise here)	Encourage all sexually active women to receive a pelvic examination, including a Pap smear if they have a high risk profile, to promote early detection of cervical cancer.
Transvaginal ultrasound	Screening for pelvic pathology to assist in diagnosing endome-trial cancers	Allows measurement of endo-metrial thickness to deter-mine if endometrial biopsy is needed for postmenopausal bleeding	• Review the risk factors for the develop-ment of endometrial cancer and reason for this screening test. • Assist in preparing the client for this examination.
CA-125	Nonspecific blood test used as a tumor marker	Elevation of marker suggests malignancy but is not spe-cific to ovarian cancer.	• Review risk factors for ovarian cancer and explain that a series of diagnostic tests may be performed (transvaginal ultra-sound, CT scan, CA-125) to assist in the diagnosis and treatment plan. • Elevated marker levels are not specific to ovarian cancer; they can be elevated in other types of cancer.

Nursing Diagnoses and Related Interventions

Upon completion of a thorough assessment, the nurse might identify several

nursing diagnoses, including:

• Deficient knowledge

• Disturbed body image

• Anxiety

• Fear

• Pain

Nursing goals, interventions, and evaluation for women with a reproductive cancer are based on the nursing diagnoses. Nursing Care Plan 8.1 may be used as a guide in planning nursing care for women with a reproductive cancer. It should be individualized based on the woman's symptoms and needs.

Nurses have traditionally served as advocates in the health care arena and should continue to be on the forefront of health education and diagnosis, acting as leaders in the fight against cancer. Over half a million women in the United States will be diagnosed with cancer this year alone and more than half will die of it (Siegel, Miller, & Jemal, 2015). The public needs to know that not only are these deaths preventable, but many of the cancers themselves are preventable. Nurses need to work to improve the availability and quality of cancer-screening services, making them accessible to underserved and socioeconomically disadvantaged clients. Through a unified effort by health care providers, health policy experts, government agencies, health insurance companies, the media, educational institutions, and women themselves, along with consistency and continuity, nurses can offer quality care to all women with cancer.

NURSING CARE PLAN 8.1

Overview of a Woman with a Reproductive Tract Cancer

Molly, a thin 28-year-old woman, comes to the free health clinic complaining of a thin, watery vaginal discharge and spotting after sex. Molly says she has had multiple sex partners since the age of 15. She had an abnormal Pap smear "a while back" but didn't return to the clinic for follow-up. Cervical cancer is suspected.

NURSING DIAGNOSIS: Anxiety related to uncertainty of diagnosis, possible diagnosis of cancer, and eventual outcome as evidenced by client's report of signs and symptoms and statements of being worried and not knowing what she would do

Outcome Identification and Evaluation
The client will demonstrate measures to cope with anxiety *as evidenced by statements acknowledging anxiety, use of positive coping strategies, and verbalization that anxiety has decreased*.

Interventions: *Reducing Anxiety*
• Encourage client to express her feelings and concerns *to reduce her anxiety and to determine appropriate interventions*.
• Assess the meaning of the diagnosis to the client, clarify misconceptions, and provide reliable, realistic information *to enhance her understanding of her condition, subsequently reducing her anxiety*.
• Assess client's psychological status *to determine the degree of emotional distress related to diagnosis and treatment options*.
• Identify and address verbalized concerns, providing information about what to expect *to decrease uncertainty about the unknown*.
• Assess the client's use of coping mechanisms in the past and their effectiveness *to foster use of positive strategies*.
• Teach client about early signs of anxiety and help her recognize them (e.g., fast heartbeat, sweating, or feeling flushed) *to minimize escalation of anxiety*.
• Provide positive reinforcement that the client's condition can be managed *to*

relieve her anxiety.

NURSING DIAGNOSIS: Deficient knowledge related to diagnosis, prevention strategies, disease course, and treatment as evidenced by client's statements about hoping nothing bad is wrong, lack of follow-up for previous abnormal Pap test, and high-risk behaviors

Outcome Identification and Evaluation

The client will demonstrate an understanding of diagnosis, *as evidenced by making health-promoting lifestyle choices, verbalizing appropriate health care practices, describing condition once diagnosed, and adhering to measures to comply with therapy.*

Interventions: *Providing Client Teaching*

• Assess client's current knowledge about her diagnosis and proposed therapeutic regimen *to establish a baseline from which to develop a teaching plan.*

• Review contributing factors associated with development of reproductive tract cancer, including lifestyle behaviors, *to foster an understanding of the etiology of cervical cancer.*

• Review information about treatments and procedures and recommendations for healthy lifestyle, obtaining feedback frequently *to validate adequate understanding of instructions.*

• Discuss strategies, including using condoms and limiting the number of sexual partners, *to reduce the risk of transmission of STIs*, including HPV, which is associated with cervical cancer.

• Encourage client to obtain prompt treatment of any vaginal or cervical infections *to minimize the risk for cervical cancer*.

• Urge the client to have an annual Pap smear and/or HPV test *to allow screening and early detection.*

• Describe the treatment measures used *to provide client with knowledge of what may be necessary*.

• Provide written material with pictures *to allow for client review and to help her visualize what is occurring in her body*.

• Inform client about available community resources and make appropriate referrals as needed *to provide additional education and support*.

• Document details of teaching and learning *to allow for continuity of care*

and further education, if needed.

NURSING DIAGNOSIS: Disturbed body image related to suspected reproductive tract cancer and impact on client's sexuality and sense of self as evidenced by statement of being worried about not being the same

Outcome Identification and Evaluation
The client will verbalize or demonstrate a positive self-esteem in relation to body image as evidenced by positive statements about self, sexuality, and participation in activities with others.

Interventions: *Promoting Healthy Body Image*
• Assess client's use of self-criticism to determine client's current state of coping and adjustment.
• Determine if the client's change in body image has contributed to social isolation to provide a direction for care.
• Provide opportunities for client to explore her feelings related to issues of sexuality, including past behaviors that may have placed her at risk, to minimize feelings of guilt about her condition.
• Acknowledge the client's feelings about possible changes in her body and sexuality and her illness to foster trust and allow client to ventilate feelings and concerns.
• Facilitate contact with other clients with the same type of cancer to promote sharing of feelings and decrease feelings of isolation.
• Initiate referrals for counseling and community support groups as necessary to assist client in gaining a positive image of herself.

Educating to Prevent Cancer

Globally, there are nearly 13 million new cases of cancer and 8 million deaths from cancer each year. The most important cause of cancer is tobacco, which causes 30% of cancer deaths. Dietary factors, including obesity, are estimated to cause around 25% of cancer deaths, and alcohol about 6% of cancer deaths. All of these factors associated with cancer are preventable (Key, 2015). Nurses need to provide clients with information to help prevent disease and enhance quality of life. Educate women about the importance of consistent and timely screenings

to identify cancer early. Emphasize the importance of having an annual pelvic examination. Also, stress the need for follow-up screenings as recommended. Provide clients with information if further diagnostic testing is required. Nurses also play a key role in promoting cancer awareness, prevention, and control. Advocate improving the availability of cancer-screening services and work to provide public education about risk factors for cancer.

Nurses can be instrumental in helping women to identify and change behaviors that put them at risk for various reproductive tract cancers (Teaching Guidelines 8.1). Do not limit your interventions to providing preventive education only: inform women about the consequences of doing nothing about their conditions and what the long-range outcomes might be without treatment. For example, stress the importance of visiting a health care provider if certain signs and symptoms appear:

• Blood in a bowel movement is considered abnormal

• Unusual vaginal discharge or chronic vulvar itching

• Persistent abdominal bloating or constipation

• Irregular vaginal bleeding

• Persistent low backache not related to standing

• Elevated or discolored vulvar lesions

• Bleeding after menopause

• Pain or bleeding after sexual intercourse

Teaching Guidelines 8.1

REDUCING YOUR RISK FOR CANCER

• Do not smoke; smoking is linked to lung cancer development.

• Drink alcohol only in moderation (no more than one drink daily).

• Be physically active daily.

• Eat a healthy diet.

• Stay current with immunizations.

• Use a condom with every sexual encounter.

- Reach and maintain a healthy weight.
- Take preventive medicines if needed.
- Get recommended screening tests:
  - Body mass index (BMI) to identify obesity
  - Mammogram every 1 to 2 years starting at age 40
  - Pap smear every 1 to 3 years if sexually active, between the ages of 21 and 65
  - Cholesterol checked annually starting at age 45
  - Blood pressure checked at least every 2 years
  - Diabetes test if hypertensive or hypercholesterolemia
  - Check for STIs if sexually active

Teaching the Client About Her Diagnosis

Provide information about tests that may be required to confirm or rule out the diagnosis. Review with the woman what she has been told about her diagnosis and her understanding of her condition. It is not unusual for the woman to hear the diagnosis and then become overwhelmed by the thought of cancer, blocking out whatever is said after that. Answer any questions she may have. Go slowly and repeat the information as necessary. Use written materials to explain and reinforce the teaching. Provide information about her condition and recommended therapies. For example, if a client is undergoing surgery, discuss

postoperative issues such as incision care, pain, and activity level. Instruct the client on health maintenance activities after treatment, and inform her and her family about available support resources.

Providing Emotional Support

Once the diagnosis is made, provide the woman and her family with emotional support. Validate the client's feelings and provide realistic hope, using a nonjudgmental approach and therapeutic communication skills during all interactions. Nurses can be invaluable when assisting women who are coping with the uncertainty of their future by providing positive communication and support. Nurses need to focus on the physical, psychosocial, and economic concerns, from diagnosis through treatment and, if applicable, until the end of life, for all of the women for whom they care. Individualize the care based on the client's cultural traditions and beliefs, as explained in the following section.

ENSURING CULTURALLY COMPETENT CANCER CARE

Cultural diversity in America is increasing, and as diverse cultures interact, conflicts inevitably ensue. These conflicts can affect health care outcomes. Providing culturally competent cancer care can improve outcomes and decrease disparities in care. If nurses are to meet the needs of ethnically diverse populations, they must be culturally sensitive, appreciative of differing health beliefs and practices, and very flexible in the way they approach health care. It is we who must adapt, expand, and learn.

Nurses have the opportunity to learn about diverse cultures, religions, and faith traditions that support clients and families during their cancer journey and while facing a serious life-limiting illness. Nursing care practices should embrace all clients with whom they come in contact and, by having a better understanding of diverse groups, nurses can build trust in clients seeking oncology care needs that range from detection to diagnosis to treatment possibly through palliative and end-of-life care also.

Be aware of the client's cultural background, religion, migration history, degree of acculturation, living conditions, educational level, and legal status,

because each of these factors can affect the client's understanding of her diagnosis and the eventual outcome. A woman's reaction to a cancer diagnosis and her decisions about treatment are influenced by an individual's cultural values and how the community views cancer. A diagnosis of cancer carries deep physical, psychosocial, and cultural implications. Sensitive cross-cultural communication and cultural competence are vital for all nurses to deliver equal care to all cancer clients. Nurses need to understand the disparities and the influence of those disparities on health outcomes. Women with cancer reflect the demographic changes occurring in the United States and represent increasing differences in culture, religion, socioeconomic status, race, and lifestyle. Through embracing and learning from these differences, nurses become stronger care providers (Surbone, 2015).

In some cultures, sharing news of a serious illness like cancer is considered disrespectful and impolite. For example, some Europeans view such sharing as inhumane; the Asian culture views a cancer diagnosis as unnecessarily cruel. The Chinese, out of respect for aging family members, withhold discussions of serious illness to avoid causing unnecessary anxieties (Lofters, 2015). Integrate this knowledge in your care to ensure a culturally competent approach.

 Take Note!

When a diagnosis of cancer is made, assessing an individual's strengths and weaknesses from a cultural perspective will help the nurse to provide culturally competent care.

As life becomes increasingly multilingual, multicultural, and multi-religious, learning about clients' values and cultural beliefs becomes challenging. Be willing to learn about client preferences; doing so promotes caring and nurturing.

SUPPORTING THE PREGNANT WOMAN WITH CANCER

Pregnancy complicated by cancer is relatively rare, occurring in one out of every 1,000 pregnancies (CancerNet, 2015a). The incidence is increasing because women in Western societies are tending to delay childbearing to the third and

fourth decade of life; this phenomenon is going to be encountered more often in the future by nurses. The most frequent malignancies diagnosed during pregnancy are breast cancer, cervical cancer, hematologic malignancies (lymphomas and acute leukemia), and melanoma. Breast cancer is the most common cancer diagnosed in pregnant women which affects approximately one in 3,000 pregnancies. Less common tumors during pregnancy are gastrointestinal, ovarian, urologic, and lung cancers (Amant et al., 2015).

Theoretically, changes in the mother's immune system during pregnancy can increase the risk of malignancy because cell-mediated immunity, which is suppressed in pregnant women, normally protects against cancerous tumors (Kim & Chu, 2015). Some research has hinted at an increased rate of progression and decreased survival times in women who develop breast and cervical cancer and then become pregnant, but this generally has not been validated by research studies. With the cooperation of multidisciplinary teams, treatment of cancer during pregnancy with normal fetal outcome is feasible (Andersson et al., 2015).

Ovarian cancer during pregnancy is rare because the disease typically occurs in older women. Because most pregnant women receive frequent medical care, including pelvic examinations, most ovarian cancers in pregnant women are found at early stages; this carries a good prognosis for both the mother and the newborn. The presence of ascites indicates advanced disease (de Haan, Verheecke, & Amant, 2015).

Endometrial cancer is the most common neoplasia of the female reproductive system, with the highest incidence among uterine malignancies. It is rarely associated with pregnancy. Adenocarcinoma associated with pregnancy is typically endometrioid, focal, well-differentiated, and minimally invasive. Active treatment of endometrial cancer is incompatible with the continuation of the pregnancy. Since routine screening for endometrial cancer is currently not recommended in the general population, few cases would be detected in the relatively young pregnant population (*Cancer in Pregnancy,* 2015a). Cervical cancer is more common in the pregnant population than other reproductive malignancies, and it can affect the woman's health status and the pregnancy. Approximately 30% of women diagnosed with cervical cancer are in their reproductive years, whereas 3% of cervical cancers are diagnosed during pregnancy (*Cancer in Pregnancy,* 2015b). Management of cervical cancer during pregnancy depends on the following factors:

• Stage of the disease (and the tumor size)

• Nodal status

• Histologic subtype of the tumor

• Term of the pregnancy

• Whether the client wishes to continue her pregnancy

• Woman's desire for future fertility

In women with early-stage disease and absence of nodal involvement who are diagnosed during the first two trimesters of pregnancy, there is an increasing tendency to preserve the pregnancy while awaiting fetal maturity. The birth (when the fetal maturity is attained) should be performed using a cesarean section (ACS, 2015c). Treatment decisions are influenced by the stage of the cancer, the histologic type, the stage of the pregnancy, and the client's wishes. Both maternal and fetal safety and well-being have to be taken into account. Termination of pregnancy is not indicated in all cases. Pregnancy preservation in tumors diagnosed during early gestation is feasible in carefully selected cases. Discussion with the client and her family is essential and treatment has to be individualized (ACS, 2015c).

Nurses caring for young clients with cervical cancer must be aware of the surgical fertility preservation options, which clients are candidates for these surgeries, and the options for future assisted reproductive technology. Nurses need to be able to coordinate care for these clients with gynecologic oncologists and reproductive endocrinologists in order to facilitate optimal outcomes.

Women diagnosed with any malignancy during pregnancy must confront the reality of the disease and its impact on their future fertility and live with the risk of recurrence. The prognosis for a pregnant woman with cancer is often the same as other women of the same age with the same type of cancer (Cancer.Net, 2015a). The wishes of the pregnant woman and her family are of paramount importance when making decisions about continuing the pregnancy and undergoing cancer treatment. Some women will decide to terminate the pregnancy for the sake of their own health; others will undergo treatment during the pregnancy to preserve the life of the unborn child. Regardless of the woman's decision, provide support, hope, and education during treatment, birth, and beyond.

OVARIAN CANCER

Ovarian cancer is a malignant neoplastic growth of the ovary (Fig. 8.1). It is the ninth most common cancer among women and the fifth most common cause of cancer deaths for women in the United States. It accounts for more deaths than any other cancer of the reproductive system (ACS, 2015d). A woman's risk of getting invasive ovarian cancer in her lifetime is about 1 in 75. Her lifetime chance of dying from invasive ovarian cancer is about 1 in 100 (ACS, 2015d). This cancer mainly develops in older women. About half of the women who are diagnosed with ovarian cancer are 63 years or older. It is more common in White women than in African American women (ACS, 2015d).

The most important variable influencing the prognosis is the extent of the disease. Survival depends on the stage of the tumor, grade of differentiation, gross findings at surgery, amount of residual tumor after surgery, and effectiveness of any adjunct treatment postoperatively. Many women with ovarian cancer will experience recurrence despite best efforts to eradicate the cancer through surgery, radiation, or chemotherapy to eliminate residual tumor cells. The likelihood of long-term survival in the event of recurrence is dismal (Matsumoto, Onada, & Yaegashi, 2015). The 5-year survival rates (the percentage of women who live at least 5 years after their diagnosis) are shown in Table 8.1 according to stage.

Pathophysiology

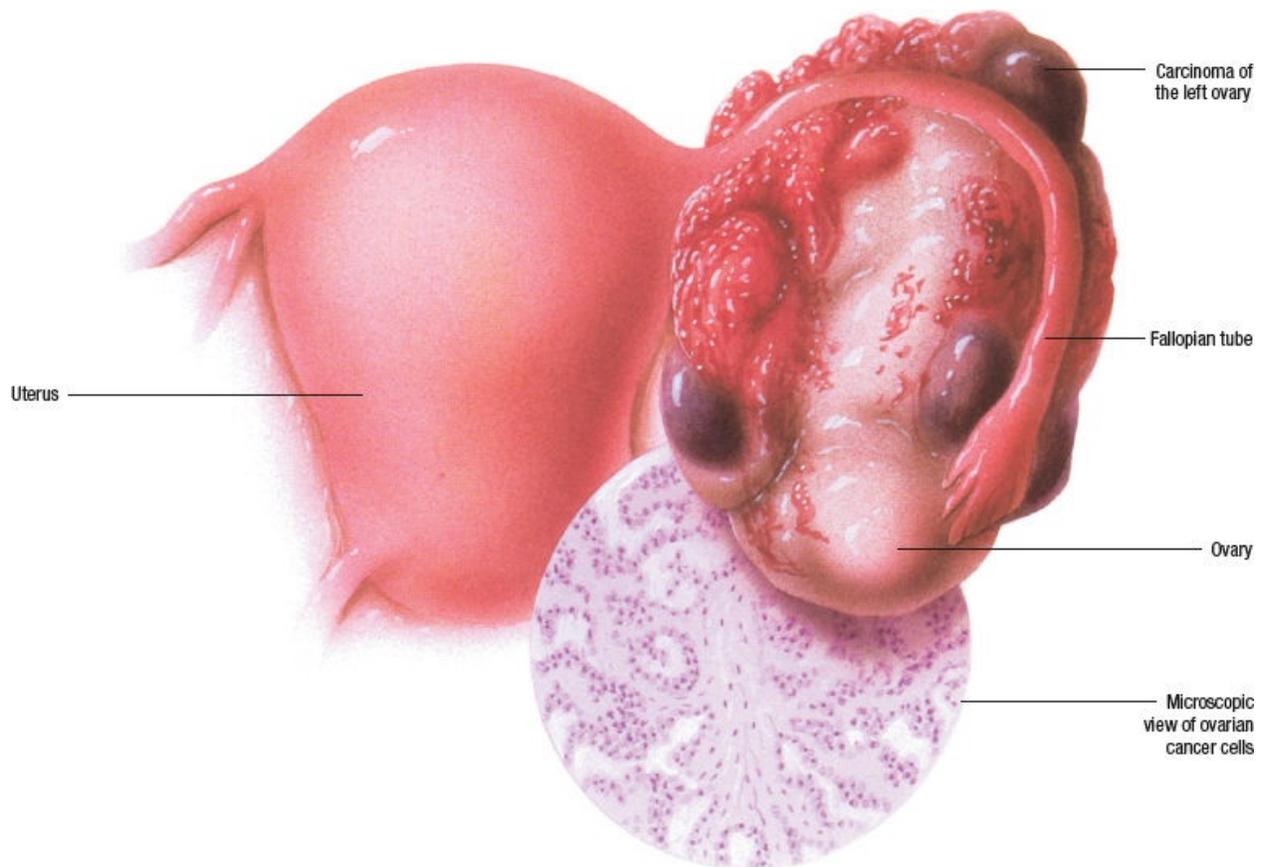
Ovarian cancer, the cause of which is unknown, can originate from different cell types. Most ovarian cancers are thought to originate in the ovarian epithelium. New insights now propose a pivotal role for the fallopian tube during ovarian cancer pathogenesis. Increasing evidence suggests that serous ovarian cancer originates from the fimbriated distal end of the fallopian tube, whereas the ovary gets only involved at a later stage. These represent 50% to 60% of all epithelial ovarian cancers. Based on this finding, a post-reproductive salpingectomy deserves consideration as a prophylactic intervention that may confer protection against an often deadly disease (Poole et al., 2015).


FIGURE 8-1 Ovarian cancer. (Asset provided by Anatomical Chart Co.)

TABLE 8.1 Five-Year Survival Rates for Ovarian Cancer

Stage	Five-Year Relative Survival Rates
I	80%–94%
II	57%–76%
III	34%–45%
IV	18%

Adapted from American Cancer Society [ACS]. (2015o). *Survival rates for ovarian cancer by stage.* Retrieved from http://www.cancer.org/cancer/ovariancancer/detailedguide/ovarian-cancer-survival-rates.

Tumors usually present as solid masses that have spread beyond the ovary and seeded into the peritoneum prior to diagnosis. A thorough understanding of the true pathogenesis of this cancer's origin could lead to the development of new and more effective therapies as well as novel biomarkers in early detection.

Screening and Diagnosis

Women with ovarian cancer are typically diagnosed at a late stage, when the cancer has spread into the peritoneal cavity and complete surgical removal is challenging. Seventy-five percent of ovarian cancers are not diagnosed until the cancer has advanced to stage III or IV, primarily because there is still no adequate screening test. The five-year survival time for women diagnosed at this stage is 30%, in contrast with a five-year survival of 90% for women diagnosed at an early stage (Wright et al., 2015). The United States Preventive Services Task Force (USPSTF) (2015), along with the American College of Obstetricians and Gynecologists (ACOG) and the American Medical Association (AMA), recently reviewed the evidence for ovarian cancer screening and did not recommend screening for women at average risk. However, women with increased risk related to BRCA ½ mutations or a family history of ovarian cancer should be considered for genetic counseling to further evaluate their risk (Cliby et al., 2015).

Two genes, BRCA1 and BRCA2, are linked with hereditary breast and ovarian cancers. Blood tests can be performed to assess DNA in white blood cells to detect mutations in the BRCA genes. These genetic markers do not predict whether the person will develop cancer. Rather, they provide information regarding the risk of developing cancer: a woman who is BRCA positive may have up to an 80% chance of developing breast cancer and a 40% chance of developing ovarian cancer (Liede, Sun, & Narod, 2015).

To assist in screening, researchers have developed an ovarian cancer symptom index that includes pelvic and abdominal pain, urinary frequency and urgency, increased abdominal size (bloating), and difficulty eating (feeling full). But this symptom index is not much help in detecting the disease early, as these symptoms tend to go unrecognized, leading to delays in diagnosis. When the presentation of such symptoms triggers a medical evaluation for ovarian cancer, the disease is diagnosed in only 1 in 100 women. The NCI reports that the present symptom index has a "low positive predictive value," especially for early-stage disease discovery (2015d).

Specific clinical guidelines for ovarian cancer screening have not been developed, so the disease is often not diagnosed until it has metastasized. The USPSTF recommends against routine screening for ovarian cancer with serum CA-125 or transvaginal ultrasound because earlier detection would have a small

effect, at best, on mortality. CA-125 is a biologic tumor marker associated with ovarian cancer. Although its levels are elevated in many women with ovarian cancer, CA-125 is not specific for this cancer, and the levels may be elevated with other malignancies too (pancreatic, liver, colon, breast, and lung cancers). Despite the discovery that CA-125 and other serum markers increase before the clinical onset of ovarian cancer, it has proven surprisingly difficult to devise a successful screening program for asymptomatic women with ovarian cancer. Currently, it is not sensitive enough to serve as a screening tool alone (Ebell et al., 2015). The USPSTF (2015) reports that there is no supporting evidence that any screening test, including CA-125, ultrasound, or pelvic exam, reduces mortality from ovarian cancer. Thus, they recommend against routine screening for ovarian cancer.

Therapeutic Management

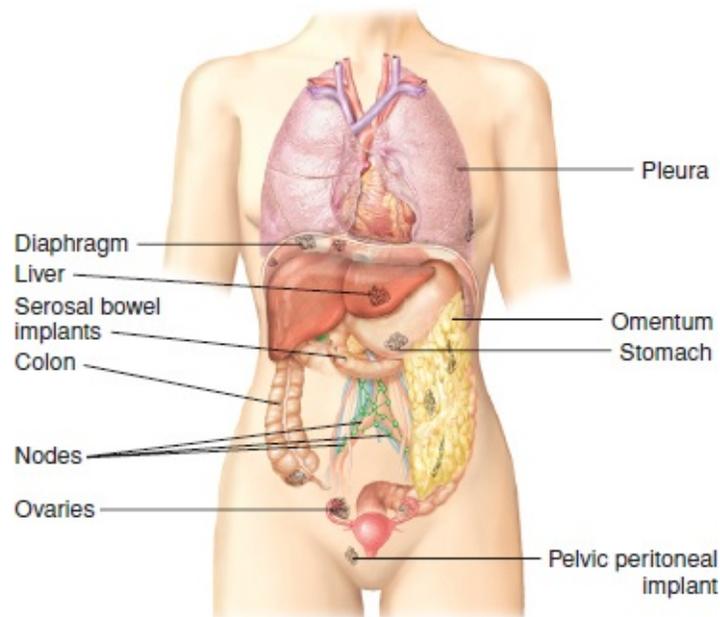
Treatment options for ovarian cancer vary depending on the stage and severity of the disease. Usually, a laparoscopy (abdominal exploration with an endoscope) is performed for diagnosis and staging, as well as evaluation for therapy. In stage I, the cancer is limited to the ovaries. In stage II, the growth involves one or both ovaries, with pelvic extension. Stage III cancer has spread to the lymph nodes and other organs or structures inside the abdominal cavity. In stage IV, the cancer has metastasized to distant sites (Alexander et al., 2014). Figure 8.2 shows the likely metastatic sites for ovarian cancer.


FIGURE 8-2 Common metastatic sites for ovarian cancer. (Asset provided by Anatomical Chart Co.)

Surgical intervention remains the mainstay of management of ovarian cancer. Surgery generally includes a total abdominal hysterectomy, bilateral salpingo-oophorectomy, peritoneal biopsies, omentectomy (excision of all or part of the omentum, which is a sheet of fat covered by the peritoneum that protects the abdominal structures), and pelvic para-aortic lymph node sampling to evaluate cancer extension (Nick et al., 2015). Because most women are diagnosed with advanced-stage ovarian cancer, aggressive management involving debulking or cytoreductive surgery is commonly performed. This surgery involves resecting all visible tumors from the peritoneum, taking peritoneal biopsies, sampling

lymph nodes, and removing all reproductive organs and the omentum. This aggressive surgery has been shown to improve long-term survival rates.

Additional therapy with radiation may be warranted. Chemotherapy is recommended for all stages of ovarian cancer. Intraperitoneal chemotherapy, combined with surgery, has produced encouraging results for overall survivals at acceptable morbidity and mortality rates. Despite all of these therapies, virtually, the only agreement about treatment for advanced disease is that surgery and chemotherapy play a role, and that current treatment is effective in far too many women (Helm, 2015a).

Nursing Assessment

Ovarian cancers are considered the worst of all the gynecologic malignancies, primarily because they develop slowly and remain silent without symptoms until the cancer is far advanced. It has been described as the "overlooked disease" or "silent killer" because women and health care providers often ignore or rationalize early symptoms. For example, women may attribute gastrointestinal problems to stress and midlife changes. However, these vague complaints may precede more obvious symptoms by months. The most common early symptoms include abdominal bloating, early satiety, fatigue, vague abdominal pain, urinary frequency, diarrhea or constipation, malaise, and unexplained weight loss or gain. The later symptoms include anorexia, dyspepsia, ascites, a palpable abdominal mass, pelvic pain, and back pain (Goldstein et al., 2015).

Obtain a thorough history of the woman's symptoms, including their onset, duration, and frequency. Review the woman's history for risk factors such as:

• Nulliparity

• Early menarche (before 12 years old)

• Late menopause (after 55 years old)

• Increasing age after menopause

• High-fat diet

• Obesity

• Persistent ovulation over time

• First-degree relative with ovarian cancer

• Genetics—women of Ashkenazi Jewish decent

• Use of perineal talcum powder or hygiene sprays

• Older than 30 years at first pregnancy

• Positive BRCA1 and BRCA2 mutations

• Personal history of breast, bladder, or colon cancer

• Hormone replacement therapy (HRT) for more than 10 years

• Infertility (CDC, 2015c)

Perform a complete physical examination. Inspect the abdomen, noting any

distention or bloating. Palpate the abdomen. Be alert for a mass or pain on palpation. Anticipate further testing to confirm the diagnosis.

Nursing Management

The complexities of ovarian cancer make a multidisciplinary approach necessary for optimal management. With the subtle nature and high risk of recurrence and mortality of this condition, most women find it an emotionally exhausting and devastating experience. The presence of hope is essential for women at the time of the diagnosis; they want to believe in being cured and able to continue their life as usual with loved ones, friends, and relatives. Still, the newly received cancer diagnosis makes women oscillate between hope and hopelessness, between positive expectations of getting cured and frightening feelings of the disease taking command. Nurses are invaluable resources in inspiring clients to find hope in life when diagnosed with cancer. Nursing management needs to focus on measures to promote early detection, educate the woman about the disease and its treatments, and provide emotional support. Nurses should show a positive attitude that communicates understanding and reassurance.

Promoting Early Detection

Nurses need to ensure that women are aware of the risk factors for ovarian cancer. Urge women not to dismiss seemingly innocuous symptoms as "just a part of aging." Encourage women to describe such nonspecific complaints at health visits.

Assess the woman's family and personal history for risk factors and encourage genetic testing for women with affected family members. Outline screening guidelines for women with hereditary cancer syndrome and inform women at high risk about the appropriate screening strategies.

Urge women to have yearly bimanual pelvic examinations and a transvaginal ultrasound to allow identification of ovarian masses in their early stages. After menopause, a mass on an ovary is not a cyst: physiologic cysts can arise only from a follicle that has not ruptured or from the cystic degeneration of the corpus luteum. Ovarian cancer is not always silent, and may manifest with several vague gastrointestinal symptoms. Although screening the general population is not recommended, nurses need to know what factors place women at high risk and really listen to women's complaints to detect this type of cancer before it becomes advanced.

A small ovarian "cyst" found on ultrasound in an asymptomatic postmenopausal woman should arouse suspicion. Any mass or ovary palpated in a postmenopausal woman should be considered cancerous until proven otherwise (Helm, 2015b).

Educating the Client

Education is a major focus of nursing care. This teaching involves risk reduction and health promotion. Teach the woman about risk reduction strategies; for instance, pregnancy, use of oral contraceptives, and breast-feeding reduce the risk of ovarian cancer. Instruct women to avoid using talc and hygiene sprays on their genitals. Review the lifetime risks related to *BRCA1* and *BRCA2* genes and options available should the woman test positive for these genes. Help to promote community awareness of ovarian cancer by educating the public about risk-reducing behaviors. See research on reproductive cancer risk factor (Evidence-Based Practice 8.1).

Instruct the woman about the importance of healthy lifestyles. Stress the importance of maintaining a healthy weight to reduce risk. Encourage women to eat a low-fat diet. Factors associated with a reduced risk of ovarian cancer include the use of oral contraceptives for 3 years or longer, pregnancy and breastfeeding before the age of 30, bilateral tubal ligation, and removal of the ovaries (Memorial Sloan Kettering Cancer Center, 2015).

EVIDENCE-BASED PRACTICE 8.1 DOES OVARIAN STIMULATION FOR IVF INCREASE GYNECOLOGICAL CANCER RISK? A SYSTEMATIC REVIEW AND META-ANALYSIS

STUDY

Drugs to stimulate ovulation have been widely used for various types of subfertility since the early 1960s, and their use has increased in recent years. The use of assisted reproductive techniques is increasing, but the possible link between fertility drugs and reproductive cancer remains controversial. Subfertile women are commonly exposed to these agents, which may be administered at high doses for long periods of time during treatment for subfertility. There is uncertainty about the safety of these drugs and the potential risk of causing cancers associated with their use. The objective of this study was to evaluate the risk of reproductive cancer in women previously treated with ovulation-stimulating drugs for infertility.

Findings

A systematic review and meta-analysis was conducted. Clinical trials that examined the association between ovarian stimulation for IVF and gynecologic cancers were included. Twelve cohort studies with 178,396 women exposed to IVF were included. The meta-analysis found no significant association between ovarian stimulation for IVF and increased ovarian, endometrial, cervical, and breast cancer risk. Ovarian stimulation for IVF, therefore, does not increase the gynecologic risk, whether hormone-dependent endometrial and breast cancer risk, or non–hormone-dependent ovarian and cervical cancer. This study found no convincing evidence of an increased risk of reproductive cancer with fertility drug treatment.

For the woman who is diagnosed with ovarian cancer, describe in simple terms the tests, treatment modalities, and follow-up needed. For example, if the woman will be having surgery, the nurse needs to provide thorough teaching about what to expect before, during, and after surgery. Outline the treatment options and the implications of choices. Assist the woman and her family to decipher the myriad of information related to staging, tests, and treatments. Teach the woman about additional treatment measures, such as radiation therapy or chemotherapy, including how to handle the common adverse effects of treatment.

Supporting the Client and Family

The diagnosis of ovarian cancer, like any cancer, can be overwhelming. In addition, the treatments and their effects can be highly stressful, both physically and emotionally. Provide one-to-one support for women facing treatment for ovarian cancer. Ovarian cancer involves the reproductive system, which has a direct impact on the woman's view of herself. Encourage open discussion of sexuality and the impact of cancer. Listen and support the woman and her family as they try to cope with this disease. By being aware of women's individual needs and different coping strategies, nurses can improve support to women in

this vulnerable situation. Encourage the use of appropriate coping strategies to allow for the best quality of life. Try to restore hope to women with ovarian cancer, and stress treatment compliance. Nurses should not forget about the family caregivers who need help with managing emotions about prognosis, balancing their own and the client's needs, work, and decision-making when there is uncertainty. If appropriate, encourage participation in clinical trials to offer hope for all women. Continue to offer support to the woman and her family members as they experience sadness and grief.

Consider This

I felt I was a lucky woman because I had been in remission from breast cancer for 12 years, and I had been given the gift of life to share with my beloved family. Recently I became ill with stomach problems: pain, indigestion, bloating, and nausea. My doctor treated me for gastric reflux disease, but the symptoms persisted. I then was referred to a gastroenterologist, a urologist, and then a gynecologist, who did an ultrasound, which was negative. I received reassurance from all three that there was nothing wrong with me. As time went by, I experienced more pain, more symptoms, and increased frustration. Six months after seeing all three specialists, a repeat ultrasound revealed I had ovarian cancer, and I needed surgery as soon as possible. I underwent a complete hysterectomy and my surgeon found I was in stage III. Since then, I have undergone chemotherapy and participated in a clinical cancer study that wasn't successful for me, and now I am facing the fact that I am going to die soon.

Thoughts: This woman has tried everything to save her life, but, alas, time has run out for her with advanced ovarian cancer. Women diagnosed with breast cancer are at a significant risk for developing ovarian cancer later in life. Of the string of doctors she saw, one has to ponder why none ordered more extensive testing, given her history of breast cancer. We are haunted with the question: If they had, would she be in stage III now? We will never know.

ENDOMETRIAL CANCER

Endometrial cancer (also known as uterine cancer) is a malignant neoplastic growth of the uterine lining. It is the fourth most common gynecologic malignancy and accounts for 6% of all cancers in women in the United States or 1 in 37 women. The NCI (2015e) estimates that about 54,870 new cases will be diagnosed in women in 2015 and that approximately 10,170 of these women will die. Endometrial cancer is responsible for over 75,000 deaths annually among women worldwide (Siegel et al., 2015). It is uncommon before the age of 55, but as women age, their risk of endometrial cancer increases. Approximately 80% of these malignancies are carcinomas of the endometrium. Because endometrial cancer is usually diagnosed in the early stages, it has a better prognosis than cervical or ovarian cancer (ACS, 2015e).

The increasing incidence and prevalence of endometrial cancer can be explained by the increase in life expectancy, increased caloric intake, increased obesity rates, infertility, null parity (never bearing children), older age of first pregnancy, and long-term use of unopposed estrogens for HRT. Protection against endometrial cancer includes increased parity, daily physical activity, use of combined oral contraceptives, and increased age of women at last childbirth (Schmid et al., 2015).

Pathophysiology

Two mechanisms are believed to be involved in the development of endometrial cancer. A history of exposure to unopposed estrogen is the cause in approximately 80% of women. Those that are spontaneous and are unrelated to estrogen or endometrial hyperplasia represent the other 25% of endometrial cancers. There has been an increase in the incidence of women using estrogen replacement therapy (without progestin) and in obesity rates (adipose fat converts androstenedione to estrone, thereby increasing circulating estrogen levels) that may contribute to endometrial cancer (Temple, 2015).

Endometrial cancer may originate in a polyp or in a diffuse multifocal pattern. The pattern of spread partially depends on the degree of cellular differentiation. Well-differentiated tumors tend to limit their spread to the surface of the endometrium. Metastatic spread occurs in a characteristic pattern and most commonly involves the lungs, inguinal and supraclavicular nodes, liver, bones, brain, and vagina (NCI, 2015f). Early tumor growth is characterized by friable and spontaneous bleeding. Later tumor growth is characterized by myometrial invasion and growth toward the cervix (Fig. 8.3).

Adenocarcinoma of the endometrium is typically preceded by hyperplasia. Carcinoma in situ is found only on the endometrial surface. Type I carcinomas, the most common, begin as endometrial hyperplasia and progress to carcinomas. Giving estrogen preparations without progestin for HRT leads to an increased risk for endometrial cancer. Type I is generally found at an earlier stage and treatment results are more favorable.

Unlike type I endometrial carcinoma, type II carcinomas appear spontaneously, are associated with a poorly differentiated cell type, and have a poor prognosis. They account for less than 10% of all endometrial cancers but contribute to the majority of all endometrial deaths. This type is unrelated to estrogen or endometrial hyperplasia (ACS, 2015f).

Remember Carmella, the woman with postmenopausal bleeding? In postmenopausal women, any bleeding is abnormal and warrants further assessment. What testing would the nurse anticipate as being ordered to confirm the diagnosis? What would be the nurse's role during this testing?

Screening and Diagnosis

There is no specific screening test currently available to detect endometrial cancer. Screening for endometrial cancer is not routinely done because it is not practical or cost effective. The ACS (2015f) recommends that women be informed about the risks and symptoms of endometrial cancer at the onset of menopause and strongly encouraged to report any unexpected bleeding or spotting to their health care provider. A pelvic examination is frequently normal in the early stages of the disease. Changes in the size, shape, or consistency of the uterus or its surrounding support structures may exist when the disease is more advanced.

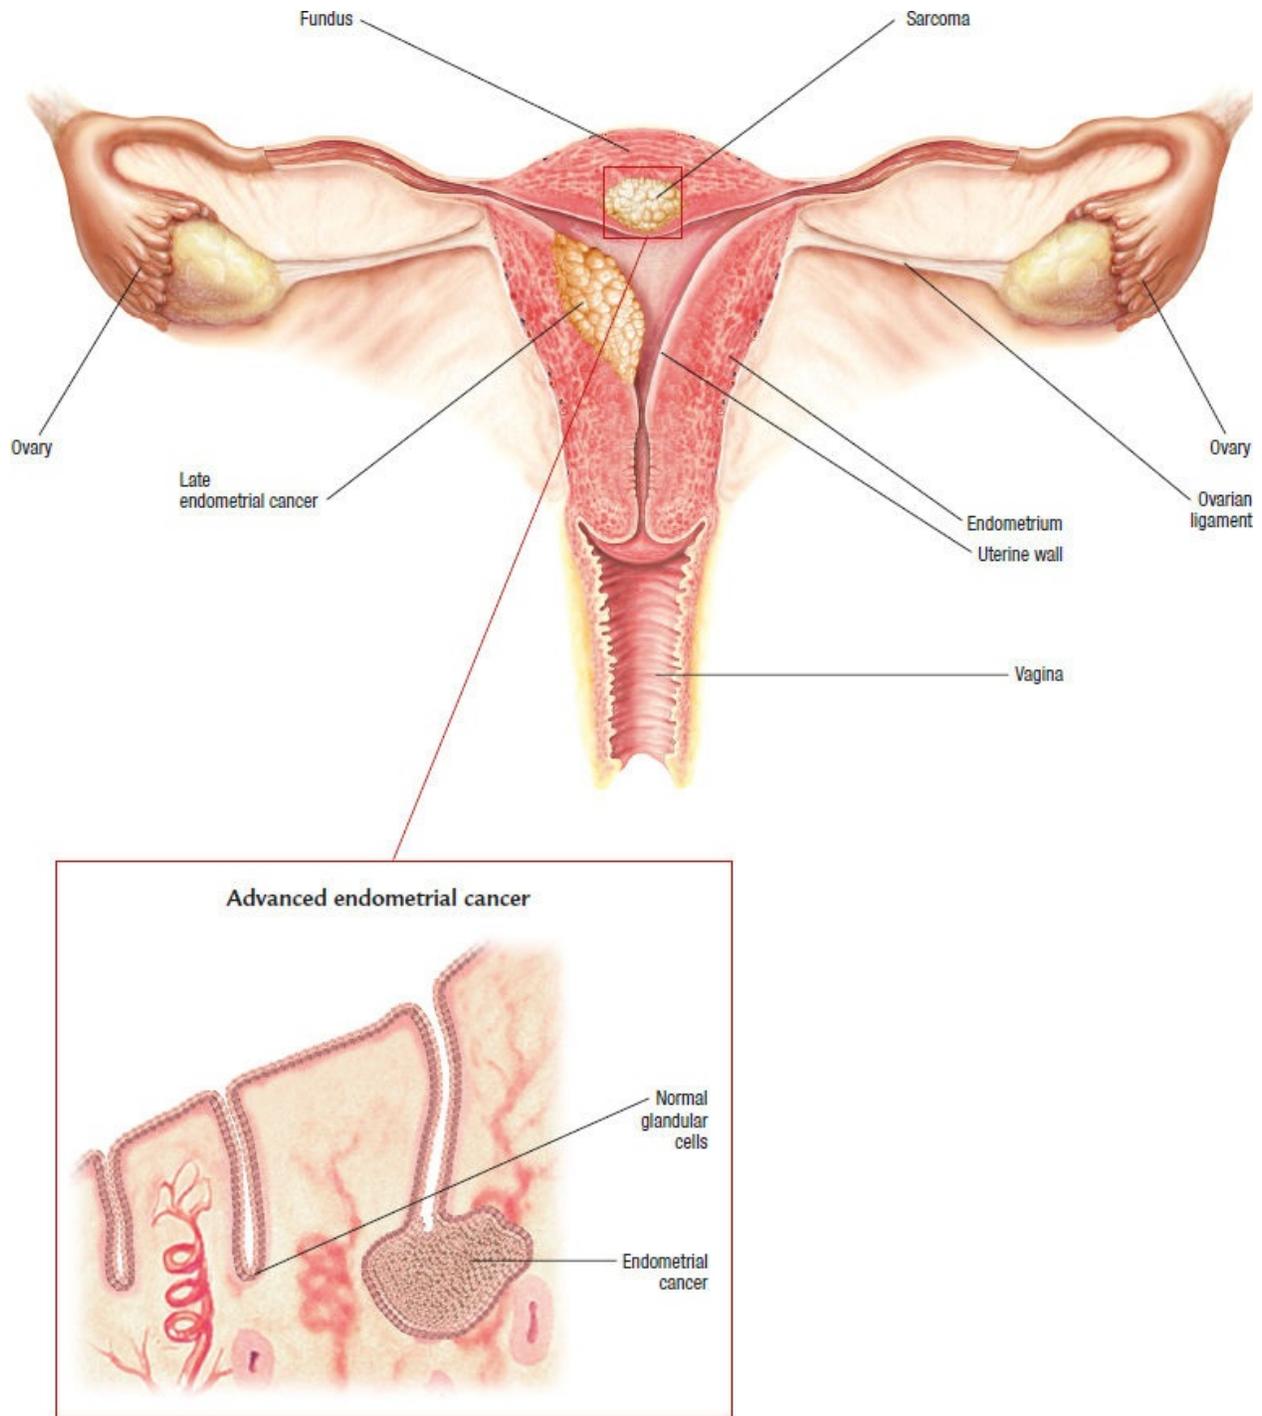
During the past two decades, the role of ultrasound in the evaluation of postmenopausal bleeding has changed markedly, from little or no role to a major role today. In the intervening years, numerous studies have shown that ultrasound is at least as sensitive as endometrial biopsy for endometrial cancer and that ultrasound can reliably exclude cancer without the need for biopsy in some women with postmenopausal bleeding. The depth of myometrium is an important diagnostic factor. In particular, numerous studies have shown that women with an endometrial thickness of 4 mm or less have an extremely low likelihood of endometrial cancer and thus do not need to undergo endometrial biopsy. Ultrasound can also help in the selection of an appropriate biopsy technique. In a woman with postmenopausal bleeding and a thick endometrium, a sonohysterogram can determine whether the endometrium is diffusely thick or has focal areas of thickening. With diffuse thickening, an endometrial biopsy is appropriate. When one or more focal areas of thickening are present, hysteroscopic biopsy is likely to be the better choice. Typically, the noninvasive ultrasound is done first before an invasive endometrial biopsy is attempted (Dueholm et al., 2015).


FIGURE 8.3 Progression of endometrial cancer. (Image 1 provided by Anatomical Chart Co.)

Transvaginal ultrasound can be used to evaluate the endometrial cavity and measure the thickness of the endometrial lining. It can be used to detect endometrial hyperplasia. If the endometrium measures less than 4 mm, then the client is at low risk for malignancy. Large prospective studies have shown that

an endometrial thickness of ≤4 mm on transvaginal ultrasound in postmenopausal women with bleeding has a low risk of malignancy. Thus, in postmenopausal clients with bleeding, biopsy is not indicted when endometrial thickness is ≤4 mm, thereby avoiding invasive diagnostics (Wong et al., 2015).

Endometrial biopsy is an office procedure that is also one of the first steps in the diagnosis of endometrial cancer in a woman with postmenopausal bleeding. The biopsy is obtained through an endometrial suction catheter that is inserted through the cervix into the uterine cavity and a tissue sample is taken. The sensitivity and specificity of the biopsy procedure tend to be in the range of 95% for detection of endometrial cancer or other pathologies (King et al., 2015).

As indicated earlier, staging is the process of looking at all of the information the doctors have learned about the tumor to determine how much the cancer may have spread. The stage of an endometrial cancer is the most important factor in choosing a treatment plan. It can spread *locally* to other parts of the uterus or *regionally* to nearby lymph nodes. The regional lymph nodes are found in the pelvis and farther away along the aorta. Finally, the cancer can spread (*metastasize*) to distant lymph nodes or organs such as lung, liver, bone, brain, and others

In stage I, the tumor is confined to the corpus uteri. In stage II, it has spread to the cervix, but not outside the uterus. In stage III, it has spread locally and regionally. In stage IV, it has invaded the bladder mucosa and bowel mucosa, with distant metastases to the lungs, liver, and bone (International Federation of Gynecology and Obstetrics, 2015).

Therapeutic Management

Typically, the stage of the disease directs treatment. It usually involves surgery with adjunct therapy based on pathologic findings. Surgery most often involves removal of the uterus (hysterectomy) and the fallopian tubes and ovaries (salpingo-oophorectomy). Removal of the fallopian tubes and ovaries is recommended because tumor cells spread early to the ovaries, and any dormant cancer cells could be stimulated to grow by ovarian estrogen. In more advanced cancers, radiation and chemotherapy are used as adjuncts to surgery. Routine surveillance intervals for follow-up care are typically every 3 to 4 months for the first 2 years, since 85% of recurrences occur in the first 3 years after diagnosis (Brennan et al., 2015).

Nursing Assessment

Obtain a thorough history from the woman, ascertaining her primary complaint. Most commonly, the major initial symptom of endometrial cancer is abnormal and painless vaginal bleeding. Obtain a menstrual history and inquire if the woman is taking any hormones. Also ascertain if she has a personal or family history of breast, ovarian, or colon cancer. These key pieces of information will assist in identifying the woman at high risk for endometrial cancer.

Take Note!

Any episode of bright-red bleeding that occurs after menopause should be investigated. Abnormal uterine bleeding is rarely the result of uterine malignancy in a young woman, but in the postmenopausal woman it should be regarded with suspicion.

Also review the woman's history for any risk factors, including:
• Nulliparity
• Obesity (more than 50 lb overweight)
• Liver disease
• Infertility
• Diabetes mellitus
• Hypertension
• History of pelvic radiation
• Polycystic ovary syndrome
• Early menarche (before 12 years old)
• High-fat diet
• Use of prolonged exogenous unopposed estrogen with an intact uterus
• Endometrial hyperplasia
• Family history of endometrial cancer
• Personal history of hereditary nonpolyposis colon cancer

• Personal history of breast, colon, or ovarian cancer

• History of uterine fibroids

• Late onset of menopause (after age 52 years)

• Tamoxifen use

• Chronic anovulation (Moses, 2015)

Assess the woman for additional manifestations, such as dyspareunia, low back pain, purulent genital discharge, dysuria, pelvic pain, weight loss, and a change in bladder and bowel habits. These may suggest advanced disease.

Perform a physical examination or assist with, as appropriate, a pelvic examination. Observe for vaginal discharge. Note any changes in the size, shape, or consistency of the uterus or surrounding structures or client reports of pain during examination. Anticipate the need for transvaginal ultrasound to identify endometrial hyperplasia (usually greater than 4 mm) and endometrial biopsy to identify malignant cells.

Nursing Management

Ensure that the woman understands all of the treatment options. Address any concerns the woman expresses, including questions about sexuality. Ensure that follow-up appointments are scheduled appropriately. Refer the client to a support group. Offer the woman and family explanations and emotional support throughout.

Educate the client about preventive measures or follow-up care if she has been treated for cancer. Education may be the most important tool currently available for the early detection of endometrial cancer. Many risk factors for endometrial cancer are modifiable or treatable, including obesity, hypertension, and diabetes. Educating women about risk factors and ways to decrease the risks is essential so that women can learn about their own risk profile and can become partners in the fight against this gynecologic cancer (Teaching Guidelines 8.2).

Teaching Guidelines 8.2

PREVENTIVE AND FOLLOW-UP MEASURES FOR ENDOMETRIAL CANCER

• Schedule regular pelvic examinations after the age of 21.

• Visit health care practitioner for early evaluation of any abnormal bleeding after menopause.

• Maintain a low-fat diet throughout life.

• Exercise daily.

• Manage weight to discourage hyperestrogenic states, which predispose to endometrial hyperplasia.

• Pregnancy serves as a protective factor by reducing estrogen.

• Ask your doctor about the use of combination estrogen and progestin pills.

• When combination oral contraceptives are taken to facilitate the regular shedding of the uterine lining, take risk reduction measures.

• Be aware of risk factors for endometrial cancer and make modifications as

needed.
- Report any of the following symptoms immediately:
  - Bleeding or spotting after sexual intercourse
  - Bleeding that lasts longer than a week
  - Reappearance of bleeding after 6 months or more of no menses
- After cancer therapy, schedule follow-up appointments for the next few years.
- After cancer therapy, frequently communicate with your health care provider concerning your status.
- After surgery, maintain a healthy weight.

Carmella's endometrial biopsy indicates endometrial adenocarcinoma. Her health care provider recommends surgery and adjuvant radiation therapy. How long will Carmella need to follow up after surgery? What lifestyle changes will the nurse need to stress with Carmella?

CERVICAL CANCER

Cervical cancer is a malignancy located in the uterine cervix. It is the third most common genital malignancy in women in the United States, after cancers of the endometrium and the ovary. The ACS (2015g) estimates that over 13,000 cases of invasive cervical cancer will be diagnosed in the United States in women in 2015 and that approximately 4,100 of these women will die. Some researchers estimate that noninvasive cervical cancer (carcinoma in situ) is about four times more common than invasive cervical cancer. The 5-year survival rate for all stages of cervical cancer is 72% (ACS, 2015g). Cervical cancer is five to eight times more common in women affected with HIV or AIDS than those who are not. Hispanic women are most likely to get cervical cancer, followed by African Americans, Asians and Pacific Islanders, and Whites. Cervical cancer remains a disease of socioeconomic disparity. The high mortality rates of minorities are indicative of barriers to health care among those living in poverty. Hispanic women also have the highest rates of poverty, poor access to health care, and language and cultural barriers. Barriers to screening and prevention of cervical cancer include procrastination, fear of finding out that they have cancer, and embarrassment about having a Papanicolaou (Pap) test. In addition, most have little to no knowledge about HPV and its link with cancer (Strohl et al., 2015).

The incidence and mortality rates of cervical cancer have decreased noticeably in the past several decades, with most of the reduction attributed to the Pap test, which detects cervical cancer and some precancerous lesions. The Pap test (also known as a Pap smear) is a procedure used to obtain cells from the cervix for cytology screening. Cervical cancer is one of the most treatable cancers when detected at an early stage (ACS, 2015g). *Healthy People 2020* identifies several goals that address cervical cancer (*Healthy People 2020* 8.1; U.S. Department of Health & Human Services, 2015). Cervical cancer tends to occur in midlife. Most cases are found in women younger than age 50. It rarely develops in women younger than age 20. Many older women do not realize that the risk of developing cervical cancer is still present as they age. The probability of a woman in the United States developing cervical cancer is approximately 1 in 120, but this statistic is age dependent; the highest incidence is in women 40 to 49 years of age (Sawaya et al., 2015).

HEALTHY PEOPLE 2020 • *8.1*

Objectives	Nursing Significance
C-3 Reduce the female breast cancer death rate	• Will help improve mortality rates and quality of life for women, and reduce health care costs related to treatment of malignancies.
C-4 Reduce the death rate from cancer of the uterine cervix	
C-10 Reduce invasive uterine cervical cancer	• Will help to promote screening and early detection. The National Institutes of Health (2015) reported that half of women diagnosed with invasive cervical cancer have never had a Pap smear and 10% have not had Pap smears during the past 5 years.
C-11 Reduce late-stage female breast cancer	
C-15 Increase the proportion of women who receive a cervical cancer screening based on the most recent guidelines	
C-17 Increase the proportion of women who receive a breast cancer screening based on the most recent guidelines	• Will raise awareness of cancer screening and prevention on a local and national level to improve and promote the health of all women.
C-18 Increase the proportion of women who were counseled about mammograms and Pap smear cancer screening consistent with current guidelines	• Will reduce the number of new cancer cases, as well as the illness, disability, and death caused by cancer. • Will reflect the importance of promoting evidence-based screening for cervical and breast cancer by lower mortality rates.
C-20 Increase the proportion of persons who participate in behaviors that reduce their exposure to harmful ultraviolet (UV) irradiation and avoid sunburn	

Note: *All cancer objectives project a 10% improvement from the baseline by 2020.*
Healthy People objectives based on data from http://www.healthypeople.gov.

Pathophysiology

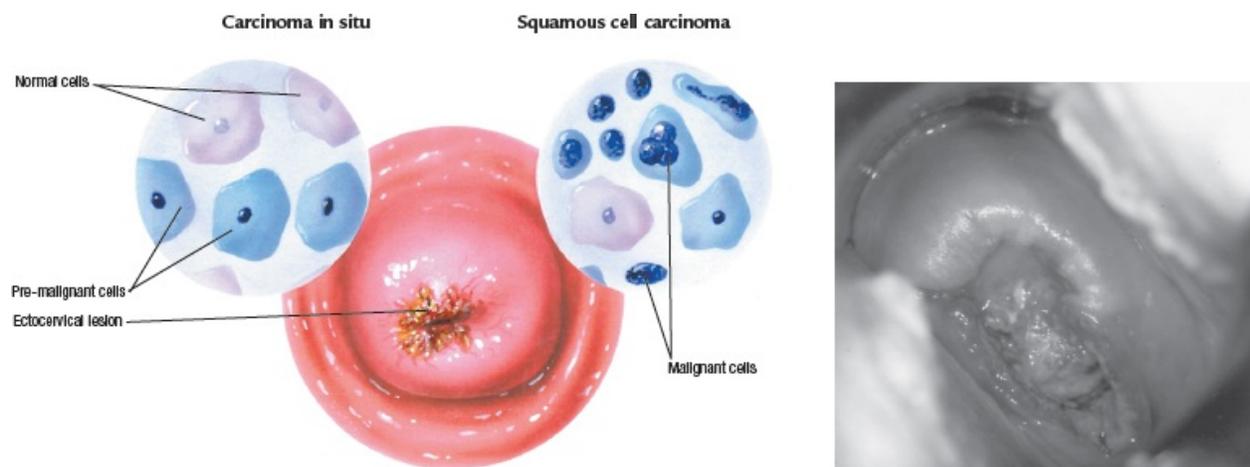
Cervical cancer starts with abnormal changes in the cellular lining or surface of the cervix. Typically, these changes occur in the squamous–columnar junction of the cervix. Here, cylindrical secretory epithelial cells (columnar) meet the protective flat epithelial cells (squamous) from the outer cervix and vagina in what is termed the transformation zone. The continuous replacement of columnar epithelial cells by squamous epithelial cells in this area makes these cells vulnerable to taking up foreign or abnormal genetic material (ACS, 2015h). Figure 8.4 shows the pathophysiology of cervical cancer.


FIGURE 8-4 Cervical cancer. (Illustration is from The Anatomical Chart Company. [2009]. *Atlas of pathophysiology* [3rd ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

HPV infection must be present for cervical cancer to occur. HPV infections occur in a high percentage of sexually active women, but a successful immune response results in viral control or clearance of HPV. Most people who have HPV are asymptomatic and, therefore, do not realize they have the virus. More than 90% of squamous cervical cancers contain HPV DNA, and the virus is now accepted as a major causative factor in the development of cervical cancer and its precursor, cervical dysplasia (disordered growth of abnormal cells). Since only a small proportion of HPV infections progress to cancer, other factors must be involved in the process of carcinogenesis.

Screening and Diagnosis

Screening for cervical cancer is very effective because the presence of a precursor lesion, cervical intraepithelial neoplasia, helps determine whether further tests are needed. Lesions start as *dysplasia* and progress in a predictable fashion over a long period, allowing ample opportunity for intervention at a precancerous stage. Progression from low-grade to high-grade dysplasia takes an average of 9 years, and progression from high-grade dysplasia to invasive cancer takes up to 2 years. Three main factors have been postulated to influence the progression of low-grade dysplasia to high-grade dysplasia. These include the type and duration of viral infection, with high-risk HPV type and persistent infection predicting a higher risk for progression; host conditions that compromise immunity, such as multiparity or poor nutritional status; and environmental factors such as smoking, oral contraceptive use, or vitamin deficiencies. In addition, various gynecologic factors, including age of menarche, age of first intercourse, and number of sexual partners, significantly increase the risk for cervical cancer (Broadman & Matthews, 2015).

Widespread use of the Pap test is credited with saving tens of thousands of women's lives and decreasing deaths from cervical cancer. Routine Pap smear testing for all sexually active women has been one of the primary screening methods for early detection of cervical irregularities related to HPV and is crucial for the prevention of cervical cancer.

Despite its outstanding record of success as a screening tool for cervical cancer (it detects approximately 90% of early cancer changes), the conventional Pap smear has a 20% false-negative rate. High-grade abnormalities missed by human screening are frequently detected by computerized instruments (NCI, 2015g). Thus, many technologies have been developed to improve the sensitivity and specificity of Pap testing, including:

- *Thin-Prep:* In this liquid-based technique, the cervical specimen is placed into a vial of preservative solution rather than on a glass slide.

- *Computer-assisted automated Pap test rescreening (Autopap):* An algorithm-based decision-making technology identifies slides that should be rescreened by cytopathologists by selecting samples that exceed a certain threshold for the likelihood of abnormal cells.

- *HPV-DNA typing (Hybrid Capture):* This system uses the association between

certain types of HPV (16, 18, 31, 33, 35, 45, 51, 52, and 56) and the development of cervical cancer. This system can identify high-risk HPV types and improves detection and management.

• *Computer-assisted technology (Cytyc CDS-1000, AutoCyte, AcCell):* These computerized instruments can detect abnormal cells that are sometimes missed by technologists (CDC, 2015d).

The high rate of false-negative results may also be due to other factors, including errors in sampling the cervix, in preparing the slide, and in client preparation. Although cytology-based nationwide cervical screening has been helpful in identifying abnormal cervical cells, the sensitivity of cytology for the detection of high-grade precursor lesions is limited. Additionally, adenocarcinoma and its precursors are often missed by cytology. The current insight that infection with HPV is the causative agent of cervical cancer and its precursors has led to the development of molecular tests for the detection of HPV. Strong evidence now supports the use of HPV testing in the prevention of cervical cancer. It is evident that HPV can be detected in urine-based testing which might eventually become a helpful tool in cervical cancer screening and HPV surveillance efforts. Nurses need to keep up to date on the latest research developments as well as the strengths and weaknesses of various screening methods (Fontenot, 2015).

Although professional medical organizations disagree as to the recommended frequency of screening for cervical cancer, ACOG (2015) recommends that cervical cancer screening should begin at age 21 years (regardless of sexual history), since women younger than age 21 are at very low risk of cancer. In addition, ACOG advises Pap smears every 3 years for women between ages 21 and 29 years and every 3 years for women between ages 30 and 65 years. A HPV co-test should be done every 5 years for this older age group. Cervical cancer screening can be stopped for women >65 years old with an adequate screening history. Women who have had a hysterectomy should stop screening. Women who have received the HPV vaccine should be screened according to the same guidelines as women who have not been vaccinated. In addition, women must have a clear understanding of the results of Pap smear testing and follow-up guidelines. High-risk women should continue to have annual Pap smears throughout their life (Table 8.2).

Pap smear results are classified using the Bethesda System (Box 8.1), which provides a uniform diagnostic terminology that allows clear communication

between the laboratory and the health care provider. The information provided by the laboratory is divided into three categories: specimen adequacy, general categorization of cytologic findings, and interpretation/result (ACS, 2015h).

TABLE 8.2 PAP SMEAR GUIDELINES

First Pap	Cervical cancer screening should begin at age 21. Women under age 21 should not be tested.
Ages 21–30 years	Should have a Pap smear every 3 years. HPV testing should not be used in this age group unless it is needed after an abnormal pap test result.
Ages 30–65 years	Should have a Pap smear plus an HPV test every 5 years. This is the preferred approach, but having a Pap smear alone every 3 years is okay also.
Ages >65 years	Women whom have had regular cervical testing with normal results should not be tested for cervical cancer. Women with a history of serious cervical pre-cancer lesions should continue testing for at least 20 years after that diagnosis, even if it continues after age 65.
HPV vaccination	Women whom have received the HPV vaccine should follow the screening recommendations for her age group.

Adapted from American Cancer Society [ACS]. (2015b). *American Cancer Society guidelines for the early detection of cancer.* Retrieved from http://www.cancer.org/healthy/findcancerearly/cancerscreeningguidelines/american-cancer-society-guidelines-for-the-early-detection-of-cancer

Therapeutic Management

Treatment for abnormal Pap smears depends on the severity of the results and the health history of the woman. Therapeutic choices all involve destroying as many affected cells as possible. With the introduction of multimodality therapy for cervical cancer, many women will be long-term survivors in need of comprehensive surveillance care. Obesity and smoking are significant comorbidities that may complicate care in cervical cancer survivors. Nurses can focus their interventions at modifying these risk factors to increase the quality of life for cervical cancer survivors. Box 8.2 describes treatment options.

Using the Bethesda System, the following management guidelines for abnormal Pap results were developed by the NCI to provide direction to health care providers and clients:

• *ASC-US:* Repeat the Pap smear in 4 to 6 months or refer for colposcopy.

• *ASC-H:* Refer for colposcopy with HPV testing.

• *Atypical glandular cells (AGC) and adenocarcinoma in situ (AIS):* Immediate colposcopy; follow-up is based on the findings.

THE BETHESDA SYSTEM FOR CLASSIFYING PAP SMEARS

Specimen Type: Conventional Pap smear vs. liquid-based

Specimen Adequacy: Satisfactory or unsatisfactory for evaluation

General Categorization: (optional)

• Negative for intraepithelial lesion or malignancy

• Epithelial cell abnormality. See interpretation/result

Automated Review: If case was examined by automated device or not

Ancillary Testing: Provides a brief description of the test methods and report results so that the health care provider understands

Interpretation/Result:

• Negative for intraepithelial lesion or malignancy

• Organisms: *Trichomonas vaginalis*; fungus; bacterial vaginosis; herpes simplex

• Other non-neoplastic findings: Reactive cellular changes associated with inflammation, radiation, intrauterine devices, atrophy

• Other: Endometrial cells in a woman >40 years of age

• Epithelial cell abnormalities:

• *Squamous cell*

  • Atypical squamous cells

    • Of undetermined significance (ASC-US)

    • Cannot exclude HSIL (ASC-H)

  • Low-grade squamous intraepithelial lesion (LSIL)

    • Encompassing HPV/mild dysplasia/CIN-1

  • High-grade squamous intraepithelial lesion (HSIL)

  • Encompassing moderate and severe dysplasia CIS/CIN-2 and CIN-3

  • With features suspicious for invasion

  • Squamous cell carcinoma

- *Glandular cell*: Atypical
  - Endocervical, endometrial, or glandular cells
    - Endocervical cells—favor neoplastic
    - Glandular cells—favor neoplastic
    - Endocervical adenocarcinoma in situ
  - Adenocarcinoma
    - Endocervical, endometrial, extrauterine
- Other malignant neoplasms (specify)

Educational Notes and Suggestions: (optional)

Adapted from American Society of Cytopathology. (2015). *The Bethesda System for reporting cervical cytology: Definitions, criteria and explanatory notes*. Retrieved from http://www.cytopathology.org/the-bethesda-system-for-reporting-cervical-cytology-definitions-criteria-and-explanatory-notes-3rd-edition/; National Cancer Institute [NCI]. (2015k). *Cervical cancer prevention*. Retrieved from http://www.cancer.gov/cancertopics/pdq/prevention/cervical/Patient/page3; and Schuiling, K. D., & Likis, F. E. (2016). *Women's gynecologic health* (3rd ed.). Sudbury, MA: Jones & Bartlett.

Colposcopy is a microscopic examination of the lower genital tract using a magnifying instrument called a colposcope. Specific patterns of cells that correlate well with certain histologic findings can be visualized.

BOX 8.2

TREATMENT OPTIONS FOR CERVICAL CANCER

- **Cryotherapy**—destroys abnormal cervical tissue by freezing with liquid nitrogen, Freon, or nitrous oxide. Studies show a 90% cure rate (NCI, 2015g). Healing takes up to 6 weeks, and the client may experience a profuse, watery vaginal discharge for 3 to 4 weeks.

- **Cone biopsy or conization**—removes a cone-shaped section of cervical tissue. The base of the cone is formed by the ectocervix (outer part of the cervix) and the point or apex of the cone is from the endocervical canal. The transformation zone is contained within the cone sample. The cone biopsy is also a treatment and can be used to completely remove any precancers and very early cancers. Two methods are commonly used for cone biopsies:

- **LEEP (loop electrosurgical excision procedure) or LLETZ (large loop excision of the transformation zone)**—the abnormal cervical tissue is removed with a wire that is heated by an electrical current. For this procedure, a local anesthetic is used. It is performed in the health care provider's office in approximately 10 minutes. Mild cramping and bleeding may persist for several weeks after the procedure.

- **Cold knife cone biopsy**—a surgical scalpel or a laser is used instead of a heated wire to remove tissue. This procedure requires general anesthesia and is done in a hospital setting. After the procedure, cramping and bleeding may persist for a few weeks.

- **Laser therapy**—destroys diseased cervical tissue by using a focused beam of high-energy light to vaporize it (burn it off). After the procedure, the woman may experience a watery brown discharge for a few weeks. Very effective in destroying precancers and preventing them from developing into cancers.

- **Hysterectomy**—removes the uterus and cervix surgically

- **Radiation therapy**—delivered by internal radium applications to the cervix or external radiation therapy that includes lymphatics of the pelvis

- **Chemoradiation**—weekly cisplatin therapy concurrent with radiation. Investigation of this therapy is ongoing (ACS, 2015h).

Nursing Assessment

Obtain a thorough history and physical examination of the woman. Investigate her history for risk factors such as:

• Early age at first intercourse (within 1 year of menarche)

• Lower socioeconomic status

• Promiscuous male partners

• Unprotected sexual intercourse

• Family history of cervical cancer (mother or sisters)

• Sexual intercourse with uncircumcised men

• Female offspring of mothers who took diethylstilbestrol (DES)

• Infections with genital herpes or chronic chlamydia

• Multiple sex partners

• Cigarette smoking

• Immunocompromised state

• HIV infection

• Oral contraceptive use

• Moderate dysplasia on Pap smear within past 5 years

• HPV infection (CDC, 2015e)

Question the woman about any signs and symptoms. Clinically, the first sign is abnormal vaginal bleeding, usually after sexual intercourse. Also be alert for reports of vaginal discomfort, malodorous discharge, and dysuria. In some cases, the woman is asymptomatic, with detection occurring at an annual gynecologic examination and Pap test.

Perform a physical examination. Inspect the perineal area for vaginal discharge or genital warts. Perform or assist with a pelvic examination, including the collection of a Pap smear as indicated (Nursing Procedure 8.1).

Take Note!

Suspect advanced cervical cancer in women with pelvic, back, or leg pain, weight loss, anorexia, weakness and fatigue, and fractures.

Prepare the woman for further diagnostic testing if indicated, such as a colposcopy. In a colposcopy, the woman is placed in the lithotomy position and her cervix is cleansed with acetic acid solution. Acetic acid makes abnormal cells appear white, which is referred to as *acetowhite*. These white areas are then biopsied and sent to the pathologist for assessment. Although this test is not painful, it has minor side effects (minor bleeding, cramping, and a risk of an infection developing after the biopsy), and can be performed safely in the clinic or office setting, and women may be apprehensive or anxious about it because it is done to identify and confirm potential abnormal cell growth. Some health care providers request that the woman pre-medicate with a mild analgesic such as ibuprofen prior to undergoing the procedure.

Nursing Management

The nurse's role involves primary prevention by educating women about risk factors and ways to prevent cervical dysplasia. Cervical cancer rates have decreased in the United States because of the widespread use of Pap testing, which can detect precancerous lesions of the cervix before they develop into cancer.

Concept Mastery Alert

Cervical Cancer Prevention

The key points to remember in cervical cancer prevention are smoking cessation, limiting alcohol consumption, and encouraging teens to refrain from early sexual activity.

NURSING PROCEDURE 8.1

Assisting with Collection of a PAP Smear

Purpose: To Obtain Cells From the Cervix for Cervical Cytology Screening

1. Explain procedure to the client (Fig. A).
2. Instruct client to empty her bladder.
3. Wash hands thoroughly.
4. Assemble equipment, maintaining sterility of equipment (Fig. B).
5. Position client on stirrups or foot pedals so that her knees fall outward.
6. Drape client with a sheet for privacy, covering the abdomen but leaving the perineal area exposed.
7. Open packages as needed.
8. Encourage client to relax.
9. Provide support to client as the practitioner obtains a sample by spreading the labia; inserting the speculum; inserting the cytobrush and swabbing the endocervix; and inserting the plastic spatula and swabbing the cervix (Figs. C–H).

10. Transfer specimen to a container (Fig. I) or a slide. If a slide is used, spray the fixative on the slide holding the spray container about 12 inches away from the slide
11. Place sterile lubricant on the practitioner's fingertip when indicated for the bimanual examination.
12. Wash hands thoroughly.
13. Label specimen according to facility policy.
14. Rinse reusable instruments and dispose of waste appropriately (Fig. J).
15. Wash hands thoroughly.
16. Assist the client up after the exam is completed.

Adapted from King, T. L., Brucker, M. C., Kriebs, J. M., Fahey, J. O., Gegor, C. L., & Varney, H. (2015). *Varney's midwifery* (5th ed.). Burlington, MA: Jones & Bartlett Learning; and Schuiling, K. D., & Likis, F. E. (2016). *Women's gynecologic health* (3rd ed.). Burlington, MA: Jones & Bartlett Learning.

Gardasil and Cervarix are vaccines approved by the United States Food and Drug Administration to protect girls and women from HPV and thus prevent cervical cancer. The vaccines prevent infection from four HPV types: HPV 6, 11, 16, and 18. These types are responsible for 70% of cervical cancers and 90% of genital warts (NCI, 2015h). Clinical trials indicate that the vaccine has high efficacy in preventing persistent HPV infection, cervical cancer precursor lesions, vaginal and vulvar cancer precursor lesions, and genital warts (NCI, 2015h). The vaccine is administered by intramuscular injection, and the recommended schedule is a three-dose series with the second and third doses administered 2 and 6 months after the first dose. The recommended age for vaccination of females is 9 to 26 years (Castle & Schmeler, 2015). The vaccines protect against infection with these types of HPV for 6 to 8 years. It is not known if the protection lasts longer. The vaccines do not protect women who are

already infected with HPV (NCI, 2015h). However, the vaccine is not a substitute for routine cervical cancer screening, and vaccinated women should have Pap smears as recommended.

Focus primary prevention education on the following:

- Identify high-risk behaviors in clients and teach them how to reduce such behaviors

- Take steps to prevent STIs.

- Avoid early sexual activity.

- Faithfully use barrier methods of contraception.

- Avoid smoking and drinking.

- Receive the HPV vaccine.

- Instruct women on the importance of screening for cervical cancer by having annual Pap smears. Outline the proper preparation before having a Pap smear (Teaching Guidelines 8.3). Reinforce specific guidelines for screening.

- Interferes with visual evaluation of the sample (Schuiling & Likis, 2016).

Teaching Guidelines 8.3

STRATEGIES TO OPTIMIZE PAP SMEAR RESULTS

- Schedule your Pap smear appointment about 2 weeks (10 to 18 days) after the first day of your last menses to increase the chance of getting the best sample of cervical cells without menses.

- Refrain from intercourse for 48 hours before the test because additional matter such as sperm can obscure the specimen.

- Do not douche within 48 hours before the test to prevent washing away cervical cells that might be abnormal.

- Do not use tampons, birth control foams, jellies, vaginal creams, or vaginal medications for 72 hours before the test, because they could cover up or obscure the cervical cell sample.

- Cancel your Pap appointment if vaginal bleeding occurs, because the presence of blood cells interferes with visual evaluation of the sample.

Nurses also can advocate for clients by making sure that the Pap smear is sent to an accredited laboratory for interpretation. Doing so reduces the risk of false-negative results. The identification and treatment of early precancerous lesions is critical to prevention of cervical cancer. Prevention measures should include educating women that the risk of infection can be reduced by delaying the onset of sexual activity, decreasing the number of sexual partners, using condoms consistently, and never start smoking.

Secondary prevention focuses on reducing or limiting the area of cervical dysplasia. Tertiary prevention focuses on minimizing disability or the spread of cervical cancer. Explain in detail all procedures that might be needed. Encourage the client who has undergone any cervical treatment to allow the pelvic area to rest for approximately 1 month. Discuss this rest period with the client and her partner to gain his cooperation. Outline alternatives to vaginal intercourse, such as cuddling, holding hands, and kissing. Remind the woman about any follow-up procedures that are needed and assist her with scheduling if necessary.

Tertiary prevention of cervical cancer involves the diagnosis and treatment of confirmed cases of cancer. Treatment is typically through surgery, radiotherapy, and, frequently, chemotherapy. Palliative care is provided to women when the disease has already reached an incurable stage. Knowing that the woman and her family have been told about her prognosis, the nurse is in a position to support them when the impact of the diagnosis is realized.

Throughout the process, provide emotional support to the woman and her family. During the decision-making process, the woman may be overwhelmed by the diagnosis and all the information being presented. Refer the woman and her family to appropriate community resources and support groups as indicated. It is crucial for all women to be given correct information regarding safe sexual practices, informed about the preventive role of the HPV vaccination, and become educated about the role of the Pap test as a secondary screening measure for cervical cancer. The emotional needs of the woman diagnosed with cancer can best be met by a warm, friendly personality, an attitude of empathy rather than sympathy, and skilled communication. Nurses across all settings are in a powerful position to be advocates for safe health care practices of women through education at personal, community, and national levels.

VAGINAL CANCER

Vaginal cancer is a rare malignant tissue growth arising in the vagina. Only about 1 of every 1,100 women will develop vaginal cancer in her lifetime. In 2015, the ACS (2015i) estimate that more than 4,000 new cases will be diagnosed in women and that over 900 of those women will die from this cancer. The peak incidence of vaginal cancer occurs at 60 to 65 years of age. The prognosis of vaginal cancer depends largely on the stage of disease and the type of tumor. The overall 5-year survival rate for squamous cell carcinoma is about 42%; that for adenocarcinoma is about 78% (NCI, 2015i). Vaginal cancer can be effectively treated, and when found early it is often curable.

Pathophysiology

The etiology of vaginal cancer has not been identified. Malignant diseases of the vagina are either primary vaginal cancers or metastatic forms from adjacent or distant organs. About 80% of vaginal cancers are metastatic, primarily from the cervix and endometrium. These cancers invade the vagina directly. Cancers from distant sites that metastasize to the vagina through the blood or lymphatic system are typically from the colon, kidneys, skin (melanoma), or breast. Tumors in the vagina commonly occur on the posterior wall and spread to the cervix or vulva (NCI, 2015i).

Squamous cell carcinomas that begin in the epithelial lining of the vagina account for about 85% of vaginal cancers. This type of cancer usually occurs in women over age 50. The SCCs develop slowly over a period of years, commonly in the upper third of the vagina. They tend to spread early by directly invading the bladder and rectal walls. They also metastasize through blood and lymphatics. The remaining 15% are adenocarcinomas, which differ from SCC by an increase in pulmonary metastases and supraclavicular and pelvic node involvement (ACS, 2015j).

Therapeutic Management

Treatment of vaginal cancer depends on the type of cells involved and the stage of the disease. If the cancer is localized, radiation, laser surgery, or both may be used. If the cancer has spread, radical surgery might be needed, such as a hysterectomy, or removal of the upper vagina with dissection of the pelvic nodes in addition to radiation therapy.

Nursing Assessment

Begin the history and physical examination by reviewing for risk factors. Although direct risk factors for the initial development of vaginal cancer have not been identified, associated risk factors include advancing age (over 60 years old), previous pelvic radiation, exposure to DES in utero, vaginal trauma, history of genital warts (HPV infection), HIV infection, cervical cancer, chronic vaginal discharge, smoking, and low socioeconomic level (ACS, 2015k).

Question the woman about any symptoms. Most women with vaginal cancer are asymptomatic. Those with symptoms have painless vaginal bleeding (often after sexual intercourse), abnormal vaginal discharge, dyspareunia, dysuria, constipation, and pelvic pain (NCI, 2015i). During the physical examination, observe for any obvious vaginal discharge or genital warts or changes in the appearance of the vaginal mucosa. Anticipate colposcopy with biopsy of suspicious lesions to confirm the diagnosis.

Nursing Management

Nursing management for this cancer is similar to that for other reproductive cancers, with emphasis on sexuality counseling and referral to local support groups. Women undergoing radical surgery need intensive counseling about the nature of the surgery, risks, potential complications, changes in physical appearance and physiologic function, and sexuality alterations. Nurses should focus their care on client education, client pain and symptom management, communication with the woman and her family, and coordination of care across of all settings.

VULVAR CANCER

Vulvar cancer is an abnormal neoplastic growth on the external female genitalia including the clitoris, vaginal lips, and opening to the vagina (Fig. 8.5). Vulvar cancer accounts for approximately 5% of all female genital malignancies. In the United States, women have a 1 in 333 chance of developing vulvar cancer at some point in their lifetime. It is the fourth most common gynecologic cancer, after endometrial, ovarian, and cervical cancers (NCI, 2015j). The ACS (2015h) estimates that, in 2015, over 5,000 cancers of the vulva will be diagnosed in the United States and over 1,000 women will die of this cancer. When detected early, it is highly curable. Typically, vulvar cancer can be advanced at diagnosis, though it is a visible cancer that can be seen by the woman as an abnormal lesion/growth in her genital region.

Vulvar cancer is found most commonly in older women in their mid-60s to mid-70s, but the incidence in women younger than 35 years old has increased during the past few decades. The overall 5-year survival rate when lymph nodes are not involved is 90%, but it drops to 50% to 70% when the lymph nodes have been invaded (ACS, 2015m).

Pathophysiology

Vulvar cancer can be classified into two groups according to predisposing factors: the first type correlates with a HPV infection and occurs mostly in younger women. The second group is not HPV associated and occurs in elderly women without cancerous disorders. Approximately 80% of vulvar tumors are squamous cell carcinomas. This type of cancer forms slowly over several years and is usually preceded by precancerous changes. These precancerous changes are termed vulvar intraepithelial neoplasia (VIN). The two major types of VIN are classic (undifferentiated) and simplex (differentiated). Classic VIN, the more common one, is associated with HPV infection (genital warts due to types 16, 18, 31, 33, 35, 45, and 54) and smoking (Alkatout et al., 2015). It typically occurs in women between 30 and 40 years old. In contrast to classic VIN, simplex VIN usually occurs in postmenopausal women and is not associated with HPV but chronic irritation over time (Cancer.Net, 2015b).

Screening and Diagnosis

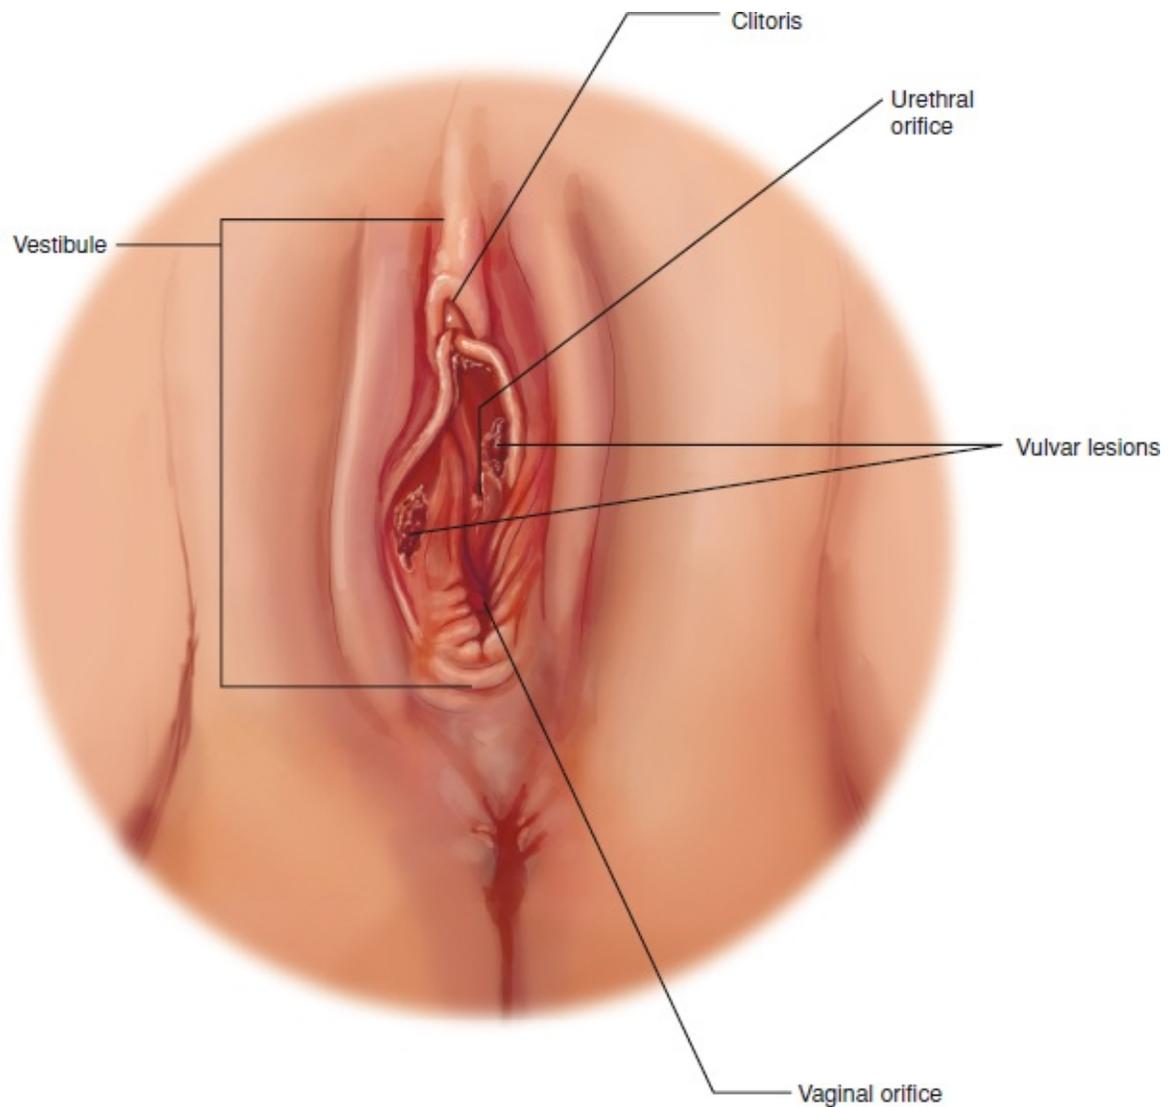
Annual vulvar examination is the most effective way to prevent vulvar cancer. Careful inspection of the vulva during routine annual gynecologic examinations remains the most productive diagnostic technique. Liberal use of biopsies of any suspicious vulvar lesion is usually necessary to make the diagnosis and to guide treatment. However, many women do not seek health care evaluation for months or years after noticing an abnormal lump or lesion. Leading presenting complaints of women with vulvar cancer include dyspareunia, long history of pruritus, ulcers on the "outside" genitalia, vulvar swelling, vulvar bleeding, and urinary problems (Alkatout et al., 2015). The diagnosis of vulvar cancer is made by a biopsy of the suspicious lesion, which is usually found on the labia majora.


FIGURE 8.5 Vulvar cancer. (The Anatomical Chart Company. [2009]. *Atlas of pathophysiology* [3rd ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

 Take Note!

Vulvar pruritus or a lump is present in the majority of women with vulvar cancer. Lumps should be biopsied even if the woman is asymptomatic.

Therapeutic Management

Treatment varies depending on the extent of the disease. Laser surgery, cryosurgery, or electrosurgical incision may be used. Larger lesions may need more extensive surgery and skin grafting. The traditional treatment for vulvar cancer has been radical vulvectomy, but more conservative techniques are being used to improve psychosexual outcomes and less morbidity, without compromising survival (Forner, Dakhil, & Lampe, 2015).

Nursing Assessment

Typically, no single specific clinical symptom heralds this disease, so diagnosis is often delayed significantly. Therefore, it is important to review the woman's history for risk factors such as:

• Exposure to HPV type 16

• Age over 50 years

• HIV infection

• VIN

• Lichen sclerosus (a patchy skin disorder)

• Melanoma or atypical moles

• Exposure to HSV type 2

• Multiple sex partners

• Smoking

• Herpes simplex

• History of breast cancer

• Immune suppression

• Hypertension

• Diabetes mellitus

• Obesity (ACS, 2015n).

In most cases, the woman reports persistent vulvar itching, burning, and edema that do not improve with the use of creams or ointments. A history of condyloma, gonorrhea, and herpes simplex are some of the factors for greater risk for VIN. Diagnosis of vulvar carcinoma is often delayed. Women neglect to seek treatment for an average of 6 months from the onset of symptoms. In addition, a delay in diagnosis often occurs after the client presents to her physician. In many cases, a biopsy of the lesion is not performed until the problem fails to respond to numerous topical therapies. During the physical examination, observe for any masses or thickening of the vulvar area. A vulvar lump or mass is most often noted. The vulvar lesion is usually raised and may be fleshy, ulcerated, leukoplakic (looking like white patches), or warty. The cancer

can appear anywhere on the vulva, although about three fourths arise primarily on the labia (Vargo & Beriwal, 2015). Less commonly, the woman may present with vulvar bleeding, discharge, dysuria, and pain.

Nursing Management

Women with vulvar cancer must clearly understand their disease, treatment options, and prognosis. To accomplish this, provide information and establish effective communication with the client and her family. Act as an educator and advocate.

Teach the woman about healthy lifestyle behaviors, such as smoking cessation and measures to reduce risk factors. For example, instruct the woman how to examine her genital area, urging her to do so monthly between menstrual periods. Tell her to look for any changes in appearance (e.g., whitened or reddened patches of skin); changes in feel (e.g., areas of the vulva becoming itchy or painful); or the development of lumps, moles (e.g., changes in size, shape, or color), freckles, cuts, or sores on the vulva. Urge the woman to report these changes to the health care provider (ACS, 2015m).

Teach the woman about preventive measures such as not wearing tight undergarments and not using perfumes and dyes in the vulvar region. Also educate her about the use of barrier methods of birth control (e.g., condoms) to reduce the risk of contracting HIV, HSV, and HPV. Other prevention measures include delaying first sexual intercourse, avoiding sexual intercourse with multiple partners, not starting smoking or quitting if a smoker already, and getting the HPV vaccine available for all boys and girls and women between 9 and 26 years old.

For the woman diagnosed with vulvar cancer, provide information and support. Discuss potential changes in sexuality if radical surgery is performed. Encourage her to communicate openly with her partner. Refer her to appropriate community resources and support groups. All nurses should come in contact with women in their clinical practices who have the potential to become cancer clients, already have suspicious signs or symptoms of cancer, are already undergoing cancer treatment, or are terminal cancer clients. The nurse should be involved with all aspects of cancer, from diagnosis through palliative care. Each nurse has an obligation to keep informed of current developments in the cancer field to function effectively and be able to educate the woman and her family.

KEY CONCEPTS

⦿ Women have a one-in-three lifetime risk of developing cancer, and one out of

every four deaths is from cancer; thus, nurses must focus on screening and educating all women regardless of risk factors.

- The nurse plays a key role in offering emotional support, determining appropriate sources of support, and helping the woman use effective coping strategies when facing a diagnosis of cancer of the reproductive tract. Although reproductive tract cancer is rare during pregnancy, the woman's vigilance and routine screenings should continue throughout.

- A woman's sexuality and culture are inextricably interwoven, and it is essential that nurses working with women of various cultures recognize this and remain sensitive to the vast changes that will take place when the diagnosis of cancer is made.

- Ovarian cancer is the eighth most common cancer among women and the fourth most common cause of cancer deaths for women in the United States, accounting for more deaths than any other cancer of the reproductive system.

- Ovarian cancer has been described as the "overlooked disease" or "silent killer" because women and health care practitioners often ignore or rationalize early symptoms. It is typically diagnosed in advanced stages.

- Unopposed endogenous and exogenous estrogens, obesity, nulliparity, menopause after the age of 52 years, and diabetes are the major etiologic risk factors associated with the development of endometrial cancer.

- The American Cancer Society recommends that women should be informed about risks and symptoms of endometrial cancer at the onset of menopause and strongly encouraged to report any unexpected bleeding or spotting to their health care providers.

- Malignant diseases of the vagina are either primary vaginal cancers or metastatic forms from adjacent or distant organs. Vaginal cancer tumors can be effectively treated and, when found early, are often curable.

- Cervical cancer incidence and mortality rates have decreased noticeably in the past several decades, with most of the reduction attributed to the Pap test, which detects cervical cancer and precancerous lesions.

- The nurse's role involves primary prevention of cervical cancer through education of women regarding risk factors and preventive vaccines to avoid cervical dysplasia.

- About 80% of the diagnosed vaginal cancers are metastatic, primarily from the cervix and endometrium. These cancers invade the vagina directly. Vulvar

cancer is often delayed significantly because there is no single specific clinical symptom that heralds it. The most common presentation is persistent vulvar itching that does not improve with the application of creams or ointments.

CHAPTER **WORKSHEET**

MULTIPLE CHOICE QUESTIONS

1. When describing ovarian cancer to a local women's group, the nurse states that ovarian cancer often is not diagnosed early because:

    a. The disease progresses very slowly.

    b. The early stages produce very vague symptoms.

    c. The disease usually is diagnosed only at autopsy.

    d. Clients do not follow up on acute pelvic pain.

2. A postmenopausal woman reports that she has started spotting again. Which of the following would the nurse do?

    a. Instruct the client to keep a menstrual diary for the next few months.

    b. Tell her not to worry, since this a common but not serious event.

    c. Have her start warm-water douches to promote healing.

    d. Anticipate that the doctor will assess her endometrium thickness.

3. Which of the following would the nurse identify as the priority psychosocial need for a women diagnosed with reproductive cancer?

    a. Research findings

    b. Hand-holding

c. Cheerfulness

d. Offering of hope

4. When teaching a group of women about screening and early detection of cervical cancer, the nurse would include which of the following as most effective?

a. Fecal occult blood test

b. CA-125 blood test

c. Pap smear and HPV test

d. Sigmoidoscopy

5. After teaching a group of students about reproductive tract cancers, the nursing instructor determines that the teaching was successful when the students identify which of the following as the deadliest type of female reproductive cancer?

a. Vulvar

b. Ovarian

c. Endometrial

d. Cervical

6. The nurse is attempting to reassure her obese female client about the discovery of an ovarian cyst after her pelvic exam. Which of the following statements is true concerning ovarian cysts? They are:

a. Frequently seen in polycystic kidney disease

b. Always painful and need to be removed surgically

c. A precursor to ovarian carcinoma

d. Part of a syndrome that includes hypertension and diabetes

7. Which of the following is considered a risk factor for vulvar cancer?

a. Vitamin B_{12} deficiency

b. Epstein–Barr virus

c. Human papillomavirus

d. Adenovirus

CRITICAL THINKING EXERCISES

1. A 27-year-old sexually active White woman visits the Health Department family planning clinic and requests information about the various available methods of contraception. In taking her history, the nurse learns that she started having sex at age 15 and has had multiple sex partners since then. She smokes two packs of cigarettes daily. Because she has been unemployed for a few months, her health insurance policy has lapsed. She has never previously obtained any gynecologic care.

   a. Based on her history, which risk factors for cervical cancer are present?

   b. What recommendations would you make for her and why?

   c. What are this client's educational needs concerning health maintenance?

2. A 60-year-old nulliparous woman presents to the gynecologic oncology clinic after her health care provider palpated an adnexal mass on her right ovary. In taking her history, the nurse learns that she has experienced mild abdominal bloating and weight loss for the past several months but felt fine otherwise. She was diagnosed with breast cancer 15 years ago and was treated with a lumpectomy and radiation. She has occasionally used talcum powder in her perineal area over the past 20 years.

A transvaginal ultrasound reveals a complex mass in the right adnexa. She undergoes a total abdominal hysterectomy and bilateral salpingo-oophorectomy and lymph node biopsy. Pathology confirms a diagnosis of stage III ovarian cancer with abdominal metastasis and positive lymph nodes.

   a. Is this client's profile typical for a woman with this diagnosis?

   b. What in her history might have increased her risk for ovarian cancer?

   c. What can the nurse do to increase awareness of this cancer for all women?

STUDY ACTIVITIES

1. During your surgical clinical rotation, interview a female client undergoing surgery for cancer of her reproductive organs. Ask her to recall the symptoms that brought her to the health care provider. Ask her what thoughts, feelings, and emotions went through her mind before and after her diagnosis. Finally, ask her how this experience will change her life in the future.

2. Visit an oncology and radiology treatment center to find out about the various treatment modalities available for reproductive cancers. Contrast the various treatment methods and report your findings to your class.

3. Visit one of the web sites listed in the extensive list of websites provided on to explore a topic of interest concerning reproductive cancers. How correct and current is the content? What is its level? Share your assessment with your classmates.

4. Taking oral contraceptives provides protection against _____ cancer.

5. Two genes, BRCA1 and BRCA2, are linked with hereditary _____ and _____ cancers.

BRINGING IT ALL TOGETHER: CASE STUDY

Jill, a 38-year old obese female with a history of infertility and irregular bleeding, returns to her OB/GYN doctor as a follow-up appointment. She had a D&C the week before to stop a profuse bleeding episode. She is informed by the doctor that her pathology report came back from the D&C showing endometrial adenocarcinoma. She is in shock over the diagnosis at her young age.

ASSESSMENT

The nurse takes Jill's history, which includes irregular menstrual cycles since her menarche. She has a BMI of 32. She takes medication to manage her diabetes and hypertension. She had been previously diagnosed with Polycystic ovary syndrome (PCOS) when she was a teenager. Her pelvic exam demonstrates an enlarged uterus. She had been to see her doctor several times because of her irregular bleeding, but she had been treated with medications until a D&C was done after months of unsuccessful drug therapy.

Go to thePoint to find questions to consider about this case.

9

Violence and Abuse

KEY TERMS

acquaintance rape
battered women syndrome
cycle of violence
date rape
female genital cutting (FGC)
human trafficking
incest
intimate partner violence (IPV)
post-traumatic stress disorder (PTSD)
rape
sexual abuse

statutory rape

Learning Objectives

Upon completion of the chapter, you will be able to:

1. Examine the incidence of violence in women.
2. Characterize the cycle of violence and appropriate interventions.
3. Evaluate the various myths and facts about violence.
4. Analyze the dynamics of rape and sexual abuse.
5. Select the resources available to women experiencing abuse.
6. Outline the role of the nurse who cares for abused women.

Dorothy came to the prenatal clinic with a complaint of recurring headaches. She had been in twice this week already, but insisted she be seen today and started to cry. When the nurse called her into the examination room, Dorothy's cell phone rang. She hurried to answer it and told the person on the other end that she was at the store. When the nurse asked if she was afraid at home, Dorothy answered "at times." What cues did the nurse pick up on to ask that question? How frequent is this problem in women?

WOW

Words of Wisdom

After being traumatized, women can decide to stay in the shallow end of the pool or they can find support and swim in the ocean.

INTRODUCTION

Imagine if you were subjected to assault, rape, sexual slavery, torture, verbal abuse, mutilation, even murder—all because of your gender. It seems rarely acknowledged that violence against women and girls exists on the scale it does. Many of these females are brutalized from cradle to grave simply because of their gender. This abuse is the most pervasive human rights violation in the world today, and yet remains silent to many ears around the globe.

Gender-based violence is a major global public health and human rights problem and one that often goes unrecognized and unreported. It is a common source of physical, psychological, and emotional morbidity. It occurs in all countries, irrespective of social, economic, religious, or cultural group. It affects women across race, ethnicity, age, socioeconomic status, religion, sexual orientation, and geographic boundaries. No segments of society are immune from the vestiges of this problem. Due to the unequal power relations between men and women, women are violated either in the family, in the community, or in the country in which they live. The causes are multidimensional and are social, economic, cultural, political, and religious. Pregnancy is a time of unique vulnerability to intimate partner violence (IPV) victimization because of changes in women's physical, social, emotional, and economic needs during pregnancy. Although the true prevalence of violence during pregnancy is unclear, research suggests it is substantial and often continues into the postpartum period. Gender-based violence is one of the most rigorous challenges of women's health and well-being; it is a harrowing worldwide public health concern with serious consequences for individuals, families, and societies (Berthold, 2015).

Female-perpetrated violence against male partners receives little attention. Although women are victims of violence more frequently than men, the prevalence of violence among men nonetheless represents a significant public health concern. One out of every four men has experienced rape, physical violence, and/or stalking by an intimate partner in their lifetime (National Coalition Against Domestic Violence, 2015).

Although women can be violent in relationships with men, and also in same-sex partnerships, the overwhelming burden of partner violence is borne by women at the hands of men. Nearly 4 in 10 women and 1 in 10 men in the United States have experienced rape, physical violence, and/or stalking by a

partner with IPV-related impact (WHO, 2015a).

