Adapted from Feigelman, S. (2011a). Preschool years. In R. M. Kliegman, Stanton, B. F., St. Geme, J. W., Schor, N. F. & R. E. Behrman, H. B. Jenson, & B. Stanton (Eds.), *Nelson textbook of pediatrics* (19th ed.). Philadelphia, PA: Saunders; Feigelman, S. (2011b). The second year. In R. M. Kliegman, Stanton, B. F., St. Geme, J. W., Schor, N. F. & R. E. Behrman, H. B. Jenson, & B. Stanton (Eds.), *Nelson textbook of pediatrics* (19th ed.). Philadelphia, PA: Saunders.

and agility, but even more is needed for buttoning and zipping. Adequate vision is necessary for the refinement of fine motor skills because eye–hand coordination is crucial for directing the fingers, hand, and wrist to accomplish small muscle tasks such as fitting a puzzle piece or stringing a bead. See Table 26.2 for age expectations for various motor skills.

### Sensory Development

Toddlers use all of their senses to explore the world around them. Toddlers examine new items by feeling them, looking at them, shaking them to hear what sound they make, smelling them, and placing them in their mouths. Toddler vision continues to progress and should be 20/50 to 20/40 in both eyes. Depth perception also continues to mature. Hearing should be at the adult level, as infants are ordinarily born with hearing intact. The sense of smell continues to mature, and toddlers may comment if they do not care for the scent of something. Though taste discrimination is not completely developed, toddlers may exhibit preferences for certain flavors of foods. The toddler is more likely to try a new food if its appearance or smell is familiar. Lack of complete taste discrimination places the toddler at risk of accidental ingestion.

### Communication and Language Development

Language development occurs rapidly during the toddler years. The acquisition of language is a dynamic and complex process. The child's age and social interactions and the types of language to which he or she has been exposed influence language development. **Receptive language** development (the ability to understand what is being said or asked) is typically far more advanced than **expressive language** development (the ability to communicate one's desires and feelings) (Feigelman, 2011b; Goldson & Reynolds, 2011). In other words, the toddler understands language and is able to follow commands far sooner than he or she can actually use the words himself or herself. Language is a very important part of the toddler's ability to organize his or her world and actually make sense of it. Thoughtfully planned use of language can provide behavior guidance and contribute to the avoidance of power struggles. In regard to expressive language development, the young toddler begins to use short sentences and will progress to a vocabulary of 50 words by 2 years of age (Feigelman, 2011b; Goldson & Reynolds, 2011). **Echolalia** (repetition of words and phrases without understanding)

TABLE 26.3 LANGUAGE DEVELOPMENT IN TODDLERS

Age	Receptive Language	Expressive Language
<b>12 months</b>	Understands common words independent of context Follows a one-step command accompanied by gesture	Uses a finger to point to things Imitates or uses gestures such as waving goodbye Communicates desires with word and gesture combinations Vocal imitation First word
<b>15 months</b>	Looks at adult when communicating Follows a one-step command without gesture Understands 100–150 words	Repeats words that he or she hears Babbles in what sound like sentences
<b>18 months</b>	Understands the word “no” Comprehends 200 words Sometimes answers the question, “What’s this?”	Uses at least 5–20 words Uses names of familiar object
<b>24 months</b>	Points to named body parts Points to pictures in books Enjoys listening to simple stories Names a variety of objects in the environment Begins to use “my” or “mine”	Vocabulary of 40–50 words Sentences of two or three words (“me up,” “want cookie”) Asks questions (“what that?”) Uses simple phrases Uses descriptive words (hungry, hot) Two thirds of what child says should be understandable Repeats overheard words
<b>30 months</b>	Follows a series of two independent commands	Vocabulary of 150–300 words
<b>36 months</b>	Understands most sentences Understands physical relationships (on, in, under) Participates in short conversations May follow a three-part command	Speech usually understood by those who know the child, about half understood by those outside family Asks “why?” Three- to four-word sentences Talks about something that happened in the past Vocabulary of 1,000 words Can say name, age, and gender Uses pronouns and plurals

Adapted from Feigelman, S. (2011a). Preschool years. In R. M. Kliegman, Stanton, B. F., St. Geme, J. W., Schor, N. F. & R. E. Behrman, H. B. Jenson, & B. Stanton (Eds.), *Nelson textbook of pediatrics* (19th ed.). Philadelphia, PA: Saunders; Feigelman, S. (2011b). The second year. In R. M. Kliegman, Stanton, B. F., St. Geme, J. W., Schor, N. F. & R. E. Behrman, H. B. Jenson, & B. Stanton (Eds.), *Nelson textbook of pediatrics* (19th ed.). Philadelphia, PA: Saunders; and Goldson, E., & Reynolds, A. (2011). Child development and behavior. In W. W. Hay, M. J. Levin, J. M. Sondheimer, & R. R. Deterding (Eds.), *Current pediatric diagnosis and treatment* (20th ed.). New York: McGraw-Hill.

normally occurs in toddlers younger than 30 months of age. “Why” and “what” questions dominate the older toddler’s language. Telegraphic speech is common in the 3-year-old. **Telegraphic speech** refers to speech that contains only the essential words to get the point across, much like a telegram. Rather than “I want a cookie and milk,” the toddler might say, “Want cookie milk.” In telegraphic speech the nouns and verbs are present and are verbalized in the appropriate order (Feigelman, 2011b). Table 26.3 gives an overview of receptive and expressive language development in the toddler.

### Take Note!

Stuttering usually has its onset between 2 and 4 years of age. It occurs more often in boys than in girls. About 75% of all cases of stuttering resolve within 1 to 2 years after they start (Prasse & Kikano, 2008).

Early identification and referral of children with potential speech delays is critical. If a delay is identified, early intervention may increase the child’s potential to acquire age-appropriate receptive and expressive language skills.

**Take Note!**

Children with preexisting conditions such as genetic syndromes that are known to have an effect on language development should be referred to a speech-language pathologist as soon as the condition is recognized rather than waiting until the child exhibits a delay.

Of special concern in the toddler years is the development of speech and language in potentially bilingual children. At the age of 1 to 2 years, the potentially bilingual child may blend two languages—that is, parts of the word in both languages are blended into one word. At age 2 to 3 years, the potentially bilingual toddler may mix languages within a sentence. Thus, the assessment of adequate language development is more complicated in bilingual children. There are websites that may be helpful to parents of potentially bilingual children, where they can find support and resources. A list of websites is included on [thePoint](http://thePoint.lww.com/ricci-kyle2e) at <http://thePoint.lww.com/ricci-kyle2e>.

**Take Note!**

Bilingual children often mix languages, and thus speech delay may be more difficult to assess in this population. The bilingual child should have command of 20 words (between both languages) by 20 months of age and should be making word combinations. If this is not the case, further investigation may be warranted (De Houwer, 2009).

## Emotional and Social Development

Emotional development in the toddler years is focused on **separation** and **individuation** (Papalia & Feldman, 2011). Seeing oneself as separate from the parent or primary caregiver is accompanied by forming a sense of self and learning to exert control over one's environment. As this need to feel in control of his or her world emerges, the toddler displays **egocentrism** (focus on self). This need for control results in emotional lability: very happy and pleasant one moment, then overreacting to limit setting with a temper tantrum in the next moment (Brazelton & Sparrow, 2006). As toddlers identify the boundaries between themselves and the parent or primary caregiver, they learn to negotiate a balance between attachment and independence. Toddlers initially rely on the parents' communication and signals in order to initiate appropriate behavior or inhibit undesirable behavior. They have a difficult time choosing between sets of behaviors as they occur in different situations. Power struggles often occur in this age group, and it is important for parents and caregivers to thoughtfully and intentionally develop the rituals and routines that will provide stability and security for the toddler (Feigelman, 2011b). Many toddlers rely on a security

**FIGURE 26.5** The toddler may be able to self-soothe and produce a sense of comfort during this stage of establishing autonomy by relying upon a security item such as a doll, bear, or blanket.

item (blanket, doll, or bear) to comfort themselves in stressful situations (Fig. 26.5). This ability to self-soothe is a function of autonomy and is viewed as a sign of a nurturing environment, rather than, as one might suspect, one of neglect.

Children also begin to learn about gender differences in the toddler years. They observe the differences between male and female body parts if they are exposed to them. Toddlers may question parents about these differences and may begin to explore their own genitals. Toddlers also begin to understand and mimic social gender differences. They make observations about gender-specific behavior dependent upon what they are exposed to.

Aggressive behaviors are typically displayed during the toddler years. Toddlers may hit, bite, or push other children and grab toys. Adults can assist the toddler in building empathy by pointing out when someone is hurt and explaining what happened. Toddlers should not be blamed for their impulsive behavior; rather, they should be guided toward socially acceptable actions in order to foster development of appropriate social judgment. It is particularly important for the parent or caregiver to serve as a role model for appropriate behavior, rather than losing his or her own temper, in order for the toddler to be able to learn how to acceptably handle frustrations. Offering limited choices is one way of allowing toddlers some control over their environment and helping them to establish a sense of mastery. Since toddlers naturally have a short attention span, they tend to dawdle. As the toddlers become more self-aware, they start to develop

emotions of self-consciousness such as embarrassment and shame.

Though toddlers are becoming more self-aware, they still do not have clear body boundaries. They do not clearly understand the body's functions, though they are beginning to make appropriate connections. Feces may be viewed as a part of the child, and the toddler may become upset at seeing it disappear in the toilet. The toddler will protect his or her body by resisting intrusive procedures such as temperature or blood pressure measurement (Hagan et al., 2008).

## Separation Anxiety

As toddlers become increasingly skilled at mobility, they realize that if they have the capability of leaving, then so does the parent. As self-awareness develops and conflicts over closeness versus exploration occur, **separation anxiety** may reemerge in the 18- to 24-month period (Brazelton & Sparrow, 2006). Power struggles may escalate and distress at separating from the parent may increase. Again, a predictable routine with appropriate limit setting may help toddlers to feel safer and more secure during this period. From the age of 24 to 36 months, separation anxiety again eases. The older toddler begins to have a concept of object constancy: he or she has an internal representation of the parent or caregiver and is better able to tolerate separation, knowing that a reunion will occur.

## Temperament

Temperament is the biological basis for personality. It is our emotional and motivational core, around which the personality develops over time (Allard & Hunter, 2010). Temperament affects how the toddler interacts with the environment. The easygoing toddler may adapt more easily and not mind changes in routine as much as other toddlers. The easygoing toddler usually sleeps and eats well and has more predictable and regular behaviors. However, the toddler may still express frustration by having a temper tantrum. The "difficult" toddler is more likely to have intense reactions, negative or positive, with temper tantrums being more likely, more frequent, and more intense than in other toddlers. The structure and routine that toddlers need to feel secure are essential for the difficult toddler; otherwise, the child feels insecure and as a result is more likely to behave inappropriately. The difficult toddler is also the most active of the three temperament types. The slow-to-warm-up toddler is more of a loner and may be very shy. He or she may experience more difficulty with separation anxiety. The behavior of the slow-to-warm-up toddler is more passive; the toddler may be very watchful and withdrawn and may take longer to mature. Changes in routine usually do not result in as much upset, since the

toddler's natural reaction is one of passivity (Feigelman, 2011b).

Based on the toddler's temperament, make suggestions to the parents for interacting with the toddler in various situations. For example, to avoid temper tantrums in the difficult toddler, suggest that the parent should be especially diligent about maintaining structure and routine as well as avoiding tantrum triggers such as fatigue and hunger. Explain to parents that they may need to exercise additional patience with new activities to which the slow-to-warm-up toddler may need extra time becoming accustomed.

## Fears

Common fears of toddlers include loss of parents (which contributes to separation anxiety) and fear of strangers. Some toddlers may be very slow to warm up to people they do not know. The nurse caring for a toddler in the outpatient or hospital setting should take the time to establish a relationship with the toddler in order to allay the toddler's fears. Toddlers may be afraid of loud noises and large or unfamiliar animals. Going to sleep may be a scary time for toddlers as they may be afraid of the dark. A nightlight in the toddler's room may be very helpful.

## Moral and Spiritual Development

During the toddler years, children may feel comfort from the routine of praying, but they do not understand religious beliefs because of their limited cognitive abilities. Reading simple Bible stories can lay a foundation for later religious teachings. Kohlberg's (1984) description of moral development places the older toddler in the pre-conventional level. The toddler is only just beginning to learn right from wrong and does not understand the larger concept of morality. The toddler will base his or her actions on the avoidance of punishment and the attainment of pleasure. Older toddlers begin to feel empathy for others.

## Cultural Influences on Growth and Development

Homelessness or poverty may directly influence the toddler's ability to grow adequately, as resources for the purchase and preparation of appropriate food may be lacking. Appropriate toys (safe ones) may also not be available in those situations. Food customs continue to have an impact on the child's diet and ability to ingest appropriate nutrients. Individual families' value systems have an impact on the toddler's development as well. Some parents desire to keep their child a "baby" for a longer period, thus delaying weaning or continuing to feed the child baby food or puréed food for a longer

period. Other families may highly value independence and encourage the toddler to walk everywhere on his or her own rather than carrying the child.

Culture may also affect emotional development. Some families start at a very young age to discourage crying in boys, encouraging them to “act like a big boy” or “be a man.” Ridicule for crying at this age may hurt the toddler’s self-concept. Educating families about normal growth and development while continuing to value and support cultural practices is important (Papalia & Feldman, 2011).

*Remember Jose Gonzales, whom you met at the beginning of the chapter? What developmental milestones would you expect him to have reached at his age?*

## THE NURSE’S ROLE IN TODDLER GROWTH AND DEVELOPMENT

The toddler’s growth and development affects his or her everyday life as well as the family’s. Though some toddlers may grow more quickly or reach developmental milestones sooner than others, growth and development remains orderly and sequential. Health care visits throughout toddlerhood continue to focus on growth and development. The nurse must have a good understanding of the changes that occur during the toddler years in order to provide appropriate anticipatory guidance and support to the family.

**FIGURE 26.6** The hospitalized toddler continues to enjoy developmental tasks appropriate for his or her age, such as playing with manipulative toys.

When the toddler is hospitalized, growth and development may be altered. The toddler’s primary task is establishing autonomy, and the toddler’s focus is mobility and language development. Hospitalization removes most opportunities for the toddler to learn through exploration of the environment. Isolation for contagious illness further constrains the toddler’s ability to find some control over the environment. The nurse caring for the hospitalized toddler must use knowledge of normal growth and development to be successful in interactions with the toddler, promote continued development, and recognize delays (see Chapter 33) (Fig. 26.6).

## NURSING PROCESS OVERVIEW

Upon completion of assessment of the toddler’s current growth and development status, problems or issues related to growth and development may be identified. The nurse may then identify one or more nursing diagnoses, including but not limited to:

- Delayed growth and development
- Imbalanced nutrition, less than body requirements
- Interrupted family processes
- Readiness for enhanced parenting
- Risk for caregiver role strain
- Risk for delayed development
- Risk for disproportionate growth
- Risk for injury

Nursing care planning for the toddler with growth and development issues should be individualized based on the toddler’s and family’s needs. The nursing care plan may be used as a guide in planning nursing care for the toddler with a growth or developmental concern. The nurse may choose the appropriate nursing diagnoses from the Nursing Care Plan (p. 932) and individualize them as needed. The nursing care plan is intended to serve as a guide only and is not intended to be an inclusive growth and development plan.

## Promoting Healthy Growth and Development

Parents who give their toddler love and respect regardless of the child’s gender, behavior, or capabilities are helping to lay the foundation for self-esteem. Self-esteem is also built through familiarity with the daily routine. Routine and ritual help toddlers develop a conscience. Making expectations known through everyday routines helps to avoid confrontations. If the toddler knows the routine, he or she knows what to expect and how he or she is expected to act. When routine and limits are absent, the toddler develops feelings of uncertainty and anxiety.

## NURSING CARE PLAN 26.1

## Growth and Development Issues in the Toddler

**NURSING DIAGNOSIS:** Risk for injury related to curiosity, increased mobility, and developmental immaturity

### Outcome Identification and Evaluation

Toddler safety will be maintained: *Toddler will remain free from injury.*

#### Interventions: Preventing Injury

- Teach and encourage appropriate use of rear-facing car seat until 2 years of age and forward-facing car seat after 2 years of age *to decrease risk of toddler injury related to motor vehicles.*
- Teach toddlers to stay away from the street and provide constant supervision *to prevent pedestrian injury.*
- Require bicycle helmet use while riding any wheeled toy *to prevent head injury and form habit of helmet use.*
- Childproof the home *to provide a developmentally safe environment for the curious and increasingly mobile toddler.*
- Post poison control center phone number *in case of accidental ingestion.*
- Never leave a toddler unattended in a tub or pool or near any body of water *to prevent drowning.*
- Teach parents first-aid measures and child CPR *to minimize consequences of injury should it occur.*
- Provide close observation and keep side rails up on crib/bed in hospital *because toddlers are at particularly high risk for falling or becoming entangled in tubing as they attempt mobility.*

**NURSING DIAGNOSIS:** Imbalanced nutrition, less than body requirements, related to inappropriate nutritional intake to sustain growth needs (excess juice or milk intake, inadequate food variety intake) as evidenced by failure to attain adequate increases in height and weight over time

### Outcome Identification and Evaluation

Toddler will consume adequate nutrients while using an appropriate feeding pattern: *Toddler will demonstrate weight gain and increases in height.*

#### Interventions: Promoting Appropriate Nutrition

- Assess current feeding schedule and usual intake, as well as methods used to feed, *to determine areas of adequacy versus inadequacy.*
- Determine toddler's ability to drink from cup, finger feed, swallow, and consume textures *to determine if additional exposure is needed or if further interventions such as speech or occupational therapy are required.*
- Weigh toddler daily on same scale if hospitalized, weekly on same scale if at home, and plot growth patterns weekly or monthly as appropriate on standardized growth charts *to determine if growth is improving.*
- Wean from bottle by 15 months of age *to discourage excess milk or juice intake in toddler who can carry bottle around.*
- Limit juice to 4 to 6 ounces per day and milk to 16 to 24 ounces per day *to discourage sense of fullness achieved with excess milk or juice intake, thereby increasing appetite for solid foods.*
- Provide three nutrient-dense meals and at least two healthy snacks per day *to encourage adequate nutrient consumption.*
- Feed toddler on a similar schedule daily, without distractions and with the family: *toddlers respond well to routine and structure and may eat better in the social context of meals, and they become distracted easily (TV should be off).*

## NURSING CARE PLAN 26.1

**Growth and Development Issues in the Toddler** (continued)

**NURSING DIAGNOSIS:** Delayed growth and development related to motor, cognitive, language, or psychosocial concerns as evidenced by delay in meeting expected milestones

**Outcome Identification and Evaluation**

Development will be enhanced: *Toddler will make continued progress toward realization of expected developmental milestones.*

**Interventions: Enhancing Growth and Development**

- Screen for developmental capabilities to *determine toddler's current level of functioning.*
- Offer age-appropriate toys, play, and activities (including gross motor) to *encourage further development.*
- Perform interventions as prescribed by physical, occupational, or speech therapist: *participation in those activities helps to promote function and accomplish acquisition of developmental skills.*
- Provide support to families of toddlers with developmental delay (*progress in achieving developmental milestones can be slow and ongoing motivation is needed*).
- Reinforce positive attributes in the toddler to *maintain motivation.*
- Model age-appropriate communication skills to *illustrate suitable means for parenting the toddler.*

**NURSING DIAGNOSIS:** Risk for disproportionate growth related to excess milk or juice intake, late bottle weaning, and consumption of inappropriate foods or in excess amounts

**Outcome Identification and Evaluation**

Toddler will grow appropriately and not become overweight or obese: *Toddler will achieve weight and height within the 5th to 95th percentiles on standardized growth charts.*

**Interventions: Promoting Proportionate Growth**

- Wean from bottle and discourage use of no-spill sippy cups by 15 months of age (*will keep mobile toddler from carrying around and continually drinking from cup or bottle*).
- Provide juice (4–6 ounces per day) and milk (16–24 ounces per day) from a cup at meal and snack time to *encourage appropriate cup drinking and limit intake of nutrient-poor, high-calorie fluids.*
- Provide only nutrient-rich foods without high sugar content for meals and snacks; *even if the toddler won't eat, it is inappropriate to provide high-calorie junk food just so the toddler eats something.*
- Ensure adequate physical activity to *stimulate development of motor skills and provide appropriate caloric expenditure. This also sets the stage for forming life-long habit of appropriate physical activity.*

(continued)

## NURSING CARE PLAN 26.1

**Growth and Development Issues in the Toddler** (continued)

**NURSING DIAGNOSIS:** Interrupted family processes related to issues with toddler development, hospitalization, or situational crisis as evidenced by decreased parental visitation in hospital, parental verbalization of difficulty with current situation, possible crisis related to health of family member other than the toddler

**Outcome Identification and Evaluation**

Family will demonstrate adequate functioning: *Family will display coping and psychosocial adjustment.*

**Interventions: Enhancing Family Functioning**

- Assess the family's level of stress and ability to cope *to determine family's ability to cope with multiple stressors.*
- Engage in family-centered care *to provide a holistic approach to care of the toddler and family.*
- Encourage the family to verbalize feelings (*verbalization is one method of decreasing anxiety levels*), and acknowledge feelings and emotions.
- Encourage family visitation and provide for sleeping arrangements for a parent or caregiver to stay in the hospital with the toddler (*contributes to family's sense of control of situation*).
- Involve family members in toddler's care, *giving them a feeling of control and connectedness.*

**NURSING DIAGNOSIS:** Readiness for enhanced parenting related to parental desire for increased skills and success with toddler as evidenced by current healthy relationships and verbalization of desire for improved skills

**Outcome Identification and Evaluation**

Parent will provide safe and nurturing environment for the toddler.

**Interventions: Increasing Parenting Skill Set**

- Use family-centered care *to provide holistic approach.*
- Educate parent about normal toddler development *to provide basis for understanding the parenting skills needed in this time period.*
- Acknowledge and encourage parent's verbalization of feelings related to chronic illness of child or difficulty with normal toddler behavior *to validate the normalcy of the parent's feelings.*
- Encourage positive parenting with respect to toddlers and their normal development (*helps parents develop approaches to toddlers that can be used in place of anger and frustration*).
- Acknowledge and admire positive parenting skills already present *to contribute to parents' confidence in their abilities to parent.*
- Role model appropriate parenting behaviors related to communicating with and disciplining the toddler (*role modeling actually shows rather than just telling the parent what to do*).