For all the strides American women have made in the past 100 years, obliterating violence against themselves is not one of them. Violence against women is a growing problem and in many countries is still accepted as part of normal behavior. According to the Federal Bureau of Investigation (FBI) (2015), up to half of all women in the United States will experience some form of physical violence during their lifetime. In North America, 40% to 60% of murders of women are committed by intimate partners (FBI, 2015). Recently, the FBI has broadened its definition of rape. The new definition, as it appears on the FBI website, is "Penetration, no matter how slight, of the vagina or anus with any body part or object, or oral penetration by a sex organ of another person, without the consent of the victim." This broader definition will have a dramatic impact on the way rape is tracked and reported nationwide (FBI, 2015).

Federal funding for the problem is trickling down to local programs, but it is not reaching victims fast enough. For example, the United States has three times more shelters for animals than for battered women (Bouchet & Braswell, 2015). In many cases, a victim escapes her abuser only to be turned away from a local shelter because it is full. The number of abused women is staggering: one woman is being battered every 12 seconds in the United States (CDC, 2015a).

Nurses play a major role in assessing women who have suffered some type of violence. Nurses have a central ethic of caring and an agenda of early intervention and health promotion for their clients to improve their health status and well-being. Often, after a woman is victimized, she will complain about physical ailments that will give her the opportunity to visit a health care setting. A visit to a health care agency is an ideal time for women to be assessed for violence. Because nurses are viewed as trustworthy and sensitive about very personal subjects, women often feel comfortable confiding in them and discussing these issues with them. As a professional nurse, the act of screening women seen in every health care setting is often the first step for a victim to start thinking about a better future. Remember, your words carry weight with your client who looks to you for help, support, and encouragement.

Take Note!

Nurses will come in contact with violence and sexual abuse no matter what health care setting they work in. Nurses must be ready to ask the right questions

and to act on the answers, because such action could be lifesaving.

This chapter addresses several types of gender-based violence: IPV, female genital cutting (FGC), human trafficking, and sexual abuse. All of these types of violence against women have devastating and costly consequences for all of society.

INTIMATE PARTNER VIOLENCE

IPV is actual or threatened physical or sexual violence or psychological/emotional abuse. Research suggests that physical violence in intimate relationships is often accompanied by psychological abuse and in one third to over one half of cases by sexual abuse (CDC, 2015b). Intimate partners include individuals who are currently in dating, cohabitating, or marital relationships, or those who have been in such relationships in the past. Some of the common terms used to describe IPV are domestic abuse, spouse abuse, domestic violence, gender-based violence, battering, and rape. IPV affects a distressingly high percentage of the population and has physical, psychological, social, and economic consequences (Fig. 9.1).

FIGURE 9.1 Intimate partner violence has significant physical, psychological, social, and economic consequences. An important role of the health care provider is to identify abusive or potentially abusive situations as soon as possible and provide support for the victim.

Because a nurse may be the first health care provider to assess and identify the signs of IPV, a nurse can have a profound impact on a woman's decision to seek help. Thus, it is important for nurses to be able to identify abuse and aid the victim. IPV can leave significant psychological scars, and a well-trained nurse can have a positive impact on the victim's mental and emotional health.

Incidence

Overall, lifetime, and 1-year estimates for sexual violence, stalking, and IPV are alarmingly high for adult Americans, with IPV alone affecting more than 12 million people each year. On average, 20 persons per minute are victims of rape, physical violence, or stalking by an intimate partner in the United States. Women are disproportionately affected. The estimated cost of violence in the United States exceeds $70 billion each year. Each year, IPV results in an estimated 2,500 deaths and 3 million injuries among women (CDC, 2015c).

Women are at risk for violence at nearly every stage of their lives. Old, young, beautiful, unattractive, married, single—no woman is completely safe from the risk of IPV. Current or former husbands or lovers kill over half of the murdered women in the United States. IPV against women causes more serious injuries and deaths than automobile accidents, rapes, and muggings combined. IPV is expensive. The medical cost of IPV approaches $4.4 trillion each year globally to pay for medical and surgical care, counseling, child care, burden on the justice system, incarceration, attorney fees, and loss of work productivity (Lomborg, 2015).

IPV is pervasive and crosses all boundaries of sexual orientation, race, and class. The intimidation of another person through abusive acts and words is not a gender issue. Violence within these relationships may go unreported for fear of harassment or ridicule. The medical community's efforts to address IPV have often neglected members of the lesbian, gay, bisexual, and transgender (LGBT) population. Heterosexual women are primarily targeted for IPV screening and intervention despite the similar prevalence of IPV in LGBT individuals and its detrimental health effects (Cannon & Buttell, 2015). Perhaps because of the multiple barriers that confront LGBT abuse victims and the invisibility of the problem in the context of IPV services, the role of the nurse as their advocate is all the more critical.

Little is known about the national prevalence of IPV, sexual violence, and stalking among the LGBT community in the United States. Research documents that rates of IPV among LGBT individuals are equal to or greater than rates observed among heterosexual individuals. Risk factors are also similar to those documented among heterosexual individuals, in addition to help-seeking leaving, and recovery process (Edwards, Sylaska, & Neal, 2015). Current findings seem to also indicate some disparities in perceptions of what constitutes abuse among

same and opposite sex couples (Russell & Chapleau, 2015). The *Violence against Women Act* has recently been renewed. It now includes coverage of same-sex partners—a big sign that attitudes are changing and improving for gays seeking shelters and help. As individuals and society come to realize same-sex partner violence as an existing problem, there is hope.

Background

Until the mid-1970s, our society tended to legitimize a man's power and control over a woman. The United States legal and judicial systems considered intervention into family disputes wrong and a violation of the family's right to privacy. IPV was often tolerated and even socially acceptable. Fortunately, attitudes and laws have changed to protect women and punish abusers. In *Healthy People 2020*, there are 13 measurable violence prevention objectives displayed in the *Healthy People 2020* table that follows. In addition to the 13 objectives listed, there are seven developmental objectives that focus on preventing sexual violence across the lifespan and preventing the different forms of partner violence including physical and sexual violence, emotional abuse, and stalking by a current or former partner.

Characteristics of Intimate Partner Violence

Although more research is needed in this area, studies have found certain risk factors for IPV in men. These risk factors can be divided into four different categories: individual factors, relationship factors, community factors, and societal factors. Specific risk factors within each category are listed in Table 9.1.

HEALTHY PEOPLE 2020 • *9.1*

Violence Prevention Objectives

Violence Prevention Objectives

Objectives	Baseline (Year)	Target (2020)
IVP-29 Reduce homicides per 100,000 population	6.1 (2007)	5.5
IVP-30 Reduce firearm-related deaths per 100,000 population	10.3 (2007)	9.3
IVP-31 Reduce nonfatal firearm-related injuries per 100,000 population	20.7 (2007)	18.6
IVP-32 Reduce nonfatal physical assault injuries per 100,000 population	512.5 (2008)	461.2
IVP-33 Reduce physical assaults per 1,000 population (12+ years)	21.2 (2008)	19.2
IVP-34 Reduce physical fighting among adolescents in grades 9–12	31.5 (2009)	28.4
IVP-35 Reduce bullying among adolescents in grades 9–12	19.9 (2009)	17.9
IVP-36 Reduce weapon carrying by adolescents on school property	5.6 (2009)	4.6
IVP-37Reduce child maltreatment deaths per 100,000 population	2.3 (2008)	2.1
IVP-38 Reduce nonfatal child maltreatment per 100,000 population	9.4 (2008)	8.5
IVP-41 Reduce nonfatal intentional self-harm injuries per 100,000	124.9 (2008)	112.4
IVP-42 Reduce children's exposure to violence <18 years old	58.8 (2008)	52.9
IVP-43 Increase the number of states that link data on violent deaths	16 states	50 states

Nursing Significance

- Will increase men and women's quality and years of healthy life
- Eliminate health disparities for survivors of violence
- Goal is to have improved adherence to screening for IPV by health care providers
- Meeting these objectives will reflect the importance of early detection, intervention, and evaluation
- Eliminating LGBT health disparities and enhancing efforts to improve LGBT health are necessary to ensure that LGBT individuals can lead long, healthy lives

Healthy People objectives based on data from http://www.healthypeople.gov.

Generation-to-Generation Continuum of Violence

Violence is a learned behavior that, without intervention, is self-perpetuating. It is a cyclical health problem. The long-term effects of violence on victims and children can be profound. Children who witness one parent abuse another are more likely to become delinquents or batterers themselves because they see abuse as an integral part of a close relationship. Thus, an abusive relationship between father and mother can perpetuate future abusive relationships. Violence in childhood and adolescence is linked to the child's perception of the family as a hostile environment and of violence against women as a corrective measure, and insults, swearing, and humiliation by their partner is acceptable (Song et al., 2015). If one considers violence against children and spouses, the psychological consequences are huge, stemming from the paradox of the victim being abused by a member of the family with whom he or she expects to have a supportive, loving, and respectful relationship. Research has found that children who witness IPV are at risk for developing psychiatric disorders, post-traumatic stress disorder (PTSD), developmental problems, school failure, violence against others, and low self-esteem (Cater et al., 2015).

Childhood maltreatment is a major health problem that is associated with a wide range of physical conditions and leads to high rates of psychiatric morbidity and social problems in adulthood. Consequences of violence extend far beyond the physical and mental suffering of victims and their families and have an impact on schools, neighborhoods, businesses, and the legal and health care systems. Women who were physically or sexually abused as children have an increased risk of victimization and fear of crime, poor general health, and in addition experience adverse mental health conditions such as depression, anxiety, and low self-esteem as adults (Barrios et al., 2015).

TABLE 9.1 COMMON MYTHS AND FACTS ABOUT VIOLENCE

Myths	Facts
Battering of women occurs only in lower socioeconomic classes	Violence occurs in all socioeconomic classes
Substance abuse causes the violence	Violence is a learned behavior and can be changed. The presence of drugs and alcohol can make a bad problem worse
Men have the right to discipline their partners. Battering is not a crime	In the past, our patriarchal legal system afforded men the right to physically chastise their wives and children; we no longer live under that system. Women and children are no longer considered the property of men, and violence against them is a crime in every state
Violence occurs to only a small percentage of women	One in four women will be victims of violence
Intimate partner violence (IPV) is typically a one time, isolated occurrence	Battering is a pattern of coercion and control that one person exerts over another. It is repeated using a number of tactics, including intimidation, threats, physical injury, economic deprivation, isolation, and sexual abuse. The various forms of abuse utilized by batterers help maintain power and control over their victims
Women can easily choose to leave an abusive relationship	Women stay in the abusive relationship because they feel they have no options
Only men with mental health problems commit violence against women	Abusers often seem normal and do not appear to suffer from personality disorders or other forms of mental illness
Pregnant women are protected from abuse by their partners	One in five women is physically abused during pregnancy. The effects of violence on infant outcomes can include preterm delivery, fetal distress, low birth weight, and child abuse
Women provoke their partners to abuse them	Women may be willing to blame themselves for someone else's bad behavior, but nobody deserves to be beaten
Violent tendencies have gone on for generations and are accepted	The police, justice system, and society are beginning to make IPV socially unacceptable
IPV is only a heterosexual issue	There is as much IPV in the lesbian/gay/bisexual/transgender population as in heterosexual relationships with the added psychological abuse of "outing" (when one partner threatens to disclose the others sexual preference in an effort to maintain power and control)

Adapted from Domestic Violence Organization.(2015a). *Common myths and why they are wrong.* Retrieved from http://www.domesticviolence.org/common-myths/; Tahoe Safe Alliance. (2015). *Myths about intimate partner violence in the LGBTQUA community.* Retrieved from http://tahoesafealliance.org/for-lgbqtia/lgbtqiamyths/; and Medicine Net. (2015b). *Domestic violence.* Retrieved from http://www.medicinenet.com/domestic_violence/page4.htm#what_are_the_causes_or_risk_factors_for_intimate_partner_violence

In many cases when a parent is abused, the children are abused as well. Approximately one in eight children is abused annually in the United States. The lifetime economic cost to society of childhood maltreatment is estimated to be $124 billion dollars (Jackson & Deye, 2015). Young children who live with family violence represent a disempowered group. Developmentally, young children have relatively limited verbal skills and emotional literacy. In addition, the environment becomes one of secrecy and intimidation, as well as reduced emotional availability from the child's main caretaker. Taken together, these factors severely restrict these young children's capacity and opportunity to make their voices and needs heard (Jackson & Deye, 2015). Exposure to violence has a negative impact on children's physical, emotional, and cognitive well-being.

The cycle continues into another generation through learned responses and violent acting out. Although there are always exceptions, most children deprived of their basic physical, psychological, and spiritual needs do not develop healthy personalities. They grow up with feelings of fear, behavioral problems, substance abuse, relationship difficulties, inadequacy, anxiety, anger, hostility, guilt, and rage. They often lack coping skills, blame others, demonstrate poor impulse control, have early delinquent behavior, and generally struggle with authority (Huang et al., 2015). Unless this cycle is broken, more than half become abusers themselves (CDC, 2015e).

The Cycle of Violence

In an abusive relationship, the cycle of violence comprises three distinct phases: the tension-building phase, the acute battering phase, and the honeymoon phase (Lawrence, 2015). The cyclical behavior begins with a time of tension-building arguments, progresses to violence, and settles into a making-up or calm period. This cycle of violence increases in frequency and severity as it is repeated over and over again. The cycle can cover a long or short period of time. The honeymoon phase gradually shortens and eventually disappears altogether. Abuse in relationships typically becomes accelerated and thus more dangerous over time. The abuser no longer feels the need to apologize and indulge in a honeymoon phase as the woman becomes increasingly disempowered in the relationship.

PHASE 1: TENSION BUILDING

During the first—and usually the longest—phase of the cycle, tension escalates between the couple. Excessive drinking, jealousy, or other factors might lead to name-calling, hostility, and friction. The woman might sense that her partner is reacting to her more negatively, that he is on edge and reacts heatedly to any trivial frustration. A woman often will accept her partner's building anger as legitimately directed toward her. She internalizes what she perceives as her responsibility to keep the situation from exploding. In her mind, if she does her job well, he remains calm. But if she fails, the resulting violence is her fault.

PHASE 2: ACUTE BATTERING

The second phase of the cycle is the explosion of violence. The batterer loses control both physically and emotionally. This is when the victim may be

assaulted or murdered. After a battering episode, most victims consider themselves lucky that the abuse was not worse, no matter how severe their injuries. They often deny the seriousness of their injuries and refuse to seek medical treatment.

PHASE 3: HONEYMOON

The third phase of the cycle is a period of calm, loving, and contrite behavior on the part of the batterer. He may be genuinely sorry for the pain he caused his partner. He attempts to make up for his brutal behavior and believes he can control himself and never hurt the woman he loves. The victim wants to believe that her partner really can change. She feels responsible, at least in part, for causing the incident, and she feels responsible for her partner's well-being (Box 9.1).

BOX 9.1

CYCLE OF VIOLENCE (FEMALE VICTIM AND MALE ABUSER)

• *Phase 1—Tension building:* Verbal or minor battery occurs. Almost any subject, such as housekeeping or money, may trigger the buildup of tension. There is a breakdown of communication. The victim attempts to calm the abuser. Victim feels like "walking on egg shells" around the abuser.

• *Phase 2—Acute battering:* Characterized by uncontrollable discharge of tension. Violence is rarely triggered by the victim's behavior: she is battered no matter what her response. The start of the battering episode is unpredictable and beyond the victim's control.

• *Phase 3—Reconciliation (honeymoon)/calm phase:* First, the abuser is ashamed of his behavior. The batterer tries to minimize the abuse and blame it on the partner. The batterer becomes loving, kind, and apologetic and expresses guilt. Then the abuser works on making the victim feel responsible. This loving behavior strengthens the bond between partners and will probably convince the victim, once again, that leaving the relationship is not necessary.

Types of Abuse

Abusers may use whatever it takes to control a situation—from emotional abuse and humiliation to physical assault. Victims often tolerate emotional, physical, financial, and sexual abuse. Many remain in abusive relationships because they believe they deserve the abuse.

Emotional Abuse

Emotional abuse includes:
• Promising, swearing, or threatening to hit the victim
• Forcing the victim to perform degrading or humiliating acts
• Threatening to harm children, pets, or close friends
• Humiliating the woman by name-calling and insults
• Threatening to leave her and the children
• Isolation from family and friends
• Destroying valued possessions
• Controlling the victim's every move

Physical Abuse

Physical abuse includes:
• Hitting or grabbing the victim so hard that it leaves marks
• Throwing things at the victim
• Slapping, spitting at, biting, burning, pushing, choking, or shoving the victim
• Kicking or punching the victim, or slamming her against things
• Attacking the victim with a knife, gun, rope, or electrical cord
• Controlling access to health care for injury

Financial Abuse

Financial abuse includes:
• Preventing the woman from getting a job

• Sabotaging a current job

• Controlling how all money is spent

• Failing to contribute financially

Sexual Abuse

Sexual abuse includes:

• Forcing the woman to have vaginal, oral, or anal intercourse against her will

• Biting the victim's breasts or genitals

• Shoving objects into the victim's vagina or anus

• Forcing the woman to do something sexual that she finds degrading or humiliating

• Forcing the victim to perform sexual acts on other people or animals

Myths and Facts About Intimate Partner Violence

Table 9.2 lists many of the myths about IPV. Health care providers should take steps to dispel these myths.

Abuse Profiles

Victims

Ironically, victims rarely describe themselves as abused. In battered woman syndrome, the woman has experienced deliberate and repeated physical or sexual assault by an intimate partner. She is terrified and feels trapped, helpless, and alone. She reacts to any expression of anger or threat by avoidance and withdrawal behavior. Some women believe that the abuse is caused by a personality flaw or inadequacy in themselves (e.g., inability to keep the man happy). These feelings of failure are reinforced and exploited by their partners. After being told repeatedly that they are "bad," some women begin to believe it. Many victims were abused as children and may have poor self-esteem, poor health, PTSD, depression, insomnia, low education achievement, or a history of suicide attempts, injury, or drug and alcohol abuse (Barrios et al., 2015).

Abusers

Abusers come from all walks of life and often feel insecure, powerless, and helpless; feelings that are not in line with the macho image they would like to project. The abuser expresses his feelings of inadequacy through violence or aggression toward others (Lawson, 2015).

Violence typically occurs at home and is usually directed toward the man's intimate partner or the children who live there. Abusers refuse to share power and choose violence to control their victims. They often exhibit childlike aggression or antisocial behaviors. They may fail to accept responsibility or blame others for their own problems. They might also have a history of substance abuse problems, trouble with the justice system, few close relationships, being sensitive to criticism, having a tendency to hold grudges, involved in power struggles, emotionally dysregulated, lacking in insight, prone to feeling misunderstood, mistreated, or victimized, mental illness, arrests, troubled relationships, obsessive jealousy, controlling behaviors, generally violent behavior, erratic employment history, and financial problems (Lawson, 2015).

Violence Against Pregnant Women

Many think of pregnancy as a time of celebration and planning for the unborn child's future, but in a troubled relationship it can be a time of escalating violence. The strongest predictor of abuse during pregnancy is prior abuse. Violence against pregnant women seems to be more prevalent than diseases routinely investigated during prenatal care, such as preeclampsia and diabetes (Lévesque & Chamberland, 2015). For women who have been abused before, beatings and violence during pregnancy are "business as usual" for them.

Women are at a higher risk for violence during pregnancy. Recent research findings indicate that having children does not protect women from IPV. On the contrary, the IPV appears to last longer if women have children, and this also seems to be the case even after the partnership has come to an end (Mauri et al., 2015). Pregnant women are vulnerable during this time, and abusers can take advantage of it. An estimated 325, 000 pregnant women are abused by their partners each year (CDC, 2015a). Abuse during pregnancy poses special risks and dynamics. Various factors may lead to battering during pregnancy, including:

• Inability of the couple to cope with the stressors of pregnancy

• Young age at time of pregnancy

• Having less than a high school education for both partners

• Unemployment for either or both in partnership

• Violence in the family of origin

• Cohabitation and single marital status

• Sexual proprietariness on the part of the male partner

• Heavy drinking by partner

• Resentment toward the interference of the growing fetus and change in the woman's shape

• Doubts about paternity or the expectant mother's fidelity during pregnancy

• Perception that the baby will be a competitor

• Outside attention the pregnancy brings to the woman

• Unwanted pregnancy

- The woman's new interest in herself and her unborn baby
- Insecurity and jealousy about the pregnancy and the responsibilities it brings
- Financial burden related to expense of pregnancy and loss of income
- Stress of role transition from adult man to becoming the father of a child
- Physical and emotional changes of pregnancy that make the woman vulnerable
- Previous isolation from family and friends that limit the couple's support system

TABLE 9.2 COMMON MYTHS AND FACTS ABOUT RAPE

Myths	Facts
Women who are raped get over it quickly	It can take several years to recover emotionally and physically from rape
Most rape victims tell someone about it	The majority of women never tell anyone about it. In fact, almost two thirds of victims never report it to the police
Once the rape is over, a survivor can again feel safe in her life	The victim feels vulnerable, betrayed, and insecure afterward
If a woman does not want to be raped, it cannot happen	A woman can be forced and overpowered by most men
Women who feel guilty after having sex then say they were raped	Few women falsely cry "rape." It is very traumatizing to be a victim
Victims should report the violence to the police and judicial system	Only 1% of rapists are arrested and convicted. Factoring unreported rapes together with the odds of being arrested and getting a felony conviction, only 6% of rapists will ever spend a day in jail. In other words, 15 of 16 rapists walk free
Women blame themselves for the rape, believing they did something to provoke the rape	Women should never blame themselves for being the victim of someone else's violence
When it comes to sex, men can be provoked to "a point of no return"	Men are physically able to stop at any point during sexual activity. Rape is not an act of impulsive, uncontrolled passion; it is a premeditated act of violence
Women who wear tight, short clothes are "asking for it"	No victim invites sexual assault, and what she wears is irrelevant
Women have rape fantasies and want to be raped	Reality and fantasy are different. Dreams have nothing to do with the brutal violation of rape
Only attractive women are raped	Anyone can be raped. Children, the elderly, and people with physical and mental disabilities are easy targets of rape because of their vulnerability
Medication can help women forget about the rape	Initially medication can help, but counseling is needed

Retrieved from: https://well.wvu.edu/articles/rape_myths_and_facts

Abuse during pregnancy threatens the well-being of the mother and fetus.

Physical violence may involve injuries to the head, face, neck, thorax, breasts, and abdomen. The mental health consequences are also significant. Several studies have confirmed the relationship between abuse and poor mental health, especially depression and PTSD; poor quality of life; increased distress, fearfulness, anxiousness, and stressfulness; and increased use of tobacco, alcohol, and/or illicit drugs (Lawson, 2015). For the pregnant woman, many of these conditions most often manifest during the postpartum period.

Take Note!

Frequently the fear of harm to her unborn child will motivate a woman to escape an abusive relationship.

Women assaulted during pregnancy are at risk for:
• Injuries to themselves and the fetus
• Depression
• Panic disorder
• Fetal and maternal deaths
• Chronic anxiety
• Miscarriage
• Stillbirth
• Poor nutrition
• Insomnia
• Placental abruption
• Uterine rupture
• Excessive weight gain or loss
• Smoking and substance abuse
• Delayed or no prenatal care
• Preterm labor
• Higher rate of surgical births
• Chorioamnionitis

- Vaginitis

- Sexually transmitted infections (STIs)

- Urinary tract infections

- Premature and low-birth-weight infants (AWHONN, 2015)

Signs of abuse can emerge during pregnancy and may include poor attendance at prenatal visits, unrealistic fears, weight fluctuations, difficulty with pelvic examinations, and nonadherence to treatment. See Evidence-Based Practice 9.1 for an intervention utilized for pregnant women experiencing IPV.

Uncovering abuse in pregnant women requires a consistent and direct approach to every client by the nurse. Multiple assessments may enhance reporting by enabling the nurse to establish trust and rapport with the woman and identify changes in her behavior. Once abuse is discovered in a pregnant woman, interventions should include safety assessment, emotional support, counseling, referral to community services, and ongoing prenatal care to avoid adverse health outcomes (Hewitt, 2015).

EVIDENCE-BASED PRACTICE 9.1 EFFECTIVENESS OF HOME VISITING IN REDUCING PARTNER VIOLENCE FOR FAMILIES EXPERIENCING ABUSE: A SYSTEMATIC REVIEW

STUDY

IPV against women is a major, global societal problem with tremendous health consequences both for mother and child. Home visiting interventions by nurses for families at risk of abuse seem promising in decreasing IVP. In this systematic review, the effectiveness of home visiting was assessed as an intervention to reduce IPV experienced by mothers.

Findings

A systematic review was conducted of 1,258 articles; nineteen of them met the inclusion criteria and were examined in detail. Sixteen reported lower rates of physical assault with home visits by nurses and three studies showed no significant reduction of IPV. This systematic review found that home visiting interventions that support abused women during their pregnancy and beyond to stop IPV seem to be effective in reducing the incidence of IPV. However, it is not known whether these results are effective in long-term.

Nursing Implications

By nurses making home visits, a trusting relationship can be established between the client and nurse. By addressing factors that may increase the risk of IPV in general, such as stress as well as other contributing factors, IPV can be reduced and the cycle of violence can be broken. A major benefit of home-visiting interventions is that they succeed in reaching high-risk young pregnant women, who are notoriously hard to reach for regular prenatal services during a vulnerable stage in their lives. Nurses can see the home environment and can detect risk factors and plan interventions to address them.

Violence Against Older Women

IPV affects women of all ages, but often the literature focuses on women in the childbearing years, ignoring the problems of aging women who experience abuse. Elder mistreatment (i.e., abuse and neglect) is defined as intentional actions that cause harm or create a serious risk of harm to a vulnerable elder by a caregiver or other person who stands in a trust relationship to the elder. All 50 states have laws requiring health care providers to report elder or vulnerable person abuse. Estimates suggest that 500,000 to 2 million cases of elder abuse and neglect occur annually in the United States. It is estimated that one in ten older adults experience abuse, but only one in five to as little as one in twenty-four are reported. Research suggests that female elders are abused at a higher rate than males and that the older one is, the more likely one is to be abused. Elder abuse is expected to increase as the population ages (Wang et al., 2015). Types of abuse experienced by the older woman may include physical abuse, neglect, emotional abuse, sexual abuse, and financial/exploitation abuse (National Center on Elder Abuse, 2015).

Although an injury may bring the older woman into the health care system, the physical and emotional sequelae of IPV may be more subtle and may include depression, insomnia, chronic pain, difficulty trusting others, low self-esteem, thoughts of suicide, substance abuse, anger issues, atypical chest pain, or other kinds of somatic symptoms. Research suggests that older women usually have endured long-term abuse, have developed unhealthy strategies to cope (substance abuse, keeping the family together at all cost, and physical/mental health consequences), and shoulder blame from their adult children, yet have developed empowerment from within to be able to cope with the abuse (Policastro & Finn, 2015).

Accurate detection and assessment of abuse in older women are essential duties of all nurses. Nurses have frequent contact with older victims of abuse, providing them the opportunity to play a significant role in detecting, reporting, and intervening in such cases. As part of a thorough screening, nurses should determine what the client has done to attempt to resolve the abuse and the effectiveness of those strategies. Actions taken by the client, prior to revealing her abuse issue to the nurse, might have included passive acceptance, calling law enforcement, counseling, or other measures. In addition, taking time to establish rapport with older women builds a sense of trust, safety, and openness. Nurses

must listen carefully and nonjudgmentally. Judging or criticizing the victim for her decisions might lead to the impression that she deserves the abuse or that she is to blame. Finally, nurses should attempt to stay current in their knowledge of referral resources to assist the older woman experiencing abuse. Some of these resources may be housing, transportation, medical services, employment, social services, and local support groups. A coordinated and comprehensive response to IPV is essential to reduce its sequelae.

Nursing Management of Intimate Partner Violence Victims

Nurses encounter thousands of abuse victims each year in their practice settings, but many victims slip through the cracks. As universal violence assessment has increased in recent years, nurses need to be aware of not only how to screen for violence, but how to respond in a way that is helpful, sincere, nonjudgmental, and legally adequate. This will require nurses to move beyond a description of violence toward a response that is action-oriented and evidence-based, which includes safety planning and referrals. There are many things that nurses can do to help victims. Early recognition and intervention can significantly reduce the morbidity and mortality associated with IPV. To stop the cycle of violence, nurses need to know how to assess for and identify IPV and implement appropriate actions.

Assessment

Routine screening for IPV is the first way to detect abuse. The nurse should build rapport by listening, showing an interest in the concerns of the woman, and creating an atmosphere of openness. Communicating support through a nonjudgmental attitude and telling the woman that no one deserves to be abused are first steps toward establishing trust and rapport. Rather than overlooking abused women as "chronic complainers," astute nurses need to be vigilant for subtle clues of abuse. Learning how to assess for abuse is critical. Some basic assessment guidelines follow.

SCREEN FOR ABUSE DURING EVERY HEALTH CARE VISIT

Screening for violence takes only a few minutes and can have an enormously positive effect on the outcome for the abused woman. Any woman could be a victim; no single sign marks a woman as an abuse victim, but the following clues may be helpful:

- *Injuries*—Bruises on their chest and abdomen, scars from blunt trauma, minor lacerations, or weapon wounds on the face, head, and neck
- *Injury sequelae*—Headaches, hearing loss from ruptured ear drums, joint pain, sinus infections, teeth marks, clumps of hair missing, dental trauma, pelvic

pain, and breast or genital injuries

- Reported history of injury that is not consistent with the actual presenting problem
- *Mental health problems*—Depression, anxiety, substance abuse, eating disorders, suicidal ideation or suicide attempts, anger toward health care provider, and PTSD
- Frequent tranquilizer or sedative use
- Delay in seeking medical attention and patterns of repeated injury
- Bruises to the upper arm, neck and face, abdomen, or breasts
- Comments about emotional or physical abuse of "a friend"
- STIs or pelvic inflammatory disease
- Appears nervous, ashamed, or evasive when asked questions
- Frequent health care visits for chronic, stress-related disorders such as chest pain, headaches, back or pelvic pain, insomnia, injuries, anxiety, and gastrointestinal disturbances.
- Partner's behavior at the health care visit: appears overly solicitous or overprotective, is unwilling to leave her alone with the health care provider, answers questions for her, and attempts to control the situation (Ghandour, Campbell, & Lloyd, 2015).

> ***Dorothy,*** *who you met at the beginning of the chapter, has been frequenting the clinic with vague somatic complaints in recent weeks and admits she is sometimes afraid at home. She tells the nurse her partner doesn't want her to work, although he is only sporadically employed at low-paying jobs. What cues in her assessment might indicate abuse? What physical signs might the nurse observe?*

ISOLATE CLIENT IMMEDIATELY FROM FAMILY

If abuse is detected, immediately isolate the woman to provide privacy and to prevent potential retaliation from the abuser. Asking about abuse in front of the perpetrator may trigger an abusive episode during the interview or at home. Ways to ensure the woman's safety would be to take the victim to an area away from the abuser to ask questions. The assessment can take place anywhere that is

private and away from the abuser, for example, x-ray area, ultrasound room, elevator, ladies' room, or laboratory.

If abuse is detected, the nurse can do the following to enhance the nurse–client relationship:

• Educate the woman about the connection between the violence and her symptoms.

• Help the woman acknowledge what has happened to her and begin to deal with the situation.

• Offer her referrals so she can get the help that will allow her to begin to heal.

Dorothy returns to the prenatal clinic a month later with anemia, inadequate weight gain, bruises on her face and neck, and second-trimester bleeding. This time she is accompanied by her partner, who stays close to Dorothy. What questions should the nurse ask to assess the situation? Where is the appropriate location to ask these questions? What legal responsibilities does the nurse have concerning her observations?

ASK DIRECT OR INDIRECT QUESTIONS ABOUT ABUSE

Violence against women is often unseen, unknown, and hidden in families. Questions to screen for abuse should be routine and handled just like any other question. Many nurses feel uncomfortable asking questions of this nature, but broaching the subject is important even if the answer comes later. Opening up the possibility for women to express themselves about their experience of abuse to a nurse sends out a clear message that violence should never be tolerated and not kept hidden; it also conveys the message that nurses care about women's experiences and want to offer a best practice initial response. Just knowing that someone else knows about the abuse offers a victim some relief and may help her disclose it.

Ask difficult questions in an empathetic and nonthreatening manner and remain nonjudgmental in all responses and interactions. Choose the type of question that makes you most comfortable. Direct and indirect questions produce the same results. "Does your partner hit you?" or "Have you ever been or are you now in an abusive relationship?" are direct questions. If that approach feels uncomfortable, try indirect questions: "We see many women with injuries or complaints like yours and often they are being abused. Is that what is happening

to you?" or "Many women in our community experience abuse from their partners. Is anything like that happening in your life?" With either approach, nurses need to maintain a nonjudgmental acceptance of whatever answers the woman offers. The SAVE Model is a screening protocol that nurses can use when assessing women for violence (Box 9.2).

ASSESS IMMEDIATE SAFETY

It is essential to assist the woman by assessing her safety and the safety of her children. To do this, speak to the woman alone and ask her:

• Does she feel safe going home after her meeting with you?

• Does she need an immediate place of safety for herself or her children?

• Does she have a plan of escape if she becomes at risk for her safety?

• Does she need to consider an alternative exit from this building?

• Who are the people she could contact for help or support?

The Danger Assessment Tool (Box 9.3) helps women and health care providers assess the potential for homicidal behavior in an ongoing abusive relationship. It is based on research that showed several risk factors for abuse-related murders:

• Increased frequency or severity of abuse

• Presence of firearms

• Sexual abuse

• Substance abuse

• Precipitated by arguments and conflicts

• Generally violent behavior outside of the home

• Control issues (e.g., daily chores, friends, job, money)

• Physical abuse during pregnancy

• Suicide threats or attempts (victim or abuser)

• Child abuse (Sugg, 2015).

BOX 9.2

SAVE MODEL

SCREEN all of your clients for violence by asking:

• Within the last year, have you been physically hurt by someone?

• Do you feel you are in control of your life?

• Within the last year, has anyone forced you to engage in sexual activities?

• Can you talk about your abuse with me now?

• In general, how would you describe your present relationship?

ASK direct questions in a nonjudgmental way:

• Begin by normalizing the topic to the woman.

• Make continuous eye contact with the woman.

• Stay calm; avoid emotional reactions to what she tells you.

• Never blame the woman, even if she blames herself.

• Do not dismiss or minimize what she tells you, even if she does.

• Wait for each answer patiently. Do not rush to the next question.

• Do not use formal, technical, or medical language.

• Avoid using leading questions; be direct and to the point.

• Use a nonthreatening, accepting approach.

VALIDATE the client by telling her:

• You believe her story.

• You do not blame her for what happened.

• It is brave of her to tell you this.

• Help is available for her.

• Talking with you is a hopeful sign and a first big step.

EVALUATE, educate, and refer this client by asking her:

• What type of violence was it?

• Is she now in any danger?

• How is she feeling now?

• Does she know that there are consequences to violence?

• Is she aware of community resources available to help her?

DOCUMENT AND REPORT YOUR FINDINGS

If the interview reveals a history of abuse, accurate documentation is critical because this evidence may support the woman's case in court. Documentation must include details about the frequency and severity of abuse; the location, extent, and outcome of injuries; and any treatments or interventions. When documenting, use direct quotes and be very specific: "He choked me." Describe any visible injuries, and use a body map (outline of a woman's body) to show where the injuries are. Obtain photos (with informed consent) or document her refusal if the woman declines photos. Pictures or diagrams can be worth a thousand words. Figure 9.2 shows a sample documentation form for IPV.

Laws in many states require health care providers to alert the police to any injuries that involve knives, firearms, or other deadly weapons or that present life-threatening emergencies. If assessment reveals suspicion or actual indication of abuse, nurses can explain to the woman that they are required by law to report it.

Nursing Diagnosis

When violence is suspected or validated, the nurse needs to formulate nursing diagnoses based on the completed assessment. Possible nursing diagnoses related to violence against women might include the following:

• Deficient knowledge related to understanding the cycle of violence and availability of resources

• Anxiety related to threat to self-concept, situational crisis of abuse

• Situational low self-esteem related to negative family interactions

• Powerlessness related to lifestyle of helplessness

• Compromised individual and family coping related to abusive patterns

Interventions

The response of nurses to battered women can have a profound effect on their willingness to open up or seek help. Some responses to assist successful communication in these circumstances could include:

• *Listening*—"I hear and understand what you are saying." Being listened to can be an empowering experience for a woman who has been abused.

• *Communicating belief*–"That must have been very frightening for you."

• *Validating the decision to disclose*–"It must have been difficult for you to talk about this today."

• *Emphasizing the unacceptability of this violence*—"You don't deserve to be treated this way."

If abuse is identified, nurses can undertake interventions that can increase the woman's safety and improve her health. The goal of intervention is to enable the victim to gain control of her life. Provide sensitive, predictable care in an accepting setting. Offer step-by-step explanations of procedures. Provide educational materials about violence. Allow the victim to actively participate in her care and have control over all health care decisions. Pace your nursing interventions and allow the woman to take the lead. Communicate support through a nonjudgmental attitude. Carefully document all of your assessment findings and nursing interventions.

BOX 9.3

DANGER ASSESSMENT TOOL

Several risk factors have been associated with increased risk of homicides (murders) of women and men in violent relationships. No one can predict what will happen in your case, but we would like you to be aware of the danger of homicide in situations of abuse and for you to see how many of the risk factors apply to your situation. ("He" refers to your husband, partner, ex-husband, ex-partner, or whoever is currently physically hurting you).

_____1. Has the physical violence increased in severity or frequency over the past year?

_____2. Does he own a gun?

_____3. Have you left him after living together during the past year?

_____4. Is he unemployed?

_____5. Has he ever used a weapon against you or threatened you with a lethal weapon?

_____6. Does he threaten to kill you?

_____7. Has he avoided being arrested for domestic violence?

_____8. Do you have a child who is not his?

_____9. Has he ever forced you to have sex when you did not wish to do so?

_____10. Does he ever try to choke you?

_____11. Does he use illegal drugs? By drugs, I mean "uppers" or amphetamines, "meth," speed, angel dust, cocaine, "crack," street drugs, or mixtures.

_____12. Is he an alcoholic or problem drinker?

_____13. Does he control most or all of your daily activities? For instance: does he tell you who you can be friends with, when you can see your family, how much money you can use, or when you can take the car?

_____14. Is he violently and constantly jealous of you? (For instance, does he say "If I can't have you, no one can").

_____15. Have you ever been beaten by him while you were pregnant?

_____16. Has he ever threatened or tried to commit suicide?

_____17. Does he threaten to harm your children?

_____18. Do you believe he is capable of killing you?

_____19. Does he follow or spy on you, leave threatening notes or messages on answering machine, destroy your property, or call you when you don't want him to?

_____20. Have you ever threatened or tried to commit suicide?

_____ Total "Yes" Answers

Thank you. Please talk to your nurse, advocate, or counselor about what the Danger Assessment means in terms of your situation.

Concept Mastery Alert

Priorities in Intimate Partner Violence Interventions

Although it is certainly important that the woman in an abusive situation is safe, it is most important for a woman to regain a sense of control in her life. A lack of control is what prevents a woman from escaping an abusive situation.

A public health approach to violence prevention requires input from and coordination across sectors, including health, education, social services, justice, and policy. The goal of public health is to improve the health of the entire community or society. Depending on when in the cycle of violence the nurse encounters the abused woman, goals may fall into three groups:

• *Primary prevention*—aimed at breaking the abuse cycle through community educational initiatives by nurses, physicians, law enforcement, teachers, and clergy.

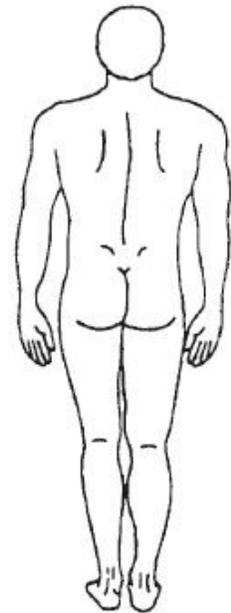
• *Secondary prevention*—focuses on screening high-risk individuals and dealing with victims and abusers in early stages, with the goal of preventing

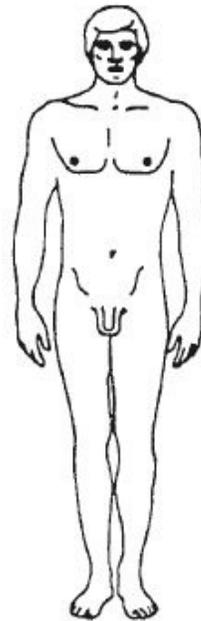
progression of abuse.

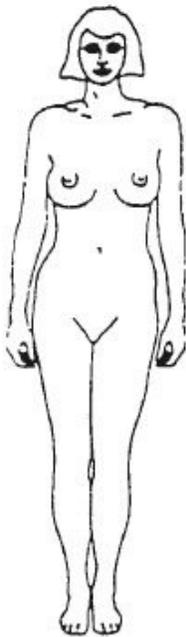
- *Tertiary prevention*—activities are geared toward helping severely abused women and children recover and become productive members of society and rehabilitating abusers to stop the cycle of violence. These activities are typically long term and expensive.

Domestic Violence Screening/Documentation Form

DV Screen
☐ DV + (Positive)
☐ DV? (Suspected)

Date _____ Patient ID# _____
Patient Name _____
Provider Name _____
Patient Pregnant? ☐ Yes   ☐ No






Assess Patient Safety

☐ Yes	☐ No	Is abuser here now?
☐ Yes	☐ No	Is patient afraid of their partner?
☐ Yes	☐ No	Is patient afraid to go home?
☐ Yes	☐ No	Has physical violence increased in severity?
☐ Yes	☐ No	Has partner physically abused children?
☐ Yes	☐ No	Have children witnessed violence in the home?
☐ Yes	☐ No	Threats of homicide?

By whom?_____

☐ Yes	☐ No	Threats of suicide?

By whom?_____

☐ Yes	☐ No	Is there a gun in the home?
☐ Yes	☐ No	Alcohol or substance abuse?
☐ Yes	☐ No	Was safety plan discussed?

Referrals

☐ Hotline number given
☐ Legal referral made
☐ Shelter number given
☐ In-house referral made

A modified tool developed by Holtz and Furniss (1993)—the ABCDES—provides a framework for providing sensitive nursing interventions to abused women (Box 9.4). Specific nursing interventions for the abused woman include educating her about community services, providing emotional support, and offering a safety plan.

BOX 9.4

THE ABCDES OF CARING FOR ABUSED WOMEN

• **A** is reassuring the woman that she is not alone. The isolation by her abuser keeps her from knowing that others are in the same situation and that health care providers can help her.

• **B** is expressing the belief that violence against women is not acceptable in any situation and that it is not her fault. Demonstrate by your actions and words that you believe her disclosure.

• **C** is confidentiality, since the woman might believe that if the abuse is reported, the abuser will retaliate. Interview her in private, without her partner or family members being present. Assure her that you will not release her information without her permission.

• **D** is documentation, which includes the following:

  • A clear quoted statement about the abuse in the woman's own words

  • Accurate descriptions of injuries and the history of them

  • Information on the first, the worst, and the most recent abusive incident

  • Photos of the injuries (with the woman's consent)

• **E** is education about the cycle of violence and that it will escalate:

  • Educate about abuse and its health effects.

  • Help her understand that she is not alone.

  • Offer appropriate community support and referrals.

  • Display posters and brochures to foster awareness of this public health problem.

• **S** is safety, the most important aspect of the intervention, to ensure that the woman has resources and a plan of action to carry out when she decides to leave.

http://www.hrw.org/sites/default/files/reports/morocco0214_ForUpload.pdf; and Ghandour, R. M., Campbell, J. C., & Lloyd, J. (2015). Screening and counseling for intimate partner violence: A vision for the future. *Journal of Women's Health*, 24(1), 57–61.

EDUCATE THE WOMAN ABOUT COMMUNITY SERVICES

A wide range of support services are available to meet the needs of victims of violence. Nurses should be prepared to help the woman take advantage of these opportunities. Services will vary by community but might include psychological counseling, legal advice, social services, crisis services, support groups, hotlines, housing, vocational training, and other community-based referrals.

Give the woman information about shelters or services even if she initially rejects it. Give the woman the National Domestic Violence hotline number: (800) 799-7233. The Joint Commission on the Accreditation of Hospitals and Health care Organizations (JCAHO), American Medical Association (AMA), American College of Obstetrician Gynecologists (ACOG), and the United States Preventive Services Task Force (USPSTF) all recommend routine IVP screening, counseling, and referrals in all health care agencies (USDHHS, 2015c).

PROVIDE EMOTIONAL SUPPORT

Providing reassurance and support to a victim of abuse is essential if the violence is to end. The physical, psychological, and emotional effects of IPV on women and their children can be severe and long-lasting. Nurses in all clinical settings can help victims to feel a sense of personal power and provide them with a safe and supportive environment. Appropriate action can help victims to express their thoughts and feelings in constructive ways, manage stress, and move on with their lives. Appropriate interventions are:

• Strengthen the woman's sense of control over her life by:
  • Teaching coping strategies to manage her stress
  • Assisting with activities of daily living to improve her lifestyle
  • Allowing her to make as many decisions as she can
  • Educating her about the symptoms of PTSD and their basis
• Encourage the woman to establish realistic goals for herself by:
  • Teaching problem-solving skills
  • Encouraging social activities to connect with other people

- Providing support and allow the woman to grieve for her losses by:
  - Listening to and clarifying her reactions to the traumatic event
  - Discussing shock, disbelief, anger, depression, and acceptance
- Explain to the woman that:
  - Abuse is never OK. She didn't ask for it and she doesn't deserve it
  - She is not alone and help is available
  - Abuse is a crime and she is a victim
  - Alcohol, drugs, money problems, depression, or jealousy does not cause violence, but these things can give the abuser an excuse for losing control and abusing her
  - The actions of the abuser are not her fault
  - Her history of abuse is believed
  - Making a decision to leave an abusive relationship can be very hard and takes time

OFFER A SAFETY PLAN

The choice to leave must rest with the victim. Nurses cannot choose a life for the victim; they can only offer choices. Leaving is a process, not an event. Victims may try to leave their abusers as many as seven or eight times before succeeding. Frequently, the final attempt to leave may result in the death of the victim. Women planning to leave an abusive relationship should have a safety plan, if possible (Teaching Guidelines 9.1).

Teaching Guidelines 9.1

SAFETY PLAN FOR LEAVING AN ABUSIVE RELATIONSHIP

- When leaving an abusive relationship, take the following items:
  - Driver's license or photo ID
  - Social Security number or green card/work permit

- Birth certificates for you and your children
- Phone numbers for social services or women's shelter
- The deed or lease to your home or apartment
- Any court papers or orders
- A change of clothing for you and your children
- Pay stubs, checkbook, credit cards, and cash
- Health insurance cards
- If you need to leave a domestic violence situation immediately, turn to authorities for assistance in gathering this material.
- Develop a "game plan" for leaving and rehearse it.
- Don't use phone cards—they leave a trail to follow.

H., Notestine, L., Garr, B., Pow, A. M., et al. (2015). Domestic violence service providers' perceptions of safety planning: A focus group study. *Journal of Family Violence*, 30(3), 381–392; and Chang, J. C. (2015). Domestic violence: Epidemiology and risk factors. *Clinical Gynecology* (2nd ed., pp. 94–101). Cambridge, UK: Cambridge University Press.

Nurses need to remember that their role is that of a guide, not a savior. A woman will make the best decision she sees fit at that moment in time. A nurse may be her most effective resource in her stress-filled environment. Just allowing the woman to talk may be the most valuable intervention. The impact of the nurse's presence and support will stay with the woman, no matter what decision she makes.

SEXUAL VIOLENCE

Sexual violence is both a public health problem and a human rights violation. Sexual violence includes IPV, human trafficking, incest, FGC, forced prostitution, bondage, exploitation, neglect, infanticide, and sexual assault. It occurs worldwide and affects up to one third of women over a lifetime (Bagwell-Gray, Messing, & Baldwin-White, 2015). Once every 2 minutes, 30 times an hour, 1,871 times a day, girls and women in America are raped. One in five women and 1 in 71 men will be sexually assaulted during their lifetime (Rape, Abuse, & Incest National Network [RAINN], 2015a). Rape has been reported against females from age 6 months to 93 years, but it still remains one of the most underreported violent crimes in the United States. Once every 2 minutes, a woman is sexually assaulted in the United States (RAINN, 2015a). The National Center for Prevention and Control of Sexual Assault estimates that two thirds of sexual assaults will not be reported (CDC, 2015f). Over the course of their lives, women may experience more than one type of violence.

Sexual violence can have a variety of devastating short- and long-term effects. Women can experience psychological, physical, and cognitive symptoms that affect them daily. They can include chronic pelvic pain, headaches, backache, STIs, pregnancy, anxiety, denial, fear, withdrawal, sleep disturbances, guilt, nervousness, phobias, substance abuse, depression, sexual dysfunction, and PTSD. Many contemplate suicide (CDC, 2015f). A traumatic experience not only damages a woman's sense of safety in the world, but it can also reduce her self-esteem and her ability to continue her education, to earn money and be productive, to have children and, if she has children, to nurture and protect them. Overall, sexually assaulted women exhibit lower functioning as adults afterward (MacGregor et al., 2015).

Take Note!

Sexual violence has been called a "tragedy of youth." More than half of all rapes (54%) of women occur before age 18 (Medicine Net, 2015a).

Characteristics of Assailants

Assailants, like their victims, come from all walks of life and all ethnic backgrounds; there is no typical profile. More than half are under age 25, and the majority are married and leading "normal" sex lives. Why do men rape? No theory provides a satisfactory explanation. So few assailants are caught and convicted that a clear profile remains elusive. What is known is that many assailants have trouble dealing with the stresses of daily life. Such men become angry and experience feelings of powerlessness. They become jealous easily; do not view women as equals; frequently are hot tempered; have a need to be reassured of their manhood; and do not handle stress in their lives well. They commit a sexual assault as an expression of power and control (Kilmartin, 2015).

Sexual Abuse

Sexual abuse occurs when a woman is forced to have sexual contact of any kind (vaginal, oral, or anal) without her consent. Current estimates indicate that one of five girls is sexually abused, and the peak ages of such abuse are from 8 to 12 years of age. At every age in the life span, females are more likely to be sexually abused by father, brother, family member, neighbor, boyfriend, husband, partner, or ex-partner than by a stranger or anonymous assailant. Sexual abuse knows no economic or cultural barriers (de Jong et al., 2015). Marriage does not constitute a tacit agreement for a spouse to inflict one's demands on the other without permission.

Childhood sexual abuse is any type of sexual exploitation that involves a child younger than 18 years old. It might include disrobing, nudity, masturbation, fondling, digital penetration, forced performance of sexual acts on the perpetrator, and intercourse (Dutton, 2015). Childhood sexual abuse has a lifelong impact on its survivors. There is strong evidence that sexual assault in childhood or adolescence is a serious risk factor for mental illness (Brooker & Durmaz, 2015). Women who were sexually abused during childhood are at a heightened risk for repeat abuse. This is because the early abuse lowers their self-esteem and their ability to protect themselves and set firm boundaries. Childhood sexual abuse is a trauma that influences the way victims form relationships, deal with adversity, cope with daily problems, relate to their children and peers, protect their health, and live. See Evidence-Based Practice 9.2 for study regarding childhood sexual abuse. Studies have shown that the more victimization a woman experiences, the more likely it is she will be revictimized (Brenner & Ben-Amitay, 2015).

Interventions for sexually abused children or women should include referral for mental health counseling. Follow up for any medical problems (e.g., genitourinary complaints) should be arranged with the child's or woman's primary care physician. If the community has an abuse referral center, refer the victim there for follow-up care according to local protocol.

The medical consequences of sexual abuse require the prophylaxis and treatment of STIs, emergency contraception, and treatment of any injuries that resulted from the abuse. Victims with post-assault bleeding require an emergent evaluation and may need emergency treatment by a gynecologist for repair of genital injury. The psychosocial aspects of sexual abuse must also be addressed

because appropriate therapeutic follow-up is essential to the victim's future emotional well-being.

EVIDENCE-BASED PRACTICE 9.2 SIBLING SEXUAL ABUSE: AN EXPLORATORY STUDY OF LONG-TERM CONSEQUENCES FOR SELF-ESTEEM AND COUNSELING CONSIDERATIONS

Today, health care providers recognize childhood sexual abuse within the family as a significant and widespread problem with consequences lasting long into adulthood. Despite this progression, the research related to interfamilial incest conducted by researchers has focused primarily on father to daughter incest, largely ignoring the experience of sibling sexual assault, although it is more common than parental incest. Clearly, sibling incest is a pandemic problem that requires more attention from health care providers.

STUDY

This study addresses experiencing sibling sexual abuse as a child and how it inversely affects the level of self-esteem in adulthood. One hundred college students were used as the sample size; 67% were female and 33% were male with a diverse cultural representation. The age of the students ranged from 20 to 59 years old. A survey with two sections was used. The first section addressed recollection of the prevalence and severity of sibling abuse; the second section of the survey addressed self-esteem using the Rosenberg Self-Esteem Scale. Reliability and validity of this tool reflected a Cronbach's alpha coefficient of 0.82.

Findings

This study supported the likelihood that sibling sexual abuse could be the most common form of child sexual abuse in the United States. In spite of the apparent prevalence of this, it is disturbing how little has been done to address the complexity surrounding this form of abuse. Both survivors and offenders of sibling sexual abuse experience the lasting impact of the abuse as they become adults in their social interactions, school, work, and family life. In addition to a low self-esteem, other mental health issues experienced include symptoms of PTSD, anxiety disorders, depression, eating disorders, angry outbursts, self-injury, somatic complaints, and suicidal ideation. Many engage in at-risk behaviors such as unprotected sex, self-medication with drugs and alcohol, and dating violence. Clearly, ignoring the problem of sibling sexual abuse has a negative effect on a sense of well-being as these children become adults.

Nursing Implications

One of the most important aspects is to establish trust with these clients and create a safe environment. An important role for nurses is in primary prevention of sibling sexual abuse through educating parents. When parents understand how to promote positive parent–child relationships and sibling interactions, the risk of abuse in the entire family tends to be reduced. Nurses can take a lead role through promotion of structured parent education programs within their communities and referrals to national networks such as Family Support America.

Adopted from Morrill, M. (2014). Sibling sexual abuse: An exploratory study of long term consequences for self-esteem and counseling considerations. *Journal of Family Violence*, 29(2), 205–213.

Incest

Incest is defined as sexual activity between persons so closely related that marriage between them is legally or culturally prohibited (Dorland's Medical Dictionary, 2015). The exact incidence of child sexual victimization is unknown. Such sexual abuse is not only a crime but also a symptom of acute and irreversible family dysfunction. Childhood incest abuse involves any kind of sexual exploitation between a child and another person that violates the social taboos of family roles; children cannot yet understand these activities and cannot give informed consent. Adult women with a history of incest exhibit a clinical syndrome that includes low self-esteem, difficulty with intimate relationships, sexual dysfunction, flashbacks and nightmares, repeated victimization, as well as suicidality, depressive symptomatology, eating disorders, and substance abuse (Harkins, 2015). Survivors of incest are often tricked, coerced, or manipulated. All adults appear to be powerful to children. Perpetrators might threaten victims so that they are afraid to disclose the abuse or might tell them the abuse is their fault. Often these threats serve to silence victims.

Incestuous relationships in the home endanger not only the child's intellectual and moral development, but also the health of the child. Many children do not ask for help because they do not want to expose their "secret." For this reason, just the tip of the iceberg is statistically visible: serious injuries, internal damage, STIs, or pregnancy. Incest can have serious long-term effects on its victims, which may include eating disorders, sexual problems in adult life, difficulty in interpersonal relationships, anxiety, PTSD, intense guilt and shame, low self-esteem, depression, and self-destructive behavior (National Center for Victims of Crime [NCVC], 2015a).

Whether an incest victim endured an isolated incident of abuse or ongoing assaults over an extended period, recovery can be painful and difficult. The recovery process begins with admission of abuse and the recognition that help and services are needed. Resources for incest victims include books, self-help groups, workshops, therapy programs, and possibly legal remedies. In addition to listening to and believing incest victims, nurses need to search for ways to prevent future generations from enduring such abuse and from continuing the cycle of abuse in their own family and relationships. Nurses have the ability and the responsibility to function within an interdisciplinary system responsible for the assessment and ongoing treatment of incestuous families. Nurses can fulfill

their roles as advocates for children, while at the same time adding necessary referrals to social services and legal authorities. Forming this partnership with the social service and judicial communities will help protect the child from future abuse and ensure the child a safe environment in which to grow and develop.

Take Note!

Childhood sexual abuse is a trauma that can affect every aspect of the victim's life.

Rape

Rape is an expression of violence, not a sexual act. Rape distorts one of the most intimate forms of human interaction. It is not an act of lust or an overzealous release of passion: it is a violent, aggressive assault on the victim's body and integrity. Those who rape do so for a number of reasons, but they basically involve the motives of anger, power, eroticized cruelty, and opportunistic mating (Keygnaert, Vettenburg, & Temmerman, 2015). Rape is a legal rather than a medical term. It denotes penile penetration of the vagina, mouth, or rectum of the female or male without consent. It may or may not include the use of a weapon. Statutory rape is sexual activity between an adult and a person under the age of 18 and is considered to have occurred even if the underage person was willing (RAINN, 2015b). Nine out of every 10 rape victims are female (Alexander et al., 2014). Enforcement of laws, education, and community empowerment are all needed to prevent rape.

Consider This

At 53 years old, I stood and looked at myself in the mirror. The image staring back at me was one of a frightened, middle-aged, cowardly woman hiding her past. I had been sexually abused by my father for many years as a child and never told anyone. My mother knew of the abuse but felt helpless to make it stop. I married right out of high school to escape and felt I lived a "happy normal life" with my husband and three children. My children have left home and live away, and my husband recently died of a sudden heart attack. I am now experiencing dreams and thoughts about my past abuse and feeling afraid again.

   Thoughts: *This woman suppressed her abusive past for most of her life and now her painful experience has surfaced. What can be done to reach out to her at this point? Did her health care providers miss the "red flags" that are common to women with a history of childhood sexual abuse all those years?*

TABLE 9.3 FOUR PHASES OF RAPE RECOVERY

Phase	Survivor's Response
Acute phase (disorganization)	Shock, fear, disbelief, anger, shame, guilt, feelings of uncleanliness; insomnia, nightmares, and sobbing
Outward adjustment phase (denial)	Appears outwardly composed and returns to work or school; refuses to discuss the assault and denies need for counseling
Reorganization	Denial and suppression do not work, and the survivor attempts to make life adjustments by moving or changing jobs and uses emotional distancing to cope
Integration and recovery	Survivor begins to feel safe and starts to trust others. She may become an advocate for other rape victims

Adapted from National Center for Victims of Crime [NCVC]. (2015b). *The trauma of victimization*. Retrieved from http://victimsofcrime. org/help-for-crime-victims/get-help-bulletins-for-crime-victims/trauma-of-victimization#ptsd; Rape, Abuse, and Incest National Network [RAINN]. (2015d). *Recovery from sexual assault*. Retrieved from http://www.rainn.org/get-information/sexual-assault-recovery; and The Advocacy Center (2015). *The path toward recovery for survivors of sexual violence*. Retrieved from http://advocacycenter.syr.edu/ students/path-of-recovery/

Many people believe that rape usually occurs on a dark night when a stranger assaults a provocatively dressed, promiscuous woman. They believe that rapists are sex-starved people seeking sexual gratification. Rape myths are destructive beliefs about sexual aggression (i.e., its scope, causes, context, and consequences) that serve to deny, downplay, or justify sexually aggressive behavior that men commit against women. A rape victim's recovery is frequently complicated by the public's failure to believe the victim and restore justice

(Klaus, Buczkowski, & Wiktorska, 2015). Rape myths serve to blame victims and exonerate perpetrators. Such myths and the facts are presented in Table 9.3.

Acquaintance Rape

In acquaintance rape, someone is forced to have sex by a person he or she knows. Rape by a coworker, a teacher, a husband's friend, or a boss is considered acquaintance rape. Date rape, an assault that occurs within a dating relationship or marriage without consent of one of the participants, is a form of acquaintance rape. Acquaintance and date rapes commonly occur on college campuses. One in four college women has been raped—that is, has been forced, physically or verbally, actively or implicitly, to engage in sexual activity (Wilson & Miller, 2015).

These forms of rape are physically and emotionally devastating for the victims. Research has indicated that the survivors of acquaintance rape report similar levels of depression, anxiety, complications in subsequent relationships, and difficulty attaining prerape levels of sexual satisfaction to those reported by survivors of stranger rape. Acquaintance rape remains a controversial topic because there is lack of agreement on the definition of consent. Despite the violation and reality of physical and emotional trauma, victims of acquaintance assault often do not identify their experience as sexual assault. Instead of focusing on the violation of the sexual assault, victims of acquaintance rape often blame themselves for the assault (RAINN, 2015c).

Although acquaintance rape and date rape do not always involve drugs, a rapist might use alcohol or other drugs to sedate his victim. In 1996, the federal government passed a law making it a felony to give an unsuspecting person a "date rape drug" with the intent of raping him or her. Even with penalties of large fines and up to 20 years in prison, the use of date rape drugs is growing (USDHHS, 2015a). Date rape drugs are also known as "club drugs" because they are often used at dance clubs, fraternity parties, and all-night raves. The most common is rohypnol (also known as "roofies," "forget pills," "mind erasers," or the "drop drug"). It comes in the form of a liquid or pill that quickly dissolves in liquid with no odor, taste, or color. This drug is 10 times as strong as diazepam (Valium). The effects can be felt within 30 minutes and produces memory loss for up to 8 hours. Gamma hydroxybutyrate (GHB; called "liquid ecstasy" or "easy lay") produces euphoria, an out-of-body high, sleepiness, increased sex drive, and memory loss. GHB takes effects in about 15 minutes

and can last 3 to 4 hours. It comes in a white powder or liquid and may cause unconsciousness, depression, and coma. The third date rape drug, ketamine (known as "Special K," "vitamin K," or "super acid"), and acts on the central nervous system very quickly to separate perception and sensation. Combining ketamine with other drugs can be fatal. Date rape drugs can be very dangerous, and women can protect themselves against them in a variety of ways (Teaching Guidelines 9.2).

Teaching Guidelines 9.2

PROTECTING YOURSELF AGAINST DATE RAPE DRUGS

- Avoid parties where alcohol is being served.
- Never leave a drink of any kind unattended.
- Don't accept a drink from someone else.
- Accept drinks from a bartender or in a closed container only.
- If a drink is left unattended, pour it out, don't drink it.
- Don't drink anything that tastes or smells strange.
- Don't drink from a punch bowl or a keg.
- If you think someone drugged you, call 911.

Rape Recovery

Rape survivors take a long time to heal from their traumatic experience. Some women never heal and never get professional counseling, but most can cope. Rape is viewed as a situational crisis that the survivor is unprepared to handle because it is an unforeseen event. Survivors typically go through four phases of recovery following rape (Table 9.4).

A significant proportion of women who are raped also experience symptoms of PTSD. PTSD develops when an event outside the range of normal human experience occurs that produces marked distress in the person. Symptoms of PTSD are divided into three groups:

1. Intrusion (reexperiencing the trauma, including nightmares, flashbacks,

recurrent thoughts)

2. Avoidance (avoiding trauma-related stimuli, social withdrawal, emotional numbing)

3. Hyperarousal (increased emotional arousal, exaggerated startle response, irritability)

Not every traumatized female develops full-blown or even minor PTSD. Symptoms usually begin within 3 months of the incident, but occasionally may only emerge years later. They must last more than a month to be considered PTSD. The condition varies from person to person. Some women recover within months, while others have symptoms for much longer. In some people, the condition becomes chronic (Darnell et al., 2015; Friedman, 2015).

Nursing Management of Rape Victims

Health care providers, along with sexual assault nurse examiners (SANE), can make a difference in the lives of survivors by understanding the facts, the effects this violence can have on mental and physical health, where to find information for themselves and their clients, and how to properly care for a survivor. A SANE is a registered nurse specially trained to conduct sexual assault evidentiary examinations for rape victims. In addition to the collection of forensic evidence, they also provide access to crisis intervention, STI testing, and emergency contraception (International Association of Forensic Nurses, 2015).

TABLE 9.4 RISK FACTORS FOR INTIMATE PARTNER VIOLENCE IN MEN

Individual Factors	Relationship Factors	Community Factors	Societal Factors
Young age	Martial conflict	Weak sanctions against IPV	Traditional gender norms
Heavy drinking	Economic stress	Poverty	Social norms supportive of violence
Personality disorders	Dysfunctional family	Low social capital	
Depression	Marital instability		
Low academic achievement	Male dominance in family		
Witnessing violence as a child	Cohabitation		
Low income and/or unemployment	Having outside sexual partners		
Experiencing violence as a child			
Desire for power and control in all relationships			
Anger and hostility	Taking aggression out on others while growing up		

Adapted from CDC. (2015d). *Intimate partner violence: Risk and protective factors*. Retrieved from http://www.cdc.gov/violenceprevention/intimatepartnerviolence/riskprotectivefactors.html; The Christian Broadcasting Network [CBN]. (2015). *12 traits of an abuser*. Retrieved from http://www.cbn.com/family/marriage/petherbridge_abusertraits.aspx; and Ghandour, R. M., Campbell, J. C., & Lloyd, J. (2015). Screening and counseling for intimate partner violence: A vision for the future. *Journal of Women's Health*, 24(1), 57–61.

Research has found that rape survivors undergo a profound and complex trauma. Exposure therapy has been used to help victims confront their trauma-related memories, feelings, and stimuli that evoke fear and anxiety (Nacasch, Rachamim, & Foa, 2015). The survivor should be provided with a safe and comfortable environment for a forensic examination. Nursing care of the rape survivor should focus on providing supportive care, collecting and documenting evidence, assessing for STIs, preventing pregnancy, and assessing for PTSD. Once initial treatment and evidence collection have been completed, follow-up care should include counseling, medical treatment, and crisis intervention. There is mounting evidence that early intervention and immediate counseling speed a rape survivor's recovery. By early intervention, it means interventions that implemented in the initials hours, days, or weeks after the traumatic event (Bryant, 2015). Nursing Care Plan 9.1 highlights a sample plan of care for a victim of rape.

NURSING CARE PLAN 9.1

Overview of the Woman Who is a Victim of Rape

Lucia, a 20-year-old college junior, was admitted to the emergency room after police found her when a passerby called 911 to report an assault. She stated, "I was raped a few hours ago while I was walking home through the park." Assessment reveals the following: numerous cuts and bruises of varying sizes on her face, arms, and legs; lip swollen and cut; right eye swollen and bruised; jacket and shirt ripped and bloodied; hair matted with grass and debris; vital signs within acceptable parameters; client tearful, clutching her clothing, and trembling; perineal bruising and tearing.

NURSING DIAGNOSIS: Rape-trauma syndrome related to report of recent sexual assault

Outcome Identification and Evaluation
Client will demonstrate adequate coping skills related to effects of rape as evidenced by her ability to discuss the event, verbalize her feelings and fears, and exhibit appropriate actions to return to her precrisis level of functioning.

Interventions: *Promoting Adequate Coping Skills*
• Stay with the client to promote feelings of safety.
• Explain the procedures to be completed based on facility's policy to help alleviate client's fear of the unknown.
• Assist with physical examination for specimen collection to obtain evidence for legal proceedings.
• Administer prophylactic medication as ordered to prevent pregnancy and STIs.
• Provide care to wounds as ordered to prevent infection.
• Assist client with hygiene measures as necessary to promote self-esteem.
• Allow client to describe the events as much as possible to encourage ventilation of feelings about the incident; engage in active listening and offer nonjudgmental support to facilitate coping and demonstrate understanding of the client's situation and feelings.
• Help the client identify positive coping skills and personal strengths used in

the past to aid in effective decision making.

- Assist client in developing additional coping strategies and teach client relaxation techniques to help deal with the current crisis and anxiety.
- Contact the rape counselor in the facility to help the client deal with the crisis.
- Arrange for follow-up visit with rape counselor to provide continued care and to promote continuity of care.
- Encourage the client to contact a close friend, partner, or family member to accompany her home to provide support.
- Provide the client with the telephone number of a counseling service or community support groups to help her cope and obtain ongoing support.
- Provide written instructions related to follow-up appointments, care, and testing to ensure adequate understanding.

Take Note!

Many rape survivors seek treatment in the hospital emergency department if no rape crisis center is available. Unfortunately, many emergency department doctors and nurses have little training in how to treat rape survivors or in collecting evidence. To make matters worse, if they have to wait for hours in public waiting rooms, survivors may leave the hospital, never to receive treatment or supply the evidence needed to arrest and convict their assailants.

PROVIDING SUPPORTIVE CARE

Establishing a therapeutic and trusting relationship will help the survivor describe her experience. Take the woman to a secure, isolated area away from family, friends, and other clients and staff so she can be open and honest when asked about the assault. Provide a change of clothes, access to a shower and toiletries, and a private waiting area for family and friends.

COLLECTING AND DOCUMENTING EVIDENCE

The victim should be instructed to bring all clothing, especially undergarments, worn at the time of the assault to the medical facility. The victim should not shower or bathe before presenting for care. Typically a specially trained nurse will collect the evidence from the victim.

ASSESSING FOR SEXUALLY TRANSMITTED INFECTIONS

As part of the assessment, a pelvic examination will be done to collect vaginal secretions to rule out any STIs. This examination is very emotionally stressful for most women and should be carried out very gently and sensitively.

PREVENTING PREGNANCY

An essential element in the care of rape survivors involves offering them pregnancy prevention. After unprotected intercourse, including rape, pregnancy can be prevented by using an emergency contraceptive pill, sometimes called postcoital contraception. Emergency contraceptive pills involve high doses of the same oral contraceptives that millions of women take every day. The emergency regimen consists of one dose taken within 72 to 120 hours of the unprotected intercourse. Emergency contraception works by preventing ovulation, fertilization, or implantation. It does not disrupt an established pregnancy and should not be confused with mifepristone (RU-486), a drug approved by the Food and Drug Administration for abortion in the first 49 days of gestation. Emergency contraception is most effective if it is taken within 12 hours of the rape; it becomes less effective with every 12 hours of delay thereafter.

ASSESSING FOR POSTTRAUMATIC STRESS DISORDER

Nurses can begin to assess the extent to which a survivor is suffering from PTSD by asking the following questions:
• To assess the presence of intrusive thoughts:
  • Do upsetting thoughts and nightmares of the trauma bother you?
  • Do you feel as though you are actually reliving the trauma?
  • Does it upset you to be exposed to anything that reminds you of that event?
• To assess the presence of avoidance reactions:
  • Do you find yourself trying to avoid thinking about the trauma?
  • Do you stay away from situations that remind you of the event?
  • Do you have trouble recalling exactly what happened?
  • Do you feel numb emotionally?
• To assess the presence of physical symptoms:

- Are you having trouble sleeping?
- Have you felt irritable or experienced outbursts of anger?
- Do you have heart palpitations and sweating?
- Do you have muscle aches and pains all over? (NCVC, 2015b).

With a growing body of knowledge about rape-related PTSD, help is available through most rape crisis and trauma centers. Support groups have been established where survivors can meet regularly to share experiences to help relieve the symptoms of PTSD. For some survivors, medication prescribed along with therapy is the best combination to relieve the pain. Just as in the treatment of any other illness, at the first opportunity, the woman should be encouraged to talk about the traumatic experience. This ventilating provides a chance to receive needed support and comfort, as well as an opportunity to begin making sense of the experience. To diminish symptoms of PTSD, survivors must work on two fronts: coming to terms with the past and alleviating stress in the present (Bryant, 2015).

In order to have a better understanding of the aftermath of criminal victimization such as sexual assault, nurses must begin to accept the reality that crime is random, senseless, and can happen to anyone regardless of the precautions that are taken to prevent it. Nurses must also understand that a victim's life is turned upside down when he or she becomes a victim of crime. In order to help victims to trust society again and regain a sense of balance and self-worth, nurses must educate all those who come in contact with victims and survivors to be sensitive to their needs.

Female Genital Cutting

FGC, also referred to as female genital mutilation (FGM) or female circumcision, is defined as a procedure involving any injury of the external female genitalia for cultural or nontherapeutic reasons. It confers severe health consequences for girls and women. The international community views this practice as a human rights violation (Gayle & Rymer, 2015). It is the surgical removal of a portion or portions of the genitalia of female infants, girls, and women, including the clitoris (type I), clitoris and labia minora (type II), and clitoris, labia minora, labia majora, and then suturing of the remaining tissue, known as fibulation, to leave only a small opening for urination, menstruation, intercourse, and childbirth (type III). There is a type IV, which encompasses all other mutilations of the female genital area such as pricking, piercing, cutting, cauterizing, and scraping of the vaginal tissue, incisions to the clitoris and vagina, and burning, scarring, or cauterizing of tissue with the aim of tightening or narrowing the vagina (Nour, 2015).

FGC is a worldwide practice that affects millions of women and girls. According to the World Health Organization (WHO) (2015b) and UNICEF, 140 million women are victims of FGC with about 130 million girls between infancy and age 15 undergoing FGC every year. Countries where this is practiced include 30 African countries and parts of the Middle East and Asia. Prevalence in countries such as Sudan and Egypt has been estimated as high as 99% (Johnsdotter, 2015). The exact origins of FGC are not known. Although FGC may be interwoven into the culture, it is not mandated by any religion. This practice predates both Islam and Christianity (Gruenbaum & Wirtz, 2015). In some cultures, it is associated with feminine beauty and often signifies a rite of passage from childhood to adulthood. Female cutting is performed to decrease a woman's sexual desires and to ensure her chastity until marriage and receipt of a dowry from the prospective groom (Farage et al., 2015). Ultimately, the reality of being ostracized by the community and the possibility of being ineligible to marry create enormous social pressure to have FGC carried out, pressure that outweighs the known physical and emotional damage of this practice (Nour, 2015).

Complications vary, depending on the type of cutting and the way it was performed. It is frequently performed without anesthesia under nonsterile conditions. Cutting tools can be anything from razors blades to knives to pieces

of glass or tin can lids. Complications can include infertility, dysmenorrhea, dyspareunia, sexual dysfunction, infection, hemorrhage after the procedure, vaginal stenosis, chronic vaginitis, pelvic inflammatory disease, chronic urinary tract infections, incontinence, genital fistulas, recurrent abscesses, transmission of HIV and hepatitis during the procedure, severe pain and shock after the procedure, difficulty walking or using stairs due to severe scarring, urinary retention, inability to experience orgasm, and difficulty in giving birth. Long-term complications related to FGC include chronic pain, dyspareunia, and difficult childbirth. The most common long-term complication is the formation of inclusion clitoral dermoid cysts and labial fusion. These become large as a grapefruit and can lead to difficulty in walking, sitting and can cause psychological distress from the deformity. The psychological effects range from eating disorders, insomnia, depression, PTSD, and negative effects on the women's self-esteem and identity (Creighton, 2015).

As immigration to the United States increases, nurses are increasingly likely to encounter women affected by FGC and its complications. The psychological pressure and trauma of being torn between two cultures and feeling different may lie heavily on the women in a new setting where FGC is foreign and banned. Nurses need updated education regarding women with FGC so that appropriate care for this population can be provided for this very sensitive health care problem. Well-informed nurses are the best tool for providing culturally sensitive care to this population. Nurses are in a unique position to contact and educate women who have been cut or are at risk for mutilation. To advocate for these women, a thorough understanding of the practice of FGC, its cultural overtones, religious implications, and psychosocial effects is needed.

 Take Note!

From a Western perspective, FGC is hard to comprehend. Because it is not talked about openly in communities that practice it, women who have undergone it accept it without question and assume it is done to all girls (Gruenbaum & Wirtz, 2015).

Background

Reasons for performing the ritual reflect the ideology and cultural values of each

community that practices it. Some consider it a rite of passage into womanhood; others use it as a means of preserving virginity until marriage. In cultures where it is practiced, it is an important part of culturally defined gender identity. In any case, all the reasons are cultural and traditional and are not rooted in any religious texts (Research Action and Information Network for the Bodily Integrity of Women [RAINBO], 2015). Since FGC has no health benefits and often leaves women with lifelong physical and emotional trauma, there is a human rights justification to end the practice. International pressure to end FGC has been mounting since 1997, when the WHO, UNICEF, and UNFPA issued a joint statement to call on governments to ban the practice (Borsand et al., 2015). Box 9.5 lists types of FGC procedures.

FOUR MAJOR TYPES OF FEMALE GENITAL MUTILATION PROCEDURES

Type I: Excision of the prepuce with excision of part or the entire clitoris

Type II: Excision of the clitoris and part or all of the labia minora

Type III (Infibulation): Excision of all or part of the external genitalia and stitching/narrowing of the vaginal opening

Type IV: Pricking, piercing, or incision of the clitoris or labia

• Stretching of the clitoris and/or labia

• Cauterizing by burning the clitoris and surrounding tissues

• Scraping or cutting the vaginal orifice

• Introduction of a corrosive substance into the vagina

• Placing herbs into the vagina to narrow it

Adapted from World Health Organization [WHO]. (2015b). *Female genital mutilation*. Retrieved from http://www.who.int/mediacentre/factsheets/fs241/en/print.html; Nour, N. M. (2015). Female genital cutting: Impact on women's health. *Seminars in Reproductive Medicine*, 33(1), 41–46; and Research Action and Information Network for the Bodily Integrity of Women [RAINBO]. (2015). *Caring for women with circumcision: Fact sheet for physicians*. Retrieved from http://www.rainbo.org/factsheet.html.

Nursing Management of Female Genital Cutting Client

Because of increasing migration, nurses throughout the world are increasingly exposed to women who have experienced these procedures and thus need to know about its impact on women's reproductive health. Helping women who have had an FGC procedure requires good communication skills and often an interpreter, since many may not speak English. As nurses, we are educated to provide comprehensive, culturally sensitive care regardless of our client's circumstances. Nurses must keep in mind that FGC is considered normal in many cultures and to not have it done would be unthinkable. Nurses have the opportunity to educate clients by providing accurate information and positive

health care experiences. Make sure that you are comfortable with your own feelings about this practice before dealing with clients. Some guidelines are as follows:

• Let the client know you are concerned and interested and want to help.

• Speak clearly and slowly, using simple, accurate terms.

• Use the term or name for this practice that the recipient uses, not "female genital cutting."

• Use pictures and diagrams to help the woman understand what you are saying.

• Be patient in allowing the client to answer questions.

• Include men in any education, as they are influential in this practice.

• Repeat back your understanding of the client's statements.

• Always look and talk directly to the client, not the interpreter.

• Place no judgment on the cultural practice.

• Maintain respect for older women who have experienced FGC.

• Encourage the client to express herself freely.

• Maintain strict confidentiality.

• Provide culturally attuned care to all women.

In short, FGC is a form of violence against women, and it is only through education and empowerment of women that real changes in this practice can be made. Because this practice often defines a woman and becomes a part of her identity, nurses must understand this to be able to assist women who have had this done to them. Only through intense education will the next generation of girls be saved from this practice.

Human Trafficking

The United Nations defines human trafficking as the recruitment, transportation, transfer, harboring or receipt of persons, by means of the threat or use of force, of abduction, of fraud, or deception to achieve the consent of a person having control over another person, for the purpose of exploitation (United Nations Office on Drugs and Crime, 2015).

A girl who was just 14 years old was held captive in a tiny trailer room, where she was forced to have sex with as many as 30 men a day. On her nightstand was a teddy bear that reminded her of her childhood in Mexico from where she was abducted and forced into sexual slavery.

This scenario describes human trafficking, the enslavement of immigrants for profit in America. Within our borders, thousands of foreign nationals and US citizens, many of them children, are forced or coerced into sex work or various forms of labor every year (Weitzer, 2015). Human trafficking is both a global problem and a domestic problem. The United States is a major receiver of trafficked persons. Human trafficking is a modern form of slavery that affects nearly 1 million people worldwide and approximately 20,000 persons in the United States annually (U.S. Department of State, 2015). Women and children are the primary victims of human trafficking, many in the sex trade as described above and others through forced-labor domestic servitude. Poverty and lack of economic opportunity make women and children potential victims of traffickers associated with international criminal organizations. They are vulnerable to false promises of job opportunities in other countries. Many of those who accept these offers from what appear to be legitimate sources find themselves in situations where their documents are destroyed, they or their families threatened with harm, or they are bonded by a debt that they have no chance of repaying.

Trafficking persons is hugely profitable: one estimate places global profits at approximately $35 billion annually. Among illegal enterprises, trafficking is second only to drug dealing and is tied with the illegal arms industry in its ability to generate dollars (Aronowitz & Koning, 2015).

The United States is a profitable destination country for traffickers, and these profits contribute to the development of organized criminal enterprises worldwide. According to findings of the Victims of Trafficking and Violence Protection Act of 2000:

• Victims are primarily women and children who lack education, employment,

and economic opportunities in their own countries.

- Traffickers promise victims employment as nannies, maids, dancers, factory workers, sales clerks, or models in the United States.
- Traffickers transport the victims from their counties to unfamiliar destinations away from their support systems.
- Once they are here, traffickers coerce them, using rape, torture, starvation, imprisonment, threats, or physical force, into prostitution, pornography, the sex trade, forced labor, or involuntary servitude.

These victims are exposed to serious and numerous health risks such as rape; physical injury such as cigarette burns, fractures, bruises; torture; HIV/AIDS; STIs; cervical cancer; violence; hazardous work environments; poor nutrition; and drug and alcohol addiction (Greenbaum et al., 2015). Health care is one of the most pressing needs of these victims, but no comprehensive care is available to undocumented immigrants. Nurses and other health care providers who encounter victims of trafficking often do not realize it, and opportunities to intervene are lost. Although no one sign can demonstrate with certainty when someone is being trafficked, clinicians should be aware of several indicators. It is important to be alert for trafficking victims in any setting and to recognize cues (Box 9.6).

BOX 9.6

IDENTIFYING VICTIMS OF HUMAN TRAFFICKING

Look beneath the surface and ask yourself: Is this person…

• A female or a child in poor health?

• Foreign-born and doesn't speak English?

• Lacking immigration documents?

• Giving an inconsistent explanation of injury?

• Reluctant to give any information about self, injury, home, or work?

• Fearful of authority figure or "sponsor" if present? ("Sponsor" might not leave victim alone with health care provider).

• Living with the employer?

Sample questions to ask the potential victim of human trafficking:

• Can you leave your job or situation if you wish?

• Can you come and go as you please?

• Have you been threatened if you try to leave?

• Has anyone threatened your family with harm if you leave?

• What are your working and living conditions?

• Do you have to ask permission to go to the bathroom, eat, or sleep?

• Is there a lock on your door so you cannot get out?

• What brought you to the United States? Are your plans the same now?

• Are you free to leave your current work or home situation?

• Who has your immigration papers? Why don't you have them?

• Are you paid for the work you do?

• Are there times you feel afraid?

• How can your situation be changed?

Adapted from United Nations Office on Drugs and Crime [UNODC]. (2015). *Human trafficking*. Retrieved from http://www.unodc.org/unodc/en/human-trafficking/what-is-human-trafficking.html;

Sanchez, R., & Stark, S. (2014). The hard truth about human trafficking. *Nursing Management*, 45(1), 18–23; and Weitzer, R. (2015). Human trafficking and contemporary slavery. *Annual Review of Sociology*, 41(1). Retrieved from http://www.annualreviews.org/doi/abs/10.1146/annurev-soc-073014-112506

Nursing interventions in the case of trafficking victims would include the following:

• Building trust is the number-one priority

• Take the time to listen and develop rapport

• Screen in a private place to ensure confidentiality and safety

• Reassure the potential victim

• One-on-one interactions are ideal

• Specifically ask about the client's safety

• Offer reworded stories

• Stay calm and on an even keel

• Understand the risk these victims are taking by disclosing their plight

• Always document your suspicion in your notes, at the very least

• Call the human trafficking hotline for guidance: 1-866-US-TIPLINE

Human trafficking is a violation of human rights. Few crimes are more repugnant than the sex trafficking of helpless and innocent victims. Nurses are one of the few groups of professionals likely to interact with trafficked victims while they are still in captivity. They have the opportunity to screen, identify, intervene, and rescue these victims. If you suspect a trafficking situation, notify local law enforcement and a regional social service organization that has experience in dealing with trafficking victims. It is imperative to reach out to these victims and stop the cycle of abuse by following through on your suspicions. Nurses can also reach out within their communities to bring about awareness through community education to human trafficking to uncover the hard truth about it to our nation's blind eyes.

SUMMARY

The causes of violence against women are complex. Previously, violence against women was largely invisible, natural, and trivial. Many laughed at the notion that intimate or community violence against women should be seen as a human rights violation. Raising awareness and developing evidence-based programs, practices, and policies to prevent IPV and sexual assault are essential in stopping violent behavior before it starts. Many women will experience some type of violence in their lives, and it can have a debilitating effect on their health and future relationships. Nurses have the skills, professional experience, and perspective to be an important part of comprehensive violence prevention efforts in communities. Violence is a preventable public health problem if multiple sectors understand patterns of violence and implement prevention strategies to reduce it (Copelon, 2015).

Violence frequently leaves a "legacy of pain" to future generations. Nurses can empower women and encourage them to move forward and take control of their lives. When women live in peace and security, free from violence, they have an enormous potential to contribute to their own communities and to the national and global society. Nurses can play an important role in working toward the creation of a violence-free community, but they must first become informed. Nurses must insist that health care agencies that employ them accept this responsibility and work together to reach out to those being abused. The time is ripe for nurses to act and ensure serious inroads are made in improving the health and well-being of all women across the globe.

Violence against women is not normal, legal, or acceptable and it should never be tolerated or justified. It can and must be stopped by the entire world community. Early education and prevention provide the best hope for creating healthy futures and fostering a global society without violence.

KEY CONCEPTS

- Violence against women is a major public health and social problem because it violates a woman's very being and causes numerous mental and physical health sequelae.
- Every woman has the potential to become a victim of violence.

- Several *Healthy People 2020* objectives focus on reducing the rate of physical assaults and the number of rapes and attempted rapes.
- Abuse may be mental, physical, or sexual in nature or a combination of all of these.
- The cycle of violence includes three phases: tension building, acute battering, and honeymoon.
- Many women experience PTSD after being sexually assaulted. PTSD can inhibit a survivor from adapting or coping in a healthy manner.
- Pregnancy can precipitate violence toward the woman or escalate it.
- FGC is practiced worldwide and nurses in the United States need to become knowledgeable about it and place no judgment on this cultural practice.
- Human trafficking is a violation against human rights, and nurses who suspect it should report it to stop the cycle of abuse against young children and women.
- The nurse's role in dealing with survivors of violence is to establish rapport; open up lines of communication; apply the nursing process to assess and screen all clients in all settings; and implement and intervene as appropriate.

Chapter WORKSHEET

MULTIPLE-CHOICE QUESTIONS

1. The primary goal of intervention in working with abused women is to:
   a. Set up an appointment with a mental health counselor for the victim
   b. Convince them to set up a safety plan to use when they leave
   c. Help them develop courage and financial support to leave the abuser
   d. Empower them and improve their self-esteem to regain control of their lives

2. The first phase of the abuse cycle is characterized by:
   a. The woman provoking the abuser to bring about battering
   b. Tension building and verbal or minor battery
   c. A honeymoon period that lulls the victim into forgetting
   d. An acute episode of physical battering

3. Women recovering from abusive relationships need to learn ways to improve their:
   a. Educational level by getting a college degree
   b. Earning power so they can move to a better neighborhood
   c. Self-esteem and communication skills to increase assertiveness
   d. Relationship skills so they will be better prepared to deal with their partners

4. Which of the following statements might empower abuse victims to take action?
   a. "You deserve better than this."
   b. "Your children deserve to grow up in a two-parent family."
   c. "Try to figure out what you do to trigger his abuse and stop it."
   d. "Give your partner more time to come to his senses about this."

5. If a woman thinks she is being stalked when driving, a good safety measure is to:
   a. Drive to a local police or fire department
   b. Take short cuts through back streets to lose them
   c. Wave a handgun to intimidate them

d. Roll down her window and confront them

6. Nurses play an important role in screening and assessment of any client abuse/violence. Which of the following statements is correct?

a. Most clients are extremely reluctant to come forth with private matters

b. Any intimate partner violence questions should be asked in the presence of both partners

c. To invite disclosure, assure the woman that you won't document her statements

d. The best statement to make to the abused victim is: "You don't deserve this."

7. What should the nurse do if a victim of intimate partner violence chooses not to disclose information about her abusive relationship during your interview?

a. Confront the victim with the physical evidence and telltale signs of abuse

b. Contact family members to tell you about their abusive relationship

c. Call the local police department to inquire about domestic disturbance calls

d. Respect the client's right of self-determination and provide her with resources

CRITICAL THINKING EXERCISE

1. Mrs. Boggs has three children under the age of 5 and is 6 months pregnant with her fourth child. She has made repeated unscheduled visits to your clinic with vague somatic complaints regarding the children as well as herself, but has missed several scheduled prenatal appointments. On occasion she has worn sunglasses to cover bruises around her eyes. As a nurse you sense there is something else bothering her, but she doesn't seem to want to discuss it with you. She appears sad and the children cling to her.

a. Outline your conversation when you broach the subject of abuse with Mrs. Boggs.

b. What is your role as a nurse in caring for a family in which you suspect abuse is occurring?

c. What ethical/legal considerations are important in planning care for this family?

STUDY ACTIVITIES

1. Visit the BellaOnline Domestic Violence website for victims of violence. Discuss what you discovered on this site and your reactions to it.

2. Research the statistics about violence against women in your state. Are law enforcement and community interventions reducing the incidence of sexual assault and intimate partner violence?

3. Attend a dorm orientation at a local college to hear about measures in place to protect women's safety on campus. Find out the number of sexual assaults reported and what strategies the college uses to reduce this number.

4. Volunteer to spend a weekend evening at the local sheriff's department 911 hotline desk to observe the number and nature of calls received reporting domestic violence. Interview the dispatch operator about the frequency and trends of these calls.

5. Identify three community resources that could be useful to a victim of violence. Identify their sources of funding and the services they provide.

BRINGING IT ALL TOGETHER: CASE STUDY

A 23-year-old pregnant female presents to the public health maternity clinic for the third time in a month with many vague complaints including insomnia, diffuse body aches and pains, poor appetite, fatigue, and constipation. This is her first pregnancy, and it was unplanned. Her recent OB examination findings and laboratory survey are within normal limits. Her past medical history is remarkable for anxiety and depression. According to the client, she does not drink or smoke. She does not work outside of the home.

ASSESSMENT

On physical examination, the nurse notes a well-dressed, pleasant, but anxious young female. Her husband of a year usually accompanies her to the office visits, but is absent today. She tends to avoid eye contact with the nurse when asked questions about her symptoms. Her vital signs and fetal heart rate are all within the normal range. On further examination, the nurse notices several

bruises on her upper arms and thighs. When questioned about these marks, the client looks away.

Go to to find questions to consider about this case.

Learning Objectives

Upon completion of the chapter, you will be able to:

1. Characterize the process of fertilization, implantation, and cell differentiation.
2. Examine the functions of the placenta, umbilical cord, and amniotic fluid.
3. Outline normal fetal development from conception through birth.
4. Compare the various inheritance patterns, including nontraditional patterns of inheritance.
5. Analyze examples of ethical and legal issues surrounding genetic testing.
6. Research the role of the nurse in genetic counseling and genetic-related activities.

__Robert__ and __Kate Shafer__ have just received the good news that Kate's pregnancy test was positive. It had been a long and anxious 3 years of trying to start a family. Although both are elated about the prospect of becoming parents, they are also concerned about the possibility of a genetic problem because Kate is 41 years old. What might be their first step in looking into their genetic concern? As a nurse, what might raise concerns for you?

Words of Wisdom

Being a nurse without awe is like food without spice. Nurses only have to witness the miracle of life to find their lost awe.

INTRODUCTION

Human reproduction is one of the most intimate spheres of an individual's life. Conception occurs when a healthy ovum from the woman is released from the ovary, passes into an open Fallopian tube, and starts its journey downward. Sperm from the male is deposited into the vagina and swims approximately 7 in to meet the ovum at the outermost portion of the Fallopian tube, the area where fertilization takes place. This process occurs in about an hour (Sermon & Viville, 2014). When one spermatozoon penetrates the ovum's thick outer membrane, a new living cell is formed that is unlike the cells of either parent. Soon, the two nuclei will fuse, bringing together about 25,000 genes to guide human development.

Nurses caring for the childbearing family need to have a basic understanding of conception and prenatal development so they can identify problems or variations and can initiate appropriate interventions should any problems occur. This chapter presents an overview of fetal development, beginning with conception. It also discusses hereditary influences on fetal development and the nurse's role in genetic counseling.

FETAL DEVELOPMENT

Fetal development during pregnancy is measured in number of weeks after fertilization. An average human pregnancy lasts for about 280 days or 40 weeks from the date of the last menstrual period (LMP). Traditionally, it has been calculated as 10 lunar months, or, in terms of the modern calendar, 9 months. Fertilization of the egg by the sperm, however, usually occurs (considering an average menstrual cycle of 28 days) 14 days after the last period. Thus, the average actual duration of a human pregnancy (gestation period) is 280 days − 14 days = 266 days.

   The three stages of fetal development during pregnancy are the:

1. **Preembryonic stage**—fertilization through the second week

2. **Embryonic stage**—end of the second week through the eighth week

3. **Fetal stage**—end of the eighth week until birth

   Fetal circulation is a significant aspect of fetal development that spans all three stages.

Preembryonic Stage

The preembryonic stage begins with **fertilization**, also called *conception.* Fertilization is the union of ovum and sperm, which is the starting point of pregnancy. Development during this stage takes place in an organized fashion that is cephalocaudal, proximal to distal, and general to specific. Fertilization typically occurs around 2 weeks after the last normal menstrual period in a 28-day cycle (Mader & Windelspecht, 2015). Fertilization requires a timely interaction between the release of the mature ovum at ovulation and the ejaculation of enough healthy, mobile sperm to survive the hostile vaginal environment through which they must travel to meet the ovum. All things considered, the act of conception is difficult at best. To say merely that it occurs when the sperm unites with the ovum is overly simple because this union requires an intricate interplay between hormonal preparation and overcoming an overwhelming number of natural barriers. A human being is truly an amazing outcome of this elaborate process.

Prior to fertilization, the ovum and the spermatozoon undergo the process of meiosis. The primary oocyte completes its first meiotic division before ovulation. The secondary oocyte begins its second meiotic division just before ovulation. Primary and secondary spermatocytes undergo meiotic division while still in the testes. Gametogenesis is the process by which gametes (ovum or sperm cells) are produced to initiate the development of a new individual. The gametes must have a haploid number of chromosomes (a single set, i.e., 23) so when they come together to form the zygote, the normal human diploid number of chromosomes (combination of two sets, i.e., 46) is established (Fig. 10.1). This smaller number of chromosome number found in eggs and sperm is vital because these gametes combine to form a new individual with 46 chromosomes.

Although each milliliter of ejaculated semen contains more than 200 million sperm, only one is able to enter the ovum to fertilize it. All others are blocked by the clear protein layer called the **zona pellucida**. The zona pellucida disappears in about 5 days. Once the sperm reaches the plasma membrane, the ovum resumes meiosis and forms a nucleus with half the number of chromosomes (23). When the nucleus from the ovum and the nucleus of the sperm make contact, they lose their respective nuclear membranes and combine their maternal and paternal chromosomes. Because each nucleus contains a haploid number of chromosomes (23), this union restores the diploid number (46). The

resulting **zygote** begins the process of a new life.

The genetic information from both ovum and sperm establishes the unique physical characteristics of the individual. Sex determination is also determined at fertilization and depends on whether the ovum is fertilized by a Y-bearing sperm or an X-bearing sperm. Approximately 50% of sperms carry the XX chromosome while the other 50% carry XY. An XX zygote will become a female and an XY zygote will become a male (Fig. 10.2). That is why it is scientifically correct to say that the sex of the infant is determined by the father and not by the mother.

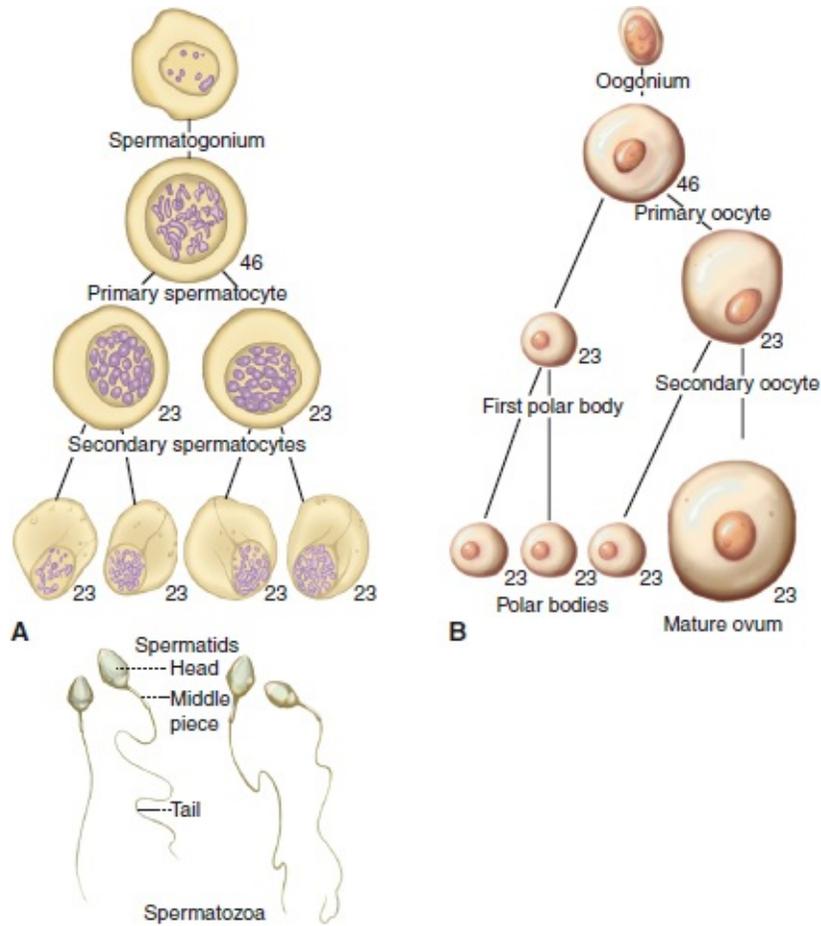
Fertilization takes place in the outer third of the ampulla of the Fallopian tube. When the ovum is fertilized by the sperm (now called a zygote), a great deal of activity immediately takes place. Mitosis, or *cleavage,* occurs as the zygote is slowly transported into the uterine cavity by tubal muscular movements (Fig. 10.3). After a series of four cleavages, the 16 cells appear as a solid ball of cells or **morula**, meaning "little mulberry." The morula continues to divide and transforms into a blastocyst as it moves further into the uterus. The morula reaches the uterine cavity about 72 hours after fertilization (Mueller, Hassel, & Grealy, 2015).


FIGURE 10.1 The formation of gametes by the process of meiosis is known as gametogenesis. **A.** Spermatogenesis. One spermatogonium gives rise to four spermatozoa. **B.** Oogenesis. From each oogonium, one mature ovum and three abortive cells are produced. The chromosomes are reduced to one half the number characteristic for the general body cells of the species. In humans, the number in the body cells is 46, and that in the mature spermatozoon and secondary oocyte is 23.
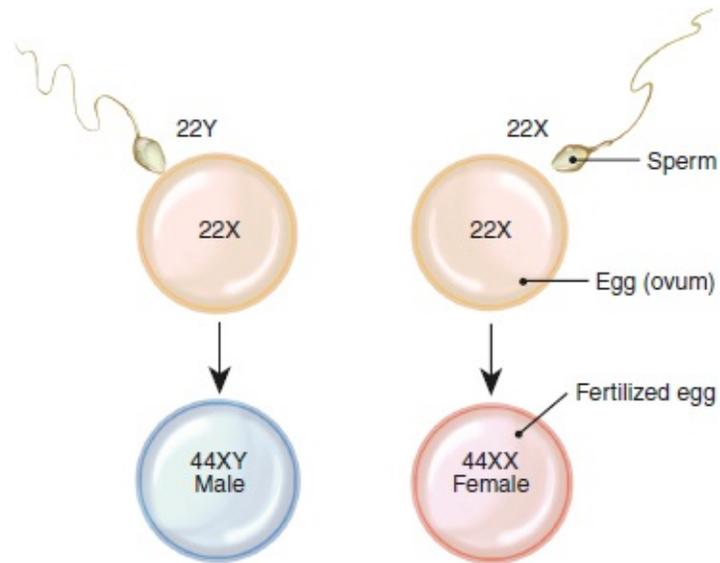

FIGURE 10.2 Inheritance of gender. Each ovum contains 22 autosomes and an X chromosome. Each spermatozoon (sperm) contains 22 autosomes and either an X chromosome or a Y chromosome. The gender of the zygote is determined at the time of fertilization by the combination of the sex chromosomes of the sperm (either X or Y) and the ovum (X).
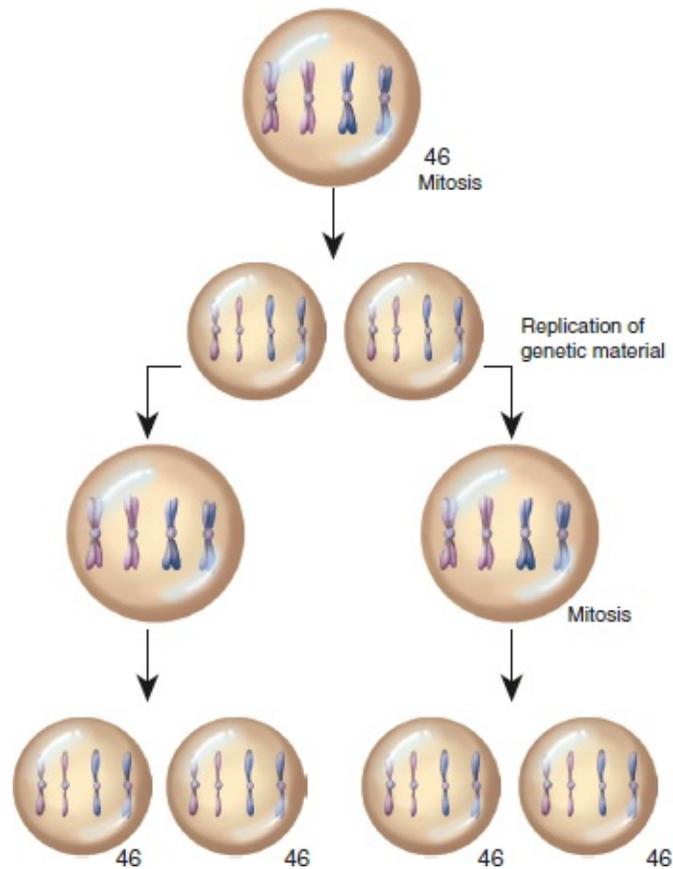

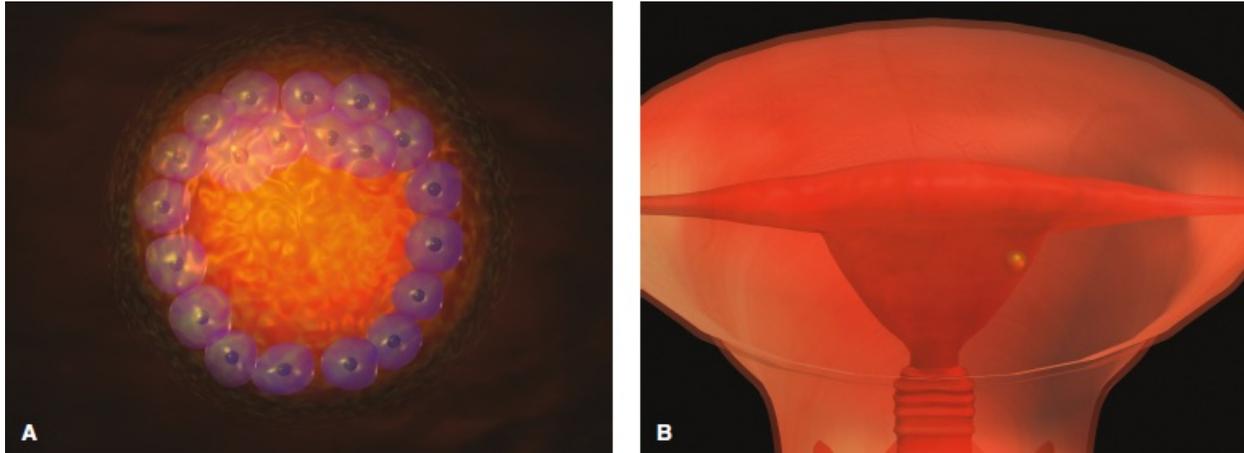

FIGURE 10.4 **A.** Fertilized human egg (zygote) having reached the blastocyst stage. Zygote contains 20 to 30 eggs and a fluid-filled blastocele is beginning to form. **B.** Implantation. All rights reserved).

   Multiple fetuses can also occur at the time of fertilization when more than one ovum is fertilized. Identical twins (also called monozygotic twins) occur when one fertilized egg splits and develops into two (or occasionally more) fetuses. The fetuses usually share one placenta. Identical twins have the same genes, so they generally look alike and are the same sex. Fraternal twins (also called dizygotic twins) develop when two separate eggs are fertilized by two different sperm. Each twin usually has its own placenta. Fraternal twins (like other siblings) share about 50% of their genes, so they can be different sexes. They generally do not look any more alike than brothers or sisters born from different pregnancies. Fraternal twins are more common than identical twins (see Chapter 19 for further details).

   With additional cell division, the morula divides into specialized cells that will later form fetal structures. Within the morula, an off-center, fluid-filled space appears, transforming it into the hollow ball of cells called a **blastocyst** (Fig. 10.4). The inner surface of the blastocyst will form the embryo and amnion. The outer layer of cells surrounding the blastocyst cavity is called a **trophoblast**. Eventually, the trophoblast develops into one of the embryonic membranes, the chorion, and helps to form the placenta.

   At this time, the developing blastocyst needs more food and oxygen to keep growing. The trophoblast attaches itself to the surface of the endometrium for

further nourishment. Normally, implantation occurs in the upper uterus (fundus), where a rich blood supply is available. This area also contains strong muscular fibers, which clamp down on blood vessels after the placenta separates from the inner wall of the uterus. Additionally, the lining is thickest here so the placenta cannot attach so strongly that it remains attached after birth. The process of attachment and placental formation is termed implantation. From a medical perspective, a pregnancy has not occurred until successful implantation has taken place (Jones & Lopez, 2014). Figure 10.5 shows the process of fertilization and implantation.

Concurrent with the development of the trophoblast and implantation, further differentiation of the inner cell mass occurs. Some of the cells become the embryo itself, and others give rise to the membranes that surround and protect it. The three embryonic layers of cells formed are:

1. *Ectoderm*—forms the central nervous system, special senses, skin, and glands.

2. *Mesoderm*—forms the skeletal, urinary, circulatory, and reproductive organs.

3. *Endoderm*—forms the respiratory system, liver, pancreas, and digestive system.

These three layers are formed at the same time as the embryonic membranes, and all tissues, organs, and organ systems develop from these three primary germ cell layers (El-Mazny, 2014). Box 10.1 summarizes preembryonic development.

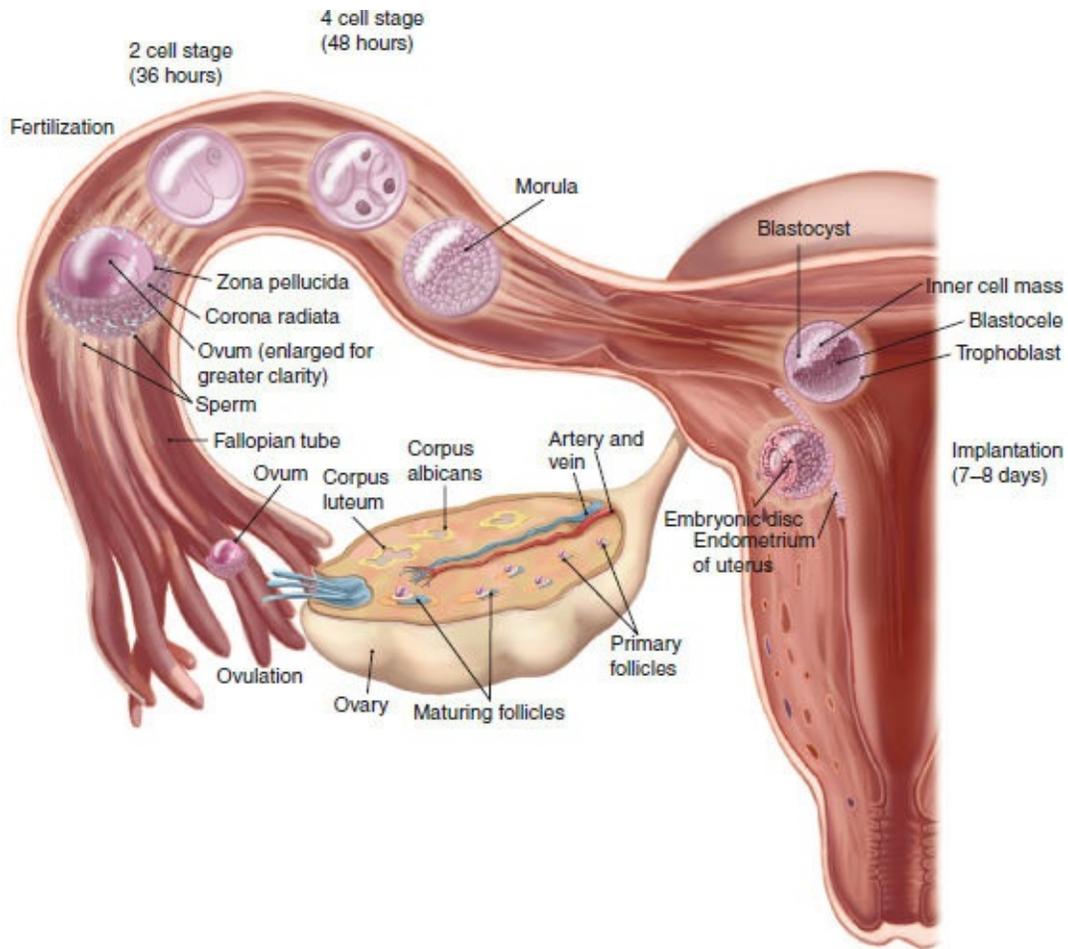
Despite the intense and dramatic activities going on internally to create a human life, many women are unaware that pregnancy has begun. Several weeks will pass before even one of the presumptive signs of pregnancy—missing the first menstrual period—will take place.


FIGURE 10.5 Fertilization and tubal transport of the zygote. From fertilization to implantation, the zygote travels through the fallopian tube, experiencing rapid mitotic division (cleavage). During the journey toward the uterus, the zygote evolves through several stages, including morula and blastocyst.

Embryonic Stage

The embryonic stage of development begins at day 15 after conception and continues through week 8. Basic structures of all major body organs and the main external features are completed during this time period, including internal organs. Table 10.1 and Figure 10.6 summarize embryonic development.

The embryonic membranes (Fig. 10.7) begin to form around the time of implantation. The chorion consists of trophoblast cells and a mesodermal lining. The chorion has finger-like projections called *chorionic villi* on its surface. The amnion originates from the ectoderm germ layer during the early stages of embryonic development. It is a thin protective membrane that contains amniotic fluid. Alongside of the amnion, a yolk sac develops as a second cavity about day 8 or 9 after conception. The yolk sac aids in transferring maternal nutrients and oxygen to the embryo during the second and third weeks of gestation when development of the uteroplacental circulation is under way. As the pregnancy progresses, the yolk sac atrophies and is incorporated into the umbilical cord. As the embryo grows, the amnion expands until it touches the chorion. These two fetal membranes form the fluid-filled amniotic sac, or bag of waters, that protects the floating embryo (Jordan et al., 2014).

Amniotic fluid surrounds the embryo and increases in volume as the pregnancy progresses, reaching approximately a liter at term. Amniotic fluid is derived from two sources: fluid transported from the maternal blood across the amnion and fetal urine. Its volume changes constantly as the fetus swallows and voids. Sufficient amounts of amniotic fluid help maintain a constant body temperature for the fetus, permit symmetric growth and development, cushion the fetus from trauma, allow the **umbilical cord** to be relatively free from

compression, and promote fetal movement to enhance musculoskeletal development. Amniotic fluid is composed of 98% water and 2% organic matter. It is slightly alkaline and contains albumin, urea, uric acid, creatinine, bilirubin, lecithin, sphingomyelin, epithelial cells, vernix, and fine hair called lanugo that floats in it. Amniotic fluid is essential for fetal growth and development, especially fetal lung development. It is dynamic, constantly changing as the fluid moves back and forth across the placental membrane (Zhang & Ducsay, 2014).

TABLE 10.1 EMBRYONIC AND FETAL DEVELOPMENT

WEEK 3

Beginning development of brain, spinal cord, and heart; Beginning development of the gastrointestinal tract; Neural tube forms, which later becomes the spinal cord; Leg and arm buds appear and grow out from body

WEEK 4

Brain differentiates; Limb buds grow and develop more

4 weeks

WEEK 5

Heart now beats at a regular rhythm; Beginning structures of eyes and ears; Some cranial nerves are visible; Muscles innervated

WEEK 6

Beginning formation of lungs; Fetal circulation established; Liver produces RBCs; Further development of the brain; Primitive skeleton forms; Central nervous system forms; Brain waves detectable

WEEK 7

Straightening of trunk; Nipples and hair follicles form; Elbows and toes visible; Legs move; Diaphragm formed; Mouth with lips and early tooth buds

WEEK 8

Rotation of intestines. Facial features continue to develop; Heart development completes; Resembles a human being; Placenta is working; Eyelids form and grow, but are sealed shut

8 weeks

WEEKS 9–12

Sexual differentiation continues; Buds for all 20 temporary teeth laid down; Digestive system shows activity; Head makes up nearly half the fetus size. Face and neck are well formed; Urogenital tract completes

development; Red blood cells are produced in the liver; Urine begins to be produced and excreted; Fetal gender can be determined by week 12; Limbs are long and thin; digits are well formed; Fetus moves, kicks and swallows

12 weeks

WEEKS 13–16

A fine hair called *lanugo* develops on the head; Fetal skin is almost transparent; Bones become harder; Fetus makes active movement; Sucking motions are made with the mouth; Amniotic fluid is swallowed; External genitalia are recognizable; Fingernails and toenails present; Weight quadruples; Fetal movement (also known as *quickening*) detected by mother

16 weeks

WEEKS 17–20

Rapid brain growth occurs; Fetal heart tones can be heard with stethoscope; Kidneys continue to secrete urine into amniotic fluid; Vernix caseosa, a white greasy film, covers the fetus; Eyebrows and head hair appear; Brown fat deposited to help maintain temperature; Nails are present on both fingers and toes; Muscles are well developed

20 weeks

WEEKS 21–24

Eyebrows and eyelashes are well formed; Fetus has a hand grasp and startle reflex; Alveoli forming in lungs; Skin is translucent and red; Eyelids remain sealed; Lungs begin to produce *surfactant*

25 weeks

WEEKS 25–28

Fetus reaches a length of 15 in; Rapid brain development; Eyelids open and close; Nervous system controls some functions; Fingerprints are set; Subcutaneous fat is visible under the skin; Blood formation shifts from spleen to bone marrow; Fetus usually assumes head-down position; Fetus responds to light and sound; Fetus can open and shut eyes and suck thumb

28 weeks

WEEKS 29–32

Rapid increase in the amount of body fat; Increased central nervous system control over body functions; Rhythmic breathing movements occur; Lungs are not fully mature; Pupillary light reflex is present; Fetus stores iron, calcium, and phosphorus

32 weeks

WEEKS 33–38

Testes are in scrotum of male fetus; Lanugo begins to disappear; Has strong hand grasp reflex; Increase in body fat; Earlobes formed and firm; Fingernails reach the end of fingertips; Small breast buds are present on both sexes; Mother supplies fetus with antibodies against disease; Fetus is considered full term at 38 weeks; Fetus fills uterus and moves to a head-down position

37 weeks

(2014). *Human reproductive biology* (4th ed.). Waltham, MA: Elsevier; Jordan, R. G., Engstrom, J., Marfell, J., & Farley, C. L. (2014). *Prenatal and postnatal care: A woman-centered approach*. Ames, Iowa: Wiley Blackwell.

The volume of amniotic fluid is important in determining fetal well-being. It gradually fluctuates throughout the pregnancy. The rate of change of amniotic fluid volume depends on the gestational age. During the fetal stage, the increase is 10 mL/week, and it increases to 50 to 60 mL/week at 19 to 25 weeks' gestation. The volume is at a maximum at 34 weeks' gestation before it undergoes a gradual decrease by term. Alterations in amniotic fluid volume can be associated with problems in the fetus. Too little amniotic fluid (<500 mL at term), termed *oligohydramnios,* is associated with uteroplacental insufficiency, fetal renal abnormalities, and higher risk of surgical births and low-birth-weight infants. Too much amniotic fluid (>2,000 mL at term), termed *hydramnios,* is

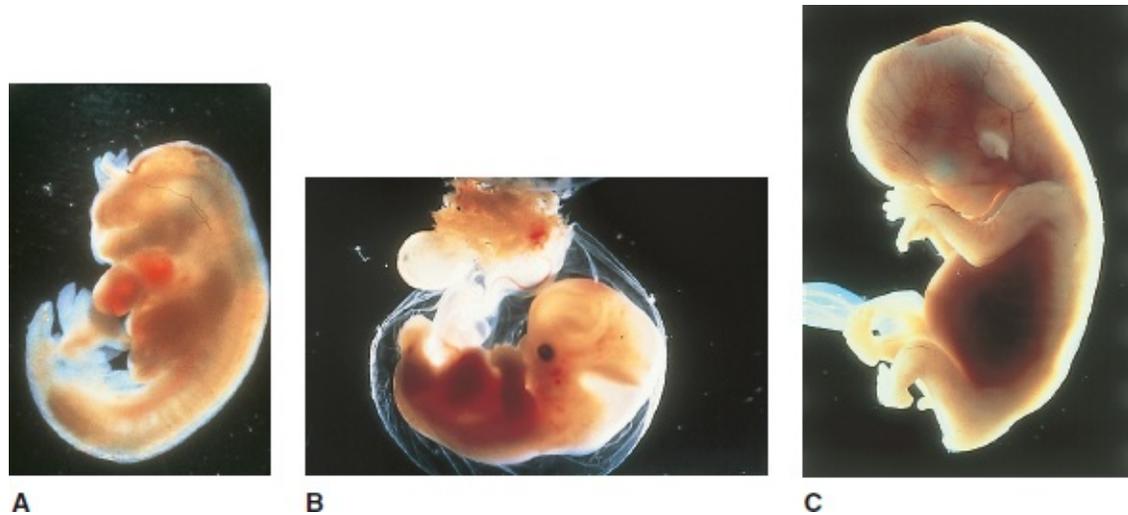
associated with maternal diabetes, neural tube defects, chromosomal deviations, and malformations of the central nervous system and/or gastrointestinal tract that prevent normal swallowing of amniotic fluid by the fetus (Moore, 2015).


FIGURE 10.6 Embryonic development. **A.** Four-week embryo. **B.** Five-week embryo. **C.** Six-week embryo.
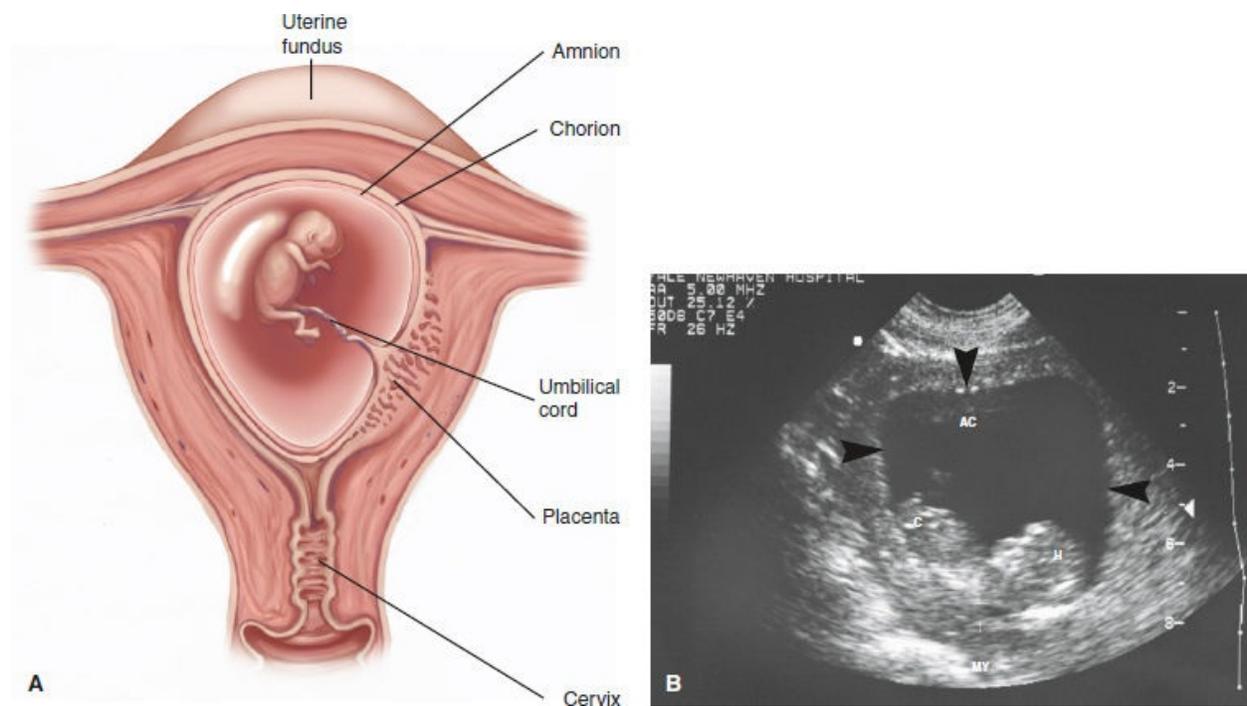

FIGURE 10.7 A. The embryo is floating in amniotic fluid, surrounded by the protective fetal membranes (amnion and chorion). **B.** Longitudinal sonogram of a pregnant uterus at 11 weeks showing the intrauterine gestational sac (*black arrowheads*) and the amniotic cavity (AC) filled with amniotic fluid; the fetus is seen

in longitudinal section with the head (H) and coccyx (C) well displayed. The myometrium (MY) of the uterus can be identified. (Figure B is courtesy of L Scoutt).

    While the placenta is developing (end of the second week), the umbilical cord is also formed from the amnion. It is the lifeline from the mother to the growing embryo. It contains one large vein and two small arteries. Wharton's jelly (a specialized connective tissue) surrounds these three blood vessels in the umbilical cord to prevent compression, which would cut off fetal blood and nutrient supply. At term, the average umbilical cord is 22-in long and about an inch wide (King et al., 2015).

    The precursor cells of the placenta—the trophoblasts—first appear 4 days after fertilization as the outer layer of cells of the blastocyst. These early blastocyst trophoblasts differentiate into all of the cells that form the **placenta**. When fully developed, the placenta serves as the interface between the mother and the developing fetus. Most commonly, the placenta develops at the uterine fundus. As early as 3 days after conception, the trophoblasts make human chorionic gonadotropin (hCG), a hormone that ensures that the endometrium will be receptive to the implanting embryo. During the next few weeks, the placenta begins to make hormones that control the basic physiology of the mother in such a way that the fetus is supplied with the nutrients and oxygen needed for growth. The placenta is the least understood human organ and arguably one of the most important. The placenta also protects the fetus from immune attack by the mother, removes waste products from the fetus, induces the mother to bring more food to the placenta and, near the time of delivery, produces hormones that ready fetal organs for life outside the uterus. The placenta allows the developing fetus to rely on the maternal circulation to fulfill its bioenergetics needs while growing undisturbed in the protected environment of the uterus (Fisher, 2015).

    Theoretically, at no time during pregnancy does the mother's blood mix with fetal blood because there is no direct contact between their bloods; layers of fetal tissue always separate the maternal blood and the fetal blood. These fetal tissues are called the *placental barrier.* Materials can be interchanged only through diffusion. The maternal uterine arteries deliver the nutrients to the placenta, which in turn provides nutrients to the developing fetus; the mother's uterine veins carry fetal waste products away. The structure of the placenta is usually completed by week 12. During its transient existence, it performs actions that are later taken on by diverse separate organs, including the lungs, liver, gut, kidneys

and endocrine glands.

The placenta is not only a transfer organ but a hormone factory as well. Placental hormones have profound effects on maternal metabolism, initially building up her energy reserves and then releasing these to support fetal growth in later pregnancy and lactation postnatally. Several hormones are produced that are necessary for normal pregnancy:

- *hCG:* preserves the corpus luteum and its progesterone production so that the endometrial lining of the uterus is maintained; this is the basis for pregnancy tests.

- *Human placental lactogen (hPL) or human chorionic somatomammotropin (hCS):* modulates fetal and maternal metabolism, participates in the development of maternal breasts for lactation, and decreases maternal glucose utilization, which increases glucose availability to the fetus.

- *Estrogen (estriol):* causes enlargement of a woman's breasts, uterus, and external genitalia; stimulates myometrial contractility.

- *Progesterone (progestin):* maintains the endometrium, decreases the contractility of the uterus, stimulates maternal metabolism and breast development, provides nourishment for the early conceptus (the products of conception after fertilization in the early stages of growth and differentiation).

- *Relaxin:* acts synergistically with progesterone to maintain pregnancy, causes relaxation of the pelvic ligaments, and softens the cervix in preparation for birth (Freemark, 2015).

The placenta acts as a pass-through between the mother and fetus, not a barrier. Almost everything the mother ingests (food, alcohol, and drugs) passes through to the developing conceptus. This is why it is so important to advise pregnant women not to use unprescribed drugs, alcohol, and tobacco, because they can be harmful to the conceptus. Although prescription drug use is common during pregnancy, the human teratogenic risks are undetermined for more than 90% of drug treatments approved in the United States during the past decades (Dutta, 2015).

During the embryonic stage, the conceptus grows rapidly as all organs and structures are forming. During this critical period of differentiation the growing embryo is most susceptible to damage from external sources, including teratogens (substances that cause birth defects, such as alcohol and drugs), infections (such as rubella or cytomegalovirus), radiation, and nutritional

deficiencies.

Teratogens

A **teratogen** is any substance, organism, physical agent, or deficiency state present during gestation that is capable of inducing abnormal postnatal structure or function by interfering with normal embryonic and fetal development (March of Dimes, 2015a). Teratogens are substances that may produce physical or functional defects in the human embryo or fetus after the pregnant woman has been exposed to that substance. Teratogens affect the fetus or embryo in a number of ways, causing physical deformities, problems in the behavioral or emotional development of the child, and decreased intellectual quotient (IQ) in the child. Additionally, teratogens may also affect pregnancies and cause complications such as preterm labors and spontaneous abortions. Susceptibility to teratogenic agents is dependent on the timing of the exposure and the developmental stage of the embryo or fetus. Teratogens are classified into four types: physical agents, metabolic conditions, infection, and drugs/chemical agents.

Selected harmful teratogens to newborns include:

• *Ionizing radiation*—leads to abnormal brain development, mental retardation, and leukemia in children.

• *Organic mercury*—leads to damage of neural system, mental retardation, behavioral and cognitive problems, and blindness in an infant.

• *Lead exposure*—can cause spontaneous abortions, delayed fetal development, increased risk of fetal death, or abnormal mental or physical development of a child.

• *Toxoplasma*—leads to spontaneous abortion, or stillbirth, underdeveloped fetal brain, blindness, and seizures.

• *Syphilis bacteria*—cause fetal death, spontaneous abortion, liver and spleen enlargement, and congenital syphilis.

• *Rubella virus*—leads to abnormal brain development in the fetus.

• *Cytomegalovirus*—leads to underdevelopment of the fetal brain, blindness, deafness, jaundice, liver and spleen dysfunction.

• *Varicella zoster*—leads to underdeveloped limbs, brain or eye malformations.

• *Herpes virus*—causes fetal death, microcephaly, herpetic pneumonia, and

meningoencephalitis.

- *Maternal conditions*—obesity, diabetes, hypothyroidism, hyperthyroidism, and phenylketonuria (PKU).

- *Drugs*—thalidomide (limb malformations), alcohol (fetal alcohol syndrome), angiotensin-converting enzyme (ACE) inhibitors (antihypertensive agents) (prematurity, intrauterine growth restriction [IUGR]); cocaine (abruptio placenta, prematurity, microcephaly); and tetracycline (yellow-brown teeth discoloration); (Dutta, 2015).

Fetal Stage

The average pregnancy lasts 280 days from the first day of the LMP. The fetal stage is the time from the end of the eighth week until birth. It is the longest period of prenatal development. During this stage, the embryo is mature enough to be called a fetus. Although all major systems are present in their basic form, dramatic growth and refinement of all organ systems take place during the fetal period (Table 10.1). Figure 10.8 depicts a 12- to 15-week-old fetus.

FIGURE 10.8 Fetal development: 12- to 15-week fetus.

Fetal Circulation

Fetal circulation differs from adult circulation due to the presence of certain vessels and shunts. These shunts will close after birth and most of these vessels will be seen as remnants in the adult circulation. The function of these shunts is to direct oxygen-rich venous blood to the systemic circulation and to ensure that oxygen-depleted venous blood bypasses the underdeveloped pulmonary circulation. The lungs finish their development after birth. Prior to this, the lung's function is taken over by the placenta, which therefore becomes the oxygen-transfer organ during fetal life (Finnemore & Groves, 2015).

The circulation through the fetus during uterine life differs from that of a child or an adult. In the extrauterine world, oxygenation occurs in the lungs and oxygenated blood returns via the pulmonary veins to the left side of the heart to be ejected by the left ventricle into the systemic circulation. In contrast, fetal circulation oxygenation occurs in the placenta, and the fetal lungs are nonfunctional as far as the transfer of oxygen and carbon dioxide is concerned. For oxygenated blood derived from the placenta to reach the fetus' systemic circulation, it has to travel through a series of shunts to accomplish this.

Thus, fetal circulation involves the circulation of blood from the placenta to and through the fetus, and back to the placenta. A properly functioning fetal circulation system is essential to sustain the fetus. Before it develops, nutrients and oxygen diffuse through the extraembryonic coelom and the yolk sac from the placenta. As the embryo grows, its nutrient needs increase and the amount of tissue easily reached by diffusion increases. Thus, the circulation must develop quickly and accurately (Jones & Lopez, 2014).

Three shunts also are present during fetal life:

1. *Ductus venosus*—connects the umbilical vein to the inferior vena cava.

2. *Ductus arteriosus*—connects the main pulmonary artery to the aorta.

3. *Foramen ovale*—anatomic opening between the right and left atrium.

 Take Note!

Fetal circulation functions to carry highly oxygenated blood to vital areas (e.g., heart, brain) while first shunting it away from less important ones (e.g., lungs,

liver). The placenta essentially takes over the functions of the lungs and liver during fetal life. As a result, large volumes of oxygenated blood are not needed.

The blood with the highest oxygen content is delivered to the fetal heart, head, neck, and upper limbs, while the blood with the lowest oxygen content is shunted toward the placenta.

The oxygenated blood is carried from the placenta to the fetus via the umbilical vein. About half of this blood passes through the hepatic capillaries and the rest flows through the ductus venosus into the inferior vena cava. Blood from the vena cava is mostly deflected through the foramen ovale into the left atrium, then to the left ventricle, into the ascending aorta, and on to the head and upper body. This allows the fetal coronary circulation and the brain to receive the blood with the highest level of oxygenation.

Deoxygenated blood from the superior vena cava flows into the right atrium, the right ventricle, and then the pulmonary artery. Because of high pulmonary vascular resistance, only a small percentage (5% to 10%) of the blood in the pulmonary artery flows to the lungs; the majority is shunted through the patent ductus arteriosus, and then to the descending aorta (American Heart Association [AHA], 2015). The fetal lungs are essentially nonfunctional because they are filled with fluid, making them resistant to incoming blood flow. They receive only enough blood for proper nourishment. Finally, two umbilical arteries carry the unoxygenated blood from the descending aorta back to the placenta.

At birth, a dramatic change in the fetal circulatory pattern occurs. The foramen ovale, ductus arteriosus, ductus venosus, and umbilical vessels are no longer needed. With the newborn's first breath, the lungs inflate, which leads to an increase in blood flow to the lungs from the right ventricle. This increase raises the pressure in the left atrium, causing a one-way flap on the left side of the foramen ovale, called the septum primum, to press against the opening, creating a functional separation between the two atria. Blood flow to the lungs increases because blood entering the right atrium can no longer bypass the right ventricle. As a result, the right ventricle pumps blood into the pulmonary artery and on to the lungs. Typically the foramen ovale is functionally closed within 1 to 2 hours after birth. It is physiologically closed by 1 month by deposits of fibrin that seal the shunt. Permanent closure occurs by the sixth month of life.

The ductus venosus, which links the inferior vena cava with the umbilical vein, usually closes with the clamping of the umbilical cord and inhibition of blood flow through the umbilical vein. This fetal structure closes by the end of

the first week. The ductus arteriosus constricts partly in response to the higher arterial oxygen levels that occur after the first few breaths. This closure prevents blood from the aorta from entering the pulmonary artery. Functional closure of the ductus arteriosus in a term infant usually occurs within the first 72 hours after birth. Permanent closure occurs at 3 to 4 weeks of age (Yudkowitz, 2015). Frequently a functional or innocent murmur is auscultated by the nursery nurse when there are delayed fetal shunt closures, but they usually are not associated with a heart lesion. Successful transition from fetal to postnatal circulation requires increased pulmonary blood flow, removal of the placement and closure of the intracardiac (foramen ovale) and the extracardiac shunts (ductus venous and ductus arteriosus. All of these changes at birth leave the newborn with the typical adult pattern of circulation with right ventricle output equaling that of the left. Figure 10.9 shows fetal circulation. Also, view the following video of fetal circulation at this YouTube URL: https://www.youtube.com/watch?v=IRkisEtzskhttp://ndl.iitkgp.ac.in:8080/xmlui/handle/123456789/56006

GENETICS

Genetics is the study of individual genes and their role in heritance (Snustad, 2015). **Genomics**, a relatively new science, is the study of all genes and includes interactions among genes as well as interactions between genes and the environment. Genomics plays a role in complex conditions such as heart disease and diabetes. Another emerging area of research is that of pharmacogenomics, the study of genetic and genomic influences on pharmacodynamics and pharmacotherapeutics. While pharmacogenetics describes genetic variations between individuals and their influence on the efficacy and side effects of drugs, pharmacogenomics examines interactions of drugs with the entire genome. The main goal of both fields is the individual prediction of desirable and undesirable drug effects. An individual's genetics influences wellness and health issues throughout that individual's life cycle. The challenge for health care providers is to find the link between the client's genetic makeup and diseases (Brazeau, 2015).

According to the Centers for Disease Control and Prevention (2015a), birth defects and genetic disorders occur in 1 in 33 infants born in the United States and cause 1 in 5 infant deaths. Every 5 minutes an infant is born with a birth defect in the United States with nearly 120,000 infants affected annually. Traditionally, genetics has been associated with making decisions about childbearing and caring for children with genetic disorders. Currently, genetic and technological advances are expanding our understanding of how genetic changes affect human diseases such as diabetes, cancer, Alzheimer's disease, and other multifactorial diseases that are prevalent in adults. Today's genetic technologies are not yet a crystal ball for seeing a child's future, but scientists are closer to routinely glimpsing the genetic blueprints of a fetus just months after sperm meets egg. The genomic reconstruction would reveal future disease risk and genetic traits in the first trimester of pregnancy. Recent research findings report that preimplantation with knowledge of the whole genome may facilitate the comprehensive diagnosis of diseases with a known genetic basis in embryos (Kumar et al., 2015). Newborn screening is perhaps the most widely used application of genetics in perinatal and neonatal care. Our ability to diagnose genetic conditions is more advanced than our ability to cure or treat the disorders. However, accurate diagnosis has led to improved treatment and

outcomes for those affected with these disorders.

FIGURE 10.9 Fetal circulation. *Arrows* indicate the path of blood. The umbilical vein carries oxygen-rich blood from the placenta to the liver and through the ductus venosus. From there it is carried to the inferior vena cava to the right atrium of the heart. Some of the blood is shunted through the foramen ovale to the left side of the heart, where it is routed to the brain and upper extremities. The rest of the blood travels down to

the right ventricle and through the pulmonary artery. A small portion of the blood travels to the nonfunctioning lungs, while the remaining blood is shunted through the ductus arteriosus into the aorta to supply the rest of the body.

Take Note!

Genetic science has the potential to revolutionize health care with regard to national screening programs, predisposition testing, detection of genetic disorders, and pharmacogenetics.

Genetics has been a part of perinatal care for decades. Rapid development and implementation of advanced genetics technology in prenatal settings includes the ability to screen for and diagnose a broader range of diseases and conditions of the fetus in early gestational ages. Ultrasounds and maternal serum screening have become routine elements of prenatal care. Preconception carrier screening for conditions such as Tay–Sachs disease has been in place among high-risk populations such as Ashkenazi Jews. Amniocentesis and chorionic villus sampling are diagnostic tests that may confirm a genetic anomaly in a developing fetus, but they are all invasive techniques A fetal nuchal translucency test, seen on ultrasound, may suggest the presence of trisomy 21 or Down syndrome if increased nuchal thickness is found (Khalil & Coates, 2015).

Testing for genetic diseases before they cause symptoms, making a diagnosis in a person who has disease symptoms, and prescribing a type or dose of medication is early in its evolution. Genetic testing currently is rarely covered by health insurance companies, as the tests are still thought of as in research stages. This will change over the next several years as more associations between genomics and health are discovered.

Today, nurses are required to have basic skills and knowledge in genetics, genetic testing, and genetic counseling so they can assume new roles and provide information and support to women and their families. Roles for maternity nurses in genetic health care have expanded significantly as genetics education and counseling have become a standard of care. Today, nurses may provide preconception counseling for women at risk for the transmission of a genetic disorder. In addition, they may provide prenatal care for women with genetically linked disorders that require specialized care or may participate in screening infants for birth defects and genetic disorders. Nurses employed in

prenatal care settings need to have accurate information they can provide to women so they understand the benefits and limitations of screening. Timely presentation of information and identification of available resources will help nurses minimize a couple's confusion and provide support for women as they proceed with pregnancy screening. Nurses at all levels should participate in risk assessments for genetic conditions and disorders, explaining genetic risk and genetic testing, and supporting informed health decisions and opportunities for early intervention (Farrell, Nutter, & Agatisa, 2015). Nurses have a social and professional responsibility to ensure they provide current accurate information to clients and their families amid rapidly developing technology. This is especially true for nurses who value and support well-informed decision making that is woman-and-family-centered. For further information suitable for client education, nurses may want to access the following CDC web page on genomics: http://www.cdc.gov/genomics/public/index.htm/

It is very clear that genomics will have a profound effect on health and illness at all levels. Modern technology makes it possible to screen for and diagnose conditions prior to birth, such as open neural tube defects, chromosomal aneuploidies (i.e., trisomies 13, 18, and 21), congenital defects, and a myriad of single gene inheritable disorders (i.e., Tay–Sachs disease, cystic fibrosis, Huntington's disease, Duchenne muscular dystrophy, hemophilia). In the future, as the era of personalized health care moves forward, nurses will be responsible for ensuring that the scientific principles, ethical standards, and professional accountability of genetics and genomics practice are integrated into nursing practice. Nurses are increasingly doing this as they gain the necessary knowledge and skills. The strength of the nursing voice in genetics and genomic research will be the link to the bedside and the commitment to ensure that new knowledge is translated into competent, safe, effective, and evidence-based client care (Latendresse & Deneris, 2015).

Advances in Genetics and Genetic Technology

Human Genome Project

The publication of the first sequence of the human genome was regarded as one of the most ambitious and successful international research collaborations in modern biology. The Human Genome Project (HGP) was an international 13-year effort to produce a comprehensive sequence of the human genome. It was started in 1990 by the Department of Energy and the National Institutes of Health and was completed in May 2003. The goals of the HGP were to map, sequence, and determine the function of all human genes, which led to advances in the field of genetics and genetic testing (Kumar, Kingsley, & DiStefano, 2015). An individual's **genome** represents his or her genetic blueprint, which determines **genotype** (the gene pairs inherited from parents; the specific genetic makeup) and **phenotype** (observed outward characteristics of an individual). An individual's genetic profile can help guide decisions made regarding prevention, diagnosing, and treating disease. This is a profound shift in thinking from genetics that addressed rare disorders to the use of genetic information in all aspects of health care (Wilson & Nicholls, 2015).

A primary goal of the HGP was to translate the findings into new strategies for the prevention, diagnosis, and treatment of genetic diseases and disorders. Two key findings from the project were that all human beings are 99.9% identical at the deoxyribonucleic acid (DNA) level, and approximately 30,000 genes make up the human genome (International Human Genome Sequencing Consortium, 2015). Refer to thePoint for more information about the HGP.

Genetic Testing, Diagnosis, and Therapy

Recent advances in genetic knowledge and technology have affected all areas of health. These advances have increased the number of health interventions that can be undertaken with regard to genetic disorders. For example, genetic diagnosis is now possible very early in pregnancy (Evidence-Based Practice 10.1). Genetic testing can now identify presymptomatic conditions in children and adults. Gene therapy can be used to replace or repair defective or missing genes with normal ones. Gene therapy has been used for a variety of disorders, including cystic fibrosis, melanoma, diabetes, HIV, and hepatitis. Gene therapy

offers the possibility of accurately and specifically targeting particular genetic abnormalities through gene correction, addition, or replacement. This ability adds a new dimension of credible therapeutic choices (Cicalese & Aiuti, 2015). The potential exists for creation of increased intelligence and size through genetic intervention. Recent research using gene therapy shows promise for the generation of insulin-producing cells to cure diabetes; perhaps achieve long-term control of diabetes is on the horizon. Recent research is working toward beta cell replacement for diabetics to reliably and automatically maintain glucose levels within a tight range as the normal pancreas does (Johannesson et al., 2015). In the future, genetic agents may replace drugs, general surgery may be replaced by gene surgery, and genetic intervention may replace radiation. Recent successful trials on the treatment of ocular diseases and inherited immune deficiencies are particularly encouraging and have risen hopes that human gene therapy as a standard treatment option will finally become a reality. Continuous progress suggests that a wide range of diseases will be treated with gene therapy in the future (Lundstrom, 2015).

EVIDENCE-BASED PRACTICE 10.1 EFFECT OF ENHANCED INFORMATION, VALUES CLARIFICATION, AND REMOVAL OF FINANCIAL BARRIERS ON USE OF PRENATAL GENETIC TESTING: A RANDOMIZED CLINICAL TRIAL

Prenatal genetic testing guidelines have focused on identifying women at increased risk of giving birth to infants with chromosomal abnormalities. The use of prenatal genetic testing for clinical decision making is increasing exponentially. The current complexity of it brings concerns about the potential erosion of informed choice. It is difficult to ascertain if clients and their families truly understand what it is about and implications of the results. There currently are genetic tests for more than 2,500 diseases, with nearly 2,300 available for use in clinical decision making. The aim of this randomized study was to promote preference-based decision making and to assess the prenatal testing choices women make in the context of being fully informed about testing options.

STUDY

Of 1,932 women screened, 1,297 were eligible, and 744 enrolled in the study. They were then randomized into interventional and control groups. The women were diverse in ethnicity, language, education, and were at 20 weeks' gestation or less. Those in the intervention group had access to a computerized, interactive, prenatal testing support guide and were told that the study would pay for any tests for which they lacked health insurance coverage. Women in the control group received usual care, but no additional study intervention or financial support to cover prenatal testing. The goal was to determine what choices women would make after being fully informed about the benefits and risks of prenatal testing.

Findings

After women received complete prenatal testing information and the opportunity to consider their values and preferences, they were less likely to undergo invasive testing and more likely to avoid testing for aneuploidy (i.e., trisomies 13, 18, and 21). Full implementation of prenatal testing guidelines may lead to more informed and preference-based prenatal decision making.

> ## Nursing Implications
>
> Based on this study's findings, nurses can utilize standard counseling in addition to computer-based interactive information to reinforce the information about genetic testing before decisions are made to proceed. The landscape for genetic testing is changing constantly and it is wise to have well-informed clients and their families making the right decisions for their situation. By utilizing computerized technology to assist in educating clients and their families about a vital decision affecting their future, nurses are providing evidence-based information to them. Nurses have a responsibility to be knowledgeable about available genetic tests so they can assist their clients to become informed consumers of genetic-based health care.
>
> Adapted from Kuppermann, M., Pena, S., Bishop, J. T., Nakagawa, S., Gregorich, S. E., Sit, A., et al. (2015). Effect of enhanced information, values clarification, and removal of financial barriers on use of prenatal genetic testing: A randomized clinical trial. *Obstetrical & Gynecological Survey*, 70(1), 7–9.

Current and potential applications of the HGP in health care include rapid and more specific diagnosis of disease, with hundreds of genetic tests available in research or clinical practice; earlier detection of genetic predisposition to disease; less emphasis on treating the symptoms of a disease and more emphasis on looking at the fundamental causes of the disease; new classes of drugs; avoidance of environmental conditions that may trigger disease; and augmentation or replacement of defective genes through gene therapy. This new genetic knowledge and technology, along with the commercialization of this knowledge, will change both professional and parental understanding of genetic disorders. Current reproductive applications, however, remain restricted to mostly the prevention of transmitting an at-risk gene or genes, but do not include treatment or cure. It is anticipated that this restriction might continue for years. As such, the scientific and ethical issues associated with reproductive applications will continue to affect decision making of at-risk individuals.

Ethical, Legal, and Social Issues of Genetic Technology

The potential benefits of these discoveries are vast, but so is the potential for

misuse. These advances challenge all health care providers to consider the many ethical, legal, and social ramifications of genetics in human lives. In the near future, individual risk profiling based on an individual's unique genetic makeup will be used to tailor prevention, treatment, and ongoing management of health conditions. This profiling will raise issues associated with client privacy and confidentiality related to workplace discrimination and access to health insurance. Issues of autonomy are equally problematic as society considers how to address the injustices that will inevitably surface when disease risk can be determined years before the disease occurs. Nurses will play an important role in developing policies and providing direction and support in this arena, and to do so they will need a basic understanding of genetics, including inheritance and inheritance patterns. (For more information on the ethical, social, and legal issues surrounding human genetic research and advances, refer to thePoint).

Inheritance

DNA and Genetic Information

The nucleus within the cell is the controlling factor in all cellular activities because it contains chromosomes, long continuous strands of DNA that carry genetic information. Each chromosome is made up of **genes**. Genes are individual units of heredity of all traits and are organized into long segments of DNA that occupy a specific location on a chromosome and determine a particular characteristic in an organism.

DNA stores genetic information and encodes the instructions for synthesizing specific proteins needed to maintain life. DNA is double stranded and takes the form of a double helix. The side pieces of the double helix are made up of a sugar, deoxyribose, and a phosphate, occurring in alternating groups. The cross-connections or rungs of the ladder are attached to the sides and are made up of four nitrogenous bases: adenine, cytosine, thymine, and guanine. The sequence of the base pairs as they form each rung of the ladder is referred to as the genetic code (Travers & Muskhelishvili, 2015) (Fig. 10.10).

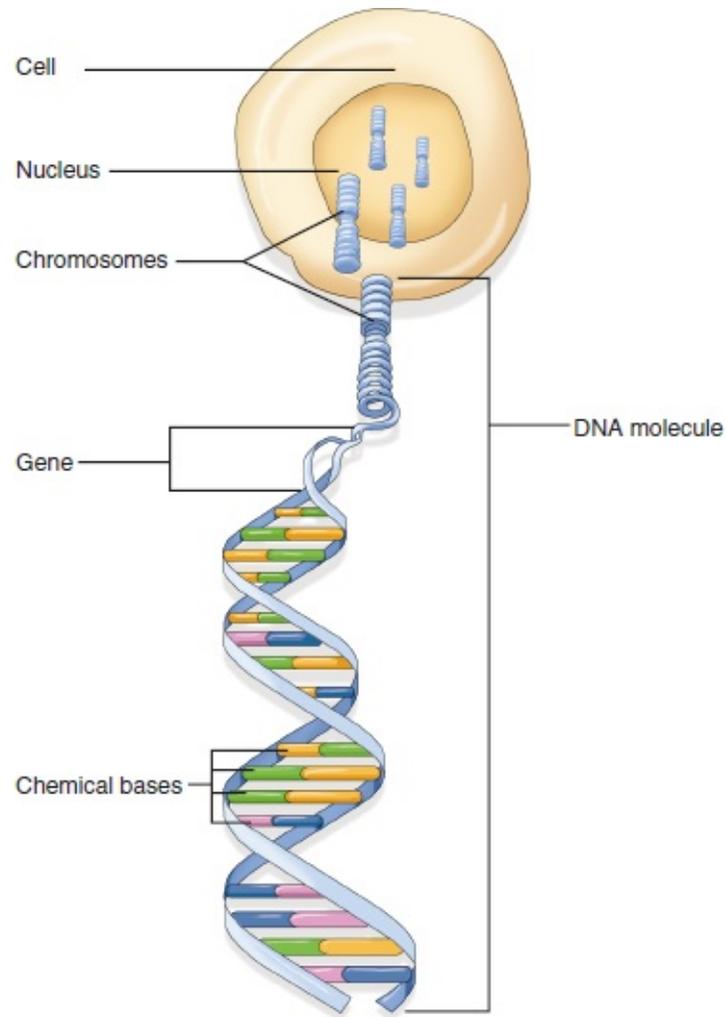
Each gene has a segment of DNA with a specific set of instructions for making proteins needed by body cells for proper functioning. Genes control the types of proteins made and the rate at which they are produced (Snustad, 2015). Any change in gene structure or location leads to a **mutation**, which may alter the type and amount of protein produced (Fig. 10.11). Genes never act in isolation; they always interact with other genes and the environment. They are arranged and lined up in a specific linear formation along a chromosome.


FIGURE 10.10 DNA is made up of four chemical bases. Tightly coiled strands of DNA are packaged in units called chromosomes, housed in the cell's nucleus. Working subunits of DNA are known as genes. (From the National Institutes of Health and National Cancer Institute. [1995]. Understanding gene testing [NIH Pub. No. 96-3905]. Washington, DC: U.S. Department of Human Services).
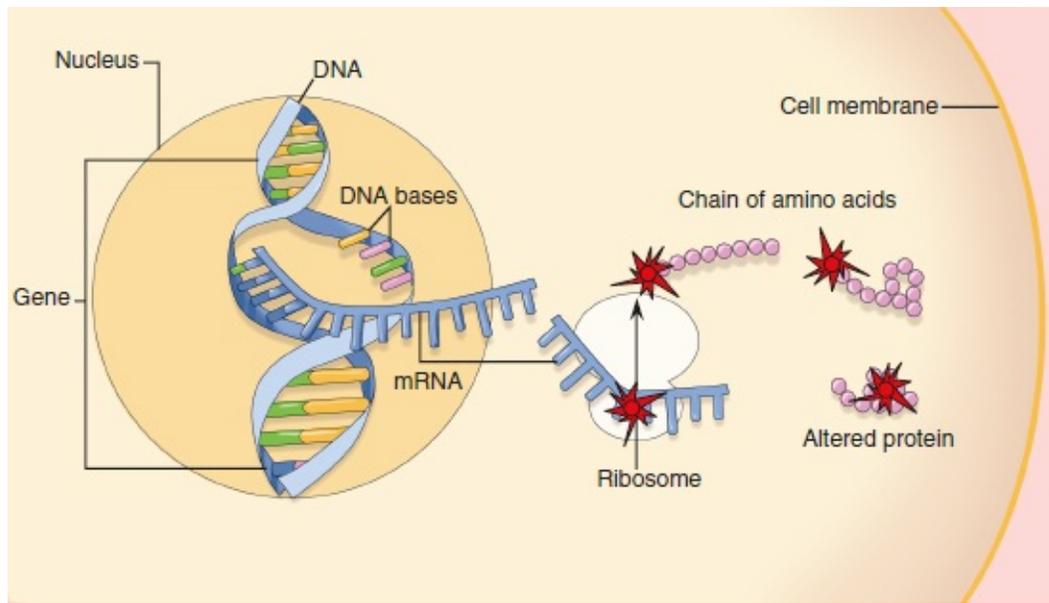

FIGURE 10.11 When a gene contains a mutation, the protein encoded by that gene will be abnormal. Some protein changes are insignificant, while others are disabling. (From the National Institutes of Health and National Cancer Institute. [1995]. Understanding gene testing [NIH Pub. No. 96-3905]. Washington, DC: U.S. Department of Human Services).

Genotypes and Alleles

The genotype—the specific genetic makeup of an individual, usually in the form of DNA—is the internally coded inheritable information. It refers to the particular **allele**, which is one of two or more alternative versions of a gene at a given position or locus on a chromosome that imparts the same characteristic of that gene. For instance, each human has a gene that controls height, but there are variations of these genes, called alleles, that code for a specific height. As another example, a gene that controls eye color may have an allele that can produce blue eyes or an allele that produces brown eyes. The genotype, together with environmental variation that influences the individual, determines the phenotype, or the observed, outward characteristics of an individual. A human inherits two genes, one from each parent. Therefore, one allele comes from the mother and one from the father. These alleles may be the same for the characteristic (**homozygous**) or different (**heterozygous**). For example, WW stands for homozygous dominant; ww stands for homozygous recessive. Heterozygous would be indicated as Ww. If the two alleles differ, such as Ww, the dominant one will usually be expressed in the phenotype of the individual.

Chromosomes

Human beings typically have 46 chromosomes. This includes 22 pairs of nonsex chromosomes or autosomes and 1 pair of sex chromosomes (two X chromosomes in females, and an X chromosome and a Y chromosome in males). Offspring receive one chromosome of each of the 23 pairs from each parent.

The pictorial analysis of the number, form, and size of an individual's chromosomes is termed the **karyotype**. This analysis commonly uses white blood cells and fetal cells in amniotic fluid. The chromosomes are numbered from the largest to the smallest, 1 to 22, and the sex chromosomes are designated by the letter X or Y. A female karyotype is designated as 46, XX and a male karyotype is designated as 46, XY. Figure 10.12 illustrates an example of a karyotyping pattern.

Genetic Mutations

Regulation and expression of the thousands of human genes are very complex processes and are the result of many intricate interactions within each cell. Alterations in gene structure, function, transcription, translation, and protein synthesis can influence an individual's health (Jones & Lopez, 2014). Gene mutations are a permanent change in the sequence of DNA.

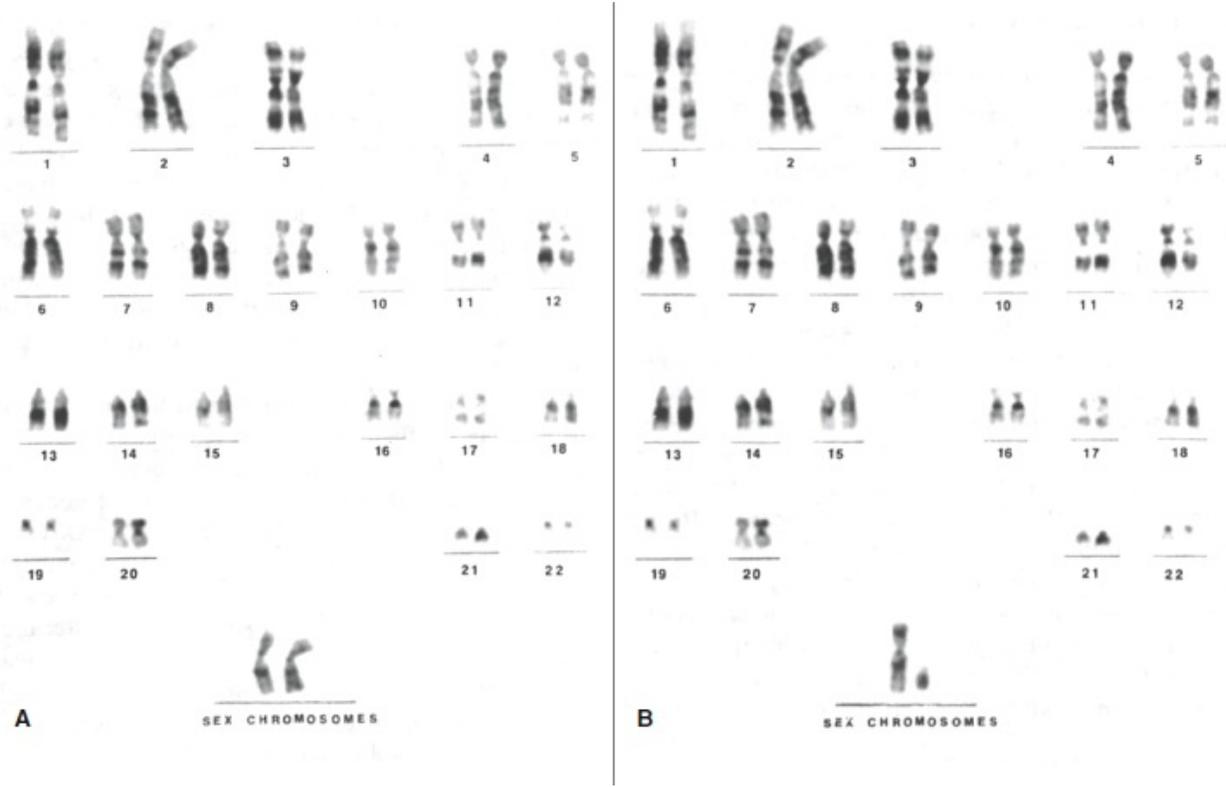
Gene mutations can be inherited, spontaneous, or acquired. Inherited gene mutations are passed on from parent to child in the egg and sperm, and are passed on to all cells in that child's body when the body cells reproduce. Cystic fibrosis is an example of an inherited mutation. A spontaneous mutation can occur in individual eggs or sperm at the time of conception. A person who has the new spontaneous mutation has the risk of passing it on to his or her offspring. An example of a spontaneous mutation would be Marfan syndrome. Acquired mutations occur in body cells other than egg or sperm. They involve changes in DNA that take place after conception, during a person's lifetime. Acquired mutations are passed on when they reproduce to daughter cells. These changes can be caused by environmental factors such as ultraviolet radiation from the sun, or can occur if a mistake is made as DNA copies itself during cell division (National Institutes of Health [NIH], 2015a). Some mutations have no significant effect, whereas others can have a tremendous impact on the health of the individual. Several genetic disorders such as cancer, sickle cell disease, PKU, and hemophilia, can result from these mutations.


FIGURE 10.12 Karyotype pattern. **A.** Normal female karyotype. **B.** Normal male karyotype.

Patterns of Inheritance for Genetic Disorders

Patterns of inheritance demonstrate how a genetic disorder can be passed on to offspring. A genetic disorder is a disease caused by an abnormality in an individual's genetic material or genome. Diagnosis of a genetic disorder is usually based on clinical signs and symptoms or on laboratory confirmation of the presence of an altered gene associated with the disorder. Accurate diagnosis can be aided by recognition of the pattern of inheritance within a family. The pattern of inheritance is also vital to understand when teaching and counseling families about the risks in future pregnancies. Some genetic conditions are caused by mutations in a single gene. These conditions are typically inherited in one of several straightforward patterns, depending on the gene involved. Some genetic disorders occur in multiple family members, while others may occur in only a single family member. A genetic disorder is caused by completely or partially altered genetic material, whereas a familial disorder is more common in relatives of the affected individual but may be caused by environmental influences and not genetic alterations.

Monogenic Disorders

The principles of genetic disease inheritance of single-gene disorders are the same principles that govern the inheritance of other traits, such as eye and hair color. These are known as Mendel's laws of inheritance, named for the genetic work of Gregor Mendel, an Austrian naturalist. These patterns occur due to a single gene being defective and are referred to as monogenic or sometimes Mendelian disorders. If the defect occurs on the autosome, the genetic disorder is termed *autosomal*; if the defect is on the X chromosome, the genetic disorder is termed *X linked*. The defect also can be classified as dominant or recessive. Monogenic disorders include autosomal dominant, autosomal recessive, X-linked dominant, and X-linked recessive patterns.

AUTOSOMAL DOMINANT INHERITANCE DISORDERS

Autosomal dominant inheritance disorders occur when a single gene in the heterozygous state is capable of producing the phenotype. In other words, the abnormal or mutant gene overshadows the normal gene and the individual will demonstrate signs and symptoms of the disorder. The affected person generally

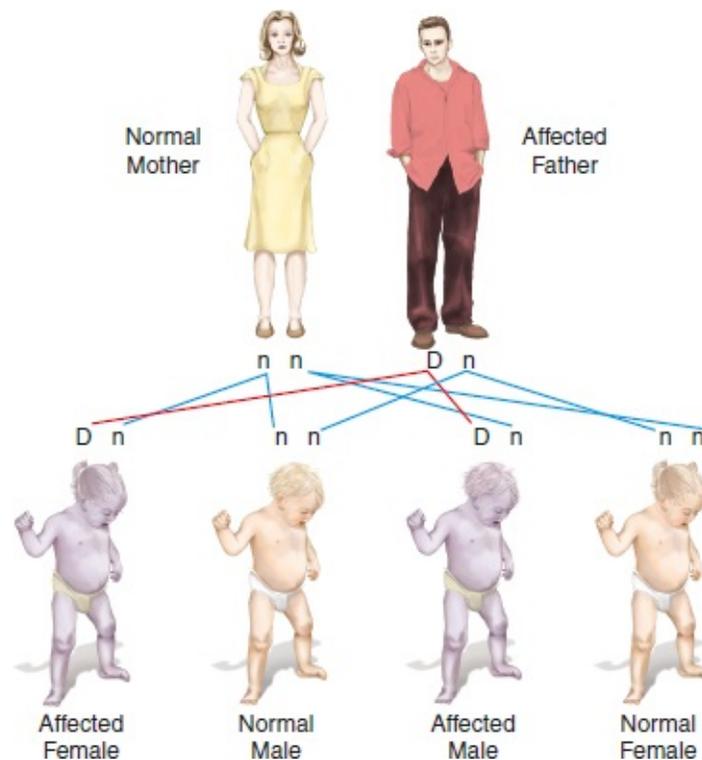
has one affected parent, and an affected person has a 50% chance of passing the abnormal gene to each of his or her children (Fig. 10.13). Affected individuals are present in every generation. Males and family members who are phenotypically normal (do not show signs or symptoms of the disorder) do not transmit the condition to their offspring. Females and males are equally affected and a male can pass the disorder on to his son. This male-to-male transmission is important in distinguishing autosomal dominant inheritance from X-linked inheritance. There are varying degrees of presentation among individuals in a family. Therefore, a parent with a mild form could have a child with a more severe form. Common types of genetic disorders that follow the autosomal dominant pattern of inheritance include neurofibromatosis (genetic disorders affecting the development and growth of neural cells and tissues); Huntington's disease (a genetic disorder affecting the nervous system characterized by abnormal involuntary movements and progressive dementia); achondroplasia (a genetic disorder resulting in disordered growth and abnormal body proportion); and polycystic kidney disease (a genetic disorder involving the growth of multiple, bilateral, grape-like clusters of fluid-filled cysts in the kidneys that eventually compress and replace functioning renal tissue).


FIGURE 10.13 Autosomal dominant inheritance.

AUTOSOMAL RECESSIVE INHERITANCE DISORDERS

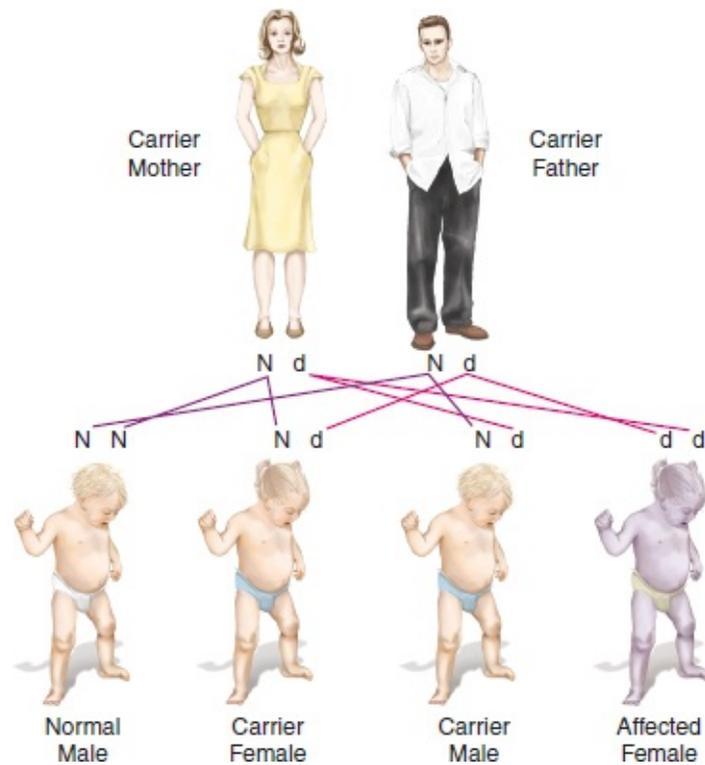
Autosomal recessive inheritance disorders occur when two copies of the mutant or abnormal gene in the homozygous state are necessary to produce the phenotype. In other words, two abnormal genes are needed for the individual to demonstrate signs and symptoms of the disorder. These disorders are generally less common than autosomal dominant disorders (NIH, 2015a). Both parents of the affected person must be heterozygous carriers of the gene (clinically normal but carry the gene), and their offspring have a 25% chance of being homozygous (a 50% chance of getting the mutant gene from each parent and therefore a 25% chance of inheriting two mutant genes). If the child is clinically normal, there is a 50% chance that he or she is a carrier (Fig. 10.14). Affected individuals are usually present in only one generation of the family. Females and males are equally affected and a male can pass the disorder on to his son. The chance that any two parents will both be carriers of the mutant gene is increased if the couple is consanguineous (having a common ancestor). Common types of genetic disorders that follow the autosomal recessive inheritance pattern include cystic fibrosis (a genetic disorder involving generalized dysfunction of the exocrine glands); PKU (a disorder involving a deficiency in a liver enzyme that leads to the inability to process the essential amino acid phenylalanine); Tay–Sachs disease (a disorder due to insufficient activity of the enzyme hexosaminidase A, which is necessary for the breakdown of certain fatty substances in the brain and nerve cells); and sickle cell disease (a genetic disorder in which the red blood cells carry an ineffective type of hemoglobin instead of the normal adult hemoglobin).


FIGURE 10.14 Autosomal recessive inheritance.

X-LINKED INHERITANCE DISORDERS

X-linked inheritance disorders are those associated with altered genes present on the X chromosome. They differ from autosomal disorders. If a male inherits an X-linked altered gene, he will express the condition. Because a male has only one X chromosome, all the genes on his X chromosome will be expressed (the Y chromosome carries no normal allele to compensate for the altered gene). Because females inherit two X chromosomes, they can be either heterozygous or homozygous for any allele. Therefore, X-linked disorders in females are expressed similarly to autosomal disorders.

 Concept Mastery Alert

Male Children in Pattern of Inheritance of Duchenne Muscular Dystrophy

The gene for Duchenne muscular dystrophy is X-linked, which means that a male child who inherits this gene will be affected by, not a carrier of, the

disease. A female child will not be affected by the disease.

Most X-linked disorders demonstrate a recessive pattern of inheritance. Males are more affected than females. A male has only one X chromosome and all the genes on his X chromosome will be expressed, whereas a female will usually need both X chromosomes to carry the disease. There is no male-to-male transmission (since no X chromosome from the male is transmitted to male offspring), but any man who is affected will have carrier daughters. If a woman is a carrier, there is a 50% chance that her sons will be affected and a 50% chance that her daughters will be carriers (Fig. 10.15). Common types of genetic disorders that follow X-linked recessive inheritance patterns include hemophilia (a genetic disorder involving a deficiency of one of the coagulation factors in the blood); color blindness; and Duchenne muscular dystrophy (a disorder involving progressive muscular weakness and wasting).

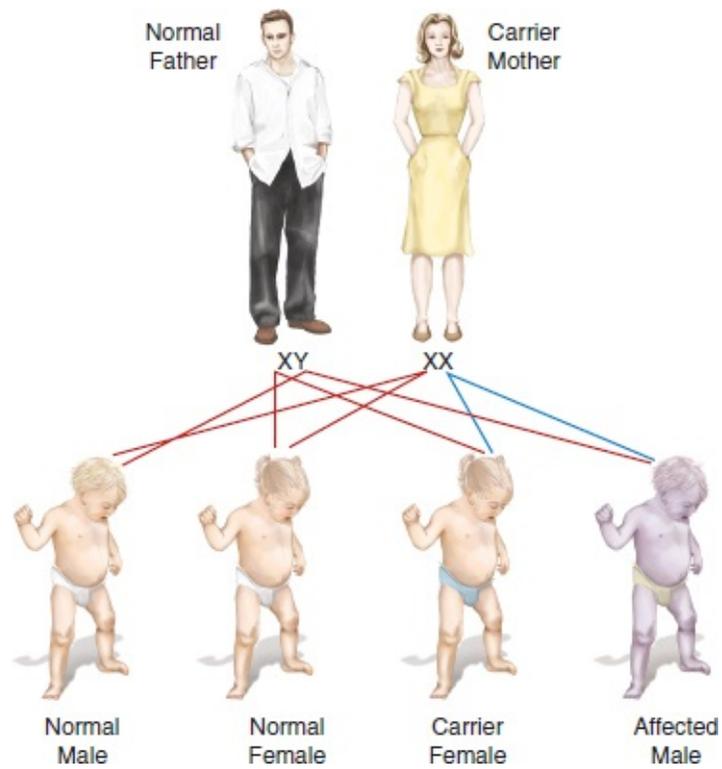
X-linked dominant inheritance is present if heterozygous female carriers demonstrate signs and symptoms of the disorder. All of the daughters and none of the sons of an affected male have the condition, while both male and female offspring of an affected woman have a 50% chance of inheriting and presenting with the condition (Fig. 10.16). X-linked dominant disorders are rare. The most common is hypophosphatemic (vitamin D–resistant) rickets (a disorder involving a softening or weakening of the bones). Fragile X syndrome is another X-linked dominant condition that causes a range of developmental problems including learning disabilities and cognitive impairment. A characteristic of X-linked dominant is that fathers cannot pass X-linked traits to their sons (no male-to-male transmission).


FIGURE 10.15 X-linked recessive inheritance.
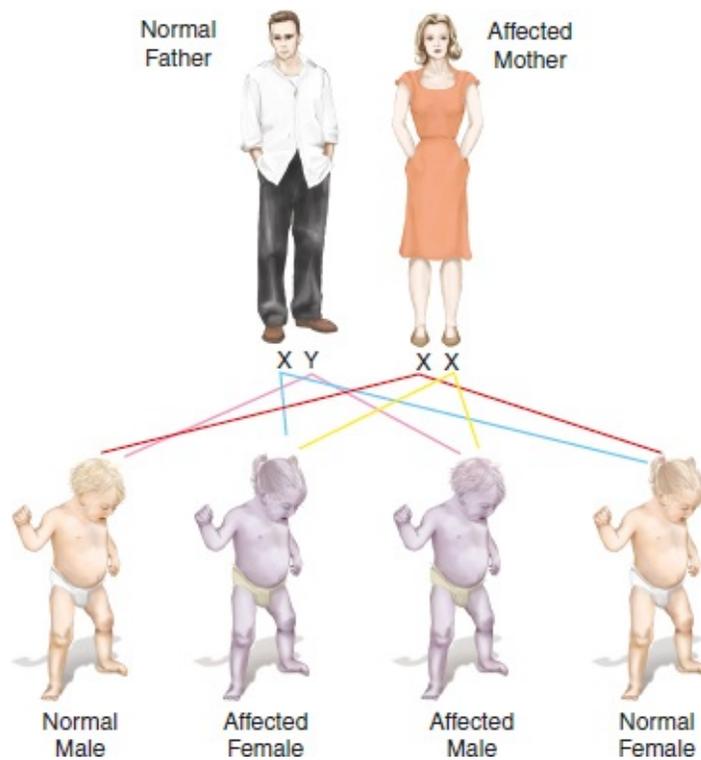

FIGURE 10.16 X-linked dominant inheritance.

Multifactorial Inheritance Disorders

Multifactorial inheritance disorders are thought to be caused by multiple genetic (polygenic) and environmental factors. Many of the common congenital malformations, such as cleft lip, cleft palate, spina bifida, pyloric stenosis, clubfoot, developmental hip dysplasia, and cardiac defects, are attributed to multifactorial inheritance. A combination of genes from both parents, along with unknown environmental factors, produces the trait or condition. An individual may inherit a predisposition to a particular anomaly or disease. The anomalies or diseases vary in severity, and often a sex bias is present. For example, pyloric stenosis is seen more often in males, while developmental hip dysplasia is much more likely to occur in females. Multifactorial conditions tend to run in families, but the pattern of inheritance is not as predictable as with single-gene disorders. The chance of recurrence is also lower than in single-gene disorders, but the degree of risk is related to the number of genes in common with the affected individual. The closer the degree of relationship, the more genes an individual has in common with the affected family member, resulting in a higher chance that the individual's offspring will have a similar defect. In multifactorial inheritance, the likelihood that both identical twins will be affected is not 100%, indicating that there are nongenetic factors involved.

Nontraditional Inheritance Patterns

Molecular studies have revealed that some genetic disorders are inherited in ways that do not follow the typical patterns of dominant, recessive, X-linked, or multifactorial inheritance. Examples of nontraditional inheritance patterns include mitochondrial inheritance and genomic imprinting. As the science of molecular genetics advances and more is learned about inheritance patterns, other nontraditional patterns of inheritance may be discovered or found to be relatively common.

Chromosomal Abnormalities

In some cases of genetic disorders, the abnormality occurs due to problems with the chromosomes. Chromosomal abnormalities arise when the normal complement of 46 chromosomes that produces a karyotype is altered, usually during cell division, either by an increase or decrease in the number of chromosomes.

About 1 in 150 live-born infants is born with a chromosomal abnormality (March of Dimes, 2015a). These often cause major defects because they involve added or missing genes. Congenital anomalies and intellectual disability are often associated with chromosomal abnormalities. These abnormalities occur on autosomal as well as sex chromosomes and can result from changes in the number of chromosomes or changes in the structure of the chromosomes.

Numerical Abnormalities

Chromosomal abnormalities of number often result from nondisjunction or failure of the chromosome pair to separate during cell division, meiosis, or mitosis. Few chromosomal numerical abnormalities are compatible with full-term development and most result in spontaneous abortion. One type of chromosomal number abnormality is **polyploidy**. Polyploidy causes an increase in the number of haploid sets (23) of chromosomes in a cell. Triploidy refers to three whole sets of chromosomes in a single cell (in humans, a total of 69 chromosomes per cell); tetraploidy refers to four whole sets of chromosomes in a single cell (in humans, a total of 92 chromosomes per cell). Polyploidy usually results in an early spontaneous abortion and is incompatible with life.

Some numerical abnormalities do support development to term because the chromosome on which the abnormality is present carries relatively few genes (such as chromosome 13, 18, 21, or X). Two common abnormalities of chromosome number are monosomies or trisomies. In **monosomies**, there is only one copy of a particular chromosome instead of the usual pair (an entire single chromosome is missing). In these cases, all fetuses spontaneously abort in early pregnancy. Survival is seen only in mosaic forms of these disorders. In **trisomies**, there are three of a particular chromosome instead of the usual two (an entire single chromosome is added). Trisomies may be present in every cell or may present in the mosaic form. The most common trisomies include trisomy

21 (Down syndrome), trisomy 18, and trisomy 13.

TRISOMY 21

Down syndrome is an example of a trisomy. The cause of Down syndrome is one of three types of abnormal cell division involving chromosome 21. All three abnormalities result in extra genetic material from chromosome 21, which is responsible for the characteristic features and developmental problems of Down syndrome. The three genetic variations that can cause Down syndrome include trisomy 21, where the infant has three copies of chromosome 21—instead of the usual two copies—in all of his or her cells; mosaic, where infants have some cells with an extra copy of chromosome 21; and translocation, where part of chromosome 21 becomes attached (translocated) to another chromosome, before or at conception. More than 90% of the cases of Down syndrome are caused by trisomy 21 (March of Dimes, 2015b) (Fig. 10.17).

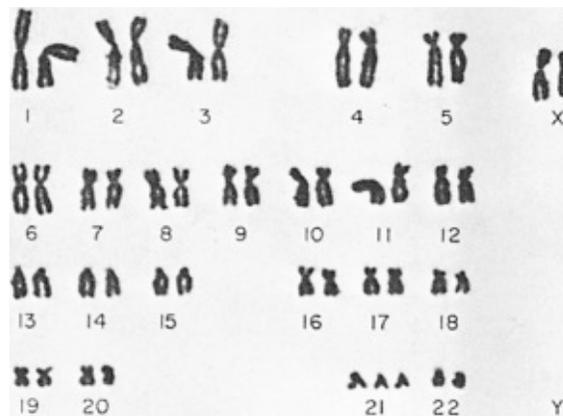
Down syndrome affects 1 in 691 live-born babies. About 6,000 infants with Down syndrome are born in the United States annually. The risk of this and other trisomies increases with maternal age. The risk of having a baby with Down syndrome is about 1 in 1,250 for a woman at age 25, 1 in 1,000 at 30, 1 in 400 at 35, 1 in 100 at age 40, and 1 in 30 at age 45 (March of Dimes, 2015b). Children with Down syndrome have characteristic features that are usually identified at birth (Fig. 10.18). These common characteristics include:


FIGURE 10.17 Karyotype of a child with Down syndrome.

- Small, low-set ears that may fold over a little at the pinna
- Hyperflexibility
- Muscle hypotonia

- Small hands and feet
- A short neck
- Wide-spaced eyes that slant upward
- Ulnar loop on the second digit
- Deep crease across palm (termed a *simian crease*)
- Flat facial profile
- Short stature in childhood and adulthood
- Small white, crescent-shaped spots on irises
- Small mouth with protruding tongue
- Broad, short fingers (National Down Syndrome Society [NDSS], 2015a)

The outlook for children with Down syndrome is much brighter now than it was years ago. Most children with Down syndrome have an intellectual disability in the mild-to-moderate range. With early intervention and special education, many learn to read and write and participate in diverse childhood activities (Grieco et al., 2015). Life expectancy for individuals with Down syndrome has increased dramatically in recent years, with the average life span approaching that of peers without Down syndrome (NDSS, 2015b).

TRISOMY 18 AND TRISOMY 13

Two other common trisomies are trisomy 18 and trisomy 13. Trisomy 18 and trisomy 13 are, respectively, the second and third most commonly diagnosed autosomal trisomies in live-born infants. These conditions are associated with a high degree of infant mortality, with most dying before their first birthday (Trisomy 18 Foundation, 2015).

Trisomy 18, or Edward syndrome, occurs in 1 of every 2,500 pregnancies in the United States, about 1 in 6,000 live births (Trisomy 18 Foundation, 2015). Prenatally, several findings are apparent on ultrasound: IUGR, hydramnios or oligohydramnios, cardiac malformations, a single umbilical artery, and decreased fetal movement. Additionally, trisomy 18 has been associated with a decrease in maternal serum levels of maternal serum alpha-fetoprotein (MSAFP) and hCG. Most affected newborns are female, with a 4:1 ratio to males. Affected newborns have 47 chromosomes (three at chromosome 18) and are characterized by severe intellectual disability, growth deficiency of the cranium (microcephaly), low-set ears, facial malformations, small-for-gestational-age size, seizures, drooping

eyelids, webbing of fingers, kidney and congenital heart defects, rocker-bottom feet, and severe hypotonia (National Organization for Rare Disorders [NORD], 2015a). Infants with trisomy 18 have multiple anomalies that are severe, and life expectancy is greatly reduced beyond a few months.

FIGURE 10.18 **A.** Typical facial features of an infant with Down syndrome. **B.** A simian line, a horizontal crease in the palm of children with Down syndrome.

FIGURE 10.19 An infant with trisomy 13 has supernumerary digits (polydactyly).

Trisomy 13, or Patau syndrome, affects 1 of 10,000 live births (Support Organization for Trisomies [SOFT], 2015). Forty-seven chromosomes (three of chromosome 13) are present. Maternal age is also thought to be a causative factor in this genetic disorder. The common abnormalities associated with trisomy 13 are microcephaly, cardiac defects, small eyes, kidney malformations, central nervous system anomalies, rocker-bottom feet, neural tube defects, omphalocele, cleft lip and palate, cryptorchidism, polydactyly (Fig. 10.19), severe intellectual disability, severe hypotonia, and seizures. Life expectancy is only a few days for most infants with trisomy 13 (NORD, 2015b). Care for these infants is supportive.

Structural Abnormalities

Chromosomal abnormalities of structure usually occur when a portion of one or more chromosomes is broken or lost, and during the repair process the broken ends are rejoined incorrectly. Structural abnormalities usually lead to having too much or too little genetic material. Altered chromosome structure can take on several forms. Deletions occur when a portion of the chromosome is missing, resulting in a loss of that chromosomal material. Duplications are seen when a portion of the chromosome is duplicated and an extra chromosomal segment is present. Clinical findings vary depending on how much chromosomal material is involved. Inversions occur when a portion of the chromosome breaks off at two points and is turned upside down and reattached; therefore, the genetic material is inverted.

The most clinically significant structural abnormality is a translocation. This occurs when part of one chromosome is transferred to another chromosome and an abnormal rearrangement is present.

Structural abnormalities can be balanced or unbalanced. Balanced abnormalities involve the rearrangement of genetic material with neither an

overall gain nor loss. Individuals who inherit a balanced structural abnormality are usually phenotypically normal but are at a higher risk for miscarriages and having chromosomally abnormal offspring. Examples of structural rearrangements that can be balanced include inversions, translocations, and ring chromosomes. Unbalanced structural abnormalities are similar to numerical abnormalities because genetic material is either gained or lost. Unbalanced structural abnormalities can encompass several genes and result in severe clinical consequences.

CRI DU CHAT SYNDROME

Cri du chat ("cry of the cat") syndrome is a rare genetic disorder in which a variable portion of the short arm of chromosome 5 is missing or deleted. It was named "cri du chat" based on the distinctive cry in newborns that resembles the mewing of a cat, which is due to a laryngeal defect. The incidence of the disorder is thought to be approximately 1 in 50,000 live births (NORD, 2015d). In addition to the cat-like, high-pitched cry in infancy, it is also associated with intellectual and psychomotor disability, microcephaly, speech delay, low birth weight and slow growth, hypotonia, failure to thrive, wide-set eyes, small jaw, low-set ears, and various organ malformations. Symptoms vary greatly from case to case depending upon the exact size and location of the deleted genetic material.

No specific treatment is available for this syndrome. With contemporary interventions, the child may survive to adulthood: 75% of deaths occur during the first several months of life and almost 90% occur in the first year. Death occurs in 6% to 8% of the overall population affected with the syndrome. Pneumonia, aspiration pneumonia, congenital heart defects, and respiratory distress are the common causes of death (Chen, 2015a). Parents should be referred for genetic counseling.

FRAGILE X SYNDROME

Fragile X syndrome, also termed Martin–Bell syndrome, is a structural abnormality involving the X chromosome, which demonstrates breaks and gaps. It is a common form of intellectual disability and autism spectrum disorder. The syndrome is usually diagnosed by the age of 3 by molecular DNA studies. Conservative estimates report that fragile X syndrome affects approximately 1 in 5,000 males and 1 in 8,000 females (CDC, 2015c). Typically, a female becomes the carrier and will be mildly affected. The male who receives the X

chromosome that has a fragile site will exhibit the full effects of the syndrome. Fragile X syndrome is characterized by intellectual disability, hyperactivity, large head, long face, short attention span, hand flapping, strabismus, hypotonia, speech delay, inflexible behavior, autistic-like behavior, poor eye contact, tactile defensiveness, double-jointedness, and perseverative speech (continued repetition of words or phrases). It is the most common form of male intellectual disability (NORD, 2015e).

Aside from the morbidity associated with intellectual disability and cognitive/behavioral/neuropsychological problems, the life span of an individual with fragile X syndrome is unaffected. This syndrome is currently not included in newborn screening panels in the United States, as it does not meet the standards for recommendation. There is no cure for this disorder. Speech, occupational, and physical therapy services usually are needed, as well as special education and counseling.

Sex Chromosome Abnormalities

Chromosomal abnormalities can also involve sex chromosomes. These cases are usually less severe in their clinical effects than autosomal chromosomal abnormalities. Sex chromosome abnormalities are gender specific and involve a missing or extra sex chromosome. They affect sexual development and may cause infertility, growth abnormalities, and possibly behavioral and learning problems. Many affected individuals lead essentially normal lives. Examples are Turner syndrome (in females) and Klinefelter syndrome (in males).

TURNER SYNDROME

Turner syndrome is a common abnormality of the sex chromosome in which a portion or all of the X chromosome is missing. It affects about 1 in 2,000 live-born female infants worldwide (March of Dimes, 2015a). It is highly variable and can differ dramatically from one person to another. Most cases of Turner syndrome are not inherited. Clinical manifestations include a low posterior hairline and webbing of the neck, short stature, broad skeletal abnormalities, kidney abnormalities, osteoporosis, heart defects, a shield-like chest with widely spaced nipples, lymphedema, cataracts, scoliosis, puffy feet, underdeveloped secondary sex characteristics, heart defects, and infertility (NORD, 2015c). Only about a third of cases are diagnosed as newborns; the remaining two thirds are diagnosed in early adolescence when they experience primary amenorrhea. No

cure exists for this syndrome. Growth hormone typically is given; hormone replacement therapy also may be used to induce puberty and stimulate continued growth. Most females with Turner syndrome are of normal intelligence and usually live essentially normal lives (NIH, 2015b).

KLINEFELTER SYNDROME

Klinefelter syndrome is a sex chromosomal abnormality that occurs only in males. About 1 in 500 to 1,000 males are born with Klinefelter syndrome (Chen, 2015b). With this syndrome an extra X chromosome (XXY) is present. The extra genetic material causes abnormal development of the testicles, resulting in decreased production of sperm and male sex hormones. Clinical manifestations may include:

• Mild intellectual disability

• Small testes that do not produce adequate testosterone

• Infertility

• Learning disabilities

• Delayed speech and language development

• Long arms and legs

• Enlarged breast tissue (gynecomastia)

• Scant facial and body hair

• Decreased sex drive (libido) (NORD, 2015f)

No treatment can correct this genetic abnormality, but testosterone replacement therapy can improve symptoms resulting from the deficiency. Surgery may be done to reduce gynecomastia. Most males with Klinefelter syndrome (XXY) are diagnosed in late puberty. Infertility is common and life expectancy is normal (Chen, 2015b).

Genetic Evaluation and Counseling

Genetic counseling is the process by which clients or relatives at risk for an inherited disorder are advised of the consequences and nature of the disorder, the probability of developing or transmitting it, and the options open to them in management and family planning in order to prevent, avoid, or ameliorate it. Nurses have long been on the forefront of genetic counseling for their clients. The knowledge derived from the HGP is transforming the health care model, with implications for nursing in genetic counseling, practice, and research (Lopes, de Omena Bomfim, & Flória-Santos, 2015). An individual should be referred for genetic counseling for any of a variety of reasons. Box 10.2 lists those who may benefit from genetic counseling. In many cases, geneticists and genetic counselors provide information to families regarding genetic diseases. However, an experienced family physician, pediatrician, or nurse who has received special training in genetics may also provide the information.

Consider This

As I waited for the genetic counselor to come into the room, my mind was filled with numerous fears and questions. What does an inconclusive amniocentesis really mean? What if this pregnancy produced an abnormal baby? How would I cope with a special child in my life? If only I had gone to the midwife sooner when I thought I was pregnant, but still in denial. Why did I not stop drinking and smoking when I found out I was pregnant? If only I had started to take my folic acid pills when prescribed. Why didn't I research my family's history to know of any hidden genetic conditions? What about my sister with a Down syndrome child? What must I have been thinking? I guess I could play the "what-if" game forever and never come up with answers. Is it was too late to do anything about this? I am 37 years old and alone…. I started to pray silently when the counselor opened the door….

Thoughts: This woman is reviewing the past few weeks, looking for answers to her greatest fears. Inconclusive screenings can introduce emotional torment for many women as they wait for validating results. Are

---

these common thoughts and fears for many women facing potential genetic disorders? What supportive interventions might the nurse offer?

BOX 10.2

THOSE WHO MAY BENEFIT FROM GENETIC COUNSELING

• Women who are pregnant or planning to be after age 35

• Paternal age 50 years or older

• Previous child, parents, or close relatives with an inherited disease, congenital anomalies, metabolic disorders, developmental disorders, or chromosomal abnormalities

• Consanguinity or incest

• Pregnancy screening abnormality, including alpha-fetoprotein, triple screen, amniocentesis, or ultrasound

• Stillborn with congenital anomalies

• Two or more pregnancy losses

• Exposure to drugs, medications, radiation, chemicals, or infections

• Concerns about genetic defects that occur frequently in their ethnic or racial group (for instance, those of African descent are most at risk for having a child with sickle cell anemia)

• Abnormal newborn screening

• Couples with a family history of X-linked disorders

• Carriers of autosomal recessive or dominant diseases

• Child born with one or more major malformations in a major organ system

• Child with abnormalities of growth

• Child with developmental delay, intellectual disability, blindness, or deafness

Adapted from March of Dimes. (2015d). *Genetic counseling*. Retrieved from http://www.marchofdimes.com/pregnancy/genetic-counseling.aspx; National Human Genome Research Institute.(2015). *What is genetic counseling and evaluation*? Retrieved from https://www.genome.gov/19016905; and Dayal, M. B., & Athanasiadis, I. (2015). Preimplantation genetic diagnosis. *eMedicine*. A genetic consultation involves evaluation of an individual or a family. Its purposes are to confirm, diagnose, or rule out genetic conditions; to identify medical management issues; to calculate and communicate genetic risks to a family; to discuss ethical and legal issues; and to provide and arrange psychosocial support. Genetic counselors serve as educators and resource persons for other health care providers and the general public.

The ideal time for genetic counseling is before conception. Preconception counseling gives couples the chance to identify and reduce potential pregnancy risks, plan for known risks, and establish early prenatal care. Unfortunately, many women delay seeking prenatal care until their second or third trimester, after the crucial time of organogenesis. Therefore, it is important that preconception counseling be offered to all women as they seek health care throughout their childbearing years, especially if they are contemplating pregnancy. This requires health care providers to take a proactive role.

Genetic screening and counseling can raise serious ethical and moral issues for a couple. The results of prenatal genetic testing can lead to the decision to terminate a pregnancy, even if the results are not conclusive but indicate a strong possibility that the child will have an abnormality. The severity of the abnormality may not be known, and some may find the decision to terminate unethical. Another difficult situation that provides an example of the ethical and moral issues surrounding genetic screening and counseling involves disorders that affect only one gender of offspring. A mother may find she is a carrier of a gene for a disorder for which there is no prenatal screening test available. In these cases, the couple may decide to terminate any pregnancy where the fetus is the affected sex, even though there is a 50% chance that the child will not inherit the disorder. In these situations, the choice is the couple's and information and support must be provided in a nondirective, nonjudgmental manner.

Genetic counseling is particularly important if a congenital anomaly or genetic disease has been diagnosed prenatally or if a child is born with a life-threatening congenital anomaly or genetic disease. In these cases, families need information urgently so they can make immediate decisions. If a diagnosis with genetic implications is made later in life, if a couple with a family history of a genetic disorder or a previous child with a genetic disorder is planning a family, or if there is suspected teratogen exposure, urgency of information is not such an issue. In these situations, the family needs time to ponder all their options. This may involve several meetings over a longer period of time.

Genetic counseling involves gathering information regarding birth history,

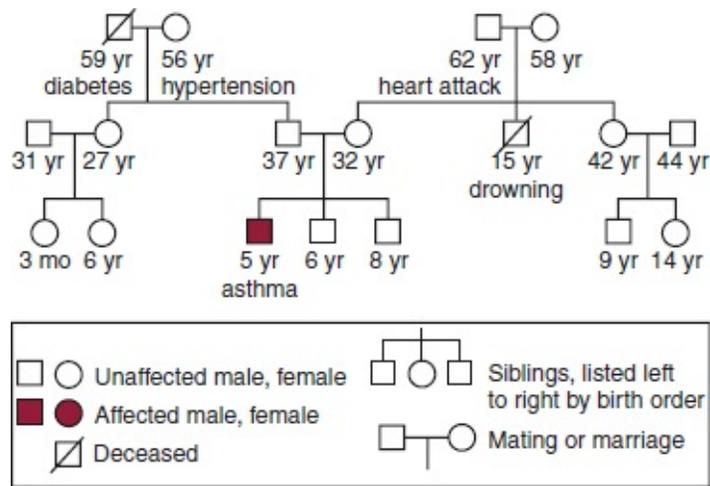
past medical history, and current health status as well as a family history of congenital anomalies, intellectual disability, genetic diseases, reproductive history, general health, and causes of death. A detailed family history is imperative and in most cases will include the development of a pedigree, which is like a family tree (Fig. 10.20). Information is ideally gathered on three generations, but if the family history is complicated, information from more distant relatives may be needed. Families receiving genetic counseling may benefit from being told in advance that this information will be necessary; they may need to discuss these sensitive, private issues with family members to obtain the needed facts. When necessary, medical records may be requested for family members, especially those who have a genetic disorder, to help ensure accuracy of the information. Sometimes a pedigree may reveal confidential information not known by all family members, such as an adoption, a child conceived through in vitro fertilization, or a husband not being the father of a baby. Therefore, maintaining confidentiality is extremely important. After careful analysis of the data obtained, referral to a genetic counselor when indicated is appropriate.


FIGURE 10.20 A pedigree is a diagram made using symbols that demonstrates the links between family members and focuses on medical and health information for each relative.

Medical genetic knowledge has increased dramatically during the past few decades. Not only is it possible to detect specific diseases with genetic mutations, but it is also possible to test for a genetic predisposition to various diseases or conditions and certain physical characteristics. This leads to complex ethical, moral, and social issues. Maintaining client privacy and confidentiality

and administering care in a nondiscriminatory manner are essential while maintaining sensitivity to cultural differences. It is essential to respect client autonomy and present information in a nondirective, nonjudgmental manner.

NURSING ROLES AND RESPONSIBILITIES

Nurses are at the forefront of client care, and will participate fully in genetic-based and genomic-based activities. Nurses will therefore have a critical role advocating for, educating, counseling, and supporting clients and families who are making gene-based health care decisions (Association of Genetic Nurses and Counselors [AGNC], 2015). The nurse is likely to interact with the client in a variety of ways related to genetics: taking a family history, scheduling genetic testing, explaining the purposes of all screening and diagnostic tests, answering questions, providing information and psychosocial support to individuals and families, and addressing concerns raised by family members. Nurses are often the first health care providers to encounter women with preconception and prenatal issues. Nurses play an important role in beginning the preconception counseling process and referring women and their partners for further genetic testing when indicated.

Nurses working with families involved with genetic counseling typically have certain responsibilities. These include:

• Using interviewing and active listening skills to identify genetic concerns

• Knowing basic genetic terminology and inheritance patterns

• Explaining basic concepts of probability and disorder susceptibility

• Safeguarding the privacy and confidentiality of clients' genetic information

• Providing complete informed consent to facilitate decisions about genetic testing

• Discussing costs of genetic services and the benefits and risks of using health insurance to pay for genetic services, including potential risks of discrimination

• Recognizing and defining ethical, legal, and social issues

• Providing accurate information about the risks and benefits of genetic testing

• Using culturally appropriate methods to convey genetic information

• Monitoring clients' emotional reactions after receiving genetic analysis

• Providing information on appropriate local support groups

• Knowing their own limitations and making appropriate referrals (Sermon &

Viville, 2014)

An accurate and thorough family history is an essential part of preconception counseling. Nurses in any practice setting can obtain a client's history during the initial encounter. The purpose is to gather client and family information that may provide clues as to whether the client has a genetic trait, inherited condition, or inherited predisposition (International Society of Nurses in Genetics, 2015). At a basic level, all nurses should be able to take a family medical history to help identify those at risk for genetic conditions, and then initiate a referral when appropriate. Box 10.3 presents examples of focused assessment questions that can be used. Based on the information gathered during the history, the nurse must decide whether a referral to a genetic specialist is necessary or whether further evaluation is needed. Families identified with genetic issues need unique clinical care including management of acute illnesses, screening for long-term complications, discussion of the etiology of the condition, connections to social supports, and clarification of the recurrence risks and prenatal testing and treatment options. Prenatal testing to assess for genetic risks and defects might be used to identify genetic disorders. These tests are described in Common Laboratory and Diagnostic Tests 10.1.

Remember Robert and Kate Shafer? Based on the information gathered from their genetic history, they were referred to a genetic specialist. What prenatal tests might be ordered to assess their risk for genetic disorders? What would be the nurse's role related to genetic counseling?

COMMON LABORATORY AND DIAGNOSTIC TESTS 10.1

PRENATAL TESTS TO ASSESS RISK FOR GENETIC DISORDERS

Test	Description	Indication	Timing
Alpha-fetoprotein	A sample of the woman's blood is drawn to evaluate plasma protein that is produced by the fetal liver, yolk sac, and gastrointestinal tract, and crosses from the amniotic fluid into the maternal blood	Increased levels might indicate a neural tube defect, Turner syndrome, tetralogy of Fallot, multiple gestation, omphalocele, gastroschisis, or hydrocephaly. Decreased levels might indicate Down syndrome or trisomy 18	Typically performed between 15 and 18 weeks' gestation
Amniocentesis	Amniotic fluid aspirated from the amniotic sac; safety concerns include infection, pregnancy loss, and fetal needle injuries	To perform chromosome analysis, alpha-fetoprotein, DNA markers, viral studies, karyotyping, tests are done to identify cystic fibrosis, sickle cell trait or disease	Usually performed between 15 and 20 weeks' gestation to allow for adequate amniotic fluid volume to accumulate; results take 2 to 4 weeks
Chorionic villus sampling	Removal of small tissue specimen from the fetal portion of the placenta, which reflects the fetal genetic makeup; main complications include severe transverse limb defects and spontaneous pregnancy loss	To detect fetal karyotype, sickle-cell anemia, phenylketonuria, Down syndrome, sickle cell trait or disease, Duchenne muscular dystrophy, cystic fibrosis, and numerous other genetic disorders	Typically performed between 10 and 12 weeks' gestation, with results available in less than a week
Percutaneous umbilical blood sampling	Insertion of a needle directly into a fetal umbilical vessel under ultrasound guidance; two potential complications: fetal hemorrhage and risk of infection	Used for prenatal diagnosis of inherited blood disorders such as hemophilia A, karyotyping; detection of fetal infection; determination of acid–base status; and assessment and treatment of isoimmunization	Generally performed after 16 weeks' gestation
Fetal nuchal translucency (FNT)	An intravaginal ultrasound that measures fluid collection in the subcutaneous space between the skin and the cervical spine of the fetus	To identify fetal anomalies; abnormal fluid collection can be associated with genetic disorders (trisomies 13, 18, and 21), Turner syndrome, cardiac deformities, and/or physical anomalies. When the FNT is greater than 3 mm, the measurement is considered abnormal	Performed between 10 and 14 weeks' gestation
Level III ultra-sound/fetal scan	Use of high-frequency sound waves to visualize the fetus	Enables early evaluation of structural changes	Typically performed after 18 weeks' gestation
Triple and quad screening tests	Triple screening includes alpha-fetoprotein, estriol, and beta-hCG; Quad screening includes alpha-fetoprotein, estriol, beta-hCG, and inhibin A	To identify risk for Down syndrome, neural tube defects, and other chromosomal disorders. Elevated hCG combined with lower-than-normal estriol and MSAFP levels indicate increased risk for Down syndrome or other trisomy condition	Performed between 15 and 18 weeks' gestation
Preimplantation genetic diagnosis	Genetic testing of embryos produced through in vitro fertilization (IVF)	Identifies embryos carrying specific genetic alterations that can cause disease. Only those without genetic alterations are later transferred into the woman's uterus to start a pregnancy. Prevents inheritable genetic disease before implantation	Usually on day 3 after egg retrieval and 2 days after fertilization, a single blastomere is removed from the developing embryo to be evaluated
Cell-free fetal DNA (cffDNA)	A noninvasive prenatal test using maternal plasma that holds a mixture of maternal and fetal DNA after 4 weeks' gestation	Determines fetal sex in pregnancies at risk for sex-linked conditions; RhD genotyping in pregnancies at risk of hemolytic disease of the newborn and fetal chromosomal abnormalities such as Down syndrome	A maternal blood sample is taken and next generation sequencing is used to analyze the cffDNA at approximately 10 weeks' gestation

BOX 10.3

FOCUSED HEALTH ASSESSMENT: GENETIC HISTORY

- What was the cause and age of death for deceased family members?
- Does any consanguinity exist between relatives?
- Do any serious illnesses or chronic conditions exist? If so, what was the age of onset?
- Do any female family members have a history of miscarriages, stillbirths, or diabetes?
- Do any female members have a history of alcohol or drug use during pregnancy?
- What were the ages of female members during childbearing, especially if older than 35 years?
- Do any family members have an intellectual disability or developmental delays?
- Do any family members have a known or suspected metabolic disorder such as PKU?
- What is the maternal age of both parents presently with this pregnancy?
- Do any family members have an affective disorder such as bipolar disorder?
- Have any close relatives been diagnosed with any type of cancer?
- What is your ethnic background (explore as related to certain disorders)?
- Do any family members have a known or suspected chromosomal disorder?
- Do any family members have a progressive neurologic disorder?