**TABLE 26.4** SIGNS OF DEVELOPMENTAL DELAY

Age or Time Frame	Concern
After independent walking for several months	<ul style="list-style-type: none"> <li>• Persistent tiptoe walking</li> <li>• Failure to develop a mature walking pattern</li> </ul>
By 18 months	<ul style="list-style-type: none"> <li>• Not walking</li> <li>• Not speaking 15 words</li> <li>• Does not understand function of common household items</li> </ul>
By 2 years	<ul style="list-style-type: none"> <li>• Does not use two-word sentences</li> <li>• Does not imitate actions</li> <li>• Does not follow basic instructions</li> <li>• Cannot push a toy with wheels</li> </ul>
By 3 years	<ul style="list-style-type: none"> <li>• Difficulty with stairs</li> <li>• Frequent falling</li> <li>• Cannot build tower of more than four blocks</li> <li>• Difficulty manipulating small objects</li> <li>• Extreme difficulty in separation from parent or caregiver</li> <li>• Cannot copy a circle</li> <li>• Does not engage in make-believe play</li> <li>• Cannot communicate in short phrases</li> <li>• Does not understand simple instructions</li> <li>• Little interest in other children</li> <li>• Unclear speech, persistent drooling</li> </ul>

Limit setting (and remaining consistent with those limits) helps toddlers master their behavior, develop self-esteem, and become successful participants in the family. Children then are able to learn about cooperation throughout the predictable flow of daily life. Nurses need to be aware of normal developmental expectations in order to determine whether the toddler is progressing appropriately. Table 26.4 lists potential signs of developmental delay. Any toddler with one or more of these concerns should be referred for further developmental evaluation.

## Promoting Growth and Development Through Play

Play is the major socializing medium for toddlers. Parents should limit television viewing and encourage creative and physical play instead. Toddlers typically play alongside another child (**parallel play**) rather than cooperatively (Fig. 26.7). The short attention span of the toddler will make him or her often change toys and types of play. It is important to provide a variety of safe toys to allow the toddler many different opportunities for exploring the environment. Toddlers do not need expensive toys; in fact, regular household items sometimes make the most enjoyable toys. Toddlers are egocentric, a normal part of their development (Piaget, 1969). This makes it difficult for them to share. As they are developing

a sense of self (who they are as a person), they may see their toys as an extension of themselves. Learning to share occurs in later toddlerhood. Toddlers also like dramatic play and play that recreates familiar activities in the home. Toddlers like to listen to music of all kinds and will often dance to whatever they hear on the radio. Toddlers enjoy drums, xylophones, cymbals, and toy pianos. Musical instruments made at home are also enjoyed.

**FIGURE 26.7** Parallel play. The toddler usually plays alongside another child rather than cooperatively.

**FIGURE 26.8** Toddlers love outdoor physical play, such as climbing on playground equipment. An adult should always supervise toddlers when they are playing outdoors.

A few pebbles or coins inside an empty water bottle with the top tightly secured is a great music maker; an empty butter tub with a lid and a pair of wooden spoons makes a nice drum.

Adequate physical activity is necessary for the development and refinement of movement skills. Toddlers need at least 30 minutes of structured physical activity and anywhere from 1 to several hours of unstructured physical activity per day (National Association for Sport & Physical Education, 2012). Indoor and outdoor play areas should encourage play activities that use the large muscle groups. The activity must occur within a safe environment. Outdoor play structures should be positioned over surfaces that are soft enough to absorb a fall, such as sand, wood chips, or sawdust (Fig. 26.8). Box 26.1 lists recommended age-appropriate toys.

## Promoting Early Learning

The parent–child relationship and the interactions between parent and child form the context for the toddler’s early learning.

### Promoting Language Development

Talking and singing to the toddler during routine activities such as feeding and dressing provides an environment that encourages conversation. Frequent, repetitive naming helps the toddler learn appropriate words for objects. The parent or caregiver should be attentive to what the toddler is saying as well as to his or her moods. Using clarification validates the toddler’s emotions and ideas. Parents should listen to and answer the toddler’s questions. They should sit down quietly with the toddler and gently repeat what the toddler is saying. Encouragement and elaboration convey confidence and interest

#### BOX 26.1

### APPROPRIATE TOYS FOR TODDLERS

- Familiar household items such as plastic bowls and cups of various sizes, large plastic serving utensils, pots and pans, wooden spoons, cardboard boxes and tubes (from paper towel rolls), old magazines, baskets, purses, hats
- Child-size household item toys (kitchen, broom, vacuum cleaner, lawnmower, telephone, and so on)
- Blocks, cars and trucks, plastic animals, trains, plastic figures (family, community helpers), simple dolls, stuffed animals, balls, doll beds and carriages
- Manipulative toys with knobs, wind-ups, and buttons that make things happen; putting large pegs or shapes into matching holes; stringing large beads on shoelaces; blocks and containers that stack; jigsaw puzzles with large pieces; toys that can be taken apart and put back together again
- Gross motor toys: play gym, push and pull toys, wagons, tricycle or other ride-on toys, tunnels
- Tape or CD players for music, various musical instruments
- Chalk, large crayons, finger paint, Play-Doh, washable markers
- Bucket, plastic shovel, and other containers for sand and water play
- Squeaking, floating, and squirting toys for the bath

Adapted from Schuman, A. T. (2007). The ABCs of toy safety: More than just child’s play. *Contemporary Pediatrics*, 24(7), 49–57, 64; and Shelov, S. P., & Altmann, T. R. (Eds.). (2009). *Caring for your baby and young child: Birth to age 5* (5th ed.). New York: Bantam Books.

to the toddler. The toddler needs time to complete his or her thoughts without being interrupted or rushed because he or she is just starting to be able to make the connections necessary to transfer thoughts and feelings into language.

Parents should not overreact to the child’s use of the word “no.” They can give the toddler opportunities to use the word “no” appropriately by asking silly questions such as, “Can a cat drive a car?” or “Is a banana purple?” When promoting language development, the parent or primary caregiver should teach the toddler appropriate words for body parts and objects and should help the toddler choose appropriate words to label feelings and emotions. Toddlers’ receptive language and interpretation of body language and subtle signs far surpass their expressive language, especially at a younger age (Feigelman, 2011b; Goldson & Reynolds, 2011).

Parents should avoid discussing scary or serious topics in the presence of the toddler, since the toddler is very adept at reading emotions.

If the parents speak a foreign language in addition to English, both languages should be used in the home.

**FIGURE 26.9** Reading to a toddler daily is one of the best ways to promote language development and school readiness.

### Encouraging Reading

Reading to the toddler every day is one of the best ways to promote language and cognitive development (Fig. 26.9). Toddlers particularly enjoy homemade or purchased books about feelings, family, friends, everyday life, animals and nature, and fun and fantasy. Board books have thick pages that are easier for young toddlers to turn; older toddlers can turn paper pages one at a time. The toddler may also enjoy “reading” the story to the parent. Reach Out and Read, a program designed to promote early literacy, offers tips for reading with young children (see Teaching Guidelines 26.1).

#### Teaching Guidelines 26.1

##### TIPS FOR READING WITH YOUNG CHILDREN

- Make reading part of every day: Read at bedtime or on the bus.
- Have fun: Children who love books learn to read. Books can be part of special time with your child.
- A few minutes is OK: Young children can sit for only a few minutes for a story, but as they grow they will sit longer.
- Talk about the pictures: You do not have to read the book to tell a story.
- Let your child turn the pages: Babies need board books and help to turn pages, but your 3-year-old can do it alone.
- Show your child the cover page: Explain what the story is about.
- Show your child the words: Run your finger along the words as you read them.

- Make the story come alive: Create voices for the story characters and use your body to tell the story.
- Ask questions about the story: What do you think will happen next? What is this?
- Let your child ask questions about the story: Use the story as an opportunity to engage in conversation and to talk about familiar activities and objects.
- Let your child tell the story: Children as young as 3 years old can memorize a story, and many children love an opportunity to express their creativity.

### Choosing a Preschool

The older toddler may benefit from the structure and socialization provided by attending preschool. Attending preschool will help the toddler become more mature and independent and give the toddler a different source for a sense of accomplishment. At this age, toddlers need supervised play with some direction that fosters their cognitive development. A strict curriculum is not necessary in this age group. When choosing a preschool, the parent or caregiver should look for an environment that has the following qualities:

- Goals and an overall philosophy with which the parents agree (promotion of independence and self-confidence through structured and free play)
- Teachers and assistants trained in early childhood development as well as child cardiopulmonary resuscitation (CPR)
- Small class sizes and an adult-to-child ratio with which the parent feels comfortable
- Disciplinary procedures consistent with the parents' values
- Parents can visit at any time
- School is childproofed inside and out
- Appropriate hygiene procedures, including prohibiting sick children from attending

Teach the parents how to ease the toddler's transition to attending preschool. Encourage parents to talk about going to preschool and visit the school a couple of times. On the first day, parents should calmly and in a matter-of-fact tone tell the toddler that they will return to pick him or her up. If the toddler expresses separation anxiety, the parent should remain calm and follow through with the plan for school attendance. After a few days of attendance, the toddler will be accustomed to the new routine and crying when parting from the parent should be minimal.

### Promoting Safety

Safety is of prime concern throughout the toddler period. Curiosity, mobility, and lack of impulse control all

contribute to the incidence of unintentional injury in toddlerhood. Even the most watchful and caring parents have toddlers who run into the street, otherwise disappear from parents, and fall down the stairs. Toddlers require direct observation and cannot be trusted to be left alone. A childproof environment provides a safe place for the toddler to explore and learn. Motor vehicle accidents, drowning, choking, burns, falls, and poisoning are the most common injuries suffered by toddlers. Safety and injury prevention focuses on these categories.

### Safety in the Car

The safest place for the toddler to ride is in the back seat of the car. Parents should use the appropriate size and style of car seat for the child's weight and age as required by the state. At a minimum, toddlers should be in a rear-facing car seat with harness straps and a clip until 2 years of age (American Academy of Pediatrics [AAP], 2012a). After age 2 years, a forward-facing seat may be used. A toddler riding in a pickup truck should never ride in the cargo area or truck bed. A full rear seat in the truck is the preferred placement for the toddler car seat. If an appropriate rear seat is unavailable, the air bag should be disarmed and the forward-facing car seat should be secured appropriately in the truck seat. The lower anchor and top tether are additionally required for all forward-facing car seats manufactured since 2002 and are accommodated by motor vehicles manufactured since that time (Fig. 26.10). In older vehicles or car seats, seat belts are utilized for installation. Drivers should avoid using the cell phone or attempting to intervene with the children while they are driving. Excellent resources about car seat safety appropriate for both parents and professionals can be found on [thePoint](#).

**FIGURE 26.10** A lower anchor and top tether secure the forward-facing car seat. (Adapted from U.S. Department of Transportation, National Highway Traffic Safety Administration, 2011.)

### Safety in the Home

Key areas of concern for keeping toddlers safe in the home include avoiding exposure to tobacco smoke, preventing injury, and preventing poisoning.

#### AVOIDING EXPOSURE TO TOBACCO SMOKE

Environmental exposure to tobacco smoke has been associated with increased risk of respiratory disease and infection, decreased lung function, and increased incidence of middle ear effusion and recurrent otitis media. It may also hinder neurodevelopment and may be associated with behavior problems (World Health Organization, 2011). Parents should avoid cigarette smoking entirely to best protect their children. Even smoking outside of the home is suboptimal because smoke lingers on parents' clothing and children who are often carried (such as younger toddlers) face more exposure. Counsel parents to stop smoking (optimal), but if they continue smoking never to smoke inside the home or car with children present.

#### PREVENTING INJURY

The toddler is able to open drawers and doors, unlock deadbolts, and climb anywhere he or she wants to go. Toddlers have a limited concept of body boundaries and essentially no fear of danger. Toddlers may fall from any height to which they can climb (e.g., play structures, tables, counters). They may also fall from wheeled toys such as tricycles. As toddlers gain additional height and hand dexterity they are able to reach potentially dangerous items on the counter or stove, leading to an accidental ingestion, burn, or cut.

To prevent injury in the home, stress the following to parents:

- Never leave a toddler unsupervised out of doors.
- Lock doors to dangerous rooms.

- Install safety gates at the top and bottom of staircases.
- Ensure that window locks are operable; if windows are left opened, then secure all window screens.
- Keep pot handles on the stove turned inward, out of an inquisitive toddler's reach.
- Teach the toddler to avoid the oven, stove, and iron.
- Keep electrical equipment, cords, and matches out of reach.
- Remove firearms from the home, or keep them in a locked cabinet out of the toddler's reach.
- Always require the child to wear a helmet approved by the Consumer Products Safety Commission (CPSC) when riding a wheeled toy. This starts the habit of helmet wearing early, so it can be more easily carried over to the bicycle-riding years of the future.
- Begin teaching the toddler about watching for cars when crossing the street, but always carry or hold the hand of the toddler when crossing the street.
- Teach the toddler to avoid unknown animals (AAP, 2012e, 2012f).

### Take Note!

"Bernie Burn," by Sarah Cruz, RN, is a book designed to educate parents and their toddlers about burn prevention while entertaining them. It is endorsed by the American Journal of Nursing, a link to which can be found on [thePoint](#).

## PREVENTING POISONING

As toddlers become more mobile, they are increasingly able to explore their environment and more easily and efficiently gain access to materials that may be unsafe for them to handle. Their natural curiosity leads them into situations that may place them in danger. Poor taste discrimination in this age group allows for ingestion of chemicals or other materials that older children would find too unpleasant to swallow. Box 26.2 lists most potentially dangerous ingested poisons. Discuss poison prevention in the home at each well-child visit (see Healthy People 2020). The American Academy of Pediatrics (2012f) recommends that potentially poisonous substances (e.g., medications, cleaners, hair care products, car care

### BOX 26.2

#### MOST DANGEROUS POTENTIAL POISONS

- Medicines (especially iron)
- Cleaning products
- Antifreeze, windshield washer solution
- Alcohol
- Pesticides
- Gasoline, kerosene, lamp oil, furniture polish
- Wild mushrooms

Adapted from American Association of Poison Control Centers. (2011). *Poisoning prevention FAQ*. Retrieved March 7, 2011, from <http://www.aapcc.org/dnn/PoisoningPrevention/FAQ.aspx>

products) be stored out of the toddler's reach, out of the toddler's sight, and in a childproof, locked cabinet.

Encourage all families to take the following safety measures:

- Store all substances in original containers only.
- Never store any liquid other than soda in a soda pop bottle.
- Do not allow toddlers access to baby powder, lotion, cream, or other toddler hygiene products.
- Ensure all medications have child-safety caps.
- Do not leave within the toddler's reach medications such as lozenges or samples that are not packaged in safety bottles.
- Be very careful with medications that are provided in transdermal patch form.
- Do not refer to medicines as candy, as the toddler may mistake pills for candy and ingest them.
- Do not expose toddlers to hazardous vapors such as paints, cleaners, tobacco smoke, and especially street drugs such as crack and marijuana.
- Keep "button" batteries secured and away from a toddler's reach.
- Keep house plants off the floor, remove them from the home, or hang them or place them on a high shelf (American Association of Poison Control Centers, 2011; Hagan et al., 2008).

### Take Note!

The American Academy of Pediatrics (2003) recommends that all families post the Poison Control Center number in a readily accessible place in the home: (800) 222-1222. The AAP discourages the use of syrup of ipecac in the home to induce vomiting after an accidental ingestion.

## Safety in the Water

Drowning is the leading cause of unintentional injury and death in US children, with the highest rate of drowning occurring in 1- to 2-year-olds (AAP, 2010a). Drowning

### HEALTHY PEOPLE 2020 • 26-1

#### Objective

Prevent an increase in the rate of non-fatal poisonings.

#### Nursing Significance

- Use every encounter with the toddler's family as an opportunity to educate about preventing poisonings.

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

## BOX 26.3

**PREVENTING DROWNING**

- Pools should be fenced with locked gates or screened with locked doors.
- Interior doors should be kept locked.
- Young children should never be left unattended in or near water.
- Water wings or “floaties” are not a substitute for adult supervision or for personal flotation devices.
- U.S. Coast Guard–approved life preservers or personal flotation devices should be available when a young child is in or near a body of water.
- Parents and caregivers should be trained in child cardiopulmonary resuscitation (CPR).

Adapted from American Academy of Pediatrics, Committee on Injury, Violence, and Poison Prevention. (2010). Prevention of drowning. *Pediatrics*, 126, 178–185.

may occur in very small volumes of water such as a toilet, bucket, or bathtub, as well as the obvious sites such as swimming pools and other bodies of water. Toddlers’ large heads in relation to their body size place them at risk for toppling over into a body of water that they are inquisitive about. Toddlers should be supervised at all times when in or around the water. In general, most children do not have the physical and cognitive capabilities necessary to truly learn how to swim until 4 years of age (AAP, 2010a). Parents who want to enroll a toddler in a swimming class should be aware that a water safety skills class would be most appropriate. However, even toddlers who have completed a swimming program still need *constant* supervision in the water (AAP, 2010a). Box 26.3 gives recommendations for the prevention of drowning.

*Remember Jose Gonzales, the 2-year-old introduced at the beginning of the chapter? What anticipatory guidance related to safety should you provide to his parents?*

**Promoting Nutrition**

The toddler’s ability to chew and swallow is improving, and he or she learns to use utensils effectively to feed himself or herself. The early years lay a foundation for the future, and a great deal of parental and societal interest is focused on nutrition and eating. Forming healthy eating habits has its foundation early in life, and diet has significant influence upon the child’s future health status. By establishing healthier food choice patterns early in life, the child is better able to continue these healthy choices later

in life. The child younger than 2 years of age should not have his or her fat intake restricted, but this does not mean that unhealthy foods such as sweets should be eaten liberally. A diet high in nutrient-rich foods and low in nutrient-poor high-calorie foods such as sweets is appropriate for children of all ages. See Healthy People 2020.

**HEALTHY PEOPLE 2020 • 26-2****Objective****Nursing Significance**

Eliminate very low food security among children.

- Counsel families about the appropriate toddler diet.
- Refer eligible families to WIC for grocery supplementation and nutritional counseling.

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

**Weaning**

The timing of weaning from breastfeeding is influenced by a number of factors such as cultural beliefs, local and regional ethnic beliefs, the mother’s work schedule, desired child spacing, or societal feelings about the nature of the mother–infant relationship. The extent and duration of breastfeeding are inversely related to the development of obesity later in life: children who breastfeed longer are less likely to become obese than those who breastfeed for shorter periods of time (AAP, 2007b). Thus, extending breastfeeding into toddlerhood is believed to be beneficial to the child. Extended breastfeeding provides nutritional, immunologic, and emotional benefits to the child. Contrary to popular belief, it is biologically possible to become pregnant while breastfeeding. Breastfeeding a newborn appropriately can occur while continuing to nurse the older sibling.

Weaning from breastfeeding tends to occur earlier in the United States than in countries around the world, despite recommendations on length of breastfeeding by a number of organizations. Most professional organizations recommend breastfeeding for at least 1 year (National Association of Pediatric Nurse Practitioners [NAPNAP], 2007).

Weaning is a highly individualized decision. Educate the mother about the benefits of extended breastfeeding and support her in her decision to wean at a given time.

Weaning from the bottle should occur by 12 to 15 months of age. Prolonged bottle-feeding is associated with the development of dental caries. No-spill “sippy cups” contain a valve that requires sucking by the toddler in order to obtain fluid, thus functioning similar to a baby bottle. Hence, no-spill sippy cups can also be associated with dental caries and are not recommended (Rychnovsky, 2000). Cups with spouts that do not contain valves are

acceptable. The 12- to 15-month-old is developmentally capable of consuming adequate fluid amounts using a cup.

### Teaching About Nutritional Needs

Adequate calcium intake and appropriate exercise lay the foundation for proper bone mineralization. The toddler requires an average intake of 500 mg calcium per day (Maqbool et al., 2011). Dairy products are considered the primary sources of dietary calcium. One cup of low-fat or whole milk, 8 ounces of low-fat yogurt, and 1½ ounces of cheddar cheese each provide 300 mg of calcium. Broccoli, oranges, sweet potatoes, tofu, and dried beans or legumes are also good sources of calcium (35 to 120 mg calcium per serving).

#### Take Note!

Though a half-cup of cooked spinach contains 120 mg of calcium, it is essentially nonbioavailable, making spinach a poor source of calcium.

Iron-deficiency anemia in the first 2 years of life may be associated with developmental and psychomotor delays (Baker, Greer, & the Committee on Nutrition, 2010). Although it is important for toddlers to consume adequate amounts of iron, they tend to have the lowest daily iron intake of any age group. When breastfeeding or formula feeding ends (most often at 1 year of age), it is often replaced with iron-poor cow's milk. Limiting milk intake to 16 ounces per day, as well as limiting juice intake, can be helpful. Encourage the parents to provide iron-fortified cereals and other foods rich in iron and vitamin C.

#### Take Note!

Toddlers who consume a strictly vegan diet (no food from animal sources) are at risk for deficiencies in vitamin D, vitamin B<sub>12</sub>, and iron. Supplementation with these nutrients should occur to promote adequate nutrition and growth (Maqbool et al., 2011).

Fat or cholesterol intake should not be restricted in children younger than age 2 years. The first 2 years of life require high energy intake because they are a time of very rapid growth and development. To promote healthy cholesterol levels, children older than age 2 years should consume a diet with a total fat content between 20% and 30% of total calories. Saturated fats should account for less than 10% of total calories (Maqbool et al., 2011). Due to daily variations and the pickiness of the toddler, fat intake should be evaluated over a period of several days. The daily recommended intake of fiber for a 1- to 3-year-old is 19 grams. Generally, toddler serving sizes should be about two-thirds

#### BOX 26.4

#### KEY NUTRIENTS PROVIDED BY FRUITS AND VEGETABLES

Dietary fiber: applesauce, carrots, corn, green beans, mangos, pears  
 Folate: avocados, broccoli, green peas, oranges, spinach and dark greens, strawberries  
 Vitamin A: apricots, cantaloupe, carrots, mangos, spinach and dark greens, sweet potatoes  
 Vitamin C: broccoli, cantaloupe, green peas, oranges, potatoes, strawberries, tomatoes

Adapted from Brown, J. (2011). *Nutrition now* (6th ed.). Florence, KY: Wadsworth Publishing.

that of an older child. Box 26.4 lists common sources of several nutrients.

Parents should encourage toddlers to drink water. Juice intake should be limited to 4 to 6 ounces per day. Milk intake should be limited to 16 to 24 ounces per day. Juice and milk should be served along with meals or snacks. Water should be offered for between-meal drinking. Toddlers should drink from a cup.

### Advancing Solid Foods

Parents should offer three full meals and two snacks daily. Portion sizes for toddlers are about one-quarter the size of adult portions. Large portions of a new or different food on the toddler's plate may intimidate the toddler. Normal toddler behaviors of mouthing, handling, tasting, extruding the food from the mouth, and then resampling the food often occur. These behaviors are distasteful to some parents but are a normal part of toddler development. Parents need to understand and tolerate these behaviors rather than scolding the toddler for them (Brazelton & Sparrow, 2006). Toddlers are often afraid to try new things anyway, so the parent or caregiver should be flexible with the toddler's acceptance or rejection of new foods. If the toddler refuses healthy food choices at meal or snack time, parents should not substitute high-fat, high-sugar, processed food "just to make sure he's eating something" (Weaver, More, & Harris, 2008). This sets the stage for future power struggles. The parent decides which foods will be served or offered. The toddler decides how much will be eaten. The toddler self-regulates the amount of food needed to sustain and allow further growth and development. The toddler may not eat well every day but generally, over the course of several days, will consume the foods he or she needs (Maqbool et al., 2011).

Foods should be served near room temperature. Some of the food on the plate should be soft and moist.

Food should always be cut into bite-size pieces. Teaching Guidelines 26.2 gives recommendations on ways to prevent choking.

### Teaching Guidelines 26.2 AVOIDING CHOKING

- Slowly add foods that are more difficult to chew as the toddler becomes more adept at chewing.
- Cut all foods into bite-sized pieces.
- Avoid foods that are hard to chew and may become lodged in the airway, such as:
  - Nuts
  - Gumdrops or other chewy candies
  - Raw carrots
  - Peanut butter (by itself)
  - Popcorn
- Cut hotdogs and grapes into quarters. Cook carrots until soft; if serving raw, then grate them.
- Always supervise the toddler while he or she is eating.

Adapted from Brown, J. (2011). *Nutrition now* (6th ed.). Florence, KY: Wadsworth Publishing.

### Promoting Self-Feeding

Toddlers most often eat with their fingers, but they do need to learn to use utensils properly. The following are suggestions for parents:

- Use a child-sized spoon and fork with dull tines.
- Seat the toddler in a high chair or at a comfortable height in a secure chair. The toddler should have his or her feet supported rather than dangling (Fig. 26.11).
- Never leave the toddler unattended while eating.
- Minimize distractions during mealtime. Turn off the television and serve food to the toddler along with the other members of the family (NAPNAP, 2011a).

### Promoting Healthy Eating Habits

Since the toddler's rate of growth has slowed somewhat compared to that in infancy, the toddler requires less caloric intake for his or her size compared to the infant. This results in **physiologic anorexia**: toddlers simply do not require as much food intake for their size as they did in infancy. The toddler will also exhibit **food jags**. During a food jag, the toddler may prefer only one particular food for several days, then not want it for weeks. Again, it is important for the parent to continue to offer healthy food choices during a food jag and not give in by allowing the toddler to eat junk food (NAPNAP, 2011a).

The normal developmental issue of testing limits will also occur for the toddler at mealtime. Since toddlers still have limited ability to express their emotions with words, they use nonverbal behaviors to do

FIGURE 26.11 The toddler should be appropriately and safely seated in the high chair. The safety strap is secure, the toddler's feet are supported, and the tray table is locked in place.

so. While eating, the toddler may dislike the taste of a particular food or experience a feeling of fullness but will communicate that feeling by screaming or throwing food. When the child exhibits these behaviors, the parent must remain calm and remove the toddler from the situation. Meals should be eaten in a calm and pleasant environment. Parents should serve as role models for appropriate eating habits, but toddlers may also be willing to try more foods if they are exposed to other children who eat those foods. Praise the child for trying a new food, and never punish the toddler for refusing to try something new. A new food may need to be offered many times in a row before the toddler chooses to try it. Parents should be sure to include foods the child is familiar with and likes to eat at the same meal that the new food is being introduced (Satter, 2012). Teaching Guidelines 26.3 lists alternative foods that meet nutritional needs and a list of books for parents of the picky eater.

### Teaching Guidelines 26.3 MEETING NUTRITIONAL NEEDS OF THE PICKY EATER

#### Alternative Food Choices for the Picky Eater

- Won't drink milk? Obtain calcium through yogurt (frozen or regular), cheese, pudding, and hot cocoa.
- Poor meat intake? Obtain iron through unsweetened iron-fortified cereals or breakfast bars, or raisins; cook with an iron skillet.

- Loves processed white bread? Encourage fiber intake with fresh fruits and vegetables, bran muffins, beans, or peas (can be in soup).
- Refuses vegetables? Encourage vitamin A intake with apricots, sweet potatoes, and vegetable juices.

#### Books for Parents of the Picky Eater

- *Coping with a Picky Eater: A Guide for the Perplexed Parent* by W. Wilkoff. New York: Simon & Schuster, 1998.
- *First Foods* by M. Stoddard. New York: Dorling-Kindersley Publishing, Inc., 1998.
- *How to Get Your Kid to Eat . . . But Not Too Much* by E. Satter. Boulder, CO: Bull Publishing Co., 1987.
- *The “Everything” Baby’s First Food Book* by J. Tarlou. Holbrook, MA: Adams Media Corp., 2001.
- *The Family Nutrition Book* by W. Sears & M. Sears. Boston: Little Brown & Co., 1999.
- *The Healthy Baby Meal Planner* by A. Karmel. New York: Simon & Schuster, 2001.

### Preventing Overweight and Obesity

In the child younger than 3 years of age, the greatest risk factor for the development of overweight or obesity is having an obese parent (AAP, 2007b). The nurse can screen for overweight in the child older than 2 years of age by calculating the body mass index (BMI) and plotting the BMI on the standardized age- and gender-appropriate growth charts (see Appendix F for growth charts, and refer to Chapter 32 for BMI calculation instructions). Trends over time may be predictive of the development of overweight or obesity.

Another factor in development of obesity in young children is juice intake (AAP, 2007a). Since most young children like the sweet taste of juice, they may drink excessive amounts of it. Toddlers who drink excess fruit juice and eat well may develop overweight or obesity because of the high sugar content in the juice. On the other end of the spectrum, some children may actually feel full from juice consumption and decrease their intake of solid foods. These children are at risk for malnutrition. Fruit juice intake should be limited to 4 to 6 ounces per day.

#### Take Note!

Young children should consume only pasteurized juice, as unpasteurized juice consumption places the toddler at increased risk of *Escherichia coli*, *Salmonella*, and *Cryptosporidium* infection.

*Refer back to Jose Gonzales. What questions should you ask his parents related to his nutritional intake? What anticipatory guidance related to nutrition would be appropriate?*

### Promoting Healthy Sleep and Rest

The 18-month-old requires 13.5 hours of sleep per day, the 24-month-old 13 hours, and the 3-year-old 12 hours (Feigelman, 2007a, 2007b). A typical toddler should sleep through the night and take one daytime nap. Most children discontinue daytime napping at around 3 years of age. The toddler who slept in a crib as an infant will need to move to a youth or toddler bed or even a full-size bed usually sometime in the toddler period. When the crib becomes unsafe (i.e., when the toddler becomes physically capable of climbing over the rails), then he or she must make the transition to a bed.

Consistent bedtime rituals help the toddler prepare for sleep. Choose a bedtime and stick to it as much as possible. The nightly routine might include a bath followed by reading a story. The routine should be a calm period with minimal outside distractions. Toddlers often require a security item to help them get to sleep. Older toddlers may be afraid of the dark, so a nightlight is often helpful.

Night waking is a problem for some toddlers. This may occur as a result of change in routine or as a desire for nighttime attention. Attention during night waking should be minimized so that the toddler receives no reward for being awake at night. The book *Solve Your Child’s Sleep Problems*, by Dr. Richard Ferber (2006, New York: Fireside Publishing), is an excellent resource for the family with a toddler who resists bedtime or is a persistent night waker. For some toddlers, night waking is caused by nightmares. As the imagination and capacity for make-believe grow, the toddler may not be able to distinguish between reality and pretend. The parent should hold and comfort the toddler after a nightmare. Limiting television viewing (especially shortly before bedtime) may be helpful in limiting nightmares.

Some families practice “co-sleeping” (when children sleep in the parents’ bed). Although some professionals believe that co-sleeping may interfere with the toddler’s struggle for independence, this theory has not been proven. The nurse should support the family’s choice for sleep arrangements unless the co-sleeping is unsafe either physically or psychologically (SafeBedSharing.org, 2011). Refer to <http://www.safebedsharing.org> for bed-sharing safety guidelines.

*Provide anticipatory guidance to Jose Gonzales’ parents in relation to his sleep.*

### Promoting Healthy Teeth and Gums

By 30 months of age, the toddler should have a full set of primary (“baby”) teeth. Parents may not be aware of the importance of preventing cavities in primary teeth since they will eventually be replaced by the permanent teeth. Poor oral hygiene, prolonged use of a bottle or

**FIGURE 26.12** The parent should brush the toddler’s teeth to ensure proper cleaning of the teeth, gums, and tongue. Use only water for brushing before 2 years of age and a pea-sized amount of fluoride-containing toothpaste after age 2 years.

no-spill sippy cup, lack of fluoride intake, and delayed or absent professional dental care may all contribute to the development of dental caries (Wagner & Oskouian, 2008). Cleaning of the toddler’s teeth should progress from brushing with simply water to using a very small amount (pea-sized) of fluoridated toothpaste with brushing beginning at 2 years of age (Fig. 26.12). Weaning from the bottle no later than 15 months of age and severely restricting use of a no-spill sippy cup (the kind that requires sucking for fluid delivery) is recommended.

At age 1 year, the toddler should have his or her first dentist visit to establish current health of the teeth and gums. Eating should be limited to meal and snack times, as “grazing” throughout the day exposes the teeth to

food throughout the day. Carbohydrate-containing foods combined with oral bacteria create a decreased oral pH level that is optimal for the development of dental caries (cavities). See Healthy People 2020.

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

Public water fluoridation is a public health initiative that ensures that most children receive adequate fluoride intake to prevent dental caries. Table 26.5 gives recommendations regarding fluoride supplementation. If the water supply contains adequate fluoride, no other supplementation is necessary other than brushing with a small amount of fluoride-containing toothpaste after age 2 years. Excess fluoride ingestion should be avoided, as it contributes to the development of fluorosis (mottling of the enamel). Fluorosis occurs most often in the toddler years (AAP, 2012c). Risk factors for fluorosis development include:

- High fluoride levels in the local water supply
- Use of fluoride-containing toothpaste prior to age 2 years
- Excessive ingestion of fluoride either in toothpaste or foods
- Fluoride-containing foods: tea, ready-to-eat infant foods containing chicken, white or purple grape juice, and beverages, processed foods, and cereals that were manufactured with fluoride-containing water

**TABLE 26.5 RECOMMENDATIONS FOR FLUORIDE SUPPLEMENTATION**

Age	Fluoride Ion Level in Drinking Water (ppm)		
	<0.3 ppm	0.3–0.6 ppm	>0.6 ppm
<b>Birth to 6 months</b>	None	None	None
<b>6 months to 3 years</b>	0.25 mg/day	None	None
<b>3–6 years</b>	0.50 mg/day	0.25 mg/day	None
<b>6–16 years</b>	1.0 mg/day	0.50 mg/day	None

ppm, parts per million is equivalent to 1 mg/liter. These recommendations are public domain at [www.ada.org](http://www.ada.org) and were approved by the American Dental Association, the American Academy of Pediatrics, and the American Academy of Pediatric Dentistry.

## Promoting Appropriate Discipline

Discipline is a common concern during toddlerhood. The toddler's intense personality and extreme emotional reactions can be difficult for parents to understand and cope with. The toddler needs firm, gentle guidance to learn what the expectations are and how to meet them. The parent's love and respect for the toddler teach the toddler to care about himself or herself and for others. Affection is as important as the guidance aspect of discipline. Having realistic expectations of what the toddler is capable of learning and understanding can help the parent in the disciplinary process. The toddler's intense push for autonomy can often test a parent's limits. The easygoing infant usually becomes more challenging in toddlerhood. The toddler's continual quest for new experiences often places the toddler at risk, and his or her negativism very often taxes the parent's patience.

In an effort to prevent the toddler from experiencing harm and in response to his or her continual testing of limits, parents often resort to spanking. Though commonly accepted, the American Academy of Pediatrics and the National Association of Pediatric Nurse Practitioners recommend against corporal or physical punishment (AAP, 2012b; NAPNAP, 2011b). Recent research points out the dangers inherent in the use of corporal punishment as well as the possibilities for negative effects on the child's future behavior (Box 26.5). Spanking or other forms of corporal punishment lead to a pro-violence attitude, create resentment and anger in some children, and contribute to the cycle of violence (NAPNAP, 2011b). See Evidence-Based Practice 26.1.

### Take Note!

Toddlers younger than 18 months of age should NEVER be spanked, as there is an increased possibility of physical injury in this age group. Also, the infant/young toddler is not capable of linking the spanking with the undesired behavior (AAP, 2012b).

Normal toddler development includes natural curiosity, and this curiosity often results in dangerous or problematic activities for the toddler (Anderson, 2008). Toddlers have a difficult time learning the rules and in general do not behave badly intentionally. Providing a childproof environment will allow the toddler to participate in safe exploration, which will meet his or her developmental needs and decrease the frequency of intervention needed on the part of the parents.

Discipline should focus on limit setting, negotiation, and techniques to assist the toddler to learn problem solving. Parents should provide consistency and commit to the limits that are set.

Offering realistic choices helps give the toddler a sense of mastery. Rules should be simple and limited in number. Maintaining the toddler's schedule of meals and rest/sleep will help to prevent conflicts that occur as a

### BOX 26.5

#### NEGATIVE IMPACT OF PHYSICAL PUNISHMENT

- Spanking is less effective than time-out or other discipline measures to reduce undesired behavior in children.
- The toddler younger than 18 months of age:
  - Is not capable of making the appropriate connections between spanking and the undesired behavior
  - Is at increased risk for physical injury from spanking than older children
- Physical punishment:
  - May lead to a pro-violence attitude
  - May create resentment in the toddler
  - Is a poor model for learning effective problem solving
  - May be correlated with antisocial and criminal behavior later in life
  - Leads to increased aggression in preschoolers, school-age children, and adults
  - When used frequently, may weaken the parent-child relationship
- Childhood corporal punishment increases the probability of depression and substance abuse in adulthood.
- Spanking may lead to more severe forms of punishment and to actual child abuse and maltreatment.
- The more frequently children are hit or spanked, the more likely they are to hit their own children and to be involved in spouse abuse as adults.

*Disciplining your child*. Retrieved June 30, 2012 from <http://www.healthychildren.org/english/family-life/family-dynamics/communication-discipline/pages/disciplining-your-child.aspx>; and National Association of Pediatric Nurse Practitioners. (2011b). NAPNAP position statement on corporal punishment. Retrieved June 30, 2012 from [http://www.napnap.org/Files/NAPNAP%20Position%20Statement%20on%20Corporal%20Punishment%20Final%202011%20\(2\).pdf](http://www.napnap.org/Files/NAPNAP%20Position%20Statement%20on%20Corporal%20Punishment%20Final%202011%20(2).pdf)

result of hunger or fatigue. Toddlers should not be made to share, as this is a concept they do not understand. Parents should encourage simple activities enjoyed by the children involved and avoid confrontation over toys. Parents should offer toddlers appropriate choices to help them develop autonomy, but should not offer a choice when none exists.

Positive reinforcement should be used as much as possible. "Catching" a child being good helps to reinforce appropriate or desirable behaviors. When the toddler is displaying appropriate behavior, the parent should reward the child consistently with praise and physical affection.

"Time-out" can be used effectively at around 2.5 to 3 years of age (refer to Chapter 27 for details). "Extinction" is a particularly useful technique with 2- and 3-year-olds.

**EVIDENCE-BASED PRACTICE 26.1****CORPORAL PUNISHMENT AND BEHAVIOR PROBLEMS IN EARLY CHILDHOOD****STUDY**

A large volume of research indicates that there are few, if any, positive developmental outcomes associated with the use of corporal punishment (spanking). In order to determine if negative consequences resulted, the authors used data from a large longitudinal ongoing multicenter study, the National Institute of Child Health and Human Development Study of Early Child Care and Youth Development. They reviewed the data from over 100 children, performing analyses that specifically controlled for contextual and parenting variables as well as for partial child effects. The Home Observation for the Measurement of the Environment (HOME) was administered when the children were 15, 36, and 54 months of age. The HOME measurement determined the use of corporal punishment. To determine the presence of behavior problems, the Child Behavior Checklist was administered at 36 months of age and again when the child was in the first grade.

Adapted from Mulvaney, M. K., & Mebert, C. J. (2007). Parental corporal punishment predicts behavior problems in early childhood. *Journal of Family Psychology, 21*(3), 389–397.

**Findings**

Multiple regression analysis was performed on the data sets, controlling for variables such as the child's gender, ethnicity, and temperament as well as maternal sensitivity and depression. The results established a causal link between the use of corporal punishment and child adjustment, particularly an increase in behavior problems during toddlerhood.

**Nursing Implications**

Targeted interventions may have a positive impact on decreasing the use of corporal punishment in young children. Advise parents about the risks associated with corporal punishment. Provide them with education about appropriate alternative methods of discipline, including limit setting with consistent follow-through, extinction, and time-out. Support parents' efforts to use alternative methods of discipline.

Extinction involves systematic ignoring of the undesired behavior. Parents sometimes unknowingly contribute to the occurrence of an unwanted behavior simply by the attention they give the toddler (even if it is negative in nature, it is still attention). Parents who want to extinguish an annoying (nondangerous) behavior should resolve to ignore it every time it occurs. When the child withholds the behavior or performs the opposite (appropriate) behavior, they should use compliments and praise. It may be difficult to ignore a difficult behavior, but the results are well worth the effort. Teaching Guidelines 26.4 provides tips on avoiding power struggles and offering appropriate guidance to toddlers.

- Pay attention to the inflection in your voice. A statement or direction should not end in a questioning tone or with “Okay?” Be clear. Statements should sound like statements, and only questions should end in a questioning tone.
- When a toddler behaves aggressively, label the child's feelings calmly, but be firm and consistent with the expectation. For example, “I know you're mad at your friend, but it is not okay to hit.”

Discipline techniques: The 12-month-old. *Contemporary Pediatrics, 25*(9), 84–87.

**Teaching Guidelines 26.4****PROVIDING TODDLERS WITH GUIDANCE**

- When giving the toddler instructions, tell the child what to do, NOT what not to do. This allows for a positive focus. If you must say “no,” “don't,” or “stop,” then follow with a direction of what to do instead.
- Offer limited choices, when a choice is truly available. Say, “Do you want to wear your blue hat or your red hat?” NOT “Do you want to put on your hat?” This gives the toddler some, but not all, control.
- Role model appropriate communication, but don't feel like you have to speak nicely all the time. If the situation warrants, use a firm and even tone to get the point across. Avoid yelling.

**Addressing Common Developmental Concerns**

Common developmental concerns of the toddler period are toilet teaching, temper tantrums, thumb sucking or pacifier use, sibling rivalry, and regression. An understanding of the normalcy of negativism, temper tantrums, and sibling rivalry will help the family cope with these issues. Prepare parents for these developmental events by giving appropriate anticipatory guidance.

**Toilet Teaching**

When myelination of the spinal cord is achieved around age 2 years, the toddler is capable of exercising

voluntary control over the sphincters. Girls may be ready for toilet teaching earlier than boys. Toddlers are ready for toilet teaching when:

- Bowel movements occur on a fairly regular schedule.
- The toddler expresses knowledge of the need to defecate or urinate. This may be through verbalization, change in activity, or gestures such as:
  - Looks into or grabs diaper
  - Squats
  - Crosses legs
  - Grimaces and/or grunts
  - Hides behind a door or the couch when defecating
- The diaper is not always wet (this indicates the ability to hold the urine for a period of time).
- The toddler is willing to follow instructions.
- The toddler walks well alone and is able to pull down his or her pants.
- The toddler follows caregivers to the bathroom.
- The toddler climbs onto the potty chair or toilet (AAP, 2012d).

Parents should approach toilet teaching with a calm, positive, and nonthreatening manner. Initially it may be helpful to allow the toddler to observe a same-sex family member using the toilet. Start with the toddler fully clothed on the potty chair or toilet while the parent or caregiver talks about what the toilet is used for and when. The toddler will feel most comfortable with a toddler potty chair that sits on the floor (Fig. 26.13). If a potty chair is unavailable, facing toward the toilet tank may make the toddler feel more secure, as the buttocks remain on the front of the seat rather than sinking through the toilet seat opening. After a week or longer, remove a dirty diaper and place the contents in the toilet. Next try having the toddler sit on the potty chair or toi-

**FIGURE 26.13** The toddler will feel most comfortable with a potty chair that sits on the floor.

let without pants or diaper on. The toddler may benefit from watching a caregiver or friend use the toilet. It may also be beneficial to demonstrate using the potty chair with a baby doll that wets.

Parents should always use gentle praise and no reproaches. Usually the best time to achieve success with defecation on the toilet is following a meal. When the toddler has achieved success with bowel control, bladder control will come next. It may be many months before nighttime bladder control is achieved, and the toddler may still require a diaper at night. Parents should use appropriate words for body parts, urination, and defecation, then use those words consistently so the toddler understands what to say and do (AAP, 2012d).