Talking with family members who have recently been diagnosed with a genetic disorder or who have had a child born with congenital anomalies is very difficult. Many times the nurse may be the one who has first contact with these parents and will be the one to provide follow-up care. Genetic disorders are significant, life-changing, and possibly life-threatening situations. Genetic information is highly technical and the field is undergoing significant technological advances. Nurses need an understanding of who will benefit from genetic counseling and must be able to discuss the role of the genetic counselor with families. The goal is to ensure that families at risk are aware that genetic counseling is available before they attempt to have another baby.

> *Based on the results of their genetic tests, Robert and Kate are placed at moderate risk for having an infant with an autosomal recessive genetic disorder. The couple asks the nurse what all of this means. What information should the nurse provide about concepts of probability and disorder susceptibility for this couple? How can the nurse help this couple to make knowledgeable decisions concerning their reproductive future?*

Nurses play an essential role in providing emotional support to the family through this challenging time. Genetics permeates all aspects of health care. Today, everyone is embracing quality and evidence-based care. Nurses who have an understanding of genetics and genomics will possess the foundation to provide quality, evidence-based care especially with follow-up counseling after the couple or family has been to the genetic specialist.

Take Note!

Nurses need to be actively engaged with clients and their families and help them consider the facts, values, and context in which they are making decisions. Nurses need to be open and honest with families as they discuss these sensitive and emotional choices.

Nurses should provide ongoing support and education for clients and their families. This includes coping with the disease burden, helping clients and families adapt to a condition in the family, and ensuring adequate understanding

of the genetic risks and the available prenatal diagnostic and reproductive choices. The nurse is in an ideal position to help families review what has been discussed during the genetic counseling sessions and to answer any additional questions they might have. Referral to appropriate agencies, support groups, and resources, such as a social worker, a chaplain, or an ethicist, is another key role when caring for families with suspected or diagnosed genetic disorders.

KEY CONCEPTS

- Fertilization, which takes place in the outer third of the ampulla of the fallopian tube, leads to the formation of a zygote. The zygote undergoes cleavage, eventually implanting in the endometrium about 7 to 10 days after conception.

- Three embryonic layers of cells are formed: ectoderm, which forms the central nervous system, special senses, skin, and glands; mesoderm, which forms the skeletal, urinary, circulatory, and reproductive systems; and endoderm, which forms the respiratory system, liver, pancreas, and digestive system.

- Amniotic fluid surrounds the embryo and increases in volume as the pregnancy progresses, reaching approximately a liter by term.

- At no time during pregnancy is there any direct connection between the blood of the fetus and the blood of the mother, so there is no mixing of blood.

- The placenta protects the fetus from immune attack by the mother, removes waste products from the fetus, induces the mother to bring more food to the placenta, and, near the time of delivery, produces hormones that mature fetal organs in preparation for life outside the uterus.

- The purpose of fetal circulation is to carry highly oxygenated blood to vital areas (heart and brain) while first shunting it away from less vital ones (lungs and liver).

- Humans have 46 paired chromosomes that are found in all cells of the body, except the ovum and sperm cells, which have just 23 chromosomes. Each person has a unique genetic constitution, or genotype.

- Research from the HGP has provided a better understanding of the genetic contribution to disease.

- Genetic disorders can result from abnormalities in patterns of inheritance or chromosomal abnormalities involving chromosomal number or structure.

- Autosomal dominant inheritance occurs when a single gene in the heterozygous state is capable of producing the phenotype. Autosomal recessive inheritance occurs when two copies of the mutant or abnormal gene in the homozygous state are necessary to produce the phenotype. X-linked inheritance disorders are those associated with altered genes present on the X chromosome. They can be dominant or recessive.

- In some cases of genetic disorders, a chromosomal abnormality occurs. Chromosomal abnormalities do not follow straightforward patterns of inheritance. These abnormalities occur on autosomal as well as sex chromosomes and can result from changes in the number of chromosomes or changes in the structure of the chromosomes.

- Genetic counseling involves evaluation of an individual or a family. Its purpose is to confirm, diagnose, or rule out genetic conditions, identify medical management issues, calculate and communicate genetic risks to a family, discuss ethical and legal issues, and assist in providing and arranging psychosocial support.

- Legal, ethical, and social issues that can arise related to genetic testing include the privacy and confidentiality of genetic information, who should have access to personal genetic information, psychological impact and stigmatization due to individual genetic differences, use of genetic information in reproductive decision making and reproductive rights, and whether testing is to be performed if no cure is available.

- Preconception screening and counseling can raise serious ethical and moral issues for a couple. The results of prenatal genetic testing can lead to the decision to terminate a pregnancy.

- Nurses play an important role in beginning the preconception counseling process and referring women and their partners for further genetic information when indicated. Many times the nurse is the one who has first contact with these women and will be the one to provide follow-up care.

- Nurses need to have a solid understanding of who will benefit from genetic counseling and must be able to discuss the role of the genetic counselor with families, ensuring that families at risk are aware that genetic counseling is available before they attempt to have another baby.

- Nurses play an essential role in providing emotional support and referrals to appropriate agencies, support groups, and resources when caring for families

with suspected or diagnosed genetic disorders. Nurses can assist clients with their decision making by referring them to a social worker, a chaplain, or an ethicist.

CHAPTER **WORKSHEET**

MULTIPLE-CHOICE QUESTIONS

1. After teaching a group of students about fertilization, the instructor determines that the teaching was successful when the group identifies which as the usual site of fertilization?

    a. Fundus of the uterus

    b. Endometrium of the uterus

    c. Upper portion of fallopian tube

    d. Follicular tissue of the ovary

2. Working in a reproductive health services clinic, the nurse is aware that the goal of the Human Genome project was to:

    a. Link specific abnormal genes to specific diseases for better treatment

    b. Map, sequence, and determine the function of all human genes

    c. Understand the underlying causes of diseases to transform health care

   d. Measure the impact of certain chromosomes on disease prevention

3. The nurse is counseling a couple, one of whom is affected by an autosomal dominant disorder. They express concerns about the risk of transmitting the disorder. What is the best response by the nurse regarding the risk that their baby may have the disease?

   a. "You have a one in four (25%) chance."

   b. "The risk is 12.5%, or a one in eight chance."

   c. "The chance is 100%."

   d. "Your risk is 50%, or a one in two chance."

4. What is the first step in determining a couple's risk for a genetic disorder?

   a. Observing the client and family over time

   b. Conducting extensive psychological testing

   c. Obtaining a thorough family health history

   d. Completing an extensive exclusionary list

5. A nurse is working in a women's health clinic. Genetic counseling would be most appropriate for the woman who:

   a. Just had her first miscarriage at 10 weeks

   b. Is 30 years old and planning to conceive

   c. Has a history with a close relative with Down syndrome

   d. Is 18 weeks pregnant with a normal triple screen result

6. Klinefelter syndrome is caused by a nondisjunction resulting in a genotype of:

   a. YYY

   b. XYY

   c. XXX

   d. XXY

7. Down syndrome results from the:

   a. Absence of one chromosome in position 21

   b. Presence of an extra chromosome in position 21

c. Absence of both chromosomes in position 21

d. Crossing over of the chromosomes in position 21

CRITICAL THINKING EXERCISE

1. Mr. and Mrs. Martin wish to start a family, but they can't agree on something important: Mr. Martin wants his wife to be tested for cystic fibrosis (CF) to see if she is a carrier. Mr. Martin had a brother with CF and watched his parents struggle with the hardship and the expense of caring for him for years, and he doesn't want to experience it in his own life. Mr. Martin has found out he is a CF carrier. Mrs. Martin doesn't want to have the test because she figures that once a baby is in their arms, they will be glad, no matter what.

    a. What information/education should this couple consider before deciding whether to have the test?

    b. How can you assist this couple in their decision-making process?

    c. What is your role in this situation if you don't agree with their decision?

STUDY ACTIVITIES

1. Obtain the video *Miracle of Life*, which shows conception and fetal development. What are your impressions? Is the title of this video realistic?

2. Select one of the websites from the extensive list of websites provided on to explore the topic of genetics. Critique the information presented. Was it understandable to a layperson? What specifically did you learn? Share your findings with your classmates during a discussion group.

3. Draw your own family pedigree, identifying inheritance patterns. Share it with your family to validate its accuracy. What did you discover about your family's past health?

4. Select one of the various prenatal screening tests (alpha-fetoprotein, amniocentesis, chorionic villus sampling, or fetal nuchal translucency) and research it in depth. Role-play with another nursing student how you would explain its purpose, the procedure, and potential findings to an expectant couple at risk for a fetal abnormality.

BRINGING IT ALL TOGETHER: CASE STUDY

A 27-year-old female of African-American descent presents to the preconception care clinic with her husband. They have been married for 2 years and are planning a pregnancy. They want to know about sickle cell anemia and other hemoglobin abnormalities. They ask if prenatal tests exist for this condition, and if they can be tested to determine their carrier status. They also want to understand the risks related to their future offspring if they are carriers. They have known several people with sickle cell anemia at their church and wonder if everyone with this disorder is affected the same way.

ASSESSMENT

A family history is taken by the nurse to determine if any of the couple's relatives have this disease or manifestations of it. They may not be aware of the various manifestations of it, but can describe behaviors and observations of their various family members. An explanation of the screening procedure to determine if they are carriers of the sickle cell trait is then offered.

Go to thePoint to find questions to consider about this case.

Maternal Adaptation During Pregnancy

KEY TERMS

ballottement
Braxton Hicks contractions
Chadwick's sign
dietary reference intakes (DRIs)
Goodell's sign
Hegar's sign
linea nigra
physiologic anemia of pregnancy
pica
quickening
trimester

Learning Objectives

Upon completion of the chapter, you will be able to:

1. Differentiate between subjective (presumptive), objective (probable), and diagnostic (positive) signs of pregnancy.
2. Describe maternal physiologic changes that occur during pregnancy.
3. Summarize the nutritional needs of the pregnant woman and her fetus.
4. Characterize the emotional and psychological changes that occur during pregnancy.

> ***Marva,*** *age 17, appeared at the health department clinic complaining that she had a stomach virus and needed to be seen right away. When the nurse asked her additional questions about her illness, Marva reported that she had been sick to her stomach and "beat tired" for days. She had stopped eating to avoid any more nausea and vomiting.*

Words of Wisdom

When a woman discovers that she is pregnant, she must remember to protect and nourish the fetus by making wise choices.

INTRODUCTION

Pregnancy is a normal life event that involves considerable physical and psychological adjustments for the mother. A pregnancy is divided into three **trimesters** of 13 weeks each (Edelman, Kudzma, & Mandle, 2014). Within each trimester, numerous adaptations take place that facilitate the growth of the fetus. The most obvious are physical changes to accommodate the growing fetus, but pregnant women also undergo psychological changes as they prepare for parenthood. A thorough understanding of these numerous changes and adaptations is essential for all nurses caring for women during pregnancy.

SIGNS AND SYMPTOMS OF PREGNANCY

Traditionally, signs and symptoms of pregnancy have been grouped into the following categories: presumptive, probable, and positive (Box 11.1). The only signs that can determine a pregnancy with 100% accuracy are positive signs.

What additional information is necessary to complete the assessment of Marva, the 17-year-old with nausea and vomiting? What diagnostic tests might be done to confirm the nurse's suspicion that she is pregnant?

Subjective (Presumptive) Signs

Presumptive signs are those signs that the mother can perceive. The most obvious presumptive sign of pregnancy is the absence of menstruation. Skipping a period is not a reliable sign of pregnancy by itself, but if it is accompanied by consistent nausea, fatigue, breast tenderness, and urinary frequency, pregnancy would seem very likely.

Presumptive changes are the least reliable indicators of pregnancy because any one of them can be caused by conditions other than pregnancy (Shields, 2015). For example, amenorrhea can be caused by early menopause, endocrine dysfunction, malnutrition, anemia, diabetes mellitus, long-distance running, cancer, or stress. Nausea and vomiting can be caused by gastrointestinal disorders, food poisoning, acute infections, or eating disorders. Fatigue could be caused by anemia, stress, or viral infections. Breast tenderness may result from chronic cystic mastitis, premenstrual changes, or the use of oral contraceptives. Urinary frequency could have a variety of causes other than pregnancy, such as infection, cystocele, structural disorders, pelvic tumors, or emotional tension (Tharpe et al., 2016).

Consider This

Jim and I decided to start our family, so I stopped taking the pill 3 months ago. One morning when I got out of bed to take the dog out, I felt queasy and light-headed. I sure hoped I was not coming down with the flu. By the end of the week, I was feeling really tired and started taking naps in the afternoon. In addition, I seemed to be going to the bathroom frequently, despite not drinking much fluid. When my breasts started to tingle and ache, I decided to make an appointment with my doctor to see what "illness" I had contracted.

After listening to my list of physical complaints, the office nurse asked me if I might be pregnant. My eyes opened wide: I had somehow missed the link between my symptoms and pregnancy. I started to think about when my last period was, and it had been 2 months ago. The office ran a pregnancy test and much to my surprise it was positive!

__Thoughts:__ Many women stop contraceptives in an attempt to achieve pregnancy but miss the early signs of pregnancy. This woman was experiencing several signs of early pregnancy—urinary frequency, fatigue, morning nausea, and breast tenderness. What advice can the nurse give this woman to ease these symptoms? What additional education related to her pregnancy would be appropriate at this time?

BOX 11.1

SIGNS AND SYMPTOMS OF PREGNANCY

Presumptive (Time of Occurrence)	Probable (Time of Occurrence)	Positive (Time of Occurrence)
Fatigue (12 wks)	Braxton Hicks contractions (16–28 wks)	Ultrasound verification of embryo or fetus (4–6 wks)
Breast tenderness (3–4 wks)	Positive pregnancy test (4–12 wks)	Fetal movement felt by experienced clinician (20 wks)
Nausea and vomiting (4–14 wks)	Abdominal enlargement (14 wks)	Auscultation of fetal heart tones via Doppler (10–12 wks)
Amenorrhea (4 wks)	Ballottement (16–28 wks)	
Urinary frequency (6–12 wks)	Goodell's sign (5 wks)	
Hyperpigmentation of the skin (16 wks)	Chadwick's sign (6–8 wks)	
Fetal movements (**quickening**; 16–20 wks)	Hegar's sign (6–12 wks)	
Uterine enlargement (7–12 wks)		
Breast enlargement (6 wks)

Ames, Iowa: Wiley-Blackwell.

Objective (Probable) Signs

Physical Signs

Probable signs of pregnancy are those that can be detected on physical examination by a health care provider. Common probable signs of pregnancy include softening of the lower uterine segment or isthmus (Hegar's sign), softening of the cervix (Goodell's sign), and a bluish-purple coloration of the vaginal mucosa and cervix (Chadwick's sign). Other probable signs include changes in the shape and size of the uterus, abdominal enlargement, Braxton Hicks contractions, and **ballottement** (the examiner pushes against the woman's cervix during a pelvic examination and feels a rebound from the floating fetus).

Pregnancy Tests

Along with these physical signs, pregnancy tests are also considered a probable sign of pregnancy. In-home pregnancy testing became available in the United States in late 1977. In-home testing appealed to the general public because of convenience, cost, and confidentiality. Several pregnancy tests are available (Table 11.1). The tests vary in sensitivity, specificity, and accuracy and are influenced by the length of gestation, specimen concentration, presence of blood, and the presence of some drugs. Human chorionic gonadotropin (hCG) is detectable in the serum of approximately 5% of clients 8 days after conception and in more than 98% of clients by day 11 (Shields, 2015). At least 25 different home pregnancy tests are currently marketed in the United States. Most of these tests claim "99% accuracy" according to a U.S. Food and Drug Administration (FDA) guideline or make other similar statements on the packaging or product insert. The 99% accuracy statement in reference to the FDA guideline is misleading in that it has no bearing on the ability of the home pregnancy test to detect early pregnancy (Shields, 2015). The limitations of these tests must be understood so that pregnancy detection is not delayed significantly. Early pregnancy detection allows for the commencement of prenatal care, potential medication changes, and lifestyle changes to promote a healthy pregnancy.

TABLE 11.1 SELECTED PREGNANCY TESTS

Type	Specimen	Example	Remarks
Agglutination inhibition tests	Urine	Pregnosticon, Gravindex	If hCG is present in urine, agglutination does not occur, which is positive for pregnancy; reliable 14–21 days after conception; 95% accurate in diagnosing pregnancy.
Immunoradiometric assay	Blood serum	Neocept, Pregnosis	Measures ability of blood sample to inhibit the binding of radiolabeled hCG to receptors; reliable 6–8 days after conception; 99% accurate in diagnosing pregnancy.
Enzyme-linked immunosorbent assay (ELISA)	Blood serum or urine	Over-the-counter home/office pregnancy tests; precise	Uses an enzyme to bond with hCG in the urine if present; reliable 4 days after implantation; 99% accurate if hCG specific.

Adapted from Jordan, R. G., Engstrom, J., Matrfell, J., & Farley, C. L. (2014). *Prenatal and postnatal care: A woman-centered approach*. Ames, Iowa: Wiley-Blackwell; King, T. L., Brucker, M. C., Kriebs, J. M., Fahey, J. O., Gegor, C. L., & Varney, H. (2015). *Varney's midwifery*. (5th ed.), Burlington, MA: Jones & Bartlett Learning; and Shields, A. D. (2015). Pregnancy diagnosis. *eMedicine*. Retrieved from http://emedicine.medscape.com/article/262591-overview.

hCG is a glycoprotein and the earliest biochemical marker for pregnancy. Many pregnancy tests are based on the recognition of hCG or a beta subunit of hCG. hCG levels in normal pregnancy usually double every 48 to 72 hours until they peak approximately 60 to 70 days after fertilization. At this point, they decrease to a plateau at 100 to 130 days of pregnancy. The hCG doubling time has been used as a marker by clinicians to differentiate normal from abnormal gestations. Low levels are associated with an ectopic pregnancy and higher-than-normal levels may indicate a molar pregnancy or multiple-gestational pregnancies (Zinaman, Johnson, & Marriott, 2015).

Take Note!

This elevation of hCG corresponds to the morning sickness period of approximately 6 to 12 weeks during early pregnancy.

Although probable signs suggest pregnancy and are more reliable than presumptive signs, they still are not 100% reliable in confirming a pregnancy. For example, uterine tumors, polyps, infection, and pelvic congestion can cause changes to uterine shape, size, and consistency. And although pregnancy tests are used to establish the diagnosis of pregnancy when the physical signs are still inconclusive, they are not completely reliable, because conditions other than pregnancy (e.g., ovarian cancer, choriocarcinoma, hydatidiform mole) can also elevate hCG levels.

Positive Signs

Usually within 2 weeks after a missed period, enough subjective symptoms are present so that a woman can be reasonably sure she is pregnant. However, an experienced health care provider can confirm her suspicions by identifying positive signs of pregnancy that can be directly attributed to the fetus. The positive signs of pregnancy confirm that a fetus is growing in the uterus. Visualizing the fetus by ultrasound, palpating for fetal movements, and hearing a fetal heartbeat are all signs that make the pregnancy a certainty.

If the pregnancy test is positive, the clinical visit should include an estimation of gestational age so that appropriate counseling can be provided. In addition, clients should receive information about the normal signs and symptoms of early pregnancy, and should be instructed to report any concerns to the health care provider for further evaluation. Once pregnancy has been confirmed, the health care provider will set up a schedule of prenatal visits to assess the woman and her fetus throughout the entire pregnancy. Assessment and education begins at the first visits and continues throughout the pregnancy (see Chapter 12).

Remember Marva, who thought she had a stomach virus? Her pregnancy test was positive. On questioning by the nurse, she acknowledged missing two menstrual periods and being sexually active with her boyfriend without using protection. What is the nurse's role at this point with Marva? What instructions might be given to her while she waits for her first prenatal visit?

PHYSIOLOGIC ADAPTATIONS DURING PREGNANCY

Every system of a woman's body changes during pregnancy to accommodate the needs of the growing fetus, and these changes occur with startling rapidity. The physical changes of pregnancy can be uncomfortable, although every woman reacts uniquely.

Reproductive System Adaptations

Significant changes occur throughout the woman's body during pregnancy to accommodate the growing human being within her. Many have a protective role for maternal homeostasis and are essential to meet the demands of both the mother and the fetus. Many adaptations are reversible after the woman gives birth, but some persist for life.

Uterus

The uterus grows at a steady and predictable rate during pregnancy. During the first few months of pregnancy, estrogen stimulates uterine growth, and the uterus undergoes a tremendous increase in size, weight, length, width, depth, volume, and overall capacity throughout pregnancy. The weight of the uterus increases from 70 g to about 1,100 to 1,200 g at term; its capacity increases from 10 to 5,000 mL or more at term (King et al., 2015). The uterine walls thin to 1.5 cm or less; the shape changes from pear shape to a solid globe in the first trimester, and then expands to become a hollow vessel.

Uterine growth occurs as a result of both hyperplasia and hypertrophy of the myometrial cells, which do not increase much in number but do increase in size. In early pregnancy, uterine growth is due to hyperplasia of uterine smooth muscle cells within the myometrium; however, the major component of myometrial growth occurs after mid-gestation due to smooth muscle cell hypertrophy caused by mechanical stretch of uterine tissue by the growing fetus (Osol & Moore, 2014). Blood vessels elongate, enlarge, dilate, and sprout new branches to support and nourish the growing muscle tissue, and the increase in uterine weight is accompanied by a large increase in uterine blood flow, which is necessary to perfuse the uterine muscle and accommodate the growing fetus. As pregnancy progresses, 80% to 90% of uterine blood flow goes to the placenta, with the remainder distributed between the endometrium and myometrium. During pregnancy, the diameter of the main uterine artery approximately doubles in size. This enlargement from a narrow to a larger-caliber vessel enhances the capacity of the uteroplacental vessels to accommodate the increased blood volume needed to supply the placenta (Osol & Moore, 2014).

Uterine contractility is enhanced as well. Spontaneous, irregular, and painless contractions, called **Braxton Hicks contractions**, begin during the first

trimester. These contractions continue throughout pregnancy, becoming especially noticeable during the last month, when they function to thin out or efface the cervix before birth (see Chapter 12 for more information).

The lower portion of the uterus (the isthmus) does not undergo hypertrophy and becomes increasingly thinner as pregnancy progresses, thereby forming the lower uterine segment. Changes in the lower uterus occurring during the first 6 to 8 weeks of gestation produce some of the typical findings, including a positive **Hegar's sign**. This softening and compressibility of the lower uterine segment results in exaggerated uterine anteflexion during the early months of pregnancy, which adds to urinary frequency (Heffner & Schust, 2014).

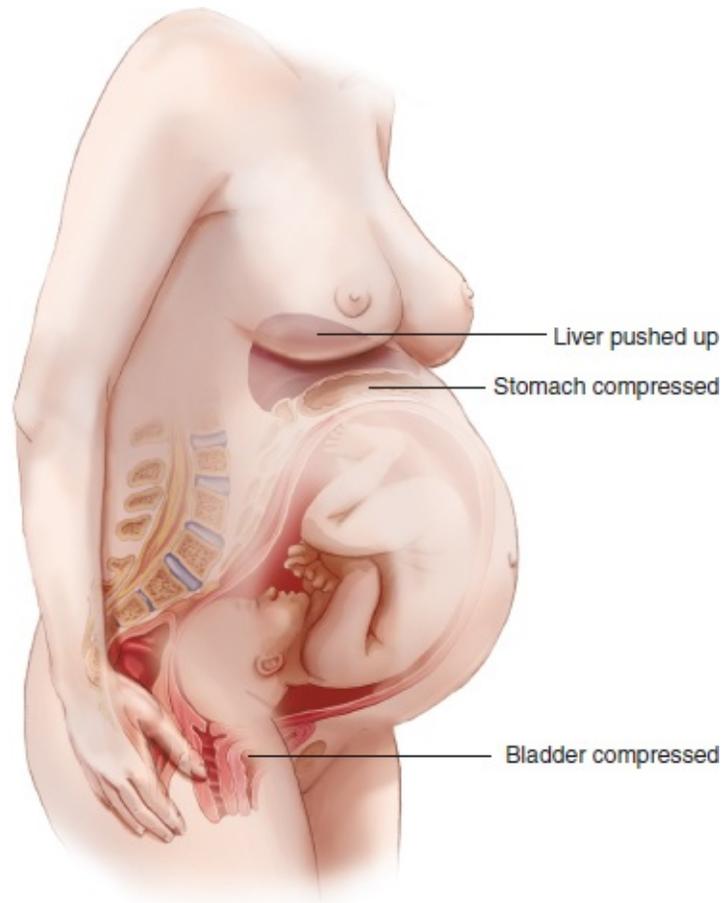
The uterus remains in the pelvic cavity for the first 3 months of pregnancy, after which it progressively ascends into the abdomen (Fig. 11.1). As the uterus grows, it presses on the urinary bladder and causes the increased frequency of urination experienced during early pregnancy. In addition, the heavy gravid uterus in the last trimester can fall back against the inferior vena cava in the supine position, resulting in vena cava compression, which reduces venous return and decreases cardiac output and blood pressure, with increasing orthostatic stress. This occurs when the woman changes her position from recumbent to sitting to standing. This acute hemodynamic change, termed supine hypotensive syndrome, causes the woman to experience symptoms of weakness, light-headedness, nausea, dizziness, or syncope (Fig. 11.2). These changes are reversed when the woman is in the side-lying position, which displaces the uterus to the left and off the vena cava.


FIGURE 11.1 The growing uterus in the abdomen.
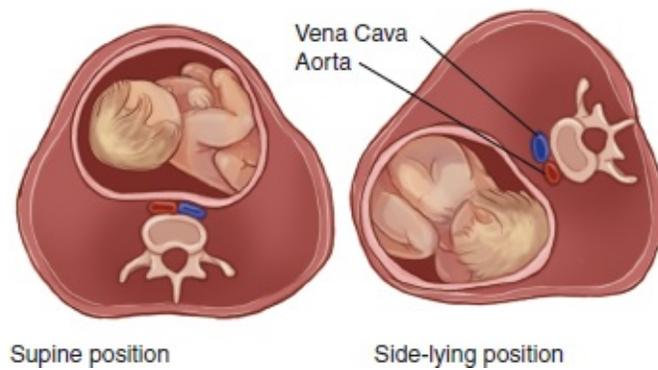

FIGURE 11.2 Supine hypotensive syndrome.

The uterus, which starts as a pear-shaped organ, becomes ovoid as length increases over width. By 20 weeks' gestation, the fundus, or top of the uterus, is at the level of the umbilicus and measures 20 cm. A monthly measurement of the height of the top of the uterus in centimeters, which corresponds to the number

of gestational weeks, is commonly used to date the pregnancy.

Fundal height usually can be correlated with gestational weeks most accurately between 18 and 32 weeks. Obesity, hydramnios, and uterine fibroids interfere with the accuracy of this correlation.

The fundus reaches its highest level, at the xiphoid process, at approximately 36 weeks. Between 38 and 40 weeks, fundal height drops as the fetus begins to descend and engage into the pelvis. Because it pushes against the diaphragm, many women experience shortness of breath. By 40 weeks, the fetal head begins to descend and engage in the pelvis, which is termed *lightening.* For the woman who is pregnant for the first time, *lightening* usually occurs approximately 2 weeks before the onset of labor; for the woman who is experiencing her second or subsequent pregnancy, it usually occurs at the onset of labor. Although breathing becomes easier because of this descent, the pressure on the urinary bladder now increases and the woman now experiences urinary frequency again, as she did in the first trimester of pregnancy.

Cervix

Between weeks 6 and 8 of pregnancy, the cervix begins to soften (**Goodell's sign**) due to vasocongestion and the influence of estrogen. Along with the softening, the endocervical glands increase in size and number and produce more cervical mucus. Under the influence of progesterone, a thick mucus plug is formed that blocks the cervical os and protects the opening from bacterial invasion. At about the same time, increased vascularization of the cervix causes **Chadwick's sign**, a cyanosis or bluish purple discoloration Cervical ripening (softening, effacement, and increased distensibility) begins about 4 weeks before birth. The connective tissues of the cervix undergo biochemical modifications in preparation for labor that result in changes to its elasticity and strength. These changes are mediated through several factors, including inflammation, cervical stretch, pressure of the fetal presenting part, and release of hormones, including oxytocin, relaxin, nitric oxide, and prostaglandins (Myers et al., 2015).

Vagina

During pregnancy, vascularity increases because of the influences of estrogen, resulting in pelvic congestion and hypertrophy of the vagina in preparation for the distention needed for birth. The vaginal mucosa thickens, the connective tissue begins to loosen, the smooth muscle begins to hypertrophy, and the vaginal vault begins to lengthen (Bope & Kellerman, 2015). Vaginal secretions become more acidic, white, and thick. Most women experience an increase in a whitish vaginal discharge, called leukorrhea, during pregnancy. This is normal except when it is accompanied by itching and irritation, possibly suggesting *Candida albicans,* a monilial vaginitis, which is a very common occurrence in this glycogen-rich environment (King et al., 2015). Symptomatic vulvovaginal candidiasis affects 15% of pregnant women (Krapf, 2015). It is a benign fungal condition that is uncomfortable for the woman and can be transmitted from an infected mother to her newborn at birth. Neonates develop an oral infection known as thrush, which presents as white patches on the mucous membranes of their mouths. It is self-limiting and is treated with local antifungal agents.

Ovaries

The increased blood supply to the ovaries causes them to enlarge until approximately the 12th to 14th week of gestation. The ovaries are not palpable after that time because the uterus fills the pelvic cavity. Ovulation ceases during pregnancy because of the elevated levels of estrogen and progesterone, which block secretion of follicle-stimulating hormone (FSH) and luteinizing hormone (LH) from the anterior pituitary. The ovaries are very active in hormone production to support the pregnancy until about weeks 6 to 7, when the corpus luteum regresses and the placenta takes over the major production of progesterone.

Breasts

The breasts increase in fullness, become tender, and grow larger throughout pregnancy under the influence of estrogen and progesterone. The breasts become highly vascular and veins become visible under the skin. The nipples become larger and more erect. Both the nipples and the areola become deeply pigmented, and tubercles of Montgomery (sebaceous glands) become prominent. These sebaceous glands keep the nipples lubricated for breast-feeding.

Changes that occur in the connective tissue of the breasts, along with the tremendous growth, lead to striae (stretch marks) in approximately half of all pregnant women (Jordan et al., 2014). Initially they appear as pink to purple lines on the skin, but they eventually fade to a silver color. Although they become less conspicuous in time, they never completely disappear.

Creamy, yellowish breast fluid called colostrum can be expressed from the breast, if squeezed, by the third trimester. This fluid provides nourishment for the breast-feeding newborn during the first few days of life (see Chapters 15 and 16 for more information). Table 11.2 summarizes reproductive system adaptations.

General Body System Adaptations

In addition to changes in the reproductive system, the pregnant woman also experiences changes in virtually every other body system in response to the growing fetus.

Gastrointestinal System

The gastrointestinal system begins in the oral cavity and ends at the rectum. During pregnancy, the gums become hyperemic, swollen, and friable and tend to bleed easily. This change is influenced by estrogen and increased proliferation of blood vessels and circulation to the mouth. In addition, the saliva produced in the mouth becomes more acidic. Some women complain about excessive salivation, termed *ptyalism*, which may be caused by the decrease in unconscious swallowing by the woman when nauseated. Ptyalism typically resolves spontaneously, although in some women it endures throughout the pregnancy. Some women get temporary relief from gum chewing or sucking on hard candies (King et al., 2015). Dental plaque, calculus, and debris deposits increase during pregnancy and are all associated with gingivitis. An increased production of female hormones during pregnancy contributes to the development of gingivitis and periodontitis because vascular permeability and possible tissue edema are both increased. It is reported that as many as 50% to 70% of pregnant women will have some level of gingivitis during pregnancy as a result of hormonal changes that promote inflammation (Anil et al., 2015). Previous studies linked periodontal disease with preterm birth; preeclampsia, and low-birth-weight risk, stillbirth and early-onset neonatal sepsis, but more recent research findings indicated no reduction in preterm births with the treatment of periodontal disease during pregnancy (Trivedi, Lal, & Singhal, 2015).

TABLE 11.2 SUMMARY OF REPRODUCTIVE SYSTEM ADAPTATIONS

Reproductive Organ	Adaptations
Uterus	Size increases to 20 times that of nonpregnant size. Capacity increases by 2,000 times to accommodate the developing fetus. Weight increases from 2 oz to approximately 2 lb at term. Uterine growth occurs as a result of both hyperplasia and hypertrophy of the myometrial cells. Increased strength and elasticity allow uterus to contract and expel fetus during birth.
Cervix	Increases in mass, water content, and vascularization. Changes from a relatively rigid to a soft, distensible structure that allows the fetus to be expelled. Under the influence of progesterone, a thick mucus plug is formed, which blocks the cervical os and protects the developing fetus from bacterial invasion.
Vagina	Increased vascularity because of estrogen influences, resulting in pelvic congestion and hypertrophy. Increased thickness of mucosa, along with an increase in vaginal secretions to prevent bacterial infections.
Ovaries	Increased blood supply to the ovaries causes them to enlarge until approximately the 12th to 14th week of gestation. They actively produce hormones to support the pregnancy until weeks 6 to 7 when the placenta takes over the production of progesterone.
Breasts	Breast changes begin soon after conception; they increase in size and areolar pigmentation. The tubercles of Montgomery enlarge and become more prominent, and the nipples become more erect. The blood vessels become more prominent, and blood flow to the breast doubles.

Concept Mastery Alert

Gum Fragility in Pregnancy

Bleeding of gums during pregnancy, results from increased estrogen levels that cause blood vessel proliferation. This then leads to increased blood vessels in the gums and an increased chance of bleeding.

Smooth muscle relaxation and decreased peristalsis occur related to the influence of progesterone. Elevated progesterone levels cause smooth muscle relaxation, which results in delayed gastric emptying and decreased peristalsis. Transition time of food throughout the gastrointestinal tract may be so much slower that more water than normal is reabsorbed, leading to bloating and constipation. Constipation can also result from low-fiber food choices, reduced fluid intake, use of iron supplements, decreased activity level, and intestinal displacement secondary to a growing uterus. Constipation, increased venous pressure, and the pressure of the gravid uterus contribute to the formation of hemorrhoids.

The slowed gastric emptying combined with relaxation of the cardiac

sphincter allows reflux, which causes heartburn. Acid indigestion or heartburn (pyrosis) seems to be a universal problem for pregnant women. It is caused by regurgitation of the stomach contents into the upper esophagus and may be associated with the generalized relaxation of the entire digestive system. Over-the-counter antacids will usually relieve the symptoms, but they should be taken with the health care provider's knowledge and only as directed.

The emptying time of the gallbladder is prolonged secondary to the smooth muscle relaxation from progesterone. Hypercholesterolemia can follow, increasing the risk of gallstone formation. Other risk factors for gallbladder disease include obesity, Hispanic ethnicity, and increasing maternal age (Heuman, Mihas, & Allen, 2015).

Nausea and vomiting, better known as morning sickness, plague about 80% of pregnant women. This condition is usually self-limiting, but the symptoms can be distressing and interfere with work, social activities, and interrupt sleep. Recently, the FDA approved doxylamine succinate 10 mg/pyridoxine hydrochloride 10 mg (Diclegis) as the first medication to specifically treat morning sickness in pregnancy (Pope, Maltepe, & Koren, 2015). Although it occurs most often in the morning, the nauseated feeling can last all day in some women. The highest incidence of morning sickness occurs between 6 and 12 weeks. The physiologic basis for morning sickness is still debatable. It has been linked to the high levels of hCG, high levels of circulating estrogens, prostaglandins, reduced stomach acidity, advancing maternal age, slowed peristalsis, genetic factors, and the lowered tone and motility of the digestive tract (King et al., 2015).

Cardiovascular System

Cardiovascular changes occur early during pregnancy to meet the demands of the enlarging uterus and the placenta for more blood and more oxygen. The changes include an increase in heart rate (25%); cardiac output increases by 30% to 50% and peaks at 25 to 30 weeks gestation; reduced total peripheral resistance; increased blood volume; increased plasma volume which leads to physiologic anemia. Perhaps the most striking cardiac alteration occurring during pregnancy is the increase in blood volume.

BLOOD VOLUME

Blood volume increases by approximately 1,500 mL, or up to 50% above

nonpregnant levels, by the 32nd week of gestation, and remains more or less constant thereafter (Foo et al., 2015). The increase is made up of 1,000 mL plasma plus 450 mL red blood cells. It begins at weeks 10 to 12, peaks at weeks 32 to 34, and decreases slightly by week 40.

Take Note!

The rise in blood volume correlates directly with fetal weight, supporting the concept of the placenta as an arteriovenous shunt in the maternal vascular compartment.

This increase in blood volume is needed to provide adequate hydration of fetal and maternal tissues, to supply blood flow to perfuse the enlarging uterus, and to provide a reserve to compensate for blood loss at birth and during postpartum. The maternal blood volume expansion occurs at a larger proportion than the increase in red blood cell mass, which results in physiologic anemia and hemodilution. Criteria of physiologic anemia include hemoglobin 10 g or less; red blood cells 3.5 million/mm^3 and normal morphology with central pallor (Sabina et al., 2015). This increase is also necessary to meet the increased metabolic needs of the mother and to meet the need for increased perfusion of other organs, especially the woman's kidneys, because she is excreting waste products for herself and the fetus.

CARDIAC OUTPUT AND HEART RATE

Cardiac output, the product of stroke volume and heart rate, is a measure of the functional capacity of the heart. It increases from 30% to 50% over the nonpregnant rate by the 32nd week of pregnancy and declines to about a 20% increase at 40 weeks' gestation. The increase in cardiac output is associated with an increase in venous return and greater right ventricular output, especially in the left lateral position (Bope & Kellerman, 2015). Heart rate increases by 10 to 15 bpm between 14 and 20 weeks of gestation, and this persists to term. There is slight hypertrophy or enlargement of the heart during pregnancy. This is probably to accommodate the increase in blood volume and cardiac output. The heart works harder and pumps more blood to supply the oxygen needs of the fetus as well as those of the mother. Both heart rate and venous return are increased in pregnancy, contributing to the increase in cardiac output seen

throughout gestation. A woman with pre-existing heart disease may become symptomatic and begin to decompensate during the time the blood volume peaks. Close monitoring is warranted during 28 to 35 weeks' gestation.

BLOOD PRESSURE

Blood pressure, especially the diastolic pressure, declines slightly during pregnancy as a result of peripheral vasodilation caused by progesterone. It usually reaches a low point at midpregnancy and thereafter increases to prepregnancy levels until term. During the first trimester, blood pressure typically remains at the prepregnancy level. During the second trimester, the blood pressure decreases 5 to 10 mm Hg and thereafter returns to first-trimester levels (Gaillard & Jaddoe, 2015). Any significant rise in blood pressure during pregnancy should be investigated to rule out gestational hypertension. Gestational hypertension is a clinical diagnosis defined by the new onset of hypertension (systolic of 140 mm Hg or higher and/or diastolic of 90 mm Hg or higher) after 20 weeks gestation.

BLOOD COMPONENTS

The number of red blood cells also increases throughout pregnancy to a level which is 25% to 33% higher than nonpregnant values, depending on the amount of iron available. This increase is necessary to transport the additional oxygen required during pregnancy. Although there is an increase in red blood cells, there is a greater increase in the plasma volume as a result of hormonal factors and sodium and water retention. Because the plasma increase exceeds the increase of red blood cell production, normal hemoglobin and hematocrit values decrease. This state of hemodilution is referred to as **physiologic anemia of pregnancy**. Changes in red blood cell volume are due to increased circulating erythropoietin and accelerated red blood cell production. The rise in erythropoietin in the last two trimesters is stimulated by progesterone, prolactin, and human placental lactogen (Jones & Lopez, 2014).

Iron requirements during pregnancy increase because of the demands of the growing fetus and the increase in maternal blood volume. The fetal tissues prevail over the mother's tissues with respect to use of iron stores. With the accelerated production of red blood cells, iron is necessary for hemoglobin formation, the oxygen-carrying component of red blood cells.

Many women enter pregnancy with insufficient iron stores and thus need supplementation to meet the extra demands of pregnancy.

Both fibrin and plasma fibrinogen levels increase along with various blood-clotting factors. These factors make pregnancy a hypercoagulable state. These changes, coupled with venous stasis secondary to venous pooling, which occurs during late pregnancy after long periods of standing in the upright position with the pressure exerted by the uterus on the large pelvic veins, contribute to slowed venous return, pooling, and dependent edema. These factors also increase the woman's risk for venous thrombosis (DeLoughery, 2015).

Respiratory System

The growing uterus and the increased production of the hormone progesterone cause the lungs to function differently during pregnancy. Oxygen consumption reflects the uptick of maternal metabolism by increasing between 20% and 30% by the time full term is reached. During pregnancy, the amount of space available to house the lungs decreases as the uterus puts pressure on the diaphragm and causes it to shift upward by 4 cm above its usual position. The growing uterus does change the size and shape of the thoracic cavity, but diaphragmatic excursion increases, chest circumference increases by 2 to 3 in, and the transverse diameter increases by an inch, allowing a larger tidal volume, as evidenced by deeper breathing (Tidal volume, or the volume of air inhaled, increases by 30% to 40% (from 500 to 700 mL) as the pregnancy progresses. This increases results in maternal hyperventilation and hypocapnia. As a result of these changes, the woman's breathing becomes more diaphragmatic than abdominal. Concomitant with the increase in tidal volume is a 30% to 40% increase in maternal oxygen consumption due to the increased oxygen requirements of the developing fetus, placenta, and maternal organs.

Anatomic and physiologic changes of pregnancy predispose the mother to increased morbidity and mortality and increase the risks of a less than optimal outcome for the fetus. The frequency and significance of acute and chronic respiratory conditions in pregnant women have increased in recent years. Because of these various changes, pregnant women with asthma, pneumonia, or other respiratory pathology are more susceptible to early decompensation

(Mehta et al., 2015).

A pregnant woman breathes faster and more deeply because she and the fetus need more oxygen. Oxygen consumption increases during pregnancy even as airway resistance and lung compliance remain unchanged. Changes in the structures of the respiratory system take place to prepare the body for the enlarging uterus and increased lung volume (Alexander et al., 2014). As muscles and cartilage in the thoracic region relax, the chest broadens, with a conversion from abdominal breathing to thoracic breathing. This leads to a 50% increase in air volume per minute. All of these structural alterations are temporary and revert back to their prepregnant state at the end of the pregnancy.

Increased vascularity of the respiratory tract is influenced by increased estrogen levels, leading to congestion. Rising levels of sex hormones and heightened sensitivity to allergens may influence the nasal mucosa, precipitating epistaxis (nosebleed) and rhinitis. This congestion gives rise to nasal and sinus stuffiness and changes in the tone and quality of the woman's voice (Jordan et al., 2014).

Renal/Urinary System

Hormonal changes during pregnancy allow for increased blood flow to the kidneys. The renal system must handle the effects of increased maternal intravascular and extracellular volume and metabolic waste products as well as excretion of fetal wastes. The predominant structural change in the renal system during pregnancy is dilation of the renal pelvis and uterus. Changes in renal structure occur as a result of the hormonal influences of estrogen and progesterone, pressure from an enlarging uterus, and an increase in maternal blood volume. Like the heart, the kidneys work harder throughout the pregnancy. Changes in kidney function occur to accommodate a heavier workload while maintaining a stable electrolyte balance and blood pressure. As more blood flows to the kidneys, the glomerular filtration rate (GFR) increases, leading to an increase in urine flow and volume, substances delivered to the kidneys, and filtration and excretion of urea, uric acid, creatinine, water and solutes (Cox & Reid, 2015).

Anatomically, the kidneys enlarge during pregnancy. Each kidney increases in length by approximately 1 to 1.5 cm and weight as a result of hormonal effects that cause increased tone and decreased motility of the smooth muscle. The renal pelvis becomes dilated. The ureters (especially the right ureter) elongate, widen,

and become more curved above the pelvic rim as early as the 10th gestational week (Thadhani & Maynard, 2015). Progesterone is thought to cause both of these changes because of its relaxing influence on smooth muscle.

Blood flow to the kidneys increases by 50% to 80% as a result of the increase in cardiac output and relaxin which causes a decrease in both efferent and afferent resistance. This in turn leads to an increase in the GFR by as much as 40% to 60% starting during the second trimester, resulting in hyperfiltration. This elevation continues until birth. This change has important clinical implications for medication use because renally excreted drugs may require higher doses and more frequent administration for therapeutic blood levels during pregnancy (Larson, 2015).

The activity of the kidneys normally increases when a person lies down and decreases on standing. This difference is amplified during pregnancy, which is one reason a pregnant woman feels the need to urinate frequently while trying to sleep. Late in the pregnancy, the increase in kidney activity is even greater when the woman lies on her side rather than her back. Lying on either side relieves the pressure that the enlarged uterus puts on the vena cava carrying blood from the legs. Subsequently, venous return to the heart increases, leading to increased cardiac output. Increased cardiac output results in increased renal perfusion and glomerular filtration. As a rule, all the physiologic changes maximize by the end of the second trimester and then start to return to the prepregnant level. However, changes in the anatomy take up to 3 months postpartum to subside (King et al., 2015).

Musculoskeletal System

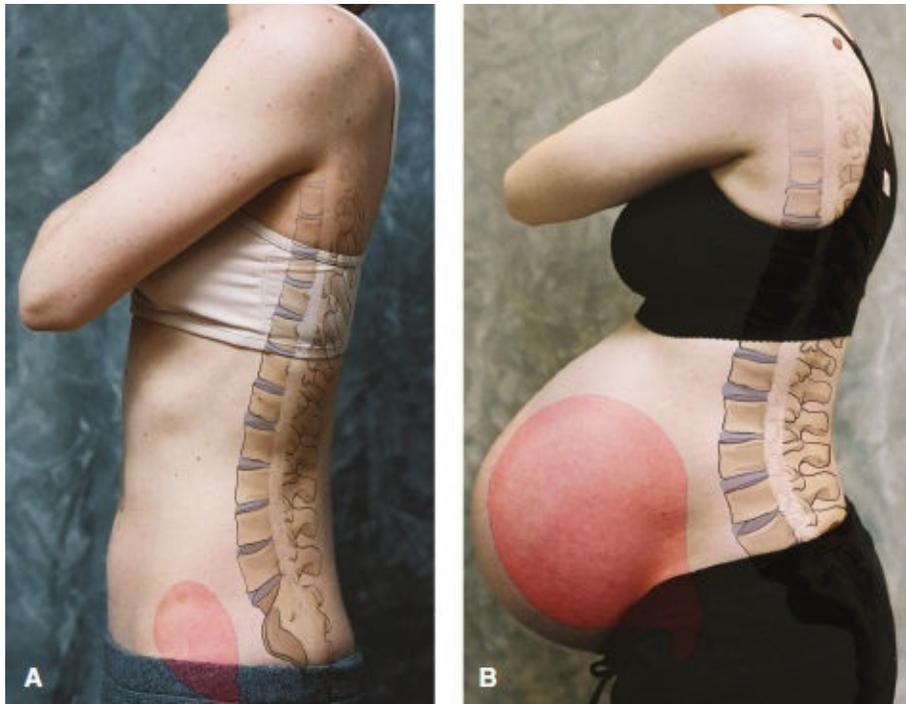
Changes in the musculoskeletal system are progressive, resulting from the influence of hormones, fetal growth, and maternal weight gain. Pregnancy is characterized by changes in posture and gait. By the 10th to 12th week of pregnancy, the ligaments that hold the sacroiliac joints and the pubis symphysis in place begin to soften and stretch, and the articulations between the joints widen and become more movable (Bope & Kellerman, 2015). The relaxation of the joints peaks by the beginning of the third trimester. The purpose of these changes is to increase the size of the pelvic cavity and to make delivery easier.


FIGURE 11.3 Postural changes during **(A)** the first trimester and **(B)** the third trimester.

The postural changes of pregnancy—an increased swayback and an upper spine extension to compensate for the enlarging abdomen—coupled with the loosening of the sacroiliac joints may result in lower back pain. The woman's center of gravity shifts forward, requiring a realignment of the spinal curvatures. Factors thought to contribute to these postural changes include the alteration to the center of gravity that come with pregnancy, the influence of the pregnancy-related hormone relaxin on the pelvic joints, and the increasing weight and position of the growing fetus.

An increase in the normal lumbosacral curve (lordosis) occurs and a compensatory curvature in the cervicodorsal area develops to assist her in maintaining her balance (Fig. 11.3). In addition, relaxation and increased mobility of joints occur because of the hormones progesterone and relaxin, which lead to the characteristic "waddle" gait that pregnant women demonstrate toward term. Increased weight gain can add to this discomfort by accentuating the lumbar and dorsal curves (Kouhkan et al., 2015).

Integumentary System

There are a variety of skin changes that are associated with pregnancy. Increased activity of the maternal adrenal and pituitary glands, along with a contribution

for the developing fetal endocrine glands, increasing cortisone levels, accelerated metabolism, and enhanced production of progesterone and estrogenic hormones are responsible for most skin changes in pregnancy (Tyler, 2015). Up to 90% of pregnant women will show signs of hyperpigmentation during pregnancy, and it is typically generalized and mild. The skin of pregnant women undergoes hyperpigmentation primarily as a result of estrogen, progesterone, and melanocyte-stimulating hormone levels. These changes are mainly seen on the nipples, areola, umbilicus, perineum, and axilla. Although many integumentary changes disappear after giving birth, some only fade. Many pregnant women express concern about stretch marks, skin color changes, and hair loss. Unfortunately, little is known about how to avoid these changes.

Complexion changes are not unusual. The increased pigmentation that occurs on the breasts and genitalia also develops on the face to form the "mask of pregnancy," which is also called facial melisma. It occurs in up to 70% of pregnant women. There is a genetic predisposition toward melasma, which is exacerbated by the sun, and it tends to recur in subsequent pregnancies. This blotchy, brownish pigment covers the forehead and cheeks in dark-haired women. Most facial pigmentation fades as the hormones subside at the end of the pregnancy, but some may linger. The skin in the middle of the abdomen may develop a pigmented line called **linea nigra**, which extends from the umbilicus to the pubic area (Fig. 11.4).

Striae gravidarum, or stretch marks, are irregular reddish streaks that appear on the abdomen, breasts, and buttocks in up to 90% of pregnant women. Striae are most prominent by 6 to 7 months. They result from genetics, reduced connective tissue strength resulting from the elevated adrenal steroid levels, and stretching of the structures secondary to growth (Tyler, 2015). They are more common in younger women, women with larger infants, and women with higher body mass indices. Nonwhites and women with a history of breast or thigh striae or a family history of striae gravidarum also are at higher risk. Several creams and lotions such as cocoa butter and olive oil have been touted as being able to prevent striae gravidarum, but research currently does not validate these claims. A study done by Tretti Clementoni and Lavagno (2015) did find that laser treatments did improve pigmentation, volume, and textural appearance of striae gravidarum in more than 50% of the women enrolled in the study.

FIGURE 11.4 Linea nigra.

VASCULAR-RELATED SKIN CHANGES

Vascular changes during pregnancy manifested in the integumentary system include varicosities of the legs, vulva, and perineum. Varicose veins commonly are the result of distention, instability, and poor circulation secondary to prolonged standing or sitting and the heavy gravid uterus placing pressure on the pelvic veins, preventing complete venous return. Interventions to reduce the risk of developing varicosities include:

• Elevating both legs when sitting or lying down

• Avoiding prolonged standing or sitting; changing position frequently

• Resting in the left lateral position

• Walking daily for exercise

• Avoiding tight clothing or knee-high hosiery

• Wearing support hose if varicosities are a pre-existing condition to pregnancy

   Another skin manifestation, believed to be secondary to vascular changes and high estrogen levels, is the appearance of small blood vessels called vascular spiders. They may appear on the neck, thorax, face, and arms. They are

especially obvious in white women and typically disappear after childbirth. Palmar erythema is a well-delineated pinkish area on the palmar surface of the hands. This integumentary change is also related to elevated estrogen levels (Trupin, 2015).

HAIR AND NAILS

Some women also notice a decline in hair growth during pregnancy. The hair follicles normally undergo a growing and resting phase. The resting phase is followed by a loss of hair; the hairs are then replaced by new ones. During pregnancy, fewer hair follicles go into the resting phase. After delivery, the body catches up with subsequent hair loss for several months. Nails typically grow faster during pregnancy. Pregnant women may experience increased brittleness, distal separation of the nail bed, whitish discoloration, and transverse grooves on the nails, but most of these conditions resolve in the postpartum period (King et al., 2015).

Endocrine System

The endocrine system undergoes many changes during pregnancy because hormonal changes are essential in meeting the needs of the growing fetus. Hormonal changes play a major role in controlling the supplies of maternal glucose, amino acids, and lipids to the fetus. Although estrogen and progesterone are the main hormones involved in pregnancy changes, other endocrine glands and hormones also change during pregnancy.

THYROID GLAND

The thyroid gland enlarges slightly and becomes more active during pregnancy as a result of increased vascularity and hyperplasia. Increased gland activity results in an increase in thyroid hormone secretion starting during the first trimester; levels taper off within a few weeks after birth and return to normal limits. Maternal thyroid hormone is transferred to the fetus beginning soon after conception and is critical for fetal brain development, neurogenesis, and organizational processes prior to 20 weeks when fetal thyroid production is low. However, even after the fetal thyroid is producing increasing amounts of hormone, much of the thyroxin (T_4) needed for development continues to be provided by the mother. Low maternal thyroid levels with thyroid insufficiency, hypothyroidism, or low or inadequate iodine intake may compromise fetal

neurologic development (Pearce, 2015). With an increase in the secretion of thyroid hormones, the basal metabolic rate (the amount of oxygen consumed by the body over a unit of time in milliliters per minute) progressively increases by 25%, along with heart rate and cardiac output (Medici et al., 2015).

PITUITARY GLAND

During pregnancy, major endocrine and metabolic alterations occur due to the physiologic hormonal secretion from the placenta. The pituitary gland adapts to these changes and all secretory axes are affected. During pregnancy, the pituitary gland enlarges; it returns to normal size after birth.

The anterior lobe of the pituitary is glandular tissue and produces multiple hormones. The release of these hormones is regulated by releasing and inhibiting hormones produced by the hypothalamus. Some of these anterior pituitary hormones induce other glands to secrete their hormones. The increase in blood levels of the hormones produced by the final target glands (e.g., the ovary or thyroid) inhibits the release of anterior pituitary hormones. Changes in levels of pituitary hormones are discussed in the following paragraphs.

FSH and LH secretion are inhibited during pregnancy, probably as a result of hCG produced by the placenta and corpus luteum, and the increased secretion of prolactin by the anterior pituitary gland. Levels remain decreased until after delivery.

Thyroid-stimulating hormone (TSH) is reduced during the first trimester but usually returns to normal for the remainder of the pregnancy. Decreased TSH is thought to be one of the factors, along with elevated hCG levels, associated with morning sickness, nausea, and vomiting during the first trimester.

Growth hormone (GH) is an anabolic hormone that promotes protein synthesis. It stimulates most body cells to grow in size and divide, facilitating the use of fats for fuel and conserving glucose. During pregnancy, there is a decrease in the number of GH-producing cells and a corresponding decrease in GH blood levels. The action of human placental lactogen (hPL) is thought to decrease the need for and use of GH. During pregnancy, prolactin is secreted in pulses and increases 10-fold to promote breast development and the lactation process. High levels of progesterone secreted by the placenta inhibit the direct influence of prolactin on the breast during pregnancy, thus suppressing lactation. At birth, as soon as the placenta is expelled and there is a drop in progesterone, lactogenesis can begin. Prolactin, released from the anterior pituitary gland in response to suckling by the newborn is the major hormonal signal responsible

for stimulation in the breasts (Crowley, 2015).

Melanocyte-stimulating hormone (MSH), another anterior pituitary hormone, increases during pregnancy. For many years, its increase was thought to be responsible for many of the skin changes of pregnancy, particularly changes in skin pigmentation (e.g., darkening of the areola, melasma, and linea nigra). However, currently it is thought that the skin changes are due to estrogen (and possibly progesterone) as well as the increase in MSH.

The two hormones oxytocin and antidiuretic hormone (ADH) released by the posterior pituitary are actually synthesized in the hypothalamus. They migrate along nerve fibers to the posterior pituitary and are stored until stimulated to be released into the general circulation. Oxytocin is released by the posterior pituitary gland, and its production gradually increases as the fetus matures (Kim, Bennett, & Terzidou, 2015). Oxytocin is responsible for uterine contractions, both before and after delivery. The muscle layers of the uterus (myometrium) become more sensitive to oxytocin near term. Toward the end of a term pregnancy, levels of progesterone decline and contractions that were previously suppressed by progesterone begin to occur more frequently and with stronger intensity. This change in the hormonal levels is believed to be one of the initiators of labor.

Oxytocin is responsible for stimulating the uterine contractions that bring about delivery. Contractions lead to cervical thinning and dilation. They also exert pressure, helping the fetus to descend in the pelvis for eventual delivery. After delivery, oxytocin secretion continues, causing the myometrium to contract and helping to constrict the uterine blood vessels, decreasing the amount of vaginal bleeding after delivery. Oxytocin is also responsible for milk ejection during breast-feeding. Stimulation of the breasts through sucking or touching stimulates the secretion of oxytocin from the posterior pituitary gland. Oxytocin causes contraction of the myoepithelial cells in the lactating mammary gland.

Women experience cramping pain and discomfort following childbirth as the uterus contracts and returns to its prepregnant size. These after pains are caused by involuntary contractions and usually last for a few days after childbirth. They are more evident in women who have previously had a baby. Breastfeeding signals the release of oxytocin, which stimulates the uterus to contract and increases the severity of after birth pains.

Vasopressin, also known as ADH functions to inhibit or prevent the formation of urine via vasoconstriction, which results in increased blood pressure. Vasopressin also exhibits an antidiuretic effect and plays an important role in the

regulation of water balance (Cheng, 2015).

PANCREAS

The pancreas is an exocrine organ, supplying digestive enzymes and buffers, and an endocrine organ. The endocrine pancreas consists of the islets of Langerhans, which are groups of cells scattered throughout, each containing four cell types. One of the cell types is the beta cell, which produces insulin. Insulin lowers blood glucose by increasing the rate of glucose uptake and utilization by most body cells. The growing fetus needs significant amounts of glucose, amino acids, and lipids. Even during early pregnancy the fetus makes demands on the maternal glucose stores. Ideally, hormonal changes of pregnancy help meet fetal needs without putting the mother's metabolism out of balance.

A woman's insulin secretion works on a supply versus demand mode. As the demand to meet the needs of pregnancy increases, more insulin is secreted. Maternal insulin does not cross the placenta, so the fetus must produce his or her own supply to maintain glucose control. (Box 11.2 gives information about pregnancy, glucose, and insulin.)

Maternal glucose metabolism during pregnancy differs from the nongravid state to allow the mother to meet her own and the growing fetus's energy needs. During the first half of pregnancy, much of the maternal glucose is diverted to the growing fetus, and thus the mother's glucose levels are low. Human placental lactogen and other hormonal antagonists increase during the second half of pregnancy. Therefore, the mother must produce more insulin to overcome the resistance by these hormones. Insulin resistance (the inability of insulin to increase glucose uptake and utilization) in pregnancy is consequent to the physiologic adaptation necessary to provide glucose to the growing fetus. Disturbance in the maternal metabolism can induce structural and functional adaptations during fetal development (Nas, Breyer, & Tuu, 2015).

PREGNANCY, INSULIN, AND GLUCOSE

- During early pregnancy, maternal glucose levels decrease because of the heavy fetal demand for glucose. The fetus is also drawing amino acids and lipids from the mother, decreasing the mother's ability to synthesize glucose. Maternal glucose is diverted across the placenta to assist the growing embryo/fetus during early pregnancy, and thus levels decline in the mother. As a result, maternal glucose concentrations decline to a level that would be considered "hypoglycemic" in a nonpregnant woman.

- During early pregnancy there is also a decrease in maternal insulin production and insulin levels. The pancreas is responsible for the production of insulin, which facilitates entry of glucose into cells. Although glucose and other nutrients easily cross the placenta to the fetus, insulin does not. Therefore, the fetus must produce its own insulin to facilitate the entry of glucose into its own cells.

- After the first trimester, hPL from the placenta and steroids (cortisol) from the adrenal cortex act against insulin. hPL acts as an antagonist against maternal insulin, and thus more insulin must be secreted to counteract the increasing levels of hPL and cortisol during the last half of pregnancy.

- Prolactin, estrogen, and progesterone are also thought to oppose insulin. As a result, glucose is less likely to enter the mother's cells and is more likely to cross over the placenta to the fetus.

Adapted from Cunningham, F. G., Leveno, K. J., Bloom, S. L., Spong, C. Y., Dashe, J. S., Hoffman, B. L., et al. (2014). *William's Obstetrics* (24th ed.). New York, NY: McGraw Hill Education.

If the mother has normal beta cells of the islets of Langerhans, there is usually no problem meeting the demands for extra insulin. However, if the woman has inadequate numbers of beta cells, she may be unable to produce enough insulin and will develop glucose intolerance during pregnancy. If the woman has glucose intolerance, she is not able to meet the increasing demands and her blood glucose level increases.

ADRENAL GLANDS

Pregnancy does not cause much change in the size of the adrenal glands themselves, but there are changes in some secretions and activity. One of the key changes is the marked increase in cortisol secretion, which regulates carbohydrate and protein metabolism and is helpful in times of stress. Although pregnancy is considered a normal condition, it is a time of stress for a woman's body. The rate of secretion of cortisol by maternal adrenals is not increased in pregnancy, but the rate of clearance is decreased. Cortisol increases in response to increased estrogen levels throughout pregnancy and returns to normal levels within 6 weeks postpartum (Banerjee & Williamson, 2015). During the stress of pregnancy, cortisol:

• Helps keep up the level of glucose in the plasma by breaking down noncarbohydrate sources, such as amino and fatty acids, to make glycogen. Glycogen, stored in the liver, is easily broken down to glucose when needed so that glucose is available in times of stress.

• Breaks down proteins to repair tissues and manufacture enzymes.

• Has anti-insulin, anti-inflammatory, and anti-allergic actions.

• Is needed to make the precursors of adrenaline, which the adrenal medulla produces and secretes (Jones & Lopez, 2014).

The amount of aldosterone, also secreted by the adrenal glands, is increased during pregnancy. It normally regulates absorption of sodium from the distal tubules of the kidney. During pregnancy, progesterone allows salt to be wasted (or lost) in the urine. Aldosterone is a key regulator of electrolyte and water homeostasis and plays a central role in blood pressure regulation. Hormonal changes during pregnancy, among them increased progesterone and aldosterone production, lead to the required plasma volume expansion of the maternal body as an accommodation mechanism for fetus growth. Aldosterone is produced in increased amounts by the adrenal glands as early as 15 weeks of pregnancy (Rossier, Baker, & Studer, 2015).

PROSTAGLANDIN SECRETION DURING PREGNANCY

Prostaglandins are not protein or steroid hormones; they are chemical mediators, or local hormones. Although hormones circulate in the blood to influence distant tissues, prostaglandins act locally on adjacent cells. The fetal membranes of the amniotic sac—the amnion and chorion—are both believed to be involved in the

production of prostaglandins. Various maternal and fetal tissues, as well as the amniotic fluid itself, are considered to be sources of prostaglandins, but details about their composition and sources are limited. It is widely believed that prostaglandins play a part in softening the cervix and initiating and/or maintaining labor, but the exact mechanism is unclear. What is theorized is that when progesterone levels drop at term, an increased production of prostaglandins occurs, which facilitates uterine contractions and increases myometrial sensitivity to oxytocin that is needed for the labor process (King et al., 2015). Along with oxytocin, the influence of prostaglandins on the uterine myometrium predominates to promote uterine contractile activity.

PLACENTAL SECRETION

The placenta is an organ that serves to prevent the direct exchange between the blood of the fetus and the blood of the mother. The placenta is not only a transfer organ but a factory as well. It is capable of synthesizing enzymes and proteins, and manufactures fats and carbohydrates that serve as a source of stored energy. The placenta also functions as an endocrine gland, manufacturing and secreting hormones. The placenta has a feature possessed by no other endocrine organ— the ability to form protein and steroid hormones. Very early during pregnancy, the placenta begins to produce the following hormones:

• hCG

• hPL

• Relaxin

• Progesterone

• Estrogen

Table 11.3 summarizes the role of these hormones.

Immune System

The immune system is made up of organs and specialized cells whose primary purpose is to defend the body from foreign substances (antigens) that may cause tissue injury or disease. The mechanisms of innate and adaptive immunity work cooperatively to prevent, control, and eradicate foreign antigens in the body.

A general enhancement of innate immunity (inflammatory response and phagocytosis) and suppression of adaptive immunity (protective response to a

specific foreign antigen) take place during pregnancy. These immunologic alterations help prevent the mother's immune system from rejecting the fetus (foreign body), increase her risk of developing certain infections such as urinary tract infections, and influence the course of chronic disorders such as autoimmune diseases. Some chronic conditions worsen (diabetes) while others seem to stabilize (asthma) during pregnancy, but this is individualized and not predictable. In general, immune function in pregnant women is similar to immune function in nonpregnant women. Table 11.4 summarizes the general body systems' adaptations to pregnancy.

> *Marva returns for her first prenatal appointment and tells the nurse that her whole body is "out of sorts." She is overwhelmed and feels poorly. Outline the bodily changes Marva can expect each trimester to help her understand the adaptations taking place. What guidance can the nurse give Marva to help her understand the changes of pregnancy?*

CHANGING NUTRITIONAL NEEDS OF PREGNANCY

Maternal body weight and diet quality, even prepregnancy, can affect the uterine environment, birth weight, and the infant's subsequent health into adulthood. Healthy eating during pregnancy enables optimal gestational weight gain and reduces complications, both of which are associated with positive birth outcomes. During pregnancy, maternal nutritional needs change to meet the demands of the pregnancy. Healthy eating can help ensure that adequate nutrients are available for both mother and fetus.

TABLE 11.3 PLACENTAL HORMONES

Hormone	Description
Human chorionic gonadotropin (hCG)	• Responsible for maintaining the maternal corpus luteum, which secretes progesterone and estrogens, with synthesis occurring before implantation. • Production by fetal trophoblast cells until the placenta is developed sufficiently to take over that function. • Basis for early pregnancy tests because it appears in the maternal bloodstream soon after implantation. • Production peaks at 8 weeks and then gradually declines.
hPL (also known as human chorionic somatomammotropin [hCS])	• Preparation of mammary glands for lactation and involved in the process of making glucose available for fetal growth by altering maternal carbohydrate, fat, and protein metabolism. • Antagonist of insulin because it decreases tissue sensitivity or alters the ability to use insulin. • Increase in the amount of circulating free fatty acids for maternal metabolic needs and decrease in maternal metabolism of glucose to facilitate fetal growth.
Relaxin	• Secretion by the placenta as well as the corpus luteum during pregnancy. • Thought to act synergistically with progesterone to maintain pregnancy. • Increase in flexibility of the pubic symphysis, permitting the pelvis to expand during delivery. • Dilation of the cervix, making it easier for the fetus to enter the vaginal canal; thought to suppress the release of oxytocin by the hypothalamus, thus delaying the onset of labor contractions.
Progesterone	• Often called the "hormone of pregnancy" because of the critical role it plays in supporting the endometrium of the uterus. • Supports the endometrium to provide an environment conducive to fetal survival. • Produced by the corpus luteum during the first few weeks of pregnancy and then by the placenta until term. • Initially, causes thickening of the uterine lining in anticipation of implantation of the fertilized ovum. From then on, it maintains the endometrium, inhibits uterine contractility, and assists in the development of the breasts for lactation.
Estrogen	• Promotes enlargement of the genitals, uterus, and breasts, and increases vascularity, causing vasodilatation. • Relaxation of pelvic ligaments and joints. • Associated with hyperpigmentation, vascular changes in the skin, increased activity of the salivary glands, and hyperemia of the gums and nasal mucous membranes. • Aids in developing the ductal system of the breasts in preparation for lactation.

New York, NY: McGraw Hill Education; Edelman, C. L., Kudzma, E.C., & Mandle, C. L. (2014). *Health promotion throughout the lifespan* (8th ed.). St. Louis, MO: Mosby Elsevier; and Shields, A. D. (2015). Pregnancy diagnosis. *eMedicine*. Retrieved from http://emedicine.medscape.com/article/262591-overview

Nutritional intake during pregnancy has a direct effect on fetal well-being and birth outcome. Inadequate nutritional intake, for example, is associated with preterm birth, low birth weight, and congenital anomalies. Excessive nutritional intake is connected with fetal macrosomia (>4,000 g), leading to a difficult birth, neonatal hypoglycemia, and continued obesity in the mother and the potential for childhood obesity and the components of metabolic syndrome (Ojha et al., 2015).

Since the requirements for so many nutrients increase during pregnancy, pregnant women should take a vitamin and mineral supplement daily. Prenatal vitamins are prescribed routinely as a safeguard against a less-than-optimal diet. In particular, iron and folic acid need to be supplemented because their increased

requirements during pregnancy are usually too great to be met through diet alone. With the exception of folic acid, there is little scientific evidence to support giving vitamin supplements to healthy pregnant women, but it seems to be the standard of care today. Prenatal vitamins are prescribed in the United States almost universally (Jordan et al., 2014). Iron and folic acid are needed to form new blood cells for the expanded maternal blood volume and to prevent anemia. Iron is essential for fetal growth and brain development and in the prevention of maternal anemia. An increase in folic acid is essential before pregnancy and in the early weeks of pregnancy to prevent neural tube defects in the fetus. For most pregnant women, supplements of 27 mg of ferrous iron and 400 to 800 mcg of folic acid per day are recommended by the **dietary reference intakes (DRIs)** (American College of OB/GYN [ACOG], 2015a); (Hankey, 2015); and (U.S. Preventive Services Task Force [USPSTF], 2015). Women with a previous history of a fetus with a neural tube defect are often prescribed a higher dose of folic acid.

TABLE 11.4 SUMMARY OF GENERAL BODY SYSTEM ADAPTATIONS

System	Adaptation
Gastrointestinal system	*Mouth and pharynx:* Gums become hyperemic, swollen, and friable and tend to bleed easily. Saliva production increases. *Esophagus:* Decreased lower esophageal sphincter pressure and tone, which increases the risk of developing heartburn. *Stomach:* Decreased tone and mobility with delayed gastric emptying time, which increases the risk of gastroesophageal reflux and vomiting. Decreased gastric acidity and histamine output, which improves symptoms of peptic ulcer disease. *Intestines:* Decreased intestinal tone motility with increased transit time, which increases risk of constipation and flatulence. *Gallbladder:* Decreased tone and motility, which may increase risk of gallstone formation.
Cardiovascular system	*Blood volume:* Marked increase in plasma (50%) and RBCs (25–33%) compared to nonpregnant values. Causes hemodilution, which is reflected in a lower hematocrit and hemoglobin. *Cardiac output and heart rate:* CO increases from 30% to 50% over the nonpregnant rate by the 32nd week of pregnancy. The increase in CO is associated with an increase in venous return and greater right ventricular output, especially in the left lateral position. Heart rate increases by 10–15 bpm between 14 and 20 weeks of gestation, and this increase will persist to term. *Blood pressure:* Diastolic pressure decreases typically 10–15 mm Hg to reach its lowest point by mid-pregnancy; it then gradually returns to nonpregnant baseline values by term. *Blood components:* The number of RBCs increases throughout pregnancy to a level 25–33% higher than nonpregnant values. Both fibrin and plasma fibrinogen levels increase, along with various blood-clotting factors. These factors make pregnancy a hypercoagulable state.
Respiratory system	Enlargement of the uterus shifts the diaphragm up to 4 cm above its usual position. As muscles and cartilage in the thoracic region relax, the chest broadens, with conversion from abdominal breathing to thoracic breathing. This leads to a 50% increase in air volume per minute. Tidal volume, or the volume of air inhaled, increases gradually by 30–40% (from 500 to 700 mL) as the pregnancy progresses.

Renal/urinary system	The renal pelvis becomes dilated. The ureters (especially the right ureter) elongate, widen, and become more curved above the pelvic rim. Bladder tone decreases and bladder capacity doubles by term. GFR increases 40–60% during pregnancy. Blood flow to the kidneys increases by 50–80% as a result of the increase in cardiac output.
Musculoskeletal system	Distention of the abdomen with growth of the fetus tilts the pelvis forward, shifting the center of gravity. The woman compensates by developing an increased curvature (lordosis) of the spine. Relaxation and increased mobility of joints occur because of the hormones progesterone and relaxin, which lead to the characteristic "waddle gait" that pregnant women demonstrate toward term.
Integumentary system	Hyperpigmentation of the skin is the most common alteration during pregnancy. The most common areas include the areola, genital skin, axilla, inner aspects of the thighs, and linea nigra. Striae gravidarum, or stretch marks, are irregular reddish streaks that may appear on the abdomen, breasts, and buttocks in about half of pregnant women. The skin in the middle of the abdomen may develop a pigmented line called linea nigra, which extends from the umbilicus to the pubic area. Melasma ("mask of pregnancy") occurs in up to 70% of pregnant women. It is characterized by irregular, blotchy areas of pigmentation on the face, most commonly on the cheeks, chin, and nose.
Endocrine system	Controls the integrity and duration of gestation by maintaining the corpus luteum via hCG secretion; production of estrogen, progesterone, hPL, and other hormones and growth factors via the placenta; release of oxytocin (by the posterior pituitary gland), prolactin (by the anterior pituitary), and relaxin (by the ovary, uterus, and placenta).
Immune system	A general enhancement of innate immunity (inflammatory response and phagocytosis) and suppression of adaptive immunity (protective response to a specific foreign antigen) take place during pregnancy. These immunologic alterations help prevent the mother's immune system from rejecting the fetus (foreign body), increase her risk of developing certain infections, and influence the course of chronic disorders such as autoimmune diseases.

There is an abundance of conflicting advice about nutrition during pregnancy and what is good or bad to eat. Overall, the following guidelines are helpful:

• Increase consumption of fruits and vegetables.

• Replace saturated fats with unsaturated ones.

• Make half the plate fruits and vegetables.

• Choose whole grains in place of refined grains.

• Choose foods with a lot of fiber to prevent constipation.

• Avoid hydrogenated or partially hydrogenated fats.

• Do not consume any alcoholic beverages.

• Use reduced-fat spreads and dairy products instead of full-fat ones.

• Eat at least two servings of fish weekly, with one of them being an oily fish.

• Consume at least 2 quarts of water daily (USDA, 2015).

In the months before conception, food choices are key. The foods and vitamins consumed can ensure that the woman and her fetus will have the nutrients that are essential for the very start of pregnancy.

While most women recognize the importance of healthy eating during

pregnancy, some find it challenging to achieve. Many women say they have little time and energy to devote to meal planning and preparation. Another barrier to healthy eating is conflicting messages from various sources, resulting in a lack of clear, reliable, and relevant information. Moreover, many women are eating less in an effort to control their weight, putting them at greater risk of inadequate nutrient intake.

Nutritional Requirements During Pregnancy

Pregnancy is one of the most nutritionally demanding periods of a woman's life. Gestation involves rapid cell division and organ development, and an adequate supply of nutrients is essential to support this tremendous fetal growth. Optimal maternal health via good nutritional practices during pregnancy reduces the risk of suboptimal fetal development.

Most women are usually motivated to eat properly during pregnancy for the sake of the fetus. The Food and Nutrition Board of the National Research Council has made recommendations for nutrient intakes for people living in the United States. The DRIs are more comprehensive than previous nutrient guidelines issued by the Board. They have replaced previous recommendations because they are not limited to preventing deficiency diseases. Rather, the DRIs incorporate current concepts about the role of nutrients and food components in reducing the risk of chronic disease, developmental disorders, and other related problems. The DRIs can be used to plan and assess diets for healthy people (Kruger & Butte, 2015).

These dietary recommendations also include information for women who are pregnant or lactating, because growing fetal and maternal tissues require increased quantities of essential dietary components. For example, the current DRIs suggest an increase in the pregnant woman's intake of protein from 60 to 80 g/day, iron from 18 to 27 g/day, and folic acid from 400 to 800 mcg/day, along with an increase of 300 calories/day over the recommended intake of 1,800 to 2,200 calories/day for nonpregnant women (Storck, 2015; Walsh & McAuliffe, 2015) (Table 11.5).

Gluten-free Diet During Pregnancy

In recent years, gluten-free foods have become popular, fueling a growing market for the Food Industry. Pregnant women may be missing out on important nutrients if they adopt gluten-free diets as many are also joining the ever-expanding "G-free" bandwagon. Many people feel that these products are healthier than their conventional counterparts. But is it really a health-promotion diet or just another trend during pregnancy? Gluten may have gotten its bad rap because it is frequently found in many processed and unhealthy foods. Several gluten-free foods contain more fat, including saturated, and sodium, but fewer minerals and vitamins than their equivalents with gluten (Pellegrini & Agostoni, 2015). Skipping processed foods altogether and focusing on fruits, vegetables, lean protein, and whole grains would provide a well-balanced healthy diet.

Eating a gluten-free diet can make it hard to get the recommended amount of folate, vitamin B, iron, calcium, fiber, and grain-servings that all pregnant women need. That is why, unless there is medical reason in which gluten must be eliminated from the diet due to celiac disease or a gluten allergy, there is no scientific reason to cut out wholesome, nutrient-dense grains from the diet (Neifeld, 2015).

USDA and MyPlate

For a pregnant woman to meet recommended DRIs, she should eat according to the U.S. Department of Agriculture (USDA) Food Guide *MyPlate* (Fig. 11.5). The USDA Food Guide *MyPlate* replaced the Food Guide Pyramid in 2011 as the government's primary food group symbol. *MyPlate* is an easy-to-understand visual cue to help consumers adopt healthy eating habits by encouraging them to build a healthy plate, consistent with the *Dietary Guidelines for Americans, 2015* (USDA & USDHHS, 2015), which are the basis for federal nutrition policy (USDA and U.S. Department of Health and Human Services [USDHHS], 2015). This new tool will serve as a basis for dietary instruction and it can be tailored to meet each woman's individual needs.

TABLE 11.5 DIETARY RECOMMENDATIONS FOR THE PREGNANT AND LACTATING WOMAN

Nutrient	Nonpregnant Women	Pregnant Woman	Lactating Woman
Calories	2,200	2,500	2,700
Protein	60 g	80 g	80 g
Water/fluids	6–8 glasses daily	8 glasses daily	8 glasses daily
Vitamin A	700 mcg	770 mcg	1,300 mcg
Vitamin C	75 mg	85 mg	120 mg
Vitamin D	5 mcg	5 mcg	5 mcg
Folate	400 mcg	600 mcg	500 mcg
Calcium	1,000 mg	1,000 mg	1,000 mg
Iodine			
Iron	18 mg	27 mg	9 mg

Prenatal nutrition. *eMedicine*. Retrieved from http://emedicine.medscape.com/article/259059-overview; and Lutz, C. A., Mazur, E., & Litch, N. (2014). *Nutrition and diet therapy* (6th ed.). Philadelphia, PA: F.A. Davis.

FIGURE 11.5 Food Guide *MyPlate* for pregnancy.

MyPlate provides guidance to help implement the dietary guidelines. The USDA has designed an interactive online diet-planning program called the Daily Food Plan for Moms that helps pregnant women personalize their dietary intake throughout their pregnancy. (Refer to for additional information about this food plan.) A summary of the new guidelines is as follows:

• Eat a variety of food from all food groups using portion control.

- Increase intake of vitamins, minerals, and dietary fiber.
- Lower intake of saturated fats, trans fats, and cholesterol.
- Consume adequate synthetic folic acid from supplements or from fortified foods.
- Increase intake of fruits, vegetables, and whole grains.
- Balance calorie intake with exercise to maintain ideal healthy weight (USDA, 2015).

An eating plan that follows *MyPlate* should provide sufficient nutrients for a healthy pregnancy. Except for iron, folic acid, and calcium, most of the nutrients a woman needs during pregnancy can be obtained by making healthy food choices. However, a vitamin and mineral supplement is generally prescribed.

Take Note!

Good food sources of folic acid include dark green vegetables, such as broccoli, romaine lettuce, and spinach; baked beans, black-eyed peas, citrus fruits, peanuts, and liver.

Food Concerns During Pregnancy

ARTIFICIAL SWEETENERS

Artificial sweeteners or intense sweeteners are sugar substitutes that are used as an alternative to table sugar. They are many times sweeter than natural sugar and contain no calories. Extensive scientific research has demonstrated the safety of the six low-calorie sweeteners currently approved for use in foods in the United States and Europe (stevia, acesulfame-K, aspartame, neotame, saccharin, and sucralose), if taken in acceptable quantities daily. But there is an ongoing debate over whether artificial sweeteners pose a health threat (Qurrat-ul-Ain & Khan, 2015).

The safety of artificial sweeteners consumed during pregnancy remains controversial also. Some health care providers advise their pregnant clients to avoid all nonnutritive sweeteners during pregnancy, while others suggest they can be used in moderation (Hankley, 2015). The debate continues on this matter until additional research can be completed.

FISH, SHELLFISH, AND LEVELS OF MERCURY

Fish and shellfish are an important part of a healthy diet because they contain high-quality protein, are low in saturated fat, and contain omega-3 fatty acids. However, nearly all fish and shellfish contain traces of mercury and some contain higher levels of mercury that may harm a developing fetus if ingested by pregnant women in large amounts. Human exposure to mercury occurs primarily through the consumption of fish contaminated through atmospheric mercury releases. The U.S. Environmental Protection Agency (EPA) and the United Nations Environment Program have identified coal-fired power plants as the source of 50% to 75% of the atmospheric mercury pollution in the United States and worldwide. Once airborne, rainfall transfers mercury particles into waterways where it is converted to the neurotoxic methylmercury form through a microbial process. Plankton absorbs the methylmercury and as the smaller fish eat the plankton and the larger predatory fish consume the smaller fish, the methylmercury bioaccumulates up the food chain to humans. Mercury exposure in pregnancy has been associated with both pregnancy complications and developmental problems in infants. Apart from the environmental exposure, mercury is likely to arise from predatory fish consumption. It would be prudent to advise all pregnant women to avoid these potential problems and minimize any risk.

All fish contain methylmercury regardless of the size or the geographic location of the waters from which the fish is caught, although size and type of fish as well as the geographic location of waters can influence lower or higher amounts of methylmercury. In addition, because methylmercury resides in the tissue of the fish, no method of cleaning or cooking will reduce the amount of mercury in a meal of contaminated fish (Nelson, 2015).

With this in mind, the FDA and the EPA are advising women who may become pregnant, pregnant women, and nursing mothers to do the following:

- Avoid consumption of fish with moderate-to-high mercury levels (e.g., for 6 to 12 months prior to conception and throughout pregnancy).

- Avoid eating shark, swordfish, king mackerel, orange roughy, ahi tuna, and tilefish because they are high in mercury levels.

- Eat up to 12 oz (two average meals) weekly of low-mercury-level fish such as shrimp, canned light tuna, salmon, pollock, and catfish.

- Check local advisories about the safety of fish caught by family and friends in local lakes, rivers, and coastal areas (FDA, 2015).

LISTERIOSIS AND PREGNANCY

Another food issue concern for pregnant women is consumption of food contaminated with the gram-positive bacillus *Listeria*. *Listeria* is a type of bacteria found in soil, water, and sometimes on plants. *Listeria* is commonly found in processed and prepared foods and in raw or unpasteurized milk. Listeriosis is associated with high morbidity and mortality. Though *Listeria* is all around our environment, most *Listeria* infections in people result from eating contaminated foods. Listeriosis during pregnancy usually presents as an unremarkable febrile illness in the mother, but can be fatal for the fetus and newborn. Reliable laboratory testing for early diagnosis is lacking. Listeriosis can be passed to an unborn baby through the placenta even if the mother is not showing signs of illness. This can lead to preterm births, miscarriages, stillbirths, and high neonatal mortality rates (Allerberger & Huhulescu, 2015). The Food Safety and Inspection Service and the FDA (2015) provide the following advice for pregnant women:

- Do not eat hot dogs, luncheon meats, or deli meats unless they are reheated until steaming hot.

- Avoid getting fluid from hot dog packages on other foods, utensils, and food preparation surfaces, and wash hands after handling hot dogs, luncheon meats, and deli meats.

- Do not eat soft cheeses such as feta, Brie, Camembert, and blue-veined cheeses.

- It is safe to eat hard cheeses, semi-soft cheeses such as mozzarella, pasteurized processed cheese slices and spreads, cream cheese, and cottage cheese.

- Do not eat refrigerated pâté or meat spreads.

- It is safe to eat canned or shelf-stable pâté and meat spreads.

- Do not eat refrigerated smoked seafood unless it is an ingredient in a cooked dish such as a casserole. Examples of refrigerated smoked seafood include salmon, trout, whitefish, cod, tuna, and mackerel and are most often labeled as "nova-style," "lox," "kippered," "smoked," or "jerky." These refrigerated smoked fish are found in the refrigerated section or sold at deli counters of grocery stores and delicatessens.

- It is safe to eat canned fish such as salmon and tuna or shelf-stable smoked seafood.

- Do not drink raw (unpasteurized) milk or eat foods that contain unpasteurized

milk.

- Use all refrigerated perishable items that are precooked or ready-to-eat as soon as possible.

- Use a refrigerator thermometer to make sure that the refrigerator always stays at 40° F (about 5° C) or below.

- Do not eat salads made in the store such as ham salad, chicken salad, egg salad, tuna salad, or seafood salad.

- Clean your refrigerator regularly.

Maternal Weight Gain

The amount of weight that a woman gains during pregnancy is not as important as what she eats. A woman can lose extra weight after a pregnancy, but she can never make up for a poor nutritional status during the pregnancy. Earlier guidelines recommended weight gain that would be optimal for the infant, but new guidelines take into account the well-being of the mother too (Table 11.6).

In 2009, the Health and Medicine Division revised the recommendations regarding maternal gestational weight gain. The revisions took into account that presently American women (1) have more multiple pregnancies; (2) are becoming pregnant at an older age; (3) are exceeding the ideal weight gain during pregnancy; and (4) tend to be more overweight and obese when becoming pregnant. The new recommendations are based on the woman's pregnancy body mass index (BMI) as follows (Box 11.3):

TABLE 11.6 NORMAL DISTRIBUTION OF WEIGHT GAIN DURING PREGNANCY

Component	Weight (pounds)
Infant birth weight	7.5
Blood volume increase	4
Uterus	2
Increase in breast tissue	2
Placenta	1.5
Maternal fluid volume	4
Maternal fat tissue	7
Amniotic fluid	2
Approximate total weight gain	30

Adapted from American College of Obstetricians and Gynecologists [ACOG]. (2015b). *Weight gain guidelines by ACOG for pregnancy.* Retrieved from http://www.womenshealthcaretopics.com/weight_gain_during_pregnancy.htm; and Lutz, C. A., Mazur, E., & Litch, N. (2014). *Nutrition and diet therapy* (6th ed.). Philadelphia, PA: F. A. Davis.

BODY MASS INDEX

Body mass index (BMI) provides an accurate estimate of total body fat and is considered a good method to assess overweight and obesity in people. BMI is a weight-to-height ratio calculation that can be determined by dividing a woman's weight in kilograms by her height in meters squared. BMI can also be calculated by weight in pounds divided by the height in inches squared, multiplied by 704.5.

The Centers for Disease Control and Prevention (CDC) (2015) categorizes BMI as follows:

• Underweight: <18.5

• Healthy weight: 18.5–24.9

• Overweight: 25–29.9

• Obese: 30 or higher

Use this example to calculate BMI:
Mary is 5 ft 5 in tall and weighs 150 lb.
1. Convert weight into kilograms: 150 ÷ 2.2 lb/kg = 68.18 kg.
2. Convert height into meters:
   a. 5 ft 5 in = 65 in ÷ 2.54 cm/in = 165.1 cm
   b. 165.1 cm ÷ 100 cm = 1.65 m
3. Then square the height in meters: 1.65 × 1.65 = 2.72
4. Calculate BMI: 68.18 kg ÷ 2.72 = 25.

Adapted from Centers for Disease Control and Prevention [CDC]. (2015). *BMI for adults: Body mass index calculator*. Retrieved from http://www.cdc.gov/nccdphp/dnpa/bmi/calc-bmi.htm

• Underweight (BMI < 18.5) total weight gain range = 28–40 lb.

• Normal weight (BMI = 18.5–24.9) total weight gain range = 25–35 lb.

• Overweight (BMI = 25–29.9) total weight gain range = 15–25 lb.

• Obese (BMI = 30 or higher) total weight gain range = 11–20 lb.

A woman who is underweight before pregnancy or who has a low maternal

weight gain pattern should be monitored carefully because she is at risk of giving birth to a low-birth-weight infant (<2,500 g or 5.5 lb). Frequently these women simply need advice on what to eat to add weight. Encourage the woman to eat snacks that are high in calories such as nuts, peanut butter, milkshakes, cheese, fruit, yogurt, and ice cream. Any woman who has a prepregnancy BMI of less than 18.5 is considered to be at high risk and should be referred to a nutritionist (Sharma et al., 2015).

Conversely, women who start a pregnancy while overweight (BMI > 25–29) run the risk of having a high-birth-weight infant, with resulting cephalopelvic disproportion and, potentially, a surgical birth. Two thirds of reproductive-age women in the United States are overweight or obese and at risk for numerous adverse pregnancy outcomes, in addition to a surgical birth. Some researchers have suggested that the uterine environment may influence the potential development of offspring obesity later in life. In a recent study, just a 10% weight loss before conception, was associated with at least a 10% lower risk of preeclampsia, gestational diabetes, preterm birth, macrosomia, and still birth (Schummers et al., 2015). Dieting during pregnancy is never recommended, even for women who are obese. Severe restriction of caloric intake is associated with a decrease in birth weight. Because of the expansion of maternal blood volume and the development of fetal and placental tissues, some weight gain is essential for a healthy pregnancy. Women who gain more than the recommended weight during pregnancy and who fail to lose this weight 6 months after giving birth are at much higher risk of being obese nearly a decade later (American College of Obstetricians and Gynecologists [ACOG], 2015a). Women who are overweight when beginning a pregnancy should gain no more than 15 to 25 lb during the pregnancy, depending on their nutritional status and degree of obesity (American College of Obstetricians and Gynecologists [ACOG], 2015a).

The best way to assess whether a pregnant woman is consuming enough calories is to follow her pattern of weight gain. All pregnant women should aim for a steady rate of weight gain throughout pregnancy. If she is gaining in a steady, gradual manner, then she is taking in enough calories. However, consuming an adequate amount of calories does not guarantee that her nutrients are sufficient. It is critical to evaluate both the quantity and the quality of the foods eaten.

During the first trimester, for women whose prepregnancy weight is within the normal weight range, weight gain should be about 3.5 to 5 lb. For underweight women, weight gain should be at least 5 lb. For overweight women, weight gain

should be about 2 lb. Much of the weight gained during the first trimester is caused by growth of the uterus and expansion of the blood volume.

During the second and third trimesters, the following pattern is recommended: For women whose prepregnancy weight is within the normal weight range, weight gain should be about 1 pound per week. For underweight women, weight gain should be slightly more than 1 pound per week. For overweight women, weight gain should be about two thirds of a pound per week (Hankley, 2015).

Nutrition Promotion

Through education, nurses can play an important role in ensuring adequate nutrition for pregnant women. During the initial prenatal visit, health care providers conduct a thorough assessment of a woman's typical dietary practices and address any conditions that may cause inadequate nutrition, such as nausea and vomiting or lack of access to adequate food. Assess and reinforce dietary information at every prenatal visit to promote good nutrition. A normal pregnancy and a well-balanced diet generally provide most of the recommended nutrients except iron and folate, both of which must be supplemented in the form of prenatal vitamins. (See Teaching Guidelines 11.1.)

Teaching Guidelines 11.1

TEACHING TO PROMOTE OPTIMAL NUTRITION DURING PREGNANCY

- Follow the USDA Food Guide *MyPlate* and select a variety of foods from each group.
- Gain between 15 and 40 lb in a gradual and steady manner depending on prepregnancy weight as follows:
  - Underweight (BMI > 18.5) total weight gain range = 28–40 lb
  - Normal weight (BMI = 18.5–24.0) total weight gain range = 25–35 lb
  - Overweight (BMI = 25–29) total weight gain range = 15–25 lb
  - Obese (BMI = 30 or higher) total weight gain range = 11–20 lb (HMD, 2009).
- Take your prenatal vitamin/mineral supplementation daily.
- Avoid weight-reduction diets during pregnancy.
- Do not skip meals; eat three meals with one or two snacks daily.
- Limit the intake of sodas and caffeine-rich drinks.
- Avoid the use of diuretics during pregnancy.

- Do not restrict the use of salt unless instructed to do so by your health care provider.
- Engage in reasonable physical activity daily.

Special Nutritional Considerations

Many factors play an important role in shaping a person's food habits, and these factors must be taken into account if nutritional counseling is to be realistic and appropriate. Nurses need to be aware of these factors to ensure individualized teaching and care.

Cultural Variations and Restrictions

Food is important to every cultural group. It is often part of celebrations and rituals. When working with women from various cultures, the nurse needs to adapt American nutritional guidelines to meet their nutritional needs within their cultural framework. Food choices and variations for different cultures might include the following:

• Bread, cereal, rice, and pasta group:
  • Bolillo
  • Couscous
  • Flaxseed
  • Hau juan
• Vegetable group:
  • Agave
  • Bok choy
  • Jicama
  • Okra
  • Water chestnuts
• Protein group:
  • Bean paste
  • Blood sausage
  • Legumes
  • Shellfish
• Fruit group:
  • Catalpa

- Kumquats
- Plantain
- Yucca fruit
- Zapote
- Milk and dairy:
  - Buffalo milk
  - Buttermilk
  - Soybean milk (Academy of Nutrition and Dietetics [AND], 2015a)

EVIDENCE-BASED PRACTICE 11.1 Interventions for Nausea and Vomiting in Early Pregnancy

Nausea, retching or dry heaving, and vomiting in early pregnancy are very common and can be very distressing for women. Many treatments are available to women with 'morning sickness', including drugs and complementary and alternative therapies. Because of concerns that taking medications may adversely affect the development of the fetus, this review aimed to examine if these treatments have been found to be effective and safe.

STUDY

The purpose of this study was to assess the effectiveness and safety of all interventions for nausea and vomiting in early pregnancy, up to 20 weeks of gestation. Thirty-seven trials involving 5,049 women met the inclusion criteria. These trials covered many interventions, including acupressure, acustimulation, acupuncture, ginger, chamomile, lemon oil, mint oil, vitamin B6, and several antiemetic drugs.

Evidence regarding the effectiveness of P6 acupressure, auricular (ear) acupressure, and acustimulation of the P6 point was limited. Acupuncture (P6 or traditional) showed no significant benefit to women in pregnancy. The use of ginger products may be helpful to women, but the evidence of effectiveness was limited and not consistent, though two recent studies support ginger over placebo. There was only limited evidence from trials to support the use of pharmacological agents including vitamin B6, and anti-emetic drugs to relieve mild or moderate nausea and vomiting. There was little information on maternal and fetal adverse outcomes and on psychological, social, or economic outcomes. The methodological quality of the included studies was mixed.

Findings

This review found a lack of high-quality evidence to back up any advice on which interventions to use. Some of the studies showed a benefit in improving nausea and vomiting symptoms for women, but generally effects were inconsistent and limited. Studies were carried out in a way that meant they were at high risk of bias and, therefore, it was difficult to draw firm conclusions. Most studies had different ways of measuring the symptoms of nausea and vomiting and therefore, could not be looked at these findings together. Few studies reported maternal and fetal adverse outcomes and there was very little information on the effectiveness of treatments for improving women's quality of life.

Lactose Intolerance

The best source of calcium is milk and dairy products, but for women with lactose intolerance, adaptations are necessary. Women with lactose intolerance lack an enzyme (lactase) needed for the breakdown of lactose into its component simple sugars, glucose, and galactose. Without adequate lactase, lactose passes through the small intestine undigested and causes abdominal discomfort, gas, and diarrhea. Lactose intolerance is especially common among women of African, Asian, and Middle Eastern descent (Szilagyi, 2015).

Additional or substitute sources of calcium may be necessary. These may include peanuts, almonds, sunflower seeds, broccoli, salmon, kale, and molasses (McIndoo, 2015). In addition, encourage the woman to drink lactose-free dairy products or calcium-enriched orange juice or soy milk (Evidence-Based Practice 11.1).

Vegetarians

Vegetarian diets are becoming increasingly prevalent in the United States.

People choose a vegetarian diet for various reasons including environmental, animal rights, philosophical, religious, and health beliefs (Dunlevy, 2015). Vegetarians choose not to eat meat, poultry, and fish. Their diets consist mostly of plant-based foods, such as legumes, vegetables, whole grains, nuts, and seeds. Vegetarians fall into groups defined by the types of foods they eat. Lacto-ovo-vegetarians omit red meat, fish, and poultry, but eat eggs, milk, and dairy products in addition to plant-based foods. Lacto-vegetarians consume milk and dairy products along with plant-based foods; they omit eggs, meat, fish, and poultry. Vegans eliminate all foods from animals, including milk, eggs, and cheese, and eat only plant-based foods (Foster & Samman, 2015).

The concern with any form of vegetarianism, especially during pregnancy, is that the diet may be inadequate in nutrients. Other risks of vegetarian eating patterns during pregnancy may include low gestational weight gain, iron-deficiency anemia, compromised protein utilization, and decreased mineral absorption (Piccoli et al., 2015). A diet can become so restrictive that a woman is not gaining weight or is consistently not eating enough from one or more of the food groups. Generally, the more restrictive the diet is, the greater the chance of nutrient deficiencies.

Well-balanced vegetarian diets that include dairy products provide adequate caloric and nutrient intake and do not require special supplementation; however, vegan diets do not include any meat, eggs, or dairy products. Pregnant vegetarians must pay special attention to their intake of protein, iron, calcium, and vitamin B_{12}. Suggestions include:

• *For protein:* substitute soy foods, beans, lentils, nuts, grains, and seeds.

• *For iron:* eat a variety of meat alternatives, along with vitamin C-rich foods.

• *For calcium:* substitute soy, calcium-fortified orange juice, and tofu.

• *For vitamin B_{12}:* eat fortified soy foods and a B_{12} supplement.

The Academy of Nutrition and Dietetics (2015b), used an evidence-based review to show that well-planned vegetarian diets are appropriate for individuals during all stages of the life cycle, including pregnancy, lactation, infancy, childhood, and adolescence, and for athletes.

Pica

Pica is a term used to describe the intense craving for and eating of non-food

items. Many women experience unusual food cravings during their pregnancy. Having cravings during pregnancy is perfectly normal. Sometimes, however, women crave substances that have no nutritional value and can even be dangerous to themselves and their fetus. Pica is the compulsive ingestion of nonfood substances. Pica is derived from the Latin term for magpie, a bird that is known to consume a variety of nonfood substances. Unlike the bird, however, pregnant women who develop a pica habit typically have one or two specific cravings.

The exact cause of pica is not known. Many theories have been advanced to explain it, but none has been proven scientifically. The incidence of pica is difficult to determine, since it is underreported. It is more common in the United States among African American women compared with other ethnicities, but the practice of pica is not limited to any one geographic area, race, creed, or culture. In the United States, pica is also common in women from rural areas and women with a family history of it. Common substances ingested include dirt, clay, and laundry starch. Other pica cravings are burnt matches, stones, charcoal, mothballs, ice, cornstarch, toothpaste, soap, sand, plaster, coffee grounds, paint chips, coffee grounds, baking soda, and cigarette ashes (Jyothi, 2015).

The three main substances consumed by women with pica are soil or clay (geophagia), ice (pagophagia), and laundry starch (amylophagia). Nutritional implications include:

• *Soil:* replaces nutritive sources and causes iron-deficiency anemia.

• *Clay:* produces constipation; can contain toxic substances and cause parasitic infection.

• *Ice:* can cause iron-deficiency anemia, tooth fractures, freezer burn injuries.

• *Laundry starch:* replaces iron-rich foods, leads to iron deficiencies, and replaces protein metabolism, thus depriving the fetus of amino acids needed for proper development (American Pregnancy Association, 2015).

Clinical manifestations of anemia often precede the identification of pica because the health care provider rarely addresses the behavior and the woman does not usually volunteer such information (King et al., 2015). Secrecy surrounding this habit makes research and diagnosis difficult because some women fail to view their behavior as anything unusual, harmful, or worth reporting. Because of the clinical implications, pica should be discussed with all pregnant women as a preventive measure. The topic can be part of a general

discussion of cravings, and the nurse should stress the harmful effects outlined above.

Suspect pica when the woman exhibits anemia although her dietary intake is appropriate. Ask about her usual dietary intake, and include questions about the ingestion of nonfood substances. Consider the potential negative outcomes for the pregnant woman and her fetus, and take appropriate action.

PSYCHOSOCIAL ADAPTATIONS DURING PREGNANCY

Pregnancy is a unique time in a woman's life. It is a time of dramatic alterations in her body and her appearance, as well as a time of change in her social status. All of these changes occur simultaneously. Concurrent with the physiologic changes within her body systems are psychosocial changes within the mother and family members as they face significant role and lifestyle changes.

Maternal Emotional Responses

Motherhood, perhaps more than any role in the society, has acquired a special significance for women. Women are taught they should find fulfillment and satisfaction in the role of the "ever-bountiful, ever-giving, self-sacrificing mother." Pregnancy and transitioning to motherhood are critical experiences in a woman's life, stirring a whole range of powerful emotions (Einstein, 2015). With such high expectations, many pregnant women experience various emotions throughout their pregnancy. The woman's approach to these emotions is influenced by her emotional makeup, her sociologic and cultural background, her acceptance or rejection of the pregnancy, whether the pregnancy was planned, if the father is known, and her support network (Alexander et al., 2014).

Despite the wide-ranging emotions associated with the pregnancy, many women experience similar responses. These responses commonly include ambivalence, introversion, acceptance, mood swings, and changes in body image.

Ambivalence

The realization of a pregnancy can lead to fluctuating responses, possibly at the opposite ends of the spectrum. For example, regardless of whether the pregnancy was planned, the woman may feel proud and excited by the news, while at the same time fearful and anxious of the implications. The reactions are influenced by several factors, including the way the woman was raised, her current family situation, the quality of the relationship with the expectant father, and her hopes for the future. Some women express concern over the timing of the pregnancy, wishing that goals and life objectives had been met before becoming pregnant. Other women may question how a newborn or infant will affect their career or their relationships with friends and family. These feelings can cause conflict and confusion about the pregnancy.

Ambivalence, or having conflicting feelings at the same time, is a universal feeling and is considered normal when preparing for a lifestyle change and new role. Pregnant women commonly experience ambivalence during the first trimester. Usually ambivalence evolves into acceptance by the second trimester, when fetal movement is felt. The woman's personality, her ability to adapt to changing circumstances, and the reactions of her partner will affect her

adjustment to being pregnant and her acceptance of impending motherhood.

Introversion

Introversion, or focusing on oneself, is common during the early part of pregnancy. The woman may withdraw and become increasingly preoccupied with herself and her fetus. As a result, she may participate less with the outside world, and she may appear passive to her family and friends.

This introspective behavior is a normal psychological adaptation to motherhood for most women. Introversion seems to heighten during the first and third trimesters, when the woman's focus is on behaviors that will ensure a safe and health pregnancy outcome. Couples need to be aware of this behavior and should be informed about measures to maintain and support the focus on the family.

Acceptance

During the second trimester, the physical changes of the growing fetus, including an enlarging abdomen and fetal movement, bring reality and validity to the pregnancy. There are many tangible signs that someone separate from herself is present. The pregnant woman feels fetal movement and may hear the heartbeat. She may see the fetal image on an ultrasound screen and feel distinct parts, recognizing independent sleep and wake patterns. She becomes able to identify the fetus as a separate individual and accepts this.

Many women will verbalize positive feelings about the pregnancy and will conceptualize the fetus. The woman may accept her new body image and talk about the new life within. Generating a discussion about the woman's feelings and offering support and validation at prenatal visits are important.

Mood Swings

Emotional liability is characteristic throughout most pregnancies. One moment a woman can feel great joy, and within a short time she can feel shock and disbelief. Frequently, pregnant women will start to cry without any apparent cause. Some women feel as though they are riding an emotional "roller-coaster." These extremes in emotion can make it difficult for partners and family members to communicate with the pregnant woman without placing blame on themselves for their mood changes. Clear explanations about how common mood swings are

during pregnancy are essential.

Change in Body Image

The way in which pregnancy affects a woman's body image varies greatly from person to person. Some women feel as if they have never been more beautiful, whereas others spend their pregnancy feeling overweight and uncomfortable. For some women pregnancy is a relief from worrying about weight, whereas for others it only exacerbates their fears of weight gain. Changes in body image are normal but can be very stressful for the pregnant woman. Offering a thorough explanation and initiating discussion of the expected bodily changes may help the family to cope with them.

Becoming a Mother

Reva Rubin (1984) identified maternal tasks that a woman must accomplish to incorporate the maternal role into her personality. Accomplishing these tasks helps the expectant mother to develop her self-concept as a mother and to form a mutually gratifying relationship with her infant. These tasks are listed in Box 11.4.

BOX 11.4

BECOMING A MOTHER

- Ensuring safe passage throughout pregnancy and birth
  - Primary focus of the woman's attention
  - First trimester: woman focuses on herself, not on the fetus
  - Second trimester: woman develops attachment of great value to her fetus
  - Third trimester: woman has concern for herself and her fetus as a unit
  - Participation in positive self-care activities related to diet, exercise, and overall well-being
- Seeking acceptance of infant by others
  - First trimester: acceptance of pregnancy by herself and others
  - Second trimester: family needs to relate to the fetus as member
  - Third trimester: unconditional acceptance without rejection
- Seeking acceptance of self in maternal role to infant ("binding in")
  - First trimester: mother accepts idea of pregnancy, but not of infant
  - Second trimester: with sensation of fetal movement (quickening), mother acknowledges fetus as a separate entity within her
  - Third trimester: mother longs to hold infant and becomes tired of being pregnant
- Learning to give of oneself
  - First trimester: identifies what must be given up to assume new role
  - Second trimester: identifies with infant, learns how to delay own desires
  - Third trimester: questions her ability to become a good mother to infant

Adapted from Rubin, R. (1984). *Maternal identity and the maternal experience*. New York, NY: Springer.

Pregnancy and Sexuality

Sexuality is an important part of health and well-being. Sexual behavior modifies as pregnancy progresses, influenced by biologic, psychological, and social factors. The way a pregnant woman feels and experiences her body during pregnancy can affect her sexuality. The woman's changing shape, emotional status, fetal activity, changes in breast size, pressure on the bladder, and other discomforts of pregnancy result in increased physical and emotional demands. These can produce stress on the sexual relationship between the pregnant woman and her partner. As the changes of pregnancy ensue, many partners become confused, anxious, and fearful of how the relationship may be affected.

The sexual desire of pregnant women may change throughout the pregnancy. During the first trimester, the woman may be less interested in sex because of fatigue, nausea, and fear of disturbing the early embryonic development. During the second trimester, her interest may increase because of the stability of the pregnancy. During the third trimester, her enlarging size may produce discomfort during sexual activity (Bope & Kellerman, 2015).

Potential complications of sex during pregnancy include preterm labor, pelvic inflammatory disease, antepartum hemorrhage in placenta previa, and venous air embolism. Generally, sexual relations are generally considered safe in pregnancy. Abstinence is usually only recommended for women who are at risk for preterm labor or for antepartum hemorrhage because of placenta previa (Boynton, 2015).

A woman's sexual health is intimately linked to her own self-image. Sexual positions to increase comfort as the pregnancy progresses as well as alternative noncoital modes of sexual expression, such as cuddling, caressing, and holding, should be discussed. Giving permission to talk about and then normalizing sexuality can help enhance the sexual experience during pregnancy and, ultimately, the couple's relationship. If avenues of communication are open regarding sexuality during pregnancy, any fears and myths the couple may have can be dispelled.

Pregnancy and the Partner

Nursing care related to childbirth has expanded from a narrow emphasis on the physical health needs of the mother and infant to a broader focus on family-related social and emotional needs. One prominent feature of this family-centered approach is the recent movement toward promoting the mother–infant bond. To achieve a truly family-centered practice, nursing must make a comparable commitment to understanding and meeting the needs of the partner in the emerging family. Recent studies suggest that the partner's potential contribution to the infant's overall development has been misperceived or devalued and that the partner's ability and willingness to assume a more active role in the infant's care may have been underestimated.

Reactions to pregnancy and to the psychological and physical changes by the woman's partner vary greatly. Some enjoy the role of being the nurturer, whereas others experience alienation and may seek comfort or companionship elsewhere. Some expectant fathers may view pregnancy as proof of their masculinity and assume the dominant role, whereas others see their role as minimal, leaving the pregnancy up to the woman entirely. Each expectant partner reacts uniquely.

Emotionally and psychologically, expectant partners may undergo fewer visible changes than women, but most of these changes remain unexpressed and unappreciated (Davies, 2015). Expectant partners also experience a multitude of adjustments and concerns. Physically, they may gain weight around the middle and experience nausea and other GI disturbances—a reaction termed *couvade syndrome* that is a sympathetic response to their partner's pregnancy. They also experience ambivalence during early pregnancy, with extremes of emotions (e.g., pride and joy versus an overwhelming sense of impending responsibility).

During the second trimester of pregnancy, partners go through acceptance of their role of breadwinner, caretaker, and support person. They come to accept the reality of the fetus when movement is felt, and they experience confusion when dealing with the woman's mood swings and introspection. During the third trimester, the expectant partner prepares for the reality of this new role and negotiates what the role will be during the labor and birthing process. Many express concern about being the primary support person during labor and birth and worry how they will react when faced with their loved one in pain. Expectant partners share many of the same anxieties as their pregnant partners. However, it is uncommon for them to reveal these anxieties to the pregnant

partner or health care providers. Often, how the expectant partner responds during the third trimester depends on the state of the marriage or partnership. When the marriage or partnership is struggling, the impending increase in responsibility toward the end of pregnancy acts to drive the expectant partner further away. Often it manifests as working late, staying out late with friends, or beginning new or superficial relationships. In the stable marriage or partnership, the expectant partner who may have been struggling to find his or her place in the pregnancy now finds concrete tasks to do—for example, painting the nursery, assembling the car seat, or attending Lamaze classes.

Pregnancy and Siblings

A sibling's reaction to pregnancy is age dependent. Some children might express excitement and anticipation, whereas others might have negative reactions. A young toddler might regress in toilet training or ask to drink from a bottle again. An older school-aged child may ignore the new addition to the family and engage in outside activities to avoid the new member. The introduction of an infant into the family is often the beginning of sibling rivalry, which results from the child's fear of change in the security of the relationship with his or her parents (Jordan et al., 2014). Preparation of the siblings for the anticipated birth is imperative and must be designed according to the age and life experiences of the sibling at home. Constant reinforcement of love and caring will help to reduce the older child's fear of change and worry about being replaced by the new family member.

FIGURE 11.6 Parents preparing sibling for the birth of a new baby.

If possible, parents should include siblings in preparation for the birth of the new baby to help them feel as if they have an important role to play (Fig. 11.6). Parents must also continue to focus on the older sibling after the birth to reduce regressive or aggressive behavior toward the newborn.

Pregnancy is an extremely busy time, not only in terms of the bodily changes taking place, but tasks that must be done such as choosing a provider to care for them, preparing for the new family member in a matter of months, and making lifestyle modifications to promote the best possible pregnancy outcome. We will

explore this more in .

KEY CONCEPTS

- Pregnancy is a normal life event that involves considerable physical, psychosocial, emotional, and relationship adjustments.
- The signs and symptoms of pregnancy have been grouped into those that are subjective (presumptive) and experienced by the woman herself, those that are objective (probable) and observed by the health care provider, and those that are the positive, certain signs.
- Physiologically, almost every system of a woman's body changes during pregnancy with startling rapidity to accommodate the needs of the growing fetus. A majority of the changes are influenced by hormonal changes.
- The placenta is a unique kind of endocrine gland; it has a feature possessed by no other endocrine organ—the ability to form protein and steroid hormones.
- Occurring in conjunction with the physiologic changes in the woman's body systems are psychosocial changes occurring within the mother and family members as they face significant role and lifestyle changes.
- Commonly experienced emotional responses to pregnancy in the woman include ambivalence, introversion, acceptance, mood swings, and changes in body image.
- Reactions of expectant partners to pregnancy and to the physical and psychological changes in the woman vary greatly.
- A sibling's reaction to pregnancy is age dependent. The introduction of a new infant to the family is often the beginning of sibling rivalry, which results from the established child's fear of change in security of their relationships with their parents. Therefore, preparation of the siblings for the anticipated birth is imperative.

CHAPTER **WORKSHEET**

MULTIPLE-CHOICE QUESTIONS

1. What factors would change during a pregnancy if the hormone progesterone were reduced or withdrawn?

   a. The woman's gums would become red and swollen and would bleed easily.

   b. The uterus would contract more and peristalsis would increase.

   c. Morning sickness would increase and would be prolonged.

   d. The secretion of prolactin by the pituitary gland would be inhibited.

2. Which of the following is a presumptive sign or symptom of pregnancy?

a. Restlessness

b. Elevated mood

c. Urinary frequency

d. Low backache

3. When obtaining a blood test for pregnancy, which hormone would the nurse expect the test to measure?

a. Human chorionic gonadotropin (hCG)

b. Human placental lactogen (hPL)

c. Follicle-stimulating hormone (FSH)

d. Luteinizing hormone (LH)

4. During pregnancy, which of the following should the expectant mother reduce or avoid?

a. Raw meat or uncooked shellfish

b. Fresh, washed fruits and vegetables

c. Whole grains and cereals

d. Protein and iron from meat sources

5. A feeling expressed by most women upon learning they are pregnant is:

a. Acceptance

b. Depression

c. Jealousy

d. Ambivalence

6. Reva Rubin identified four major tasks that the pregnant woman undertakes to form a mutually gratifying relationship with her infant. What is "binding in?"

a. Ensuring safe passage through pregnancy, labor, and birth.

b. Seeking acceptance of this infant by others.

c. Seeking acceptance of self as mother to the infant.

d. Learning to give of oneself on behalf of the infant.

7. A pregnant client close to term comes in the clinic for an exam. The woman

complains about experiencing shortness of breath. The nurse knows that this complaint can be explained as the:

a. Fetus needs more oxygen now that his/her size is larger.

b. Fundus of the uterus is high and pushing the diaphragm upwards.

c. Woman is experiencing an allergic reaction because of high histamine levels.

d. Oxygen partial pressure concentration is lower in the third trimester.

8. Which of the following fish should be limited in a pregnant woman's diet because of the high mercury content?

a. Salmon

b. Cod

c. Shrimp

d. Sword fish

CRITICAL THINKING EXERCISES

1. When interviewing a woman at her first prenatal visit, the nurse asks about her feelings. The woman replies, "I'm frightened and confused. I don't know whether I want to be pregnant or not. Being pregnant means changing our whole life, and now having somebody to care for all the time. I'm not sure I would be a good mother. Plus I'm a bit afraid of all the changes that would happen to my body. Is this normal? Am I okay?"

a. How should the nurse answer this question?

b. What specific information is needed to support the client during this pregnancy?

2. Sally, age 23, is 9 weeks pregnant. At her clinic visit she says, "I'm so tired I can barely make it home from work. Then once I'm home, I don't have the energy to make dinner." She says she is so sick in the morning that she is frequently late to work and spends much of the day in the bathroom. Sally's current lab work is within normal limits.

a. What explanation can the nurse offer Sally about her discomforts?

b. What interventions can the nurse offer to Sally?

3. Bringing a new infant into the family affects the siblings. What strategies can a nurse discuss when a mother asks how to deal with this?

STUDY ACTIVITIES

1. Go to your local health department's maternity clinic and interview several women regarding their feelings and the bodily changes that have taken place since they became pregnant. Based on your findings, place them into appropriate trimesters of their pregnancy.

2. Search the Internet for information about the psychological changes that occur during pregnancy. Share information from the websites you found with your clinical group.

3. During pregnancy, the plasma volume increases by 50% but the RBC volume increases by only 25% to 33%. This disproportion is manifested as _____.

4. When a pregnant woman in her third trimester lies on her back and experiences dizziness and light-headedness, the underlying cause of this is _____.

BRINGING IT ALL TOGETHER: CASE STUDY

A 22-year-old pregnant client presents to the maternity clinic with a 4-day history of loss of appetite, constipation, and abdominal pain. She is in the first trimester of her first pregnancy and came to this country recently from India. Her mother accompanies her and answers most of the questions for her daughter. After much questioning, the mother reveals that her daughter frequently eats dirt, which is a common practice in her country.

ASSESSMENT

Examination reveals a tired-looking young woman, normal vital signs, moist pale mucous membranes, and a moderately distended abdomen. Bowel sounds are slow and faint. The fetal heart rate is within normal range.

Nursing Management During Pregnancy

KEY TERMS

alpha-fetoprotein
amniocentesis
biophysical profile (BPP)
chorionic villus sampling (CVS)
gravida
high-risk pregnancy
linea nigra
natural childbirth
para
perinatal education
preconception care

Learning Objectives

Upon completion of the chapter, you will be able to:

1. Relate the information typically collected at the initial prenatal visit.
2. Determine an appropriate reproductive life plan based on a couple's risk profile.
3. Select the assessments completed at follow-up prenatal visits.
4. Evaluate the tests used to assess maternal and fetal well-being, including nursing management for each.
5. Outline appropriate nursing management to promote maternal self-care and to minimize the common discomforts of pregnancy.
6. Examine the key components of perinatal education.

__Linda__ and her husband, Rob, are eager to start a family within the next year. They are stable in their careers and financially secure. They decide to investigate a new nurse–midwife practice associated with the local hospital, and they go for a preconception appointment. They leave their appointment overwhelmed with all the information they were given about having a healthy pregnancy.

WOW

Words of Wisdom

The secret of human touch is simple: showing a sincere liking and interest in people. Nurses need to use touch often.

INTRODUCTION

Pregnancy is a time of many physiologic and psychological changes that can positively or negatively affect the woman, her fetus, and her family. Misconceptions, inadequate information, and unanswered questions about pregnancy, birth, and parenthood are common. The ultimate goal of any pregnancy is the birth of a healthy newborn, and nurses play a major role in helping the pregnant woman and her partner achieve this goal. Ongoing assessment and education are essential.

This chapter describes the nursing management required during pregnancy. It begins with a brief discussion of preconception care and then describes the assessment of the woman at the first prenatal visit and on follow-up visits. The chapter discusses tests commonly used to assess maternal and fetal well-being, including specific nursing management related to each test. The chapter also identifies important strategies to minimize the common discomforts of pregnancy and promote self-care. Finally, the chapter discusses perinatal education, including childbirth education, birthing options, health care provider options, preparation for breast-feeding or bottle-feeding, and final preparation for labor and birth.

PRECONCEPTION CARE

Ideally, couples thinking about having a child should schedule a visit with their health care provider for preconception counseling to ensure that they are in the best possible state of health before pregnancy. **Preconception care** is the promotion of the health and well-being of a woman and her partner before pregnancy. The goal of preconception care is to identify and modify biomedical, behavioral, and social risks to a woman's health or pregnancy outcome through prevention and management interventions (Centers for Disease Control and Prevention [CDC], 2015a).

Preconception care is advocated throughout the world as a tool for improving perinatal outcomes. Preconception care should occur any time a health care provider sees a woman of reproductive age. Primary care for all women of childbearing age by nurses should include a routine assessment of a woman's reproductive goals and planning. Women who could potentially become pregnant should be assessed for preconception risks and educated about the importance of maternal health in ensuring healthy pregnancies. Women may be motivated to address modified health risks by learning about the way their present health will affect a future pregnancy. For women not intending a pregnancy soon, preconception care should focus on contraception counseling (Callegari, Ma, & Schwartz, 2015). Personal and family history, physical examination, laboratory screening, reproductive plan, nutrition, supplements, weight, exercise, vaccinations, and injury prevention should be reviewed in all women. Encourage folic acid 400 to 800 mcg per day depending on risk profile, as well as proper diet and exercise. Women should receive the influenza vaccine if planning pregnancy during flu season; the rubella and varicella vaccines if there is no evidence of immunity to these viruses; and tetanus/diphtheria/pertussis if lacking adult vaccination. Offer specific interventions to reduce morbidity and mortality for both the woman who has been identified with chronic diseases or exposed to teratogens or illicit substances and her baby. Several interventions have been proven to effectively improve pregnancy outcome when provided as preconception care. Recent research suggests that events that occur in the uterine decidua, even before a woman knows she is pregnant, may have a significant impact on fetal growth and the outcome of pregnancy. In addition, an intact immune system optimizes

placental development and function and is essential for fetal survival (Regal, Gilbert, & Burwick, 2015). New insights reveal that the early embryo is extremely sensitive to signals from gametes, trophoblastic tissue, and periconception maternal lifestyles. Also, environmental factors prior to and after conception have an enormous impact on the developing embryo and cause long-term health problems. There is a growing body of evidence that environmental factors during embryonic development can cause irreversible alteration in epigenetic markers and induce various adult diseases, such as cardiovascular, neurologic, and metabolic disorders later in life (Keytash, Jones, & Frances, 2015). With this in mind, shifting the focus on the periconception period and the very early stages of pregnancy should offer significant benefits to the health of both the mother and her infant. The overall aim should be to effectively use every pregnancy as the health care opportunity of two lifetimes (Steeggers-Theunissen & Steegers, 2015).

The CDC (2015b) formulated 10 guidelines for preconception care (see Box 12.1).

Risk Factors for Adverse Pregnancy Outcomes

Preconception care is just as important as prenatal care to reduce adverse pregnancy outcomes such as maternal and infant mortality, preterm births, and low–birth-weight infants. Adverse pregnancy outcomes constitute a major public health challenge: 13% of infants are born premature; 8.3% are born with low birth weight; 1 in 33 live births have major birth defects; and 32% of women suffer pregnancy complications (CDC, 2015c). Risk factors for these adverse pregnancy outcomes are prevalent among women of reproductive age, as demonstrated by the following statistics:

• 10% of women smoke during pregnancy, contributing to fetal addiction to nicotine.
• 7.6% consume alcohol during pregnancy, leading to fetal alcohol spectrum disorder.
• 70% of women do not take folic acid supplements, increasing the risk of neural tube defects in the newborn. Taking folic acid reduces the incidence of neural tube defects by two thirds.
• 35% of women starting a pregnancy are obese, which may increase their risk of developing hypertension, diabetes, and thromboembolic disease and may increase the need for cesarean birth.
• 3% take prescription or over-the-counter drugs that are known teratogens (substances harmful to the developing fetus).
• 5% of women have preexisting medical conditions that can negatively affect pregnancy if unmanaged (CDC, 2015d).

BOX 12.1

TEN GUIDELINES FOR PRECONCEPTION CARE

- **Recommendation 1.** Individual responsibility across the lifespan: Each woman, man, and couple should be encouraged to have a reproductive life plan.

- **Recommendation 2.** Consumer awareness: Increase public awareness of the importance of preconception health behaviors and preconception care services by using information and tools appropriate across various ages; literacy, including health literacy; and cultural/linguistic contexts.

- **Recommendation 3.** Preventive visits: As a part of primary care visits, provide risk assessment and educational and health promotion counseling to all women of childbearing age to reduce reproductive risks and improve pregnancy outcomes.

- **Recommendation 4.** Interventions for identified risks: Increase the proportion of women who receive interventions as follow-up to preconception risk screening, focusing on high-priority interventions (i.e., those with evidence of effectiveness and greatest potential impact).

- **Recommendation 5.** Interconception care: Use the interconception period to provide additional intensive interventions to women who have had a previous pregnancy that ended in an adverse outcome (i.e., infant death, fetal loss, birth defects, low birth weight, or preterm birth).

- **Recommendation 6.** Prepregnancy checkup: Offer, as a component of maternity care, one prepregnancy visit for couples and persons planning pregnancy.

- **Recommendation 7.** Health insurance coverage for women with low incomes: Increase public and private health insurance coverage for women with low incomes to improve access to preventive women's health and preconception and interconception care.

- **Recommendation 8.** Public health programs and strategies: Integrate components of preconception health into existing local public health and related programs, including emphasis on interconception interventions for women with previous adverse outcomes.

- **Recommendation 9.** Research: Increase the evidence base and promote the use of the evidence to improve preconception health.
- **Recommendation 10.** Monitoring improvements: Maximize public health surveillance and related research mechanisms to monitor preconception health.

All of the preceding factors pose risks to pregnancy and could be addressed with early interventions if the woman seeks preconception health care. Specific recognized risk factors for adverse pregnancy outcomes that fall into one or more of these categories are listed in Box 12.2.

The period of greatest environmental sensitivity and consequent risk for the developing embryo is between days 17 and 56 after conception. The first prenatal visit, which is usually a month or later after a missed menstrual period, may occur too late to affect reproductive outcomes associated with abnormal organogenesis secondary to poor lifestyle choices. In some cases, such as with unplanned pregnancies, women may delay seeking health care because they deny that they are pregnant. Thus, commonly used prevention practices may begin too late to avert the morbidity and mortality associated with congenital anomalies and low birth weight. A more global preventative strategy is needed to reduce the high rates of pregnancy complications in all populations. Securing international-level political priority for maternal and newborn care remains critical to accomplish the goal of better health for all families. All couples should take on the responsibility of developing their reproductive life plan and share it with their health care providers at office visits (Darmstadt, Shiffman, & Lawn, 2015).

What is the purpose of couples like Linda and Rob going for preconception counseling? What are the goals of preconception care for this couple? What psychological support can be offered by the nurse to this couple at this stage?

Nursing Management

In the United States, rates of maternal mortality, unintended pregnancies, low birth weight, and preterm infants continue to rise, making the need for preconception care a priority for all nurses. Traditionally, women have thought that preconception care is a single visit made before getting pregnant; however, the maximum benefits are obtained when the woman and her partner receive care throughout her reproductive years. The nurse's role is vital in identifying risk factors and encouraging healthier behaviors that potentially improve maternal and perinatal outcomes. Preconception care involves obtaining a complete health history and physical examination of the woman and her partner. Key areas include:

• immunization status of the woman;

• underlying medical conditions, such as cardiovascular and respiratory problems or genetic disorders;

• reproductive health data, such as pelvic examinations, use of contraceptives, and STIs;

• sexuality and sexual practices, such as safer-sex practices and body image issues;

• nutrition history and present status;

• lifestyle practices, including occupation and recreational activities;

• psychosocial issues such as levels of stress and exposure to abuse and violence;

• medication and drug use, including use of tobacco, alcohol, over-the-counter and prescription medications, and illicit drugs;

• support system, including family, friends, and community.

BOX 12.2

RISK FACTORS FOR ADVERSE PREGNANCY OUTCOMES

• **Isotretinoins.** Use of isotretinoins (e.g., Accutane®) in pregnancy to treat acne can result in **alcohol misuse**. No time during pregnancy is safe to drink alcohol, and harm can occur early, before a woman has realized that she is or might be pregnant. Fetal alcohol syndrome and other alcohol-related birth defects can be prevented if women cease intake of alcohol before conception.

• **Antiepileptic drugs.** Certain antiepileptic drugs are known teratogens (e.g., valproic acid). Recommendations suggest that before conception, women who are on a regimen of these drugs and who are contemplating pregnancy should be prescribed a lower dosage of these drugs.

• **Diabetes (preconception).** The threefold increase in the prevalence of birth defects among infants of women with type 1 and type 2 diabetes is substantially reduced through proper management of diabetes.

• **Folic acid deficiency.** Daily use of vitamin supplements containing folic acid (400 mcg) has been demonstrated to reduce the occurrence of neural tube defects by two thirds.

• **Hepatitis B.** Vaccination is recommended for men and women who are at risk for acquiring hepatitis B virus (HBV) infection. Preventing HBV infection in women of childbearing age prevents transmission of infection to infants and eliminates risk to the woman of HBV infection and sequelae, including hepatic failure, liver carcinoma, cirrhosis, and death.

• **HIV/AIDS.** If HIV infection is identified before conception, timely antiretroviral treatment can be administered, and women (or couples) can be given additional information that can help prevent mother-to-child transmission.

• **Rubella seronegativity.** Rubella vaccination provides protective seropositivity and prevents congenital rubella syndrome.

• **Obesity.** Adverse perinatal outcomes associated with maternal obesity include neural tube defects, preterm delivery, diabetes, cesarean section, and hypertensive and thromboembolic disease. Appropriate weight loss and

nutritional intake before pregnancy reduce these risks.

- **Sexually transmitted infections** (**STIs**)**.** *Chlamydia trachomatis* and *Neisseria gonorrhoeae* have been strongly associated with ectopic pregnancy, infertility, and chronic pelvic pain. STIs during pregnancy might result in fetal death or substantial physical and developmental disabilities, including intellectual disability and blindness. Early screening and treatment prevent these adverse outcomes.

- **Smoking.** Preterm birth, low birth weight, and other adverse perinatal outcomes associated with maternal smoking in pregnancy can be prevented if women stop smoking before or during early pregnancy. Because only 20% of women successfully control tobacco dependency during pregnancy, cessation of smoking is recommended before pregnancy.

Figure 12.1 gives a sample preconception screening tool.

This information provides a foundation for planning health promotion activities and education. For example, to have a positive impact on the pregnancy:

- ensure that the woman's immunizations are up to date;

- create a reproductive life plan to address and outline their reproductive needs;

- take a thorough history of both partners to identify any medical or genetic conditions that need treatment or a referral to specialists;

- identify history of STIs and high-risk sexual practices so they can be modified;

- complete a dietary history combined with nutritional counseling;

- gather information regarding exercise and lifestyle practices to encourage daily exercise for well-being and weight maintenance;

- stress the importance of taking folic acid to prevent neural tube defects;

- urge the woman to achieve optimal weight before a pregnancy;

- identify work environment and any needed changes to promote health;
- address substance use issues, including smoking and drugs;
- identify victims of violence and assist them to get help;
- manage chronic conditions such as diabetes and asthma;
- educate the couple about environmental hazards, including metals and herbs;
- offer genetic counseling to identify carriers;
- suggest the availability of support systems, if needed (Hurst & Linton, 2015; Templeton, 2015).

PRECONCEPTION SCREENING AND COUNSELING CHECKLIST

NAME	BIRTHPLACE	AGE

DATE: / /   ARE YOU PLANNING TO GET PREGNANT IN THE NEXT SIX MONTHS? ___ Y ___N

IF YOUR ANSWER TO A QUESTION IS YES, PUT A CHECK MARK ON THE LINE IN FRONT OF THE QUESTION. FILL IN OTHER INFORMATION THAT APPLIES TO YOU.

DIET AND EXERCISE

What do you consider a healthy weight for you?_____
___Do you eat three meals a day?
___Do you follow a special diet (vegetarian, diabetic, other)?
___Which do you drink (__ coffee __ tea __ cola __ milk __ water __ soda/pop
other_____)?
___Do you eat raw or undercooked food (meat, other)?
___Do you take folic acid?
___Do you take other vitamins daily (__ multivitamin __ vitamin A __ other)?
___Do you take dietary supplements (__ black cohosh __ pennyroyal __ other)?
___Do you have current/past problems withh eating disorders?
___Do you exercise? Type/frequency:_____

Notes:

LIFESTYLE

___Do you smoke cigarettes or use other tobacco products?
How many cigarettes/packs a day?_____
___Are you exposed to second-hand smoke?
___Do you drink alcohol?
What kind?_____How often?_____How much?_____
___Do you use recreational drugs (cocaine, heroin, ecstasy, meth/ice, other?
List:_____
___Do you see a dentist regularly?
What kind of work do you do?_____
___Do you work or live near possible hazards (chemicals, x-ray or other radiation,
lead)? List:_____
___Do you use saunas or hot tubs?

Notes:

MEDICATION /DRUGS

___Are you taking prescribed drugs (Accutane, valproic acid, blood thinners)? List
them_____
___Are you taking non-prescribed drugs?
List them:_____
___Are you using birth control pills?
___Do you get injectable contraceptives or shots for birth control?
___Do you use any herbal remedies or alternative medicine?
List:_____

NOTES:

MEDICAL/FAMILY HISTORY

Do you have or have you ever had:
___Epilepsy?
___Diabetes?
___Asthma?
___High blood pressure?
___Heart disease?
___Anemia?
___Kidney or bladder disorders?
___Thyroid disease?
___Chickenpox?
___Hepatitis C?
___Digestive problems?
___Depression or other mental health problem?
___Surgeries?
___Lupus?
___Scleroderma?
___Other conditions?
Have you ever been vaccinated for:
___Measles, mumps, rubella?
___Hepatitis B?
___Chickenpox?

NOTES:

WOMEN'S HEALTH

___Do you have any problems with your menstrual cycle?
___How many times have you been pregnant?
What was/ were the outcomes(s)?_____
___Did you have difficulty getting pregnant last time?
___Have you been treated for infertility?
___Have you had surgery on your uterus, cervix, ovaries, or tubes?
___Did you mother take the hormone DES during pregnancy?
___Have you ever had HPV, genital warts or chlamydia?
___Have you ever been treated for a sexually transmitted infection (genital herpes,
gonorrhea, syphilis, HIV/AIDS, other)? List:_____

NOTES:

GENETICS

Does your family have a history of	Or	Your partner's family
___Hemophilia?		___
___Other bleeding disorders?		___
___Tay-Sachs disease?		___
___Blood diseases (sickle cell, thalassemia, other)?		___
___Muscular dystrophy?		___
___Down syndrome/mental retardation?		___
___Cystic fibrosis?		___
___Birth defects (spine/heart/kidney)?		___

Your ethnic background is:_____
Your partner's ethnic background is: _____

NOTES:

HOME ENVIRONMENT

___Do you feel emotionally supported at home?
___Do you have help from relatives or friends if needed?
___Do you feel you have serious money/financial worries?
___Are you in a stable relationship?
___Do you feel safe at home?
___Does anyone threaten or physically hurt you?
___Do you have pets (cats, rodents, exotic animals)? List:_____
___Do have any contact with soil, cat litter, or sandboxes?

Baby preparation (if planning pregnancy):
___Do you have a place for a baby to sleep?
___Do you need any baby items?

FIGURE 12.1 Sample preconception screening tool. (Used with permission. Copyright March of Dimes.)

Nurses can act as advocates and educators, creating healthy, supportive communities for women and their partners in the childbearing phases of their lives. It is important to enter into a collaborative partnership with the woman and her partner, enabling them to examine their own health and its influence on the health of their future baby. Provide information to allow the woman and her partner to make an informed decision about having a baby, but keep in mind that this decision rests solely with the couple.

 Take Note!

Because all women of reproductive age, from menarche to menopause, benefit from preventive care, preconception care should be an integral part of that continuum (Boggess & Berggren, 2015).

Linda and Rob decide to change several aspects of their lifestyle and nutritional habits before conceiving a baby, based on advice from the nurse-midwife. They both want to lose weight, stop smoking, and increase their intake of fruits and vegetables. How will these lifestyle and dietary changes benefit Linda's future pregnancy? What other areas might need to be brought up to date to prepare for a future pregnancy?

THE FIRST PRENATAL VISIT

Once a pregnancy is suspected and, in some cases, tentatively confirmed by a home pregnancy test, the woman should seek prenatal care to promote a healthy outcome. Although the most opportune window (preconception) for improving pregnancy outcomes may be missed, appropriate nursing management starting at conception and continuing throughout the pregnancy can have a positive impact on the health of pregnant women and their unborn children.

The assessment process begins at this initial prenatal visit and continues throughout the pregnancy. The initial visit is an ideal time to screen for factors that might place the woman and her fetus at risk for problems such as preterm delivery. The initial visit also is an optimal time to begin educating the client about changes that will affect her life.

Prenatal care can be delivered in one of the two methods: individually or in a group format termed *centering*. The first method is the traditional model whereby a pregnant woman sees her health care provider at specified interims throughout her pregnancy and all visits occur on a one-to-one basis. The centering pregnancy model of group prenatal care involves groups of up to a dozen women in similar gestational ages meeting with their health care provider for 10 sessions of approximately 1.5 to 2 hours each. The centering group method has been theorized to produce better birth outcomes than traditional individually delivered prenatal care due to increased client–provider interaction, increased social support, and greater perceived empowerment (Tracy, 2014). See Evidence-Based Practice 12.1.

The International Association of Diabetes and Pregnancy Study Groups (IADPSG) recently issued recommendations on the diagnosis and classification of hyperglycemia in pregnancy. Specific recommendations for diagnosing hyperglycemic disorders in pregnancy include the following:

• At the *first prenatal visit*, measure fasting plasma glucose, HbA1c, or random plasma glucose of all women or all high-risk women based on her risk factors, weight status, and family history. Thresholds for diagnosis of overt diabetes during pregnancy are shown in Box 12.3.

• If glucose testing is not diagnostic of overt diabetes, the woman should be tested for gestational diabetes from 24 to 28 weeks of gestation with a 2-hour 75-g oral glucose tolerance test (American Diabetes Association [ADA],

2015).

Given our society's poor food choices, sedentary tendencies, obesity, increasing life stresses, and the increasing immigration of high-risk populations (Hispanic, African American, Southeast Asian, Arab, Afro-Caribbean, Mediterranean, and Native American), the incidence of gestational diabetes is growing. The American College of Obstetricians and Gynecologists (ACOG), the American Diabetes Association (ADA), and the World Health Organization (WHO) have all recommended screening at the first prenatal visit for women who are over 25 years old, overweight, have polycystic ovary syndrome, history of gestational diabetes, and a positive family history of diabetes (Satyan et al., 2015). Global guidelines for screening, diagnosis, and classification have been established, and offer the potential to stop the cycle of diabetes and obesity caused by hyperglycemia in pregnancy. Normoglycemia is the goal in all aspects of pregnancy and offers the benefits of decreased short-term and long-term complications of diabetes.

EVIDENCE-BASED PRACTICE 12.1 THE EFFECTS OF CENTERING PREGNANCY GROUP PRENATAL CARE ON GESTATIONAL AGE, BIRTH WEIGHT, AND FETAL DEMISE

STUDY

Although rates of infant mortality in the United States have declined over the last several decades, rates of preterm births (<27 weeks gestation) and low birth weight (<2,500 g) have increased. Access to quality prenatal care has demonstrated improvement of maternal and child outcomes, and may help reduce infant mortality, preterm birth, and low-weight infants. The centering group prenatal care model has been theorized to produce better birth outcomes than traditional individually delivered prenatal care due to increased patient–provider interaction, increased social support, greater perceived empowerment, and increased exposure to useful skills and information about pregnancy, birthing, and childcare.

   This study compared birth outcomes for women who received two different forms of prenatal care. The objective of this study was to examine the effects of centering prenatal care versus individually delivered prenatal care on gestational age, birth weight, and fetal demise. Samples of 6,155 women were divided into two groups—individual prenatal care and group prenatal care at five sites. The sample included women who received prenatal care at one of the five sites that offered both individual and group prenatal care.

Findings

Results indicated that women in the centering pregnancy group prenatal care, compared with women in traditional individually delivered prenatal care, had significantly longer gestational ages ($b = 0.35$, 95% CI [.29, 0.41]) and higher overall birth weights ($b = 28.6$, 95 % CI [4.8, 52.3]). Results also indicated that group-delivered prenatal care was associated with significantly and substantially lower odds of very low birth weight and fetal demise.

Nursing Implications

At present there is support to provide centering group prenatal care where possible according to guidelines. The results indicated largely beneficial effects of group prenatal care on women's birth outcomes. Health policy reforms aimed at reducing adverse birth outcomes may consider group prenatal care a promising alternative format for delivering prenatal care. Nurses should continue to encourage all women to obtain prenatal care (group or traditional) as part of their reproductive plan to enhance the outcomes of their pregnancy and all of their future children. Given the evidence of beneficial effects of centering group prenatal care and the cost implications of widespread implementation will be critical for informing state and local health policies aimed at improving maternal and perinatal health outcomes.

Adapted from Tanner-Smith, E., Steinka-Fry, K., & Lipsey, M. (2014). The effects of centering pregnancy group prenatal care on gestational age, birth weight, and fetal demise. *Maternal & Child Health Journal*, 18(4), 801–809.

Counseling and education of the pregnant woman and her partner are critical to ensure healthy outcomes for mother and her infant. Pregnant women and their partners frequently have questions, misinformation, or misconceptions about what to eat, weight gain, physical discomforts, drug and alcohol use, sexuality, and the birthing process. The nurse needs to allow time to answer questions and provide anticipatory guidance during the pregnancy and to make appropriate community referrals to meet the needs of these clients. To address these issues and foster the overall well-being of pregnant women and their fetuses, specific national health goals have been established (see *Healthy People 2020*).

Comprehensive Health History

During the initial visit, a comprehensive health history is obtained, including age, menstrual history, prior obstetric history, past medical and surgical history, psychological screening, family history, genetic screening, dietary habits, lifestyle and health practices, medication or drug use, and history of exposure to STIs (Moses, 2015a). Often, use of a prenatal history form (Fig. 12.2) is the best way to document the data collected (see Evidence-Based Practice 12.2).

The initial health history typically includes questions about three major areas: the reason for seeking care; the client's past medical, surgical, and personal history, including that of the family and her partner; and the client's reproductive history. During the history-taking process, the nurse and client establish the foundation of a trusting relationship and jointly develop a plan of care for the pregnancy. They tailor this plan to the client's lifestyle as much as possible and focus primarily on education for overall wellness during the pregnancy. The ultimate goal for the first prenatal visit is to collect baseline data about the woman and her partner and to detect any risk factors that need to be addressed to facilitate a healthy pregnancy (King et al., 2015). See *Healthy People 2020 12.1*.

HEALTHY PEOPLE 2020 • *12.1*

Objective	Nursing Significance
MICH-10 Increase the proportion of pregnant women who receive early and adequate prenatal care by 10% over *HP 2010* goal.	Will contribute to reduced rates of perinatal illness, disability, and death by helping to identify possible risk factors and implementing measures to lessen these factors that contribute to poor outcomes
MICH-12 (Developmental) Increase the proportion of pregnant women who attend a series of prepared childbirth classes.	Will contribute to a positive birthing experience because women will be prepared for what they will face; will also help in reducing pain and anxiety
MICH-13 (Developmental) Increase the proportion of mothers who achieve a recommended weight gain during their pregnancies.	Will reduce the risks associated with weight for better perinatal outcomes for mother and infant
MICH-16 Increase the proportion of women delivering a live birth who received preconception care services and practiced key recommended preconception health behaviors: • Took multivitamins/folic acid prior to pregnancy • Did not smoke prior to pregnancy • Did not drink alcohol prior to pregnancy • (Developmental) Used contraception to plan pregnancy	The risk of maternal and infant mortality and pregnancy-related complications can be reduced by increasing access to quality preconception care. This will enhance healthy birth outcomes and early identification and treatment of health.

EVIDENCE-BASED PRACTICE 12.2 ANTENATAL DIETARY EDUCATION AND SUPPLEMENTATION TO INCREASE ENERGY AND PROTEIN INTAKE

STUDY

Gestational weight gain is positively associated with fetal growth, and observational studies of food supplementation in pregnancy have reported increases in gestational weight gain and fetal growth. During pregnancy, the fetus develops based on the nutrition of the mother. Inadequate intake during pregnancy can lead to malnutrition and poor outcomes for the fetus. The objective of this study was to assess the effects of education during pregnancy to increase energy and protein intake, or of actual energy and protein supplementation, on energy and protein intake, and the effect on maternal and infant health outcomes.

Findings

The review included 17 randomized controlled trials, involving 9,030 women. Four main findings included (1) providing nutritional advice resulted in an increase in the mother's protein intake with resulting fewer preterm births and low birth weights; (2) giving mothers balanced energy and protein supplements was associated with fewer infants dying during labor and infants had an increase in birth weights; (3) high protein supplementation showed no benefit for women and potential harm for the infant with more becoming small for gestational age at birth; and (4) isocaloric protein supplementations showed no benefit for higher birth weight in the infant and weekly gestational gain for the mothers.

Nursing Implications

This review provides encouraging evidence that prenatal nutritional education with the aim of increasing energy and protein intake in the maternal population appears to be effective in reducing the risk of preterm birth, low birth weight, increasing head circumference at birth, increasing birth weight among undernourished women, and increasing protein intake. There remains question about high protein supplementation being beneficial. Nurses can continue to provide good sound evidence-based nutritional education to their pregnant clients to bring about healthy outcomes.

Reason for Seeking Care

The woman commonly comes for prenatal care based on the suspicion that she is pregnant. She may report that she has missed her menstrual period or has had a positive result on a home pregnancy test. Ask the woman for the date of her last normal menstrual period (LMP). Also ask about any presumptive or probable signs of pregnancy that she might be experiencing. Typically a urine or blood test to check for evidence of human chorionic gonadotropin (hCG) is done to confirm the pregnancy.

Past History

Ask about the woman's past medical and surgical history. This information is important because conditions that the woman experienced in the past (e.g., urinary tract infections) may recur or be exacerbated during pregnancy. Also, chronic illnesses, such as diabetes or heart disease, can increase the risk for complications during pregnancy for the woman and her fetus. Ask about any history of allergies to medications, foods, or environmental substances. Ask about any mental health problems, such as depression or anxiety. Gather similar information about the woman's family and her partner.

   The woman's personal history also is important. Ask about her occupation, possible exposure to teratogens, exercise and activity level, recreational patterns (including the use of substances such as alcohol, tobacco, and drugs), use of alternative and complementary therapies, sleep patterns, nutritional habits, and general lifestyle. Each of these may have an impact on the outcome of the pregnancy. For example, if the woman smokes during pregnancy, nicotine in the cigarettes causes vasoconstriction in the mother, leading to reduced placental perfusion. As a result, the newborn may be small for gestational age. The newborn will also go through nicotine withdrawal soon after birth. In addition, no safe level of alcohol ingestion in pregnancy has been determined. Many fetuses exposed to heavy alcohol levels during pregnancy develop fetal alcohol syndrome, a collection of deformities and disabilities.

Reproductive History

The woman's reproductive history includes a menstrual, obstetric, and gynecologic history. Typically, this history begins with a description of the woman's menstrual cycle, including her age at menarche, number of days in her

cycle, typical flow characteristics, and any discomfort experienced. The use of contraception also is important, including when the woman last used any contraception.

Establishing an accurate due date is one of the most important assessments for a pregnant woman, one that has both social and medical significance. For women and their families, this estimated due date (EDD) represents the long-awaited birthday of their child and is a time frame around which many economic and social activities are planned. This end point date provides guidance for the timing of specific maternal and fetal testing throughout pregnancy, gauges fetal growth parameters, and provides well-established timelines for specific interventions in the management of prenatal complications. In fact, critical decisions, such as preterm labor management, timing of postdate induction of labor, and identification of fetal growth restriction (FGR), are all based on the presumed gestational age of the fetus, which is calculated backwards from the EDD (Bond, 2015).

Ask the woman the date of her LMP to determine the estimated or EDD. Several methods may be used to estimate the date of birth. Nagele's rule can be used to establish the EDD (Box 12.4). Using this rule, subtract 3 months from the month of her LMP and then add 7 days to the first day of the LMP. Then correct the year by adding 1 to it where necessary. An alternative way is to add 7 days and then add 9 months = year where needed. This date has a margin of error of plus or minus 2 weeks. For instance, if a woman reports that her LMP was October 14, 2015, you would subtract 3 months (July) and add 7 days (21), then add 1 year (2016). The woman's EDD is July 21, 2016.

Because of the normal variations in women's menstrual cycles, differences in the normal length of gestation among ethnic groups, and errors in dating methods, there is no such thing as an exact due date. In general, a birth 2 weeks before or 2 weeks after the EDD is considered normal. Nagele's rule is less accurate if the woman's menstrual cycles are irregular, if the woman conceives while breast-feeding or before her regular menstrual cycle is established after childbirth, if she is ovulating although she is amenorrheic, or after she discontinues oral contraceptives (Schuiling & Likis, 2016).

A gestational or birth calculator or wheel can also be used to calculate the due date (Fig. 12.3). Some practitioners use ultrasound to more accurately determine the gestational age and date the pregnancy. Ultrasound is typically the most accurate method of dating a pregnancy.

Typically, an obstetric history provides information about the woman's past pregnancies, including any problems encountered during the pregnancy, labor,

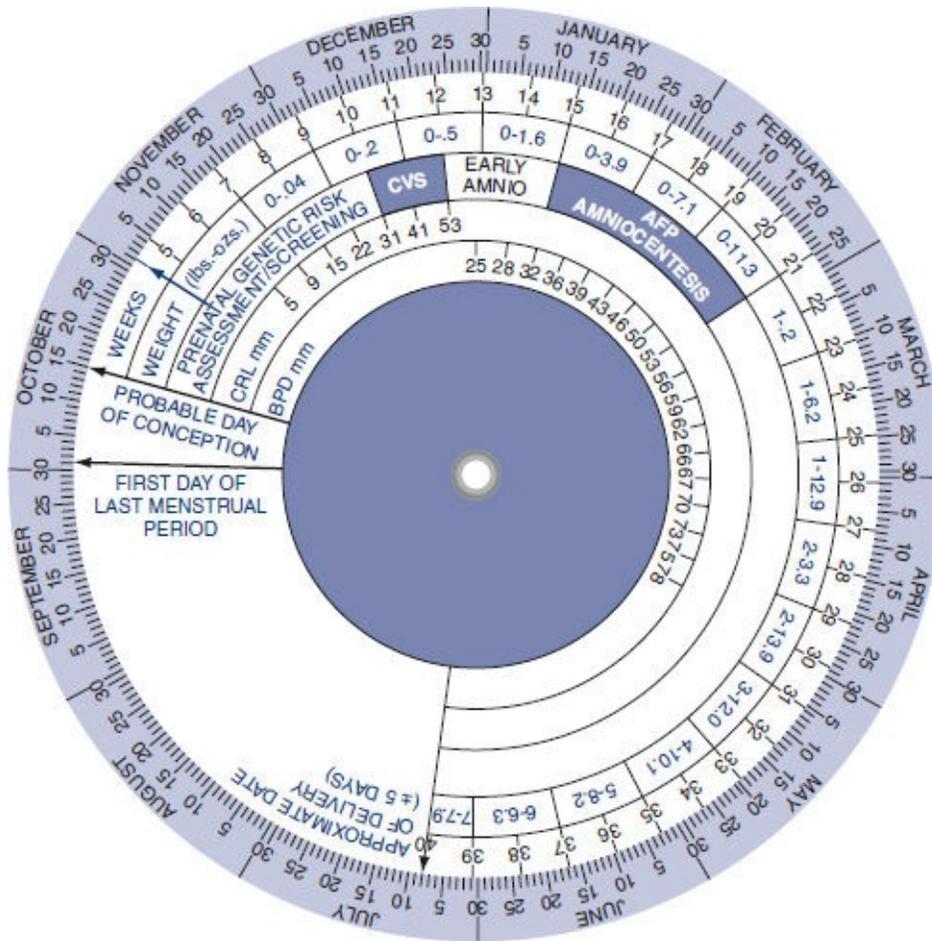
birth, and postpartum. Such information can provide clues to problems that might develop in the current pregnancy. Some common terms used to describe and document an obstetric history include gravid, **gravida**, gravida I (primigravida), gravida II (secundigravida), multigravida, and **para** (Table 12.1).


FIGURE 12.3 EDD using a birth wheel. The first day of the woman's last normal menstrual period was October 1. Using the birth wheel, her EDD would be approximately July 8 of the following year. (Used with permission. Copyright March of Dimes, 2015.)

Other systems may be used to document a woman's obstetric history. These systems often break down the category of para more specifically (Box 12.5).

Information about the woman's gynecologic history is important. Ask about any reproductive tract surgeries the woman has undergone. For example, surgery on the uterus may affect its ability to contract effectively during labor. A history of tubal pregnancy increases the woman's risk for another tubal pregnancy. Also ask about safe-sex practices and any history of STIs.

Physical Examination

The next step in the assessment process is the physical examination, which detects any physical problems that may affect the pregnancy outcome. The initial physical examination provides the baseline for evaluating changes during future visits.

OBSTETRIC HISTORY TERMS: GTPAL OR TPAL

G, gravida; T, term births; P, preterm births; A, abortions; L, living children

• G—the current pregnancy to be included in count

• T—the number of term gestations delivering between 38 and 42 weeks

• P—the number of preterm pregnancies ending >20 weeks or viability but before completion of 37 weeks

• A—the number of pregnancies ending before 20 weeks or viability

• L—the number of children currently living

Consider this example:
Mary Johnson is pregnant for the fourth time. She had one abortion at 8 weeks gestation. She has a daughter who was born at 40 weeks gestation and a son born at 34 weeks. Mary's obstetric history would be documented as follows:

• Using the gravida/para method: gravida 4, para 2

• Using the TPAL method: 1112 (T = 1 [daughter born at 40 weeks]; P = 1 [son born at 34 weeks]; A = 1 [abortion at 8 weeks]; L = 2 [two living children])

TABLE 12.1 PREGNANCY TERMS

Term	Definition
Gravid	The state of being pregnant
Gravida/ Gravidity	The total number of times a woman has been pregnant, regardless of whether the pregnancy resulted in a termination or if multiple infants were born from a pregnancy.
Nulligravida	A woman who has never experienced pregnancy
Primigravida	A woman pregnant for the first time
Secundigravida	A woman pregnant for the second time
Multigravida	A woman pregnant for at least the third time
Para	The number of times a woman has given birth to a fetus of at least 20 gestational weeks (viable or not), counting multiple births as one birth event.
Parity	Refers to the number of pregnancies, not the number of fetuses, carried to the point of viability, regardless of the outcome
Nullipara (para 0)	A woman who has not produced a viable offspring.
Primipara	A woman who has given birth once after a pregnancy of at least 20 wks, commonly referred to as a "primip" in clinical practice.
Multipara	A woman who has had two or more pregnancies of at least 20 wks gestation resulting in viable offspring. Commonly referred to as a "multip."

Preparation

Instruct the client to undress and put on a gown. Also ask her to empty her bladder and, in doing so, to collect a urine specimen. Typically this specimen is a clean-catch urine specimen that is sent to the laboratory for a urinalysis to detect a possible urinary tract infection.

Begin the physical examination by obtaining vital signs, including blood pressure, respiratory rate, temperature, and pulse. Also measure the client's height and weight. Abnormalities such as an elevated blood pressure may suggest pregestational hypertension, requiring further evaluation. Abnormalities in pulse rate and respiration require further investigation for possible cardiac or respiratory disease. If the woman weighs less than 100 pounds or more than 200 pounds or there has been a sudden weight gain, report these findings to the primary care provider; medical treatment or nutritional counseling may be necessary.

Head-to-Toe Assessment

A complete head-to-toe assessment is usually performed by the health care provider. Every body system is assessed. Some of the major areas are discussed here. Throughout the assessment, be sure to drape the client appropriately to ensure privacy and prevent chilling.

HEAD AND NECK

Assess the head and neck area for any previous injuries and sequelae. Evaluate for any limitations in range of motion. Palpate for any enlarged lymph nodes or swelling. Note any edema of the nasal mucosa or hypertrophy of gingival tissue in the mouth; these are typical responses to increased estrogen levels in pregnancy. Palpate the thyroid gland for enlargement. Slight enlargement is normal, but marked enlargement may indicate hyperthyroidism, requiring further investigation.

CHEST

Auscultate heart sounds, noting any abnormalities. A soft systolic murmur caused by the increase in blood volume may be noted. Anticipate an increase in heart rate by 10 to 15 beats per minute (bpm) (starting between 14 and 20 weeks of pregnancy) secondary to increases in cardiac output and blood volume. The

body adapts to the increase in blood volume with peripheral dilation to maintain blood pressure. Progesterone causes peripheral dilation.

Auscultate the chest for breath sounds, which should be clear. Also note symmetry of chest movement and thoracic breathing patterns. Estrogen promotes relaxation of the ligaments and joints of the ribs, with a resulting increase in the anteroposterior chest diameter. Expect a slight increase in respiratory rate to accommodate the increase in tidal volume and oxygen consumption.

Inspect and palpate the breasts and nipples for symmetry and color. Increases in estrogen and progesterone and blood supply make the breasts feel full and more nodular, with increased sensitivity to touch. Blood vessels become more visible and there is an increase in breast size. Striae gravidarum (stretch marks) may be visible in women with large breasts. Darker pigmentation of the nipple and areola is present, along with enlargement of Montgomery's glands. Colostrum (yellowish secretion that precedes mature breast milk) is excreted typically in the third trimester.

 Take Note!

Use this opportunity to reinforce and teach breast self-examination if the woman has a high-risk history.

ABDOMEN

The appearance of the abdomen depends on the number of weeks of gestation. The abdomen enlarges progressively as the fetus grows. Inspect the abdomen for striae, scars, shape, and size. Inspection may reveal striae gravidarum (stretch marks) and **linea nigra**, a thin brownish black pigmented line running from the umbilicus to the symphysis pubis, depending on the duration of the pregnancy. Palpate the abdomen, which should be rounded and nontender. A decrease in muscle tone may be noted due to the influence of progesterone.

Typically, the height of the fundus is measured when the uterus arises out of the pelvis to evaluate fetal growth. At 12 weeks gestation the fundus can be palpated at the symphysis pubis. At 16 weeks gestation the fundus is midway between the symphysis and the umbilicus. At 20 weeks the fundus can be palpated at the umbilicus and measures approximately 20 cm from the symphysis pubis. By 36 weeks the fundus is just below the xiphoid process and measures approximately 36 cm. The uterus maintains a globular/ovoid shape

throughout pregnancy (Bope & Kellerman, 2015).

EXTREMITIES

Inspect and palpate both legs for dependent edema, pulses, and varicose veins. If edema is present in early pregnancy, further evaluation may be needed to rule out gestational hypertension. During the third trimester, dependent edema is a normal finding. Ask the woman if she has any pain in her calf that increases when she ambulates. This might indicate a deep vein thrombosis (DVT). High levels of estrogen during pregnancy place women at higher risk for DVT.

Pelvic Examination

The pelvic examination provides information about the internal and external reproductive organs. In addition, it aids in assessing some of the presumptive and probable signs of pregnancy and allows for determination of pelvic adequacy. During the pelvic examination, remain in the examining room to assist the health care provider with any specimen collection, fixation, and labeling. Also provide comfort and emotional support for the woman, who might be anxious. Throughout the examination, explain what is happening and why, and answer any questions as necessary.

EXTERNAL GENITALIA

After the client is placed in the lithotomy position and draped appropriately, the external genitalia are inspected visually. They should be free from lesions, discharge, hematomas, varicosities, and inflammation upon inspection. A culture for STIs may be collected at this time.

INTERNAL GENITALIA

Next, the internal genitalia are examined via a speculum. The cervix should be smooth, long, thick, and closed. Because of increased pelvic congestion, the cervix will be softened (Goodell's sign), the uterine isthmus will be softened (Hegar's sign), and there will be a bluish coloration of the cervix and vaginal mucosa (Chadwick's sign).

The uterus typically is pear shaped and mobile, with a smooth surface. It will undergo cell hypertrophy and hyperplasia so that it enlarges throughout the pregnancy to accommodate the growing fetus.

During the pelvic examination, a Papanicolaou (Pap) smear may be obtained.

Additional cultures, such as for gonorrhea and chlamydia screening, also may be obtained. Ensure that all specimens obtained are labeled correctly and sent to the laboratory for evaluation. A rectal examination is done last to assess for lesions, masses, prolapse, or hemorrhoids.

Once the examination of the internal genitalia is completed and the speculum is removed, a bimanual examination is performed to estimate the size of the uterus to confirm dates and to palpate the ovaries. The ovaries should be small and nontender, without masses. At the conclusion of the bimanual examination, the health care provider reinserts the index finger into the vagina and the middle finger into the rectum to assess the strength and regularity of the posterior vaginal wall.

PELVIC SIZE, SHAPE, AND MEASUREMENTS

The size and shape of the women's pelvis can affect her ability to deliver vaginally. Pelvic shape is typically classified as one of the four types: gynecoid, android, anthropoid, and platypelloid. Refer to Chapter 13 for an in-depth discussion of pelvic size and shape.

Taking internal pelvic measurements determines the actual diameters of the inlet and outlet through which the fetus will pass. This is extremely important if the woman has never given birth vaginally. Taking pelvic measurements is unnecessary for the woman who has given birth vaginally before (unless she has experienced some type of trauma to the area) because vaginal delivery demonstrates that the pelvis is adequate for the passage of the fetus.

Three measurements are assessed: diagonal conjugate, true conjugate, and ischial tuberosity (Fig. 12.4). The diagonal conjugate is the distance between the anterior surface of the sacral prominence and the anterior surface of the inferior margin of the symphysis pubis (Bope & Kellerman, 2015). This measurement, usually 12.5 cm or greater, represents the anteroposterior diameter of the pelvic inlet through which the fetal head passes first. The diagonal conjugate is the most useful measurement for estimating pelvic size because a misfit with the fetal head occurs if it is too small.

The true conjugate, also called the obstetric conjugate, is the measurement from the anterior surface of the sacral prominence to the posterior surface of the inferior margin of the symphysis pubis. This diameter cannot be measured directly; rather, it is estimated by subtracting 1 to 2 cm from the diagonal conjugate measurement. The average true conjugate diameter is at least 11.5 cm (Cunningham et al., 2014). This measurement is important because it is the

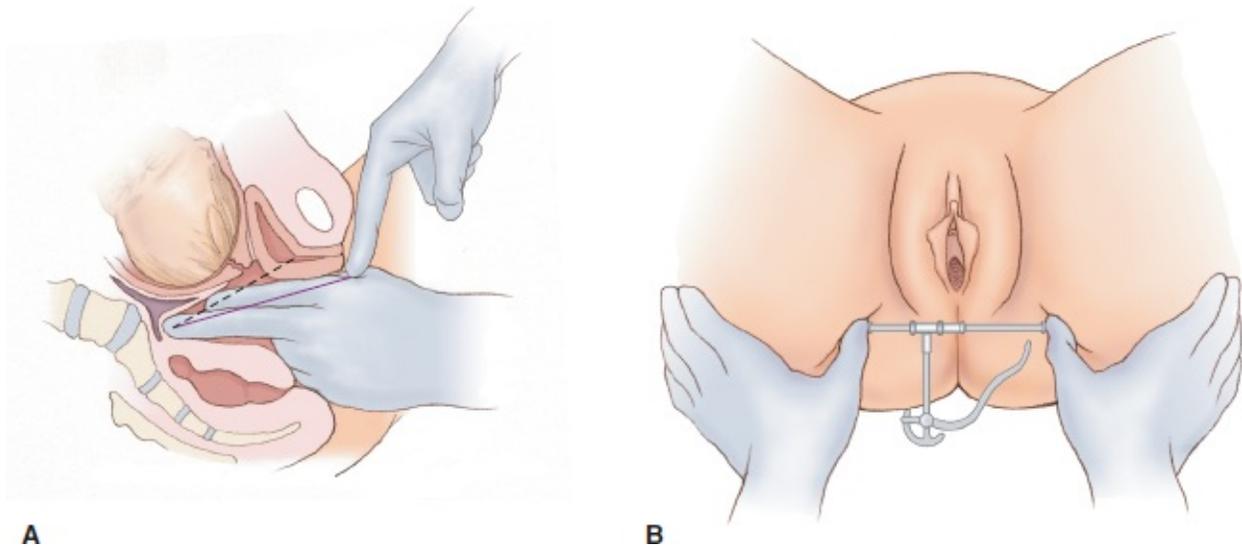
smallest front-to-back diameter through which the fetal head must pass when moving through the pelvic inlet.


FIGURE 12.4 Pelvic measurements. **A.** Diagonal conjugate (*solid line*) and true conjugate (*dotted line*). **B.** Ischial tuberosity diameter.

The ischial tuberosity diameter is the transverse diameter of the pelvic outlet. This measurement is made outside the pelvis at the lowest aspect of the ischial tuberosities. A diameter of 10.5 cm or more is considered adequate for passage of the fetal head (Tharpe, Farley, & Jordan, 2016).

Laboratory Tests

A series of tests is generally ordered during the initial visit so that baseline data can be obtained, allowing for early detection and prompt intervention if any problems occur. Tests that are generally conducted for all pregnant women include urinalysis and blood studies. The urine is analyzed for albumin, glucose, ketones, and bacteria casts. Blood studies usually include a complete blood count (CBC) (hemoglobin, hematocrit, red and white blood cell counts, and platelets), blood typing and Rh factor, glucose screening for high-risk women, a rubella titer, hepatitis B surface antibody antigen, HIV, venereal disease research laboratory (VDRL) or rapid plasma reagin (RPR) tests, and cervical smears to detect STIs (Common Laboratory and Diagnostic Tests 12.1). In addition, most offices and clinics have ultrasound equipment available to validate an intrauterine pregnancy and assess early fetal growth.

The need for additional laboratory studies is determined by a woman's history, physical examination findings, current health status, and risk factors identified in the initial interview. Additional tests can be offered (e.g., screening for genetic diseases, blood lead screening, rubeola, and so on), but ultimately the woman and her partner make the decision about undergoing them. Educate the client and her partner about the tests, including the rationale. In addition, support the client and her partner in their decision-making process, regardless of whether you agree with the couple's decision. The couple's decisions about their health care are based on the ethical principle of autonomy, which allows an individual the right to make decisions about his or her own body.

Remember Linda and Rob, the couple who want to start a family? Ten months after the preconception appointment, Linda calls to make a first prenatal appointment. What key areas will be addressed at this first prenatal visit? What interventions might be suggested for Linda to implement in order to ensure a healthy newborn? What emotional support might be needed by Linda at this time in her first trimester of pregnancy?

FOLLOW-UP VISITS

Continuous prenatal care is important for a successful pregnancy outcome. The recommended follow-up visit schedule for a healthy pregnant woman is as follows:

• Every 4 weeks up to 28 weeks (7 months)

• Every 2 weeks from 29 to 36 weeks

• Every week from 37 weeks to birth

   At each subsequent prenatal visit, the following assessments are completed:

• Weight and blood pressure, which are compared with baseline values

• Urine testing for protein, glucose, ketones, and nitrites

• Fundal height measurement to assess fetal growth

• Assessment for quickening/fetal movement to determine fetal well-being

• Assessment of fetal heart rate (should be 110 to 160 bpm)

COMMON LABORATORY AND DIAGNOSTIC TESTS 12.1

Test	Explanation
Complete blood cell count (CBC)	Evaluates hemoglobin (12–14 g) and hematocrit (42% ± 5%) levels and red blood cell count (4.2–5.4 million/mm^3) to detect the presence of anemia; identifies white blood cell level (5,000–10,000 mm^{-3}), which if elevated may indicate an infection; determines platelet count (150,000–450,000 mL^3) to assess clotting ability.
Blood typing	Determines woman's blood type and Rh status to rule out any blood incompatibility issues early; Rh-negative mother would likely receive RhoGAM (at 28 weeks gestation) and again within 72 hours after childbirth, if she is Rh sensitive.
Rubella titer	Detects antibodies for the virus that causes German measles; if titer is 1:8 or less, the woman is not immune; requires immunization after birth, and woman is advised to avoid people with undiagnosed rashes.
Hepatitis B	Determines if mother has hepatitis B by detecting presence of hepatitis antibody surface antigen (HbsAg) in her blood.
HIV testing	Detects HIV antibodies and if positive requires more specific testing, counseling, and treatment during pregnancy with antiretroviral medications to prevent transmission to fetus.
STI screening: VDRL or RPR serologic tests or by cervical smears, cultures, or visual identification of suspicious lesions	Detects STIs (such as syphilis, herpes, HPV, gonorrhea) so that treatment can be initiated early to prevent transmission to fetus.
Cervical smears	Detects abnormalities such as cervical cancer (Pap test) or infections such as gonorrhea, chlamydia, or group B streptococcus so that treatment can be initiated if positive.

Adapted from Fischbach, F., & Dunning, M. B. (2014). *A manual of laboratory and diagnostic tests* (9th ed.). Philadelphia, PA: Lippincott Williams & Wilkins; Ferri, F. F. (2014). *Ferri's best test: A practical guide to laboratory medicine and diagnostic imaging* (3rd ed.). Philadelphia, PA: Elsevier Health Sciences.

At each follow-up visit answer questions, provide anticipatory guidance and education, review nutritional guidelines, and evaluate the client for adherence to prenatal vitamin therapy. Throughout the pregnancy, encourage the woman's partner to participate if possible.

Follow-Up Visit Intervals and Assessments

Up to 28 weeks gestation, follow-up visits involve assessment of the client's blood pressure and weight. The urine is tested for protein and glucose. Fundal height and fetal heart rate are assessed at every office visit.

The best procedure for screening and diagnosing gestational diabetes remains controversial. All strategies involve an oral glucose test, but there remains disagreement about how many grams of glucose (50, 75, or 100) the woman ingests and how long afterwards, her blood sample is drawn. A recent *Cochrane Review* concluded that there was insufficient evidence to permit assessment of which is the best method to use to identify women who have gestational diabetes (Farrar et al., 2015). Screening for gestational diabetes is best done between 24 and 28 weeks gestation, unless screening is warranted in the first trimester for high-risk reasons (obesity, >25 years old, family history of diabetes, history of gestational diabetes, or woman is of a certain ethnic group: Hispanic, Native Americans, Asian, or African American) (U.S. Preventive Services Task Force [USPSTF], 2015). Between weeks 24 and 28, a blood glucose level is obtained using an oral 50-g glucose load followed by a 1-hour plasma glucose determination. If the result is more than 130 (ADA) to140 (ACOG) mg/dL, further testing, such as a 3-hour 100-g glucose tolerance test, is warranted to determine whether gestational diabetes is present (Farrar et al., 2015). Because insulin resistance increases as pregnancy advances, testing at this gestational point yields a higher rate of abnormal test results.

During this time, review the common discomforts of pregnancy, evaluate any client complaints, and answer questions. Reinforce the importance of good nutrition and use of prenatal vitamins, along with daily exercise.

Between 29 and 36 weeks gestation, all the assessments of previous visits are completed, along with assessment for edema. Special attention is focused on the presence and location of edema during the last trimester. Pregnant women commonly experience dependent edema of the lower extremities from constriction of blood vessels secondary to the heavy gravid uterus. Periorbital edema around the eyes, edema of the hands, and pretibial edema (edema on the front, or shin part of the leg) are abnormal and could be signs of gestational hypertension. Inspecting and palpating both extremities, listening for complaints of tight rings on fingers, and observing for swelling around the eyes are important assessments. Abnormal findings in any of these areas need to be

reported.

If the mother is Rh negative, her antibody titer is evaluated. RhoGAM is given if indicated. RhoGAM is used to prevent development of antibodies to Rh$^+$ red cells whenever fetal cells are known or suspected of entering the maternal circulation such as after a spontaneous abortion or amniocentesis. It is also recommended for prophylaxis at 28 weeks gestation and following birth if the infant is Rh$^+$ (King et al., 2015). The client also is evaluated for risk of preterm labor. At each visit, ask if she is experiencing any common signs or symptoms of preterm labor (e.g., uterine contractions, dull backache, feeling of pressure in the pelvic area or thighs, increased vaginal discharge, menstrual-like cramps, vaginal bleeding). If the woman has had a previous preterm birth, she is at risk for another and close monitoring is warranted. An initial preterm labor evaluation if the woman reports signs and symptoms of preterm labor includes: review of prenatal record for risk factors, evaluation of reported symptoms (uterine contractions, vital signs, fetal heart rate, pelvic exam for cervical dilation and effacement assessment, and status of fetal membranes), and a urine culture to diagnose asymptomatic bacteriuria (Jordan et al., 2014). If positive for preterm labor, the woman may be requested to rest and medications to stop contractions may be in order.

Counsel the woman about choosing a health care provider for the newborn, if she has not selected one yet. Along with completion of a breast assessment, the nurse should discuss and educate the client about the choice of breast-feeding versus bottle-feeding. The American Academy of Pediatrics (AAP) does encourage all mothers to breast-feed their offspring, but the decision to do so is the woman's ultimately. The nurse can refer the client to *Nursing Mothers* and *La Leche League* web sites for further information to assist her in making that decision. Reinforce the importance of daily fetal movement monitoring as an indicator of fetal well-being. Re-evaluate hemoglobin and hematocrit levels to assess for anemia.

Between 37 and 40 weeks gestation, the same assessments are done as for the previous weeks. In addition, screening for group B streptococcus, gonorrhea, and chlamydia is done. Fetal presentation and position (via Leopold's maneuvers) are assessed. Review the signs and symptoms of labor and forward a copy of the prenatal record to the hospital labor department for future reference. Review the client's desire for family planning after birth as well as her decision to breast-feed or bottle-feed. Remind the client that an infant car seat is required by law and must be used to drive the newborn home from the hospital or birthing center.

Fundal Height Measurement

Fundal height is the distance (in centimeters) measured with a tape measure from the top of the pubic bone to the top of the uterus (fundus) with the client lying on her back with her knees slightly flexed (Fig. 12.5). Measurement in this way is termed the McDonald's method. Fundal height typically increases as the pregnancy progresses; it reflects fetal growth and provides a gross estimate of the duration of the pregnancy.

Between 12 and 14 weeks gestation, the fundus can be palpated above the symphysis pubis. The fundus reaches the level of the umbilicus at approximately 20 weeks and measures 20 cm. Fundal measurement should approximately equal the number of weeks of gestation until week 36. For example, a fundal height of 24 cm suggests a fetus at 24 weeks gestation. After 36 weeks, the fundal height then drops due to lightening and may no longer correspond with the week of gestation.

It is expected that the fundal height will increase progressively throughout the pregnancy, reflecting fetal growth. However, if the growth curve flattens or stays stable, it may indicate the presence of FGR. If the fundal height measurement is greater than 4 cm from the estimated gestational age, further evaluation is warranted if a multifetal gestation has not been diagnosed or hydramnios has not been ruled out (Weber & Kelley, 2014).

FIGURE 12.5 Fundal height measurement.

Fetal Movement Determination

Perception of fetal movement typically begins in the second trimester, and occurs earlier in multiparous women versus nulliparous women. The mother's first perception of fetal movement, termed "quickening," is commonly described as a gentle fluttering. This perceived fetal movement is most often related to trunk and limb motion and rollovers, or flips (Moses, 2015b). Maternal perception of fetal movement is an important screening method for fetal well-being, because decreased fetal movement is associated with a range of pregnancy pathologies and poor pregnancy outcomes. Decreased fetal movement may indicate asphyxia and FGR. If compromised, the fetus decreases its oxygen requirements by decreasing activity. Reduced fetal movement is thought to represent fetal compensation in a chronic hypoxic environment due to inadequacies in the placental supply of oxygen and nutrients (Fretts, 2014). A decrease in fetal movement may also be related to other factors as well, such as maternal use of central nervous system depressants, fetal sleep cycles, hydrocephalus, bilateral renal agenesis, stillbirth, placental dysfunction, and bilateral hip dislocation (Heazell, 2015).

Fetal movement counting is a method used by the mother to quantify her fetus's movement. However, the optimal number of movements and the ideal duration of counting them remain controversial. Many variations for determining fetal movement, also called fetal movement counts, have been developed, but the one most common method is described as follows. Determining fetal movement is a noninvasive method of screening and can be easily taught to all pregnant women. Any technique used requires client participation and cooperation.

Instruct the client about how to count fetal movements, the reasons for doing so, and the significance of decreased fetal movements. Urge the client to perform the counts in a relaxed environment and a comfortable position, such as semi-Fowler's or side-lying. Provide the client with detailed information concerning fetal movement counts and stress the need for consistency in monitoring (at approximately the same time each day) and the importance of informing the health care provider promptly of any reduced movements. Providing clients with "fetal kick count" charts to record movement helps promote adherence to your instructions. No values for fetal movement have been established that indicate fetal well-being, so the woman needs to be aware of a decrease in the number of movements when last assessed. The most common method used is "Count to

10," whereby a woman focuses her attention on her fetus's movement and records how long it takes to document 10 movements. If it takes longer than 2 hours, the woman should contact her health care provider for further evaluation. Fetal kick counting in current prenatal care appears to be underutilized and nurses need to educate women about this assessment in their pregnancy care.

Fetal Heart Rate Measurement

Fetal heart rate measurement is integral to fetal surveillance throughout the pregnancy. Auscultating the fetal heart rate with a handheld Doppler at each prenatal visit helps confirm that the intrauterine environment is still supportive to the growing fetus. The purpose of assessing fetal heart rate is to determine the rate and rhythm. The normal fetal heart rate range is 110 to 160 bpm. Nursing Procedure 12.1 lists the steps in measuring fetal heart rate.

NURSING PROCEDURE 12.1

Measuring Fetal Heart Rate

Purpose: To Assess Fetal Well-Being

1. Assist the woman onto the examining table and have her lie down.

2. Cover her with a sheet to ensure privacy, and then expose her abdomen.

3. Palpate the abdomen to determine the fetal lie, position, and presentation.

4. Locate the back of the fetus (the ideal position to hear the heart rate).

5. Apply lubricant gel to abdomen in the area where the back has been located.

6. Turn on the handheld Doppler device and place it on the spot over the fetal back.

7. Listen for the sound of the amplified heart rate, moving the device slightly from side to side as necessary to obtain the loudest sound. Assess the woman's pulse rate and compare it to the amplified sound. If the rates appear the same, reposition the Doppler device.

8. Once the fetal heart rate has been identified, count the number of beats in 1 minute and record the results.

9. Remove the Doppler device and wipe off any remaining gel from the woman's abdomen and the device.

10. Record the heart rate on the woman's medical record; normal range is 110 to 160 bpm.

11. Provide information to the woman regarding fetal well-being based on findings.

Teaching About the Danger Signs of Pregnancy

It is important to educate the client about danger signs during pregnancy that require further evaluation. Explain that she should contact her health care provider immediately if she experiences any of the following:

• *During the first trimester:* spotting or bleeding (miscarriage), painful urination (infection), severe persistent vomiting (hyperemesis gravidarum), fever >100 °F (37.7 °C; infection), and lower abdominal pain with dizziness and accompanied by shoulder pain (ruptured ectopic pregnancy)

• *During the second trimester:* regular uterine contractions (preterm labor); pain in calf, often increased with foot flexion (blood clot in deep vein); sudden gush or leakage of fluid from vagina (premature rupture of membranes); and absence of fetal movement for more than 12 hours (possible fetal distress or demise)

• *During the third trimester:* sudden weight gain; periorbital or facial edema, severe upper abdominal pain, or headache with visual changes (gestational hypertension and/or preeclampsia); and a decrease in fetal daily movement for more than 24 hours (possible demise). Any of the previous warning signs and symptoms can also be present in this last trimester (March of Dimes, 2015a).

Early Contractions

One of the warning signs that should be emphasized is early contractions, which can lead to preterm birth. The woman should not confuse these early preterm contractions with Braxton Hicks contractions, which are not true labor pains because they go away when walking around or resting. They often go away when the woman goes to sleep. Braxton Hicks contractions are usually felt in the abdomen versus in the lower back with true preterm labor contractions. Signs of preterm labor that a woman may experience include contractions every 10 minutes or more frequently, change in vaginal discharge, pelvic pressure, low, dull backache, pelvic cramps, and diarrhea (Nagtalon-Ramos, 2014).

All pregnant women need to be able to recognize early signs of contractions to prevent preterm labor, which is a major public health problem in the United States. Approximately 12% of all live births—or one out of nine infants —is born too soon. Our nation's rate of premature births has increased by 36% over the last 25 years. Worldwide, 15 million infants are born too soon each year

(March of Dimes, 2015b). These preterm infants (born at less than 37 weeks gestation) can suffer lifelong health consequences such as intellectual disability, chronic lung disease, cerebral palsy, seizure disorders, and blindness (March of Dimes, 2015c). Preterm labor can happen to any pregnant women at any time. In many cases it can be stopped with medications if it is recognized early, before significant cervical dilation has taken place. If the woman experiences menstrual-like cramps occurring every 10 minutes accompanied by a low, dull backache, she should stop what she is doing and lie down on her left side for 1 hour and drink two or three glasses of water. If the symptoms worsen or do not subside after 1 hour, she should contact her health care provider.

ASSESSMENT OF FETAL WELL-BEING

During the antepartum period, several tests are performed routinely to monitor fetal well-being and to detect possible problems. When a high-risk pregnancy is identified, additional antepartum testing can be initiated to promote positive maternal, fetal, and neonatal outcomes. **High-risk pregnancies** include those that are complicated by maternal or fetal conditions (coincidental with or unique to pregnancy) that jeopardize the health status of the mother and put the fetus at risk for uteroplacental insufficiency, hypoxia, and death (CDC, 2015d). However, additional antepartum fetal testing should take place only when the results obtained will guide future care, whether it is reassurance, more frequent testing, admission to the hospital, or the need for immediate delivery (Brown, 2015).

Ultrasonography

Since its introduction in the late 1950s, ultrasonography has become a very useful diagnostic tool in obstetrics. Real-time scanners can produce a continuous picture of the fetus on a monitor screen. A transducer that emits high-frequency sound waves is placed on the mother's abdomen and moved to visualize the fetus (Fig. 12.6). The fetal heartbeat and any malformations in the fetus can be assessed and measurements can be made accurately from the picture on the monitor screen.

Obstetric ultrasound is a standard component of prenatal care used to identify pregnancy complications and to establish an accurate gestational age in order to improve pregnancy outcomes. Because the ultrasound procedure is noninvasive, it is a safe, but not evidence-based practice for low-risk women, accurate, and cost-effective tool. It provides important information about fetal activity, growth, and gestational age; assesses fetal well-being; and determines the need for invasive intrauterine tests (Maeda, 2015).

There are no hard-and-fast rules as to the number of ultrasounds a woman should have during her pregnancy. A low-risk woman does not necessarily require any, but most practices do them as part of their prenatal care routine. A transvaginal ultrasound may be performed in the first trimester to confirm pregnancy, exclude ectopic (in which a fertilized egg implants somewhere other than the main cavity of the uterus) or molar (hydatidiform mole, a benign tumor that develops in the uterus) pregnancies, and confirm cardiac pulsation. A second abdominal scan may be performed at about 18 to 20 weeks to look for congenital malformations, exclude multifetal pregnancies, and verify dates and growth. A third abdominal scan may be done at around 34 weeks to evaluate fetal size, assess fetal growth, and verify placental position (Everett & Peebles, 2015). An ultrasound is used to confirm placental location during amniocentesis and to provide visualization during chorionic villus sampling (CVS). An ultrasound is also ordered whenever an abnormality is suspected.

FIGURE 12.6 Ultrasound. **A.** Ultrasound device being applied to client's abdomen. **B.** View of monitor.

During the past several years, ultrasound technology has advanced significantly. Now available for expecting parents is 3D/4D ultrasound imaging. Unlike traditional 2D imaging, which takes a look at the developing fetus from one angle (thus creating the "flat" image), 3D imaging takes a view of the fetus from three different angles. Software then takes these three images and merges them to produce a 3D image. Because the fourth dimension is time and movement, with 4D parents are able to watch the live movements of their fetus in 3D.

Nursing management during the ultrasound procedure focuses on educating the woman about the ultrasound test and reassuring her that she will not experience any sensation from the sound waves during the test. No special client preparation is needed before performing the ultrasound, although in early pregnancy the woman may need to have a full bladder. Inform her that she may experience some discomfort from the pressure on the full bladder during the scan, but it will last only a short time. Tell the client that the conducting gel used on the abdomen during the scan may feel cold initially.

Doppler Flow Studies

Comprehensive assessment of fetal well-being involves monitoring of fetal growth, placental function, central venous pressure, and cardiac function. Ultrasound evaluation of the fetus using 2D, color Doppler, and pulse-wave Doppler techniques forms the foundation of prenatal diagnosis of structural anomalies, rhythm abnormalities, and altered fetal circulation (Pruetz, Votava-Smith, & Miller, 2015). Doppler flow studies can be used to measure the velocity of blood flow via ultrasound. Doppler flow studies can detect fetal compromise in high-risk pregnancies. The test is noninvasive and has no contraindications. The color images produced help to identify abnormalities in diastolic flow within the umbilical vessels. The velocity of the fetal red blood cells can be determined by measuring the change in the frequency of the sound wave reflected off the cells. Thus, Doppler flow studies can detect the movement of red blood cells in vessels (Everett & Peebles, 2015). In pregnancies complicated by hypertension or FGRs, diastolic blood flow may be absent or even reversed (Alfirevic, Stampalija, & Medley, 2015). Doppler flow studies also can be used to evaluate the blood flow through other fetal blood vessels, such as the aorta and those in the brain. Research continues to determine the indications for Doppler flow studies to improve pregnancy outcomes. Nursing management of the woman undergoing Doppler flow studies is similar to that described for an ultrasound.

Alpha-Fetoprotein Analysis

Alpha-fetoprotein (AFP) is a glycoprotein produced initially by the yolk sac and fetal gut, and later predominantly by the fetal liver. In a fetus, the serum AFP level increases until approximately 14 to 15 weeks, and then falls progressively. In normal pregnancies, AFP from fetal serum enters the amniotic fluid (in microgram quantities) through fetal urination, fetal gastrointestinal secretions, and transudation across fetal membranes (amnion and placenta). About 30 years ago, elevated levels of maternal serum AFP or amniotic fluid AFP were first linked to the occurrence of fetal neural tube defects. This biomarker screening test is now recommended for all pregnant women along with other prenatal screening test depending on risk profile (ACOG, 2015b; Alexander et al., 2014).

AFP is present in amniotic fluid in low concentrations between 10 and 14 weeks of gestation and can be detected in maternal serum beginning at approximately 12 to 14 weeks of gestation (Callahan, 2016). If a developmental defect is present, such as failure of the neural tube to close, more AFP escapes into amniotic fluid from the fetus. AFP then enters the maternal circulation by crossing the placenta, and the level in maternal serum can be measured. The optimal time for AFP screening is 16 to 18 weeks of gestation. Currently, ACOG recommends offering screening and diagnostic tests to all pregnant women, regardless of age or risk factors present (2015b). Correct information about gestational dating, maternal weight, race, number of fetuses, and insulin dependency is necessary to ensure the accuracy of this screening test. If incorrect maternal information is submitted or the blood specimen is not drawn during the appropriate time frame, false-positive results may occur, increasing the woman's anxiety. Subsequently, further testing might be ordered based on an inaccurate interpretation, resulting in additional financial and emotional costs to the woman.

A variety of situations can lead to elevation of maternal serum AFP, including open neural tube defect, underestimation of gestational age, the presence of multiple fetuses, gastrointestinal defects, low birth weight, oligohydramnios, maternal age, diabetes, and decreased maternal weight (King et al., 2015). Lower-than-expected maternal serum AFP levels are seen when fetal gestational age is overestimated or in cases of fetal death, hydatidiform mole, increased maternal weight, maternal type 1 diabetes, and fetal trisomy 21 (Down syndrome) or trisomy 18 (Edward's syndrome) (Khalil & Coates, 2015).

Measurement of maternal serum AFP is minimally invasive, requiring only a venipuncture for a blood sample. AFP has now been combined with other biomarker screening tests to determine the risk of neural tube defects and Down syndrome.

Nursing management for AFP testing consists of preparing the woman for this screening test by gathering accurate information about the date of her LMP, weight, race, and gestational dating. Accurately determining the window of 16 to 18 weeks gestation will help to ensure that the test results are correct. Also explain that the test involves obtaining a blood specimen.

Marker Screening Tests

Using maternal serum is an effective, noninvasive method for identifying fetal risk for aneuploidy (trisomies 13, 18, and 21) and neural tube defects. Prenatal screening for Down syndrome in the early second trimester with multiple maternal serum markers has been available for more than 15 years. Abnormalities in maternal serum marker levels and fetal measurements obtained during the first trimester screening can be markers for not only certain chromosomal disorders and anomalies in the fetus, but also for specific pregnancy complications. Pregnancy-associated plasma protein A (PAPP-A) is a key regulator of insulin-like growth factor essential for normal fetal development. In maternal blood, this protein increases with gestational age. It is routinely used for Down syndrome screening in the first trimester. A low maternal serum PAPP-A, at 11 to 13 weeks of gestation, is associated with stillbirth, infant death, preterm birth, preeclampsia, and chromosomal abnormalities (Kalousová, Muravská, & Zima, 2014; Patil, Panchanadikar, & Wagh, 2014). Multiple blood screening tests may be used to determine the risk of open neural tube defects and Down syndrome: the triple-marker screen (AFP, hCG, and unconjugated estriol) or the quad screen, which includes the triple screening tests with the addition of a fourth marker, inhibin A (glycoprotein secreted by the placenta). The quad screen is used to enhance the accuracy of screening for Down syndrome in women younger than 35 years of age. Low inhibin A levels indicate the possibility of Down syndrome (ACOG, 2015b). These biomarkers are merely screening tests and identify women who need further definitive procedures (i.e., ultrasound, amniocentesis, and genetic counseling) to make a diagnosis of neural tube defects (anencephaly, spina bifida, and encephalocele) or Down syndrome in the fetus. Most screening tests are performed between 15 and 22 weeks of gestation (16 to 18 weeks is ideal), except for the cffDNA test which can be performed around 9 to 10 weeks gestation (Dempsey & Overton, 2015).

With these multiple screening tests, low maternal serum AFP (MSAFP), unconjugated estriol levels, and a high hCG level suggest the possibility of Down syndrome. Elevated levels of MSAFP are associated with open neural tube defects, ventral wall defects, some renal abnormalities, multiple gestation, certain skin disorders, fetal demise, and placental abnormality. The multiple marker combination with the highest screening performance currently available

is AFP, unconjugated estriol (uE3), hCG, and inhibin A, together with maternal age (the so-called quad marker test). With this combination, a detection rate of 80% at a 5% false-positive rate is achieved (Hixson et al., 2015).

A number of factors influence the interpretation of an MSAFP value. The most important is the accuracy of the gestational age determination. A variation of 2 weeks can be misleading and lead to a wrong interpretation. Maternal weight (>250 pounds), ethnicity, maternal smoking habits, fetal gender, gravidity, para status, and women with insulin-dependent diabetes also may alter the levels of MSAFP and need to be taken into consideration when interpreting the results (Latendresse & Deneris, 2015). Recent research studies indicate prenatal testing with the use of cell free DNA (cfDNA) has significantly lower false positives and high positive predictive values for detection of trisomies than standard testing (Greeley, Kessler, & Vohra, 2015).

Nursing Management

Accurate test interpretation and risk determination are dependent on accurate pregnancy dating and reporting of relevant maternal characteristics. This is why it is so important for nurses, if an abnormal test result is reported, for them to confirm pregnancy dating and report any significant maternal factors relevant to test accuracy. In addition, nurses have a big role in providing education about the tests to the couples. Prenatal screening has become standard in prenatal care. However, for many couples it remains confusing, emotionally charged, and filled with uncertain risks. Offer a thorough explanation of the test, reinforcing the information given by the health care professional. Provide couples with a description of the risks and benefits of performing these screens, emphasizing that these tests are for screening purposes only. Remind the couple that a definitive diagnosis is not made without further tests such as an amniocentesis. Answer any questions about these prenatal screening tests and respect the couple's decision if they choose not to have them done. Many couples may choose not to know because they would not consider having an abortion regardless of the test results.

Nuchal Translucency Screening

Nuchal translucency screening (ultrasound) is also done in the first trimester between 11 and 14 weeks. This allows for early detection and diagnosis of some fetal chromosomal and structural abnormalities. Over the years, it has become clear that increased nuchal translucency is a marker for chromosomal abnormalities, and is also associated with a wide spectrum of structural anomalies, genetic syndromes, and high risk of abortion and fetal death (Rayburn, Jolley, & Simpson, 2015). Ultrasound is used to identify an increase in nuchal translucency, which is due to the subcutaneous accumulation of fluid behind the fetal neck. Increased nuchal translucency is associated with chromosomal abnormalities such as trisomies 21, 18, and 13. Infants with trisomies tend to have more collagen and elastic connective tissue, allowing for accumulation. In addition, diaphragmatic hernias, cardiac defects, and fetal skeletal and neurologic abnormalities have been associated with increased nuchal translucency measurements (Evans, Andriole, & Evans, 2015). See Chapter 10 for more information.

Amniocentesis

Amniocentesis involves a transabdominal puncture of the amniotic sac to obtain a sample of amniotic fluid for analysis. The fluid contains fetal cells that are examined to detect chromosomal abnormalities and several hereditary metabolic defects in the fetus before birth. In addition, amniocentesis is used to confirm a fetal abnormality when other screening tests detect a possible problem.

Amniocentesis is performed in the second trimester, usually between 15 and 18 weeks gestation. At this age, the amount of fluid is adequate (approximately 150 mL), and the ratio of viable to nonviable cells is the greatest (Hehir, Dalrymple, & Malone, 2015). More than 40 different chromosomal abnormalities, inborn errors of metabolism, and neural tube defects can be diagnosed with amniocentesis. It can replace a genetic probability with a diagnostic certainty, allowing the woman and her partner to make an informed decision about the option of therapeutic abortion.

Amniocentesis can be performed in any of the three trimesters of pregnancy. An early amniocentesis (performed between weeks 11 and 14) is done to detect genetic anomalies. However, early amniocentesis has been associated with a high risk of spontaneous miscarriage and postprocedural amniotic fluid leakage compared with transabdominal chorionic villus screening (King et al., 2015).

In the second trimester, the procedure is performed between 15 and 20 weeks to detect chromosomal abnormalities, evaluate the fetal condition when the woman is sensitized to the Rh-positive blood, diagnose intrauterine infections, and investigate amniotic fluid AFP when the MSAFP level is elevated (March of Dimes, 2015d).

In the third trimester, amniocentesis is most commonly indicated to determine fetal lung maturity after the 35th week of gestation via analysis of lecithin-to-sphingomyelin ratios and to evaluate the fetal condition with Rh isoimmunization. Table 12.2 lists amniotic fluid analysis findings and their implications.

Procedure

Amniocentesis is performed after an ultrasound examination identifies an adequate pocket of amniotic fluid free of fetal parts, the umbilical cord, or the placenta (Fig. 12.7). The health care provider inserts a long pudendal or spinal

needle, a 22-gauge, 5-inch needle, into the amniotic cavity and aspirates amniotic fluid, which is placed in an amber or foil-covered test tube to protect it from light. When the desired amount of fluid has been withdrawn, the needle is removed and slight pressure is applied to the site. If there is no evidence of bleeding, a sterile bandage is applied to the needle site. The specimens are then sent to the laboratory immediately for the cytologist to evaluate.

Examining a sample of fetal cells directly produces a definitive diagnosis rather than a "best guess" diagnosis based on indirect screening tests. It is an invaluable diagnostic tool, but the risks include lower abdominal discomfort and cramping that may last up to 48 hours after the procedure, spontaneous abortion (1 in 200), maternal or fetal infection, postamniocentesis chorioamnionitis that has an insidious onset, fetal–maternal hemorrhage, leakage of amniotic fluid in 2% to 3% of women after the procedure, and higher rates of fetal loss in earlier amniocentesis procedures (<15 weeks gestation) versus later ones (Akolekar et al., 2015). Obtaining the test results may take up to 3 weeks. Women today are choosing noninvasive prenatal testing rather than undergoing invasive testing such as amniocentesis or CVS despite those tests not being 100% correct. Women with reassuring noninvasive results and normal ultrasound findings seem satisfied over the risk of procedure-related pregnancy loss (Biswas & Choolani, 2015). The number of invasive procedures has declined since the availability of noninvasive prenatal testing, and it is predicted that they will replace the more invasive procedures in the future.

TABLE 12.2 AMNIOTIC FLUID ANALYSIS AND IMPLICATIONS

Test Component	Normal Findings	Fetal Implications of Abnormal Findings
Color	Clear with white flecks of vernix caseosa in a mature fetus	Blood of maternal origin is usually harmless. "Port wine" fluid may indicate abruptio placentae. Fetal blood may indicate damage to the fetal, placental, or umbilical cord vessels.
Bilirubin	Absent at term	High levels indicate hemolytic disease of the neonate in isoimmunized pregnancy.
Meconium	Absent (except in breech presentation)	Presence indicates fetal hypotension or distress.
Creatinine	More than 2 mg/dL in a mature fetus	Decrease may indicate immature fetus (less than 37 wks).
Lecithin-to-sphingomyelin ratio (L/S ratio)	More than 2 generally indicates fetal pulmonary maturity.	A ratio of less than 2 indicates pulmonary immaturity and subsequent respiratory distress syndrome.
Phosphatidylglycerol	Present	Absence indicates pulmonary immaturity.
Glucose	Less than 45 mg/dL	Excessive increases at term or near term indicate hypertrophied fetal pancreas and subsequent neonatal hypoglycemia.
Alpha-fetoprotein	Variable, depending on gestation age and laboratory technique; highest concentration (about 18.5 ng/mL) occurs at 13–14 wks	Inappropriate increases indicate neural tube defects such as spina bifida or anencephaly, impending fetal death, congenital nephrosis, or contamination of fetal blood.
Bacteria	Absent	Presence indicates chorioamnionitis.
Chromosomes	Normal karyotype	Abnormal karyotype may indicate fetal sex and chromosome disorders.
Acetylcholinesterase	Absent	Presence may indicate neural tube defects, exomphalos, or other serious malformations.

Nursing Management

When preparing the woman for an amniocentesis, explain the procedure and its potential complications, and encourage her to empty her bladder just before the procedure to avoid the risk of bladder puncture. Inform her that a 20-minute electronic fetal monitoring strip usually is obtained to evaluate fetal well-being and obtain a baseline to compare after the procedure is completed. Obtain and record maternal vital signs.

After the procedure, assist the woman to a position of comfort and administer RhoGAM intramuscularly if the woman is Rh negative to prevent potential sensitization to fetal blood. Assess maternal vital signs and fetal heart rate every 15 minutes for an hour after the procedure. Observe the puncture site for bleeding or drainage. Instruct the client to rest after returning home and remind her to report fever, leaking amniotic fluid, vaginal bleeding, or uterine

contractions or any changes in fetal activity (increased or decreased) to the health care provider.

FIGURE 12.7 Technique for amniocentesis: Inserting needle.

When the test results come back, be available to offer support, especially if a fetal abnormality is found. Also prepare the woman and her partner for the need for genetic counseling. Trained genetic counselors can provide accurate medical information and help couples to interpret the results of the amniocentesis so they can make the decisions that are right for them as a family.