After a couple of weeks of successful toileting, the toddler may start wearing training pants. When toddlers have an accident and don't make it to the toilet, gently remind them about toileting and let them help clean up. Toddlers should never be punished for bowel or bladder "accidents."

With so much attention focused on the genitalia during toilet teaching and the frequency of being without a diaper, it is natural for toddlers to become more focused on their own genitalia. Boys and girls both will explore their genitalia and discover the resulting pleasurable sensation. Masturbation in the toddler often causes a great deal of discomfort in the parent. The parent should not draw attention to the activity, as that may increase its frequency. The parent should calmly explain to the toddler that this is an activity that may only be done in private (Feigelman, 2007b). If the toddler is masturbating excessively or refuses to stop when in public, then there may be additional stressors in the toddler's life that should be explored.

## Negativism

Negativism is common in the toddler period (Brazelton & Sparrow, 2006). As the toddler separates from the parent, recognizes his or her own individuality, and exerts autonomy, negativism abounds. Parents should understand that this negativism is a normal developmental occurrence and not necessarily deliberate defiance (though that also occurs). Avoid asking yes-or-no questions, as the toddler's usual response will be "no," whether he or she means it or not. Offering the child simple choices will give the toddler a sense of control. The parent should not ask the toddler if he or she "wants" to do something, if there is actually no choice. "Do you want to use the red cup or the blue cup?" is more appropriate than "Do you want your milk now?" When it is time to go outside, don't ask, "Do you want to put your shoes on?" Instead, state in a matter-of-fact tone that shoes must be worn outside, and give the toddler a choice of type of shoe or color of socks. If the child continues with negative answers, then the parent should remain calm and make the decision for the child.

**FIGURE 26.14** Tantrums are a normal component of toddler development.

## Temper Tantrums

Even children who displayed an easygoing personality as infants may lose their temper frequently during the toddler years (Fig. 26.14). A toddler who was more intense as an infant may have more temper tantrums. Temper tantrums are a natural result of the frustration that toddlers experience. Toddlers are eager to explore new things, but their efforts are often thwarted (usually for safety reasons). Toddlers do not behave badly on purpose. They need time and maturity to learn the rules and regulations. Some of their frustration may come from lack of language skills to express themselves. Toddlers are just starting to learn how to verbalize feelings and to use alternative actions rather than just “pitching a fit.” The temper tantrum may be manifested as a screaming and crying fit or a full-blown episode in which the toddler throws himself or herself on the floor kicking, screaming, and pounding, perhaps even holding the breath. Fatigue or hunger may limit the toddler’s coping abilities and promote negative behavior and temper tantrums (Pendley, 2012).

Although tantrums are annoying to parents and caregivers, they are a normal part of the toddler’s quest for independence. As toddlers mature, they become better able to express themselves and to understand their environment.

Parents need to learn their toddler’s behavioral cues in order to limit activity that is frustrating. When the parent notes the beginnings of frustration, a friendly warning might be given. Intervening early with an activity change might prevent a tantrum. Use distraction, refocusing, or removal from the situation.

When a temper tantrum does occur, the best course of action is to ignore the behavior and ensure that the

child is safe during the tantrum. Physical punishment will probably just prolong the tantrum and in fact produce more intense negative behavior. If the tantrum occurs in public, it may be necessary for the parent to immobilize the child with a big bear hug and use a calm voice to soothe the toddler. It is very important for parents to model self-control. Since toddlers’ tantrums most often result from frustration, the role-modeled behavior of self-control helps to teach toddlers to control their temper when they can’t get what they want (Pendley, 2012).

## Thumb Sucking and Pacifiers

Infants bring their hands to their mouths and begin thumb sucking as a form of self-soothing (Brazelton & Sparrow, 2006). This habit may continue into the toddler years and beyond. The pacifier is used for the same reason. Toddlers may calm themselves in a stressful situation by thumb sucking or sucking on a pacifier. Opinions about thumb and finger sucking and pacifier use are significantly affected by family history and culture. For most children there is no need to worry about a sucking habit until it is time for the permanent teeth to erupt. Prolonged and frequent sucking in the withdrawn child is more likely to yield changes to the tooth and jaw structure than sucking that is primarily used for self-soothing. Parents must sort through their own feelings about thumb sucking and pacifier use and then decide how they want to handle the habit.

To ensure safety with pacifier use:

- Use only one-piece pacifiers.
- Replace worn pacifiers with new ones.
- Never tie a pacifier around a toddler’s neck.

Parents may want to limit thumb sucking and pacifier use to bedtime, in the car, and in stressful situations. The parent should calmly discuss these limits with the toddler and then remain consistent about enforcing them (Sexton & Natale, 2009).

## Sibling Rivalry

Many families have subsequent children when their first child is a toddler. The toddler has been accustomed to being the baby and receiving a great deal of attention, both at home and with the extended family. Since toddlers are normally egocentric, bringing a new baby into the home may be quite disruptive. To minimize issues with **sibling rivalry**, parents should attempt to keep the toddler’s routine as close to normal as possible. Spend individual time with the toddler on a daily basis. Involve the toddler in the care of the baby. The toddler is capable of fetching a diaper or T-shirt, entertaining the baby with a toy, or helping sing a song to calm the baby (Brazelton & Sparrow, 2006). “Helping” the parent care for the baby gives the toddler a sense of importance (Fig. 26.15). The toddler will need significant support while holding the baby.

**FIGURE 26.15** The toddler may be more likely to accept the new baby in a positive manner if she feels that this is “our baby,” not just “mommy’s baby.” This toddler is meeting her new brother for the first time.

## Regression

Some toddlers experience **regression** during a stressful event (e.g., the birth of a sibling, hospitalization). Stress in a toddler’s life affects his or her ability to master new developmental tasks. During regression, the toddler may want to go back to an earlier stage. He or she may desire a bottle or pacifier long ago forgotten. The toddler may stop displaying previously achieved language or motor skills. A significant stress in the toddler’s life may also disrupt the toilet teaching process (toilet teaching may not be achieved near the time a sibling is born). When regression occurs, parents should ignore the regressive behavior and offer praise for age-appropriate behavior or attainment of skills (Brazelton & Sparrow, 2006).

*Refer to Jose Gonzales, the 2-year-old in the case study. List common developmental concerns of the toddler. What anticipatory guidance related to these concerns would the nurse provide to Jose’s parents?*

### KEY CONCEPTS

- Cognitive development in toddlerhood progresses from sensorimotor in nature to preoperational.
  - The toddler refines gross motor skills after learning to walk and builds fine motor skills through the use of utensils and various manipulative toys.
  - The toddler progresses from limited expressive language capabilities to a vocabulary of 900 words by age 3 years.
  - Toddlers use all of their senses to explore and learn about their environment.
  - Visual acuity progresses to at least 20/50 in the toddler period.
  - Negativism abounds in toddlers as they attempt to exert their independence.
  - Very ritualistic, toddlers feel safer and more secure when clear limits are enforced and a structured routine is followed.
  - The toddler is starting to learn right from wrong and bases actions on punishment avoidance.
  - Toddler development may be promoted through active gross motor play, books, music, and block building.
  - Safety is a primary concern in the toddler years as the child is more mobile, very curious, and experimenting with autonomy.
  - Poisoning in the toddler period may be prevented through proper storage of medications and other potentially poisonous substances and appropriate supervision.
  - Consistent bedtime rituals help ease the toddler’s transition to sleep.
  - All primary teeth are erupted by 30 months of age and may be kept healthy with appropriate tooth brushing and fluoride supplementation.
  - The toddler may experience a decrease in appetite as growth slows, yet he or she still needs appropriate nutritional intake for continued development.
  - Toilet teaching can be achieved after myelination of the spinal cord is complete, usually around 2 years of age.
  - Thumb sucking, pacifier use, security items, and temper tantrums are expected issues in the toddler years.
  - Toddler discipline should focus on clear limits and consistency. It should not involve spanking. It should be balanced with a caring and nurturing environment along with frequent praise for appropriate behavior.
- The toddler’s organ systems are continuing to mature, and growth slows during this period as compared with infancy.
  - The psychosocial task of the toddler years is to attain a sense of autonomy and to experience separation and individuation.

- Parental role modeling of appropriate behavior, especially related to dealing with frustration, is beneficial to toddlers.
- Parents play an important role in toddler development, not only by providing a loving environment but also by role modeling appropriate behavior in most areas of daily life.

## MULTIPLE CHOICE QUESTIONS

1. The nurse is caring for a hospitalized 30-month-old who is resistant to care, is angry, and yells “no” all the time. The nurse identifies this toddler’s behavior as
  - a. Problematic, as it interferes with needed nursing care.
  - b. Normal for this stage of growth and development.
  - c. Normal because the child is hospitalized and out of his routine.
2. The mother of a 15-month-old is concerned about a speech delay. She describes her toddler as being able to understand what she says, sometimes following commands, but using only one or two words with any consistency. What is the nurse’s best response to this information?
  - a. The toddler should have a developmental evaluation as soon as possible.
  - b. If the mother would read to the child, then speech would develop faster.
  - c. Receptive language normally develops earlier than expressive language.
  - d. The mother should ask her child’s physician for a speech therapy evaluation.
3. A 2-year-old is having a temper tantrum. What advice should the nurse give the mother?
  - a. For safety reasons, the toddler should be restrained during the tantrum.
  - b. Punishment should be initiated, as tantrums should be controlled.
  - c. The mother should promise the toddler a reward if the tantrum stops.
  - d. The tantrum should be ignored as long as the toddler is safe.
4. What is the best advice about nutrition for the toddler?
  - a. Encourage cup drinking and give water between meals and snacks.
  - b. Encourage unlimited milk intake, because toddlers need the protein for growth.
  - c. Avoid sugar-sweetened fruit drinks and allow as much natural fruit juice as desired.
  - d. Allow the toddler unlimited access to the sippy cup to ensure adequate hydration.
5. To gain cooperation from a toddler, what is the best approach by the nurse?
  - a. Immediately pick the toddler up from the mother’s lap.
  - b. Kneel in front of the toddler while he or she is on the mother’s lap.
  - c. Do the nursing tasks quickly so the toddler can play.
  - d. Ask the toddler if it is okay if you begin the needed task.

## CRITICAL THINKING EXERCISES

1. Develop a teaching plan about safety to present to a toddler-age preschool class.
2. Construct a 3-day menu for a 2-year-old, one that is realistic and will provide the nutrients needed.
3. Develop a plan for educating the parent of a 34-month-old who has been resistant to toilet teaching. Include assessments the nurse will make as well as the plan for teaching.

## STUDY ACTIVITIES

1. Visit a preschool that provides care for special-needs toddlers as well as typical toddlers. Perform a developmental assessment on a typical toddler and one with special needs (both the same age). Compare and contrast your findings.
2. Care for two average 2-year-olds in the clinical setting. Describe each toddler’s behavior, response to the parent, and response to the nurse and list strategies used to gain compliance and minimize stress to the toddler.
3. Observe in the toddler classroom of a typical preschool. Choose two toddlers the same age with different temperaments. Record the toddlers’ differences and similarities in response to structure and authority, interactions with classmates, attention levels, and language and activity levels.

## Growth and Development of the Preschooler

### Learning Objectives

*Upon completion of the chapter, you will be able to:*

1. Define the key terms used in this chapter.
2. Identify normal physiologic, cognitive, and psychosocial changes occurring in the preschool-age child.
3. Express an understanding of language development in the preschool years.
4. Implement a nursing care plan that addresses common concerns or delays in the preschooler's development.
5. Integrate knowledge of preschool growth and development with nursing care and health promotion of the preschool-age child.
6. Develop a nutrition plan for the preschool-age child.
7. Identify common issues related to growth and development during the preschool years.
8. Demonstrate knowledge of appropriate anticipatory guidance for common developmental issues that arise in the preschool period.

*Nila Patel is a 4-year-old girl brought to the clinic by her mother and father for her school check-up. During your assessment you measure her weight to be 44 pounds and her height 40 inches. As the nurse caring for her, assess Nila's growth and development, and then provide appropriate anticipatory guidance to her parents.*

#### Words of Wisdom

Quality parenting is achieved only by example.

**The** preschool period is the period between 3 and 6 years of age. This is a time of continued growth and development. Physical growth continues much more slowly compared to earlier years. Gains in cognitive, language, and psychosocial development are substantial throughout the preschool period. Many tasks that began during the toddler years are mastered and perfected during the preschool years. The child has learned to tolerate separation from parents, has a longer attention span, and continues to learn skills that will lead to later success in the school-age period. Preparation for success in school continues during the preschool period because most children enter elementary school by the end of the preschool period.

## GROWTH AND DEVELOPMENT OVERVIEW

The healthy preschooler is slender and agile, with an upright posture. The formerly clumsy toddler becomes more graceful, demonstrating the ability to run more smoothly. Athletic abilities may begin to develop. Major development occurs in the area of fine motor coordination. Psychosocial development is focused on the accomplishment of initiative. Preconceptual thought and intuitiveness dominate cognitive development. The preschooler is an inquisitive learner and absorbs new concepts like a sponge absorbs water.

### Physical Growth

The average preschool-age child will grow 2.5 to 3 inches (6.5 to 7.8 cm) per year. The average 3-year-old is 37 inches tall (96.2 cm), the average 4-year-old is 40.5 inches tall (103.7 cm), and the average 5-year-old is 43 inches tall (118.5 cm). Average weight gain during this time period is about 4 to 5 pounds (2.3 kg) per year (Feigelman, 2011). The average weight of a 3-year-old is 32 pounds (14.5 kg), increasing to an average weight of 41 pounds (18.6 kg) by age 5. The loss of baby fat and the growth of muscle during the preschool years give the child a stronger and more mature appearance (Fig. 27.1). The length of the skull also increases slightly, with the lower jaw becoming more pronounced. The upper jaw widens through the preschool years in preparation for the emergence of permanent teeth, usually starting around age 6.

### Organ System Maturation

Most of the body systems have matured by the preschool years. Myelination of the spinal cord allows for bowel and bladder control to be complete in most children by age 3 years. The respiratory structures are continuing to grow

**FIGURE 27.1** The preschool child has a more slender appearance and erect posture than the toddler.

in size, and the number of alveoli continues to increase, reaching the adult number at about 7 years of age. The Eustachian tubes remain relatively short and straight. Heart rate decreases and blood pressure increases slightly during the preschool years. An innocent heart murmur may be heard upon auscultation, and splitting of the second heart sound may become evident. The preschooler should have 20 deciduous teeth present.

The small intestine is continuing to grow in length. Stool passage usually occurs once or twice per day in the average preschooler. The 4-year-old generally has adequate bowel control. The urethra remains short in both boys and girls, making them more susceptible to urinary tract infections than adults. Bladder control is usually present in the 4- and 5-year-old child, but an occasional accident may occur, particularly in stressful situations or when the child is absorbed in an interesting activity.

The bones continue to increase in length and the muscles continue to strengthen and mature. However, the musculoskeletal system is still not fully mature, making the preschooler susceptible to injury, particularly with overexertion or excess activity.

### Psychosocial Development

According to Erik Erikson, the psychosocial task of the preschool years is establishing a sense of initiative versus guilt (Erikson, 1963). The preschooler is an inquisitive learner, very enthusiastic about learning new things.

**FIGURE 27.2** Allowing the preschooler to assist with simple household tasks such as preparing a sandwich encourages the development of initiative.

Preschoolers feel a sense of accomplishment when succeeding in activities (Fig. 27.2), and feeling pride in one's accomplishment helps the child to use initiative. However, when the child extends himself or herself further than current capabilities allow, he or she may feel a sense of guilt. The superego or conscience development is completed during the preschool period, and this is the basis for moral development (understanding right and wrong). Table 27.1 gives examples illustrating the stage of initiative versus guilt.

## Cognitive Development

According to Jean Piaget's theory (1969), the preschool-age child continues in the preoperational stage. **Preoperational thought** dominates during this stage and is based on a self-centered understanding of the world. In the pre-conceptual phase of preoperational thought, the child remains egocentric and is able to approach a problem from a single point of view only. The young preschooler may understand the concept of counting and begins to engage in fantasy play (Papalia & Felman, 2011).

**Magical thinking** is a normal part of preschool development. The preschooler believes that his or her thoughts are all-powerful. The fantasy experienced through magical thinking allows the preschooler to make room in his or her world for the actual or the real. Through make-believe and magical thinking, preschool children satisfy their curiosity about differences in the world around them (Papalia & Felman, 2011).

The preschooler often has an **imaginary friend** as well. This friend serves as a creative way for the preschooler to sample different activities and behaviors and practice conversational skills (Brazelton & Sparrow, 2002). Despite this imagination, the preschooler is able

to switch easily between fantasy and reality throughout the day.

The child in the intuitive phase can count 10 or more objects, correctly name at least four colors, and better understand the concept of time, and he or she knows about things that are used in everyday life, such as appliances, money, and food. The preschooler uses **transduction** when reasoning: he or she extrapolates from a particular situation to another, even though the events may be unrelated. The preschooler also attributes life-like qualities to inanimate objects (**animism**) (Papalia & Felman, 2011). Table 27.1 gives further examples illustrating this developmental stage.

The acquisition of language skills in the toddler period is enhanced in the preschool period. The expansion of vocabulary enables the preschooler to progress further with symbolic thought. At this age, children do not completely understand the concept of death or its permanence: they may ask when their grandparent or pet who died is returning.

## Moral and Spiritual Development

The preschool child can understand the concepts of right and wrong and is developing a conscience. That inner voice that warns or threatens is developing in the preschool years. Kohlberg identified this stage (between 2 and 7 years) as the preconventional stage, which is characterized by a punishment-and-obedience orientation (Kohlberg, 1984). Preschool children see morality as external to themselves; they defer to power (that of the adult). The child's moral standards are those of their parents or other adults who influence them, not necessarily their own. Preschoolers adhere to those standards to gain rewards or avoid punishment. Since the preschool child is facing the psychosocial task of initiative versus guilt, it is natural for the child to experience guilt when something goes wrong. The child may have a strong belief that if someone is ill or dying, then he or she may be at fault and the illness or death is punishment (Ford, 2007).

As the child's moral development progresses, he or she learns how to deal with angry feelings. Sometimes the way the child chooses to deal with those feelings may be inappropriate, such as fighting and biting. Preschoolers are so involved in imagination and fantasy that lying begins to occur at this age (Brazelton & Sparrow, 2002). Preschoolers also use their limited life experiences to make sense of and help them cope with crises. They need to learn the socially acceptable limits of behavior and are also learning the rewards of manners. The preschool child begins to help out in the family and begins to understand the concept of give-and-take in relationships.

During the preoperational phase of cognitive development, the preschooler's concept of faith is intuitive

TABLE 27.1 DEVELOPMENTAL THEORIES

Theorist	Stage	Activities
<b>Erikson</b>	Initiative vs. Guilt Age 3–6 years	Likes to please parents Begins to plan activities, make up games Initiates activities with others Acts out the roles of other people (real and imaginary) Develops sexual identity Develops conscience May take frustrations out on siblings Likes exploring new things Enjoys sports, shopping, cooking, working Feels remorse when makes wrong choice or behaves badly Cooperates with other children Negotiates solutions to conflicts
<b>Piaget</b>	Preoperational substage: Preconceptual phase Age: 2–4 years  Preoperational substage: Intuitive phase Age 4–7 years	Exhibits egocentric thinking, which lessens as the child approaches age 4 Has short attention span Learns through observing and imitating Displays animism Forms concepts that are not as complete or as logical as the adult's Is able to make simple classifications By age 4 understands the concept of opposites (hot/cold, soft/hard) Reasoning is that of specific to specific Has an active imagination Is able to classify and relate objects Has intuitive thought processes; knows if something is right or wrong, though cannot state why Tolerates others' differences but doesn't understand them Is very curious about facts Knows acceptable cultural rules Uses words appropriately but often without true understanding of their meaning Has a more realistic sense of causality May begin to question parents' values
<b>Kohlberg</b>	Punishment–obedience orientation Age 2–7 years (preconventional morality)	Determines good vs. bad dependent upon associated punishment Children may learn inappropriate behavior at this stage if parental intervention does not occur (if the child hits, bites, or is verbally disrespectful but is not punished for these activities, the child will view those behaviors as good and continue to participate in them)
<b>Freud</b>	Phallic stage Age 3–7 years	Child's pleasure centers on genitalia and masturbation. Superego is developing and conscience is emerging. Oedipal stage occurs: jealousy and rivalry toward same-sex parent, with love of the opposite-sex parent. This usually resolves by the end of the preschool years, when the child develops a strong identification with the same-sex parent.

**FIGURE 27.3** The preschool child may participate in religious rituals without having full understanding of their meaning.

and projective in nature (Ford, 2007). The preschool child's imagination allows for anything to be possible, so he or she does not have a logical view of the world (as adults do). Preschool children have limited life experiences, so they may project a feeling onto a new person or situation. They may use this projection to help them

understand what is going on around them. Preschoolers may project their parents' or caregiver's feelings or characteristics onto "God": if mommy gets angry, then God is probably also angry.

The family's religious beliefs may affect the child's diet, the mode of discipline that parents use, and even how the parents view their children. Knowing about a family's practices of prayer or meditation is helpful to the pediatric nurse, who can help continue the ritual when the child is ill or hospitalized (Ford, 2007) (Fig. 27.3).

## Motor Skill Development

As the preschooler's musculoskeletal system continues to mature, existing motor skills become refined and new ones develop. The preschooler has more voluntary control over his or her movements and is less clumsy than the toddler. Significant refinement in fine motor skills occurs during the preschool period (Table 27.2).

## Gross Motor Skills

The preschooler is agile while standing, walking, running, and jumping (Fig. 27.4). He or she can go up and down stairs and walk forward and backward easily. Standing on tiptoes or on one foot still requires extra concentration. The preschooler seems to be in constant motion. He or she also uses the body to understand new concepts (such as using the arms in

**TABLE 27.2** MOTOR SKILL DEVELOPMENT

Age	Expected Gross Motor Skills	Expected Fine Motor Skills
<b>4 years</b>	<ul style="list-style-type: none"> <li>• Throws ball overhand</li> <li>• Kicks ball forward</li> <li>• Catches bounced ball</li> <li>• Hops on one foot</li> <li>• Stands on one foot up to 5 seconds</li> <li>• Alternates feet going up and down steps</li> <li>• Moves backward and forward with agility</li> </ul>	<ul style="list-style-type: none"> <li>• Uses scissors successfully</li> <li>• Copies capital letters</li> <li>• Draws circles and squares</li> <li>• Traces a cross or diamond</li> <li>• Draws a person with two to four body parts</li> <li>• Laces shoes</li> </ul>
<b>5 years</b>	<ul style="list-style-type: none"> <li>• Stands on one foot 10 seconds or longer</li> <li>• Swings and climbs well</li> <li>• May skip</li> <li>• Somersaults</li> <li>• May learn to skate and swim</li> </ul>	<ul style="list-style-type: none"> <li>• Prints some letters</li> <li>• Draws person with body and at least six parts</li> <li>• Dresses/undresses without assistance</li> <li>• Can learn to tie laces</li> <li>• Uses fork, spoon, and knife (supervised) well</li> <li>• Copies triangle and other geometric patterns</li> <li>• Mostly cares for own toileting needs</li> </ul>

(2011). *A child's world: Infancy through adolescence* (12th ed.). New York, NY: McGraw-Hill.

**FIGURE 27.4** The preschooler runs well, navigate stairs, and can balance on one foot.

a “chug-chug” motion when describing how the train wheels work).

## Fine Motor Skills

The 3-year-old can move each finger independently and is capable of grasping utensils and crayons in adult fashion, with the thumb on one side and the fingers on the other. He or she can also scribble freely, copy a circle, trace a square, and feed himself or herself without spilling much. These skills become refined over the next 2 years, and by 5 years of age the child can write letters, cut with scissors more accurately, and tie shoelaces (Fig. 27.5).

## Sensory Development

Hearing is intact at birth and should remain so throughout the preschool years. The senses of smell and touch continue to develop throughout the preschool years. The young preschooler may have a less discriminating sense of taste than the older child, putting him or her at increased risk for accidental ingestion. Visual acuity continues to progress and should be equal bilaterally. The typical 5-year-old has visual acuity of 20/40 or 20/30. Color vision is intact at this age.

**FIGURE 27.5** The 5-year-old has the fine motor dexterity to cut well with scissors.

## Communication and Language Development

The acquisition of language allows the preschool child to express thoughts and creativity. The preschool years are a time of refinement of language skills. The 3-year-old exhibits **telegraphic speech**, using short sentences that contain only the essential information. Vocabulary at 3 years is composed of about 900 words. The preschool child may acquire as many as 10 to 20 new words per day and at age 5 usually has a vocabulary of 2,100 words (Taylor, 2008). By the end of the preschool period, the child is using sentences that are adultlike in structure (Table 27.3).

The 3- to 6-year-old is starting to develop fluency (the ability to smoothly link sounds, syllables, and words when speaking). Initially, the child may exhibit dysfluency or stuttering. Speech may sound choppy, or the child may say repeated consonants or “um.” Stuttering usually has its onset between 2 and 4 years of age, and about 75% of children will recover from it without therapy (Prasse & Kikano, 2008). Parents should slow down their speech and should give the child time to speak without rushing or interrupting. Some sounds remain difficult for the preschooler to enunciate properly: “f,” “v,” “s,” and “z” sounds are usually mastered by age 5 years, but some children do not master the sounds of “sh,” “l,” “th,” and “r” until age 6 or later.

Communication in preschool children is concrete in nature, as they are not yet capable of abstract thought. Despite its concrete nature, the preschooler’s communication can be quite elaborate and involved; he or she may talk about dreams and fantasies. In addition to acquiring vocabulary and learning the correct use of grammar, the preschool child’s receptive language skills are also becoming refined.

TABLE 27.3

## COMMUNICATION SKILLS IN THE PRESCHOOL CHILD

Age	Communication Abilities
4 years	<ul style="list-style-type: none"> <li>• Speaks in complete sentences using adultlike grammar</li> <li>• Tells a story that is easy to follow</li> <li>• 75% of speech understood by others outside of family</li> <li>• Asks questions with “who,” “how,” “how many”</li> <li>• Stays on topic in a conversation</li> <li>• Understands the concepts of “same” and “different”</li> <li>• Asks many questions</li> <li>• Knows names of familiar animals</li> <li>• Names common objects in books and magazines</li> <li>• Knows at least one color</li> <li>• Uses language to engage in make-believe</li> <li>• Follows a three-part command</li> <li>• Can count a few numbers</li> <li>• Vocabulary of 1,500 words</li> </ul>
5 years	<ul style="list-style-type: none"> <li>• Persons outside of the family can understand most of the child’s speech</li> <li>• Explains how an item is used</li> <li>• Participates in long, detailed conversations</li> <li>• Talks about past, future, and imaginary events</li> <li>• Answers questions that use “why” and “when”</li> <li>• Can count to 10</li> <li>• Recalls part of a story</li> <li>• Speech should be completely intelligible, even if the child has articulation difficulties</li> <li>• Speech is generally grammatically correct</li> <li>• Vocabulary of 2,100 words</li> <li>• Says name and address</li> </ul>

Adapted from Feigelman, S. (2011). The preschool years. In R. M. Kliegman, Stanton, B. F., St. Geme, J. W., Schor, N. F. & R. E. Behrman, H. B. Jenson, & B. Stanton (Eds.), *Nelson textbook of pediatrics* (19th ed.). Philadelphia, PA: Saunders; Papalia, D., & Felman, R. (2011). *A child’s world: Infancy through adolescence* (12th ed.). New York, NY: McGraw-Hill; and Taylor, E. (2008). Providing developmentally based care for preschoolers. *AORN Journal*, 88(2), 267–273.

The preschooler is very much in tune with the parent’s moods and easily picks up on negative emotions in conversations. If the preschooler hears parents discussing things that are frightening to the child, the preschooler’s imagination may fuel the development of fears and lead to misinterpretation of what the child has heard.

In the potentially bilingual child, by 4 years of age the child will cease the language mixing exhibited during the toddler years and should be able to use each language as a separate system (De Houwer, 2009).

### Emotional and Social Development

By the time a child enters kindergarten, he or she should have developed a useful set of social skills that will help him or her have successful experiences in the school setting as well as in life in general. These skills include cooperation, sharing (of things and feelings), kindness, generosity, affection display, conversation, expression of feelings, helping others, and making friends.

Preschoolers tend to have strong emotions. They can be very excited, happy, and giddy in one moment, then extremely disappointed in the next. The preschool child has a vivid imagination, and fears are very real to preschoolers. Most children this age have learned to control their behaviors. They should be able to name the feelings they are having rather than acting on them. Strong feelings may be expressed through outlets such as clay or Play-Doh, water play, drawing or painting, or dramatic play such as with puppets.

Preschoolers are developing a sense of identity. They recognize that they are boys or girls. They know that they belong to a particular family, community, or culture. They take pride in using self-control rather than giving in to their impulses. The preschool child is capable of helping others and being involved in routines and transitions.

Parents can encourage and assist preschool children with developing the social and emotional skills that will be needed when the child enters school. Preschool children thrive on one-to-one communication with a parent. During interactive communication, children learn to

express their feelings and ideas. Interactive communication fosters not only emotional and moral development but also self-esteem and cognitive development. Asking the preschool child questions requires the child to think out his or her own intention or motivation and encourages vocabulary development. Parents may use individual communication as a time to explore right and wrong, thus further contributing to moral development. Being listened to while answering parents' questions gives preschoolers a sense that they are valued, that what they think and have to say matters.

Establishing a few simple rules and enforcing them consistently gives preschoolers the structure and security they need while promoting moral development. Parents or caregivers can help the child give a name to the emotion that is being experienced. Fears are very real to preschoolers because of their active imaginations and may result in a variety of emotions. Parents should validate the feeling or emotion, then discuss with the child alternatives for dealing with the emotion.

Preschoolers are developing their sense of identity, and parents should encourage preschoolers to do simple things for themselves, like dressing and washing their hands and face (Fig. 27.6). Parents should give the child the time he or she needs to complete the task. This helps to establish a sense of accomplishment.

At this age, the child may begin to show an interest in basic sexuality (Papalia & Felman, 2011). The preschooler may want to know why boys' and girls' bodies are different, how the reproductive organs function, and where babies come from. The parent should answer the

**FIGURE 27.6** Encouraging the preschooler to complete simple tasks by himself or herself helps to build self-esteem.

**FIGURE 27.7** The preschool child begins to develop friendships.

child honestly and directly, using the correct anatomic terms. Long explanations are not necessary, just simple answers. This curiosity is a normal function of the preschool years, and the curiosity may also involve playing with the genitals (see the section on masturbation later in this chapter).

## Friendships

Preschoolers need interactions with friends as well. Learning how to make and keep a friend is an important part of social development. Friends may be other children in the neighborhood or those at preschool or day care. A special friend is someone the preschooler can care about, talk to, and play with (Fig. 27.7). The preschooler is more likely to agree to rules and wants to please friends and be like them. The preschooler loves to sing, dance, and act and will enjoy these activities with friends. Disagreements may occur, but the parent can encourage the children to express their views, discuss and resolve conflicts, and continue being friends.

## Temperament

By the time children are 3 years old, they recognize that what they do actually matters. It is helpful for the parent to view the child as an active participant in the parent-child relationship. The child's temperament has become a reliable indicator of how a parent might expect the child to react in a certain situation. When the parent is in

tune with the preschooler's temperament, it is easier to find ways to ease transitions and changes for that child. In the area of task orientation, temperament may range from the highly attentive and persistent to the more distractible and active (Grist & McCord, 2010).

A child's social flexibility is also evident by this age. A child who is quite adaptable will handle stimuli from the outside world in an approaching rather than a withdrawing manner. Temperament also determines the extent of reactivity (the child's sensory threshold of responsiveness, high versus low). This determines the quality of the child's mood and the intensity of reactions to stimuli, change, or situations. When the parents are familiar with the child's task orientation, social flexibility, and reactivity, they can better structure activities and situations for the child.

The 4-year-old is better at learning self-control and can use setbacks in appropriate behavior as opportunities for growth. Temper tantrums should ease off by this age, as the child's language skills are more capable of keeping up with complex ideas. The 4-year-old is able to see the rewards of growing up. This awareness of self-power may, however, lead to additional fears. The 5-year-old who has a more vulnerable type of temperament, as opposed to a confident temperament, may be more apt to experience fears.

## Fears

With their vivid imaginations, preschoolers experience a variety of fears. Preschoolers may be scared of loud noises such as fire engine sirens or barking dogs. Imaginary monsters may scare the child. Preschoolers are often afraid of people they do not know as well as strange people (Santa Claus or people who look or dress very differently from what they are accustomed to). Many preschoolers are afraid of the dark. Preschoolers may also fear insects as well as animals they are not familiar with. The preschooler's memory is long enough that he or she may fear returning to the doctor's office when a painful procedure occurred during the prior visit.

Parents should acknowledge fears rather than minimizing them. They can then collaborate with the child on strategies for dealing with the fear.

### Cultural Influences on Growth and Development

Children may learn prejudice or bias at home before entering school or day care. The ways that families view other races or cultures may be subtly or overtly demonstrated in routine daily activities. The preschool child is developing a conscience, so attitudes of tolerance or bias

may influence the child's values. As in the toddler period, the value that the family places on independence will affect the child's development of a healthy self-concept.

Some cultures value reading and education more than others. If reading is not valued in the home, the preschool child's first experience with books may not occur until he or she is in school.

Food served in the home is often very specific to the family's ethnic background. As the preschool child is exposed to persons of other cultures in school, he or she may or may not like the food that is served. Exploring customs or cultural practices that the family participates in is important so that these practices may be safely incorporated into the child's plan of care.

*Refer back to Nila, who was introduced in the beginning of the chapter. What developmental milestones would you expect Nila to have reached at this age? Nila's mother expresses concerns about her child's imaginary friend, Sasha. How would you respond?*

## THE NURSE'S ROLE IN PRESCHOOL GROWTH AND DEVELOPMENT

Growth and development in the preschool child remains orderly and sequential. Some preschoolers grow faster than others or reach various developmental milestones sooner than others. Nurses must be aware of the usual growth and development patterns for this age group so that they can assess preschool children appropriately and provide guidance to their families. The changes that the preschool child is experiencing affect not only the child but also the family. Health care visits throughout the preschool period continue to focus on expected growth and development and anticipatory guidance. An additional concern is the preparation for school entry (**school readiness**).

If the preschooler is hospitalized, growth and development may be altered. Hospitalization hinders the preschool child's ability to explore the environment and engage in make-believe play and thus presents a challenge for the curious and inquisitive child. If the child must be isolated for a contagious illness, the opportunities for exploration and experimentation are further restricted. In addition, a sick preschooler may feel a sense of guilt, worrying that maybe he or she caused the illness by negative thoughts or behaviors.

When caring for the hospitalized preschooler, the nurse must use knowledge of normal growth and development to recognize potential delays, promote continued

appropriate growth and development, and interact successfully with the preschooler.

## NURSING PROCESS OVERVIEW

Upon completion of assessment of the preschool child's growth and development status, problems or issues related to growth and development may be identified. The nurse may then identify one or more nursing diagnoses, including but not limited to:

- Delayed growth and development
- Imbalanced nutrition, less than body requirements
- Interrupted family processes
- Readiness for enhanced parenting
- Risk for caregiver role strain
- Risk for delayed development
- Risk for disproportionate growth
- Risk for injury

Planning nursing care for the preschool child with growth and development issues should take into account the preschooler's and family's individual needs. The nursing care plan may be used as a guide in planning nursing care for the preschooler with a growth or developmental concern. The nurse may choose the appropriate nursing diagnoses from the Nursing Care Plan 27.1 and individualize them as needed. The nursing care plan is intended to serve as a guide only and is not intended to be an inclusive growth and development plan.

## Promoting Healthy Growth and Development

The building of self-esteem continues throughout the preschool period. It is of particular importance during these years, as the preschooler's developmental task is focused on the development of initiative rather than guilt. A sense of guilt will contribute to low self-esteem, whereas a child who is rewarded for his or her initiative will have increased self-confidence. The parent who provides a loving and nurturing environment for the preschooler builds upon the earlier foundation.

Routine and ritual continue to be important throughout the preschool years, as they help the child to develop a sense of time as well as provide the structure for the child to feel safe and secure. Daily routine continues to assist with the development of conscience in the preschooler. As in toddlerhood, making expectations known through everyday routines helps to avoid confrontations. The preschooler is developing the maturity to know how to behave in various situations and is capable of learning manners.

**TABLE 27.4** SIGNS OF DEVELOPMENTAL DELAY

Age	Concern
4 years	<ul style="list-style-type: none"> <li>• Cannot jump in place or ride a tricycle</li> <li>• Cannot stack four blocks</li> <li>• Cannot throw ball overhand</li> <li>• Does not grasp crayon with thumb and fingers</li> <li>• Has difficulty with scribbling</li> <li>• Cannot copy a circle</li> <li>• Does not use sentences with three or more words</li> <li>• Cannot use the words “me” and “you” appropriately</li> <li>• Ignores other children or does not show interest in interactive games</li> <li>• Will not respond to people outside the family; still clings or cries if parents leave</li> <li>• Resists using toilet, dressing, sleeping</li> <li>• Does not engage in fantasy play</li> </ul>
By 5 years	<ul style="list-style-type: none"> <li>• Is unhappy or sad often</li> <li>• Has little interest in playing with other children</li> <li>• Is unable to separate from parent without major protest</li> <li>• Is extremely aggressive</li> <li>• Is extremely fearful or timid, or unusually passive</li> <li>• Cannot build tower of six to eight blocks</li> <li>• Is easily distracted; cannot concentrate on single activity for 5 minutes</li> <li>• Rarely engages in fantasy play</li> <li>• Has trouble with eating, sleeping, or using the toilet</li> <li>• Cannot use plurals or past tense</li> <li>• Cannot brush teeth, wash and dry hands, or undress efficiently</li> </ul>

Setting limits (and remaining consistent with those limits) continues to be important in the preschool period. Consistent limits provide the preschooler with expectation and guidance. As the preschooler increasingly participates in fantasy and imagination, the limits of routine and structure help guide his or her behavior and ability to distinguish reality.

Nurses caring for preschoolers should have knowledge of normal developmental expectations so they can determine whether the preschool child is progressing appropriately. Table 27.4 lists potential signs of developmental delay. A preschool child with one or more of these concerns should be referred for further developmental evaluation.

## NURSING CARE PLAN 27.1

## Growth and Development Issues in the Preschool Child

**NURSING DIAGNOSIS:** Risk for injury related to developmental age, environment, and motor vehicle travel

### Outcome Identification and Evaluation

Child's safety will be maintained: *Child will remain free from injury.*

#### Interventions: Preventing Injury

- Teach and encourage appropriate use of forward-facing car seat or booster seat *to decrease risk of injury related to motor vehicles.*
- Teach preschoolers to stay away from street and to cross the street only when holding the hand of an adult *to prevent pedestrian injury.*
- Require bicycle helmet use while riding any wheeled toy *to prevent head injury and form habit of helmet use.*
- Teach the preschooler appropriate safety rules in the home (avoiding electric outlets, etc.): *the preschooler is able to follow simple directions and carry out directives. Limits help him or her to organize the environment.*
- Post Poison Control Center phone number *(in case of accidental ingestion; the preschool child is very curious).*
- Never leave a preschool child unattended in a tub or pool or near any body of water *to prevent drowning.*
- Provide swimming lessons for children age 4 or 5 *to encourage water safety, but not as a replacement for adult supervision.*
- Teach parents first-aid measures and child CPR *to minimize consequences of injury should it occur.*
- Provide close observation and keep side rails up on bed in hospital *because the preschool child continues to be at risk for falling or injuring self on equipment or tubing (because of curiosity).*

**NURSING DIAGNOSIS:** Imbalanced nutrition, less than body requirements, related to inappropriate nutritional intake to sustain growth needs (excess juice or milk intake, inadequate food variety intake) as evidenced by failure to attain adequate increases in height and weight over time

### Outcome Identification and Evaluation

Child will consume adequate nutrients: *Child will demonstrate weight gain and increases in height.*

#### Interventions: Promoting Appropriate Nutrition

- Assess current feeding schedule and usual intake, as well as methods used to feed, *to determine areas of adequacy versus inadequacy.*
- Determine if the preschooler is unable to drink from a cup or does not finger feed or use utensils properly, or if the child has difficulty swallowing or tolerating certain textures of foods *to determine if further interventions such as speech or occupational therapy are required.*
- Weigh child daily on same scale if hospitalized, weekly on same scale if at home, and plot growth patterns weekly or monthly as appropriate on standardized growth charts *to determine if growth is improving.*
- Limit juice to 4 to 6 ounces per day, milk to 16 to 24 ounces per day, *to discourage sense of fullness achieved with excess milk or juice intake, thereby increasing appetite for appropriate solid foods.*
- Provide three nutrient-dense meals and at least two healthy snacks per day *to encourage adequate nutrient consumption.*
- Feed child on a similar schedule daily, without distractions and with the family: *preschool children continue to respond well to routine and structure. They are more interested in the social context of meals and are still apt to become distracted easily, so the TV should be off at mealtimes.*

## NURSING CARE PLAN 27.1

**Growth and Development Issues in the Preschool Child** (continued)

**NURSING DIAGNOSIS:** Delayed growth and development related to motor, cognitive, language, or psychosocial concerns as evidenced by delay in meeting expected milestones

**Outcome Identification and Evaluation**

Development will be enhanced: *Child will make continued progress toward realization of expected developmental milestones.*

**Interventions: Enhancing Growth and Development**

- Screen for developmental capabilities *to determine child's current level of functioning.*
- Offer age-appropriate toys, play, and activities (including gross motor) *to encourage further development.*
- Perform interventions as prescribed by physical, occupational, or speech therapist: *participation in those activities helps to promote function and accomplish acquisition of developmental skills.*
- Provide support to families of preschoolers with developmental delay *(progress in achieving developmental milestones can be slow and ongoing motivation is needed).*
- Reinforce positive attributes in the child *to maintain motivation.*
- Model age-appropriate communication skills *to illustrate suitable means for parenting the preschooler.*

**NURSING DIAGNOSIS:** Risk for disproportionate growth related to excess milk or juice intake, consumption of inappropriate foods or in excess amounts

**Outcome Identification and Evaluation**

Child will grow appropriately and not become overweight or obese: *Child will achieve weight and height within the 5th to 85th percentiles on standardized growth charts.*

**Interventions: Promoting Appropriate Growth**

- Discourage use of no-spill sippy cups *(they contribute to dental caries and allow unlimited access to fluids, possibly decreasing appetite for appropriate solid foods).*
- Provide juice (4–6 ounces per day) and milk (16–24 ounces per day) from a cup at meal and snack time and water in between *to avoid having the child drink excessive juice or milk.*
- Provide only nutrient-rich foods without high sugar content for meals and snacks; *even if the preschooler is a picky eater, it is inappropriate to provide high-calorie junk food just so the child eats something.*
- Teach parents to role model appropriate eating (nutrient-rich, varied diet) *to encourage child to try/accept new foods, as well as become familiar with a variety of food.*
- Severely limit the intake of fast foods and foods with high sugar and fat content *to decrease intake of nutrient-poor, high-calorie foods.*
- Ensure adequate physical activity *to stimulate development of motor skills and provide appropriate caloric expenditure. This also sets the stage for forming lifelong habit of appropriate physical activity.*
- Teach parents to limit television viewing to 1 to 2 hours per day *to encourage participation in physical activities.*

(continued)

## NURSING CARE PLAN 27.1

**Growth and Development Issues in the Preschool Child** (continued)

**NURSING DIAGNOSIS:** Interrupted family processes related to issues with preschool child's development, hospitalization, or situational crisis as evidenced by decreased parental visitation in hospital, parental verbalization of difficulty with current situation, possible crisis related to health of family member other than the preschool child

**Outcome Identification and Evaluation**

Family will demonstrate adequate functioning: *Family will display coping and psychosocial adjustment.*

**Interventions: Enhancing Family Functioning**

- Assess the family's level of stress and ability to cope to *determine family's ability to cope with multiple stressors.*
- Engage in family-centered care to *provide a holistic approach to care of the preschooler and family.*
- Encourage the family to verbalize feelings (*verbalization is one method of decreasing anxiety levels*) and acknowledge feelings and emotions.
- Use puppets or dramatic play with the child to *elicit the preschooler's feelings about the current situation.*
- Encourage family visitation and provide for sleeping arrangements for a parent or caregiver to stay in the hospital with the preschooler; *this contributes to family's sense of control in situation.*
- Involve family members in preschooler's care, *giving them a feeling of control and connectedness.*

**NURSING DIAGNOSIS:** Readiness for enhanced parenting related to parental desire for increased skill level and success with preschool child as evidenced by current healthy relationships and verbalization of desire for improved skills

**Outcome Identification and Evaluation**

Parent will provide safe and nurturing environment for the preschool child: *Parents will verbalize new skills they will employ in the family.*

**Interventions: Increasing Parenting Skill Set**

- Use family-centered care to *provide holistic approach.*
- Educate parent about normal preschool development to *provide basis of understanding for parenting skills needed in this time period.*
- Acknowledge and encourage parents' verbalization of feelings related to chronic illness of child or difficulty with normal preschool behavior; *this validates the normalcy of parents' feelings.*
- Encourage positive parenting and respect for preschooler and his or her normal development (*helps parents develop approaches to preschoolers that can be used in place of anger and frustration*).
- Acknowledge and admire positive parenting skills already present to *contribute to parents' confidence in their abilities to parent.*
- Role model appropriate parenting behaviors related to communicating with and disciplining the child (*role modeling actually demonstrates rather than just verbalizes what the parent should strive for*).