Chorionic Villus Sampling

Chorionic villus sampling (CVS) is an invasive procedure involving an 18-gauge needle stick through the abdomen or passage of a suction catheter through the cervix under ultrasound guidance. This test is used to obtain a sample of the chorionic villi from the placenta for prenatal evaluation of chromosomal disorders such as Down syndrome or cystic fibrosis, enzyme deficiencies, and fetal gender determination and to identify sex-linked disorders such as hemophilia, sickle cell anemia, and Tay–Sachs disease (Greeley et al., 2015). Chorionic villi are fingerlike projections that cover the embryo and anchor it to the uterine lining before the placenta is developed. Because they are of embryonic origin, sampling provides information about the developing fetus. CVS can be used to detect numerous genetic disorders, with the exception of neural tube defects (Latendresse & Deneris, 2015).

There has been an impetus to develop earlier prenatal diagnostic procedures so that couples can make an early decision to terminate the pregnancy if an anomaly is confirmed. Early prenatal diagnosis by CVS has been proposed as an alternative to routine amniocentesis, which carries fewer risks if done later in the pregnancy. In addition, results of CVS testing are available sooner than those of amniocentesis, usually within 48 hours.

Procedure

CVS is generally performed 10 to 13 weeks after the LMP. Earlier, chorionic villi may not be sufficiently developed for adequate tissue sampling and the risk of limb defects is increased (Khalil & Coates, 2015). First, an ultrasound is done to confirm gestational age and viability. Then, under continuous ultrasound guidance, CVS is performed using either a transcervical or transabdominal approach. With the transcervical approach, the woman is placed in the lithotomy position and a sterile catheter is introduced through the cervix and inserted in the placenta, where a sample of chorionic villi is aspirated. This approach requires the client to have a full bladder to push the uterus and placenta into a position that is more accessible to the catheter. A full bladder also helps in better visualization of the structures. With the transabdominal approach, an 18-gauge spinal needle is inserted through the abdominal wall into the placental tissue and a sample of chorionic villi is aspirated. Regardless of the approach used, the

sample is sent to the cytogenetics laboratory for analysis.

Potential complications of CVS include postprocedure vaginal bleeding and cramping (most common), hematomas, spontaneous abortion, limb abnormalities, rupture of membranes, infection, chorioamnionitis, and fetal–maternal hemorrhage (March of Dimes, 2015e). The pregnancy loss rate or procedure-related miscarriage rate is approximately 0.5% to 1.0%, which is the same rate for amniocentesis. In addition, women who are Rh negative should receive immune globulin (RhoGAM) to avoid isoimmunization (Jordan et al., 2014).

Nursing Management

Explain to the woman that the procedure will last about 15 minutes. An ultrasound will be done first to locate the embryo, and a baseline set of vital signs will be taken before starting. Make sure she is informed of the risks related to the procedure, including their incidence. If a transabdominal CVS procedure is planned, advise her to fill her bladder by drinking increased amounts of water. Inform her that a needle will be inserted through her abdominal wall and samples will be collected. Once the samples are collected, the needle will be withdrawn and the samples will be sent to the genetics laboratory for evaluation.

For transcervical CVS, inform the women that a speculum will be placed into the vagina under ultrasound guidance. Then the vagina is cleaned and a small catheter is inserted through the cervix. The samples obtained through the catheter are then sent to a laboratory.

After either procedure, assist the woman to a position of comfort and clean any excess lubricant or secretions from the area. Instruct her about signs to watch for and report, such as fever, cramping, and vaginal bleeding. Urge her not to engage in any strenuous activity for the next 48 hours. Assess the fetal heart rate for changes and administer RhoGAM to an unsensitized Rh-negative woman after the procedure.

Nonstress Test

The nonstress test (NST) is the most common method of prenatal testing used in practice today. The NST provides an indirect measurement of uteroplacental function. Unlike the fetal movement counting done by the mother alone, this procedure requires specialized equipment and trained personnel. The basis for the NST is that the normal fetus produces characteristic fetal heart rate patterns in response to fetal movements. In the healthy fetus there is an acceleration of the fetal heart rate with fetal movement. Currently, an NST is recommended twice weekly (after 28 weeks of gestation) for clients with diabetes and other high-risk conditions, such as IUGR, preeclampsia, post-term pregnancy, renal disease, and multifetal pregnancies (Cunningham et al., 2014). NST is a noninvasive test that requires no initiation of contractions. It is quick to perform and there are no known side effects.

Procedure

Before the procedure, the client eats a meal to stimulate fetal activity. Then she is placed in the left lateral recumbent position to avoid supine hypotension syndrome. An external electronic fetal monitoring device is applied to her abdomen. The device consists of two belts, each with a sensor. One of the sensors records uterine activity, while the second sensor records fetal heart rate. The client is handed an "event marker" with a button that she pushes every time she perceives fetal movement. When the button is pushed, the fetal monitor strip is marked to identify that fetal movement has occurred. The procedure usually lasts 20 to 30 minutes.

Nursing Management

Prior to the NST, explain the testing procedure and have the woman empty her bladder. Position her in a semi-Fowler's position and apply the two external monitor belts. Document the date and time the test is started, client information, the reason for the test, and the maternal vital signs. Obtain a baseline fetal monitor strip over 15 to 30 minutes.

During the test, observe for signs of fetal activity with a concurrent acceleration of the fetal heart rate. Interpret the NST as reactive or nonreactive. A reactive NST includes at least two fetal heart rate accelerations from the

baseline of at least 15 bpm for at least 15 seconds within the 20-minute recording period. If the test does not meet these criteria after 40 minutes, it is considered nonreactive. A nonreactive NST is characterized by the absence of two fetal heart rate accelerations using the 15-by-15 criterion in a 20-minute time frame. A nonreactive test has been correlated with a higher incidence of fetal distress during labor, fetal mortality, and IUGR. Additional testing, such as a biophysical profile, should be considered (King et al., 2015).

After the NST procedure, assist the woman off the table, provide her with fluids, and allow her to use the restroom. Typically the health care provider discusses the results with the woman at this time. Provide teaching about signs and symptoms to report. If serial NSTs are being done, schedule the next testing session.

Biophysical Profile

A **biophysical profile (BPP)** uses a real-time ultrasound and NST to allow assessment of various parameters of fetal well-being. A BPP includes ultrasound monitoring of fetal movements, fetal tone, and fetal breathing and ultrasound assessment of amniotic fluid volume with or without assessment of the fetal heart rate. A BPP is performed in an effort to identify infants who may be at risk of poor pregnancy outcome, so that additional assessments of well-being may be performed, or labor may be induced or a cesarean section performed to expedite birth. The primary objectives of the BPP are to reduce stillbirth and to detect hypoxia early enough to allow delivery in time to avoid permanent fetal damage resulting from fetal asphyxia. These parameters, together with the NST, constitute the biophysical profile. Each parameter is controlled by a different structure in the fetal brain: fetal tone by the cortex; fetal movements by the cortex and motor nuclei; fetal breathing movements by the centers close to the fourth ventricle; and the NST by the posterior hypothalamus and medulla. The amniotic fluid is the result of fetal urine volume. Some facilities do not perform an NST unless other parameters of the profile are abnormal (King et al., 2015). The BPP is based on the concept that a fetus that experiences hypoxia loses certain behavioral parameters in the reverse order in which they were acquired during fetal development (normal order of development: tone at 8 weeks; movement at 9 weeks; breathing at 20 weeks; and fetal heart rate reactivity at 24 weeks).

Scoring and Interpretation

The BPP is a scored test with five components, each worth two points if present. A total score of 10 is possible if the NST is used. Thirty minutes are allotted for testing, although less than 10 minutes is usually needed. The following criteria must be met to obtain a score of 2; anything less is scored as 0 (Moses, 2015c):

- *Body movements:* three or more discrete limb or trunk movements

- *Fetal tone:* one or more instances of full extension and flexion of a limb or trunk

- *Fetal breathing:* one or more fetal breathing movements of more than 30 seconds

• *Amniotic fluid volume:* one or more pockets of fluid measuring 2 cm
• *NST:* normal NST = 2 points; abnormal NST = 0 points

Interpretation of the BPP score can be complicated, depending on several fetal and maternal variables. Because it is indicated as a result of a nonreassuring finding from previous fetal surveillance tests, this test can be used to quantify the interpretation, and intervention can be initiated if appropriate. A maximum score of 10 can be achieved and the test is complete once all of the variables have been observed. For the test to be judged abnormal and a score of zero awarded for the absence of fetal movement, fetal tone, or fetal breathing movements, a period of not less than 30 minutes must have elapsed. Because of the excellent sensitivity of fetal NST for fetal acidemia, it has been proposed that this acute marker alone may be used for fetal assessment in combination with the amniotic fluid volume assessment, a chronic marker. This combination, also known as the modified BPP, has been shown to have excellent false-negative rates that compare with that of the complete BPP. In addition, a recent study reported that BPP scores correlates fairly closely with the APGAR scores obtained after birth (Nisa et al., 2015).

One of the important factors is the amniotic fluid volume, taken in conjunction with the results of the NST. Amniotic fluid is largely composed of fetal urine. As placental function decreases, perfusion of fetal organs, such as kidneys, decreases, and this can lead to a reduction of amniotic fluid. If oligohydramnios or decreased amniotic fluid is present, the potential exists for antepartum or intrapartum fetal compromise (Lakshmi & Jyothsna, 2015).

Overall, a score of 8 to 10 is considered normal if the amniotic fluid volume is adequate. A score of 6 or below is suspicious, possibly indicating a compromised fetus; further investigation of fetal well-being is needed.

Because the BPP is an ultrasonographic assessment of fetal behavior, it requires more extensive equipment and more highly trained personnel than other testing modalities. The cost is much greater than with less sophisticated tests. It permits conservative therapy and prevents premature or unnecessary intervention. There are fewer false-positive results than with the NST alone (Callahan, 2016).

Nursing Management

Nursing management focuses primarily on offering the client support and

answering her questions. Expect to complete the NST before scheduling the biophysical profile, and explain why further testing might be needed. Tell the woman that the ultrasound will be done in the diagnostic imaging department.

NURSING MANAGEMENT FOR THE COMMON DISCOMFORTS OF PREGNANCY

Most women experience common discomforts during pregnancy and ask a nurse's advice about ways to minimize them. However, other women will not bring up their concerns unless asked. Therefore, the nurse needs to address the common discomforts that occur in each trimester at each prenatal visit and provide realistic measures to help the client deal with them (Teaching Guidelines 12.1). Nursing Care Plan 12.1 applies the nursing process to the care of a woman experiencing some discomforts of pregnancy.

Teaching Guidelines 12.1

TEACHING TO MANAGE THE DISCOMFORTS OF PREGNANCY

Urinary Frequency or Incontinence

• Try pelvic floor exercises to increase control over leakage.

• Empty your bladder when you first feel a full sensation.

• Avoid caffeinated drinks, which stimulate voiding.

• Reduce your fluid intake after dinner to reduce nighttime urination.

Fatigue

• Attempt to get a full night's sleep, without interruptions.

• Eat a healthy balanced diet.

• Schedule a nap in the early afternoon daily.

• When you are feeling tired, rest.

Nausea and Vomiting

• Avoid an empty stomach at all times.

• Eat dry crackers/toast in bed before arising.

- Eat several small meals throughout the day.
- Avoid brushing teeth immediately after eating to avoid gag reflex.
- Acupressure wristbands can be worn daily.
- Drink fluids between meals rather than with meals.
- Avoid greasy, fried foods or ones with a strong odor, such as cabbage or Brussels sprouts.

Backache
- Avoid standing or sitting in one position for long periods.
- Apply heating pad (low setting) to the small of your back.
- Support your lower back with pillows when sitting.
- Use proper body mechanics for lifting anything.
- Avoid excessive bending, lifting, or walking without rest periods.
- Wear supportive low-heeled shoes; avoid high heels.
- Stand with your shoulders back to maintain correct posture.

Leg Cramps
- Elevate legs above heart level frequently throughout the day.
- If you get a cramp, straighten both legs and flex your feet toward your body.
- Ask your health care provider about taking additional calcium supplements, which may reduce leg spasms.

Varicosities
- Walk daily to improve circulation to extremities.
- Elevate both legs above heart level while resting.
- Avoid standing in one position for long periods of time.
- Don't wear constrictive stockings and socks.
- Don't cross the legs when sitting for long periods.
- Wear support stockings to promote better circulation.

Hemorrhoids
- Establish a regular time for daily bowel elimination.
- Avoid constipation and straining during defecation.
- Prevent straining by drinking plenty of fluids and eating fiber-rich foods and

exercising daily.

• Use warm sitz baths and cool witch hazel compresses for comfort.

Constipation

• Increase your intake of foods high in fiber and drink at least eight 8-ounce glasses of fluid daily.

• Ingest prunes or prune juice which are natural laxatives.

• Consume warm liquids (tea) on rising, to stimulate peristalsis.

• Exercise each day (brisk walking) to promote movement through the intestine.

• Reduce the amount of cheese consumed.

Heartburn/Indigestion

• Avoid spicy or greasy foods and eat small frequent meals.

• Sleep on several pillows so that your head is elevated 30 degrees.

• Stop smoking and avoid caffeinated drinks to reduce stimulation.

• Avoid lying down for at least 3 hours after meals.

• Try drinking sips of water to reduce burning sensation.

• Avoid foods that trigger symptoms—fried foods, citrus, soda, chocolate.

• Take antacids sparingly if burning sensation is severe.

Braxton Hicks Contractions

• Keep in mind that these contractions are a normal sensation. Try changing your position or engaging in mild exercise to help reduce the sensation.

• Drink more fluids if possible.

First-Trimester Discomforts

During the first 3 months of pregnancy, the woman's body is undergoing numerous changes. Some women experience many discomforts, but others have few. These discomforts are caused by the changes taking place within the body and they pass as the pregnancy progresses.

Urinary Frequency or Incontinence

Urinary frequency or incontinence is common in the first trimester because the growing uterus compresses the bladder. This also is a common complaint during the third trimester, especially when the fetal head settles into the pelvis. However, the discomfort tends to improve in the second trimester, when the uterus becomes an abdominal organ and moves away from the bladder region.

After infection and gestational diabetes have been ruled out as causative factors of increased urinary frequency, suggest that the woman decrease her fluid intake 2 to 3 hours before bedtime and limit her intake of caffeinated beverages. Increased voiding is normal, but encourage the client to report any pain or burning during urination. Also explain that increased urinary frequency may subside as she enters her second trimester, only to recur in the third trimester. Teach the client to perform pelvic floor muscle training exercises, formally termed Kegel exercises, to increase support of the uterus, bladder, small intestine, and rectum) throughout the day to help strengthen perineal muscle tone, thereby enhancing urinary control and decreasing the possibility of incontinence.

Fatigue

Fatigue plagues all pregnant women, primarily in the first and third trimesters (the highest energy levels typically occur during the second trimester), even if they get their normal amount of sleep at night. First-trimester fatigue most often is related to the many physical changes (e.g., increased oxygen consumption, increased levels of progesterone and relaxin, increased metabolic demands) and psychosocial changes (e.g., mood swings, multiple role demands) of pregnancy. Third-trimester fatigue can be caused by sleep disturbances from increased weight (many women cannot find a comfortable sleeping position due to the enlarging abdomen), physical discomforts such as heartburn, and insomnia due

to mood swings, multiple role anxiety, and a decrease in exercise (Rigby, 2015).

NURSING CARE PLAN 12.1

Overview of the Woman Experiencing Common Discomforts of Pregnancy

Alicia, a 32-year-old, G1 P0, at 10 weeks gestation, comes to the clinic for a visit. During the interview she tells you, "I'm running to the bathroom to urinate it seems like all the time, and I'm so nauseous that I'm having trouble eating." She denies any burning or pain on urination. Vital signs are within acceptable limits.

NURSING DIAGNOSIS: Impaired urinary elimination related to frequency secondary to physiologic changes of pregnancy

Outcome Identification and Evaluation
The client will report a decrease in urinary complaints, as evidenced by a decrease in the number of times she uses the bathroom to void, reports that she feels her bladder is empty after voiding, and use of Kegel exercises.

Interventions: *Promoting Normal Urinary Elimination Patterns*
• Assess client's usual bladder elimination patterns to establish a baseline for comparison.
• Obtain a urine specimen for analysis to rule out infection or glucosuria.
• Review with client the physiologic basis for the increased frequency during pregnancy; inform client that frequency should abate during the second trimester and that it most likely will return during her third trimester. This will promote understanding of the problem.
• Encourage the client to empty her bladder when first feeling a sensation of fullness to minimize risk of urinary retention.
• Suggest client avoid caffeinated drinks, which can stimulate the need to void.
• Encourage client to drink adequate amounts of fluid throughout the day; however, have client reduce her fluid intake before bedtime to reduce nighttime urination.
• Urge client to keep perineal area clean and dry to prevent irritation and excoriation from any leakage.

- Instruct client in Kegel exercises to increase perineal muscle tone and control over leakage.
- Teach client about the signs and symptoms of urinary tract infection and urge her to report them should they occur to ensure early detection and prompt intervention.

NURSING DIAGNOSIS: Imbalanced nutrition, less than body requirements, related to nausea and vomiting

Outcome Identification and Evaluation
The client will ingest adequate amounts of nutrients for maternal and fetal well-being as evidenced by acceptable weight gain pattern and statements indicating an increase in food intake with a decrease in the number of episodes of nausea and vomiting.

Interventions: *Promoting Adequate Nutrition*
- Obtain weight and compare to baseline to determine effects of nausea and vomiting on nutritional intake.
- Review client's typical dietary intake over 24 hours to determine nutritional intake and patterns so that suggestions can be individualized.
- Encourage client to eat five or six small frequent meals throughout the day to prevent her stomach from becoming empty.
- Suggest that she munch on dry crackers, toast, cereal, or cheese, or drink a small amount of lemonade before arising to minimize nausea.
- Encourage client to arise slowly from bed in the morning and avoid sudden movements to reduce stimulation of the vomiting center.
- Advise client to drink fluids between meals rather than with meals to avoid overdistention of the abdomen and subsequent increase in abdominal pressure.
- Encourage her to increase her intake of foods high in vitamin B_6 such as meat, poultry, bananas, fish, green leafy vegetables, peanuts, raisins, walnuts, and whole grains, as tolerated, to ensure adequate nutrient intake.
- Advise the client to avoid greasy, fried, or highly spiced foods and to avoid strong odors, including foods such as cabbage, to minimize gastrointestinal upset.
- Encourage the client to avoid wearing tight or restricting clothes to

minimize pressure on the expanding abdomen.
• Arrange for consultation with nutritionist as necessary to assist with diet planning.

Once anemia, infection, and blood dyscrasias have been ruled out as contributing to the client's fatigue, advise her to arrange work, child care, and other demands in her life to permit additional rest periods. Work with the client to devise a realistic schedule for rest. Using pillows for support in the left-side-lying position relieves pressure on major blood vessels that supply oxygen and nutrients to the fetus when resting (Fig. 12.8). Also recommend the use of relaxation techniques, providing instructions as necessary, and suggest she increase her daily exercise level.

Nausea and Vomiting

It is estimated that somewhere between 70% and 80% of pregnant women experience nausea and vomiting. In the United States, this translates to approximately 4 million women. It is found more often in Western countries and urban populations, and is rare among Africans, Native Americans, Eskimos, and most Asian populations (Callahan, 2016). The problem is generally time limited, with the onset about the fifth week after the last menstrual period, a peak at 8 to 12 weeks, and resolution by 16 to 18 weeks. Despite popular use of the term *morning sickness*, nausea and vomiting of pregnancy persist throughout the day in the majority of affected women and has been found to be limited to the morning in less than 2% of women (Tyler & Nagtalon-Ramos, 2015). The physiologic changes that cause nausea and vomiting are unknown, but research suggests that unusually high levels of estrogen, progesterone, and hCG, and a vitamin B_6 deficiency may be contributing factors. Symptoms generally last until the second trimester and are generally associated with a positive pregnancy outcome, in terms of lower rates of miscarriages, congenital malformations, and preterm births (Cunningham et al., 2014). In summary, the etiology of nausea and vomiting in pregnancy is physiologic, thus assessment of the condition focuses on severity, and the management is largely supportive.

FIGURE 12.8 Using pillows for support in the side-lying position.

Nausea and vomiting of pregnancy can take a physical and psychological toll on the pregnant woman, and may have an adverse effect on her partner, family members, and even co-workers. The burden it places on the woman is usually minimized, as it is considered a normal part of pregnancy, thus it may not be worthy of evaluation, diagnosis, management, and emotional support. As a result, it may not be taken seriously because it is so common and time-limited; leading some women to feel frustrated and feel guilty that they are even complaining about their symptoms. Nurses need to pick up on this, address it, and provide support for her.

The goal of treatment is to improve symptoms while minimizing risks to mother and fetus. Treatment management ranges from simple dietary modifications to drug therapy. To help alleviate nausea and vomiting, advise the woman to eat small, frequent meals that are bland and low in fat (five or six times a day) to prevent her stomach from becoming completely empty. Other helpful suggestions include eating dry crackers, Cheerios, or cheese or drinking lemonade before getting out of bed in the morning and increasing her intake of foods high in vitamin B_6, such as meat, poultry, bananas, fish, green leafy vegetables, peanuts, raisins, walnuts, and whole grains, or making sure she is receiving enough vitamin B_6 by taking her prescribed prenatal vitamins.

Pharmacologic treatment of nausea and vomiting in pregnancy is limited. The Food and Drug Administration (FDA) recently approved doxylamine–pyridoxine therapy for use in pregnancy, which seems to work fairly well based on the current reviews (Slaughter et al., 2014). Other pharmacotherapies that might be considered may include diphenhydramine (e.g., Benadryl),

dimenhydrinate (e.g., Dramamine), meclinine (e.g., Antivert), prochlorperazine (e.g., Compazine), promethazine (e.g., Phenergan), or ondansetron (e.g., Zofran). Other helpful tips to deal with nausea and vomiting include the following:

• Get out of bed in the morning very slowly.

• Avoid sudden movements.

• Avoid triggers that stimulate or exacerbate nausea—strong food odors.

• Eat a high-protein snack before retiring at night to prevent an empty stomach.

• Take ginger (up to 1 g in divided doses daily; 250 mg capsules QID), which increases tone and peristalsis in the gastrointestinal tract.

• Open a window to remove odors of food being cooked.

• Eat more protein than carbohydrates and take in more liquids than solids.

• Limit intake of fluids or soups during meals (drink them between meals).

• Avoid fried foods and foods cooked with grease, oils, or fatty meats, because they tend to upset the stomach.

• Avoid highly seasoned foods such as those cooked with garlic, onions, peppers, and chili.

• Drink a small amount of caffeine-free carbonated beverage (ginger ale) if nauseated.

• Trying acupressure using a wristband has been FDA approved for nausea.

• Avoid wearing tight or restricting clothes, which might place increased pressure on the expanding abdomen.

• Avoid stress (Bope & Kellerman, 2015; Jordan et al., 2014; King et al., 2015).

Breast Tenderness

As a result of increased estrogen and progesterone levels, which cause the fat layer of breasts to thicken and the number of milk ducts and glands to increase during the first trimester, many women experience breast tenderness. Offering a thorough explanation to the woman about the reasons for the breast discomfort is important. Wearing a larger bra with good support can help alleviate this discomfort. Advise her to wear a supportive bra, even while sleeping. As her breasts increase in size, advise her to change her bra size to ensure adequate support.

Constipation

Constipation affects up to 38% of pregnancies (Verghese, Futaba, & Latthe, 2015). Increasing levels of progesterone during pregnancy lead to decreased contractility of the gastrointestinal tract, slowed movement of substances through the colon, and a resulting increase in water absorption. All of these factors lead to constipation. Lack of exercise or too little fiber or fluids in the diet can also promote constipation. In addition, the large bowel is mechanically compressed by the enlarging uterus, adding to this discomfort. The iron and calcium in prenatal vitamins can also contribute to constipation during the first and third trimesters.

Explain how pregnancy exacerbates the symptoms of constipation and offer the following suggestions:

• Eat fresh or dried fruit daily.

• Eat more raw fruits and vegetables, including their skins.

• Eat whole-grain cereals and breads such as raisin bran or bran flakes.

• Participate in physical activity every day.

• Engage in pelvis floor exercises, stretching exercises and yoga daily

• Eat meals at regular intervals.

• Establish a time of day to defecate, and elevate feet on a stool to avoid straining.

• Drink six to eight glasses of water daily.

• Decrease intake of refined carbohydrates.

• Drink warm fluids on arising to stimulate bowel motility.

• Decrease consumption of sugary sodas.

• Avoid eating large amounts of cheese.

If the suggestions above are ineffective, suggest that the woman use a bulk-forming laxative such as Metamucil®.

Nasal Stuffiness, Bleeding Gums, Epistaxis (Nosebleeds)

Increased levels of estrogen cause edema of the mucous membranes of the nasal and oral cavities. Advise the woman to drink extra water for hydration of the mucous membranes or to use a cool mist humidifier in her bedroom at night. If

she needs to blow her nose to relieve nasal stuffiness, advise her to blow gently, one nostril at a time. Advise her to avoid the use of nasal decongestants and sprays.

If a nosebleed occurs, advise the woman to loosen the clothing around her neck, sit with her head tilted forward, pinch her nostrils with her thumb and forefinger for 10 to 15 minutes, and apply an ice pack to the bridge of her nose.

If the woman has bleeding gums, encourage her to practice good oral hygiene by using a soft toothbrush and flossing daily. Warm saline mouthwashes can relieve discomfort. If the gum problem persists, instruct her to see her dentist.

Cravings

Food craving refers to an intense desire to consume a specific food. Desires for certain foods and beverages are likely to begin during the first trimester but do not appear to reflect any physiologic need. Foods with a high sodium or sugar content often are the ones craved. At times, some women crave nonfood substances such as clay, cornstarch, laundry detergent, baking soda, soap, paint chips, dirt, ice, or wax. As explained in Chapter 11, this craving for nonfood substances, termed *pica*, may indicate a severe dietary deficiency of minerals or vitamins, or it may have cultural roots (Jyothi, 2015).

Leukorrhea

Increased vaginal discharge begins during the first trimester and continues throughout pregnancy. The physiologic changes behind leukorrhea arise from the high levels of estrogen, which cause increased vascularity and hypertrophy of cervical glands as well as vaginal cells (Cunningham et al., 2014). The result is progressively increasing vaginal secretions throughout pregnancy.

Advise the woman to keep the perineal area clean and dry, washing the area with mild soap and water during her daily shower. Also recommend that she avoid wearing pantyhose and other tight-fitting nylon clothes that prevent air from circulating to the genital area. Encourage the use of cotton underwear and suggest wearing a nightgown rather than pajamas to allow for increased airflow. Also instruct the woman to avoid douching and tampon use.

Second-Trimester Discomforts

A sense of well-being typically characterizes the second trimester for most women. By this time, the fatigue, nausea, and vomiting have subsided and the uncomfortable changes of the third trimester are a few months away. Not every woman experiences the same discomforts during this time, so nursing assessments and interventions must be individualized.

Backache

Musculoskeletal pain is a common occurrence in pregnancy and postpartum. Half of women report having back pain at some point during pregnancy. This can seriously impact the quality of life of women and have socioeconomic issues from loss days at work. The pain can be lumbar or sacroiliac. The pain may also be present only at night. Back pain is thought to be due to multiple factors, which include shifting of the center of gravity caused by the enlarging uterus, increased joint laxity due to an increase in relaxin, stretching of the ligaments (which are pain-sensitive structures), and pregnancy-related circulatory changes.

Treatment is heat and ice, acetaminophen, massage, proper posturing, good support shoes, and a good exercise program for strength and conditioning. Pregnant women may also relieve back pain by placing one foot on a stool when standing for long periods of time and placing a pillow between the legs when lying down (Plastaras & Appasamy, 2015). After exploring other reasons that might cause backache, such as uterine contractions, urinary tract infection, ulcers, or musculoskeletal back disorders, the following instructions may be helpful:

• Maintain correct posture, with head up and shoulders back.

• Wear low-heeled shoes with good arch support.

• When standing for long periods, place one foot on a stool or box.

• Use good body mechanics when lifting objects.

• When sitting, use foot supports and pillows behind the back.

• Try pelvic tilt or rocking exercises to strengthen the back (ACOG, 2015c).

The pelvic tilt or pelvic rock is used to alleviate pressure on the lower back during pregnancy by stretching the lower back muscles. It can be done sitting,

standing, or on all fours. To do it on all fours, the hands are positioned directly under the shoulders and the knees under the hips. The back should be in a neutral position with the head and neck aligned with the straight back. The woman then presses up with the lower back and holds this position for a few seconds, then relaxes to a neutral position. This action of pressing upward is repeated frequently throughout the day to prevent a sore back (Rigby, 2015).

Leg Cramps

Many women experience leg cramps in pregnancy. They become more common as pregnancy progresses and are especially troublesome at night. They occur primarily in the second and third trimesters and could be related to the pressure of the gravid uterus on pelvic nerves and blood vessels. During pregnancy, up to 50% of women can be affected by leg cramps, and up to 25% can be affected by restless legs syndrome (King et al., 2015). Along with lack of exercise, diet can also be a contributing factor if the woman is not consuming enough of certain minerals, such as calcium and magnesium. The sudden stretching of leg muscles may also play a role in causing leg cramps (Kondhare & Khodgire, 2015).

Encourage the woman to gently stretch the muscle by dorsiflexing the foot up toward the body. Wrapping a warm, moist towel around the leg muscle can also help the muscle to relax. Advise the client to avoid stretching her legs, pointing her toes, and walking excessively. Stress the importance of wearing low-heeled shoes and support hose and arising slowly from a sitting position. If the leg cramps are due to deficiencies in minerals, the condition can be remedied by eating more foods rich in these nutrients. Also instruct the woman on calf-stretching exercises: have her stand 3 feet from the wall and lean toward it, resting her lower arms against it, while keeping her heels on the floor. This may help reduce cramping if it is done before going to bed.

Elevating the legs throughout the day will help relieve pressure and minimize strain. Wearing support hose and avoiding curling the toes may help to relieve leg discomfort. Also instruct the client to avoid standing in one spot for a prolonged period or crossing her legs. If she must stand for prolonged periods, suggest that she change her position at least every 2 hours by walking or sitting to reduce the risk of leg cramps. Encourage her to drink eight 8-ounce glasses of fluid throughout the day to ensure adequate hydration. Taking daily walks can also help reduce leg cramping because ambulation improves circulation to the muscles.

Varicosities of the Vulva and Legs

Varicosities of the vulva and legs are associated with the increased venous stasis caused by the pressure of the gravid uterus on pelvic vessels and the vasodilation resulting from increased progesterone levels. Progesterone relaxes the vein walls, making it difficult for blood to return to the heart from the extremities; pooling can result. Genetic predisposition, inactivity, obesity, and poor muscle tone are also contributing factors.

Encourage the client to wear support hose and teach her how to apply them properly. Advise her to elevate her legs above her heart while lying on her back for 10 minutes before she gets out of bed in the morning, thus promoting venous return before she applies the hose. Instruct the client to avoid crossing her legs and avoid wearing knee-high stockings. They cause constriction of leg vessels and muscles and contribute to venous stasis. Also encourage the client to elevate both legs above the level of the heart for 5 to 10 minutes at least twice a day (Fig. 12.9); to wear low-heeled shoes; and to avoid long periods of standing or sitting, frequently changing her position. If the client has vulvar varicosities, suggest she apply ice packs to the area when she is lying down.

FIGURE 12.9 Woman elevating her legs while working.

Hemorrhoids

Hemorrhoids are varicosities of the rectum and may be external (outside the anal

sphincter) or internal (above the sphincter) (ACOG, 2015d). They occur as a result of progesterone-induced vasodilation and from pressure of the enlarged uterus on the lower intestine and rectum. Hemorrhoids are more common in women with constipation, poor fluid intake or poor dietary habits, smokers, or those with a previous history of hemorrhoids (Zielinski, Searing, & Deibel, 2015).

Instruct the client in measures to prevent constipation, including increasing fiber intake and drinking at least 2 L of fluid per day. Recommend the use of topical anesthetics (e.g., Preparation H®, Anusol, witch hazel compresses such as Tucks®) to reduce pain, itching, and swelling, if permitted by the health care provider. Teach the client about local comfort measures such as warm sitz baths, witch hazel compresses, or cold compresses. To minimize her risk of straining while defecating, suggest that she elevates her feet on a stool. Also encourage her to avoid prolonged sitting or standing (ACOG, 2015d).

Flatulence With Bloating

Flatulence and gas pain are another result of decreased gastrointestinal motility. The physiologic changes that result in constipation (reduced gastrointestinal motility and dilation secondary to progesterone's influence) may also result in increased flatulence. As the enlarging uterus compresses the bowel, it delays the passage of food through the intestines, thus allowing more time for gas to be formed by bacteria in the colon. The woman usually reports increased passage of rectal gas, abdominal bloating, or belching. Instruct the woman to avoid gas-forming foods, such as beans, cabbage, and onions, as well as foods that have a high content of white sugar. Adding more fiber to the diet, increasing fluid intake, and increasing physical exercise are also helpful in reducing flatus. In addition, reducing the amount of swallowed air, if chewing gum, will reduce gas build-up. The knee–chest position may also help with discomfort from unexpelled gas. Reducing the intake of carbonated beverages and cheese and eating mints can also help reduce flatulence during pregnancy (Almansa, De Vault, & Houghton, 2015).

Third-Trimester Discomforts

As women enter their third trimester, many experience a return of the first-trimester discomforts of fatigue, urinary frequency, leukorrhea, and constipation. These discomforts are secondary to the ever-enlarging uterus compressing adjacent structures, increasing hormone levels, and the metabolic demands of the fetus. In addition to these discomforts, many women experience shortness of breath, heartburn and indigestion, swelling, and Braxton Hicks contractions.

Shortness of Breath and Dyspnea

Dyspnea is a common complaint in pregnant women. Physiologic and hemodynamic changes can result in a significant dyspnea in such cases. In some women, dyspnea in normal daily activities can be a sign of heart and lung disease and may be associated with poor perinatal and cardiac outcomes in which early detection can prevent adverse events. The increasing growth of the uterus prevents complete lung expansion late in pregnancy. As the uterus enlarges upward in the second and third trimesters, the expansion of the diaphragm is limited. Dyspnea can occur when the woman lies on her back and the pressure of the gravid uterus against the vena cava reduces venous return to the heart (Tara et al., 2015).

Explain to the woman that dyspnea is normal and will improve when the fetus drops into the pelvis (lightening). Instruct her to adjust her body position to allow for maximum expansion of the chest and to avoid large meals, which increase abdominal pressure. Raising the head of the bed on blocks or placing pillows behind her back is helpful too. Under normal circumstances, resting with the head elevated while taking slow, deep breaths reduces shortness of breath symptoms. In addition, stress to her that lying on her left side will displace the uterus off the vena cava and improve her breathing. Having the woman periodically stand up and stretch her arms above her head and take a deep breath is helpful to relieve dyspnea. Also, advise the woman to avoid exercise that precipitates dyspnea, to rest after exercise, and to avoid overheating in warm climates. If she still smokes, encourage her to stop.

Heartburn and Indigestion

Heartburn and indigestion result when high progesterone levels cause relaxation

of the cardiac sphincter, allowing food and digestive juices to flow backward from the stomach into the esophagus. Irritation of the esophageal lining occurs, causing the burning sensation known as heartburn. It occurs in up to 70% of women at some point during pregnancy, with an increased frequency seen in the third trimester (King et al., 2015). The pain may radiate to the neck and throat. It worsens when the woman lies down, bends over after eating, or wears tight clothes. Indigestion (vague abdominal discomfort after meals) results from eating too much or too fast; from eating when tense, tired, or emotionally upset; from eating food that is too fatty or spicy; and from eating heavy food or food that has been badly cooked or processed (Nagtalon-Ramos, 2014). In addition, the stomach is displaced upward and compressed by the large uterus in the third trimester, thus limiting the stomach's capacity to empty quickly. Food sits, causing heartburn and indigestion.

Review the client's usual dietary intake and suggest that she limit or avoid gas-producing or fatty foods and large meals. Instruct the woman to pay attention to the timing of the discomfort. Usually it is heartburn when the pain occurs 30 to 45 minutes after a meal. Encourage the client to maintain proper posture and remain in the sitting position for 1 to 3 hours after eating to prevent reflux of gastric acids into the esophagus by gravity. Urge the client to consume small, frequent meals, to eat slowly, chewing her food thoroughly to prevent excessive swallowing of air, which can lead to increased gastric pressure. Instruct the client to avoid foods that act as triggers such as caffeinated drinks, greasy, gas-forming foods, citrus, spiced foods, chocolate, coffee, alcohol, and spearmint or peppermint. These items stimulate the release of gastric digestive acids, which may cause reflux into the esophagus. Avoid late-night or large meals and gum chewing. Avoid lying down within 3 hours after eating. Finally, elevate the head of the bed by 10 to 30 degrees.

Dependent Edema

Swelling is the result of increased capillary permeability caused by elevated hormone levels and increased blood volume. Sodium and water are retained and thirst increases. Edema occurs most often in dependent areas such as the legs and feet throughout the day due to gravity; it improves after a night's sleep. Warm weather or prolonged standing or sitting may increase edema. Generalized edema, appearing in the face, hands, and feet, can signal preeclampsia if accompanied by dizziness, blurred vision, headaches, upper quadrant pain, or

nausea (Rigby, 2015). This edema should be reported to the health care provider. Appropriate suggestions to minimize dependent edema include the following:

• Elevate your feet and legs above the level of the heart periodically throughout the day.

• Wear support hose when standing or sitting for long periods.

• Change position frequently throughout the day.

• Walk at a sensible pace to help contract leg muscles to promote venous return.

• When taking a long car ride, stop to walk around every 2 hours.

• When standing, rock from the ball of the foot to the toes to stimulate circulation.

• Lie on your left side to keep the gravid uterus off the vena cava to return blood to the heart.

• Avoid foods high in sodium, such as lunch meats, potato chips, and bacon.

• Avoid wearing knee-high stockings.

• Drink six to eight glasses of water daily to replace fluids lost through perspiration.

• Avoid high intake of sugar and fats, because they cause water retention.

Braxton Hicks Contractions

Braxton Hicks contractions are irregular, painless contractions that occur without cervical dilation. Typically they intensify in the third trimester in preparation for labor. In reality, they have been present since early in the pregnancy but may have gone unnoticed. They are thought to increase the tone of uterine muscles for labor purposes (Grant, Strevens, & Thornton, 2015).

Consider This

One has to wonder sometimes why women go through what they do. During my first pregnancy I was sick for the first 2 months. I would experience waves of nausea from the moment I got out of bed until midmorning. Needless to say, I wasn't the happiest camper around. After the third month,

my life seemed to settle down and I was beginning to think that being pregnant wasn't too bad after all. For the moment, I was fooled. Then, during my last 2 months, another wave of discomfort struck—heartburn and constipation—a double whammy! I now feared eating anything that might trigger acid indigestion and also might remain in my body too long. I literally had to become the "fiber queen" to combat these two challenges. Needless to say, my "suffering" was well worth our bright-eyed baby girl in the end.

   Thoughts: *Despite the various discomforts associated with pregnancy, most women wouldn't change their end result. Do most women experience these discomforts? What suggestions could be made to reduce them?*

   Reassure the client that these contractions are normal. Instruct the client in how to differentiate between Braxton Hicks and labor contractions. Explain that true labor contractions usually grow longer, stronger, and closer together and occur at regular intervals. Walking usually strengthens true labor contractions, whereas Braxton Hicks contractions tend to decrease in intensity and taper off. Advise the client to keep herself well hydrated and to rest in a left-side-lying position to help relieve the discomfort. Suggest that she use breathing techniques such as Lamaze techniques to ease the discomfort.

NURSING MANAGEMENT TO PROMOTE SELF-CARE

Pregnancy is considered a time of health, not illness. Health promotion and maintenance activities are essential to promoting an optimal outcome for the woman and her fetus. Pregnant women commonly have many questions about the changes occurring during pregnancy: how these changes affect their usual routine, such as working, traveling, exercising, or engaging in sexual activity; how the changes influence their typical self-care activities, such as bathing, perineal care, or dental care; and whether these changes are signs of a problem.

 Take Note!

Women may have heard stories about or been told by others what to do and what not to do during pregnancy, leading to many misconceptions and much misinformation.

Nurses can play a major role in providing anticipatory guidance and teaching to foster the woman's responsibility for self-care, helping to clarify misconceptions and correct any misinformation. Educating the client to identify threats to safety posed by her lifestyle or environment and proposing ways to modify them to avoid a negative outcome are important. Counseling should also include healthy ways to prepare food, advice to avoid medications unless they are prescribed for her, and advice on identifying teratogens within her environment or at work and how to reduce her risk from exposure. The pregnant client can better care for herself and the fetus if her concerns are anticipated and identified by the nurse and are incorporated into teaching sessions at each prenatal visit.

Personal Hygiene

Hygiene is a necessity for the maintenance of good health. Cleansing the skin removes dirt, bacteria, sweat, dead skin cells, and body secretions. Counsel women to wash their hands and under their fingernails frequently throughout the day in order to lower the bacterial count on both. During pregnancy a woman's sebaceous (sweat) glands become more active under the influence of hormones, and sweating is more profuse. This increase may make it necessary to use a stronger deodorant and shower more frequently. The cervical and vaginal glands also produce more secretions during pregnancy. Frequent showering helps to keep the area dry and promotes better hygiene. Encourage the use of cotton underwear to allow greater air circulation. Taking a tub bath in early pregnancy is permitted, but closer to term, when the woman's center of gravity shifts, it is safer to shower to prevent the risk of slipping.

Hot Tubs and Saunas

Caution pregnant women to avoid using hot tubs, saunas, whirlpools, and tanning beds during pregnancy. The heat may cause fetal tachycardia as well as raise the maternal temperature. Exposure to bacteria in hot tubs that have not been cleaned sufficiently is another reason to avoid them during pregnancy.

Perineal Care

The glands in the cervical and vaginal areas become more active during pregnancy secondary to hormonal influences. This increase in activity will produce more vaginal secretions, especially in the last trimester. Advise pregnant women to shower frequently and wear all-cotton underwear to minimize the effects of these secretions. Caution pregnant women not to douche, because douching can increase the risk of infection, and not to wear panty liners, which block air circulation and promote moisture. Explain that they should also avoid perfumed soaps, lotions, perineal sprays, and harsh laundry detergents to help prevent irritation and potential infection.

Dental Care

Physiologic changes that occur in pregnant women can adversely affect oral

health. Elevations in estrogen and progesterone enhance the inflammatory response and consequently alter gingival tissue. During pregnancy, the incidence of gingivitis and periodontitis increases (Anil et al., 2015). Pregnancy is a time when a woman can be very receptive to health messaging. Pregnancy is no longer a contraindication for dental treatment; it is also a time when nurses can help clients understand that good oral health is important to a healthy pregnancy and can decrease the risk of dental caries in their children. When women see oral health as a priority for themselves, they are more likely to place a high priority on their children's oral health.

Periodontal disease is a contributing factor to systemic conditions, such as heart disease, respiratory diseases, diabetes mellitus, adverse pregnancy outcomes (preterm births, low–birth-weight infants, and small-for-gestational-age infants), anemia, and stroke (Trivedi, Lal, & Singhal, 2015). Research has established that the elevated levels of estrogen and progesterone during pregnancy cause women to be more sensitive to the effects of bacterial dental plaque, which can cause gingivitis, an oral infection characterized by swollen and bleeding gums (ACOG, 2013). Brushing and flossing teeth twice daily will help reduce bacteria in the mouth. Advise the woman to visit her dentist early in the pregnancy to address any dental caries and have a thorough cleaning to prevent possible infection later in the pregnancy. Advise her to avoid exposure to x-rays by informing the hygienist of the pregnancy. If x-rays are necessary, the abdomen should be shielded with a lead apron.

Researchers have reported an association between prematurity and periodontitis, an oral infection that spreads beyond the gum tissues to invade the supporting structures of the teeth. Periodontitis is characterized by bleeding gums, loss of tooth attachment, loss of supporting bone, and bad breath due to pus formation. Unfortunately, because this infection is chronic and often painless, women frequently do not realize they have it and a preterm birth can result. During pregnancy, gingivitis occurs in 35% to 100% of women, depending upon the study (Trivedi et al., 2015). Nurses should assess all pregnant women's oral health status by taking an oral health history; checking their mouths for swollen or bleeding gums, untreated dental decay, mucosal lesions, and signs of infection; and document findings in the prenatal record.

Additional guidelines that the nurse should stress regarding maintaining dental health include the following:

• Seek professional dental care during the first trimester for assessment and care.

• Be reassured that oral health care is safe during pregnancy.

- Obtain treatment for dental pain and infection promptly during pregnancy.
- Brush twice daily for 2 minutes, especially before bed, with fluoridated toothpaste and rinse well. Use a soft-bristled toothbrush and be sure to brush at the gum line to remove food debris and plaque to keep gums healthy.
- Floss teeth daily with dental floss and rinse well afterward with plain water.
- Eat healthy foods, especially those high in vitamins A, C, and D, and calcium.
- Avoid sugary snacks.
- Chew sugar-free gum for 10 minutes after a meal if brushing is not possible.
- After vomiting, rinse your mouth immediately with baking soda (1/4 teaspoon) and warm water (1 cup) to neutralize the acid (National Maternal and Child Oral Health Resource Center, 2015).

Breast Care

Because the breasts enlarge significantly and become heavier throughout pregnancy, stress the need to wear a firm, supportive bra with wide straps to balance the weight of the breasts. Instruct the woman to anticipate buying a larger-sized bra about halfway through her pregnancy because of the increasing size of the breasts. Advise her to avoid using soap on the nipple area because it can be very drying. Encourage her to rinse the nipple area with plain water while bathing to keep it clean. The Montgomery glands (located in the areolar part of the nipple) secrete a lubricating substance that keeps the nipples moist and discourages growth of bacteria, so there is no need to use alcohol or other antiseptics on the nipples.

If the mother has chosen to breast-feed, nipple preparation is unnecessary unless her nipples are inverted and do not become erect when stimulated. Breast shells can be worn during the last 2 months to address this issue (Alexander et al., 2014).

Around week 16 of pregnancy, colostrum secretion begins, which the woman may notice as moisture in her bra. Advise the woman to place breast pads or a cotton cloth in her bra and change them frequently to prevent buildup, which may lead to excoriation.

Clothing

Many contemporary clothes are loose fitting and layered, so the woman may not need to buy an entirely new wardrobe to accommodate her pregnancy. Some pregnant women may continue to wear tight clothes. Point out that loose clothing will be more comfortable for the client and her expanding waistline.

Advise pregnant women to avoid wearing constricting clothes and girdles that compress the growing abdomen. Urge the woman to avoid knee-high hose, which might impede lower-extremity circulation and increase the risk of developing DVT. Low-heeled shoes will minimize pelvic tilt and possible backache. Wearing layered clothing that can be removed as the temperatures fluctuate may be more comfortable, especially toward term, when the woman may feel overheated.

Exercise

A physically inactive lifestyle is associated with an increase in chronic diseases such as cardiovascular disease, type 2 diabetes, osteoporosis, and cancer. The proportion of pregnant women who are overweight or obese is increasing globally, thus exercise is essential to reduce these risks and promote a healthy pregnancy. Exercise is well tolerated by a healthy woman during pregnancy. It promotes a feeling of well-being; improves circulation; helps reduce constipation, bloating, and swelling; may help prevent or treat gestational diabetes; promotes muscle tone, strength, and endurance; may improve the woman's ability to cope with labor; increases energy level; improves posture; helps sleep and promotes relaxation and rest; and relieves the lower back discomfort that often arises as the pregnancy progresses (Barakat, Lucia, & Ruiz, 2015). However, the duration and difficulty of exercise should be modified throughout pregnancy because of a decrease in performance efficiency with gestational age. Some women continue to push themselves to maintain their prior level of exercise, but most find that as their shape changes and their abdominal area enlarges, they must modify their exercise routines. Modification also helps to reduce the risk of injury caused by laxity of the joints and connective tissue due to the hormonal effects (Petrov, Glantz, & Fagevik Olsen, 2015).

Exercise during pregnancy is contraindicated in women with preterm labor, poor weight gain, anemia, facial and hand edema, pain, hypertension, threatened abortion, dizziness, shortness of breath, multiple gestation, decreased fetal activity, cardiac disease, and palpitations (Rigby, 2015).

Federal physical activity guidelines recommend at least 150 minutes of moderate-intensity exercise per week during pregnancy (Fig. 12.10) (Dietz, 2015). It is believed that pregnancy is a unique time for behavior modification and that healthy behaviors maintained or adopted during pregnancy may improve the woman's health for the rest of her life. The excess weight gained in pregnancy, which some women never lose, is a major public health problem (Truong et al., 2015). Exercise helps the woman avoid gaining excess weight during pregnancy.

Exercise during pregnancy helps return a woman's body to good health after the baby is born. The long-term benefits of exercise that begin in early pregnancy include improved posture, weight control, and improved muscle tone.

Exercise also aids in the prevention of osteoporosis after menopause, reduces the risk of hypertension and diabetes, and assists in keeping the birth weight of the fetus within the normal range (Barakat et al., 2015). Teaching Guidelines 12.2 highlights recommendations for exercise during pregnancy.

 Teaching Guidelines 12.2

TEACHING TO PROMOTE EXERCISE DURING PREGNANCY

- Consume liquids before, during, and after exercising.
- Ask your health care provider before you start a new exercise routine.
- Avoid exercising in hot, humid weather or when you have a fever.
- Stop exercising if you experience vaginal bleeding, dizziness, chest pain, headache, muscle weakness, calf pain or swelling, uterine contractions, decreased fetal movement, or fluid leaking from the vagina.
- Exercise three or four times each week, not sporadically.
- Engage in brisk walking, swimming, biking, or low-impact aerobics; these are considered ideal activities.
- Avoid getting overheated during exercise.
- Wear comfortable exercise footwear that gives strong ankle and arch support.
- Contact sports should be avoided during pregnancy.
- Include relaxation and stretching before and after your exercise program.
- Reduce the intensity of workouts in late pregnancy.
- Avoid jerky, bouncy, or high-impact movements.
- Avoid lying flat (supine) after the fourth month because of hypotensive effect.
- Use pelvic tilt and pelvic rocking to relieve backache.
- Start with 5 to 10 minutes of stretching exercises.
- Rise slowly following an exercise session to avoid dizziness.

- Avoid activities such as skiing, surfing, scuba diving, and ice hockey.
- Never exercise to the point of exhaustion.

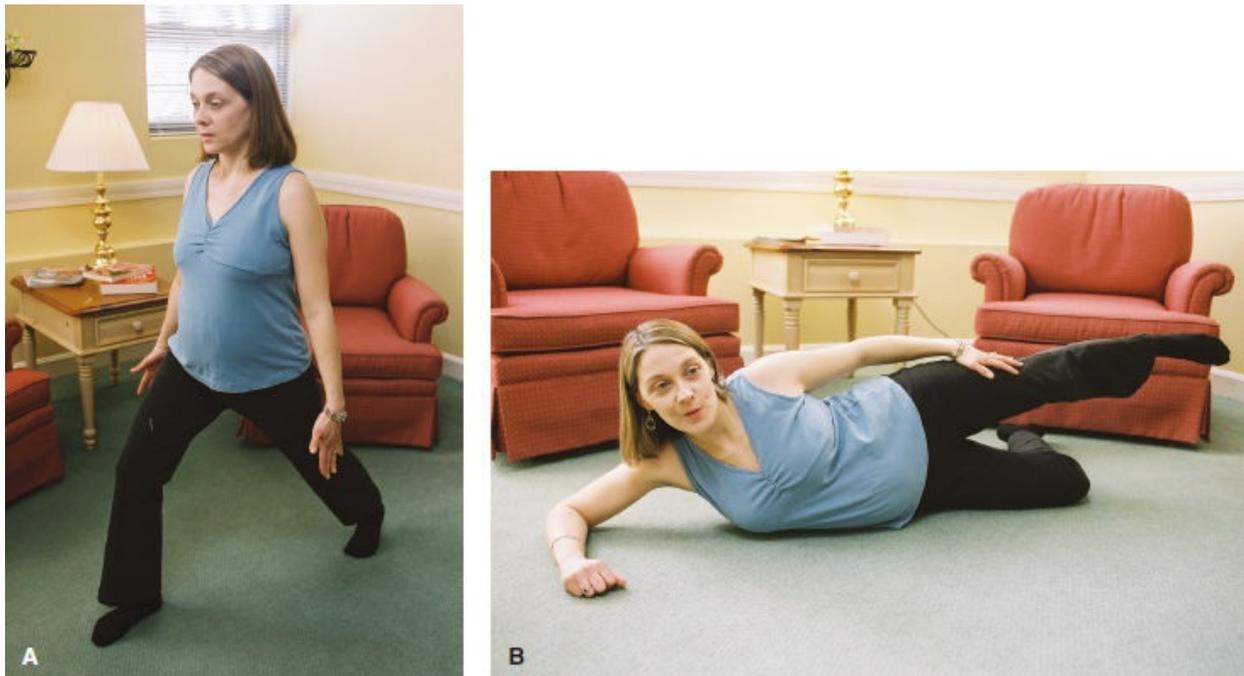

FIGURE 12.10 Exercising during pregnancy.

Sleep and Rest

Getting enough sleep helps a person feel better and promotes optimal performance levels during the day. The body releases its greatest concentration of growth hormone during sleep, helping the body to repair damaged tissue and grow. Also, with the increased metabolic demands during pregnancy, fatigue is a constant challenge to many pregnant women, especially during the first and third trimesters. The following tips can help promote adequate sleep:

• Stay on a regular schedule by going to bed and waking up at the same times.

• Eat regular meals at regular times to keep external body cues consistent.

• Take time to unwind and relax before bedtime.

• Establish a bedtime routine or pattern and follow it.

• Create a proper sleep environment by reducing the light and lowering the room temperature.

• Go to bed when you feel tired; if sleep does not occur, read a book until you are sleepy.

• Reduce caffeine intake later in the day.

• Limit fluid intake after dinner to minimize trips to the bathroom.

• Exercise daily to improve circulation and well-being.

• Use a modified Sims position to improve circulation in the lower extremities.

• Avoid lying on your back after the fourth month, which may compromise circulation to the uterus.

• Avoid sharply bending your knees, which promotes venous stasis below the knees.

• Keep anxieties and worries out of the bedroom. Set aside a specific area in the home or time of day for them.

Sexual Activity and Sexuality

Sexuality is an important part of health and well-being. Pregnancy is characterized by intense biologic, psychological, and social changes. These changes have direct and indirect, conscious and unconscious effects on a woman's sexuality. The woman experiences dramatic alterations in her physiology, her appearance, and her body, as well as her relationships. A woman's sexual responses during pregnancy vary widely. Common symptoms such as fatigue, nausea, vomiting, breast soreness, and urinary frequency may reduce her desire for sexual intimacy. However, many women report enhanced sexual desire due to increasing levels of estrogen. Usually sexual satisfaction does not change in pregnancy compared with the prepregnancy patterns despite a decline of sexual activity during the third trimester. A discussion of expected changes in sexuality should be routinely done in order to improve couples' perception of possible sexual modifications induced by pregnancy. It is clear that, despite some difficulties related to sexual activity during pregnancy, its need and importance are recognized for both participants.

Take Note!

Fluctuations in sexual desire are normal and a highly individualized response throughout pregnancy.

The physical and emotional adjustments of pregnancy can cause changes in body image, fatigue, mood swings, and sexual activity. The woman's changing shape, emotional status, fetal activity, changes in breast size, pressure on the bladder, and other common discomforts of pregnancy result in increased physical and emotional demands. These can produce stress on the sexual relationship of the pregnant woman and her partner. However, most women adjust well to the alterations and experience a satisfying sexual relationship. Research indicates that sexual intercourse is safe in the absence of ruptured membranes, bleeding, or placenta previa, but pregnant women engage in sex less often as the pregnancy progresses (ACOG, 2015f).

Often pregnant women ask whether sexual intercourse is allowed during pregnancy or whether there are specific times when they should refrain from

having sex. This is a good opportunity to educate clients about sexual behavior during pregnancy and also to ask about their expectations and individual experience related to sexuality and possible changes. It is also a good time for nurses to address the impact of the changes associated with pregnancy on sexual desire and behavior. Couples may enjoy sexual activity more because there is no fear of pregnancy and no need to disrupt spontaneity by using birth control. An increase in pelvic congestion and lubrication secondary to estrogen influence may heighten orgasm for many women. Some women have a decrease in desire because of a negative body image, fear of harming the fetus by engaging in intercourse, and fatigue, nausea, and vomiting (Boynton, 2015). Condom use can be recommended to decrease the release of prostaglandins in the semen that may stimulate contractions. A couple may need assistance to adjust to the various changes brought about by pregnancy.

Reassure the women and her partner that sexual activity is permissible during pregnancy unless there is a history of any of the following:

• Vaginal bleeding

• Placenta previa

• Risk of preterm labor

• Cervical insufficiency

• Premature rupture of membranes

• Presence of infection (Rigby, 2015)

Inform the couple that the fetus will not be injured by intercourse. Suggest that alternative positions may be more comfortable (e.g., woman on top, side-lying), especially during the later stages of pregnancy. Some of the physical changes in pregnancy, which can affect a couple's relationship, for example, halitosis which can result from dehydration, but can be alleviated through extra fluids and better oral hygiene. Women can have breast tenderness and skin changes that can cause them feel unattractive to their partner during pregnancy. In addition, they can be worried about increases in vaginal discharge and need to know what is normal and what can be a sign of infection. Nurses should make women feel comfortable talking about their fears, encouraging them to take pride in their changing bodies.

Many women feel a particular need for closeness during pregnancy, and the woman should communicate this need to her partner (Halford, Petch, & Creedy, 2015). Emphasize to the couple that closeness and cuddling need not culminate

in intercourse, and that other forms of sexual expression, such as mutual masturbation, foot massage, holding hands, kissing, and hugging can be very satisfying (Halford et al., 2015).

Sex in pregnancy is normal. Research suggests that prepregnancy sexuality plays an important role in maintaining sexuality during pregnancy and postpartum (Yildiz, 2015). There are very few proven contraindications and risks to intercourse in low-risk pregnancies, and therefore, these clients should be reassured. In pregnancies complicated by placenta previa or an increased risk of preterm labor, the evidence to support abstinence is lacking, but it is a reasonable benign recommendation given the theoretical catastrophic consequences (Yeniel & Petri, 2014).

Women will experience a myriad of symptoms, feelings, and physical sensations during their pregnancy. Having a satisfying sexual relationship during pregnancy is certainly possible, but it requires honest communication between partners to determine what works best for them and a good relationship with their health care provider to ensure safety (March of Dimes, 2015f).

Employment

Nearly three-quarters of pregnant women in the United States will continue to work outside the home until the last month of pregnancy (Jordan et al., 2014). For the most part, women can continue working until giving birth if they have no complications during their pregnancy and the workplace does not present any special hazards (Zolotor & Carlough, 2014). Hazardous occupations include health care workers, daycare providers, laboratory technicians, chemists, painters, hairstylists, veterinary workers, and carpenters (Guidotti, 2014). Jobs requiring strenuous work such as heavy lifting, climbing, carrying heavy objects, and standing for prolonged periods place a pregnant woman at risk if modifications are not instituted.

Assess for environmental and occupational factors that place a pregnant women and her fetus at risk for injury. Interview the woman about her employment environment. Ask about possible exposure to teratogens (substances with the potential to alter the fetus permanently in form or function) and the physical demands of employment: Is she exposed to temperature extremes? Does she need to stand for prolonged periods in a fixed position? A description of the work environment is important in providing anticipatory guidance to the woman. Stress the importance of taking rest periods throughout the day, because constant physically intensive workloads increase the likelihood of low birth weight and preterm labor and birth (Cunningham et al., 2014).

Because of the numerous physiologic and psychosocial changes that women experience during their pregnancies, the employer may need to make special accommodations to reduce the pregnant woman's risk of hazardous exposures and heavy workloads. The employer may need to provide adequate coverage so that the woman can take rest breaks; remove the woman from any areas where she might be exposed to toxic substances; and avoid work assignments that require heavy lifting, hard physical labor, continuous standing, or constant moving. Some recommendations for working while pregnant are given in Teaching Guidelines 12.3.

Teaching Guidelines 12.3

TEACHING FOR THE PREGNANT WORKING WOMAN

• Plan to take two 10- to 15-minute breaks within an 8-hour work day.

• Be sure there is a place available for you to rest, preferably in the side-lying position, with a restroom readily available.

• Avoid jobs that require strenuous workloads; if this is not possible, then request a modification of work duties (lighter tasks) to reduce your workload.

• Change your position from standing to sitting or vice versa at least every 2 hours.

• Ensure that you are allowed time off without penalty, if necessary, to ensure a healthy outcome for you and your fetus.

• Make sure the work environment is free of toxic substances.

• Ensure the work environment is smoke-free so passive smoking is not a concern.

• Minimize heavy lifting if associated with bending.

Travel

Pregnancy does not curtail a woman's ability to travel in a car or in a plane. However, women should follow a few safety guidelines to minimize risk to themselves and their fetuses. According to ACOG (2015g), pregnant women can travel safely throughout their pregnancy, although the second trimester is perhaps the best time to travel because there is the least chance of complications. Pregnant women considering international travel should evaluate the problems that could occur during the journey as well as the quality of medical care available at the destination.

A woman in the third trimester should be advised to defer overseas travel because of concerns about access to medical care in case of problems such as hypertension, phlebitis, or premature labor (CDC, 2015e). Pregnant women should be advised to consult with their health care providers before making any travel decisions.

Take Note!

Clinical manifestations that indicate the need for immediate medical attention while traveling are vaginal bleeding, passing tissue or clots, abdominal pain or cramps, contractions, ruptured membranes, excessive leg swelling or pain, headaches, or visual problems (Leggat & Zuckerman, 2015).

Advise pregnant women to be aware of the potential for injuries and traumas related to traveling, and teach women ways to prevent these from occurring. Teaching Guidelines 12.4 offers tips for safe travel on planes and to foreign areas.

Teaching Guidelines 12.4

TEACHING TO PROMOTE SAFE TRAVEL ON PLANES AND IN FOREIGN COUNTRIES

- Bring along a copy of the prenatal record if your travel will be prolonged in case there is a medical emergency away from home.
- When traveling abroad, carry a foreign dictionary that includes words or phrases for the most common pregnancy emergencies.
- Travel with at least one companion at all times for personal safety.
- Check with your health care provider before receiving any immunizations necessary for foreign travel; some may be harmful to the fetus.
- When in a foreign country, avoid fresh fruit, vegetables, and local water.
- Avoid any milk that is not pasteurized.
- Eat only meat that is well cooked to avoid exposure to toxoplasmosis.
- Request an aisle seat and walk about the airplane every 2 hours.
- While sitting on long flights, practice calf-tensing exercises to improve circulation to the lower extremities.
- Be aware of typical problems encountered by pregnant travelers, such as fatigue, heartburn, indigestion, constipation, vaginal discharge, leg cramps, urinary frequency, and hemorrhoids.
- Always wear support hose while flying to prevent the development of blood clots.
- Drink plenty of water to keep well hydrated throughout the flight.
- Postpone travel if risks outweigh benefits.

Adapted from American College of Obstetricians and Gynecologists. (2015e). *Travel during pregnancy: FAQ 055*. Retrieved from http://www.acog.org/~/media/for%20patients/faq055.ashx; Centers for Disease Control and Prevention. (2015e). *Pregnant travelers*. Retrieved from http://wwwnc.cdc.gov/travel/yellowbook/2014/chapter-8-advising-travelers-with-specific-needs/pregnant-travelers

When traveling by car, the major risk is a car accident. Motor vehicle accidents account for more than 50% of all traumas during pregnancy and 82% of fetal deaths occurring during these accidents (Eshaghabadi & Barati, 2015). The impact and momentum can lead to traumatic separation of the placenta from the wall of the uterus. Shock and massive hemorrhage might result. Tips that nurses can offer to promote safety during ground travel include the following:

- Always wear a three-point seat belt, no matter how short the trip, to prevent

ejection or serious injury from collision.

• Apply a nonpadded shoulder strap properly; it should cross between the breasts and over the upper abdomen, above the uterus (Fig. 12.11).

• If no seat belts are available (buses or vans), ride in the back seat of the vehicle.

• Use a lap belt that crosses over the pelvis below the uterus.

• Deactivate the airbag if possible. If you cannot, move the seat as far back from the dashboard as possible to minimize impact on the abdomen.

• Never use a cellular phone while driving to prevent distraction.

• Avoid driving when very fatigued in the first and third trimesters.

• Avoid late-night driving, when visibility might be compromised.

• Direct a tilting steering wheel away from the abdomen (CDC, 2015e).

FIGURE 12.11 Proper application of a seat belt during pregnancy.

Immunizations and Medications

Vaccines are among the greatest public health achievements of the twenty-first century, credited with significant reduction of morbidity and mortality from many diseases caused by bacteria and viruses (Senie, 2014). Ideally, clients should receive all childhood immunizations before conception to protect the fetus from any risk of congenital anomalies. If the client comes for a preconception visit, discuss immunizations such as measles, mumps, and rubella (MMR), hepatitis B, and diphtheria/tetanus (every 10 years); administer them at this time if needed.

The risk to a developing fetus from vaccination of the mother during pregnancy is primarily theoretical. Routine immunizations are not usually indicated during pregnancy. However, no evidence exists of risk from vaccinating pregnant women with inactivated virus or bacterial vaccines or toxoids. A number of other vaccines have not been adequately studied, and thus theoretical risks of vaccination must be weighed against the risks of the disease to mother and fetus (CDC, 2015f).

 Take Note!

Advise pregnant women to avoid live virus vaccines (MMR and varicella) and to avoid becoming pregnant within 1 month of having received one of these vaccines because of the theoretical risk of transmission to the fetus (CDC, 2015f).

CDC guidelines for vaccine administration are highlighted in Box 12.6.

Little is known about the effects of taking most medications during pregnancy. Less than 10% of medications approved by the FDA since 1980 have enough information to determine their risk for birth defects (CDC, 2015g). Based on this lack of evidence, it is best for pregnant women not to take any medications during their pregnancy. At the very least, encourage them to discuss with the health care provider their current medications and any herbal remedies they take so that they can learn about any potential risks should they continue to take them during pregnancy. Generally, if the woman is taking medicine for seizures, high blood pressure, asthma, or depression, the benefits of continuing the medicine

during pregnancy outweigh the risks to the fetus. The safety profile of some medications may change according to the gestational age of the fetus. Embryogenesis is completed by the end of the first trimester, when all fetal organs are complete. Thus, to cause a malformation, fetal drug exposure must occur in the first 12 weeks of gestation (Gadot & Koren, 2015).

Vaccines That Should Be Considered if Otherwise Indicated

- Hepatitis B
- Influenza (inactivated) injection
- Tetanus/diphtheria (Tdap)
- Meningococcal
- Rabies

Vaccines Contraindicated During Pregnancy

• Influenza (live, attenuated vaccine) nasal spray

• Measles

• Mumps

• Rubella

• Varicella

• BCG (tuberculosis)

• Meningococcal

• Typhoid

Adapted from Centers for Disease Control and Prevention. (2015f). *Vaccines for pregnant women*. Retrieved from http://www.cdc.gov/vaccines/adults/rec-vac/pregnant.html; March of Dimes. (2015h). *Vaccinations during pregnancy*. Retrieved from http://www.marchofdimes.com/pregnancy/vaccinations-during-pregnancy.aspx

The FDA has developed a system of ranking drugs that appears on drug labels and package inserts. These risk categories are summarized in Box 12.7. Always advise women to check with the health care provider for guidance.

A common concern of many pregnant women involves the use of over-the-counter medications and herbal agents. Many women consider these products benign simply because they are available without a prescription (King et al., 2015). Although herbal medications are commonly thought of as "natural" alternatives to other medicines, they can be just as potent as some prescription medications. A major concern about herbal medicine is the lack of consistent potency in the active ingredients in any given batch of product, making it difficult to know the exact strength by reading the label. Also, many herbs contain chemicals that cross the placenta and may cause harm to the fetus.

Nurses are often asked about the safety of over-the-counter medicines and herbal agents. Unfortunately, many drugs have not been evaluated in controlled studies, and it is difficult to make general recommendations for these products. Therefore, encourage pregnant women to check with their health care provider before taking anything. Questions about the use of over-the-counter and herbal

products are part of the initial prenatal interview.

FDA PREGNANCY RISK CLASSIFICATION OF DRUGS

• The Pregnancy subsection will provide information relevant to the use of the drug in pregnant women, such as dosing and potential risks to the developing fetus, and will require information about whether there is a registry that collects and maintains data on how pregnant women are affected when they use the drug or biological product. Information in drug labeling about the existence of any pregnancy registries has been previously recommended but not required until now.

• The Lactation subsection will provide information about using the drug while breastfeeding, such as the amount of drug in breast milk and potential effects on the breastfed child.

• The Females and Males of Reproductive Potential subsection will include information about pregnancy testing, contraception and about infertility as it relates to the drug. This information has been included in labeling, but there was no consistent placement for it until now.

NURSING MANAGEMENT TO PREPARE THE WOMAN AND HER PARTNER FOR LABOR, BIRTH, AND PARENTHOOD

Pregnancy and birth are unique to every woman. Women and families hold different expectations during childbearing based on their knowledge, experiences, belief systems, culture, and social and family backgrounds. These differences should be understood and respected by the nurse, and care to them adapted to meet the individual needs of the women and families. Knowing a woman's needs, values, cultural background, preferences, and expectations during childbirth helps nurses to provide high-quality care to them. Childbirth today is a very different experience from childbirth in previous generations. In the past, women were literally "put to sleep" with anesthetics, and they woke up with a baby. Most women never remembered the details and had a passive role in childbirth as the physician delivered the newborn. In the 1950s, consumers began to insist on taking a more active role in their health care, and couples desired to be together during the extraordinary event of childbirth. Beginning in the 1970s, the father or significant other support person remained with the mother throughout labor and birth. Fathers today want to be seen as individuals who are part of the laboring couple. If fathers are left out, they tend to feel helpless; this can result in a feeling of panic and can put their support for their partner at risk (Schytt & Bergstrom, 2014).

Health beliefs related to pregnancy and childbirth exist in various cultures globally. A woman's perception of her own status is critical to her decision-making process, because her personal behaviors can significantly alter her pregnancy-related risks. Pregnant women of diverse cultures hold a number of beliefs related to diet, behavior related to prenatal care, and the use of herbs during pregnancy and postnatally. Nurses need to be aware of these cultural beliefs so as to incorporate those into their practices, while those posing a health risk should be discouraged respectfully (M'soka, Mabuza, & Pretorius, 2015).

Childbirth education began because women demanded to become more involved in their birthing experience rather than simply turning control over to a health care provider. Nurses played a pivotal role in bringing about this change by providing information and supporting clients and their families, fostering a more active role in preparing for the upcoming birth.

Traditional childbirth education classes focused on developing and practicing techniques for use in managing pain and facilitating the progress of labor. Recently, the focus of this education has broadened: it now encompasses not only preparation for childbirth, but also preparation for breast-feeding, infant care, transition to new parenting roles, relationship skills, family health promotion, and sexuality (Varner, 2015). The term used to describe this broad range of topics is **perinatal education**. Subjects commonly addressed in perinatal education include the following:

• Anatomy and physiology of reproduction

• Fetal growth and development

• Prenatal maternal exercise

• Physiologic and emotional changes during pregnancy

• Sex during pregnancy

• Infant growth and development

• Nutrition and healthy eating habits during pregnancy

• Teratogens and their impact on the fetus

• Signs and symptoms of labor

• Preparation for labor and birth (for parents, siblings, and other family members)

• Options for birth

• Infant nutrition, including preparation for breast-feeding

• Infant care, including safety, CPR, and first aid

• Family planning (March of Dimes, 2015g)

Childbirth Education Classes

Childbirth education classes teach pregnant women and their support person about pregnancy, birth, and parenting. The classes are offered in local communities or online and are usually taught by certified childbirth educators. Most childbirth classes support the concept of **natural childbirth** (a birth without pain-relieving medications) so that the woman can be in control throughout the experience as much as possible. The classes differ in their approach to specific comfort techniques and breathing patterns. The three most common childbirth methods are the Lamaze (psychoprophylactic) method, the Bradley (partner-coached childbirth) method, and the Dick-Read (natural childbirth) method.

Lamaze Method

Lamaze is a psychoprophylactic ("mind prevention") method of preparing for labor and birth that promotes the use of specific breathing and relaxation techniques. Dr. Fernand Lamaze, a French obstetrician, popularized this method of childbirth preparation in the 1960s. Lamaze believed that conquering fear through knowledge and support was important. He also believed women needed to alter the perception of suffering during childbirth. This perception change would come about by learning conditioned reflexes that, instead of signaling pain, would signal the work of producing a child, and thus would carry the woman through labor awake, aware, and in control of her own body (Lamaze International, 2015). Lamaze felt strongly that all women have the right to deliver their babies with minimal or no medication while maintaining their dignity, minimizing their pain, maximizing their self-esteem, and enjoying the miracle of birth.

Lamaze classes include information on toning exercises, relaxation exercises and techniques, and breathing methods for labor. The breathing techniques are used in labor to enhance relaxation and to reduce the woman's perception of pain. The goal is for women to become aware of their own comfortable rate of breathing in order to maintain relaxation and adequate oxygenation of the fetus. The following breathing techniques are an effective attention-focusing strategy to reduce pain:

• *Paced breathing* involves breathing techniques used to decrease stress

responses and therefore decrease pain. This type of breathing implies self-regulation by the woman. The woman starts off by taking a cleansing breath at the onset and end of each contraction. This cleansing breath symbolizes freeing her mind from worries and concerns. This breath enhances oxygenation and puts the woman in a relaxed state.

- *Slow-paced breathing* is associated with relaxation and should be half the normal breathing rate (6 to 9 breaths per minute). This type of breathing is the most relaxed pattern and is recommended throughout labor. Abdominal or chest breathing may be used. It is generally best to breathe in through the nose and breathe out either through the nose or mouth, whichever is more comfortable for the woman.

- *Modified-paced breathing* can be used for increased work or stress during labor to increase alertness or focus attention or when slow-paced breathing is no longer effective in keeping the woman relaxed. The woman's respiratory rate increases, but it does not exceed twice her normal rate. Modified-paced breathing is a quiet upper chest breath that is increased or decreased according to the intensity of the contraction. The inhalation and the exhalation are equal. This breathing technique should be practiced during pregnancy for optimal use during labor.

- *Patterned-paced breathing* is similar to modified-paced breathing but with a rhythmic pattern. It uses a variety of patterns, with an emphasis on the exhalation breath at regular intervals. Different patterns can be used, such as 4/1, 6/1, 4/1. A 4/1 rhythm is four upper chest breaths followed by an exhalation (a sighing out of air, like blowing out a candle). Random patterns can be chosen for use as long as the basic principles of rate and relaxation are met.

Couples practice these breathing patterns typically during the last few months of the pregnancy until they feel comfortable using them. Focal points (visual fixation on a designated object), effleurage (light abdominal massage by woman or partner), massage, and imagery (journey of the mind to a relaxing place) are also added to aid in relaxation. From the nurse's perspective, encourage the woman to breathe at a level of comfort that allows her to cope. Always remain quiet during the woman's periods of imagery and focal point visualization to avoid breaking her concentration.

Bradley (Partner-Coached) Method

The Bradley method uses various exercises and slow, controlled abdominal breathing to accomplish relaxation. Dr. Robert Bradley, a Denver-based obstetrician, advocated a completely unmedicated labor and birth experience. The Bradley method emphasizes the pleasurable sensations of childbirth, teaching women to concentrate on these sensations while "turning on" to their own bodies (Bradley Method, 2014). In 1965, Bradley wrote *Husband-Coached Childbirth,* which advocated the active participation of the husband as labor coach.

A woman is conditioned to work in harmony with her body using breath control and deep abdominopelvic breathing to promote general body relaxation during labor. This method stresses that childbirth is a joyful, natural process and emphasizes the partner's involvement during pregnancy, labor, birth, and the early newborn period. Thus, the training techniques are directed toward the coach, not the mother. The coach is educated in massage/comfort techniques to use on the mother throughout the labor and birth process.

Dick-Read Method

In 1944, Grantly Dick-Read, a British obstetrician, wrote *Childbirth Without Fear.* He believed that the attitude of a woman toward her birthing process had a considerable influence on the ease of her labor, and he believed that fear is the primary pain-producing agent in an otherwise normal labor. He felt that fear builds a state of tension, creating an antagonistic effect on the laboring muscles of the uterus, which results in pain. A private, undisturbed, and dark environment, where women can feel safe, can promote the release of oxytocin, the hormone responsible for uterine contractions and though to promote the release of the pain-relieving hormones endorphins. When this is not achieved, women can experience fear–tension–pain syndrome, impeding labor progress and causing increased levels of pain (Westbury, 2015). Dick-Read sought to interrupt the circular pattern of fear, tension, and pain during the labor and birthing process. He promoted the belief that the degree of fear could be diminished with increased understanding of the normal physiologic response to labor (Alexander et al., 2014).

Dick-Read believed that prenatal instruction was essential for pain relief and that emotional factors during labor interfered with the normal labor progression. The woman achieves relaxation and reduces pain by arming herself with the

knowledge of normal childbirth and using abdominal breathing during contractions.

Nursing Management and Childbirth Education

Childbirth education is less about methods than about mastery. The overall aim of any of the methods is to promote an internal locus of control that will enable each woman to yield her body to the process of birth. As the woman gains success and tangible benefits from the exercises she is taught, she begins to reframe her beliefs and gains practical knowledge, and the impetus will be there for her to engage in the conscious use of the techniques (Fig. 12.12). Nurses play a key role in supporting and encouraging each couple's use of the techniques taught in childbirth education classes.

Every woman's labor is unique, and it is important for nurses not to generalize or stereotype women. The most effective support a nurse can offer a couple using prepared childbirth methods is encouragement and presence. These nursing measures must be adapted to each individual throughout the labor process. Offering encouraging phrases such as "great job" or "you can do it" helps to reinforce their efforts and at the same time empowers them to continue. Using eye-to-eye contact to engage the woman's total attention is important if she appears overwhelmed or appears to lose control during the transition phase of labor.

Nurses play a significant role in enhancing the couple's relationship by respecting the involvement of the partner and demonstrating concern for his needs throughout labor. Offering to stay with the woman to give him a break periodically allows him to meet his needs while at the same time still actively participating. Offer anticipatory guidance to the couple and assist during critical times in labor. Demonstrate many of the coping techniques to the partner and praise their successful use, which increases self-esteem. Focus on their strengths and the positive elements of the labor experience. Congratulating the couple for a job well done is paramount.

Throughout the labor experience, demonstrate personal warmth and project a friendly attitude. Frequently, a nurse's touch may help to prevent a crisis by reassuring the mother that she is doing fine.

Options for Birth Settings and Care Providers

From the moment a woman discovers she is pregnant, numerous decisions await her—where the infant will be born, what birth setting is best, and who will assist with the birth. The majority of women are well and healthy and can consider the full range of birth settings—hospital, birth center, or home setting—and care providers. They should be given information about each to ensure the most informed decision.

Birth Settings

HOSPITALS

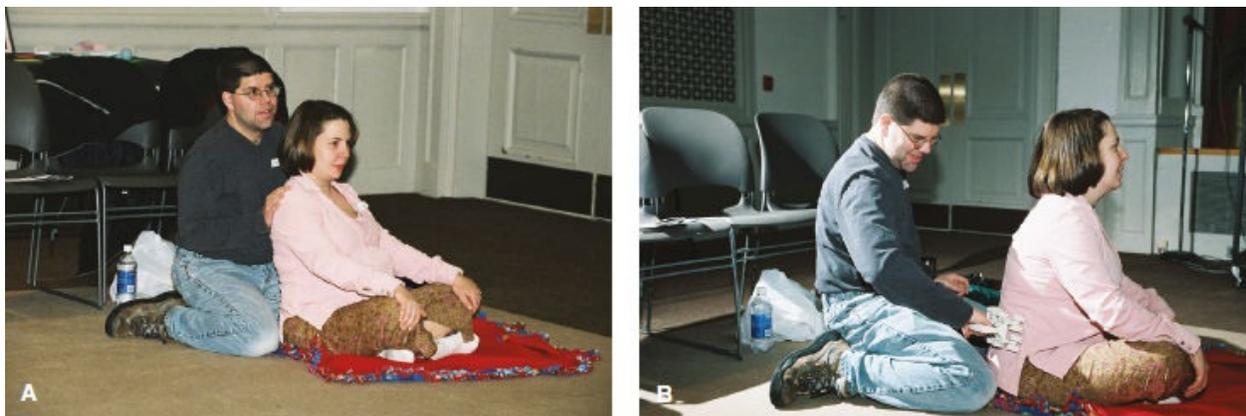
Hospitals are the most common site for birth in the United States. If the woman has a serious medical condition or is at high risk for developing one, she will probably need to plan to give birth in a hospital setting under the care of an obstetrician. Giving birth in a hospital is advantageous for several reasons. Hospitals are best equipped to diagnose and treat women and newborns with complications; trained personnel are available if necessary; and no transportation is needed if a complication should arise during labor or birth. Disadvantages include the high-tech atmosphere; strict policies and restrictions that might limit who can be with the woman; and the medical model of care.


FIGURE 12.12 A couple practicing the techniques taught in a childbirth education class.

Within the hospital setting, however, choices do exist regarding birth environments. The conventional delivery room resembles an operating room,

where the health care professional delivers the newborn from the woman, who is positioned in stirrups. The woman is then transferred to the recovery area on a stretcher and then again to the postpartum unit. The birthing suite is the other option within the hospital setting. In the birthing suite, the woman and her partner remain in one place for labor, birth, and recovery. The birthing suite is a private room decorated to look as homelike as possible. For example, the bed converts to allow for various birthing positions, and there may be a rocking chair or an easy chair for the woman's partner. Despite the homey atmosphere, the room is still equipped with emergency resuscitative obstetric equipment and electronic fetal monitors in case they are needed quickly (Fig. 12.13A). Such settings provide a more personal childbirth experience in a less formal and intimidating atmosphere compared to the traditional delivery room.

FREESTANDING BIRTH CENTER

A freestanding birth center offers women a comfortable setting where they can receive maternity care with appropriate levels of intervention. A freestanding birth center (Fig. 12.13B) can be a good choice for a woman who wants more personalized care than in a hospital but does not feel comfortable with a home birth. In contrast to the institutional environment in hospitals, most freestanding birth centers have a homelike atmosphere, and many are, in fact, located in converted homes. Some are located on hospital property and are affiliated with them. Birth centers are designed to provide maternity care to women judged to be at low risk for obstetric complications. Women are allowed and encouraged to give birth in the position most comfortable for them. Care in birth centers is often provided by midwives and is more relaxed, with no routine intravenous lines, fetal monitoring, and restrictive protocols. A disadvantage of the birth center is the need to transport the woman to a hospital quickly if an emergency arises, because emergency equipment is not readily available. In a research study comparing homelike to conventional institutional settings, the author concluded that there appeared to be some benefits from homelike settings for childbirth, although increased support from caregivers may be more important (Alliman, Jolles, & Summers, 2015).

HOME BIRTHS

Rates of planned home births have been increasing since the 1970s, with 1 in 49 non-Hispanic White women giving birth outside the hospital setting now (Zielinski, Ackerson, & Low, 2015). Most women who choose a home birth

believe that birth is a natural process that requires little medical intervention (Lewis, 2015). Research has shown that women believe that planned home births increase privacy, comfort, and convenience; are associated with reduced rates of medical interventions; and facilitate family involvement in a relaxed, peaceful atmosphere (Budin, 2015).

The safety of home births is an ongoing debate in the United States. The American College of Nurse Midwives (ACNM), the American Public Health Association (APHA), and WHO state that planned home birth is safe, as long as the woman falls under certain criteria, such as a low-risk pregnancy, singleton fetus, cephalic fetus at term, and the absence of pre-existing conditions (Declercq & Stotland, 2015). Home births can be safe if there are qualified, experienced attendants and an emergency transfer system in place in case of serious complications. Many women choose the home setting out of a strong desire to control their child's birth and to give birth surrounded by family members. Most home birth caregivers are midwives who have provided continuous care to the woman throughout the pregnancy. Disadvantages include the need to transport the woman to the hospital during or after labor if a problem arises, and the limited pain management available in the home setting.

FIGURE 12.13 **A.** Birthing suite in hospital setting. **B.** Childbirth room in birthing center.

Care Providers

While most women in the United States still receive pregnancy care from an obstetrician, an increasing number are choosing a midwife for their care. The difference is a matter of degrees. Obstetricians must finish a 4-year residency in obstetrics and gynecology in addition to medical school. Certified nurse-midwives are registered nurses who have graduated from a nurse-midwifery

education program accredited by the Accreditation Commission for Midwifery Education (ACME) and have passed a national certification examination to receive the professional designation of certified nurse-midwife. As of 2010, a graduate degree is required for entry into midwifery practice in the United States. Midwives usually care for low-risk women in a variety of settings. They are able to write prescriptions, provide prenatal care, childbirth care, postpartum care, newborn care, and well-women's care throughout the lifespan. Family practice doctors also provide maternity, woman's care, and well-baby care. Many deliver their clients' newborns in the hospital or birthing centers. Obstetricians can handle high-risk pregnancies and delivery emergencies; can administer or order pain-relief drugs; and are assisted by a support staff in the hospital setting. Midwives work in hospitals, birthing centers, and home settings to deliver care. They believe in the normalcy of birth and tolerate wide variations of what is considered normal during labor, which leads to fewer interventions applied during the childbirth process. Midwives attend approximately 8% of total United States births (American College of Nurse-Midwives, 2015). Midwives do handle high-risk and emergency births because many are not always predictable—they typically have an obstetrician as back up when they do occur to assist them.

In addition to the woman's primary health care provider, some women hire a doula to be with them during the childbearing process. *Doula* is a Greek word that means "woman's servant." A doula is a laywoman trained to provide women and their families with encouragement, emotional and physical support, and information through late pregnancy, labor, birth, and postpartum. Doulas provide the woman with continuous support throughout labor but do not perform any clinical procedures.

Preparation for Breast-Feeding or Bottle-Feeding

Pregnant women are faced with a decision about which method of feeding to choose. Educate the pregnant client about the advantages and disadvantages of each method, allowing the woman and her partner to make an informed decision about the best method for their situation. Providing the client and her partner with this information will increase the likelihood of a successful experience regardless of the method of feeding chosen. As part of health promotion/evidence-based interventions, nurses should be encouraging and educating all women on breast-feeding.

Breast-Feeding

Substantial scientific evidence exists documenting the health benefits of breast-feeding for newborns. Current evidence cited by the AAP showed improved outcomes for breast-fed infants with regard to otitis media, lower respiratory infections, gastroenteritis, atopic dermatitis, childhood asthma, childhood obesity, type 1 and type 2 diabetes, childhood leukemia, sudden infant death syndrome, and cognitive development, and for their mothers with regard to breast cancer, ovarian cancer, and type 2 diabetes. The AAP recommends that infants be breast-fed exclusively until the age 6 months, and continue to be breast-fed for a year and for as long as it is mutually desired (2012). In addition, a lack of breast-feeding has a negative impact on the health care system by increasing the number of client visits, hospital admissions, rate of obesity, and health care costs. Most researchers agree that the duration of breast-feeding is inversely associated with overweight risk. Breast-feeding is a cost-effective, natural, and effective prevention strategy for reducing childhood obesity. A recent study estimates that $13 billion a year would be saved and 1,000 deaths prevented each year if 90% of infants in the United States were exclusively breast-fed until 6 months (Office on Women's Health, 2014).

Human milk provides an ideal balance of nutrients for newborns (ACOG, 2015h). Breast-feeding is advantageous for the following reasons:

• Human milk is digestible and economical and requires no preparation.

• Bonding between mother and child is promoted.

• Cost is less than purchasing formula.

- Ovulation is suppressed (however, this is not a reliable birth control method).
- The risk of ovarian cancer and the incidence of premenopausal breast cancer are reduced for the woman.
- Extra calories are used, which promotes weight loss gradually without dieting.
- Oxytocin is released to promote more rapid uterine involution with less bleeding.
- Sucking helps to develop the muscles in the infant's jaw.
- Absorption of lactose and minerals in the newborn is improved.
- The immunologic properties of breast milk help prevent infections in the baby.
- The composition of breast milk adapts to meet the infant's changing needs.
- Constipation in the baby is not a problem with adequate intake.
- Food allergies are less likely to develop in the breast-fed baby.
- The incidence of otitis media and upper respiratory infections in the infant is reduced.
- Breast-fed babies are less likely to be overfed, thus reducing the risk of adult obesity.
- Breast-fed newborns are less prone to vomiting (AAP 2015; ACOG, 2015h; American Academy of Family Physicians, 2015; Women, Infant & Children [WIC], 2015).

One could say that lactation and breast-feeding are so natural that they should just happen on their own accord, but this is not the case. Learning to breast-feed takes practice, requires support from the partner, and requires dedication and patience on the part of the mother; it may be necessary to work closely with a lactation consultant to be successful and comfortable when breast-feeding. (Figure 12.14 show the different positions that may be used for breast-feeding.) Nurses can encourage breast-feeding for all mothers except those that are HIV+, and are untreated, have active tuberculosis, use illicit drugs, or take prescribed cancer chemotherapeutic agents.

Breast-feeding also has some side effects. These include breast discomfort, sore nipples, mastitis, engorgement, milk stasis, vaginal dryness, and decreased libido (Alekseev, Vladimir, & Nadezhda, 2015). The most common cause of nipple pain is an improper latch and such discomfort is piercing, immediate, and short-lived, typically occurring as soon as the baby starts nursing and gradually

subsiding during the feeding. Some mothers feel it is inconvenient or embarrassing, limits other activities, limits partner involvement, increases their dependency by being tied to the infant all the time, and restricts their use of alcohol or drugs. Nurses can help mothers to cope with their fear of dependency and feelings of obligation by emphasizing the positive aspects of breast-feeding and encouraging bonding experiences. Nurses can be instrumental in helping mothers prepare and continue to breastfeed after they return to work.

PREPARATION FOR BREAST-FEEDING

Nipple preparation is not necessary during the prenatal period unless the nipples are inverted and do not become erect when stimulated. Assess for this by placing the forefinger and thumb above and below the areola and compressing behind the nipple. If it flattens or inverts, advise the client to wear breast shields during the last 2 months of pregnancy. Breast shields exert a continuous pressure around the areola, pushing the nipple through a central opening in the inner shield (La Leche League International, 2014). The shields are worn inside the bra. Initially the shields are worn for 1 hour, and then the woman progressively increases the wearing time up to 8 hours daily. The client maintains this schedule until after childbirth, and then she wears the shield 24 hours a day until the infant latches on easily (La Leche League International, 2014). In addition, suggest that the woman wear a supportive nursing bra 24 hours a day.

Encourage the woman to request a certified lactation specialist (CLS) at the hospital, if giving birth there. Lactation specialists are health care providers who specialize in the clinical management of breast-feeding. Some run their own breast-feeding support groups as well. In addition, suggest that the woman attends a breast-feeding support group (e.g., La Leche League), provide her with sources of information about infant feeding, and suggest that she reads a good reference book about lactation. All of these activities will help in her decision-making process and will be invaluable to her should she choose to breast-feed her newborn. Women returning to work can pump their breasts and store the milk in the freezer for future use.

Bottle-Feeding

Recent research indicates that infants who are fed formula within the first 6 months do have an increased incidence of otitis media, diabetes, asthma, atopic dermatitis, reflux, diarrhea, colic, constipation, and lower respiratory infections

(Schram, 2014). It is important to inform mothers and their partners of this.

Bottle-feeding an infant is not just a matter of "open, pour, and feed." Parents need information on types of formulas, preparation and storage of formula, equipment, and feeding positions. It is recommended that normal full-term infants receive conventional cow's milk-based formula; the physician should direct this choice. If the infant has a reaction (diarrhea, vomiting, abdominal pain, excessive gas) to the first formula, another formula should be tried. Sometimes a soy-based formula is substituted. In terms of preparation of formula and its use, the following guidelines should be stressed:

• Obtain adequate equipment (six 4-ounce bottles, eight 8-ounce bottles, and nipples).

• Consistency is important. Stay with a nipple that is comfortable to the infant.

• Frequently assess nipples for any loose pieces of rubber at the opening.

• Correct formula preparation is critical to the health and development of the infant. Formula is available in three forms: ready-to-feed, concentrate, and powder.

• Read the formula label thoroughly before mixing.

• Correct formula dilution is important to avoid fluid imbalances. For ready-to-use formula, use as is without dilution. For concentrated formulas, dilute with equal parts of water. For powdered formulas, mix one scoop of powder with 2 ounces of water

• If the water supply is safe, sterilization is not necessary.

• Bottles and nipples should be washed in hot, sudsy water using a bottle brush.

• Formula should be served at room temperature.

• If the water supply is questionable, water should be boiled for 5 minutes before use.

• Formula should not be heated in a microwave oven, because it is heated unevenly.

• Formula can be prepared 24 hours ahead of time and stored in the refrigerator.

FIGURE 12.14 Positions for breast-feeding. **A.** Cradle hold—infant's head is held in the mother's forearm to nurse. **B.** Cross cradle or transitional hold—infant is held along the opposite arm from the breast. **C.** Clutch or football hold—infant is held on mother's side hip almost under the mother's arm. **D.** Side-lying position—infant lies parallel to mother's side-lying position to nurse. **E.** Prone or laid-back position—infant lies stomach-to-stomach on top of mother to nurse. (From the Office on Women's Health, U.S. Department of Health and Human Services, 2014. Available at: http://www.womenshealth.gov/breastfeeding/learning-to-breastfeed.html.)

Teach the woman and other caretakers to feed the infant in a semi-upright position using the cradle hold in the arms. This position allows for face-to-face contact between the infant and caretaker. Advise the caretaker to hold the bottle so that the nipple is kept full of formula to prevent excessive air swallowing. Instruct the caretaker to feed the infant every 3 to 4 hours and adapt the feeding times to the infant's needs. Frequent burping of the infant (every ounce) helps prevent gas from building up in the stomach. Caution the caretaker not to prop the bottle; propping the bottle can cause choking.

Bottle-feeding should mirror breast-feeding as closely as possible. While nutrition is important, so are the emotional and interactive components of feeding. Encourage the caretaker to cuddle the infant closely and position the infant so that his or her head is in a comfortable position. Also encourage communication with the infant during feedings. Nurses should know the different types of formulas available to provide advice to mothers who have made the informed choice not to breastfeed or to stop breastfeeding.

Take Note!

Warn the caretaker about the danger of putting the infant to bed with a bottle. This can lead to "baby bottle tooth decay" (nursing caries) because sugars in the formula stay in contact with the infant's developing teeth for prolonged periods.

Final Preparation for Labor and Birth

The nurse has played a supportive/education role for the couple throughout the pregnancy and now needs to assist in preparing them for their "big event" by making sure they have made informed decisions and completed the following checklist:

• Attended childbirth preparation classes and practiced breathing techniques

• Selected a birth setting and made arrangements there

• Know what to expect during labor and birth

• Toured the birthing facility

• Packed a suitcase to take to the birthing facility when labor starts

• Made arrangements to have siblings and/or pets taken care of during labor

• Been instructed on signs and symptoms of labor and what to do

• Know what to do if membranes rupture prior to going into labor

• Know how to reach their health care provider when labor starts

• Communicated their needs and desires concerning pain management

• Discussed the possibility of a cesarean birth if complications occur

• Discussed possible names for the newborn

• Selected a feeding method (breast or bottle) with which they feel comfortable

• Made a decision regarding circumcision if they have a boy

• Purchased an infant safety car seat in which to bring their newborn home

• Decided on a pediatrician

• Have items needed to prepare for the newborn's homecoming:

  • Infant clothes in several sizes

  • Nursing bras

  • Infant crib with spaces between the slats that are 2 inches or less apart

  • Diapers (cloth or disposable)

  • Feeding supplies (bottles and nipples if bottle-feeding)

  • Infant thermometer

• Selected a family planning method to use after the birth

At each prenatal visit the nurse has had the opportunity to discuss and reinforce the importance of being prepared for the birth of the child with the parents. It is now up to the parents to use the nurse's guidance and put it into action to be ready for the upcoming birth.

A recent national survey entitled *Listening to Mothers III: Pregnancy and Birth* revealed concerns about overuse of maternity care practices and women's readiness to make informed decisions. Key findings point to the need for quality improvement, consumer engagement, and shared decision making (Declercq, Sakala, Corry, Applebaum, & Herrlick, 2014). These findings present a challenge for all nurses caring for maternity clients to thoroughly explain all procedures, along with their rationales, and truly listen to what the woman desires to make her childbirth experience outcome a positive one for her.

All nurses have the responsibility to impart their knowledge to all women and their families—and that starts with teaching themselves first. The evidence is clear that women have better outcomes when nurses intervene only when needed in the childbirth process. Nurses need to personalize their care to every woman based on her needs, her desires, and her state of health. Nurses must focus on teaching women and their families to understand the value of birth and its long-lasting effects on the family. In addition, nurses must provide birth settings that are safe, whether in the hospital, birth center, or at home. This includes, but is not limited to, providing continuous support in labor, allowing women the freedom to move and assume positions of choice, offering nourishment of the woman's body and spirit, using nonpharmacologic pain-relief modalities whenever possible, and ensuring seamless, collaborative teamwork. Continuous labor support is a nonpharmacologic, evidence-based strategy associated with reduced cesarean rates (Baum, Crawford, & Humphrey-Shelton, 2015).

KEY CONCEPTS

- Preconception care is the promotion of the health and well-being of a woman and her partner before pregnancy. The goal of preconception care is to identify any areas such as health problems, lifestyle habits, or social concerns that might unfavorably affect pregnancy.
- A thorough history and physical examination are performed on the initial prenatal visit.
- A primary aspect of nursing management during the antepartum period is counseling and educating the pregnant women and her partner to promote

healthy outcomes for all involved.

- Nagele's rule can be used to establish the estimated date of birth. Using this rule, subtract 3 months from the month of their last LMP, add 7 days to the first day of the LMP, then correct the year by adding 1 to it. This date is within plus or minus 2 weeks (margin of error).

- Pelvic shape is typically classified as one of the four types: gynecoid, android, anthropoid, and platypelloid. The gynecoid type is the typical female pelvis and offers the best shape for a vaginal delivery.

- Continuous prenatal care is important for a successful outcome. The recommended schedule is every 4 weeks up to 28 weeks (7 months); every 2 weeks from 29 to 36 weeks; and every week from 37 weeks to birth.

- The height of the fundus is measured when the uterus arises out of the pelvis to evaluate fetal growth.

- The fundus reaches the level of the umbilicus at approximately 20 weeks and measures 20 cm. The fundal measurement should approximately equal to the number of weeks of gestation until week 36.

- At each visit the woman is asked whether she is having any common signs or symptoms of preterm labor, which might include uterine contractions, dull backache, pressure in the pelvic area or thighs, increased vaginal discharge, menstrual-like cramps, and vaginal bleeding.

- Prenatal screening has become standard in prenatal care to detect neural tube defects and genetic abnormalities.

- The nurse should address matter-of-factly common discomforts that occur in each trimester at all prenatal visits and should provide realistic measures to help the client deal with them effectively.

- The pregnant client can better care for herself and the fetus if her concerns are anticipated by the nurse and incorporated into guidance sessions at each prenatal visit.

- Iron and folic acid need to be supplemented because their increased requirements during pregnancy are usually too great to be met through diet alone.

- Throughout pregnancy, a well-balanced diet is critical for a healthy baby.

- Perinatal education has broadened its focus to include preparation for pregnancy and family adaptation to the new parenting roles. Childbirth

education began because of increasing pressure from consumers who wanted to become more involved in their birthing experience.

- Three common childbirth education methods are Lamaze (psychoprophylactic), Bradley (partner-coached childbirth), and Dick-Read (natural childbirth).

- The great majorities of women in the United States are well and healthy and can consider the full range of birth settings: hospital, birth center, or home setting.

- All pregnant women need to be able to recognize early signs of contractions to prevent preterm labor.