## Promoting Growth and Development Through Play

Providing sincere encouragement for the preschool child's efforts and accomplishments helps him or her develop a sense of initiative. Giving children opportunities to decide how and with whom they want to play also helps them develop initiative. Preschool children like to write, color, draw, paint with a brush or their fingers, and trace or copy patterns (Fig. 27.8). They may start small collections that may be sorted. They like using toys for their intended purpose as well as for whatever invented purpose they can imagine.

Preschoolers begin to play cooperatively with one another. Play may be focused around a distinct theme. They define roles, make up rules, and assign jobs. They are able to work together toward a common goal such as building a house or fort with discarded boxes. Cooperative play encourages the preschool child to learn to share, take turns and compromise, listen to others' opinions, consider the feelings of others, and use self-control and overcome fears.

**FIGURE 27.8** The preschool child loves to create things, so coloring and molding clay are ideal activities for children this age.

**FIGURE 27.9** Preschool children enjoy imitative play.

Preschoolers have incredible imaginations and love to play “make-believe” (Fig. 27.9). Encouraging pretend play and providing props for dress-up stimulates curiosity and creativity. Fantasy play is usually cooperative in nature. It encourages the preschooler to develop social skills such as taking turns, communication, paying attention, and responding to one another's words and actions. Fantasy play also allows preschoolers to explore complex social ideas such as power, compassion, and cruelty. Through role playing, children begin to develop their sexual identity as well.

Since preschool children have vivid imaginations, it is important to be careful about what television they watch. The preschooler should be limited to 1 to 2 hours per day of quality television (Gavin, 2011). The violence in some television programs may scare the preschool child or inspire him or her to act out violent behavior.

Most preschoolers also engage in dramatic play, fueled by their innate curiosity and vivid imaginations. Three-year-olds may not realize that they are pretending. They run from scary creatures, make plans, and pack their backpacks (never intending to actually leave). Four-year-olds are more sophisticated with dramatic or pretend play: they know they are pretending, and they use dress-up clothes and props to act out more complex roles and scenarios (Fig. 27.10). Five-year-olds are capable of quite complex scenarios. They pretend they are real or fantasy characters. They often use dramatic play to express anxiety, try out negative feelings, or conquer their fears. For example, a child who is afraid of getting a shot at

FIGURE 27.10 Preschool children love to dress up and pretend.

the doctor's office may work through that feeling with pretend play.

Parents should encourage physical activity in the preschool child. Regular physical activity improves gross motor skills, may enhance the child's self-confidence, and allows the child to expend excess energy. Establishing the habit of daily physical activity in the early years is important in the long-term goal of avoiding obesity. The main goal of organized sports at this age should be fun and enjoyment, although of course safety must remain a priority.

Expensive toys that claim to teach the young child are not necessary. Toys that require interactive rather than passive play, and that may include the involvement of the parent, are recommended (Schuman, 2007; Shelov & Altmann, 2009). Box 27.1 lists appropriate playthings for the preschool child.

## Promoting Early Learning

The family is the foundation for the child's early growth and development. Parents serve as role models for behavior related to education and learning, as well as instilling values in their children. School readiness is a topic that has received a significant amount of national attention in recent years (High, 2008). To succeed in school, children need a safe, responsive home environment that allows them to learn and explore, as well as structure and limits that allow them to learn the socially acceptable behaviors that they will need in school. Language development is critical to the ability to succeed in school and can be encouraged through books and reading. Each of these components is important in readying the child for education in a more formal setting. Promoting language development, choosing a preschool, and making the transition to kindergarten are discussed in more detail below.

### BOX 27.1

#### APPROPRIATE TOYS FOR PRESCHOOLERS

- Blocks, simple jigsaw puzzles (four to six large pieces), pegboards, wooden bead with string
- Supplies for creativity: chalk, large crayons, finger paint, Play-Doh or clay, washable markers, paper, paint and paintbrush, scissors, paste, or glue
- Puppets, dress-up clothes and props for dramatic play
- Bucket, plastic shovel, and other containers for sand and water play
- Play kitchen with accessories and pretend food (empty food boxes can be recycled for kitchen play)
- Squeaking, floating, squirting toys for the bath
- Sandbox with shovel and various toys for building
- Dolls that can be dressed and undressed (large buttons, zippers, and snaps), doll care accessories (diapers, bottles, carriage, crib)
- Gross motor toys: tricycle or big wheel (with helmet), jungle gym or swing set (with supervision), hula hoop, tunnel, wagon
- Blocks, Legos, cars and trucks, plastic animals, trains, plastic figures (family, community helpers), stuffed animals, balls, sewing cards
- Tape or CD players for music, various musical instruments
- Simple card and board games (older preschooler)
- Dollhouse with furniture and accessories, people, and animals

Adapted from Schuman, A. T. (2007). The ABCs of toy safety: More than just child's play. *Contemporary Pediatrics*, 24(7), 49–57, 64; and Shelov, S. P., & Altmann, T. R. (Eds.). (2009). *Caring for your baby and young child: Birth to age 5* (5th ed.). New York, NY: Bantam Books.

## Promoting Language Development

The parent serves as the child's first teacher. The interactions between parent and child in relation to books and other play activities model the types of interactions that the child will later have in school. Asking open-ended questions stimulates the development of thinking as well as language in the preschool child. The preschooler is a great imitator, so the parent should serve as a role model for appropriate language. Parents should avoid swearing, as the child is sure to repeat "bad words" even if he or she does not understand what they mean. Allowing children to pursue interests at their own pace will help them to develop the literacy and numeric skills that will enable them to later focus on academic skills.

Preschoolers enjoy books with pictures that tell stories (Fig. 27.11). Stories with repeated phrases help to keep the child's attention. Children like stories that describe experiences similar to their own. The preschool

**FIGURE 27.11** Preschool children enjoy being read to and looking at the pictures that go along with the story.

child demonstrates early literacy skills by reciting stories or portions of books. He or she also may retell the story from the book, pretend to read books, and ask questions about the story. The preschool child has enough focus and expanded attention to notice when a page is skipped during reading and will call it to the parent's attention.

#### **Take Note!**

Risk factors for lack of social and emotional readiness for school include insecure attachment in the early years, maternal depression, parental substance abuse, and low socioeconomic status. Nurses should screen for these factors and make referrals if appropriate.

## **Choosing a Preschool/ Starting Kindergarten**

Many parents choose to enroll their child in preschool. Preschool should be used primarily as an opportunity to foster the child's social skills and accustom him or her to the group environment. When selecting a preschool, the parent may want to consider the accreditation of the school, the teachers' qualifications, and recommendations of other parents. The focus of the school environment is also important: What is the daily schedule of activities? Is the school very structured, or does it have a looser environment? The parents must decide how focused on curriculum they want the school to be. The parent should observe the classroom, evaluating the environment, noise level, and sanitary practices as well

as how the children interact with each other and how the teachers interact with the children.

The type of discipline used in the school is also an important factor. Parents should not choose a preschool that uses corporal punishment. The American Academy of Pediatrics (AAP) discourages the use of corporal punishment in the school setting (AAP, 2010a). Corporal punishment may hurt a child's self-esteem as well as his or her ability to achieve in school (Mulvaney & Mebert, 2007). It may also lead to disruptive and violent behavior in the classroom. As preschool is the foundation for later education, the child should have the opportunity to build self-esteem and the skills needed for the more formal setting of elementary school.

Whether or not the child attended preschool, kindergarten will be the next big step. Kindergarten hours may be longer than preschool hours, and kindergarten is usually held 5 days per week. This may be a significant change for some children. For most children, the setting and personnel in kindergarten will be new to the child. Rules and expectations are often very different as well. When discussing starting kindergarten with the preschool child, parents should do so in an enthusiastic fashion, keeping the conversation light and positive. Parents should meet with the child's teacher prior to the start of school, if possible, to discuss particular needs or concerns. Parents may want to schedule a tour of the school for the preschooler or attend the school's open house with the child to ease the transition. Practicing the new daily routine prior to the start of school will also be helpful.

Most states require up-to-date immunizations and a health screening of the child before he or she enters kindergarten, so advise parents to plan ahead and schedule these in a timely fashion so that school entrance is not delayed (Centers for Disease Control and Prevention, 2011).

## **Promoting Safety**

In the United States, accidental injury remains the leading cause of death for children between the ages of 1 and 14 years (National Center for Injury Prevention and Control, 2006). Preschoolers are at an ideal age to be taught about safety and safe behaviors. They are cognitively able to absorb concrete information and they desire to master the situations they are in, but they continue to display poor judgment related to safety issues. Their engagement in fantasy is so strong that it makes it difficult for them to master complicated cause-and-effect relationships. The preschool child is capable of learning safe behaviors but may not always be able to transfer those behaviors to a different situation. Parents must continue to closely supervise preschool children to avoid accidental injury during this period.

**FIGURE 27.12** The older preschool child should be appropriately secured in an approved booster seat.

### Safety in the Car

The preschooler up until 4 years of age whose height meets the car seat size requirement should use a forward-facing car seat with harness and top tether. All preschoolers after reaching the car seat height restriction should ride in a booster seat that uses both the lap and shoulder belts (Fig. 27.12). It is recommended

that the booster seat continue to be used until a height of 4 feet 9 inches and age of 8 to 12 years are reached (AAP, 2012a). The back seat of the car is always the safest place for a child to ride. If a child younger than 12 years of age must sit in the front seat because there are not enough rear seats available, then the front passenger seat air bag should be deactivated. Children should never ride in the cargo area of a pickup truck (AAP, 2007). See Healthy People 2020 and Evidence-Based Practice 27.1.

#### HEALTHY PEOPLE 2020

Objective	Nursing Significance
Increase age-appropriate vehicle restraint system use in children.	<ul style="list-style-type: none"> <li>Encourage car seat and booster seat use until the child is of the appropriate size and age to progress to seat belts.</li> </ul>

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

#### EVIDENCE-BASED PRACTICE 27.1

#### INTERVENTIONS DIRECTED TOWARD ACQUIRING AND USING BOOSTER SEATS FOR CHILDREN 4 TO 8 YEARS OLD

##### STUDY

Children outgrow toddler car seats around the age of 4 years or when they weigh 40 pounds. Regular seat belts do not fit children properly. The purpose of booster seats for the 4- to 8-year-old child is to raise him or her higher on the seat of the car, in order for the adult seat belt to secure the child properly. Booster seats provide increased comfort and safety for this age group. Booster seat use in this age group has been shown to decrease injury and death via motor vehicle accident by nearly 60%. The authors reviewed five studies involving 3,070 subjects and performed a meta-analysis of the study results. Each of the randomized controlled trials reviewed assessed the efficacy of interventions directed toward increasing booster seat use.

##### Findings

The authors' meta-analysis of the studies revealed that interventions directed toward improving booster seat use can make a difference. Enforcement of booster seat law was the weakest intervention. More successful interventions all included education of parents about the importance and appropriate use of booster seats. Providing a free booster seat upon completion of the training or an incentive coupon to receive a discount upon purchase were the most helpful interventions.

##### Nursing Implications

Parents want to protect their children from injury when riding in motor vehicles, but many may lack the knowledge or financial resources to do so. Nurses are in a unique position to provide ongoing, repeated education about the importance of booster seat use for the preschooler to families wherever they encounter them. Nurses can also seek out resources in their individual communities to provide financial incentives to assist families with obtaining a booster seat. Nurses should always praise preschoolers for complying with booster seat use while riding in vehicles.

Adapted from Ehiri, J. E., Ejere, H. O. D., Magnussen, L., Emusu, D., King, W., & Osberg, J. S. (2007). Interventions for promoting booster seat use in four to eight year olds traveling in motor vehicles. *The Cochrane Library* 2007, 4.

### Take Note!

Although motor vehicle accidents remain a major cause of injury and death in the preschool age group, many families do not use appropriate car seat/seat belt safety with their children. Child passenger safety technicians are available to provide proper installation of car seats. To find one in your area, visit <http://www.nhtsa.dot.gov/people/injury/childps/contacts> or <http://www.seatcheck.org>. The National Highway Traffic Safety Administration (NHTSA) Auto Safety Hot Line may be reached at (888) 327-4236.

## Safety in the Home

Handguns, matches, bodies of water, bicycle riding, and poisons continue to be sources of potential injury during the preschool years. Falls account for the highest percentage of nonfatal injuries among preschoolers. In this age group, motor vehicle accidents are responsible for the most fatal injuries, followed by drowning. A significant number of injuries also occur in or around the home, including burns and poisoning (National Center for Injury Prevention and Control, 2006).

### PREVENTING EXPOSURE TO TOBACCO SMOKE

Parents should protect their preschoolers from second-hand tobacco smoke. Exposure to tobacco smoke is associated with an increased incidence of otitis media and respiratory infections, as well as increased symptoms and medication use in children with asthma. Other effects include decreased lung function and behavioral difficulties (World Health Organization, 2011). The preschool child should never be in an enclosed space (such as a car) where tobacco smoke is present.

### PREVENTING INJURY

The preschool child who runs out into the street is at risk for being struck by a car. Teach preschoolers to stop at the curb and never go into the street without a grown-up. The preschooler may learn to ride a bicycle (with or without training wheels). The child must wear an approved bicycle helmet any time he or she rides the bicycle, even if it is just in the driveway. Requiring helmet use in the early years may lead to the habit of helmet use as the child gets older. Allowing the preschooler to choose his or her own helmet may encourage the child to use the helmet.

Bicycles should be safe for this age group. The size must be correct; the balls of the feet should reach both pedals while the child is sitting on the seat and has both hands on the handlebars. Children younger than 5 years of age have difficulty learning to use hand-operated brakes, so traditional pedal-back brakes are recommended in this age group. Preschoolers are not mature enough to ride a bicycle in the street even if they are riding with adults, so they should always ride on the sidewalk (AAP, 2012c).

It is important to make the inside of the home safe for the preschool child. Parents should install and

maintain smoke alarms in the home. Increased physical dexterity and refinement of motor skills enable the preschooler to strike matches or use a lighter and start a fire. The preschool child is capable of washing his or her hands independently, so the water heater should be set at 120°F or below to prevent scalding (AAP, 2012c).

The preschooler's active imagination and desire to play make-believe may result in a firearm injury. The average preschooler is physically capable of handling and firing a gun, particularly a handgun, which is smaller and lighter. If present in the home, firearms should be kept in a locked cabinet with the ammunition stored elsewhere (AAP, 2012c, 2012d).

### PREVENTING POISONING

Though it is continuing to develop, preschoolers still have unrefined taste discrimination, placing them at risk for accidental ingestion. Parents should never try to coax a child to take a vitamin supplement, tablet, or pill by calling it "candy." Dangerous fluids should be stored in their original containers and should be kept out of reach of preschoolers; they should not be poured into containers that look like ordinary drinking glasses or cups. Potentially dangerous cleaning or personal health and beauty products, gardening and pool chemicals, and automotive materials should be kept out of reach of preschoolers and in a locked cabinet if possible. Medications should have childproof caps and should be kept in a locked cabinet. The Poison Control Center telephone number should be posted on or near the home phone (1-800-222-1222) (American Association of Poison Control Centers, 2011).

## Safety in the Water

Five years of age is an appropriate time for a child to learn to swim (AAP, 2010b). Children at this age are physically capable of this activity and have the cognitive maturity to accomplish the task of swimming and basic water safety. Swimming programs should focus on appropriate swim techniques as well as safety measures. Parents and caregivers should be trained in infant/child cardiopulmonary resuscitation (CPR). Homes with swimming pools should have lifesaving devices readily accessible. Preschoolers should be taught never to dive into water until an adult has verified its depth. Preschoolers are still too young to be left unattended around any body of water, even if they know how to swim. Preschoolers should never be allowed to swim in a canal or any fast-moving water. Preschoolers who are riding in boats or fishing off riverbanks should wear a personal flotation device. Parents should also be cautioned about close supervision of young children walking, skating, or riding near thin or weak ice. See Healthy People 2020.

**HEALTHY PEOPLE 2020****Objective****Nursing Significance**

Reduce drowning deaths.

- Never leave a young child unattended in or near the water.
- Educate families about water safety.
- Remind families that the preschooler's ability to swim does not replace the need for constant supervision while in the pool or other body of water.

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

**Take Note!**

The American Academy of Pediatrics recommends that all swimming pools be secured by a fence that is at least 5 feet high and has a self-latching gate to protect young children from entering a pool area unattended (AAP, 2010b).

*Recall Nila Patel, the 4-year-old presented at the beginning of the chapter. What anticipatory guidance related to safety should you provide to her parents?*

**Promoting Nutrition**

The preschool child has a full set of primary teeth, is able to chew and swallow competently, and has learned to use utensils fairly effectively to feed himself or herself (Fig. 27.13). As in the toddler years, it is important for the preschool child to continue to learn and build upon

**FIGURE 27.13** The preschool child has the manual dexterity to handle utensils appropriately and feed himself or herself independently.

healthy eating habits. These habits will last throughout the child's life. A diet high in nutrient-rich foods such as whole grains, vegetables, fruits, appropriate dairy foods, and lean meats is appropriate for the preschooler. Nutrient-poor, high-calorie foods such as sweets and typical fast foods should be offered only in limited amounts.

**Nutritional Needs**

The 3- to 5-year-old requires 500 to 800 mg calcium and 10 mg iron daily (Krebs, Primark, & Haemer, 2011). Box 27.2 lists good calcium and iron sources. Preschoolers should consume a minimum of 19 mg dietary fiber daily (Brown, 2011). The typical preschooler requires about 85 kcal/kg of body weight, usually between 1000 and 1600 calories/day depending upon the child's age and size. Saturated fats should account for less than 10% of total calories. Preschool children's diets should include a daily total fat intake of no less than 20% and not more than 35% of total calories to promote and maintain healthy cholesterol levels (Krebs et al., 2011).

**Take Note!**

Drinking excess amounts of milk may lead to iron deficiency, as the calcium in milk blocks iron absorption.

**Promoting Healthy Eating Habits**

Preschool children may be picky eaters. They may eat only a limited variety of foods or foods prepared in certain ways and may not be very willing to try new things. The 3- or 4-year-old may exhibit "food fads," eating only certain foods over a several-day period. As the child gets older, pickiness lessens. By 5 years of age the child is more focused on the social context of eating: table conversation and manners. The 5-year-old is generally more willing to at least try new foods and may like to help with meal preparation and clean-up as appropriate.

If the preschooler is growing well, then the pickiness is not a cause for concern. A larger concern may be the negative relationship that can develop between the parent and child relating to mealtime. The more the parent coaxes, cajoles, bribes, and threatens, the less likely the child is to try new foods or even eat the ones he or she likes that are served. The parent must maintain a positive and patient demeanor at mealtime. The child should be offered a healthy diet, with foods from all groups over the course of the day as recommended by the U.S. Department of Agriculture (USDA). Additional information for parents of preschoolers can be found on the USDA website, <http://www.choosemyplate.gov/preschoolers/growth.html> where individualized food plans may be created for the preschooler.

The parent should maintain a matter-of-fact approach, offer the meal or snack, and then allow the

**DAILY CALCIUM AND IRON RECOMMENDATIONS FOR PRESCHOOL CHILDREN**

**Calcium: 500 mg**  
**(3-year-old), 800 mg**  
**(4- to 8-year-old)**

**Calcium in Foods**

- 8 oz low-fat or whole milk: 300 mg
- 8 oz low-fat yogurt: 300 mg
- 1½ oz cheddar cheese: 300 mg
- 1 oz dried white beans (cooked): 160 mg
- ¼ cup tofu: 125 mg
- 1 medium orange: 50 mg
- ½ cup mashed sweet potatoes: 44 mg
- ½ cup cooked or 1½ cup raw broccoli: 35 mg

**Iron: 10 mg**

**Iron in Foods**

- ¾ cup 100% fortified prepared cereal: 18 mg
- ¾ cup 50% fortified prepared cereal: 9 mg
- 3 oz beef: 3 mg
- 3 oz chicken leg: 3 mg
- ½ cup cooked lentils: 3 mg
- 3 oz chicken breast: 2 mg
- ¼ cup fresh cooked spinach: 1.6 mg
- ¼ cup tofu: 0.9 mg
- 1 slice enriched bread: 0.8 to 0.9 mg
- ¼ cup frozen spinach, cooked: 0.7 mg

Adapted from U.S. Department of Agriculture. (2011). *USDA national nutrient database for standard reference*. Retrieved March 21, 2011, from <http://www.ars.usda.gov/Services/docs.htm?docid=8964>

child to decide how much of the food, if any, he or she is going to eat. High-fat, nutrient-poor snacks should not be substituted for healthy foods just to coax the child to “eat something.” See Healthy People 2020.

**HEALTHY PEOPLE 2020****Objective****Nursing Significance**

Increase consumption of calcium in the population aged 2 years and older.