CHAPTER **WORKSHEET**

MULTIPLE CHOICE QUESTIONS

1. Which of the following biophysical profile findings indicate poor oxygenation to the fetus?

   a. Two pockets of amniotic fluid

   b. Well-flexed arms and legs

   c. Nonreactive fetal heart rate

   d. Fetal breathing movements noted

2. The nurse teaches the pregnant client how to perform Kegel exercises as a way to accomplish which of the following?

   a. Prevent perineal lacerations

   b. Stimulate labor contractions

   c. Increase pelvic muscle tone

   d. Lose pregnancy weight quickly

3. During a clinic visit, a pregnant client at 30 weeks gestation tells the nurse, "I've had some mild cramps that are pretty irregular. What does this mean?" The cramps are probably:

   a. The beginning of labor in the very early stages

   b. An ominous finding indicating that the client is about to have a miscarriage

   c. Related to over hydration of the woman

   d. Braxton Hicks contractions, which occur throughout pregnancy

4. The nurse is preparing her teaching plan for a woman who has just had her pregnancy confirmed. Which of the following should be included in it? Select all that apply.

   a. Prevent constipation by taking a daily laxative

b. Balance your dietary intake by increasing your calories by 300 daily

c. Continue your daily walking routine just as you did before this pregnancy

d. Tetanus, measles, mumps, and rubella vaccines will be given to you now

e. Avoid tub baths now that you are pregnant to prevent vaginal infections

f. Sexual activity is permitted as long as your membranes are intact

g. Increase your consumption of milk to meet your iron needs

5. A pregnant client's LMP was on August 10. Using Nagele's rule, the nurse calculates that her EDD will be which of the following?

a. June 23

b. July 10

c. July 30

d. May 17

6. Which of the following is not true about breast-feeding?

a. Breast-fed infants experience more obesity and allergies

b. Breast milk is perfectly suited to the infant's nutritional needs

c. Breast milk contains maternal antibodies to stimulate infant's immunity

d. Breast-feeding enhances maternal bonding and attachment

7. Practicing good oral hygiene is important for all women throughout their pregnancy. As a nurse providing anticipatory guidance for pregnant women, what condition can result from periodontal disease if good dental care isn't practiced?

a. Postdates pregnancy

b. Large for gestational age infant

c. Advanced reproductive cancer

d. Preterm or low–birth-weight infant

8. Anticipatory guidance regarding sexual activity during pregnancy includes: Select all that apply:

a. Sexual activity is contraindicated throughout pregnancy

b. Most women don't desire intimacy after the first trimester

c. Sexual activity may continue up until the end of the second trimester

d. Sexual intercourse is prohibited if a history of preterm labor exists

e. Women's sexual desire may change throughout the pregnancy

f. Couples can try a variety of positions of comfort during pregnancy

9. Which of the following would be considered risk factors for psychological well-being in pregnancy? Select all that apply:

a. Limited support system and network of friends and family

b. Introverted personality at any point in the pregnancy

c. Ambivalence any time during the pregnancy

d. High levels of stress due to family discord

e. History of previous high-risk pregnancy with complications

f. Depression prior to pregnancy and on medication

CRITICAL THINKING EXERCISES

1. Mary Jones comes to the Women's Health Center, where you work as a nurse. She is in her first trimester of pregnancy and tells you her main complaints are nausea and fatigue, to the point that she wants to sleep most of the time and eats one meal daily. She appears pale and tired. Her mucous membranes are pale. She reports that she gets 8 to 9 hours of sleep each night but still can't seem to stay awake and alert at work. She tells you she knows that she is not eating as she should, but she isn't hungry. Her hemoglobin and hematocrit are low.

a. What subjective and objective data do you have to make your assessment?

b. What is your impression of this woman?

c. What nursing interventions would be appropriate for this client?

d. How will you evaluate the effectiveness of your interventions?

2. Monica, a 16-year-old African-American high school student, is here for her first prenatal visit. Her LMP was 2 months ago, and she states she has been "sick ever since." She is 5 feet, 6 inches tall, and weighs 110 pounds. In completing her dietary assessment, the nurse asks about her intake of milk and dairy products. Monica reports that she doesn't like "that stuff" and doesn't

want to put on too much weight because it "might ruin my figure."

    a. In addition to the routine obstetric assessments, which additional ones might be warranted for this teenager?

    b. What dietary instruction should be provided to this teenager based on her history?

    c. What follow-up monitoring should be included in subsequent prenatal visits?

3. Maria, a 27-year-old Hispanic woman in her last trimester of pregnancy (34 weeks), complains to the clinic nurse that she is constipated and feels miserable most of the time. She reports that she has started taking laxatives, but they don't help much. When questioned about her dietary habits, she replies that she eats beans and rice and drinks tea with most meals. She says she has tried to limit her fluid intake so she doesn't have to go to the bathroom so much because she doesn't want to miss any of her daytime soap operas on television.

    a. What additional information would the nurse need to assess her complaint?

    b. What interventions would be appropriate for Maria?

    c. What adaptations will Maria need to make to alleviate her constipation?

STUDY ACTIVITIES

1. Visit a freestanding birth center and compare it to a traditional hospital setting in terms of restrictions, type of pain management available, and costs.

2. Arrange to shadow a nurse-midwife for a day to see her role in working with the childbearing family.

3. Visit the student resources on and select two of the supplied websites that correspond to this chapter. Note their target audience, the validity of information offered, and their appeal to expectant couples. Present your findings.

4. Request permission to attend a childbirth education class in your local area and help a woman without a partner practice the paced breathing exercises. Present the information you learned and think about how you can apply it

while taking care of a woman during labor.

5. A laywoman with a specialized education and experience in assisting women during labor is a _____.

BRINGING IT ALL TOGETHER: CASE STUDY

A 19-year-old female came to the public health clinic. This was her first prenatal visit, although she was 8 months pregnant. Her explanation as to why she had not been there before was: "It was summer and everything had been going good until my back starting hurting two days ago."

ASSESSMENT

Her vital signs were within in normal range. Weight was 175 pounds. On physical exam, the back area was normal without tenderness when palpated. Fundal height was 36 cm; fetal heart rate was 150 bpm; urinalysis was negative for blood, glucose, or leukocytes. The pelvic exam showed the cervix to be long, thick, and closed. Missed routine prenatal lab work was done since this was her first visit. When questioned further about when her back seemed to cause her the most discomfort, she stated that she was a waitress and when she finished her shift, she could barely walk home.

Learning Objectives

Upon completion of the chapter, you will be able to:

1. Relate premonitory signs of labor.
2. Compare and contrast true versus false labor.
3. Categorize the critical factors affecting labor and birth.
4. Analyze the cardinal movements of labor.
5. Evaluate the maternal and fetal responses to labor and birth.
6. Classify the stages of labor and the critical events in each stage.
7. Characterize the normal physiologic/psychological changes occurring during all four stages of labor.
8. Formulate the concept of pain as it relates to the woman in labor.

> ***Kathy*** *and Chuck have been eagerly awaiting the birth of their first child for what seems to them an eternity. When Kathy finally feels contractions in her abdomen, she and Chuck rush to the birthing center. After the OB nurse finishes a complete history and physical assessment, she informs Kathy and her husband that she must have experienced "false labor" and that they should return home until she starts true labor.*

Words of Wisdom

Intense physical and emotional support promotes a positive and memorable birthing experience.

INTRODUCTION

The process of labor and birth involves more than the birth of a newborn. Numerous physiologic and psychological events occur that ultimately result in the birth of a newborn and the creation or expansion of the family. This chapter describes labor and birth as a process. It addresses initiation of labor, the premonitory signs of labor, including true and false labor, critical factors affecting labor and birth, maternal and fetal response to the laboring process, and the four stages of labor. The chapter also identifies critical factors related to each stage of labor: the "10 P's of labor."

INITIATION OF LABOR

Labor is a physiologic event involving a sequential and integrated set of changes within the myometrium, decidua, and cervix that occurs gradually over a period of days to weeks in order to expel the fetus from the uterus. It is difficult to determine exactly why labor begins and what initiates it. Although several theories have been proposed to explain the onset and maintenance of labor, none of these has been proved scientifically. It is widely believed that labor is influenced by a cascade of events, including uterine stretch from the fetus and amniotic fluid volume, progesterone withdrawal to estrogen dominance, increased oxytocin sensitivity, and increased release of prostaglandins.

One theory suggests that labor is initiated by a change in the estrogen-to-progesterone ratio. During the last trimester of pregnancy, estrogen levels increase and progesterone levels decrease. This change leads to an increase in the number of myometrium gap junctions. Gap junctions are proteins that connect cell membranes and facilitate coordination of uterine contractions and myometrial stretching (Norwitz, 2015).

Although physiologic evidence for the role of oxytocin in the initiation of labor is inconclusive, the number of oxytocin receptors in the uterus increases at the end of pregnancy. This creates an increased sensitivity to oxytocin. Estrogen, the levels of which are also rising, increases myometrial sensitivity to oxytocin. With the increasing levels of oxytocin in the maternal blood in conjunction with increasing fetal cortisol levels that synthesize prostaglandins, uterine contractions are initiated. Oxytocin also aids in stimulating prostaglandin synthesis through receptors in the decidua. Prostaglandins lead to additional contractions, cervical softening, gap junction induction, and myometrial sensitization, thereby leading to a progressive cervical **dilation** (the opening or enlargement of the external cervical os). Uterine contractions have two main functions: to dilate the cervix and to push the fetus through the birth canal (Funai & Norwitz, 2015).

PREMONITORY SIGNS OF LABOR

Before the onset of labor, a pregnant woman's body undergoes several changes in preparation for the birth of the newborn. The changes that occur often lead to characteristic signs and symptoms that suggest that labor is near. These premonitory signs and symptoms can vary, and not every woman experiences every one of them.

Cervical Changes

Before labor begins, cervical softening and possible cervical dilation with descent of the presenting part into the pelvis occur. These changes can occur 1 month to 1 hour before actual labor begins.

As labor approaches, the cervix changes from an elongated structure to a shortened, thinned segment. Cervical collagen fibers undergo enzymatic rearrangement into smaller, more flexible fibers that facilitate water absorption, leading to a softer, more stretchable cervix. These changes occur secondary to the effects of prostaglandins and pressure from Braxton Hicks contractions. The ripening and softening of the cervix are essential for effacement and dilation, which reflect the enhanced collagen breakdown that was previously inhibited by progesterone (Grant, Strevens, & Thornton, 2015).

Lightening

Lightening occurs when the fetal presenting part begins to descend into the true pelvis. The uterus lowers and moves into a more anterior position. The shape of the abdomen changes as a result of the change in the uterus. With this descent, the woman usually notes that her breathing is much easier and that there is a decrease in gastric reflux. However, she may complain of increased pelvic pressure, leg cramping, dependent edema in the lower legs, and low back discomfort. She may notice an increase in vaginal discharge and more frequent urination. In primiparas, lightening can occur 2 weeks or more before labor begins; among multiparas it may not occur until labor starts (Cheng & Caughey, 2015a).

Increased Energy Level

Some women report a sudden increase in energy before labor. This is sometimes referred to as nesting, because many women will focus this energy toward childbirth preparation by cleaning, cooking, preparing the nursery, and spending extra time with other children in the household. The increased energy level usually occurs 24 to 48 hours before the onset of labor. It is thought to be the result of an increase in epinephrine release caused by a decrease in progesterone (Jordan et al., 2014).

Bloody Show

At the onset of labor or before, the mucous plug that fills the cervical canal during pregnancy is expelled as a result of cervical softening and increased pressure of the presenting part. These ruptured cervical capillaries release a small amount of blood that mixes with mucus, resulting in the pink-tinged secretions known as bloody show.

Braxton Hicks Contractions

Braxton Hicks contractions, which the woman may have been experiencing throughout the pregnancy, may become stronger and more frequent. Braxton Hicks contractions are typically felt as a tightening or pulling sensation of the top of the uterus. They occur primarily in the abdomen and groin and gradually spread downward before relaxing. In contrast, true labor contractions are more commonly felt in the lower back. These contractions aid in moving the cervix from a posterior position to an anterior position. They also help in ripening and softening the cervix. However, the contractions are irregular and can be decreased by walking, voiding, eating, increasing fluid intake, or changing position.

Braxton Hicks contractions usually last about 30 seconds but can persist for as long as 2 minutes. As birth draws near and the uterus becomes more sensitive to oxytocin, the frequency and intensity of these contractions increase. However, if the contractions last longer than 30 seconds and occur more often than four to six times an hour, advise the woman to contact her health care provider so that she can be evaluated for possible preterm labor, especially if she is less than 38 weeks pregnant.

Take Note!

An infant born between 34 0/7 and 36 6/7 weeks of gestation is identified as "late preterm" and experiences many of the same health issues as other preterm birth infants (Horgan, 2015).

Spontaneous Rupture of Membranes

Rupture of membranes with loss of amniotic fluid prior to the onset of labor is termed prelabor rupture of membranes (PROM). It occurs in 8% to 10% of women with term pregnancies, the majority of whom will begin labor spontaneously within 24 hours (King et al., 2015). The rupture of membranes can result in either a sudden gush or a steady leakage of amniotic fluid. Although much of the amniotic fluid is lost when the rupture occurs, a continuous supply is produced to ensure protection of the fetus until birth.

After the amniotic sac has ruptured, the barrier to infection is gone and an ascending infection is possible. In addition, there is a danger of cord prolapse if engagement has not occurred with the sudden release of fluid and pressure with rupture. Due to the possibility of these complications, advise women to notify their health care provider and go in for an evaluation.

Consider This

I always pictured myself a dignified woman and behaved in ways to demonstrate that, for that was the way I was raised. My mother and grandmother always stressed that you should look good, dress well, and do nothing to embarrass yourself in public. I did a fairly good job of living up to their expectations until an incident occurred at the end of my first pregnancy. I recall I was overdue according to my dates and was miserable in the summer heat. I decided to go to the store for some ice cream. As I waddled down the grocery aisles, all of a sudden my water broke and came pouring down my legs all over the floor. Not wanting to make a spectacle of myself and remembering what my mother always said about being dignified at all times in public, I quickly reached up onto the grocery shelf and "accidentally" knocked off a large jar of pickles right where my puddle was. As I walked hurriedly away from that mess without my ice cream, I heard on the store loudspeaker, "Clean-up on aisle 13!"

Thoughts: We tend to live by what we are taught, and in this case, this woman needed to save face from her ruptured membranes. Many women

experience ruptured membranes before the onset of labor, so it is not out of the ordinary for this to happen in public. What risks can occur when membranes do rupture? What action should this woman take now to minimize these risks? How will the nurse validate this woman's ruptured membranes?

TRUE VERSUS FALSE LABOR

False labor is a condition occurring during the latter weeks of some pregnancies in which irregular uterine contractions are felt, but the cervix is not affected. In contrast, true labor is characterized by contractions occurring at regular intervals that increase in frequency, duration, and intensity. True labor contractions bring about progressive cervical dilation and effacement. Table 13.1 summarizes the differences between true and false labor. False labor, prodromal labor, and Braxton Hicks contractions are all names for contractions that do not contribute in a measurable way toward the goal of birth. Distinguishing between true and false labor is an essential nursing assessment skill and one that develops with experience.

TABLE 13.1 DIFFERENCES BETWEEN TRUE AND FALSE LABOR

Parameters	True Labor	False Labor
Contraction timing	Regular, becoming closer together, usually 4–6 min apart, lasting 30–60 s	Irregular, not occurring close together
Contraction strength	Become stronger with time, vaginal pressure is usually felt	Frequently weak, not getting stronger with time or alternating (a strong one followed by weaker ones)
Contraction discomfort	Starts in the back and radiates around toward the front of the abdomen	Usually felt in the front of the abdomen
Any change in activity	Contractions continue no matter what positional change is made	Contractions may stop or slow down with walking or making a position change
Stay or go?	Stay home until contractions are 5 min apart, last 45–60 s, and are strong enough so that a conversation during one is not possible—then go to the hospital or birthing center.	Drink fluids and walk around to see if there is any change in the intensity of the contractions; if the contractions diminish in intensity after either or both—stay home.

Adapted from Cunningham, F. G., Leveno, K. J., Bloom, S. L., Spong, C. Y., Dashe, J. S., Hoffman, B. L., et al. (2014). *Williams' obstetrics* (24th ed.). New York, NY: McGraw-Hill Education; King, T. L., Brucker, M. C., Kriebs, J. M., Fahey, J. O., Gegor, C. L., & Varney, H. (2015). *Varney's midwifery* (5th ed.), Burlington, MA: Jones & Bartlett Learning.; and Tharpe, N. L., Farley, C. L., & Jordan, R. (2016). *Clinical practice guidelines for midwifery & women's health* (4th ed.). Sudbury, MA: Jones & Bartlett.

Many women fear being sent home from the hospital with false labor. All women feel anxious when they feel contractions, but they should be informed that labor could be a long process, especially if it is their first pregnancy. Encourage the woman to think of false labor or prelabor signs as positive, because they are part of the entire labor continuum. With first pregnancies, the cervix can take up to 20 hours to dilate completely (Cunningham et al., 2014).

Remember Kathy and Chuck, the anxious couple who came to the hospital too early? Kathy felt sure she was in labor and is now confused. What explanations and anticipatory guidance should be offered to this couple? What term would describe her earlier contractions?

FACTORS AFFECTING THE LABOR PROCESS

Traditionally, the critical factors that affect the process of labor and birth are outlined as the "five **P**s:"

1. **P**assageway (birth canal)

2. **P**assenger (fetus and placenta)

3. **P**owers (contractions)

4. **P**osition (maternal)

5. **P**sychological response

These critical factors are commonly accepted and discussed by health care providers. However, five additional "P's" can also affect the labor process:

1. **P**hilosophy (low tech, high touch)

2. **P**artners (support caregivers)

3. **P**atience (natural timing)

4. **P**atient (client) preparation (childbirth knowledge base)

5. **P**ain management (comfort measures)

These five additional **P**s are helpful in planning care for the laboring family. These client-focused factors are an attempt to foster labor that can be managed through the use of high touch, patience, support, knowledge, and pain management.

Passageway

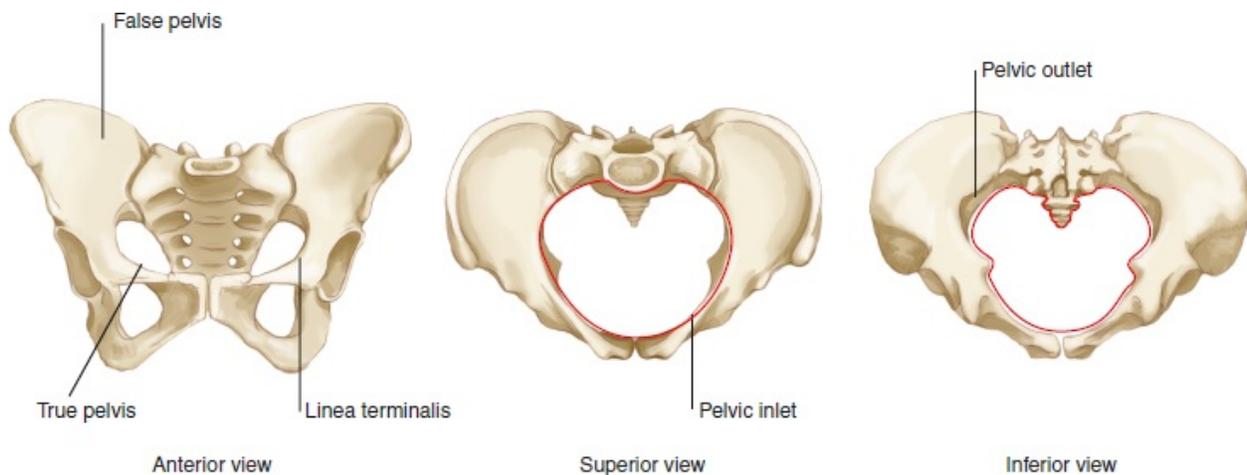
The birth passageway is the route through which the fetus must travel to be born vaginally. Compared to other primates, childbirth is remarkably difficult in humans because the head of the neonate is large relative to the birth-relevant dimensions of the maternal pelvis. The passageway consists of the maternal pelvis and soft tissues. Of the two, however, the maternal bony pelvis is more important because it is relatively unyielding (except for the coccyx). Typically the pelvis is assessed and measured during the first trimester, often at the first visit to the health care provider, to identify any abnormalities that might hinder a successful vaginal birth. As the pregnancy progresses, the hormones relaxin and estrogen cause the connective tissues to become more relaxed and elastic and cause the joints to become more flexible to prepare the mother's pelvis for birth. Additionally, the soft tissues usually yield to the forces of labor.


FIGURE 13.1 The bony pelvis.

Bony Pelvis

The maternal bony pelvis can be divided into the true and false portions. The false (or greater) pelvis is composed of the upper flared parts of the two iliac bones with their concavities and the wings of the base of the sacrum. The false pelvis is divided from the true pelvis by an imaginary line drawn from the sacral prominence at the back to the superior aspect of the symphysis pubis at the front of the pelvis. This imaginary line is called the linea terminalis. The false pelvis lies above this imaginary line; the true pelvis lies below it (Fig. 13.1). The true

pelvis is the bony passageway through which the fetus must travel. It is made up of three planes: the inlet, the mid-pelvis (cavity), and the outlet.

PELVIC INLET

The pelvic inlet allows entrance to the true pelvis. It is bounded by the sacral prominence in the back, the ilium on the sides, and the superior aspect of the symphysis pubis in the front (Jones & Lopez, 2014). The pelvic inlet is wider in the transverse aspect (sideways) than it is from front to back.

MID-PELVIS

The mid-pelvis (cavity) occupies the space between the inlet and outlet. It is through this snug, curved space that the fetus must travel to reach the outside. As the fetus passes through this small area its chest is compressed, causing lung fluid and mucus to be expelled. This expulsion removes the space-occupying fluid so that air can enter the lungs with the newborn's first breath.

PELVIC OUTLET

The pelvic outlet is bound by the ischial tuberosities, the lower rim of the symphysis pubis, and the tip of the coccyx. In comparison with the pelvic inlet, the outlet is wider from front to back. For the fetus to pass through the pelvis, the outlet must be large enough. To ensure the adequacy of the pelvic outlet for vaginal birth, the following pelvic measurements are assessed:

• Diagonal conjugate of the inlet (distance between the anterior surface of the sacral prominence and the anterior surface of the inferior margin of the symphysis pubis).

• Transverse or ischial tuberosity diameter of the outlet (distance at the medial and lowest aspect of the ischial tuberosities, at the level of the anus; a known hand span or clenched-fist measurement is generally used to obtain this measurement).

• True or obstetric conjugate (distance estimated from the measurement of the diagonal conjugate; 1.5 cm is subtracted from the diagonal conjugate measurement).

For more information about pelvic measurements, see .

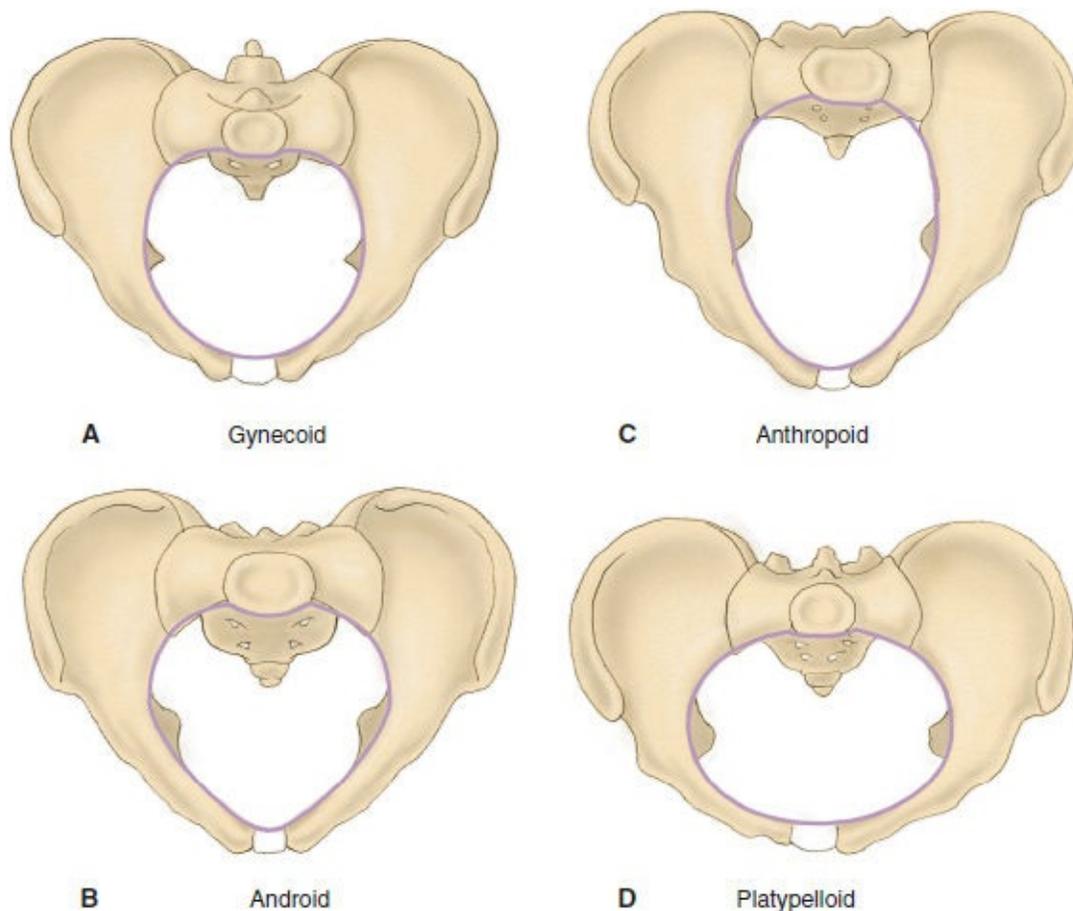
If the diagonal conjugate measures at least 11.5 cm and the true or obstetric conjugate measures 10 cm or more (1.5 cm less than the diagonal conjugate, or

about 10 cm), then the pelvis is large enough for a vaginal birth of what would be considered a normal-size newborn.

Pelvic Shape

In addition to size, the shape of a woman's pelvis is a determining factor for a vaginal birth. Each plane of the pelvis has a shape, which is defined by the anterior-posterior and transverse diameters. The pelvis is divided into four main shapes: gynecoid, anthropoid, android, and platypelloid (Fig. 13.2).

GYNECOID PELVIS

The gynecoid pelvis is considered the true female pelvis, occurring in about 40% of all women; it is less common in men (Fischer & Mitteroecker, 2015). Vaginal birth is most favorable with this type of pelvis because the inlet is round and the outlet is roomy. This shape offers the optimal diameters in all three planes of the pelvis. This type of pelvis allows early and complete fetal internal rotation during labor.


A   Gynecoid   C   Anthropoid

B   Android   D   Platypelloid

ANTHROPOID PELVIS

The anthropoid pelvis is common in men and is most common in the non-White women. It occurs in approximately 25% of women (Marani & Koch, 2014). The pelvic inlet is oval and the sacrum is long, producing a deep pelvis (wider front to back [anterior to posterior] than side to side [transverse]). Vaginal birth is more favorable with this pelvic shape compared with the android or platypelloid shape (Tharpe, Farley, & Jordan, 2016).

ANDROID PELVIS

The android pelvis is considered the male-shaped pelvis and is characterized by a funnel shape. It occurs in approximately 20% of women (Cunningham et al., 2014). The pelvic inlet is heart-shaped and the posterior segments are reduced in all pelvic planes. Descent of the fetal head into the pelvis is slow, and failure of the fetus to rotate is common. The prognosis for labor is poor, subsequently leading to cesarean birth.

PLATYPELLOID (FLAT) PELVIS

The platypelloid or flat pelvis is the least common type of pelvic structure among men and women, with an approximate incidence of 3% (King et al., 2015). The pelvic cavity is shallow but widens at the pelvic outlet, making it difficult for the fetus to descend through the mid-pelvis. Labor prognosis is poor with arrest at the inlet occurring frequently. It is not favorable for a vaginal birth unless the fetal head can pass through the inlet. Women with this type of pelvis usually require cesarean birth.

An important principle is that most pelvises are not purely defined but occur in nature as mixed types. Many women have a combination of these four basic pelvis types, with no two pelves being exactly the same. Regardless of the shape, the newborn can be born vaginally if size and positioning remain compatible. The narrowest part of the fetus attempts to align itself with the narrowest pelvic dimension (e.g., biparietal to interspinous diameters, which means the fetus generally tends to rotate to the most ample portion of the pelvis).

Soft Tissues

The soft tissues of the passageway consist of the cervix, the pelvic floor muscles,

and the vagina. Through **effacement**, the cervix effaces (thins) to allow the presenting fetal part to descend into the vagina.

Take Note!

The process of cervical effacement and dilation is similar to that of pulling a turtleneck sweater over your head.

The pelvic floor muscles help the fetus to rotate anteriorly as it passes through the birth canal. The soft tissues of the vagina expand to accommodate the fetus during birth.

Passenger

The fetus (with placenta) is the passenger. The fetal head (size and presence of molding), fetal attitude (degree of body flexion), fetal lie (relationship of body parts), fetal presentation (first body part), fetal position (relationship to maternal pelvis), fetal station, and fetal engagement are all important factors that have an impact on the ultimate outcome in the birthing process.

Fetal Head

The fetal head is the largest fetal structure, making it an important factor in relation to labor and birth. Considerable variation in the size and diameter of the fetal skull is often seen.

Compared with an adult's head, the fetal head is large in proportion to the rest of the body, usually about one quarter of the body surface area (Martin, Fanaroff, & Walsh, 2014). The bones that make up the face and cranial base are fused and essentially fixed. However, the five bones that make up the rest of the cranium (two frontal bones, two parietal bones, and the occipital bone) are not fused; rather, they are soft and pliable, with gaps between the plates of bone. These gaps, membranous spaces between the cranial bones, are called sutures, and the intersections of these sutures are called fontanelles. Sutures are important because they allow the cranial bones to overlap in order for the head to adjust in shape (elongate) when pressure is exerted on it by uterine contractions or the maternal bony pelvis. Some diameters shorten, whereas others lengthen as the head is molded during the labor and birthing process. This malleability of the fetal skull may decrease fetal skull dimensions by 0.5 to 1 cm (King et al., 2015). After birth, the sutures close as the bones grow and the brain reaches its full growth.

The changed (elongated) shape of the fetal skull at birth as a result of overlapping of the cranial bones is known as **molding**. Along with molding, fluid can also collect in the scalp (caput succedaneum) or blood can collect beneath the scalp (cephalohematoma), further distorting the shape and appearance of the fetal head. Caput succedaneum can be described as edema of the scalp at the presenting part. This swelling crosses suture lines and disappears within 3 to 4 days. Cephalohematoma is a collection of blood between the periosteum and the bone that occurs several hours after birth. It does not cross

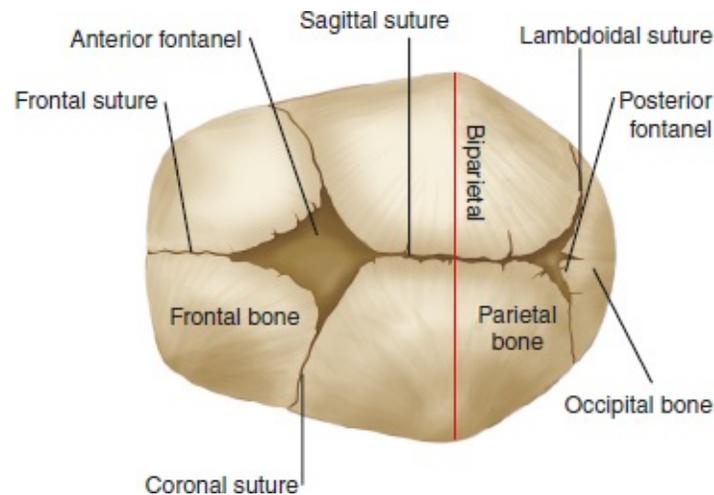
suture lines and is generally reabsorbed over the next 6 to 8 weeks (Collins & Reed, 2014).


FIGURE 13.3 Fetal skull.

Take Note!

Parents may become concerned about the distortion of their newborn's head. However, reassurance that the oblong shape is only temporary is usually all that is needed to reduce their anxiety.

Sutures also play a role in helping to identify the position of the fetal head during a vaginal examination. Figure 13.3 shows a fetal skull. During a pelvic examination, palpation of these sutures by the examiner reveals the position of the fetal head and the degree of rotation that has occurred.

The anterior and posterior fontanelles are also useful in helping to identify the position of the fetal head. They allow for molding, and are important when evaluating the newborn. The anterior fontanelle is the famous "soft spot" of the newborn's head. It is a diamond-shaped space that measures from 1 to 4 cm. It remains open for 12 to 18 months after birth to allow for growth of the brain (Verklan & Walden, 2014). The posterior fontanelle corresponds to the anterior one but is located at the back of the fetal head; it is triangular. This one closes within 8 to 12 weeks after birth and measures, on average, 1 to 2 cm at its widest diameter (Weber & Kelley, 2014).

The diameter of the fetal skull is an important consideration during the labor

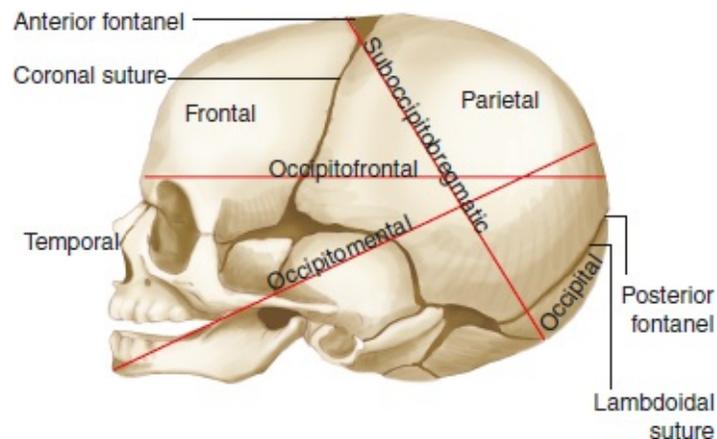
and birth process. Fetal skull diameters are measured between the various landmarks of the skull. Diameters include occipitofrontal, occipitomental, suboccipitobregmatic, and biparietal (Fig. 13.4). The two most important diameters that can affect the birth process are the suboccipitobregmatic (approximately 9.5 cm at term) and the biparietal (approximately 9.25 cm at term) diameters. The suboccipitobregmatic diameter, measured from the base of the occiput to the center of the anterior fontanelle, identifies the smallest anteroposterior diameter of the fetal skull. The biparietal diameter measures the largest transverse diameter of the fetal skull: the distance between the two parietal bones. In a cephalic (head first) presentation, which occurs in 95% of all term births, if the fetus presents in a flexed position in which the chin is resting on the chest, the optimal or smallest fetal skull dimensions for a vaginal birth are demonstrated. If the fetal head is not fully flexed at birth, the anteroposterior diameter increases. This increase in dimension might prevent the fetal skull from entering the maternal pelvis.


FIGURE 13.4 Fetal skull diameters.

Fetal Attitude

Fetal attitude is another important consideration related to the passenger. Fetal **attitude** refers to the posturing (flexion or extension) of the joints and the relationship of fetal parts to one another. The most common fetal attitude when labor begins is with all joints flexed—the fetal back is rounded, the chin is on the chest, the thighs are flexed on the abdomen, and the legs are flexed at the knees (Fig. 13.5). This normal fetal position is most favorable for vaginal birth, presenting the smallest fetal skull diameters to the pelvis.

When the fetus presents to the pelvis with abnormal attitudes (no flexion or

extension), their nonflexed position can increase the diameter of the presenting part as it passes through the pelvis, increasing the difficulty of birth. An attitude of extension tends to present larger fetal skull diameters, which may make birth difficult.

FIGURE 13.5 Fetal attitude: full flexion. Note that the smallest diameter presents to the pelvis.

A. Longitudinal lie

B. Transverse lie

FIGURE 13.6 Fetal lie.

Fetal Lie

Fetal **lie** refers to the relationship of the long axis (spine) of the fetus to the long

axis (spine) of the mother. There are three possible lies: longitudinal (which is the most common), transverse (Fig. 13.6), and oblique.

A longitudinal lie occurs when the long axis of the fetus is parallel to that of the mother (fetal spine to maternal spine side-by-side). A transverse lie occurs when the long axis of the fetus is perpendicular to the long axis of the mother (fetal spine lies across the maternal abdomen and crosses her spine). In an oblique lie, the fetal long axis is at an angle to the bony inlet, and no palpable fetal part is presenting. This lie is usually transitory and occurs during fetal conversion between other lies. A fetus in a transverse or oblique lie position cannot be delivered vaginally (Cunningham et al., 2014).

Fetal Presentation

Fetal **presentation** refers to the body part of the fetus that enters the pelvic inlet first (the "presenting part"). This is the fetal part that lies over the inlet of the pelvis or the cervical os. Knowing which fetal part is coming first at birth is critical for planning and initiating appropriate interventions.

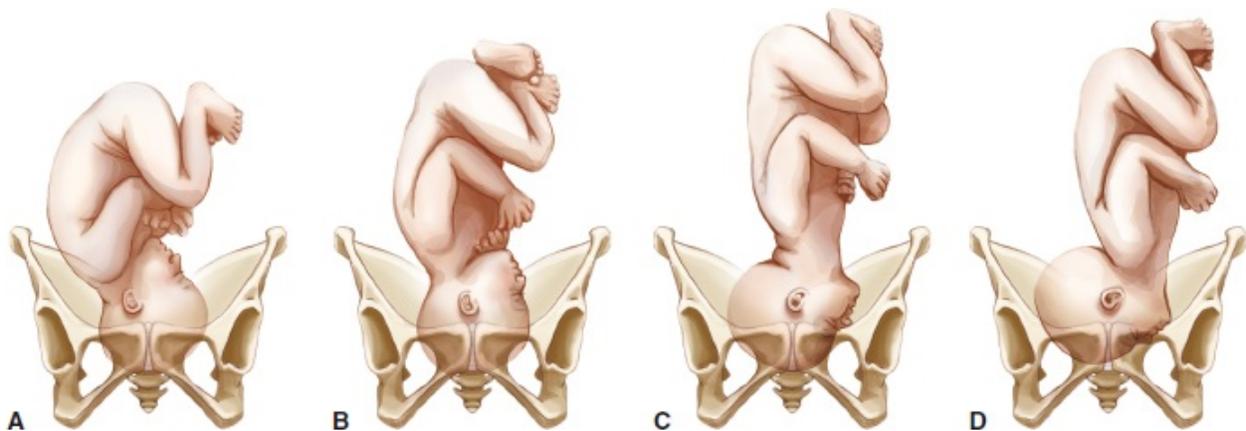
The three main fetal presentations are cephalic (head first), breech (pelvis first), and shoulder (scapula first). The majority of term newborns (95%) enter this world in a cephalic presentation; breech presentations account for 3% of term births, and shoulder presentations for approximately 2% (Tharpe et al., 2016).


FIGURE 13.7 Fetal presentation: cephalic presentations. **A.** Vertex. **B.** Military. **C.** Brow. **D.** Face.

In a cephalic presentation, the presenting part is usually the occipital portion of the fetal head (Fig. 13.7). This presentation is also referred to as a vertex presentation. Variations in a vertex presentation include the military, brow, and

facial presentations.

BREECH PRESENTATION

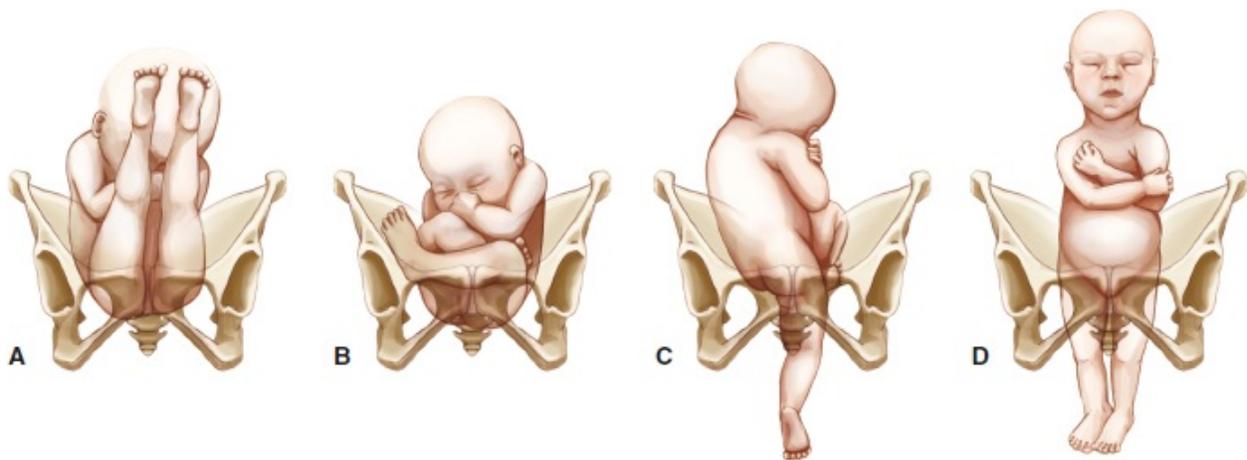
By term, approximately 97% of infants actively turn to a cephalic presentation. It is determined by abdominal palpation (Hofmeyr, 2015). Breech presentation occurs when the fetal buttocks or feet enter the maternal pelvis first and the fetal skull enters last. This abnormal presentation poses several challenges at birth. Primarily, the largest part of the fetus (skull) is born last and may become "hung up" or stuck in the pelvis. In addition, the umbilical cord can become compressed between the fetal skull and the maternal pelvis after the fetal chest is born because the head is the last to exit. Moreover, unlike the hard fetal skull, the buttocks are soft and are not as effective as a cervical dilator during labor compared with a cephalic presentation. Finally, there is the possibility of trauma to the head as a result of the lack of opportunity for molding.


FIGURE 13.8 Breech presentations. **A.** Frank breech. **B.** Complete breech. **C.** Single footling breech. **D.** Double footling breech.

The types of breech presentations are determined by the positioning of the fetal legs (Fig. 13.8). In a frank breech (50% to 70%), the buttocks present first with both legs extended up toward the face. In a full or complete breech (5% to 10%), the fetus sits crossed-legged above the cervix. In a footling or incomplete breech (10% to 30%), one or both legs are presenting. Breech presentations are associated with prematurity, placenta previa, multiparity, uterine abnormalities (fibroids), and some congenital anomalies such as hydrocephaly (Hofmeyr, 2015). A frank breech can result in a vaginal birth, but complete, footling, and

incomplete breech presentations generally necessitate a cesarean birth.

SHOULDER PRESENTATION

A shoulder presentation or shoulder dystocia occurs when the fetal shoulders present first, with the head tucked inside. Clinically, signs of shoulder dystocia appear while the woman is pushing as the neonate's head slowly extends and emerges over the perineum, but then retracts back into the vagina, commonly referred to as the "turtle sign." Odds of a shoulder presentation are 1 in 300 births (Cunningham et al., 2014). The fetus is in a transverse lie with the shoulder as the presenting part. Conditions associated with shoulder dystocia include placenta previa, prematurity, high parity, premature rupture of membranes, multiple gestation, or fetal anomalies. A cesarean birth is usually necessary if identified before labor begins, but will be evaluated based on the length of gestation, the size of the fetus, the position of the placenta, and whether the membranes have ruptured (Sharshiner & Silver, 2015).

Fetal Position

Fetal **position** describes the relationship of a given point on the presenting part of the fetus to a designated point of the maternal pelvis (King et al., 2015). The landmark fetal presenting parts include the occipital bone (O), which designates a vertex presentation; the chin (mentum [M]), which designates a face presentation; the buttocks (sacrum [S]), which designate a breech presentation; and the scapula (acromion process [A]), which designates a shoulder presentation.

Right occiput posterior (ROP)   Left occiput transverse (LOT)   Left occiput anterior (LOA)

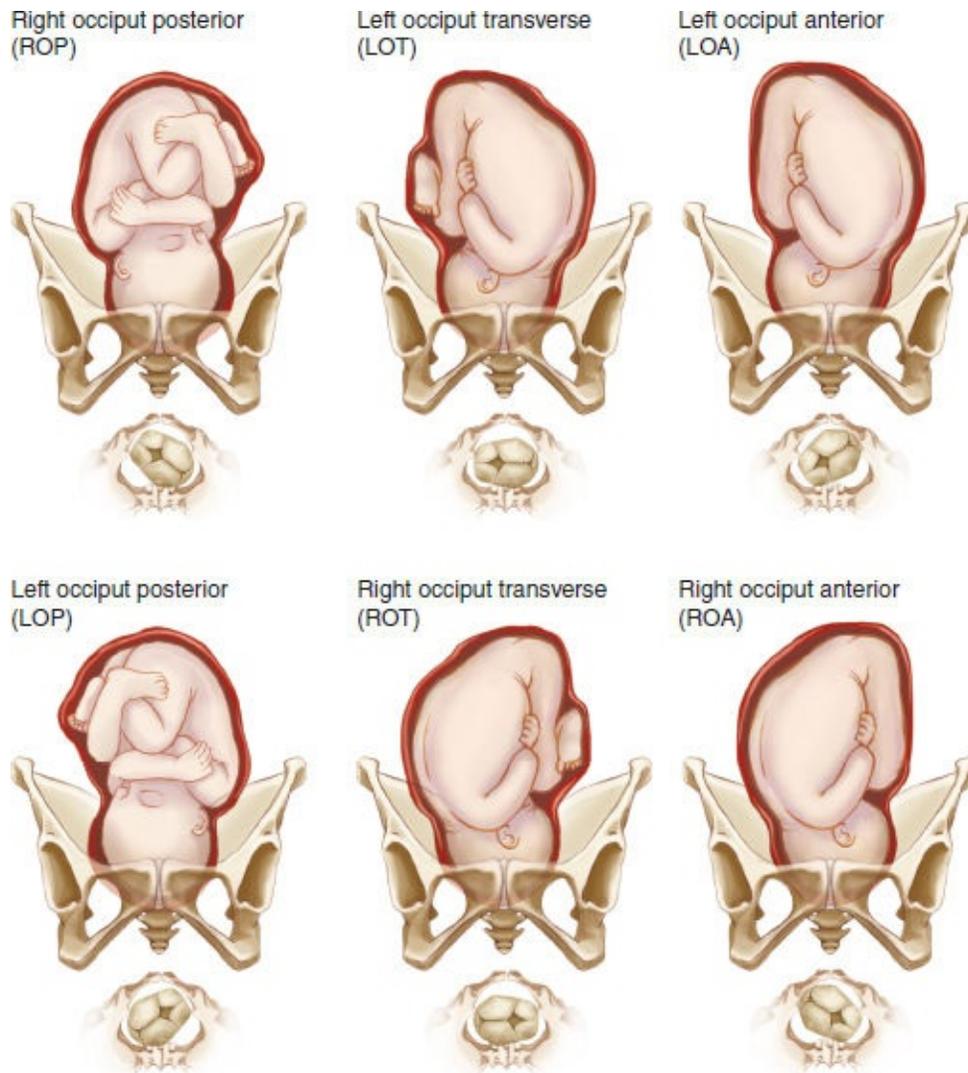
Left occiput posterior (LOP)   Right occiput transverse (ROT)   Right occiput anterior (ROA)


FIGURE 13.9 Examples of fetal positions in a vertex presentation. The lie is longitudinal for each illustration. The attitude is one of flexion. Notice that the view of the top illustration is seen when facing the pregnant woman. The bottom view is that seen with the woman in a dorsal recumbent position.

In addition, the maternal pelvis is divided into four quadrants: right anterior, left anterior, right posterior, and left posterior. These quadrants designate whether the presenting part is directed toward the front, back, left, or right side of the pelvis. Fetal position is determined first by identifying the presenting part and then the maternal quadrant the presenting part is facing (Fig. 13.9). Position is indicated by a three-letter abbreviation as follows:

- The first letter defines whether the presenting part is tilted toward the left (L) or the right (R) side of the maternal pelvis.
- The second letter represents the particular presenting part of the fetus: O for

occiput, S for sacrum (buttocks), M for mentum (chin), A for acromion process, and D for dorsal (refers to the fetal back) when denoting the fetal position in shoulder presentations (Cheng & Caughey, 2015a).

• The third letter defines the location of the presenting part in relation to the anterior (A) portion of the maternal pelvis or the posterior (P) portion of the maternal pelvis. If the presenting part is directed to the side of the maternal pelvis, the fetal presentation is designated as transverse (T).

For example, if the occiput is facing the left anterior quadrant of the pelvis, then the position is termed left occiput anterior and is recorded as LOA.

 Take Note!

LOA is the most common (and most favorable) fetal position for birthing today, followed by right occiput anterior (ROA). The positioning of the fetus allows the fetal head to contour to the diameters of the maternal pelvis. LOA and ROA are optimal positions for a vaginal birth.

An occiput posterior position may lead to a long and difficult birth, and other positions may or may not be compatible with vaginal birth.

Fetal Station

Fetal **station** refers to the relationship of the presenting part to the level of the maternal pelvic ischial spines. Fetal station is measured in centimeters and is referred to as a minus or plus, depending on its location above or below the ischial spines. Typically, the ischial spines are the narrowest part of the pelvis and are the natural measuring point for the birth progress.

Zero (0) station is designated when the presenting part is at the level of the maternal ischial spines. When the presenting part is above the ischial spines, the distance is recorded as minus stations. When the presenting part is below the ischial spines, the distance is recorded as plus stations. For instance, if the presenting part is above the ischial spines by 1 cm, it is documented as being a −1 station; if the presenting part is below the ischial spines by 1 cm, it is documented as being a +1 station.

An easy way to understand this concept is to think in terms of meeting the

goal, which is the birth. If the fetus is descending downward (past the ischial spines) and moving toward meeting the goal of birth, then the station is positive and the centimeter numbers grow bigger from +1 to +4. If the fetus is not descending past the ischial spines, then the station is negative and the centimeter numbers grow bigger from −1 to −4. The farther away the presenting part from the outside, the larger the negative number (−4 cm). The closer the presenting part of the fetus is to the outside, the larger the positive number (+4 cm). Figure 13.10 shows stations of the presenting part.

Fetal Engagement

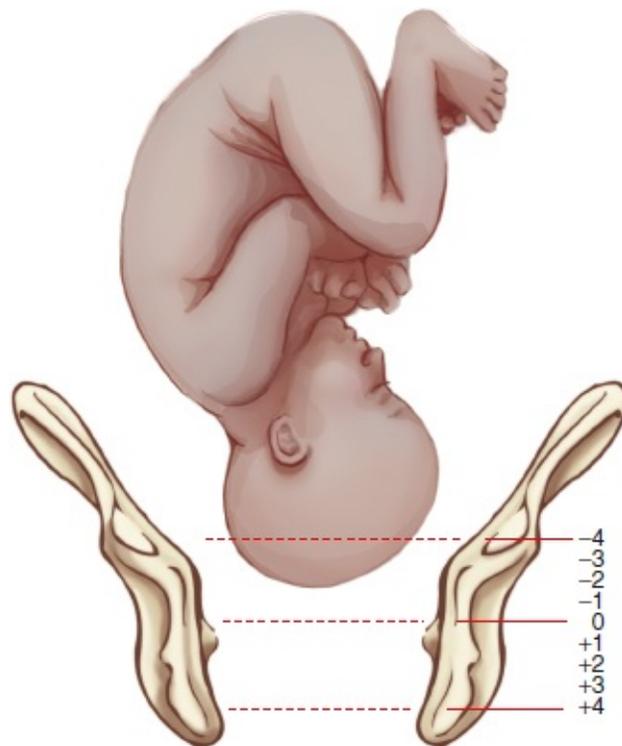
Fetal **engagement** signifies the entrance of the largest diameter of the fetal presenting part (usually the fetal head) into the smallest diameter of the maternal pelvis (Alexander et al., 2014). The fetus is said to be engaged in the pelvis when the presenting part reaches 0 station. Engagement is determined by pelvic examination.


FIGURE 13.10 Fetal stations.

The largest diameter of the fetal head is the biparietal diameter. It extends from one parietal prominence to the other. It is an important factor in the

navigation through the maternal pelvis. Engagement typically occurs in primigravidas 2 weeks before term, whereas multiparas may experience engagement several weeks before the onset of labor or not until labor begins.

Take Note!

The term *floating* is used when engagement has not occurred, because the presenting part is freely movable above the pelvic inlet.

Cardinal Movements of Labor

The fetus goes through many positional changes as it travels through the passageway. These positional changes are known as the cardinal movements of labor. They are deliberate, specific, and very precise movements that allow the smallest diameter of the fetal head to pass through a corresponding diameter of the mother's pelvic structure. Although cardinal movements are conceptualized as separate and sequential, the movements are typically concurrent (Fig. 13.11).

ENGAGEMENT

Engagement occurs when the greatest transverse diameter of the head in vertex (biparietal diameter) passes through the pelvic inlet (usually 0 station). The head usually enters the pelvis with the sagittal suture aligned in the transverse diameter.

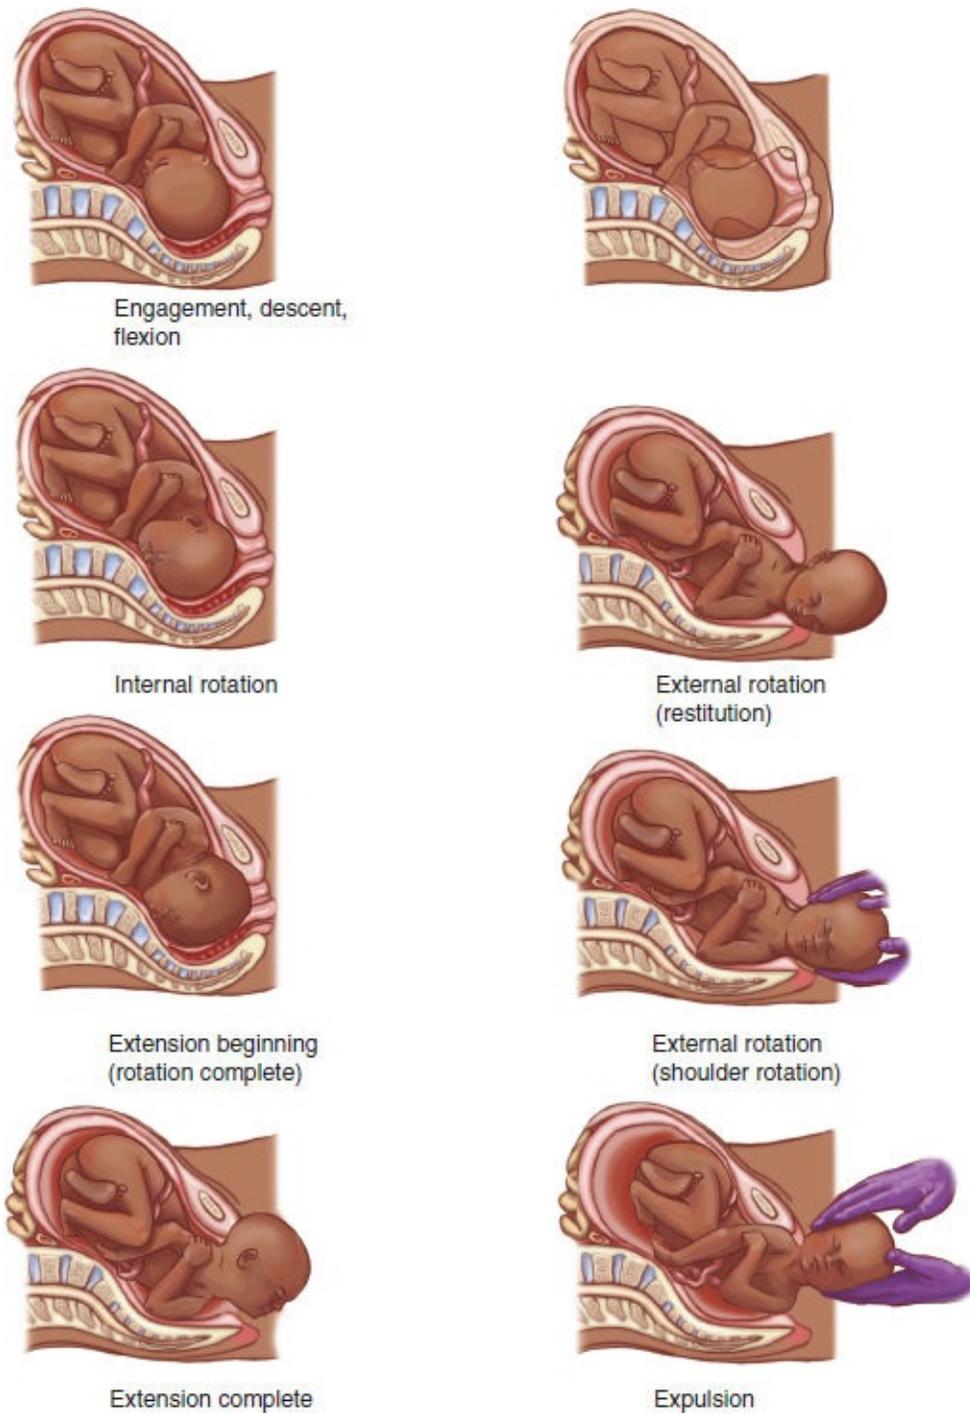
Expulsion


FIGURE 13.11 Cardinal movements of labor.

DESCENT

Descent is the downward movement of the fetal head until it is within the pelvic inlet. Descent occurs intermittently with contractions and is brought about by

one or more of the following forces:

• Pressure of the amniotic fluid

• Direct pressure of the fundus on the fetus's buttocks or head (depending on which part is located in the top of the uterus)

• Contractions of the abdominal muscles (second stage)

• Extension and straightening of the fetal body

Descent occurs throughout labor, ending with birth. During this time, the mother experiences discomfort, but she is unable to isolate this particular fetal movement from her overall discomfort.

FLEXION

Flexion occurs as the vertex meets resistance from the cervix, the walls of the pelvis, or the pelvic floor. As a result, the chin is brought into contact with the fetal thorax and the presenting diameter is changed from occipitofrontal to suboccipitobregmatic (9.5 cm), which achieves the smallest fetal skull diameter presenting to the maternal pelvic dimensions.

INTERNAL ROTATION

After engagement, as the head descends, the lower portion of the head (usually the occiput) meets resistance from one side of the pelvic floor. As a result, the head rotates about 45 degrees anteriorly to the midline under the symphysis. This movement is known as *internal rotation*. Internal rotation brings the anteroposterior diameter of the head in line with the anteroposterior diameter of the pelvic outlet. It aligns the long axis of the fetal head with the long axis of the maternal pelvis. The widest portion of the maternal pelvis is the anteroposterior diameter, and thus the fetus must rotate to accommodate the pelvis.

EXTENSION

With further descent and full flexion of the head, the nucha (the base of the occiput) becomes impinged under the symphysis. Resistance from the pelvic floor causes the fetal head to extend so that it can pass under the pubic arch. *Extension* occurs after internal rotation is complete. The head emerges through extension under the symphysis pubis along with the shoulders. The anterior fontanel, brow, nose, mouth, and chin are born successively.

EXTERNAL ROTATION (RESTITUTION)

After the head is born and is free of resistance, it untwists, causing the occiput to move about 45 degrees back to its original left or right position (restitution). The sagittal suture has now resumed its normal right-angle relationship to the transverse (bisacromial) diameter of the shoulders (i.e., the head realigns with the position of the back in the birth canal). *External rotation* of the fetal head allows the shoulders to rotate internally to fit the maternal pelvis.

EXPULSION

Expulsion of the rest of the body occurs more smoothly after the birth of the head and the anterior and posterior shoulders (Cheng & Caughey, 2015a). See Figure 13.3 for an image of a fetal skull.

Powers

The primary stimulus powering labor is uterine contraction. Contractions cause complete dilation and effacement of the cervix during the first stage of labor. The secondary powers in labor involve the use of intra-abdominal pressure (voluntary muscle contractions) exerted by the woman as she pushes and bears down during the second stage of labor.

Uterine Contractions

Uterine contractions are involuntary and therefore cannot be controlled by the woman experiencing them, regardless of whether they are spontaneous or induced. Uterine contractions are rhythmic and intermittent, with a period of relaxation between contractions. This pause allows the woman and the uterine muscles to rest. In addition, this pause restores blood flow to the uterus and placenta, which is temporarily reduced during each uterine contraction.

Uterine contractions are responsible for thinning and dilating the cervix, then thrusting the presenting part toward the lower uterine segment. The cervical canal reduces in length from 2 cm to a paper-thin entity and is described in terms of percentages from 0% to 100%. In primigravidas, effacement typically starts before the onset of labor and usually begins before dilation; in multiparas, however, neither effacement nor dilation may start until labor ensues (Fig. 13.12). On clinical examination the following may be assessed:

• Cervical canal 2 cm in length would be described as 0% effaced.

• Cervical canal 1 cm in length would be described as 50% effaced.

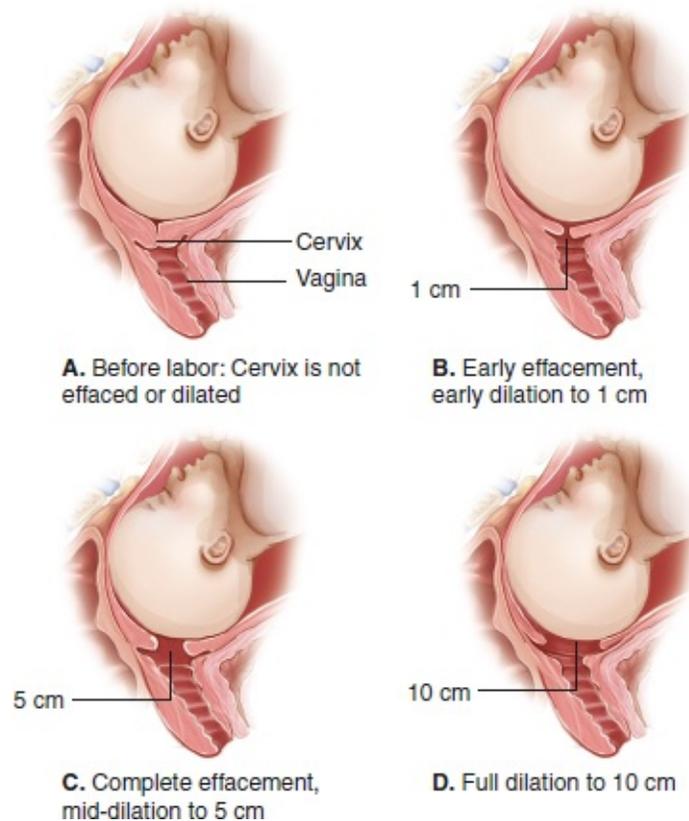
• Cervical canal 0 cm in length would be described as 100% effaced.


FIGURE 13.12 Cervical effacement and dilation. Cervical dilation is expressed in centimeters. **A.** Shows cervix not effaced or dilated. **B.** 50% effaced. **C.** 100% effaced. **D.** Fully dilated at 10 centimeters.

Dilation is dependent on the pressure of the presenting part and the contraction and retraction of the uterus. The diameter of the cervical os increases from less than 1 cm to approximately 10 cm to allow for birth. When the cervix is fully dilated, it is no longer palpable on vaginal examination. Descriptions may include the following:

• External cervical os closed: 0 cm dilated

• External cervical os half open: 5 cm dilated

• External cervical os fully open: 10 cm dilated

During early labor, uterine contractions are described as mild, they last about 30 seconds, and they occur about every 5 to 7 minutes. As labor progresses, contractions last longer (60 seconds), occur more frequently (2 to 3 minutes apart), and are described as being moderate to high in intensity. Each contraction has three phases: increment (buildup of the contraction), acme (peak or highest intensity), and decrement (descent or relaxation of the uterine muscle fibers; Fig.

).

Uterine contractions are monitored and assessed according to three parameters: frequency, duration, and intensity.

1. **Frequency** refers to how often the contractions occur and is measured from the beginning of one contraction to the beginning of the next contraction.

2. **Duration** refers to how long a contraction lasts and is measured from the beginning of one contraction to the end of that same contraction.

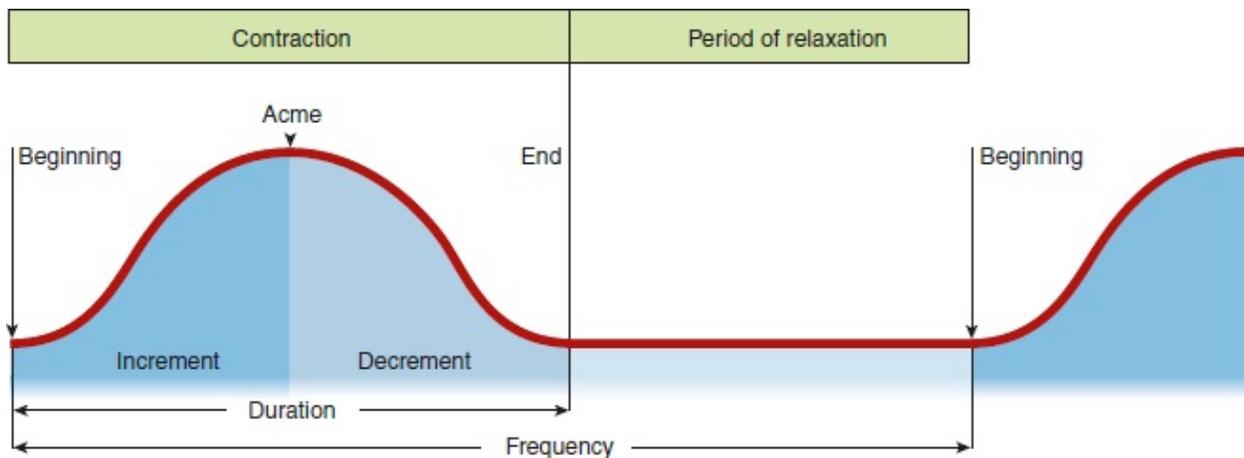
3. **Intensity** refers to the strength of the contraction determined by manual palpation or measured by an internal intrauterine pressure catheter. The catheter is positioned in the uterine cavity through the cervix after the membranes have ruptured. It reports intensity by measuring the pressure of the amniotic fluid inside the uterus in millimeters of mercury. It is not recommended for routine use in low-risk laboring women due to the potential risk of infection and injury to the placenta or fetus. In a recent meta-analysis involving more than 2,000 laboring women, the researchers found increase in surgical births and no advantages of using internal intrauterine pressure catheters over external monitoring during labor augmentation (Milton, Chelmow, & Ramus, 2015).


FIGURE 13.13 The three phases of a uterine contraction.

Intra-Abdominal Pressure

Increased intra-abdominal pressure (voluntary muscle contractions) compresses the uterus and adds to the power of the expulsion forces of the uterine contractions (Grant et al., 2015). Coordination of these forces in unison

promotes birth of the fetus and expulsion of the fetal membranes and placenta from the uterus. Interference with these forces (such as when a woman is highly sedated or extremely anxious) can compromise the effectiveness of these powers.

Position (Maternal)

Positioning for normal labor and birth has evolved. Until about 250 years ago, women were depicted in art and described in essays as sitting upright with flexed hips, squatting, or less commonly standing or kneeling during the childbirth process. These positions maintain flexion at the hip joint and somewhat straighten the pelvis (Nieuwenhuijze et al., 2014). In the past 250 years, dorsal and dorsal lithotomy positions evolved for unclear reasons and have been ascribed to Western medicine. Childbirth medicalization has reduced laboring women's opportunity in a spontaneous position of choice to a recumbent one. Medical historians say the evolution was to facilitate forceps usage, to promote men's power over women and for convenience after administration of anesthesia (Marani & Koch, 2014).

Maternal positioning during labor has only recently been the subject of well-controlled research. Scientific evidence has shown that nonmoving, back-lying positions during labor are not healthy (Gizzo et al., 2014). However, despite this evidence to the contrary, many women continue to lie flat on their backs during labor. Some of the reasons why this practice continues include the beliefs that:

• laboring women need to conserve their energy and not tire themselves

• nurses cannot keep track of the whereabouts of ambulating women

• it is the preference of the health care provider

• the fetus can be monitored better in this position

• the supine position facilitates vaginal examinations and external belt adjustment

• a bed is "where one is supposed to be" in a hospital setting

• the position is more convenient for the delivering health care provider

• laboring women are "connected to things" that impede movement (Hanson & VandeVusse, 2014).

Although many labor and birthing facilities claim that all women are allowed to adopt any position of comfort during their laboring experience, many women spend their time on their backs during labor and birth. Women should be encouraged to assume any position of comfort for them. In a recently randomized, controlled study, the use of a peanut-shaped ball during labor

decreased the length of labor and increased the rate of vaginal births. The peanut ball was associated with a significantly lower incidence of cesarean births. The peanut ball can be a potentially successful nursing intervention to help progress labor and support vaginal birth for women laboring under epidural analgesia (Tussey et al., 2015).

 Take Note!

If the only furniture provided is a bed, this is what the woman will use. Furnishing rooms with comfortable chairs, beanbags, and other birth props allows a woman to choose from a variety of positions and to be free to move during labor.

Changing positions and moving around during labor and birth offer several benefits. Maternal position can influence pelvic size and contours. Changing position and walking affect the pelvis joints, which may facilitate fetal descent and rotation. Squatting enlarges the pelvic inlet and outlet diameters, whereas a kneeling position removes pressure on the maternal vena cava and helps to rotate the fetus from a posterior position to an anterior one to facilitate birth (Budin, 2015). The use of any upright or lateral position, compared with supine or lithotomy positions, may:

• reduce the length of the first stage of labor

• reduce the duration of the second stage of labor

• reduce the number of assisted deliveries (vacuum and forceps)

• reduce episiotomies and perineal tears

• contribute to fewer abnormal fetal heart rate patterns

• increase comfort/reduce requests for pain medication

• enhance a sense of control by the mother

• alter the shape and size of the pelvis, which assists in descent

• assist gravity to move the fetus downward (Cox & King, 2015)

Using the research available can bring better outcomes, heightened professionalism, and evidence-based practice to childbearing practices. The National Institute for Health and Care Excellence (NICE) guidelines recommend

discouraging women from lying supine or semi-supine during labor and encourage them to adapt to any other position that they find comfortable since lying on their backs is associated with longer labors, increase in surgical births, increased pain, and a higher incidence of FHR abnormalities. The Cochrane collaboration supports the current NICE guidance of positions (Camorcia, 2015).

Psychological Response

Childbearing can be one of the most life-altering experiences for a woman. The experience of childbirth goes beyond the physiologic aspects: it influences a woman's self-confidence, self-esteem, and view of life, relationships, and children. Her state of mind (psyche) throughout the entire process is critical to bring about a positive outcome for her and her family. Factors promoting a positive birth experience include:

• clear information about procedures

• support; not being alone

• sense of mastery, self-confidence

• trust in staff caring for her

• positive reaction to the pregnancy

• personal control over breathing

• preparation for the childbirth experience

Having a strong sense of self and meaningful support from others can often help women manage labor well. Feeling safe and secure typically promotes a sense of control and ability to withstand the challenges of the childbearing experience. Anxiety and fear, however, decrease a woman's ability to cope with the discomfort of labor. Maternal catecholamines secreted in response to anxiety and fear can inhibit uterine blood flow and placental perfusion. In contrast, relaxation can augment the natural process of labor (Leonard, 2015). Preparing mentally for childbirth is important so that the woman can work with, rather than against, the natural forces of labor.

Philosophy

Not everyone views childbirth in the same way. A philosophical continuum exists that extends from viewing labor as a disease process to a normal process. One philosophy assumes that women cannot manage the birth experience adequately and therefore need constant expert monitoring and management. The other philosophy assumes that women are capable and reasoning individuals who can actively participate in their birth experience.

The health care system in the United States today appears to be leaning toward the former philosophy, applying technological interventions to most mothers who enter the hospital system. Giving birth in a hospital in the 21st century for many women has become "intervention intensive"—designed to start, continue, and end labor through medical management rather than allowing the normal process of birth to unfold. Advances in medical care have improved the safety for women with high-risk pregnancies. However, the routine use of intravenous therapy, electronic fetal monitoring, augmentation, and epidural anesthesia has not necessarily improved birth outcomes for all women (Leonard, 2015). Perhaps a middle-of-the-road philosophy for intervening when circumstances dictate, along with weighing the risks and benefits before doing so, may be appropriate.

During the 1970s, family-centered maternity care was developed in response to the consumer reaction to the depersonalization of birth. The hope was to shift the philosophy from "technologization" to personalization to humanize childbirth. The term *family-centered birthing* is more appropriate today to denote the low-tech, high-touch approach requested by many childbearing women, who view childbirth as a normal process.

Certified nurse midwives (CNMs) are champions of family-centered birthing, and their participation in the childbirth process is associated with fewer unnecessary interventions when compared with obstetricians. CNMs subscribe to a normal birth process where the woman uses her own instincts and bodily signs during labor. In short, midwives empower women within the birthing environment (Casey et al., 2015).

No matter what philosophy is held, it is ideal if everyone involved in the particular birth process—from the health care provider to the mother—shares the same philosophy toward the birth process.

Partners

Women desire support and attentive care during labor and birth. Caregivers can convey emotional support by offering their continued presence and words of encouragement. Throughout the world, few women are left to labor totally alone: emotional, physical, or spiritual support during labor is the norm for most cultures. According to the Childbirth Connection's ongoing *Listening to Mothers Initiative III survey*, almost all women (99%) reported having received some type of supportive care during labor (Edmonds, Cwiertniewicz, & Stoll, 2015). A caring partner can use massage, light touch, acupressure, hand-holding, stroking, and relaxation; can help the woman communicate her wishes to the staff; and can provide a continuous, reassuring presence, all of which bring some degree of comfort to the laboring woman (Capogna, 2015). Although the presence of the mother's significant other at the birth provides special emotional support, a partner can be anyone who is present to support the woman throughout the experience. For many women, the essential ingredients for a safe and satisfying birth include a sense of empowerment and success in coping with or transcending the experience, in addition to having solid, positive encouragement from a support companion.

Worldwide, women usually support other women in childbirth. **Doula** is a Greek word meaning woman servant or caregiver. It now commonly refers to a woman who offers emotional and practical support to a mother or couple before, during, and after childbirth. A doula believes in "mothering the mother," but clinical support remains the job of the midwife or medical staff (Ahlemeyer & Mahon, 2015). The continuous presence of a trained female support person reduces the need for medication for pain relief, the use of vacuum or forceps delivery, and the need for cesarean births. Continuous support was also associated with a slight reduction in the length of labor. The doula, who is an experienced labor companion, provides the woman and her partner with emotional and physical support and information throughout the entire labor and birth experience.

A recent study in the United States found that nursing care decreases the likelihood of negative evaluations of the childbirth experience, feelings of tenseness during labor, and finding labor worse than expected. Also reported were less perineal trauma, reduced difficulty in mothering, and reduced likelihood of early cessation of breast-feeding. Continuous support by nurses

included reassurance, encouragement, praise, and explanation (Iravani et al., 2015).

Given the many benefits of intrapartum support, laboring women should always have the option to receive partner support, whether from nurses, doulas, significant others, or family. Whoever the support partner is, he or she should provide the mother with continuous presence and hands-on comfort and encouragement. The overall objective of providing support for women during childbirth is to create a positive experience for her, while preserving her physical and psychological health.

Patience

The birth process takes time. If more time were allowed for women to labor naturally without intervention, the cesarean birth rate would most likely be reduced. In one study, continuous support provided by midwives during labor reduced the duration of labor and the number of cesarean births; this model of support should be available to all women (Cox & King, 2015). The literature suggests that delaying interventions can give a woman enough time to progress in labor and reduce the need for surgical intervention (American College of Obstetricians and Gynecologists [ACOG], 2014b; Society for Maternal-Fetal Medicine [SMFM], 2014).

Healthy People 2020 has two goals related to cesarean births in the United States:

1. Reduce the rate of cesarean births among low-risk (full-term, singleton, vertex presentation) women having their first child to 23.9% of live births, from a baseline of 26.5%.

2. Reduce the rate of cesarean births among women who have had a prior cesarean birth to 81.7% of live births, from a baseline of 90.8% (U.S. Department of Health and Human Services, 2010).

We are a long way from achieving these goals—the current cesarean birth rate in the United States, at 32.7%, approximately one in three births, is the highest since these data first became available from birth certificates in 1989. Cesarean birth rate is associated with increased morbidity and mortality for both mother and infant as well as increased inpatient length of stay and health care costs (Centers for Disease Control and Prevention [CDC], 2014a).

It is difficult to predict how a labor will progress and therefore equally difficult to determine how long a woman's labor will last. There is no way to estimate the likely strength and frequency of uterine contractions, the extent to which the cervix will soften and dilate, and how much the fetal head will mold to fit the birth canal. We cannot know beforehand whether the complex fetal rotations needed for an efficient labor will take place properly. All of these factors are unknown when a woman starts labor.

Induction of Labor

There is a trend in health care to attempt to manipulate the process of labor through medical means such as artificial rupture of membranes (amniotomy) and augmentation of labor with oxytocin (Kriebs, 2015). The labor induction rate has doubled in the United States since the 1990s (Moses, 2015).

Approximately one in four women are induced or have labor augmented with uterine-stimulating drugs or artificial rupture of membranes to accelerate her progress, and early term (in the 37th and 38th week) inductions have also increased. An amniotomy (artificial rupture of the fetal membranes) may be performed to augment or induce labor when the membranes have not ruptured spontaneously. Doing so allows the fetal head to have more direct contact with the cervix to dilate it. This procedure is performed with the fetal head at −2 station or lower, with the cervix dilated to at least 3 cm. Synthetic oxytocin (Pitocin) is also used to induce or augment labor by stimulating uterine contractions. It is administered piggybacked into the primary intravenous line with an infusion pump titrated to uterine activity.

Elective induction of labor is at an all-time high in the United States despite known associated risks. It can lead to birth of an infant too early, a long labor, exposure to a high-alert medication with its potential side effects, unnecessary cesarean birth, and maternal and neonatal morbidity. Elective induction has a cascade of related interventions, such as an intravenous line, continuous electronic fetal monitoring, confinement to bed, amniotomy, pharmacologic labor-stimulating agents, parental pain medications, and regional anesthesia, each with its own set of potential complications and risks. These risks apply to all women having the procedure; however, for nulliparous women before 41 weeks of gestation with an unfavorable cervix, the main risk is cesarean birth after unsuccessful labor induction with the potential for maternal and neonatal morbidity and increased health care costs. When cesarean occurs, subsequent births are likely to be via cesarean as well (Caughey, 2014). Compelling evidence indicates that elective induction of labor may increase the risk of cesarean birth, especially for nulliparous women (Le Ray et al., 2015). Elective induction of labor in nulliparas is associated with increased rates of cesarean, postpartum hemorrhage, neonatal resuscitation, and longer hospitalizations without improvement in neonatal outcomes (Glavind & Uldbjerg, 2015). The belief is that many cesarean births could be avoided if women were allowed to labor longer and if the natural labor process were allowed to complete the job. The longer wait (using the intervention of patience) usually results in less intervention.

The ACOG attributes the dramatic increase in inductions in part to pressure from women, convenience for physicians, and liability concerns. Other reasons for the increase in inductions include the availability of better cervical ripening agents and a more relaxed attitude toward marginal indications for inductions. They recommend a cautious approach regarding elective induction until clinical trials can validate a more liberal use of labor inductions (ACOG, 2014b). Current medical indications for inducing labor include:

• spontaneous rupture of membranes and when labor does not start,

• large size fetus not expected to navigate the maternal pelvis,

• fetal growth restriction (FGR) where external intervention is needed,

• a pregnancy of more than 42 weeks' gestation,

• maternal hypertension, diabetes, or lung disease, and

• a uterine infection (March of Dimes, 2015).

When the laboring woman feels the urge to bear down, pushing begins. Most women respond extremely well to messages from their body without being directed by the nurse. A more natural, undirected approach allows the woman to wait and bear down when she feels the urge to push. Having patience and letting nature take its course will reduce the incidence of physiologic stress in the mother, resulting in less trauma to her perineal tissue.

Patient (Client) Preparation: Prenatal Education

Basic prenatal education can help women manage their labor process and feel in control of their birthing experience. The literature indicates that if a woman is prepared before the labor and birth experience, the labor is more likely to remain normal or natural (without the need for medical intervention) (Byrne et al., 2014). An increasing body of evidence also indicates that the well-prepared woman, with good labor support, is less likely to need analgesia or anesthesia and is unlikely to require cesarean birth (Hoang, 2014).

Prenatal education teaches the woman about the childbirth experience and increases her sense of control. She is then able to work as an active participant during the labor and birth experience (Jordan et al., 2014). The research also suggests that prenatal preparation may affect intrapartum and postpartum psychosocial outcomes (Budin, 2014). For example, prenatal education covering parenting communication classes had a significant effect on postpartum anxiety and postpartum adjustment. In a recent study of Hispanic women attending a community prenatal education program, they found that many women experienced anguish from unknowns during their pregnancy, leading to a yearning to learn and understand more, but with a desire to do so without sacrificing their cultural identity (Fitzgerald, Cronin, & Boccella, 2015). In another study involving Somali couples, most did not attend prenatal classes because their religion does not allow women and men to learn in the same room, and the men are not allowed to look at naked figures displayed in photos and videos (Wojnar, 2015). If the prenatal educational setting were more respectful of their beliefs, attendance would improve. These findings have important implications for nurses teaching prenatal classes to diverse cultures. Prenatal education should be viewed as an opportunity to strengthen families by providing anticipatory guidance and improving family members' life skills. In short, prenatal education helps to promote healthy families during the transition to parenthood and beyond (Woods & Chesser, 2015).

There is increasing evidence that women use herbs to induce labor and also during labor for pain relief. Desire to have control over their health has been cited as the strongest motive for women to use herbal medicine. A few of the herbs used include *Caulophyllum,* made from the herb blue cohosh to induce labor contractions; blue and black cohosh, raspberry leaves, castor oil, and evening primrose oil used for cervical ripening and induction of labor; and

Chanlibao to shorten the second stage of labor by strengthening the contractions (Ramasubramaniam et al., 2015). The use of herbs during labor have been found to benefit some women by easing the labor process without side effects, but clinical trials are lacking to prove the safety and effectiveness of them.

 Take Note!

Learning about labor and birth allows women and couples to express their needs and preferences, enhance their confidence, and improve communication between themselves and the staff.

Pain Management

Labor and birth, although a normal physiologic process, can produce significant pain. Pain during labor is a nearly universal experience. Controlling the uterine discomfort without harm to the fetus or labor process is the major focus of pain management during childbirth. Pain is a subjective experience involving a complex interaction of physiologic, spiritual, psychosocial, cultural, and environmental influences (Van der Gucht & Lewis, 2015). Cultural values and learned behaviors influence perception and response to pain, as do anxiety and fear, both of which tend to heighten the sense of pain (Jones, 2015). The challenge for care providers is to find the right combination of pain/coping management methods to keep the discomfort manageable while minimizing the negative effect on the fetus, the normal physiology of labor, maternal–infant bonding, breast-feeding, and a woman's perception of the labor itself (King et al., 2015). Chapter 14 presents a full discussion of pain management during labor and birth.

PHYSIOLOGIC RESPONSES TO LABOR

Labor is the process by which the birth canal is prepared to allow the fetus to pass from the uterine cavity to the outside world. During pregnancy, progesterone secreted from the placenta suppresses the spontaneous contractions of a typical uterus, keeping the fetus within the uterus. In addition, the cervix remains firm and noncompliant. At term, however, changes occur in the cervix that make it softer. In addition, uterine contractions become more frequent and regular, signaling the onset of labor.

The labor process involves a series of rhythmic, involuntary, usually quite uncomfortable uterine muscle contractions. The contractions bring about a shortening that causes effacement and dilation of the cervix and a bursting of the fetal membranes. Uterine contractions of an intensity of 30 mm Hg or greater promote cervical dilation. Then, accompanied by both reflex and voluntary contractions of the abdominal muscles (pushing), the uterine contractions result in the birth of the baby (Grant et al., 2015). During labor, the mother and fetus make several physiologic adaptations.

Maternal Responses

As the woman progresses through childbirth, numerous physiologic responses occur that assist her to adapt to the labor process. The labor process stresses several of the woman's body systems, which react through numerous compensatory mechanisms. Maternal physiologic responses include:

• Heart rate increases by 10 to 20 bpm.

• Cardiac output increases by 12% to 31% during the first stage of labor and by 50% during the second stage of labor.

• Blood pressure increases by up to 35 mm Hg during uterine contractions in all labor stages.

• The white blood cell count increases to 25,000 to 30,000 cells/mm^3, perhaps as a result of tissue trauma.

• Respiratory rate increases and more oxygen is consumed related to the increase in metabolism.

• Gastric motility and food absorption decrease, which may increase the risk of nausea and vomiting during the transition stage of labor.

• Gastric emptying and gastric pH decrease, increasing the risk of vomiting with aspiration.

• Temperature rises slightly, possibly due to an increase in muscle activity.

• Muscular aches/cramps occur as a result of the stressed musculoskeletal system.

• Basal metabolic rate increases and blood glucose levels decrease because of the stress of labor (Cheng & Caughey, 2015a).

A woman's ability to adapt to the stress of labor is influenced by her psychological and physical state. Among the many factors that affect her coping ability are:

• Previous birth experiences and their outcomes (complications and previous birth outcomes)

• Current pregnancy experience (planned versus unplanned, discomforts experienced, age, risk status of pregnancy, chronic illness, weight gain)

• Cultural considerations (values and beliefs about health status)

- Support system (presence and support of a valued partner during labor)
- Childbirth preparation (attended childbirth classes and has practiced paced breathing techniques)
- Exercise during pregnancy (muscles toned; ability to assist with intra-abdominal pushing)
- Expectations of the birthing experience (viewed as a meaningful or stressful event)
- Anxiety level (excessive anxiety may interfere with labor progress)
- Fear of labor and loss of control (fear may enhance pain perception, augmenting fear)
- Fatigue and weariness (not up for the challenge/duration of labor) (King et al., 2015)

Fetal Responses

Although the focus during labor may be on assessing the mother's adaptations, several physiologic adaptations occur in the fetus as well. The fetus is experiencing labor along with the mother. If the fetus is healthy, the stress of labor usually has no adverse effects. The nurse needs to be alert to any abnormalities in the fetus's adaptation to labor. Fetal responses to labor include:

• Periodic fetal heart rate accelerations and slight decelerations related to fetal movement, fundal pressure, and uterine contractions

• Decrease in circulation and perfusion to the fetus secondary to uterine contractions (a healthy fetus is able to compensate for this drop)

• Increase in arterial carbon dioxide pressure (PCO_2)

• Decrease in fetal breathing movements throughout labor

• Decrease in fetal oxygen pressure with a decrease in the partial pressure of oxygen (PO_2) (Verklan & Walden, 2014)

Take Note!

Respiratory changes during labor help to prepare the fetus for extrauterine respiration immediately after birth.

STAGES OF LABOR

Labor is typically divided into four stages: dilation, expulsive, placental, and restorative. Table 13.2 summarizes the major events of each stage.

The first stage is the longest: it begins with the first true contraction and ends with full dilation (opening) of the cervix. Because this stage lasts so long, it is divided into three phases, each corresponding to the progressive dilation of the cervix.

Stage two of labor, or the expulsive stage, begins when the cervix is completely dilated and ends with the birth of the newborn. The expulsive stage can last from minutes to hours. The contractions typically occur every 2 to 3 minutes, lasting 60 to 90 seconds and are strong by palpation. The woman is usually intent on the work of pushing during this stage.

The third stage, or placental expulsion, starts after the newborn is born and ends with the separation and birth of the placenta. Continued uterine contractions typically cause the placenta to be expelled within 5 to 30 minutes. If the newborn is stable, bonding of infant and mother takes place during this stage through touching, holding, and skin-to-skin contact.

The fourth stage, or the restorative stage or immediate postpartum period, lasts from 1 to 4 hours after birth. This period is when the mother's body begins to stabilize after the hard work of labor and the loss of the products of conception. The fourth stage is often not recognized as a true stage of labor, but it is a critical period for maternal physiologic transition as well as new family attachment. Close monitoring of both the mother and her newborn are done during this stage (Green, 2015).

TABLE 13.2 STAGES AND PHASES OF LABOR

	First Stage	Second Stage	Third Stage	Fourth Stage
Description	From 0–10 cm dilation; consists of three phases	From complete dilation (10 cm) to birth of the newborn; may last up to 3 h	Separation and delivery of the placenta; usually takes 5–10 min, but may take up to 30 min	1–4 h after the birth of the newborn; time of maternal physiologic adjustment
Phases	**Latent phase** (0–3 cm dilation) • Cervical dilation from 0 to 3 cm • Cervical effacement from 0% to 40% • Nullipara, lasts up to 9 h; multipara, lasts up to 5–6 h • Contraction frequency every 5–10 min • Contraction duration 30–45 s • Contraction intensity mild to palpation **Active phase** (4–7 cm dilation) • Cervical dilation from 4 to 7 cm • Cervical effacement from 40% to 80% • Nullipara, lasts up to 6 h; multipara, lasts up to 4 h • Contraction frequency every 2–5 min • Contraction duration 45–60 s • Contraction intensity moderate to palpation **Transition phase** (8–10 cm dilation) • Cervical dilation from 8 to 10 cm • Cervical effacement from 80% to 100% • Nullipara lasts up to 1 h; multipara, lasts up to 30 min • Contraction frequency every 1–2 min • Contraction duration 60–90 s • Contraction intensity strong by palpation	**Pelvic phase** (period of fetal descent) **Perineal phase** (period of active pushing) • Nullipara, lasts up to 1 h; multipara, lasts up to 30 min • Contraction frequency every 2–3 min or less • Contraction duration 60–90 s • Contraction intensity strong by palpation • Strong urge to push during the later perineal phase	**Placental separation:** detaching from uterine wall **Placental expulsion:** coming outside the vaginal opening

First Stage

During the first stage of labor, the fundamental change underlying the process is progressive dilation of the cervix. Cervical dilation is gauged subjectively by vaginal examination and is expressed in centimeters. The first stage ends when the cervix is dilated to 10 cm in diameter and is large enough to permit the passage of a fetal head of average size. The fetal membranes, or bag of waters, usually rupture during the first stage, but they may have burst earlier or may even remain intact until birth. For the primigravida, the first stage of labor lasts about 12 hours. However, this time can vary widely; for the multiparous woman, it is usually only half of that.

During the first stage of labor, women usually perceive the visceral pain of diffuse abdominal cramping and uterine contractions. Pain during the first stage of labor is primarily a result of the dilation of the cervix and lower uterine segment, and the distention (stretching) of these structures during contractions. The first stage is divided into three phases: latent or early phase, active phase, and transition phase.

Latent or Early Phase

The latent or early phase gives rise to the familiar signs and symptoms of labor. This phase begins with the start of regular contractions and ends when rapid cervical dilation begins. Cervical effacement occurs during this phase, and the cervix dilates from 0 to 3 cm.

Contractions usually occur every 5 to 10 minutes, last 30 to 45 seconds, and are described as mild by palpation by the nurse. Assessment of intensity is evaluated by pressing down on the fundus during a contraction to see if it can be dented with the nurse's fingers. The ability to indent the fundus at the peak of the contraction would typically indicate a mild contraction. Effacement of the cervix is from 0% to 40%. Most women are very talkative during this period, perceiving their contractions to be similar to menstrual cramps. Women may remain at home during this phase, contacting their health care provider about the onset of labor.

For the nulliparous woman, the latent phase typically lasts about 9 hours; in the multiparous woman, it lasts about 6 hours (Cheng & Caughey, 2015a). During this phase, women are apprehensive but excited about the start of their

labor after their long gestational period.

Think back to the couple who were sent home from the hospital birthing center. Three days later Kathy awoke with a wet sensation and intense discomfort in her back, spreading around to her abdomen. She decided to go for a walk, but her contractions didn't diminish. Instead, her contractions continued to occur every few minutes and grew stronger in intensity. She and Chuck decided to go back to the hospital birthing center. Was there a difference in the location of Kathy's discomfort this time? What changes will the admission nurse find in Kathy if this is true labor?

Active Phase

The active phase of labor encompasses the time from an increase in the rate of cervical dilation (end of latent phase of labor) until completion of cervical dilation. Cervical dilation begins to occur more rapidly during the active phase. The cervix usually dilates from 4 to 7 cm, with 40% to 80% effacement taking place. This phase can last up to 6 hours for the nulliparous woman and 4.5 hours for the multiparous woman (Leap & Hunter, 2015). The fetus descends farther in the pelvis. Contractions become more frequent (every 2 to 5 minutes) and increase in duration (45 to 60 seconds). The woman's discomfort intensifies (moderate to strong by palpation). She becomes more intense and inwardly focused, absorbed in the serious work of her labor. She limits interactions with those in the room. If she and her partner have attended childbirth education classes, she will begin to use the relaxation and paced breathing techniques that they learned to cope with the contractions. The typical dilation rate for the nulliparous woman is 1.2 cm/hr; for the multiparous woman, it is 1.5 cm/hr (Cunningham et al., 2014).

Transition Phase

The transition phase is the last phase of the first stage of labor. During this phase, dilation slows, progressing from 8 to 10 cm, with effacement from 80% to 100%. The transition phase is the most difficult and, fortunately, the shortest phase for the woman, lasting approximately 1 hour in the first birth and perhaps 15 to 30 minutes in successive births (Tharpe et al., 2016). During transition, the contractions are stronger (hard by palpation), more painful, more frequent (every

1 to 2 minutes), and they last longer (60 to 90 seconds). The average rate of fetal descent is 1 cm/hr in nulliparous women and 2 cm/hr in multiparous women. Pressure on the rectum is great, and there is a strong desire to contract the abdominal muscles and push.

Other maternal symptoms during the transitional phase include nausea and vomiting, trembling extremities, backache, increased apprehension and irritability, restless movement, increased bloody show from the vagina, inability to relax, diaphoresis, feelings of loss of control, and being overwhelmed (the woman may say, "I can't take it anymore") (Cunningham et al., 2014).

In assessing Kathy, the nurse finds she is 4 cm dilated and 50% effaced with ruptured membranes. In what stage and phase of labor would this assessment finding place Kathy?

Second Stage

The second stage of labor begins with complete cervical dilation (10 cm) and effacement and ends with the birth of the newborn. Although the previous stage of labor primarily involved the thinning and opening of the cervix, this stage involves moving the fetus through the birth canal and out of the body. The cardinal movements of labor occur during the early phase of passive descent in the second stage of labor.

Contractions occur every 2 to 3 minutes, last 60 to 90 seconds, and are described as strong by palpation. The average length of the second stage of labor in a nullipara is approximately 1 hour and less than half that time for the multipara. During this expulsive stage, the mother usually feels more in control and less irritable and agitated. She is focused on the work of pushing. The maternal urge to push is generally felt when there is direct contact of the fetus to the pelvic floor. Stretch receptors in the wall of the vagina, rectum, and perineum communicate the pressure of the fetus descending in the birth canal that, along with increased abdominal pressure, causes the overwhelming urge to push described by laboring women (Camorcia, 2015).

Pushing

The second stage of labor has two phases (pelvic and perineal) related to the existence and quality of the maternal urge to push and to obstetric conditions related to fetal descent. The early phase of the second stage is called the pelvic phase, because it is during this phase that the fetal head is negotiating the pelvis, rotating, and advancing in descent. The later phase is called the perineal phase, because at this point the fetal head is lower in the pelvis and is distending the perineum. The occurrence of a strong urge to push characterizes the later phase of the second stage and has also been called the phase of active pushing (Cheng & Caughey, 2015b).

The later perineal phase occurs when the mother feels a tremendous urge to push as the fetal head is lowered and is distending the perineum. The perineum bulges and there is an increase in bloody show. The fetal head becomes apparent at the vaginal opening but disappears between contractions. When the top of the head no longer regresses between contractions, it is said to have crowned. The fetus rotates as it maneuvers out. Evidence now shows that labor actually

progresses slower than we thought in the past. Many women might need a little more time to labor and give birth vaginally instead of moving to a surgical birth (ACOG, 2014c). The second stage commonly lasts up to 3 hours in a first labor and up to an hour in subsequent ones (Fig. 13.14).

SPONTANEOUS PUSHING VERSUS DIRECTED PUSHING

There are two ways of conducting the second stage of labor: *spontaneous pushing* (following the mother's spontaneous urge) and *directed pushing* (pushing directed by the caregiver). Spontaneous pushing represents a natural way of managing the second stage of labor. However, lately, and as a result of epidural analgesia, health care providers frequently resort to directed pushing without taking into account the negative repercussions it has on the woman and her fetus.

Evidence is mounting that the management of the second stage, particularly pushing, is a modifiable risk factor in long-term perinatal outcomes (ACOG, 2014b). Research supports spontaneous physiologic approaches to second stage labor care; however, many women in hospital settings continue to receive direction from nurses to use prolonged Valsalva (holding breath) bearing-down efforts as soon as the cervix is completely dilated. Traditionally, women have been taught to hold their breath to the count of 10, inhale again, push again, and repeat the process several times during a contraction. This sustained, strenuous style of pushing, i.e., Valsalva bearing-down and supine maternal positions, is linked to hemodynamic changes in the mother and interferes with oxygen exchange between the mother and the fetus. In addition, it is associated with pelvic floor damage: the longer the push, the more damage to the pelvic floor.

In clinical practice, health care providers sometimes resist delaying the onset of pushing after the second stage of labor has begun because of a belief that it will increase labor time. Delaying maternal bearing-down efforts during the second stage until the woman feels the urge to push (laboring down) allows for optimal use of maternal energy, has no detrimental maternal effects, and results in improved fetal oxygenation (Osborne & Hanson, 2014). Research shows that delaying pushing for up to 90 minutes after complete cervical dilation resulted in a significant decrease in the time mothers spend pushing without a significant increase in total time in second stage of labor (King et al., 2015). Because research does not support a policy of directed pushing, and some evidence suggests it may be harmful, the practice of directed pushing should be abandoned (Brodric, 2014). The newest protocol from the Association of

Women's Health, Obstetric and Neonatal Nurses (AWHONN, 2014) recommends an open-glottis method in which air is released during pushing to prevent the buildup of intrathoracic pressure. Doing so also supports mother's involuntary bearing-down efforts (Holvey, 2014). The adoption of a physiologic, woman-directed approach to bearing down is advocated (King et al., 2015).

Behaviors demonstrated by laboring women during this time include pushing at the onset of the urge to bear down; using their own pattern and technique of bearing down in response to sensations they experience; using open-glottis bearing down with contractions; pushing with variations in strength and duration; pushing down with progressive intensity; and using multiple positions to increase progress and comfort. This approach is in stark contrast to management by arbitrary time limits and the directed bearing-down efforts seen in practice today. Labor nurses need to develop an evidence-based approach that acknowledges and reinforces women's innate ability to give birth and refrain from trying to direct women's pushing behaviors (Reed, 2015).

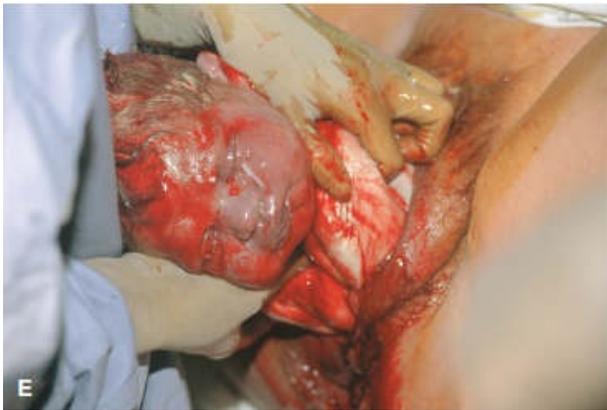
Laboring down (promotion of passive descent) is an alternative strategy for second-stage management in women with epidurals. Using this approach, the fetus descends and is born without coached maternal pushing.


FIGURE 13.14 Birth sequence from crowning through birth of the newborn. **A.** Early crowning of the fetal head. Notice the bulging of the perineum. **B.** Late crowning. Notice that the fetal head is appearing face down. This is the normal OA position. **C.** As the head extends, you can see that the occiput is to the mother's right side–ROA position. **D.** The cardinal movement of extension. **E.** The shoulders are born. Notice how the head has turned to line up with the shoulders—the cardinal movement of external rotation. **F.** The body easily follows the shoulders. **G.** The newborn is held for the first time. (© B. Proud.)

Third Stage

The third stage of labor begins with the birth of the newborn and ends with the separation and birth of the placenta. It consists of two phases: placental separation and placental expulsion. Worldwide, approximately 800 women die each day from preventable causes related to childbirth. The single most common cause is severe bleeding, which can kill a woman within hours if care is delayed. Prompt and effective management is paramount to saving the lives of these women and prevention measures can be initiated in the third stage of labor. Controversy continues about active verses expectant management of the third stage of labor. See Evidence-Based Practice 13.1.

Placental Separation

After the infant is born, the uterus continues to contract strongly and can now retract, decreasing markedly in size. These contractions cause the placenta to pull away from the uterine wall. The following signs of separation indicate that the placenta is ready to deliver:

• The uterus rises upward.

• The umbilical cord lengthens.

• A sudden trickle of blood is released from the vaginal opening.

• The uterus changes its shape to globular.

Spontaneous birth of the placenta occurs in one of two ways: the fetal side (shiny gray side) presenting first (called Schultz's mechanism or more commonly called "shiny Schultz's") or the maternal side (red raw side) presenting first (termed Duncan's mechanism or "dirty Duncan").

EVIDENCE-BASED PRACTICE 13.1 ACTIVE VERSES EXPECTANT MANAGEMENT FOR WOMEN IN LABOR

STUDY

Once birth has taken place, the uterus continues to contract, causing the placenta to separate from the wall of the uterus. The mother then delivers the placenta without outside intervention. This is termed expectant management of the third stage of labor. Active management of the third stage of labor involves giving a prophylactic uterotonic drug to contract the uterus, clamping the umbilical cord early before cord pulsations stops; and traction is applied to the cord with counter-pressure on the uterus to deliver the placenta. Active management was introduced to try to reduce postpartum hemorrhage, a major contributor to maternal mortality. The objective of this study was to compare the effectiveness of active verses expectant management of the third stage of labor.

Findings

Seven studies involving 8247 women were analyzed. Because of the clinical heterogeneity of the sample, random-effects were used in the analysis. Active management showed a significant decrease in primary blood loss greater than 500 mL and subsequent anemia. However it reduced the newborn's birthweight and increased the mother's blood pressure. Overall, the quality of the evidence was low and more data are needed to be confident in the findings.

Placental Expulsion

After separation of the placenta from the uterine wall, continued uterine contractions cause the placenta to be expelled within 2 to 30 minutes unless there is gentle external traction to assist. After the placenta is expelled, the uterus is massaged briefly by the attending physician or midwife until it is firm so that uterine blood vessels constrict, minimizing the possibility of hemorrhage. Normal blood loss is approximately 500 mL for a vaginal birth and 1,000 mL for a cesarean birth. Blood loss of over 1,000 mL is considered severe (Pavord & Maybury, 2015).

If the placenta does not spontaneously deliver, the health care provider assists with its removal by manual extraction. On expulsion, the placenta is inspected for its intactness by the health care provider and the nurse to make sure all sections are present. If any piece is still attached to the uterine wall, it places the woman at risk for postpartum hemorrhage because it becomes a space-occupying object that interferes with the ability of the uterus to contract fully and effectively.

Fourth Stage

The fourth stage begins with completion of the expulsion of the placenta and membranes and ends with the initial physiologic adjustment and stabilization of the mother (1 to 4 hours after birth). This stage initiates the postpartum period. The mother usually feels a sense of peace and excitement, is wide awake, and is very talkative initially. The attachment process begins with her inspecting her newborn and desiring to cuddle and breast-feed him or her. The mother's fundus should be firm and well contracted. Typically it is located at the midline between the umbilicus and the symphysis, but it then slowly rises to the level of the umbilicus during the first hour after birth (Jordan et al., 2014). If the uterus becomes boggy, it is massaged to keep it firm. The lochia (vaginal discharge) is red, mixed with small clots, and of moderate flow. If the woman has had an episiotomy during the second stage of labor, it should be intact, with the edges approximated and clean and no redness or edema present.

The focus during this stage is to monitor the mother closely to prevent hemorrhage, bladder distention, and venous thrombosis. Usually the mother is thirsty and hungry during this time and may request food and drink. Her bladder is hypotonic and thus she has limited sensation to acknowledge a full bladder or to void. Vital signs, the amount and consistency of the vaginal discharge (lochia), and the uterine fundus are usually monitored every 15 minutes for at least 1 hour. The woman will be feeling cramp-like discomfort during this time due to the contracting uterus.

KEY CONCEPTS

- Labor is a complex, multifaceted interaction between the mother and fetus. Thus, it is difficult to determine exactly why labor begins and what initiates it.

- Before the onset of labor, a pregnant woman's body undergoes several changes in preparation for the birth of the newborn, often leading to characteristic signs and symptoms that suggest that labor is near. These changes include cervical changes, lightening, increased energy level, bloody show, Braxton Hicks contractions, and spontaneous rupture of membranes.

- False labor is a condition seen during the latter weeks of some pregnancies in which irregular uterine contractions are felt, but the cervix is not affected.

- The critical factors in labor and birth are designated as the 10 P's: passageway (birth canal), passenger (fetus and placenta), powers (contractions), position (maternal), psychological response, philosophy (low tech, high touch), partners (support caregivers), patience (natural timing), patient (client) preparation (childbirth knowledge base), and pain management (comfort measures).

- The size and shape of a woman's pelvis are determining factors for a vaginal birth. The female pelvis is classified according to four main shapes: gynecoid, anthropoid, android, and platypelloid.

- The labor process is comprised of a series of rhythmic, involuntary, usually quite uncomfortable uterine muscle contractions that bring about a shortening (effacement) and opening (dilation) of the cervix, and a bursting of the fetal membranes. Important parameters of uterine contractions are frequency, duration, and intensity.

- The diameters of the fetal skull vary considerably, with some diameters shortening and others lengthening as the head is molded during the labor and birth process.

- Pain during labor is a nearly universal experience for childbearing women. Having a strong sense of self and meaningful support from others can often help women manage labor well and reduce their sensation of pain.

- Preparing mentally for childbirth is important for women to enable them to work with the natural forces of labor and not against them.

- As the woman experiences and progresses through childbirth, numerous physiologic responses occur that assist her adaptation to the laboring process.

- Labor is typically divided into four stages that are unequal in length.

- During the first stage, the fundamental change underlying the process is progressive dilation of the cervix. It is further divided into three phases: latent phase, active phase, and transition.

- The second stage of labor is from complete cervical dilation (10 cm) and effacement through the birth of the infant.

- The third stage is that of separation and birth of the placenta. It consists of two phases: placental separation and placental expulsion.

- The fourth stage begins after the birth of the placenta and membranes and ends with the initial physiologic adjustment and stabilization of the mother (1 to 4

hours).

CHAPTER **WORKSHEET**

MULTIPLE-CHOICE QUESTIONS

1. When determining the frequency of contractions, the nurse would measure which of the following?

   a. Start of one contraction to the start of the next contraction

   b. Beginning of one contraction to the end of the same contraction

   c. Peak of one contraction to the peak of the next contraction

   d. End of one contraction to the beginning of the next contraction

2. Which fetal lie is most conducive to a spontaneous vaginal birth?

   a. Transverse

   b. Longitudinal

   c. Perpendicular

   d. Oblique

3. Which of the following observations would suggest that placental separation is occurring?

   a. Uterus stops contracting altogether.

   b. Umbilical cord pulsations stop.

   c. Uterine shape changes to globular.

   d. Maternal blood pressure drops.

4. As the nurse is explaining the difference between true versus false labor to her childbirth class, she states that the major difference between them is:

   a. Discomfort level is greater with false labor.

   b. Progressive cervical changes occur in true labor.

   c. There is a feeling of nausea with false labor.

   d. There is more fetal movement with true labor.

5. The shortest but most intense phase of labor is the:

   a. Latent phase

   b. Active phase

   c. Transition phase

   d. Placental expulsion phase

6. A laboring woman is admitted to the labor and birth suite at 6-cm dilation. She would be in which phase of the first stage of labor?

a. Latent

b. Active

c. Transition

d. Early

7. Which assessment would indicate that a woman is in true labor?

a. Membranes are ruptured and fluid is clear.

b. Presenting part is engaged and not floating.

c. Cervix is 4 cm dilated, 90% effaced.

d. Contractions last 30 seconds, every 5 to 10 minutes.

8. Interventions that are underutilized in promoting a normal birth. Select all that apply.

a. Oral nutrition and fluids in labor

b. Open glottis pushing in the second stage of labor

c. Skin-to-skin contact after birth for infant bonding

d. Routine artificial rupture of membranes (amniotomy)

e. Labor induction with Pitocin given intravenously

f. Routine episiotomy to shorten labor length

9. Physiologic preparation for labor would be demonstrated by:

a. Decrease in Braxton Hicks contractions felt by mother

b. Weight gain and an increase in appetite by mother

c. Lightening, whereby the fetus drops into true pelvis

d. Fetal heart rate accelerations and increased movements

CRITICAL THINKING EXERCISES

1. Cindy, a 20-year-old primipara, calls the birthing center where you work as a nurse and reports that she thinks she is in labor because she feels labor pains. Her due date is this week. The midwives have been giving her prenatal care

throughout this pregnancy.

    a. What additional information do you need to respond appropriately?

    b. What suggestions/recommendations would you make to her?

    c. What instructions need to be given to guide her decision making?

    d. What other premonitory signs of labor might the nurse ask about?

    e. What manifestations would be found if Cindy is experiencing true labor?

2. You are assigned to lead a community education class for women in their third trimester of pregnancy to prepare them for their upcoming birth. Prepare an outline of topics that should be addressed.

STUDY ACTIVITIES

1. During clinical post conference, share with the other nursing students how the critical forces of labor influenced the length of labor and the birthing process for a laboring woman assigned to you.

2. The cardinal movements of labor include which of the following? Select all that apply.

    a. Extension and rotation

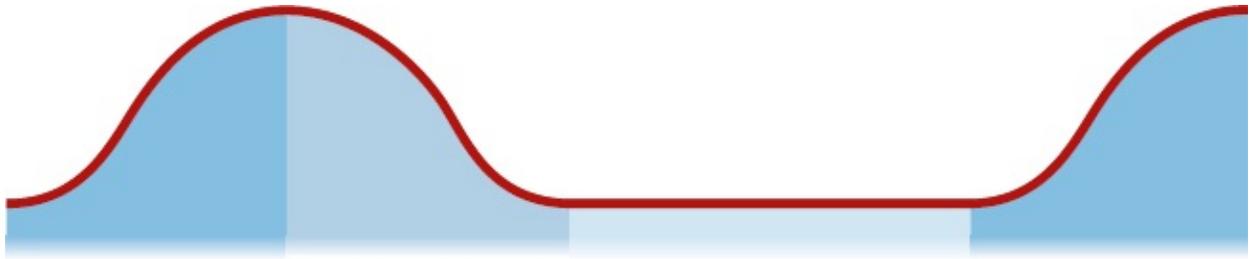
    b. Descent and engagement

    c. Presentation and position

    d. Attitude and lie

    e. Flexion and expulsion

3. Interview a woman on the mother–baby unit who has given birth within the past few hours. Ask her to describe her experience and examine psychological factors that may have influenced her laboring process.

4. On the following illustration, identify the parameters of uterine contractions by marking an "X" where the nurse would measure the duration of the contraction.


BRINGING IT ALL TOGETHER: CASE STUDY

Moritza is a 20-year-old pregnant female who comes to the prenatal clinic with her boyfriend for her prenatal visit at 39 weeks' gestation. This is her first pregnancy and she has missed several of her previous prenatal office visits. Her pregnancy has been uneventful thus far, but she is concerned today about impending labor and how she will know when to go to the hospital. She feels unprepared for labor and admits she is very afraid of the pain since many of her friends and family members have shared their 'horror' stories about their experiences. She admits she is scared about having an IV in her arm at the hospital. She wants a normal physiologic childbirth.

ASSESSMENT

Moritza has taken good care of herself during this pregnancy, having only gained 22 pounds. She didn't attend any of the prepared childbirth classes offered free through the health department, so she has numerous questions about her labor and birth forthcoming. Fetal heart rate is 140 bpm, fetus active upon palpation, no dependent edema in extremities. Urine specimen was negative for glucose or protein. Today's weight is 138 pounds.

Go to thePoint to find questions to consider about this case.

14

Nursing Management During Labor and Birth

KEY TERMS

accelerations
artifact
baseline fetal heart rate
baseline variability
crowning
deceleration
electronic fetal monitoring (EFM)
episiotomy
Leopold's maneuvers

neuraxial analgesia/anesthesia
periodic baseline changes

Learning Objectives

Upon completion of the chapter, you will be able to:

1. Examine the measures used to evaluate maternal status during labor and birth.
2. Differentiate the advantages and disadvantages of external and internal fetal monitoring, including the appropriate use for each.
3. Choose appropriate nursing interventions to address nonreassuring fetal heart rate patterns.
4. Outline the nurse's role in fetal assessment.
5. Appraise the various comfort promotion and pain relief strategies used during labor and birth.
6. Summarize the assessment data collected on admission to the perinatal unit.
7. Relate the ongoing assessments involved in each stage of labor and birth.
8. Analyze the nurse's role throughout the labor and birth process.

Sheila was admitted in active labor to the labor and birth unit. She has progressed to the transition phase (dilated 8 cm) and is becoming increasingly more uncomfortable. She is using a patterned-paced breathing pattern now, but is thrashing around in the hospital bed.

Words of Wisdom

Wise nurses are not always silent, but they know when to be during the miracle of birth.

INTRODUCTION

The laboring and birthing process is a life-changing event for many women. Nurses need to be respectful, available, encouraging, supportive, and professional in dealing with all women. Nursing management for labor and birth involves assessment, comfort measures, emotional support, information and instruction, advocacy, and support for the partner. Providing the highest quality in maternity care is dependent on nurses valuing the childbirth experience and recognizing it as a life-changing experience for women and their families; caring nurse practice encompasses technical skills and caring behaviors; giving care that protects, promotes, and supports physiologic childbirth; providing optimal, evidence-based care; and recognizing health disparity and cultural diversity in all women cared for to improve their childbirth experience across time, settings, and disciplines. One of the components for evidence-based care and woman-centered care is women preferences to guide care for themselves during the birthing process. In a recent study, women's needs and expectations during labor and birth were assessed. Seven themes emerged—physiologic needs (nutrition, room environment, hygiene, comfort, and privacy); psychologic needs (empathy and advocacy, constant emotional support and encouragement); informational needs (about labor process and hospital policies); communication needs (health care provider and familiar attendant); esteem needs (sense of value, confidence, involvement in decisions); security needs (calming fears); and medical needs (pain relief and prevention of unnecessary interventions during labor and birth) (Iravani et al., 2015). It is important that nurses identify the expectations and needs of women in their care, so as to empower them to fully participate in their childbirth experience.

The health of mothers and their infants is of critical importance, both as a reflection of the current health status of a large segment of our population and as a predictor of the health of the next generation. The United States Department of Health and Human Services [USDHHS] (2010) addresses maternal health in two objectives: reducing maternal deaths and reducing maternal illness and complications due to pregnancy (complications during hospitalized labor and delivery). In addition, two more objectives address increasing the proportion of pregnant women who receive early and adequate prenatal care. A goal in development seeks to increase the proportion of pregnant women who attend a

series of prepared childbirth classes. (See for more information on these objectives.)

This chapter provides information about nursing management during labor and birth. First, the essentials for in-depth assessment of maternal and fetal status during labor and birth are discussed. This is followed by a thorough description of the major methods of promoting comfort and providing pain management during the labor and birth process. The chapter concludes by putting all the information together with a discussion of the nursing care specific to each stage of labor, including the necessary data to be obtained with the admission assessment, methods to evaluate labor progress during the first stage of labor, and key nursing measures that focus on maternal and fetal assessments and pain relief for all stages of labor.

MATERNAL ASSESSMENT DURING LABOR AND BIRTH

During labor and birth, various techniques are used to assess maternal status. These techniques provide an ongoing source of data to determine the woman's response and her progress in labor:

• Assess maternal vital signs, including temperature, blood pressure, pulse, respiration, and pain, which are primary components of the physical examination and ongoing assessment.

• Also review the prenatal record to identify risk factors that may contribute to a decrease in uteroplacental circulation during labor.

• If there is no vaginal bleeding on admission, a vaginal examination is performed to assess cervical dilation, after which it is monitored periodically as necessary to identify progress.

• Evaluate maternal pain and the effectiveness of pain management strategies at regular intervals during labor and birth.

Vaginal Examination

The World Health Organization (WHO) recommends digital vaginal examinations at intervals of 4 hours for routine assessment and identification of a delay in active labor (2014). Although not all nurses perform vaginal examinations on laboring women in all practice settings, most nurses working in community hospitals do so because physicians are not routinely present in labor and birth suites. Since most newborns in the United States are born in community hospitals, nurses are performing vaginal examinations along with midwives and physicians (American Hospital Association, 2015).

 Take Note!

A vaginal examination is an assessment skill that takes time and experience to develop; only by doing it frequently in clinical practice can the practitioner's skill level improve.

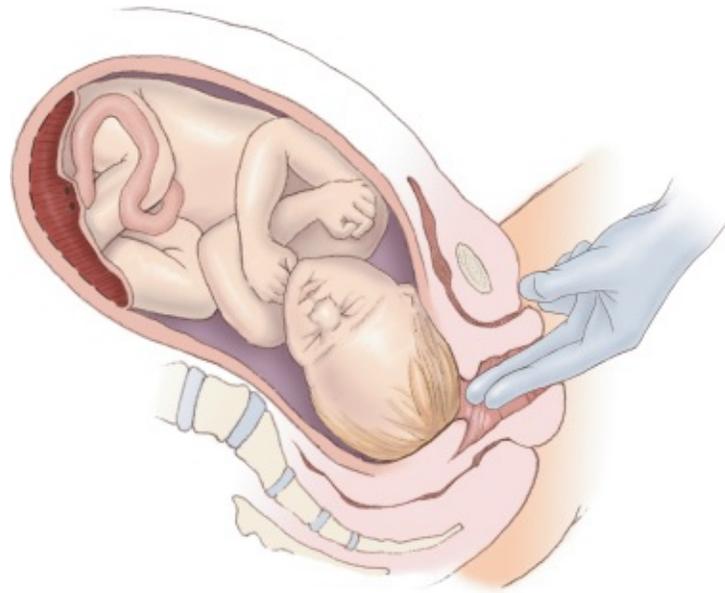
The purpose of performing a vaginal examination is to assess the amount of cervical dilation, the percentage of cervical effacement, and the fetal membrane status and to gather information on presentation, position, station, degree of fetal head flexion, and presence of fetal skull swelling or molding (Fig. 14.1). Prepare the woman by informing her about the procedure, what information will be obtained from it, how she can assist with the procedure, how it will be performed, and who will be performing it.


FIGURE 14.1 Vaginal examination to determine cervical dilation and effacement.

The woman is typically on her back during the vaginal examination. The vaginal examination is performed gently, with concern for the woman's comfort. If it is the initial vaginal examination to check for membrane status, water is used as a lubricant.

After donning sterile gloves, the examiner inserts his or her index and middle fingers into the vaginal introitus. Next, the cervix is palpated to assess dilation, effacement, and position (e.g., posterior or anterior). If the cervix is open to any degree, the presenting fetal part, fetal position, station, and presence of molding can be assessed. In addition, the membranes can be evaluated and described as intact, bulging, or ruptured.

At the conclusion of the vaginal examination, the findings are discussed with the woman and her partner to bring them up to date about labor progress. In addition, the findings are documented either electronically or in writing and reported to the primary health care provider in charge of the case.

Cervical Dilation and Effacement

The amount of cervical dilation (opening) and the degree of cervical effacement (thinning) are key areas assessed during the vaginal examination as the cervix is palpated with the gloved index finger. Although this finding is somewhat subjective, experienced examiners typically come up with similar findings. The width of the cervical opening determines dilation, and the length of the cervix

assesses effacement. Effacement and dilation are used to assess cervical changes as follows:

• Effacement:
  • 0%: cervical canal is 2 cm long
  • 50%: cervical canal is 1 cm long
  • 100%: cervical canal is obliterated
• Dilation:
  • 0 cm: external cervical os is closed
  • 5 cm: external cervical os is halfway dilated
  • 10 cm: external os is fully dilated and ready for birth passage

The information yielded by this examination serves as a basis for determining which stage of labor the woman is in and what her ongoing care should be.

Fetal Descent and Presenting Part

In addition to cervical dilation and effacement findings, the vaginal examination can also determine fetal descent (station) and presenting part. During the vaginal examination, the gloved index finger is used to palpate the fetal skull (if vertex presentation) through the opened cervix or the buttocks in the case of a breech presentation. Station is assessed in relation to the maternal ischial spines and the presenting fetal part. These spines are not sharp protrusions but rather blunted prominences at the midpelvis. The ischial spines serve as landmarks and have been designated as zero station. If the presenting part is palpated higher than the maternal ischial spines, a negative number is assigned; if the presenting fetal part is felt below the maternal ischial spines, a plus number is assigned, denoting how many centimeters below zero station (see Chapter 13 for a more detailed discussion).

Progressive fetal descent (−5 to +4) is the expected norm during labor—moving downward from the negative stations to zero station to the positive stations in a timely manner. If progressive fetal descent does not occur, a disproportion between the maternal pelvis and the fetus might exist and needs to be investigated.

Rupture of Membranes

The integrity of the membranes can be determined during the vaginal

examination. Typically, if intact, the membranes will be felt as a soft bulge that is more prominent during a contraction. If the membranes have ruptured, the woman may have reported a sudden gush of fluid. Membrane rupture also may occur as a slow trickle of fluid. When membranes rupture, the priority focus should be on assessing fetal heart rate (FHR) first to identify a deceleration, which might indicate cord compression secondary to cord prolapse. If the membranes are ruptured when the woman comes to the hospital, the health care provider should ascertain when it occurred. Prolonged ruptured membranes increase the risk of infection as a result of ascending vaginal pathological organisms for both mother and fetus. Signs of intrauterine infection to be alert for include maternal fever, fetal and maternal tachycardia, foul odor of vaginal discharge, and an increase in white blood cell count.

To confirm that membranes have ruptured, a sample of fluid is taken from the vagina via a nitrazine yellow dye swab to determine the fluid's pH. Vaginal fluid is acidic, whereas amniotic fluid is alkaline and turns a nitrazine swab blue. Sometimes, however, false-positive results can occur, especially in women experiencing a large amount of bloody show, because blood is alkaline. The membranes are most likely intact if the nitrazine swab remains yellow to olive green, with pH between 5 and 6. The membranes are probably ruptured if the nitrazine swab turns a blue-green to deep blue, with pH ranging from 6.5 to 7.5 (Tharpe, Farley, & Jordan, 2016).

If the nitrazine test is inconclusive, an additional test, called the *fern test*, can be used to confirm rupture of membranes. With this test, a sample of vaginal fluid is obtained, applied to a microscope slide, and allowed to dry. Using a microscope, the slide is examined for a characteristic fern pattern that indicates the presence of amniotic fluid.

Assessing Uterine Contractions

The primary power of labor is uterine contractions, which are involuntary. Uterine contractions increase intrauterine pressure, causing tension on the cervix. This tension leads to cervical dilation and thinning, which in turn eventually forces the fetus through the birth canal. Normal uterine contractions have a contraction (systole) and a relaxation (diastole) phase. The contraction resembles a wave, moving downward to the cervix and upward to the fundus of the uterus. Each contraction starts with a building up (increment), gradually reaching an acme (peak intensity), and then a letting down (decrement). Each contraction is followed by an interval of rest, which ends when the next contraction begins. At the acme (peak) of the contraction, the entire uterus is contracting, with the greatest intensity in the fundal area. The relaxation phase follows and occurs simultaneously throughout the uterus.

Uterine contractions during labor are monitored by palpation and by electronic monitoring. Assessment of the contractions includes frequency; duration, intensity, and uterine resting tone (see Chapter 13 for a more detailed discussion). Uterine contractions with intensity of 30 mm Hg or greater initiate cervical dilation. During active labor, the intensity usually reaches 50 to 80 mm Hg. Resting tone is normally between 5 and 10 mm Hg in early labor and between 12 and 18 mm Hg in active labor (Hiersch et al., 2015).

To palpate the fundus for contraction intensity, place the pads of your fingers on the fundus and describe how it feels: like the tip of the nose (mild), like the chin (moderate), or like the forehead (strong). Palpation of intensity is a subjective judgment of the indentability of the uterine wall; a descriptive term is assigned (mild, moderate, or strong) (Fig. 14.2).

FIGURE 14.2 Nurse palpating the woman's fundus during a contraction.

 Take Note!

Frequent clinical experience is needed to gain accuracy in assessing the intensity of uterine contractions.

The second method used to assess the intensity of uterine contractions is electronic monitoring, either external or internal. Both methods provide a reasonable measurement of the intensity of uterine contractions. Although the external fetal monitor is sometimes used to estimate the intensity of uterine contractions, it is not as accurate an assessment tool.

Performing Leopold's Maneuvers

Leopold's maneuvers are a method for determining the presentation, position, and lie of the fetus through the use of four specific steps. This method involves inspection and palpation of the maternal abdomen as a screening assessment for malpresentation. A longitudinal lie is expected, and the presentation can be cephalic, breech, or shoulder. Each maneuver answers a question:

• *Maneuver 1*: What fetal part (head or buttocks) is located in the fundus (top of the uterus)?

• *Maneuver 2*: On which maternal side is the fetal back located? (Fetal heart tones are best auscultated through the back of the fetus.)

• *Maneuver 3*: What is the presenting part?

• *Maneuver 4*: Is the fetal head flexed and engaged in the pelvis?

Leopold's maneuvers are described in Nursing Procedure 14.1. Also see Chapter 12.

NURSING PROCEDURE 14.1

Performing Leopold's Maneuvers

Purpose: To Determine Fetal Presentation, Position, and Lie

1. Place the woman in the supine position and stand beside her.

2. Perform the first maneuver to determine presentation.

   a. Facing the woman's head, place both hands on the abdomen to determine fetal position in the uterine fundus.
   b. Feel for the buttocks, which will feel soft and irregular (indicates vertex presentation); feel for the head, which will feel hard, smooth, and round (indicates a breech presentation).

3. Complete the second maneuver to determine position.

    a. While still facing the woman, move hands down the lateral sides of the abdomen to palpate on which side the back is located (feels hard and smooth).

    b. Continue to palpate to determine on which side the limbs are located (irregular nodules with kicking and movement).

4. Perform the third maneuver to confirm presentation.

    a. Move hands down the sides of the abdomen to grasp the lower uterine segment and palpate the area just above the symphysis pubis.

    b. Place thumb and fingers of one hand apart and grasp the presenting part by bringing fingers together.

    c. Feel for the presenting part. If the presenting part is the head, it will be round, firm, and ballottable; if it is the buttocks, it will feel soft and irregular.

5. Perform the fourth maneuver to determine attitude.

    a. Turn to face the client's feet and use the tips of the first three fingers of each hand to palpate the abdomen.

    b. Move fingers toward each other while applying downward pressure in the direction of the symphysis pubis. If you palpate a hard area on the side opposite the fetal back, the fetus is in flexion, because you have palpated the chin. If the hard area is on the same side as the back, the fetus is in extension, because the area palpated is the occiput.

Also, note how your hands move. If the hands move together easily, the fetal head is not descended into the woman's pelvic inlet. If the hands do not move together and stop because of resistance, the fetal head is engaged into the woman's pelvic inlet (Walker & Sabrosa, 2014).

FETAL ASSESSMENT DURING LABOR AND BIRTH

A fetal assessment identifies well-being or signs that indicate compromise. The character of the amniotic fluid is assessed, but the fetal assessment focuses primarily on determining the FHR pattern. Umbilical cord blood analysis and fetal scalp stimulation are additional assessments performed as necessary in the case of questionable FHR patterns.

Analysis of Amniotic Fluid

Amniotic fluid should be clear when the membranes rupture. Rupturing of membranes is either spontaneous or artificial by means of an amniotomy, during which a disposable plastic hook (an amnihook) is used to perforate the amniotic sac. Cloudy or foul-smelling amniotic fluid indicates infection. Green fluid may indicate that the fetus has passed meconium secondary to transient hypoxia, prolonged pregnancy, cord compression, intrauterine growth restriction (IUGR), maternal hypertension, diabetes, or chorioamnionitis; however, it is considered a normal occurrence if the fetus is in a breech presentation. If it is determined that meconium-stained amniotic fluid is due to fetal hypoxia, the maternity and pediatric teams work together to prevent meconium aspiration syndrome. This would necessitate suctioning after the head is born before the infant takes a breath and perhaps direct tracheal suctioning after birth if the Apgar score is low. In some cases an amnioinfusion (introduction of warmed, sterile normal saline or Ringer's lactate solution into the uterus) is used to dilute moderate to heavy meconium released in utero to assist in preventing meconium aspiration syndrome.

Analysis of the FHR

Analysis of the FHR is one of the primary evaluation tools used to determine fetal oxygen status indirectly. FHR assessment can be done intermittently using a fetoscope (a modified stethoscope attached to a headpiece) or a Doppler (ultrasound) device, or continuously with an electronic fetal monitor applied externally or internally. The object of FHR monitoring is to reduce the mortality/morbidity by ensuring that all fetal hypoxic insults are identified in time to allow removal or alteration of the reason for it, or to enable a safe birth of the fetus before irreversible asphyxia damage occurs (Hastings, 2015).

Intermittent FHR Monitoring

Intermittent FHR monitoring involves auscultation via a fetoscope or a handheld Doppler device that uses ultrasound waves that bounce off the fetal heart, producing echoes or clicks that reflect the rate of the fetal heart (Fig. 14.3). Traditionally, a fetoscope was used to assess FHR, but the handheld Doppler device has been found to have a greater sensitivity than the fetoscope. Intermittent auscultation of the fetal heart rate is an acceptable option for low-risk laboring women, yet it is underutilized in the hospital setting. Recently several professional organizations have proposed the use of intermittent auscultation as a means of promoting physiologic births (Wisner, 2015); thus, at present it is used in some clinical settings. See Evidence-Based Practice 14.1 for more information.

FIGURE 14.3 Nurse using a handheld Doppler to obtain a fetal heart rate.

Take Note!

Doppler devices to detect FHRs are relatively low in cost and are used in hospitals and in home births and birthing centers routinely. Many nurses use them in their work settings.

Intermittent FHR monitoring allows the woman to be mobile in the first stage of labor. She is free to move around and change position at will since she is not attached to a stationary electronic fetal monitor. However, intermittent monitoring does not provide a continuous FHR recording and does not document how the fetus responds to the stress of labor (unless listening is done during the contraction). The best way to assess fetal well-being would be to start listening to the FHR at the end of the contraction (not after one) so that late decelerations could be detected. However, the pressure of the device during a contraction is uncomfortable and can distract the woman from using her paced-breathing patterns.

Intermittent FHR auscultation can be used to detect FHR baseline and rhythm and changes from baseline. However, it cannot detect variability and types of decelerations, as electronic fetal monitoring (EFM) can (Wisner, 2015). During intermittent auscultation to establish a baseline, the FHR is assessed for a full minute after a contraction. From then on, unless there is a problem, listening for 30 seconds and multiplying the value by two is sufficient. If the woman experiences a change in condition during labor, auscultation assessments should be more frequent. Changes in condition include ruptured membranes or the onset of bleeding. In addition, more frequent assessments occur after periods of ambulation, a vaginal examination, administration of pain medications, or other clinically important events (King et al., 2015).

EVIDENCE-BASED PRACTICE 14.1 INTRAPARTUM FETAL MONITORING

STUDY

Electronic fetal monitoring (EFM) is a widely utilized means of assessing fetal status during labor and has been a central component of intrapartum care. Currently, EFM is the most common method used to evaluate the fetus during labor without substantial evidence to suggest a benefit. Clinicians spend valuable time and energy trying to characterize and distinguish between different types of FHR decelerations even though most of them have been shown to have little association with fetal acidosis. The purpose of this review was to determine if continuous EFM verses intermittent auscultation improved perinatal outcomes.

Findings

A Cochrane review of 13 trials, which included over 37,000 women, found that continuous EFM provided no significant improvement in perinatal death rate (risk rate 0.86; confidence interval 0.59 to 1.23) or cerebral palsy rate (risk rate 1.75; confidence interval 0.84 to 3.63) as compared with intermittent auscultation; however, there was a significant increase in cesarean births (risk rate 1.63; confidence interval 1.29 to 2.07) and operative vaginal births (risk rate 1.15; confidence interval 1.01 to 1.33).

Nursing Implications

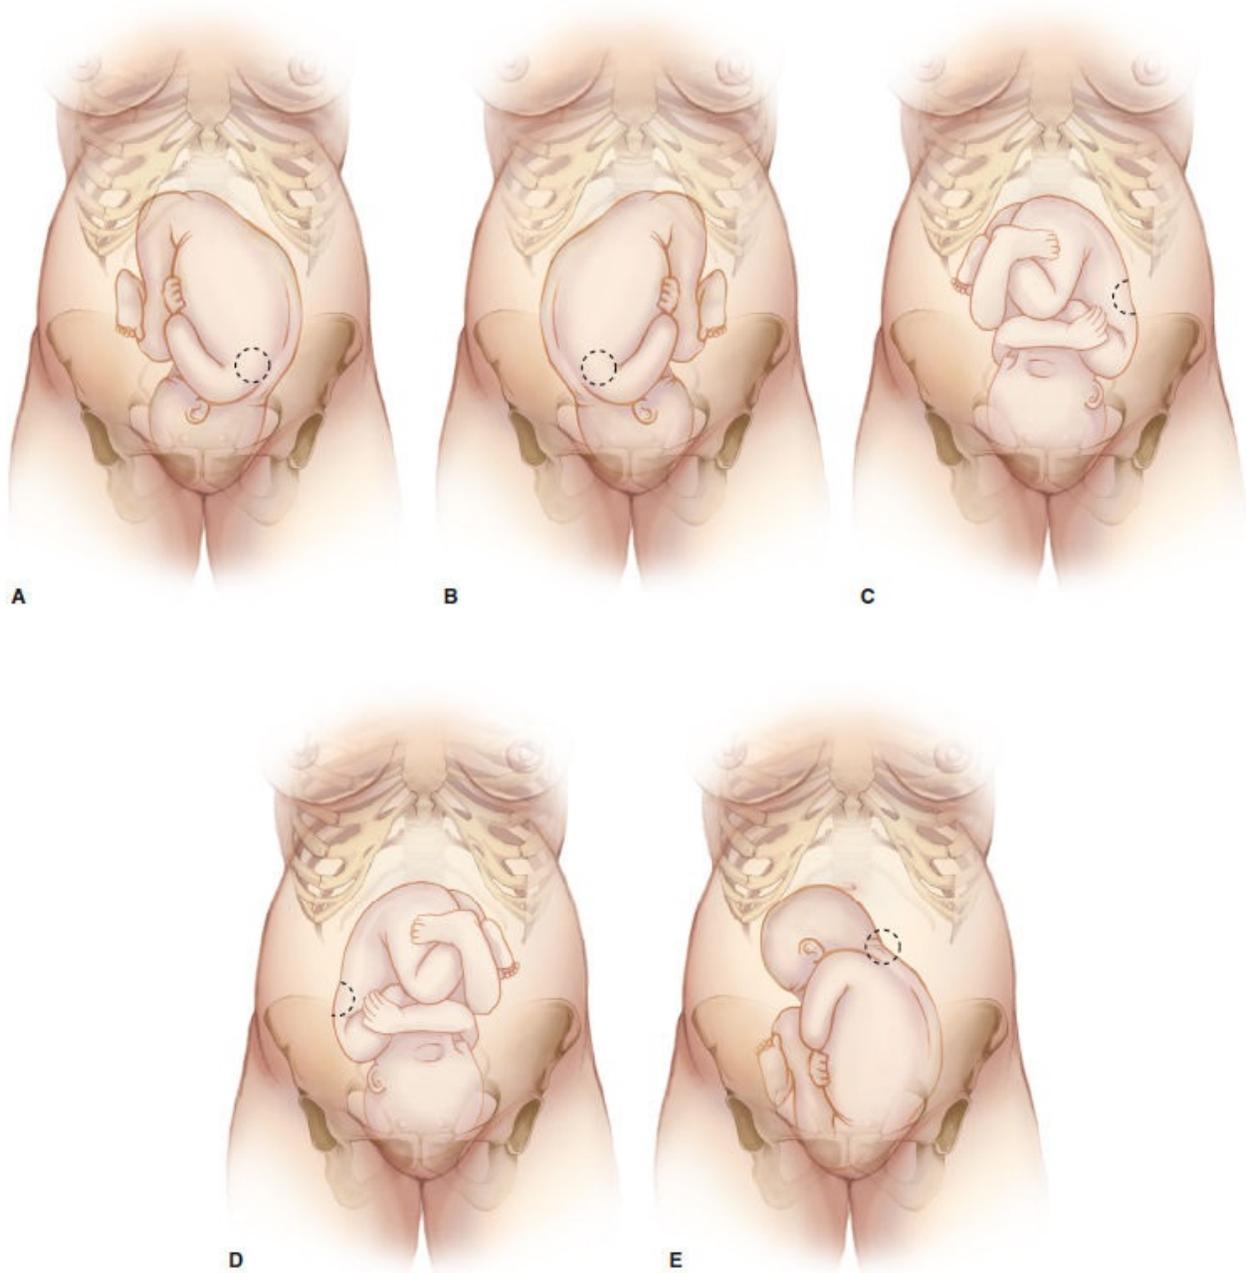
Despite the lack of scientific evidence to support routinely using continuous EFM to reduce adverse perinatal outcomes, its use is almost universal in the hospital setting and very likely has contributed to the rise in cesarean birth rates. Nurses are uniquely positioned to influence the monitoring method used in labor by offering intermittent auscultation to low risk women, and requesting orders from the health care providers that include it as an option. The high-touch nature of intermittent auscultation may help nurses reconnect to their clients and to the essence of nursing practice.


FIGURE 14.4 Locations for auscultating fetal heart rate based on fetal position. **A.** Left occiput anterior (LOA). **B.** Right occiput anterior (ROA). **C.** Left occiput posterior (LOP). **D.** Right occiput posterior (ROP). **E.** Left sacral anterior (LSA).

The FHR is heard most clearly at the fetal back. In a cephalic presentation, the FHR is best heard in the lower quadrant of the maternal abdomen. In a breech presentation, it is heard at or above the level of the maternal umbilicus (Fig. 14.4). As labor progresses, the FHR location will change accordingly as the fetus

descends into the maternal pelvis for the birthing process. To ensure that the maternal heart rate is not confused with the FHR, palpate the client's radial pulse simultaneously while the FHR is being auscultated through the abdomen.

For low risk women, the FHR and contraction characteristics should be assessed every 15 to 30 minutes in active labor and every 5 to 15 minutes while pushing, as well as before and after any digital vaginal examinations, membrane rupture, medication administered, and ambulation to the restroom (Freeman, 2015).

Nursing Procedure 12.1 lists detailed steps for using a Doppler device to assess FHR. In brief, a small amount of water-soluble gel is applied to the woman's abdomen or ultrasound device before auscultation with the Doppler device to promote sound wave transmission. Usually the FHR is best heard in the woman's lower abdominal quadrants; if the FHR is not found quickly, it may help to locate the fetal back by performing Leopold's maneuvers.

Although the intermittent method of FHR assessment allows the client to move about during labor, the information obtained fails to provide a complete picture of the well-being of the fetus from moment to moment. This leads to the question of what the fetal status is during the times that are not assessed. For women who are considered at low risk for complications, this period of nonassessment is not a problem. However, for the undiagnosed high-risk woman, it might prove ominous.

GUIDELINES FOR ASSESSING FETAL HEART RATE

National professional organizations have provided general guidelines for the frequency of assessments based on existing evidence. The American College of Obstetricians and Gynecologists (ACOG), the Institute for Clinical Systems Improvement (ICSI), and the Association of Women's Health, Obstetric and Neonatal Nurses (AWHONN) have published guidelines designed to assist clinicians in caring for laboring clients. Their recommendations are supported by large controlled studies. They recommend the following guidelines for assessing FHR:

• Initial 10- to 20-minute continuous FHR assessment on entry into labor/birth area

• Completion of a prenatal and labor risk assessment on all clients

• Intermittent auscultation every 30 minutes during active labor for a low-risk woman and every 15 minutes for a high-risk woman

- During the second stage of labor, every 15 minutes for the low-risk woman and every 5 minutes for the high-risk woman and during the pushing stage (Agency for Healthcare Research and Quality [AHRQ, 2014]; Association of Women's Health, Obstetric and Neonatal Nurses [AWHONN], 2015; Institute for Clinical Systems Improvement [ICSI], 2015a).

EVIDENCE-BASED RESULTS: INTERMITTENT VERSUS ELECTRONIC MONITORING

In several randomized controlled studies comparing intermittent auscultation with electronic monitoring in both low- and high-risk clients, no difference in intrapartum fetal death was found. However, in each study a nurse–client ratio of 1:1 was consistently maintained during labor (ICSI, 2015a). This suggests that adequate staffing is essential with intermittent FHR monitoring to ensure optimal outcomes for the mother and fetus. There is insufficient evidence to indicate specific situations where continuous electronic FHR monitoring might result in better outcomes when compared to intermittent assessment. However, in pregnancies involving an increased risk of perinatal death, cerebral palsy, or neonatal encephalopathy and when oxytocin is used for induction or augmentation, it is recommended that continuous EFM be used rather than intermittent fetal auscultation (Society of Obstetricians and Gynecologists of Canada, 2015).

Continuous Electronic Fetal Monitoring

EFM detects the fetal pulse by sensing and analyzing tissue movements via Doppler ultrasound. The machine uses a transducer that is capable of both sending and receiving ultrasound waves. The waves travel through the ultrasound gel, then body tissues, and are eventually reflected by any tissue. The fast reflections are analyzed and software in the machine determines the FHR. EFM is the recommended method of intrapartum fetal surveillance for high-risk pregnancies. Despite the questions about its efficacy and controversy regarding increased rates of surgical births associated with its use, continuous cardiotocography (CTG) remains the predominant method of fetal monitoring today (Nageotte, 2015). The indications for offering women continuous fetal monitoring in labor are documented in the National Institute for Health and Care Excellence (NICE) guidelines. These include women receiving oxytocin infusing; women having epidural analgesia; and a variety of problems related to

a compromise in either fetal or maternal health—prolonged rupture of membranes (>24 hours), moderate hypertension (>150/100), confirmed delay in the first or second stage of labor; and the presence of meconium (National Institute for Health and care Excellence [NICE], 2014).

Electronic fetal monitoring (EFM) uses a machine to produce a continuous tracing of the FHR. When the monitoring device is in place, a sound is produced with each heartbeat. In addition, a graphic record of the FHR pattern is produced. The primary objective of EFM is to provide information about fetal oxygenation and prevent fetal injury that could result from impaired fetal oxygenation during labor. The purpose of EFM is to detect FHR changes early before they are prolonged and profound. Fetal hypoxia is demonstrated in a heart rate pattern change and is by far the most common etiology of fetal injury and death that can be prevented with optimal fetal surveillance during labor and early interventions (Cox & King, 2015).

Current methods of continuous EFM were introduced in the United States during the 1970s, specifically for use in clients considered to be at high risk. However, the use of these methods gradually increased and they eventually came to be used for women other than just those at high risk. This increased use has become controversial because it is suspected of being associated with the steadily increasing rates of cesarean births with no decrease in the rate of cerebral palsy (Omo-Aghoja, 2015). Many studies suggest that when compared with standardized intermittent auscultation, the use of intrapartum continuous EFM seems to increase the number of preterm and surgical births but has no significant effect on reducing the incidence of intrapartum death or long-term neurologic injury. When a woman is admitted to the labor unit, a fetal monitor is applied and the FHR is monitored continuously. An impetus for this is the litigious nature of current society, but the benefits have not been proven scientifically. EFM has been given excessive importance in legal cases. Before assigning fault on events at birth, a better understanding of developmental neurobiology and limitations of the present biomarkers is warranted (Freeman, 2015). To date, continuous EFM is not evidence-based for determining fetal health status.

With EFM, there is a continuous record of the FHR: no gaps exist, as they do with intermittent auscultation. The concept of hearing and evaluating every beat of the fetus's heart to allow for early intervention seems logical. On the downside, however, using continuous monitoring can limit maternal movement and encourages the woman to lie in the supine position, which reduces placental

perfusion. Despite the criticisms, EFM remains an accurate method for determining fetal health status by providing a moment-to-moment printout of FHR status.

Various groups within the medical community have criticized the use of continuous fetal monitoring for all pregnant clients, whether high risk or low risk. Concerns about the efficiency and safety of routine EFM in labor have led expert panels in the United States to recommend that such monitoring be limited to high-risk pregnancies. However, its use in low-risk pregnancies continues globally (Maso et al., 2015). This remains an important research issue.

Continuous EFM can be performed externally (indirectly), with the equipment attached to the maternal abdominal wall, or internally (directly), with the equipment attached to the fetus. Both methods provide a continuous printout of the FHR, but they differ in their specificity. The efficacy of EFM depends on the accurate interpretation of the tracings, not necessarily which method (external vs. internal) is used.

CONTINUOUS EXTERNAL MONITORING

In external or indirect monitoring, two ultrasound transducers, each of which is attached to a belt, are applied around the woman's abdomen. They are similar to the handheld Doppler device. One transducer is called a tocotransducer, a pressure-sensitive device that is applied against the uterine fundus. It detects changes in uterine pressure and converts the pressure registered into an electronic signal that is recorded on graph paper (Farine, 2015). The tocotransducer is placed over the uterine fundus in the area of greatest contractility to monitor uterine contractions. The other ultrasound transducer records the baseline FHR, long-term variability, accelerations, and decelerations. It is positioned on the maternal abdomen in the midline between the umbilicus and the symphysis pubis. The diaphragm of the ultrasound transducer is moved to either side of the abdomen to obtain a stronger sound and is then attached to the second elastic belt. This transducer converts the fetal heart movements into beeping sounds and records them on graph paper (Fig. 14.5).

FIGURE 14.5 Continuous external electronic fetal monitoring device applied to the woman in labor.

Good continuous data are provided on the FHR. External monitoring can be used while the membranes are still intact and the cervix is not yet dilated, but also can be used with ruptured membranes and a dilating cervix. It is noninvasive and can detect relative changes in abdominal pressure between uterine resting tone and contractions. External monitoring also measures the approximate duration and frequency of contractions, providing a permanent record of FHR (Casanova, 2015).

However, external monitoring can restrict the mother's movements. It also cannot detect short-term variability. Signal disruptions can occur due to maternal obesity, fetal malpresentation, and fetal movement as well as by artifact. The term **artifact** is used to describe irregular variations or absence of the FHR on the fetal monitor record that result from mechanical limitations of the monitor or electrical interference. For instance, the monitor may pick up transmissions from citizen's band (CB) radios used by truck drivers on nearby roads and translate them into a signal. Additionally, gaps in the monitor strip can occur periodically without explanation.

CONTINUOUS INTERNAL MONITORING

Continuous internal monitoring is usually indicated for women or fetuses considered to be at high risk. Possible conditions might include multiple gestation, decreased fetal movement, abnormal FHR on auscultation, IUGR, maternal fever, preeclampsia, dysfunctional labor, preterm birth, or medical conditions such as diabetes or hypertension. It involves the placement of a spiral

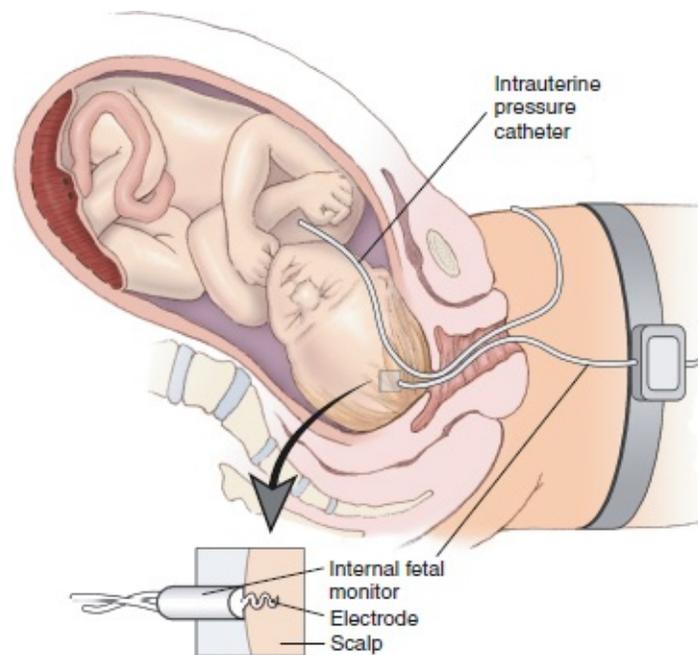
electrode into the fetal presenting part, usually the head, to assess FHR, and a pressure transducer placed internally within the uterus to record uterine contractions (Fig. 14.6). The fetal spiral electrode is considered the most accurate method of detecting fetal heart characteristics and patterns because it involves receiving a signal directly from the fetus (Nageotte, 2015). Specially trained labor and birth nurses are permitted to place the spiral electrode on the fetal head when the membranes rupture to assess the FHR in some health care facilities, but they do not place the intrauterine pressure catheter in the uterus. Internal monitoring does not have to include both an intrauterine pressure catheter and a scalp electrode. A fetal scalp electrode can be used to monitor the fetal heartbeat without monitoring the maternal intrauterine pressure.


FIGURE 14.6 Continuous internal electronic fetal monitoring.

Both the FHR and the duration and interval of uterine contractions are recorded on the graph paper. This method permits evaluation of baseline heart rate and changes in rate and pattern.

Four specific criteria must be met for this type of monitoring to be used:
• Ruptured membranes
• Cervical dilation of at least 2 cm
• Presenting fetal part low enough to allow placement of the scalp electrode

• Skilled practitioner available to insert spiral electrode (ICSI, 2015b)

Compared with external monitoring, continuous internal monitoring can accurately detect both short-term (moment-to-moment) changes and variability (fluctuations within the baseline) and FHR dysrhythmias. In addition, maternal position changes and movement do not interfere with the quality of the tracing.

Determining FHR Patterns

Due to the rising costs of litigations related to birth asphyxia of the newborn and increasing complexity of obstetric populations, it has become absolutely mandatory that all nurses responsible for the care of women in labor are trained adequately in interpretation and documentation of CTG tracings, as well as the guidelines for interventions based on the assessment of the tracing and overall clinical situation. Assessment parameters of the FHR include baseline FHR and variability, presence of accelerations, periodic or episodic decelerations, and changes or trends of FHR patterns over time. The nurse must be able to interpret the various parameters to determine if the FHR pattern is a *category I*, which is strongly predictive of normal fetal acid–base status at the time of observation and needs no intervention; a *category II*, which is not predictive of abnormal fetal acid–base status and but does require evaluation and continued monitoring; or a *category III*, which is predictive of abnormal fetal acid–base status at the time of observation and requires prompt evaluation and interventions, such as giving maternal oxygen, changing maternal position, discontinuing labor augmentation medication, and/or treating maternal hypotension (Freeman, 2015). Table 14.1 summarizes these categories.

BASELINE FHR

Baseline fetal heart rate refers to the average FHR that occurs during a 10-minute segment that excludes periodic or episodic rate changes, such as tachycardia or bradycardia. It is assessed when the woman has no contractions and the fetus is not experiencing episodic FHR changes. The normal baseline FHR ranges between 110 and 160 beats per minute (bpm) (National Institute of Child Health and Human Development [NICHD], 2015). The normal baseline FHR can be obtained by auscultation, ultrasound, or Doppler, or by a continuous internal direct fetal electrode.

Fetal bradycardia occurs when the FHR is below 110 bpm and lasts 10

minutes or longer (Maso et al., 2015). It can be the initial response of a healthy fetus to asphyxia. Causes of fetal bradycardia might include fetal hypoxia, prolonged maternal hypoglycemia, fetal acidosis, administration of analgesic drugs to the mother, hypothermia, anesthetic agents (epidural), maternal hypotension, fetal hypothermia, prolonged umbilical cord compression, and fetal congenital heart block (Nageotte, 2015). Bradycardia may be benign if it is an isolated event, but it is considered an ominous sign when accompanied by a decrease in baseline variability and late decelerations.

Fetal tachycardia is a baseline FHR greater than 160 bpm that lasts for 10 minutes or longer (NICHD, 2015). It can represent an early compensatory response to asphyxia. Other causes of fetal tachycardia include fetal hypoxia, maternal fever, maternal dehydration, amnionitis, drugs (e.g., cocaine, amphetamines, nicotine), maternal hyperthyroidism, maternal anxiety, fetal anemia, prematurity, fetal infection, chronic hypoxemia, congenital anomalies, fetal heart failure, and fetal arrhythmias. Fetal tachycardia is considered an ominous sign if it is accompanied by a decrease in variability and late decelerations (Yuan, 2015).

TABLE 14.1 Interpreting FHR Patterns

Category I: normal	Predictive of normal fetal acid–base status and do not require intervention • Baseline rate (110–160 bpm) • Baseline variability moderate • Present or absent accelerations • Present or absent early decelerations • No late or variable decelerations Can be monitored with intermittent auscultation during labor
Category II: indeterminate	Not predictive of abnormal fetal acid–base status, but require evaluation and continued surveillance • Fetal tachycardia (>160 bpm) present • Bradycardia (<110 bpm) not accompanied by absent baseline variability • Absent baseline variability not accompanied by recurrent decelerations • Minimal or marked variability • Recurrent late decelerations with moderate baseline variability • Recurrent variable decelerations accompanied by minimal or moderate baseline variability; overshoots, or shoulders • Prolonged decelerations >2 min but <10 min
Category III: abnormal	Predictive of abnormal fetus acid–base status and require intervention • Fetal bradycardia (<110 bpm) • Recurrent late decelerations • Recurrent variable decelerations—declining or absent • Sinusoidal pattern (smooth, undulating baseline)

BASELINE VARIABILITY

Baseline variability is defined as irregular fluctuations in the baseline fetal heart rate, which is measured as the amplitude of the peak to trough in bpm (Sholapurkar, 2015). It represents the interplay between the parasympathetic and sympathetic nervous systems. The constant interplay (push-and-pull effect) on the FHR from the parasympathetic and sympathetic systems produces a moment-to-moment change in the FHR. Because variability is in essence the combined result of autonomic nervous system branch function, its presence implies that the both branches are working and receiving adequate oxygen (Timmins & Clark, 2015). Thus, variability is one of the most important characteristics of the FHR. Variability is described in four categories as follows:

• fluctuation range undetectable

• fluctuation range observed at <5 bpm

• fluctuation range from 6 to 25 bpm

• fluctuation range >25 bpm

Absent or minimal variability typically is caused by fetal acidemia secondary to uteroplacental insufficiency, cord compression, a preterm fetus, maternal hypotension, uterine hyperstimulation, abruptio placenta, or a fetal dysrhythmia. Interventions to improve uteroplacental blood flow and perfusion through the umbilical cord include lateral positioning of the mother, increasing the IV fluid rate to improve maternal circulation, administering oxygen at 8 to 10 L/min by mask, considering internal fetal monitoring, documenting findings, and reporting to the health care provider. Preparation for a surgical birth may be necessary if no changes occur after attempting the interventions.

Moderate viability indicates that the autonomic and central nervous systems (CNSs) of the fetus are well developed and well oxygenated. It is considered a good sign of fetal well-being and correlates with the absence of significant metabolic acidosis (Fig. 14.7).

Marked variability occurs when there are more than 25 beats of fluctuation in the FHR baseline. Causes of this include cord prolapse or compression, maternal hypotension, uterine hyperstimulation, and abruptio placenta. Interventions include determining the cause if possible, lateral positioning, increasing intravenous fluid rate, administering oxygen at 8 to 10 L/min by mask, discontinuing oxytocin infusion, observing for changes in tracing, considering

internal fetal monitoring, communicating an abnormal pattern to the health care provider, and preparing for a surgical birth if no change in pattern is noted (Freeman, 2015).

FHR variability is an important clinical indicator that is predictive of fetal acid–base balance and cerebral tissue perfusion. It is influenced by fetal oxygenation status, cardiac output, and drug effects (King et al., 2015). As the CNS is desensitized by hypoxia and acidosis, FHR decreases until a smooth baseline pattern appears. Loss of variability may be associated with a poor outcome.

Take Note!

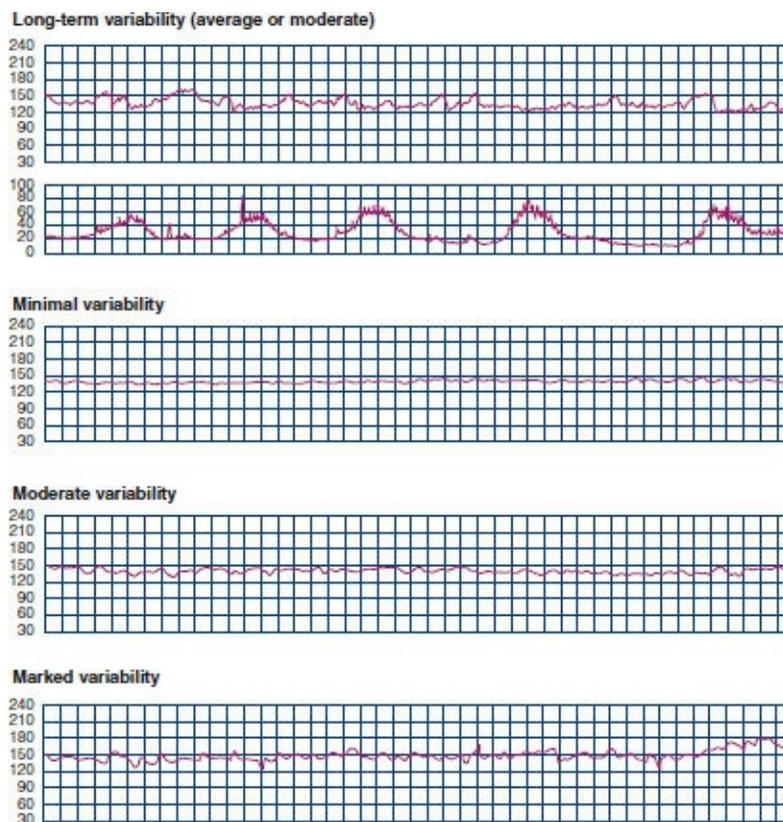
External electronic fetal monitoring cannot assess variability accurately. Therefore, if external monitoring shows a baseline that is smoothing out, use of an internal spiral electrode should be considered to gain a more accurate picture of the fetal health status.


FIGURE 14.7 Examples of fetal monitoring strips. **A.** Long-term variability (average or moderate). **B.**

Minimal variability. **C.** Moderate variability. **D.** Marked variability.

PERIODIC BASELINE CHANGES

Periodic baseline changes are temporary, recurrent changes made in response to a stimulus such as a contraction. The FHR can demonstrate patterns of acceleration or deceleration in response to most stimuli. Fetal **accelerations** are transitory abrupt increases in the FHR above the baseline that last <30 seconds from onset to peak. They are associated with sympathetic nervous stimulation. They are visually apparent, with elevations of FHR of more than 15 bpm above the baseline, and their duration is >15 seconds, but less than 2 minutes (NICHD, 2015). They are generally considered reassuring and require no interventions. Accelerations denote fetal movement and fetal well-being and are the basis for nonstress testing.

 Concept Mastery Alert

Responding to Fetal Heart Rate Distress During Labor

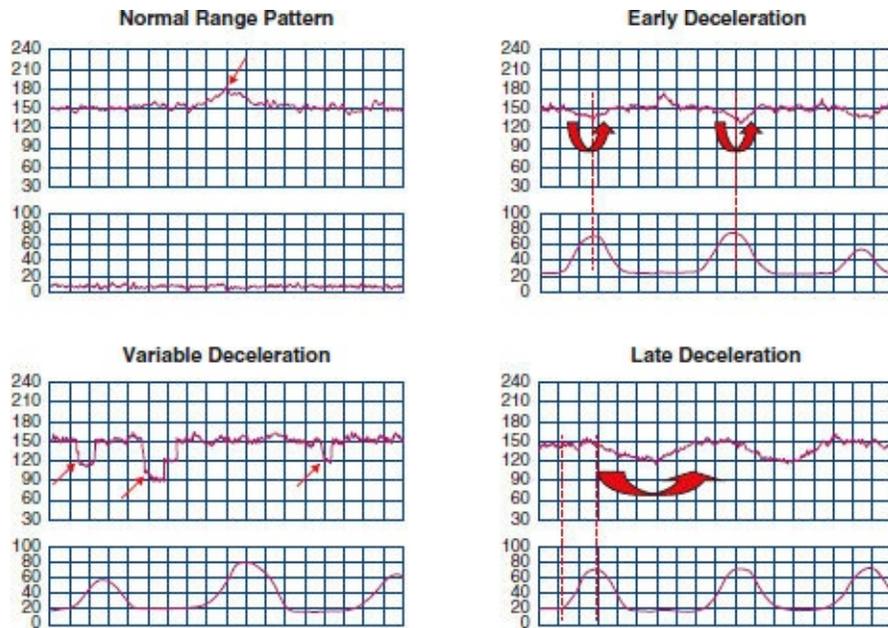
During possible fetal distress that involves lack of variability, late decelerations, and fetal tachycardia, simply changing the woman's position is inadequate. The nurse should notify the healthcare provider immediately regarding the situation.


FIGURE 14.8 Decelerations. **A.** Early. **B.** Variable. **C.** Late.

A **deceleration** is a transient fall in FHR caused by stimulation of the parasympathetic nervous system. Decelerations are described by their shape and association to a uterine contraction. They are classified as early, late, and variable only (Fig. 14.8).

Early decelerations are visually apparent, usually symmetrical, and characterized by a gradual decrease in the FHR in which the nadir (lowest point) occurs at the peak of the contraction. They rarely decrease more than 30 to 40 bpm below the baseline. Typically, the onset, nadir, and recovery of the deceleration occur at the same time as the onset, peak, and recovery of the contraction. They are most often seen during the active stage of any normal labor, during pushing, crowning, or vacuum extraction. They are thought to be a result of fetal head compression that results in a reflex vagal response with a resultant slowing of the FHR during uterine contractions. Early decelerations are not indicative of fetal distress and do not require intervention.

Late decelerations are visually apparent, usually symmetrical, transitory decreases in FHR that occur after the peak of the contraction. The FHR does not return to baseline levels until well after the contraction has ended. Delayed timing of the deceleration occurs, with the nadir of the uterine contraction. Late decelerations are associated with uteroplacental insufficiency, which occurs when blood flow within the intervillous space is decreased to the extent that fetal hypoxia or myocardial depression exists (Martin, Fanaroff, & Walsh, 2014).

Conditions that may decrease uteroplacental perfusion with resultant decelerations include maternal hypotension, gestational hypertension, placental aging secondary to diabetes and postmaturity, hyperstimulation via oxytocin infusion, maternal smoking, anemia, and cardiac disease. They imply some degree of fetal hypoxia. Recurrent or intermittent late decelerations are always category II (indeterminate) or category III (abnormal) regardless of depth of deceleration. Acute episodes with moderate variability are more likely to be correctable, whereas chronic episodes with loss of variability are less likely to be correctable (Sholapurkar, 2015). Box 14.1 highlights interventions for category III decelerations.

Variable decelerations present as visually apparent abrupt decreases in FHR below baseline and have an unpredictable shape on the FHR baseline, possibly demonstrating no consistent relationship to uterine contractions. The shape of variable decelerations may be U, V, or W, or they may not resemble other patterns (Cahill & Spain, 2015). Variable decelerations usually occur abruptly with quick deceleration. They are the most common deceleration pattern found in the laboring woman and are usually transient and correctable (Ugwumadu, 2015). Variable decelerations are associated with cord compression. However, they are classified either as category II or III depending on the accompanying change in baseline variability (ICSI, 2015a). The pattern of variable deceleration consistently related to the contractions with a slow return to FHR baseline warrants further monitoring and evaluation.

INTERVENTIONS FOR CATEGORY III PATTERNS

- Notify the health care provider about the pattern and obtain further orders, making sure to document all interventions and their effects on the FHR pattern.
- Discontinue oxytocin or other uterotonic agent as dictated by the facility's protocol, if it is being administered.
- Turn the client on her left or right lateral, knee-chest, or hands and knees to increase placental perfusion or relieve cord compression.
- Administer oxygen via nonrebreather face mask to increase fetal oxygenation.
- Increase the intravenous fluid rate to improve intravascular volume and correct maternal hypotension.
- Assess the client for any underlying contributing causes.
- Provide reassurance that interventions are to effect pattern change.
- Modify pushing in the second stage of labor to improve fetal oxygenation.
- Document any and all interventions and any changes in FHR patterns.
- Prepare for an expeditious surgical birth if the pattern is not corrected in 30 minutes.

Adapted from American College of Obstetricians and Gynecologists [ACOG]. (2014). Safe prevention of the primary cesarean delivery. Obstetric Care Consensus 1, *Obstetrics & Gynecology*, 123, 693–711; Freeman, R. K. (2015). Intrapartum fetal heart rate monitoring. *Protocols for high-risk pregnancies: An evidence-based approach* (pp. 418–422, 6th ed.). John Wiley & Sons; and Cahill, A. G., & Spain, J. (2015). Intrapartum fetal monitoring. *Clinical Obstetrics and Gynecology*, 58(2), 263–268.

Prolonged decelerations are abrupt FHR declines of at least 15 bpm that last longer than 2 minutes, but less than 10 minutes (NICHD, 2015). The rate usually drops to less than 90 bpm. Many factors are associated with this pattern, including prolonged cord compression, abruptio placenta, cord prolapse, supine maternal position, vaginal examination, fetal blood sampling, maternal seizures,

regional anesthesia, or uterine rupture (ACOG & SMFM 2014). Prolonged decelerations can be remedied by identifying the underlying cause and correcting it.

A *sinusoidal pattern* is described as having a visually apparent smooth, sinewave-like undulating pattern in the FHR baseline with a cycle frequency of 3 to 5 bpm that persists for >20 minutes. It is attributed to a derangement of CNS control of FHR and occurs when a severe degree of hypoxia secondary to fetal anemia and hypovolemia is present. It is always considered a Category III pattern, and to correct it a fetal intrauterine transfusion would be needed (Nageotte, 2015).

Combinations of FHR patterns obtained by EFM during labor are not infrequent. Category II and III patterns are more significant if they are mixed, persist for long periods, or have frequent prolonged late decelerations, absent or minimal variability, bradycardia or tachycardia, and prolonged variable decelerations lower than 60 bpm. The likelihood of fetal compromise is increased if Category II and III patterns are associated with decreased baseline variability or abnormal contraction patterns (ICSI, 2015a).

Other Fetal Assessment Methods

In situations suggesting the possibility of fetal compromise, such as Category II or Category III FHR patterns, further ancillary testing such as umbilical cord blood analysis and fetal scalp stimulation may be used to validate the FHR findings and assist in planning interventions.

Take Note!

In recent years, the use of fetal scalp sampling has decreased, being replaced by techniques that yield similar information. It has been shown to have a poor positive predictive value for intrapartum hypoxia and recent systematic reviews have reported no evidence of benefit in reducing cesarean section rates (Chandraharan, 2014).

Umbilical Cord Blood Analysis

Neonatal and childhood mortality and morbidity, including cerebral palsy, are often attributed to fetal acidosis, as defined by a low cord pH at birth. Umbilical cord blood acid–base analysis drawn at birth provides an objective method of evaluating a newborn's condition, identifying the presence of intrapartum hypoxia and acidemia. This test is considered a good indicator of fetal oxygenation and acid–base condition at birth (Martin, Fanaroff, & Walsh, 2014). The normal mean pH value range is 7.2 to 7.3. The pH values are useful for planning interventions for the newborn born with low 5-minute Apgar scores, severe FGR, Category II and III patterns during labor, umbilical cord prolapse, uterine rupture, maternal fever, placental abruption, meconium-stained amniotic fluid, and post-term births (Gujral & Nayar, 2015). The interventions needed for the compromised newborn might include providing an optimal extrauterine environment, fluids, oxygen, medications, and other treatments.

Fetal Scalp Stimulation

An indirect method used to evaluate fetal oxygenation and acid–base balance to identify fetal hypoxia is fetal scalp stimulation or vibroacoustic stimulation. If the fetus does not have adequate oxygen reserves, carbon dioxide builds up,

leading to acidemia and hypoxemia. These metabolic states are reflected in abnormal FHR patterns as well as fetal inactivity. Fetal stimulation is performed to promote fetal movement with the hope that FHR accelerations will accompany the movement.

Fetal movement can be stimulated with a vibroacoustic stimulator (artificial larynx) applied to the woman's lower abdomen and turned on for 3 to 5 seconds to produce sound and vibration or by placing a gloved finger on the fetal scalp and applying firm pressure. A well-oxygenated fetus will respond when stimulated (tactile or by noise) by moving in conjunction with an acceleration of 15 bpm above the baseline heart rate that lasts at least 15 seconds. This FHR acceleration reflects a pH of more than 7 and a fetus with an intact CNS. Fetal scalp stimulation is not done if the fetus is preterm, or if the woman has an intrauterine infection, a diagnosis of placenta previa (which could lead to hemorrhage), or a fever (which increases the risk of an ascending infection) (King et al., 2015). If no acceleratory response by the fetus is exhibited with either scalp stimulation or vibroacoustic stimulation, further evaluation of the fetus is warranted.

Nurses play an essential role in the evaluation of maternal and fetal status during labor, continued surveillance, initiation of corrective measures when indicated, and reevaluation. A vital attribute of nursing surveillance is that it is a systematic process for assessment, intervention, and evaluation.

PROMOTING COMFORT AND PROVIDING PAIN MANAGEMENT DURING LABOR

Pain during labor is a universal experience, although the intensity of the pain may vary. Labor pain is unique to every woman based on various contributing physiologic, emotional, social, and cultural factors. Although labor and childbirth are viewed as natural processes, both can produce significant pain and discomfort. The physical causes of pain during labor include cervical stretching, hypoxia of the uterine muscle due to a decrease in perfusion during contractions, pressure on the urethra, bladder, and rectum, and distention of the muscles of the pelvic floor (Leonard, 2015).

Pain during labor is a physiological phenomenon. The etiology of pain during the first stage of labor is associated with ischemia of the uterus during contractions. In the second stage, pain is caused by the stretching of the vagina and perineum and compression of the pelvic structures. A woman's pain perception can be influenced by her previous experiences with pain, fatigue, pain anticipation, genetics, positive or negative support system, health care provider's presence and encouragement, labor and birth environment, cultural expectations, and level of emotional stress and anxiety. Pain perception during labor changes in intensity and nature as labor progresses, and this is associated with behavioral changes in the laboring woman (Liu, Fernando, & Mon, 2015).

The techniques used to manage the pain of labor vary according to geography and culture. For example, some Appalachian women believe that placing a hatchet or knife under the bed of a laboring woman may help "cut the pain of childbirth," and a woman from this background may wish to do so in the hospital setting (Bowers, 2015). Asian, Latino, and Orthodox Jewish women may request that their own mothers, not their husbands, attend their births; husbands do not actively participate in the birthing process. Cherokee, Hmong, and Japanese women will often remain quiet during labor and birth and not complain of pain because outwardly expressing pain is not appropriate in their cultures. Never interpret their quietness as freedom from pain. The concept of pain and pain expression during labor has different meanings for women of different cultures. Several points for the nurse to consider when caring for diverse cultural clients include using a qualified interpreter to communicate about pain as needed, offer and support culturally acceptable forms of pain relief, and assess for pain

frequently (Wojnar & Narruhn, 2016).

Immigrating to a new country is a stressful process of readjustment and change. Effective verbal communication and understanding nonverbal social cues are invaluable when providing care to diverse cultures. Culturally diverse childbearing families present to the labor and birth suites with the same needs and desires of all families. Give them the same respect and sense of welcome shown to all families. Make sure they have a high-quality birth experience: uphold their religious, ethnic, and cultural values and integrate them into care.

Today, women have many safe nonpharmacologic and pharmacologic choices for the management of pain during labor and birth, which may be used separately or in combination with one another. Pharmacologic approaches are directed at eliminating the physical sensation of labor pain, whereas nonpharmacologic approaches are largely directed at prevention of suffering.

Nurses are in an ideal position to provide childbearing women with balanced, clear, concise information about effective nonpharmacologic and pharmacologic measures to relieve pain. Pain management standards issued by the Joint Commission mandate that pain be assessed in all clients admitted to a health care facility. Attention to the pain that occurs during labor and childbirth should be a priority of care for all nurses (Jones et al., 2015). A pain assessment tool named the *Coping with Labor Algorithm* uses the FOCUS format "Plan, Do, Check, and Act" cycle in laboring women. This tool provides a mechanism for pain documentation and links it to nursing care interventions (Roberts et al., 2010). Thus, it is important for nurses to be knowledgeable about the most recent scientific research on labor pain relief modalities, to make sure that accurate and unbiased information about effective pain relief measures is available to laboring women, to be sure that the woman determines what is an acceptable labor pain level for her, and to allow the woman the choice of pain relief method.

Nonpharmacologic Measures

Nonpharmacologic measures may include continuous labor support, hydrotherapy, hypnosis, ambulation and maternal position changes, transcutaneous electrical nerve stimulation (TENS), acupuncture and acupressure, attention focusing and imagery, therapeutic touch and massage, breathing techniques, and effleurage. Most of these methods are based on the *gate control theory of pain*, which proposes that local physical stimulation can interfere with pain stimuli by closing a hypothetical gate in the spinal cord, thus blocking pain signals from reaching the brain (McGeary, Swanholm, & Gatchel, 2015). It has long been a standard of care for labor nurses to first provide or encourage a variety of nonpharmacologic measures before moving to the pharmacologic interventions.

Nonpharmacologic measures are usually simple, safe, and inexpensive to use. Many of these measures are taught in childbirth classes, and women should be encouraged to try a variety of methods prior to the real labor. Many of the measures need to be practiced for best results and coordinated with the partner/coach. The nurse provides support and encouragement for the woman and her partner using nonpharmacologic methods. Although women cannot consciously direct the labor contractions, they can control how they respond to them, thereby enhancing their feelings of control. See Evidence-Based Practice 14.2 for more information.

Continuous Labor Support

Continuous labor support involves offering a sustained presence to the laboring woman by providing emotional support, comfort measures, advocacy, information and advice, and support for the partner. It is a non-pharmacologic, evidence-based strategy associated with reduced cesarean rates (Jackson & Gregory, 2015). A woman's family, a midwife, a nurse, a doula, or anyone else close to the woman can provide this continuous presence. A support person can assist the woman to ambulate, reposition herself, and use breathing techniques. A support person can also aid with the use of acupressure, massage, music therapy, or therapeutic touch. During the natural course of childbirth, a laboring woman's functional ability is limited secondary to pain, and she often has trouble making decisions. The support person can help make them based on his or her

knowledge of the woman's birth plan and personal wishes.

Research has validated the value of continuous labor support versus intermittent support in terms of fewer operative deliveries, cesarean births, and requests for pain medication. Continuous labor support has shown to have beneficial effects on the mother and the newborn primarily due to the reduction in anxiety during the laboring experience. Most women expressed greater satisfaction with their childbirth experience (Iravani et al., 2015).

EVIDENCE-BASED PRACTICE 14.2 EFFECTIVENESS OF AROMATHERAPY AND BIOFEEDBACK IN PROMOTION OF LABOR OUTCOME DURING CHILDBIRTH AMONG PRIMIGRAVIDAS

STUDY

Labor pain is described as the most severe form of pain that every woman may experience during their lifetime. When considering labor analgesia, one is faced with a number of choices each with different advantages and disadvantages depending on the woman's expectations and preferences. Many women would like to avoid taking medications or invasive methods for pain management because of the potential negative impact on their fetus during labor. Severe pain triggers a stress response which may lead to harmful effects on both mother and fetus. The purpose of this study was to evaluate the effect of aromatherapy (essential oils from plants are massaged in the skin and inhaled) and biofeedback (mother was asked to experience both the fetal heart sound and variation in contractions and consciously regulate them) in promotion of labor outcome during childbirth.

Findings

Six hundred nulliparous women were selected randomly and assigned to an Aromatherapy group (n = 200), a biofeedback group (n = 200), or a control group (n = 200). The researchers rated pain by using a visual pain analog scale during their labors. Sixty nine percent of cases in the aromatherapy group expressed it was helpful, provided pain relief and emotional well-being during their labors. Biofeedback was also effective in reducing pain and duration of labor during childbirth compared with the control group.

Take Note!

The human presence is of immeasurable value to make the laboring woman feel secure.

Hydrotherapy

Hydrotherapy is a nonpharmacologic measure that may involve showering or soaking in a regular tub or whirlpool bath. When showering is the selected method of hydrotherapy, the woman stands or sits in a shower chair in a warm shower and allows the water to gently glide over her abdomen and back. If a tub or whirlpool is chosen, the woman immerses herself in warm water for relaxation and relief of discomfort. When the woman enters the warm water, the warmth and buoyancy help to release muscle tension and can impart a sense of well-being (Taghavi, Barband, & Khaki, 2015). Warm water provides soothing stimulation of nerves in the skin, promoting vasodilation, reversal of sympathetic nervous response, and a reduction in catecholamines (Dalal, 2015). Contractions are usually less painful in warm water because the warmth and buoyancy of the water have a relaxing effect. Recent research findings reported that women who used hydrotherapy had significantly reduced surgical birth rates, a shorter second stage of labor, reduced analgesic requirements, and a lower incidence of perineal trauma (Taghavi, Barband, & Khaki, 2015). The research concluded that

hydrotherapy during labor significantly aids the labor process, minimizes the use of analgesic medications, offers fast- and short-acting pain and anxiety relief, and should he considered as a safe and effective birthing aid (Taghavi, Barband, & Khaki, 2015).

A wide range of hydrotherapy options are available, from ordinary bathtubs to whirlpool baths and showers, combined with low lighting and music. Many hospitals provide showers and whirlpool baths for laboring women for pain relief. However, hydrotherapy is more commonly practiced in birthing centers managed by midwives. The recommendation for initiating hydrotherapy is that the woman be in active labor (more than 5 cm dilated) to prevent the slowing of labor contractions secondary to muscular relaxation. The woman's membranes can be intact or ruptured. Women are encouraged to stay in the bath or shower as long as they feel they are comfortable. The water temperature should not exceed body temperature.

Hydrotherapy is an effective pain management option for many women. Women who are experiencing a healthy pregnancy can be offered this option. The potential risks associated with hydrotherapy including hyperthermia, hypothermia, changes in maternal heart rate, fetal tachycardia, and unplanned underwater birth. The benefits include reducing pain, relieving anxiety, and promoting a sense of control during labor (Nutter, 2016).

Ambulation and Position Changes

Ambulation and position changes during labor are another extremely useful comfort measure. Historically, women adopted a variety of positions during labor, rarely using the recumbent position until during the first half of the twentieth century. The medical profession has favored recumbent positions during labor, but without evidence to demonstrate their appropriateness. A recent Cochrane database systematic review reported there is evidence that walking and upright positions in the first stage of labor reduce the length of labor and do not seem to be associated with increased intervention or negative effects on mothers' and babies' well-being. In an upright posture, gravity directs the weight of the fetus and amniotic fluid downwards, successively dilating the cervix and the birth canal. Uterine contractions have been shown to be better spaced, stronger and more efficient in dilating the cervix when the mother is in an upright position than when she is supine (Cox & King, 2015). Women should be encouraged to take up whatever position they find most comfortable in the first

stage of labor (Cheng & Caughey, 2015a).

Changing position frequently (every 30 minutes or so)—sitting, walking, kneeling, standing, lying down, getting on hands and knees, and using a birthing ball—helps relieve pain (Fig. 14.9). Position changes also may help to speed labor by adding the benefits of gravity and changing the shape of the pelvis. Research has found that the position that the woman assumes and the frequency of position changes have a profound effect on uterine activity and efficiency. Allowing the woman to obtain a position of comfort frequently facilitates a favorable fetal rotation by altering the alignment of the presenting part with the pelvis. As the mother continues to change position based on comfort, the optimal presentation is afforded (King et al., 2015). Supine positions should be avoided, since they may interfere with labor progress and can cause compression of the vena cava and decrease blood return to the heart.

FIGURE 14.9 Various positions for use during labor. **A.** Ambulation. **B.** Leaning forward. **C.** Sitting in a chair. **D.** Using a birthing ball.

FIGURE 14.10 Nurse massaging the client's back during a contraction while she ambulates during labor.

Swaying from side to side, rocking, or other rhythmic movements may also be comforting. If labor is progressing slowly, ambulating may speed it up again. Upright positions such as walking, kneeling forward, or doing the lunge on the birthing ball give most women a greater sense of control and active movement than just lying down. Table 14.2 highlights some of the more common positions that can be used during labor and birth.

Acupuncture and Acupressure

Acupuncture and acupressure can be used to relieve pain during labor. Although controlled research studies of these methods are limited, there is adequate evidence that both are useful in relieving pain associated with labor and birth. However, both methods require a trained, certified clinician, and such a person is not available in many birth facilities (Halpern & Garg, 2015).

Acupuncture involves stimulating key trigger points with needles. This form of Chinese medicine has been practiced for approximately 3,000 years. Classical Chinese teaching holds that throughout the body there are meridians or channels of energy (*qi*) that when in balance regulate body functions. Pain reflects an

imbalance or obstruction of the flow of energy. The purpose of acupuncture is to restore thus diminishing pain (Adams et al., 2015). Stimulating the trigger points causes the release of endorphins, reducing the perception of pain.

Acupressure involves the application of a firm finger or massage used in acupuncture to reduce the pain sensation. The amount of pressure is important. The intensity of the pressure is determined by the needs of the woman. Holding and squeezing the hand of a woman in labor may trigger the point most commonly used for both techniques. Some acupressure points are found along the spine, neck, shoulder, toes, and soles of the feet. Pressure along the side of the spine can help relieve back pain during labor (Fig. 14.10) (Mollart, Adam, & Foureur, 2015). A Cochrane collaboration review found that acupuncture may indeed reduce labor pain, increasing satisfaction with pain management and reduced use of pharmacologic management. However, there is a need for further research (Simkin & Klein, 2015).

Application of Heat and Cold

Superficial applications of heat and/or cold, in various forms, are popular with laboring women. They are easy to use, inexpensive, require no prior practice, and have minimal negative side effects when used properly. Heat is typically applied to the woman's back, lower abdomen, groin, and/or perineum. Heat sources include a hot water bottle, heated rice-filled sock, warm compress (washcloth soaked in warm water and wrung out), electric heating pad, warm blanket, and warm bath or shower. In addition to being used for pain relief, heat is used to relieve chills or trembling, decrease joint stiffness, reduce muscle spasm, and increase connective tissue extensibility (Liu, Fernando, & Mon, 2015).

Cold therapy, or cryotherapy, is usually applied on the woman's back, chest, and/or face during labor. Forms of cold include a bag or surgical glove filled with ice, a frozen gel pack, camper's "ice," a hollow, plastic rolling pin or bottle filled with ice, a washcloth dipped in cold water, soda cans chilled in ice, and even a frozen bag of vegetables. "Instant" cold packs, often available in hospitals, usually are not cold enough to effectively relieve labor pain. Women who feel cold usually need to feel warm before they can comfortably tolerate using a cold pack. Chilled soda cans and rolling pins filled with ice give the added benefit of mechanical pressure when rolled on the low back. Cold has the additional effects of relieving muscle spasms and reducing inflammation and

edema (Tharpe, Farley, & Jordan, 2016).

TABLE 14.2 Common Positions for use During Labor and Birth

Standing	• Takes advantage of gravity during and between contractions • Makes contractions feel less painful and be more productive • Helps fetus line up with angle of maternal pelvis • Helps to increase urge to push in second stage of labor
Walking	• Has the same advantages as standing • Causes changes in the pelvic joints, helping the fetus move through the birth canal
Standing and leaning forward on partner, bed, birthing ball	• Has the same advantages as standing • Is a good position for a backrub • May feel more restful than standing • Can be used with electronic fetal monitor
Slow dancing (standing with woman's arms around partner's neck, head resting on his chest or shoulder, with his hands rubbing woman's lower back; sway to music and breathe in rhythm if it helps)	• Has the same advantages as walking • Back pressure helps relieve back pain • Rhythm and music help woman relax and provide comfort
The lunge (standing facing a straight chair with one foot on the seat with knee and foot to the side; bending raised knee and hip, and lunging sideways repeatedly during a contraction, holding each lunge for 5 seconds; partner holds chair and helps with balance)	• Widens one side of the pelvis (the side toward lunge) • Encourages rotation of baby • Can also be done in a kneeling position
Sitting upright	• Helps promote rest • Has more gravity advantage than lying down • Can be used with electronic fetal monitor
Semi-sitting (setting the head of the bed at a 45-degree angle with pillows used for support)	• Has the same advantages as sitting upright • Is an easy position if on a bed

Sitting on toilet or commode	• Has the same advantages as sitting upright • May help relax the perineum for effective bearing down
Rocking in a chair	• Has the same advantages as sitting upright • May help speed labor (rocking movement)
Sitting, leaning forward with support	• Has the same advantages as sitting upright • Is a good position for a backrub
On all fours, on hands and knees	• Helps relieve backache • Assists rotation of baby in posterior position • Allows for pelvic rocking and body movement • Relieves pressure on hemorrhoids • Allows for vaginal examinations • Is sometimes preferred as a pushing position by women with back labor
Kneeling, leaning forward with support on a chair seat, the raised head of the bed, or on a birthing ball	• Has the same advantages as all-fours position • Puts less strain on wrists and hands
Side-lying	• Is a very good position for resting and convenient for many kinds of medical interventions • Helps lower elevated blood pressure • May promote progress of labor when alternated with walking • Is useful to slow a very rapid second stage • Avoids vena cava syndrome • May offer increased control of pushing efforts • Takes pressure off hemorrhoids • Facilitates relaxation between contractions

Squatting	• May relieve backache • Takes advantage of gravity • Requires less bearing-down effort • Widens pelvic outlet by approximately 28% • Pressure is evenly distributed to the perineum, reducing the need for episiotomy • May help fetus turn and move down in a difficult birth • Helps if the woman feels no urge to push • Allows freedom to shift weight for comfort • Offers an advantage when pushing, since upper trunk presses on the top of the uterus
Supported squat (leaning back against partner, who supports woman under the arms and takes the entire woman's weight; standing up between contractions)	• Requires great strength in partner • Lengthens trunk, allowing more room for fetus to maneuver into position • Lets gravity help
Dangle (partner sitting high on bed or counter with feet supported on chairs or footrests and thighs spread; woman leaning back between partner's legs, placing flexed arms over partner's thighs; partner gripping sides with his thighs; woman lowering herself and allowing partner to support her full weight; standing up between contractions)	• Has the same advantages of a supported squat • Requires less physical strength from the partner

To date, no randomized controlled studies have evaluated the use of heat and cold, so further study is needed to determine if either approach is efficacious. With appropriate safety precautions, heat and cold offer comfort and relief, and

their use should be dictated by the desires and responses of the laboring woman.

Attention Focusing and Imagery

Attention focusing and imagery use many of the senses and the mind to focus on stimuli. The woman can focus on tactile stimuli such as touch, massage, or stroking. She may focus on auditory stimuli such as music, humming, or verbal encouragement. Visual stimuli might be any object in the room, or the woman can imagine the beach, a mountaintop, a happy memory, or even the contractions of the uterine muscle pulling the cervix open and the fetus pressing downward to open the cervix. Some women focus on a particular mental activity such as a song, a chant, counting backwards, or a Bible verse. Breathing, relaxation, positive thinking, and positive visualization work well for mothers in labor. The use of these techniques keeps the sensory input perceived during the contraction from reaching the pain center in the cortex of the brain (Capogna, 2015a).

Effleurage and Massage

Effleurage is a light, stroking, superficial touch of the abdomen, in rhythm with breathing during contractions. It is used as a relaxation and distraction technique from discomfort. External fetal monitor belts may interfere with the ability to accomplish this.

   Effleurage and massage use the sense of touch to promote relaxation and pain relief. Massage works as a form of pain relief by increasing the production of endorphins in the body. Endorphins reduce the transmission of signals between nerve cells and thus lower the perception of pain. Because touch receptors go to the brain faster than pain receptors, massage—anywhere on the body—can block the pain message to the brain. In addition, light touch has been found to release endorphins and induce a relaxed state. In addition, touching and massage distract the woman from discomfort. Massage involves manipulation of the body's soft tissues. It is commonly used to help relax tense muscles and to soothe and calm the individual. Massage may help to relieve pain by assisting with relaxation, inhibiting sensory transmission in the pain pathways, or improving blood flow and oxygenation of tissues (Neetu & Panchal, 2015).

Breathing Techniques

Conscious use of breath by the woman has the power to profoundly influence

her labor and how she engages with it. The first action anyone takes in any situation is a breath. The breath affects the lungs, immediately cueing the nervous system. The nervous system responds by sending messages, which impact our entire psycho-physiologic system. Messages sent from the nervous system affect us physically, emotionally, and mentally. If we alter how we breathe, we alter the constellation of messages and reactions in our entire mind–body experience (Cheng & Caughey, 2015a).

Breathing techniques are effective in producing relaxation and pain relief through the use of distraction. If the woman is concentrating on slow-paced rhythmic breathing, she is not likely to fully focus on contraction pain. Breathing techniques are often taught in childbirth education classes (see Chapter 12 for additional information).

Controlled breathing helps reduce the pain experienced by using stimulus–response conditioning. The woman selects a focal point within her environment to stare at during the first sign of a contraction. This focus creates a visual stimulus that goes directly to her brain. The woman takes a deep cleansing breath, which is followed by rhythmic breathing. Verbal commands from her partner supply an ongoing auditory stimulus to her brain. Benefits of practicing patterned breathing include: breathing

• becomes an automatic response to pain.

• increases relaxation and can be used for deal with life's everyday stresses.

• is calming during labor.

• provides a sense of well-being and a measure of control.

• brings purpose to each contraction, making them more productive.

• provides more oxygen for the mother and fetus (American Pregnancy Association, 2015).

Many couples learn patterned-paced breathing during their childbirth education classes. Three levels may be taught, each beginning and ending with a cleansing breath or sigh after each contraction. In the first pattern, also known as slow-paced breathing, the woman inhales slowly through her nose and exhales through pursed lips. The breathing rate is typically 6 to 9 bpm. In the second pattern, the woman inhales and exhales through her mouth at a rate of four breaths every 5 seconds. The rate can be accelerated to two breaths per second to assist her to relax. The third pattern is similar to the second pattern except that the breathing is punctuated every few breaths by a forceful exhalation through

pursed lips. All breaths are kept equal and rhythmic and can increase as contractions increase in intensity (Lindholm & Hildingsson, 2015).

Many childbirth educators do not recommend specific breathing techniques or try to teach parents to breathe the "right" way during labor and birth. Couples are encouraged to find breathing styles that enhance their relaxation and use them. There are numerous benefits to controlled and rhythmic breathing in childbirth (outlined previously), and many women choose these techniques to manage their discomfort during labor.

Pharmacologic Measures

With varying degrees of success, generations of women have sought ways to relieve the pain of childbirth. Pharmacologic pain relief during labor includes systemic analgesia and regional or local anesthesia. Women have seen dramatic changes in pharmacologic pain management options over the years. Methods have evolved from biting down on a stick to control their pain, experiencing 'twilight sleep' during their labors and not remembering what happened, to a more complex pharmacologic approach such as epidural/intrathecal analgesia. Systemic analgesia and regional analgesia/anesthesia have become less common, while newer neuraxial analgesia/anesthesia techniques involving minimal motor blockade have become more popular. **Neuraxial analgesia/anesthesia** is the administration of analgesic (opioids) or anesthetic (capable of producing a loss of sensation in an area of the body) agents, either continuously or intermittently, into the epidural or intrathecal space to relieve pain. Low-dose and ultra-low-dose epidural analgesia, spinal analgesia, and combined spinal–epidural analgesia have replaced the traditional epidural for labor. Neuraxial analgesia does not interfere with the progress or outcome of labor. There is no need to withhold neuraxial analgesia until the active stage of labor (Grant et al., 2015). This shift in pain management techniques allows a woman to be an active participant in labor.

 Take Note!

Regardless of which approach is used during labor, the woman has the right to choose the methods of pain control that will best suit her and meet her needs.

Systemic Analgesia

Systemic analgesia involves the use of one or more drugs administered orally, intramuscularly, or intravenously; they become distributed throughout the body via the circulatory system. Depending on which administration method is used, the therapeutic effect of pain relief can occur within minutes and last for several hours. The most important complication associated with the use of this class of drugs is respiratory depression. Therefore, women given these drugs require

careful monitoring. Opioids given close to the time of birth can cause CNS depression in the newborn, necessitating the administration of naloxone (Narcan) to reverse the depressant effects of the opioids.

Several drug categories may be used for systemic analgesia:

- *Opioids*, such as butorphanol (Stadol), nalbuphine (Nubain), meperidine (Demerol), morphine, or fentanyl (Sublimaze)

- *Ataractics*, such as hydroxyzine (Vistaril), promethazine (Phenergan), or prochlorperazine (Compazine)

- *Benzodiazepines*, such as diazepam (Valium) or midazolam (Versed)

Drug Guide 14.1 highlights some of the major drugs used for systemic analgesia.

Systemic analgesics are typically administered parenterally, usually through an existing intravenous line. Nearly all medications given during labor cross the placenta and have a depressant effect on the fetus; therefore, it is important for the woman to receive the least amount of systemic medication that relieves her discomfort so that it does not cause any harm to the fetus (Cheng & Caughey, 2015a). Historically opioids have been administered by nurses, but in the past decade there has been increasing use of client-controlled intravenous analgesia (patient-controlled analgesia). With this system, the woman is given a button connected to a computerized pump on the intravenous line. When the woman desires analgesia, she presses the button and the pump delivers a preset amount of medication. This system provides the woman with a sense of control over her own pain management and active participation in the childbirth process.

DRUG GUIDE 14.1 Common Agents Used for Systemic Analgesia

Type	Drug	Comments
Opioids	Morphine 2–5 mg IV	May be given IV or epidurally Rapidly crosses the placenta, causes a decrease in FHR variability Can cause maternal and neonatal CNS depression Decreases uterine contractions
	Meperidine (Demerol) 25–75 mg IV	May be given IV, intrathecally, or epidurally with maximal fetal uptake 2–3 hr after administration Can cause CNS depression Decreases fetal variability
	Butorphanol (Stadol) 1–2 mg IV	Is given IV
	Q 2–4 hr	Is rapidly transferred across the placenta Causes neonatal respiratory depression
	Nalbuphine (Nubain) 10–20 mg IV	Is given IV Causes less maternal nausea and vomiting Causes decreased FHR variability, fetal bradycardia, and respiratory depression
	Fentanyl (Sublimaze) 50–100 mcg IV	Is given IV or epidurally Can cause maternal hypotension, maternal and fetal respiratory depression Rapidly crosses placenta
Antiemetics	Hydroxyzine (Vistaril) 50–100 mg IM	Does not relieve pain but reduces anxiety and potentiates opioid analgesic effects; cannot be given IV Is used to decrease nausea and vomiting
	Promethazine (Phenergan) 25–50 mg IV or IM	Is used for antiemetic effect when combined with opioids Causes sedation and reduces apprehension May contribute to maternal hypotension and neonatal depression
	Prochlorperazine (Compazine) 5–10 mg IV or IM	Frequently given with morphine sulfate for sleep during prolonged latent phase; counteracts the nausea that opioids can produce
Benzodiazepines	Diazepam (Valium) 2–5 mg IV	Is given to enhance pain relief of opioid and cause sedation May be used to stop eclamptic seizures Decreases nausea and vomiting Can cause newborn depression; therefore, lowest possible dose should be used
	Midazolam (Versed) 1–5 mg IV	Is not used for analgesic but amnesia effect Is used as adjunct for anesthesia Is excreted in breast milk

IV, intravenous.

OPIOIDS

Opioids are morphine-like medications that are most effective for the relief of moderate to severe pain. Opioids typically are administered intravenously. All opioids are lipophilic and cross the placental barrier, but do not affect labor progress in the active phase. Opioids are associated with newborn respiratory depression, decreased alertness, inhibited sucking, and a delay in effective feeding (King et al., 2015).

Opioids decrease the transmission of pain impulses by binding to receptor site pathways that transmit the pain signals to the brain. The effect is increased tolerance to pain and respiratory depression related to a decrease in sensitivity to

carbon dioxide (Skidmore-Roth, 2015). All opioids are considered good analgesics. However, respiratory depression can occur in the mother and fetus depending on the dose given. They may also cause a decrease in FHR variability identified on the fetal monitor strip. This FHR pattern change is usually transient. Other systemic side effects include nausea, vomiting, pruritus, delayed gastric emptying, drowsiness, hypoventilation, and newborn depression. To reduce the incidence of newborn depression, birth should occur within 1 hour or after 4 hours of administration to prevent the fetus from receiving the peak concentration (Cheng & Caughey, 2015a).

A recent study reported that parenteral opioids provide some relief from pain in labor, but are associated with neonatal respiratory distress. Maternal satisfaction with opioid analgesia appeared moderate at best (Kerr, Taylor, & Evans, 2015).

Opioid antagonists such as naloxone (Narcan) are given to reverse the effects of the CNS depression, including respiratory depression, caused by opioids. Opioid antagonists also are used to reverse the side effects of neuraxial opioids, such as pruritus, urinary retention, nausea, and vomiting, without significantly decreasing analgesia (Skidmore-Roth, 2015). Consult a current drug guide for more specifics on these drug categories.

ANTIEMETICS

The antiemetic group of medications is used in combination with an opioid to decrease nausea and vomiting and lessen anxiety. These adjunct drugs potentiate the effectiveness of the opioid so that a lesser dose can be given. They may also be used to increase sedation. Promethazine (Phenergan) can be given intravenously, but hydroxyzine (Vistaril) must be given by mouth or by intramuscular injection into a large muscle mass. Neither drug affects the progress of labor, but either may cause a decrease in FHR variability and possible newborn depression (Skidmore-Roth, 2015). Prochlorperazine (Compazine) is typically given intravenously or intramuscularly with morphine sulfate for sleep during a prolonged latent phase. It counteracts the nausea associated with opioids (King et al., 2015).

BENZODIAZEPINES

Benzodiazepines are used for minor tranquilizing and sedative effects. Diazepam (Valium) also is given intravenously to stop seizures resulting from eclampsia. It can be administered to calm a woman who is out of control, thereby enabling her

to relax enough so that she can participate effectively during her labor process rather than fighting against it. Lorazepam (Ativan) can also be used for its tranquilizing effect, but increased sedation is experienced with this medication (Skidmore-Roth, 2015). Midazolam (Versed), also given intravenously, produces good amnesia but no analgesia. It is most commonly used as an adjunct for anesthesia. Diazepam and midazolam cause CNS depression for both the woman and the newborn.

Inhaled Analgesics

Nitrous oxide is known by most people as "laughing gas." For labor pain, half nitrous oxide gas (50%) is mixed with half oxygen (50%) and breathed through a mask or mouthpiece. This has been recently introduced in the United States, but has been in widespread use in Europe and Canada for many years. Women have generally reported satisfaction with the use of nitrous oxide for pain relief in labor. An additional factor that may contribute to the decreased perception of pain is maternal control—it is self-administered. Self-administration is not only empowering for women, but it also acts as a safety mechanism because it is almost impossible to overdose when it is self-administered (Halpern & Garg, 2015). Potential side effects of N_2O/O_2 include nausea and vomiting, dizziness, and dysphoria, although these are rare. No FHR abnormalities have been attributed to its use (Badve & Vallejo, 2015).

Regional Analgesia/Anesthesia

Regional analgesia/anesthesia provides pain relief without loss of consciousness. It involves the use of local anesthetic agents, with or without added opioids, to bring about pain relief or numbness through the drug's effects on the spinal cord and nerve roots. Obstetric regional analgesia generally refers to a partial or complete loss of pain sensation below the T8 to T10 level of the spinal cord (Stocks & Griffiths, 2015).

The routes for regional pain relief include epidural block, combined spinal–epidural, local infiltration, pudendal block, and intrathecal (spinal) analgesia/anesthesia. Local and pudendal routes are used during birth for episiotomies (surgical incision into the perineum to facilitate birth); epidural and intrathecal routes are used for pain relief during active labor and birth. The major advantage of regional pain management techniques is that the woman can participate in the birthing process and still have good pain control.

EPIDURAL ANALGESIA