- Screen preschoolers for appropriate dietary intake of calcium.
- Educate families about calcium content in foods.
- Assist families with choosing a diet that meets calcium needs and is appealing to the young child.

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

**Preventing the Development of Overweight and Obesity**

Worldwide, over 22 million children younger than 5 years old are obese. In the past 30 years, the number of US children and adolescents who are overweight has doubled. According to the National Health and Nutrition Examination Survey, 21% of all 2- to 5-year-olds are either overweight or at risk of overweight (National Association of Pediatric Nurse Practitioners [NAPNAP], 2006). Overweight and obese children are at risk for hypertension, hyperlipidemia, and the development of insulin resistance. Obese

preschoolers have a 20% chance of being obese as adults. This risk increases to 80% if they are obese as adolescents (AAP, 2007b). The risk is increased if one or both parents are overweight.

Parents are in an opportune position to exert a positive influence on their preschooler's nutritional intake and activity level. The habits learned in early childhood will likely carry over into the school-age, adolescent, and adult years. Children whose parents take an authoritarian approach to mealtime may learn to overeat, as they are encouraged to finish the entire meal (“Clean your plate!”). If they are offered appropriate, healthy food choices and access to high-calorie, nutrient-poor food is limited, preschoolers will learn to self-regulate (eat only until full). Food should not be used as either reward or punishment.

Parents should remain positive and patient at mealtime. Mealtimes should continue to be structured. Unstructured meals lead to an increase in fat and calorie consumption. Children who eat nutrient-dense and lower-fat foods are less likely to become overweight (Institute of Medicine, 2011). To limit the chance that overeating will occur, preschoolers should be offered a variety of healthy foods at each meal. This may include one each of a protein source, grain, vegetable, and fruit. The preschool child's serving size is usually one third to one half of the recommended size of an adult serving. The preschool child may imitate the other eaters at the table. Parents have a prime chance to be good role models, setting an example of eating vegetables and fruits.

As with toddlers, fruit juice should be limited to 4 to 6 ounces per day, as excess consumption can lead to excess weight gain (AAP, 2007a). Preschoolers should be encouraged to drink water.

Limiting television viewing and encouraging physical activity are also important strategies for the prevention of overweight and obesity.

*Refer back to Nila Patel, the 4-year-old introduced at the beginning of the chapter. What questions should you ask Nila's parents related to nutritional intake? What anticipatory guidance related to nutrition would be appropriate? Nila's mother expresses concerns regarding obesity. How would you address these?*

## Promoting Healthy Sleep and Rest

The preschool child needs about 11 to 12 hours of sleep each day (Feigelman, 2011). Some preschool children continue to take a nap during the day. Unless very tired, many preschool children will resist going to bed from time to time. Bedtime rituals continue to be reassuring to children, and it is important to continue them in the preschool years. Having a time of relaxation with a decrease in stimulation will allow the child to fall asleep more easily. Some children continue to need a security item at bedtime or naptime. A nightlight in the bedroom may be necessary, as many children this age are afraid of the dark. Teaching Guidelines 27.1 gives information about assisting parents to establish a bedtime routine.

### Teaching Guidelines 27.1

#### BEDTIME ROUTINES

- Establish a bedtime as well as morning wake-up time, and enforce them consistently.
- Avoid sugar or caffeine consumption in the evening.
- Avoid stimulating activities such as roughhousing before bedtime.
- Do not allow television watching in bed.
- Make the child's bedroom an inviting and comfortable area of the home.
- Provide a nightlight in the child's bedroom if he or she is afraid of the dark.
- Conform to a nightly routine:
  - Television off at a certain time
  - Bath
  - Quiet game or story reading/telling
  - Bedtime prayer or song
- Maintain quiet in the bedroom and nearby to increase the child's ability to fall asleep.

Adapted from Dowshen, S. (2011). *Sleep and your preschooler*. Retrieved July 4, 2012 from [http://kidshealth.org/parent/growth/sleep/sleep\\_preschool.html](http://kidshealth.org/parent/growth/sleep/sleep_preschool.html); and Goldson, E., & Reynolds, A. (2011). Child development and behavior. In W. W. Hay, M. J. Levin, J. M. Sondheimer, & R. R. Deterding (Eds.), *Current pediatric diagnosis and treatment* (20th ed.). New York, NY: McGraw-Hill.

Nightmares often occur in preschool children as a result of the child's struggle to distinguish what is real from what is not. When a child awakens from a nightmare, he or she is often crying and may be able to recount what the dream was about. Parents should validate the child's fear rather than discounting it (Goldson & Reynolds, 2011). Saying, "Yes, I agree, monsters are scary; it's a good thing they aren't real" is more appropriate than, "Don't be silly: monsters aren't real." Sometimes children benefit from reading stories about dreams. Recommended books include:

- *Bedtime for Frances* by Russell Hoban
- *Ben's Dream* by Chris van Allsburg
- *In the Night Kitchen* by Maurice Sendak
- *There's a Nightmare in My Closet* by Mercer Mayer

Nightmares should not be confused with night terrors. After a nightmare, the child is aroused and interactive, but night terrors are different: a short time after falling asleep, the child seems to awaken and is screaming. The child usually does not respond much to the parent's soothing, but he or she eventually stops screaming and goes back to sleep. Night terrors are often frightening for parents because the child does not seem to be responding to them. One technique that may help to decrease the incidence of night terrors is to wake the child about 30 to 45 minutes into the sleep cycle. If continued nightly for about a week, the cycle of night terrors may be broken (Hopkins & Glaze, 2008). See Comparison Chart 27.1.

*Think back to Nila Patel. What anticipatory guidance would you provide to her parents in relation to sleep during the preschool years?*

## Promoting Healthy Teeth and Gums

Dental caries prevention continues to be important and can be achieved through daily brushing and flossing. Parents should use only a pea-sized amount of toothpaste to prevent excess fluoride consumption, which can contribute to fluorosis (AAP, 2011b). The preschooler may brush his or her own teeth, but the parent must continue to supervise to ensure adequate brushing. Parents must perform flossing because the preschool child cannot perform this task adequately.

Cariogenic foods should be avoided. If sugary foods are consumed, the mouth should be rinsed with water if it is not possible to brush the teeth immediately (Wagner & Oskouian, 2008). The preschool child should visit the dentist every 6 months.

## COMPARISON CHART 27.1

## NIGHTMARES VERSUS NIGHT TERRORS

	Nightmare	Night Terror
<i>Definition</i>	Scary or bad dream followed by awakening	Partial arousal from deep sleep
<i>When parents become aware</i>	Child awakens parent after episode is over	Screaming and thrashing during the episode awakens the parent
<i>Timing</i>	Usually in the second half of the night	Usually about an hour after falling asleep
<i>Behavior</i>	Crying, may be scared after awakening	Sits up, thrashes, cries, screams, talks, looks wild-eyed. Sweats, may have racing heartbeat
<i>Responsiveness</i>	Responsive to parent's soothing and reassurances	Child unaware of parent's presence, may scream and thrash more if restrained
<i>Return to sleep</i>	Difficulty going back to sleep if afraid	Rapidly returns to sleep without full awakening
<i>Memory of occurrence</i>	May remember the dream and talk about it later	No memory of event

Adapted from Hopkins, B., & Glaze, D. (2008). Disorders of arousal in children. *Pediatric Annals*, 37(7), 481–487.

**Take Note!**

Dental caries prevention is important in the primary teeth, because loss of these teeth to caries may affect the proper formation of permanent teeth as well as the width of the dental arch.

## Promoting Appropriate Discipline

Successful discipline results from a loving and nurturing environment in which the preschooler's self-esteem is fostered and where limits are well chosen and enforced consistently. Spanking (striking with the open hand) is the least effective discipline practice and is discouraged by the American Academy of Pediatrics (2012b) and the National Association of Pediatric Nurse Practitioners (2011). Belts, switches, paddles, or other items should never be used to strike a child. The use of physical punishment has been associated with a number of additional problems in adulthood, such as antisocial and criminal behaviors (Sears & Sears, 2011).

If parents are consistent with discipline while encouraging the preschooler's normal growth and development of imagination and make-believe, the child will learn to accept that certain things are not allowed. The sense of initiative can be preserved and guilt avoided if the rules are clear and enforced consistently (Sears & Sears, 2011).

**Take Note!**

The more frequently children are hit, the more likely they are to display aggression as children, and as adults (Sears & Sears, 2011).

Minimize the occurrence of misbehavior by anticipating conditions likely to lead to the undesired or risky action. When the situation becomes difficult, parents should use distraction to change the preschooler's focus. When discussing the misbehavior, be certain to label the behavior and not the child. This helps to preserve the preschooler's self-esteem. When teaching preschoolers about undesired behavior, be sure they also understand the reason why it is wrong or unacceptable to do it. This helps to encourage the child to use internal controls over behavior. Parents should serve as role models for self-control, including choice of words, the tone they are delivered in, and the actions that accompany them.

Children work harder to obtain praise than to receive punishment, so always reward positive behaviors. Preschool children are becoming capable of understanding the concept of right and wrong. They start to understand each other's feelings (**empathy**) and are cognitively capable of remembering basic rules (Erikson, 1963).

Time-out or time away from the situation can be very effective in this age group. The punishment should be used only for intentional misbehavior (knowing something is forbidden but doing it anyway). It is particularly helpful with dangerous or destructive behavior. The preschooler is given a warning that time-out will occur if the behavior does not stop. The preschooler is removed from the situation and must stay in time-out for a specified period of time. A particular time-out area is helpful; a boring corner of the room without distractions available is a good location. The generally recommended period of time is to require 1 minute of time-out per year of age; thus, a 4-year-old would be in time-out for

4 minutes (Shelov & Altmann, 2009). Set the timer so the child will know when the time-out is over. If the child gets up before the prescribed time, replace the child in time-out and restart the timer. Time-out works best if used each and every time the undesirable behavior occurs. Also, praise the child when he or she follows the rules and behaves appropriately.

A simple and clear explanation of the misbehavior should be given to the child; parents should also talk about acceptable alternative strategies that the child can use in the future instead of the undesired behavior. Removal of a privilege such as playing with a favorite toy can be as effective as time-out.

Books and other media that are available to help educate parents about appropriate discipline and to help the child learn self-control are listed in Box 27.3.

### Addressing Common Developmental Concerns

Common developmental concerns of the preschool period include lying, sex education, and masturbation (Shelov & Altmann, 2009). Parents often express difficulty in dealing with these issues with their preschool children. Offering appropriate anticipatory guidance may give the parents the support and confidence they need to deal with these issues.

### Lying

Lying is common in preschool children. It may occur because the child fears punishment, has gotten carried away with imagination, or is imitating what he or she sees the parent do. The parent should ascertain the reason for the lie before punishing the child. If the child has broken a rule and fears punishment, then the parent must determine the truth. The child needs to learn that lying is usually far worse than the misbehavior itself. The punishment for the misbehavior should be lessened if the child admits the truth. The parent should remain calm and serve as a role model of an even temper. The next time the misbehavior occurs, the child will be more apt to simply tell the truth.

If the child's lying is really just his or her imagination getting carried away, then the parent should guide the child in distinguishing between myth and reality (Brazelton & Sparrow, 2002). The preschooler's imagination is very vivid, and the child needs direction in the use of that faculty. Parents should serve as role models of appropriate behavior for their children to learn it. Children who lie because they hear their parents lying simply must not see or hear their parents do it.

### BOX 27.3

#### SELECTED RESOURCES FOR PARENTS AND PRESCHOOLERS

##### Books for Parents (about discipline)

- *How to Talk so Kids Will Listen and Listen so Kids Will Talk* by A. Faber & E. Mazlish (Harper Resource)
- *Kids Are Worth It: Giving Your Children the Gift of Inner Discipline* by B. Colorosos (Harper Collins Publishers)
- *Positive Discipline A to Z: 1001 Solutions to Everyday Parenting Problems* by J. Nelson, L. Lott, & S. G. Glenn (Three Rivers Press)
- *Setting Limits With Your Strong-Willed Child: Eliminating Conflict by Establishing Clear, Firm and Respectful Boundaries* by R. MacKenzie (Three Rivers Press)
- *The Case Against Spanking: How to Discipline Children Without Hitting* by I. A. Hyman (Jossey-Bass)
- *The Nurturing Parent: How to Raise Creative, Loving, Responsible Children* by J. S. Dacey & A. J. Packer (Fireside)
- *Without Spanking or Spoiling: A Practical Approach to Toddler and Preschool Guidance* by E. Crary (Parenting Press)

##### Books for Preschoolers (about dealing with feelings and learning how to behave)

- *Hands Are Not for Hitting* by M. Agassi (Free Spirit Publishing)
- *I Can't Wait* by E. Crary (Parenting Press)
- *I Want It* by E. Crary (Parenting Press)
- *I Want to Play* by E. Crary (Parenting Press)
- *I Was so Mad* by M. Mayer (Golden Books)
- *I Was so Mad* by N. Simon & D. Leder (Albert Whitman & Company)
- *I'm Excited* by E. Crary (Parenting Press)
- *I'm Frustrated* by E. Crary (Parenting Press)
- *I'm Mad* by E. Crary (Parenting Press)
- *I'm Scared* by E. Crary (Parenting Press)
- *Feet Are Not for Kicking* by E. Verdick (Free Spirit Publishing)
- *Teeth Are Not for Biting* by E. Verdick (Free Spirit Publishing)
- *When Sophie Gets Angry . . . Really, Really Angry* by M. Bang (Blue Sky Press)
- *Words Are Not for Hurting* by E. Verdick (Free Spirit Publishing)

### Sex Education

Preschoolers are keen observers but are still not able to interpret all that they see correctly. The child may recognize, but not understand, sexual activity. Preschoolers are very inquisitive and want to learn about everything around them; therefore, they are very likely to ask questions about sex and where babies come from. Before attempting to answer

questions, parents should try to find out first what the child is really asking and what the child already thinks about that subject. Then they should provide a simple, direct, and honest answer. The child needs only the information that he or she is requesting. Additional questions will occur in the future and should be addressed as they arise.

## Masturbation

The normal curiosity of the preschool years often leads children to explore their own genitals (Shelov & Altmann, 2009). This behavior may be upsetting to some parents, but masturbation is a healthy and natural part of normal preschool development if it occurs in moderation. If the parent overreacts to this behavior, then it may occur more frequently. Masturbation should be treated in a matter-of-fact way by the parent. The child needs to learn certain rules about this activity: nudity and masturbation are not acceptable in public. The child should also be taught safety: no other person can touch the private parts unless it is the parent, doctor, or nurse checking to see when something is wrong.

*Think back to Nila Patel. What are some developmental concerns that are common during the preschool years? What anticipatory guidance related to these concerns would you provide to Nila's parents?*

### KEY CONCEPTS

- The preschool child grows at a slower rate and takes on a more slender and upright appearance than the toddler.
- The primary psychosocial task of the preschool period is developing a sense of initiative.
- Cognitive development moves from an egocentric approach to the world toward a more empathetic understanding of what happens outside of the self.
- The preschooler gains additional motor skills and displays significant refinement of fine motor abilities.
- Cognitive and language skills that develop in the preschool years help prepare the child for success in school.
- Dysfluency or hesitancy in speech is a normal finding in the preschool period and occurs as a result of the fast pace with which the preschooler is gaining language skills and vocabulary.
- The vocabulary of a preschooler increases to about 2,100 words, and the child speaks in full sentences with appropriate use of tense and prepositions.
- Appropriate growth and development should be maintained in the ill or hospitalized child.
- Recognizing concerns or delays in growth and development is essential so that the appropriate referrals may be made and intervention can begin.
- The preschool child requires a well-balanced diet with fat content between 20% and 30% of calories consumed.
- Adequate physical activity and provision of a nutrient-dense diet (rather than foods high in fat and sugar) are the foundation for obesity prevention in the preschool child.
- Adequate dental care is important for the health of the primary teeth.
- Preschoolers need about 12 hours of sleep per day and benefit from a structured bedtime routine.
- Due to the active imagination of the preschooler, nightmares and night terrors may begin during this period.
- Safety and injury prevention remain a focus in the preschool years.
- Structure, appropriate limit setting, and consistency are the keys for effective discipline in the preschool period.
- Time-out is an effective disciplinary measure for preschoolers.
- Masturbation may occur as the preschooler discovers his or her body. If not excessive, it is considered a normal part of growth and development.

## MULTIPLE CHOICE QUESTIONS

- The nurse is caring for a hospitalized 4-year-old who insists on having the nurse perform every assessment and intervention on her imaginary friend first. She then agrees to have the assessment or intervention done to herself. The nurse identifies this preschooler's behavior as
  - Problematic; the child is old enough to begin to have a basis in reality.
  - Normal, because the child is hospitalized and out of her routine.
  - Normal for this stage of growth and development.
  - Problematic, as it interferes with needed nursing care.
- The mother of a 3-year-old is concerned about her child's speech. She describes her preschooler as hesitating at the beginning of sentences and repeating consonant sounds. What is the nurse's best response?
  - Hesitancy and dysfluency are normal during this period of development.
  - Reading to the child will help model appropriate speech.
  - Expressive language concerns warrant a developmental evaluation.
  - The mother should ask her child's physician for a speech therapy evaluation.
- The mother of a 4-year-old asks for advice on using time-out for discipline with her child. What advice should the nurse give the mother?
  - If spanking is not working, then time-out is not likely to be helpful either.
  - Place the child in time-out for 4 minutes.
  - Use time-out only if removing privileges is unsuccessful.
  - The child should stay in time-out until crying ceases.
- A 5-year-old child is not gaining weight appropriately. Organic problems have been ruled out. What is the priority action by the nurse?
  - Allow the child unlimited access to the sippy cup to ensure adequate hydration.
  - Encourage sweets for the extra caloric content.
  - Teach the mother about nutritional needs of the preschooler.
  - Assess the child's usual intake pattern at home.

## CRITICAL THINKING EXERCISES

- Teach a preschool class about bicycle and street safety. Be certain to design the content at an appropriate developmental level.
- Construct a 3-day menu for a picky 4-year-old. Include three daily meals and two snacks. Follow the nutritional guidelines recommended by the USDA.
- Color or draw with a preschool child. Analyze the drawings and interactions or discussions you have with the child, relating them to psychosocial and cognitive development expected at this age.

## STUDY ACTIVITIES

- Care for two average 3-, 4-, or 5-year-old children in the clinical setting (make sure both are the same age). Describe each child's development level, response to hospitalization, and family dynamics.
- Visit a preschool that provides care for special needs children as well as typically developing children. Perform a development assessment on a typical child and one with special needs (both the same age). Compare and contrast your findings.
- Observe in a 3-, 4- or 5-year-old classroom of a typical preschool. Choose two children who are the same age with different temperaments. Record the differences and similarities in their response to structure and authority, interactions with classmates, attention levels, and language and activity levels.

## Growth and Development of the School-Age Child

### Learning Objectives

*Upon completion of the chapter, you will be able to:*

1. Define the key terms used in this chapter.
2. Identify normal physiologic, cognitive, and moral changes occurring in the school-age child.
3. Describe the role of peers and schools in the development and socialization of the school-age child.
4. Identify the developmental milestones of the school-age child.
5. Identify the role of the nurse in promoting safety for the school-age child.
6. Demonstrate knowledge of the nutritional requirements of the school-age child.
7. Identify common developmental concerns in the school-age child.
8. Demonstrate knowledge of the appropriate nursing guidance for common developmental concerns.

*Lawrence Jones is a 10-year-old boy brought to the clinic by his mother for his annual school check-up. During your assessment you measure his weight at 62 pounds and his height at 54 inches. As the nurse caring for him, assess Lawrence's growth and development, and then provide appropriate anticipatory guidance to his mother.*

#### **Words of Wisdom**

Always give a hundred percent, and you will never doubt your ability to succeed.

**School-age** children, between the ages of 6 and 12 years, are experiencing a time of slow progressive physical growth, while their social and developmental growth accelerates and increases in complexity. The focus of their world expands from family to teachers, peers, and other outside influences (e.g., coaches, media). The child at this stage becomes increasingly more independent while participating in activities outside the home.

## GROWTH AND DEVELOPMENT OVERVIEW

The school-age years are a time of continued maturation of the child's physical, social, and psychological characteristics. It is during this time that children move toward abstract thinking and seek approval of peers, teachers, and parents. Their eye–hand–muscle coordination allows them to participate in organized sports in school or the community. The **school-age child** typically values school attendance and school activities. The nurse uses knowledge of normal growth and development of the school-age child to assist the child with coping with disruptions and changes during this time period.

### Physical Growth

From 6 to 12 years of age, children grow an average of 2.5 inches (6 to 7 centimeters) per year, increasing their height by at least 1 foot. An increase of 7 pounds (3 to 3.5 kilograms) per year is expected (Feigelman, 2011a). In the early school-age years, girls and boys are similar in height and weight and appear thinner and more graceful than in previous years. In later school-age

years, most girls begin to surpass boys in both height and weight. (See Appendix F for growth charts.)

Preadolescent boys and girls do not want to be different from peers of the same sex or the opposite sex, although there are differences in physical and physiologic growth during the school-age years. These differences, especially **secondary sexual characteristics**, are concerning and often a source of embarrassment for both sexes.

The differences between girls and boys are more apparent at the end of the middle-school years and may become extreme and a source of emotional problems. These differences in height and weight relationships, and changes in growth patterns, should be explained to parents and children (Fig. 28.1). Physical maturity is not necessarily associated with emotional and social maturity. An 8-year-old who is the size of an 11-year-old will think and act like an 8-year-old. Many times, the expectations placed on these children are unrealistic and can impact the self-esteem and competence of the child. This can work in reverse, to similar effect, for an 11-year-old who is the size of an 8-year-old and is therefore treated as such.

### Organ Systems Maturation

Maturation of organs may differ with age or gender. Maturation of organs remains fairly consistent until late school age. In the late school-age years (10- to 12-year-olds), boys experience a slowed growth in height and increased weight gain, which may lead to obesity. During this time, girls may begin to have changes in the body that soften body lines. Preadolescence is a period of rapid growth, especially for girls.

**FIGURE 28.1** The different growth rates of school-age children are depicted by these same-age school-age children.

## Neurologic System

The brain and skull grow very slowly during the school-age years. Brain growth is complete by the time the child is 10 years of age. The shape of the head is longer and the growth of the facial bones changes facial proportions.

## Respiratory System

The respiratory system continues to mature with the development of the lungs and alveoli, resulting in fewer respiratory infections. Respiratory rates decrease, abdominal breathing disappears, and respirations become diaphragmatic in nature. The frontal sinuses are developed by 7 years of age. Tonsils decrease in size from the preschool years, but they remain larger than adolescents'. The adenoids and tonsils may appear large normally, even in the absence of infection.

## Cardiovascular System

The school-age child's blood pressure increases and the pulse rate decreases. The heart grows more slowly during the middle years and is smaller in size in relation to the rest of the body than at any other development stage.

## Gastrointestinal System

During the school-age years, all 20 primary deciduous teeth are lost, replaced by 28 of 32 permanent teeth, with the exception of the third molars (commonly known as wisdom teeth). The school-age child experiences fewer gastrointestinal upsets compared with earlier years. Stomach capacity increases, which permits retention of food for longer periods of time. In addition, the caloric needs of the school-age child are lower than in the earlier years.

## Genitourinary System

Bladder capacity increases, but varies among individual children. Girls generally have a greater bladder capacity than boys. Urination patterns vary with the amount of fluids ingested, the time they were ingested, and the stress level of the child. The formula for bladder capacity is age in years plus 2 ounces. Therefore, the bladder capacity of the 7-year-old would be 9 ounces. The larger capacity of the bladder allows for the child to experience longer periods between voiding.

## Prepubescence

The late school-age years are also referred to as *preadolescence* (the time between middle childhood and the 13th birthday). During preadolescence, **prepubescence** occurs. Prepubescence typically occurs in the 2 years before the beginning of puberty and is characterized by

the development of secondary sexual characteristics, a period of rapid growth for girls, and a period of continued growth for boys. There is approximately 2 years' difference in the onset of prepubescence between boys and girls. Sexual development in both boys and girls can lead to a negative perception of physical appearance and lowered self-esteem. Early development in girls can lead to embarrassment, concern over physical appearance, and low self-esteem. Delayed development in boys can lead to a negative self-concept, resulting in substance abuse or reckless use of nonautomobile vehicles. Early development may lead to risk-taking behaviors in both boys and girls. It is important for the nurse and parents to educate the late school-age child about body changes to decrease anxiety and promote comfort with these body changes.

## Musculoskeletal System

Musculoskeletal growth leads to greater coordination and strength, yet the muscles are still immature and can be injured easily. Bones continue to ossify throughout childhood, but mineralization is not complete until maturity.

## Immune System

Lymphatic tissues continue to grow until the child is 9 years old; immunoglobulins A and G (IgA and IgG) reach adult levels at around 10 years of age. Due to the lymphatic system becoming more competent in localizing infections and producing antibody-antigen responses, school-age children may have fewer infections. They may experience more infections during the first 1 to 2 years of school due to exposure to other children who may have infections.

## Psychosocial Development

Erikson (1963) describes the task of the school-age years to be a sense of **industry** versus **inferiority** (Feigelman, 2011a). During this time, the child is developing his or her sense of self-worth by becoming involved in multiple activities at home, at school, and in the community, which develops his or her cognitive and social skills. The child is very interested in learning how things are made and work. The school-age child's satisfaction from achieving success in developing new skills leads him or her to an increased sense of self-worth and level of competence. It is the role of the parents, teachers, coaches, and nurses of the school-age child to identify areas of competency and to build on the child's successful experiences to promote mastery, success, and self-esteem. If the expectations of adults are set too high, the child will develop a sense of inferiority and incompetence that can affect all aspects of his or her life. See Table 28.1 for a further explanation of psychosocial development in school-age children.

TABLE 28.1 DEVELOPMENTAL THEORIES

Theorist	Stage	Activities
Erikson	Industry vs. inferiority	Interested in how things are made and run Success in personal and social tasks Increased activities outside home—clubs, sports Increased interactions with peers Increased interest in knowledge Needs support and encouragement from important people in child's life Needs support when child is not successful Inferiority occurs with repeated failures with little support or trust from those who are important to the child
Piaget	Concrete operational	Learns by manipulating concrete objects Lacks ability to think abstractly Learns that certain characteristics of objects remain constant Understands concepts of time Engages in serial ordering, addition, subtraction Classifies or groups objects by their common elements Understands relationships among objects Starts collections of items Can reverse thought process
Kohlberg	Conventional Stage 3: interpersonal conforming, “good child, bad child” Age 7–10 years Stage 4: “law and order” Age 10–12 years	An act is wrong because it brings punishment Behavior is completely wrong or right Does not understand the reason behind rules If child and adult differ in opinions, the adult is right Can put self in another person's position Begins to exercise the “golden rule” Acts are judged in terms of intention, not just punishment
Freud	Latency	A time of tranquility between the Oedipal phase of early childhood and adolescence—focuses on activities that develop social and cognitive skills Develops social skills in relating to same-sex friends through joining clubs like Brownies, Girl Scouts, Boy Scouts

Adapted from Erikson, E. (1963). *Childhood and society* (2nd ed.). New York: Norton; Kohlberg, L. (1984). *Moral development*. New York: Harper & Row; Piaget, J. (1969). *The theory of stages in cognitive development*. New York: McGraw-Hill; and Feigelman, S. (2011b). Chapter 6: Overview and assessment of variability. In R. M. Kliegman, B. F. Stanton, J.W. St. Geme, N.F. Schor, & R.E. Behrman, (Eds.), *Nelson's textbook of pediatrics* (19th ed., p. 26). Philadelphia: Saunders.

## Cognitive Development

Piaget's stage of cognitive development for the 7- to 11-year-old is the period of concrete operational thoughts (Feigelman, 2011a). In developing concrete operations, the child is able to assimilate and coordinate information about his or her world from different dimensions. The child is able to see things from another person's point of view and think through an action, anticipating its consequences and the possibility of having to rethink the action. He or she is able to use stored memories of past experiences to evaluate and interpret present situations. The school-age child also develops the ability to classify or divide things into different sets and to identify their relationships to each other. The school-age child is able

to classify members of four generations on a family tree vertically and horizontally, and at the same time see that one person can be a father, son, uncle, and grandson. It is at this time that the school-age child develops an interest in collecting objects. The child starts out collecting multiple objects and becomes more selective as he or she gets older. Also, during concrete operational thinking, the school-age child develops an understanding of the **principle of conservation**—that matter does not change when its form changes. For example, if the child pours a half-cup of water into a short, wide glass and into a tall, thin glass, she still only has a half-cup of water despite the fact that it looks like the tall, thin glass has more (Fig. 28.2). She learns about conserving matter in a sequence ranging from the simplest to the more complex. See Table 28.1

**FIGURE 28.2** School-age children understand the theory of conservation (A). If you pour an equal amount of liquid into two glasses of unequal shape (B), the amount of water you have remains the same despite the unequal appearance in the two glasses (C).

for further information about cognitive development of school-age children.

### Moral and Spiritual Development

During the school-age years, the child's sense of morality is constantly being developed. According to Kohlberg, the school-age child is at the conventional stage of moral development (Kohlberg, 1984). The 7- to 10-year-old usually follows rules out of a sense of being a "good" person. He or she wants to be a good person to parents, friends, and teachers and to himself or herself. The adult is viewed as being right. This is stage 3: interpersonal conformity (good child, bad child), according to Kohlberg. Ten- to 12-year-olds progress to stage 4: the "law and order" stage. At this stage, the child can determine if an action is good or bad based on the reason for the action, not just on the possible consequences of the action. The older school-age child's behavior is guided by his or her desire to cooperate and by his or her respect for others. This leads to the school-age child's ability to understand and incorporate into his or her behavior the concept of the "golden rule" (Feigelman, 2011a). See Table 28.1 for additional information about the moral development of school-age children.

It is during school age that children may develop a desire to understand more about their religion (Ford, 2007). They are still concrete thinkers and are guided by their family's religious and cultural beliefs. They are comforted by the rituals of their religion, but are just beginning to understand the differences between natural and supernatural. Incorporating religious practices in their lives can assist school-age children in coping with different stressors.

### Motor Skill Development

Gross and fine motor skills continue to mature throughout the school-age years. Refinement of motor skills occurs, and speed and accuracy increase. To assess the motor skills of school-age children, ask questions about

participation in sports and after-school activities, band membership, constructing models, and writing skills.

### Gross Motor Skills

During the school-age years, coordination, balance, and rhythm improve, facilitating the opportunity to ride a two-wheel bike, jump rope, dance, and participate in a variety of other sports (Fig. 28.3). Older school-age children may become awkward due to their bodies growing faster than their ability to compensate.

School-age children between the ages of 6 and 8 enjoy gross motor activities such as bicycling, skating, and swimming. They are enthralled with the world and are in constant motion. Sometimes fear is limited due to the strong impulses of exploration. Children between 8 and 10 years of age are less restless, but their energy

**FIGURE 28.3** Jumping rope is an example of the increased development of gross motor skills of the school-age child.

level continues to be high with activities more subdued and directed. These children exhibit greater rhythm and gracefulness of muscular movements, allowing them to participate in physical activities that require longer and more concentrated attention and effort, such as baseball or soccer.

Between the ages of 10 and 12 years (the pubescent years for girls), energy levels remain high but are more controlled and focused. Physical skills in this age group are similar to adults', with strength and endurance increasing during adolescence.

All school-age children should be encouraged to engage in physical activities and learn physical skills that contribute to their health for the rest of their lives. Cardiovascular fitness, weight control, emotional tension release, and development of leadership and following skills are enhanced through physical activity and team sports.

## Fine Motor Skills

Myelination of the central nervous system is reflected by refinement of fine motor skills. Eye–hand coordination and balance improve with maturity and practice. Hand usage improves, becoming steadier and independent and granting an ease and precision that allows these children to write, print words, sew, or build models or other crafts. The child between 10 and 12 years of age begins to exhibit manipulative skills comparable to adults. School-age children take pride in activities that require dexterity and fine motor skills such as playing musical instruments (Fig. 28.4). Talent and practice become the keys to proficiency.

### Sensory Development

All senses are mature early in the school-age years. The typical school-age child has 20/20 visual acuity (Jarvis, 2008). In addition, ocular muscular control, peripheral

**FIGURE 28.4** School-age children improve their fine motor skills so they can play musical instruments well.

vision, and color discrimination are fully developed by the time the child is 7 years of age. Good vision is essential to the physical development and educational progression of school-age children. Vision screening programs conducted by school nurses identify problems with vision and result in appropriate referrals when warranted. Some problems frequently identified include amblyopia (lazy eye), uncorrected refractive errors or other eye defects, and malalignment of the eyes (called *strabismus*). Amblyopia is reduced vision in an eye that has not been adequately used during early development. Inadequate use can result from conditions such as strabismus, one eye being more nearsighted, farsighted, or astigmatic than the other eye. Amblyopia is the leading cause of visual impairment in children (National Eye Institute, 2008). If untreated by age 9 years, amblyopia can cause irreversible visual loss. This condition is correctable prior to this time with glasses or patching. Recent studies have suggested that older children (7 to 17 years) may benefit from these treatments, which are more commonly used on younger children (National Eye Institute, 2008). Proper screening and referral, as well as notification to parents of the existing condition, are essential to the education and socialization of the school-age child.

Hearing deficits that are severe are usually diagnosed in infancy, but the less severe may not be diagnosed until the child enters school and has difficulty learning or with speech. It is important to screen children for hearing deficits to ensure proper educational and social progression.

#### Take Note!

With loud music heard over long periods of time each day, there are concerns about these environmental noises affecting hearing in the school-age and adolescent populations.

The sense of smell is mature and can be tested in the school-age child by using scents that children are familiar with, such as chocolate or other familiar odors. In addition, the school-age child may be tested for the sense of touch with objects to discriminate cold from hot, soft from hard, and blunt from sharp.

### Communication and Language Development

Language skills continue to accelerate during the school-age years and vocabulary expands. Culturally specific words are used, with bilingual children speaking English in school and a second language at home. The school-age child learns to read and reading efficiency improves language skills. Reading skills are improved with increased reading exposure. School-age children begin to use more

complex grammatical forms such as plurals and pronouns. Also, they develop metalinguistic awareness—an ability to think about language and comment on its properties. This enables them to enjoy jokes and riddles due to their understanding of double meanings and play on words and sounds. They are also beginning to understand metaphors such as “a stitch in time saves nine.” School-age children may experiment with profanity and dirty jokes if exposed. This age group tends to imitate parents, family members, or others. Therefore, role modeling is very important.

### Emotional and Social Development

Patterns of temperamental traits identified in infancy may continue to influence behavior in the school-age child. Analyzing past situations may provide clues to the way a child may react to new or different situations. Children may react differently over time due to their experiences and abilities. **Self-esteem** is the child’s view of his or her individual worth. This view is impacted by feedback from family, teachers, and other authority figures.

### Temperament

Temperament has been described as the way individuals behave. Some descriptions of temperament are that the child is *easy*, *slow to warm*, or *difficult* (Feigelman, 2011b). These behaviors vary from the child who is easy (even-tempered, predictable, and adaptable) to the child labeled as difficult (due to high activity levels, easily frustrated, and moodiness) (Feigelman, 2011b). The child who is easy may adapt to school entry and other experiences smoothly and with little or no stress. The slow-to-warm child may be slow to adapt to changes. The slow-to-warm school-age child may exhibit discomfort when placed in different or new situations such as school. This child may need time to adjust to the new place or situation, and may demonstrate frustration with tears or somatic complaints. The slow-to-warm child should be allowed time to adjust to new situations and people (such as teachers) within his or her own time frame. All of these factors may impact the younger school-age child upon entering the school environment, with changes in authority and the introduction of many peers. The difficult or easily distracted child may benefit from an introduction to the new experience and people by role-playing, by visiting the site and being introduced to the teachers, and by hearing stories or participating in conversations about the upcoming school experience. These children require patience, firmness, and understanding to make the transition into a new situation or experience such as school. The Behavioral Style Questionnaire

(BSQ) (McDevitt & Carey, 1978) is a temperament questionnaire for children 3 to 7 years old; the Middle Childhood Temperament Questionnaire is another tool for children 8 to 12 years of age (Hegvik, McDevitt, & Carey, 1982). These tools may be useful for determining type of temperament and guiding interventions.

### Self-Esteem Development

Self-esteem mirrors the child’s individual self-worth and consists of both positive and negative qualities. Children strive to achieve internalized goals of attainment, although they continually receive feedback from individuals they perceive as authorities (parent or teacher). By the school-age years, children have received feedback related to their performance or tasks. The direction of this feedback influences the child’s opinion of self-worth, which influences self-esteem and self-evaluation.

Children face the process of self-evaluation from a framework of either self-confidence or self-doubt. Children who have mastered the earlier developmental task of autonomy and initiative face the world with feelings of pride rather than shame (Erikson, 1963).

If school-age children regard themselves as worthwhile, they have a positive self-concept and high self-esteem. Significant adults in school-age children’s lives can manipulate the environment to facilitate success. This success impacts the self-esteem of the child.

### Body Image

Body image is how the school-ager perceives his or her body. School-age children are knowledgeable about the human body but may have different perceptions about body parts. School-age children are very interested in peers’ views and acceptances of their body, body changes, and clothing. This age group may model themselves after parents, peers, and persons in movies or on television. It is important for late school-agers to feel accepted by peers. If they feel different and are teased, there may be lifelong effects.

### School-Age Fears

School-age children are less fearful of harm to their body than in their preschool years, but fear being kidnapped or undergoing surgery. They continue to fear the dark and worry about their past behaviors. They fear death and are fascinated by death and dying. They are less fearful of animals, such as dogs and noises. The school-age child needs reassurance that his or her fears are normal for this developmental age. Parents, teachers, and other caretakers should discuss the fears and answer questions posed by the child (Lyness, 2010).

## Peer Relationships

The school-age child's concept of self is shaped not only by his or her parents but also by relationships with others. Peer relationships influence children's independence from parents. Peers play an important role in the approval and critiquing of skills of school-age children. Previously, only adults such as parents and teachers have been authorities; now, peers influence school-age children's perceptions of themselves. Peer relationships help to support the school-age child by providing enough security to risk the parental conflict brought about when establishing independence. School-age children associate with peers of the same sex most of the time. Although games and other activities are shared by both boys and girls, the child's concept of the appropriate sex role is influenced by his or her relationship with peers.

Continuous peer relationships provide the most important social interaction for school-age children. Valuable lessons are learned from interactions with children their own age. Children learn to respect differing points of view that are represented in their groups (Fig. 28.5). Peer groups establish norms and standards that signify acceptance or rejection. Children may modify behavior to gain acceptance. A characteristic of school-age children is their formation of groups with rules and values. Peer and peer-group identification are important to the socialization of the school-age child (Feigelman, 2011a).

## Teacher and School Influences

School serves as a means to transmit values of society and to establish peer relationships. Secondary only to the family, school exerts a profound influence on the social development of the child. Often school requires changes for the child and parent. The child enters an environment that requires conforming to group activities that

**FIGURE 28.5** School-age children like to join clubs. These children, in the acting club at school, are rehearsing for a play.

are structured and directed by an adult other than the parent. The parent's attitude and support influences the child's transition into the school setting. Parents that are positive and supportive promote a smooth entry into school. Parents that encourage clinging behaviors may delay a successful transition into school.

To facilitate the transition from home to school, the teacher must have the personality and knowledge of development that will allow him or her to meet the needs of young children. Even though the teacher's responsibilities are primarily to stimulate and guide intellectual development, they must share in shaping the child's attitudes and values. The system of awards and punishment administered by teachers affects the self-concept of children and influences their response to school. Teachers and school are important in shaping the socialization, self-concept, and intellectual development of children.

## Family Influences

The school-age years are a time for peer relationships, questioning of parents, and the potential for parental conflict but continued respect for family values. School-age years are the beginning of the time of peer-group influence, with testing of parental and family values. Although the peer group is influential, the family's values usually predominate when parental and peer-group values come into conflict. Even though the school-age child may question the parents' values, the child will usually incorporate the values from parents into his or her values.

Many times in the late school-age and preadolescent period, the child may prefer to be in the company of peers and show a decreased interest in family functions. This may require an adjustment for parents. Parents' awareness of this developmental trend and their continuing support for the child are important while they continue to enforce restrictions and control of behaviors. The school-ager is beginning to strive for independence, but parental authority and controls continue to impact choices and values.

### Take Note!

School-age children continue to need parenting. They do not need parents as pals.

## Cultural Influences on Growth and Development

Culture influences habits, beliefs, language, and values. School-age children thrive on learning the music, language, traditions, holidays, games, values, gender roles, and other aspects of culture. Nurses must be aware of the effects on children of various groups' family structures

and traditional values. The school-age child's cultural and ethnic backgrounds must be considered when assessing growth and development, including differences in growth in children of different racial and cultural backgrounds. Cultural implications must be considered for all children and families in order to provide appropriate care.

*Refer back to Lawrence Jones, who was introduced at the beginning of this chapter. What developmental milestones would you expect him to have reached by this age?*

## THE NURSE'S ROLE IN SCHOOL-AGE GROWTH AND DEVELOPMENT

Growth and development in the school-age child occurs in irregular spurts with a wide variation of sizes, shapes, and abilities seen. Nurses must be aware of the usual growth and development patterns for this age group so that they can assess school-age children appropriately and provide guidance to the child and his or her family. This is a time when children compare themselves to peers and self-esteem is a central issue. The school-age child is separating from his or her parents and seeks acceptance from peers and adults outside of his or her family. Health care visits throughout the school-age period continue to focus on expected growth and development and anticipatory guidance. Visits are more infrequent during the school-age years; therefore, the nurse needs to assess the child's functioning not only at home but also at school and within the community.

If the school-age child is hospitalized, growth and development may be altered. The school-age child is able to understand the reason for hospitalization and what will happen. He or she is often worried about pain or changes that may occur to his or her body. It is important for physicians and family members to be honest and open with the school-age child. The school-age child may miss school and the interactions with his or her peers. The school-age child may regress and exhibit behaviors of a younger child, such as needing special comfort toys or demanding attention from his or her parents. Hospitalization for the school-age child can bring with it a loss of control. The school-age child is used to controlling his or her self-care and making choices about his or her meals and activities.

When caring for the hospitalized school-age child, the nurse must use knowledge of normal growth and development to recognize potential delays, promote continued appropriate growth and development, and interact successfully with the school-age child. Provide opportunities for the school-age child to maintain independence, gain control, and increase self-esteem.

## NURSING PROCESS OVERVIEW

Upon completion of assessment of the school-age child's current growth and development status, problems or issues related to growth and development may be identified. The nurse may then identify one or more nursing diagnoses, including:

- Risk for disproportionate growth
- Imbalanced nutrition: more than body requirements
- Delayed growth and development
- Risk for caregiver role strain
- Risk for injury

Nursing care planning for the school-age child with growth and development issues should be individualized based on the school-age child's and family's needs. The nursing care plan can be used as a guide in planning nursing care for the school-age child with a growth and development concern. The nurse may choose the appropriate nursing diagnoses from Nursing Care Plan 28.1 and individualize them as needed. The nursing care plan is intended to serve as a guide, not to be an all-inclusive growth and development care plan.

## Promoting Healthy Growth and Development

The family plays a critical role in promoting healthy growth and development of the school-age child. Respectful interchange of communication between the parent and child will foster self-esteem and self-confidence. This respect will give the child confidence in achieving personal, educational, and social goals appropriate for his or her age. The nurse should study interactions between parents and school-age children to observe for this respect or lack of respect ("putting the child down"). The nurse can model appropriate behaviors by listening to the child and making appropriate responses. The nurse can be a resource for parents and an advocate for the child in promoting healthy growth and development.

## Promoting Growth and Development Through Play

Cooperative play is exhibited by the school-age child. Play for the school-age child includes both organized cooperative activities (such as team sports) and solitary activities. School-age children have the coordination and intellect to participate with other children their age in sports such as soccer, baseball, football, and tennis. The school-age child comprehends that his or her cooperation with others will lead to a unified whole for the team. Additionally, the child learns rules and the value of playing by the rules.

## NURSING CARE PLAN 28.1

**Growth and Development Issues of the School-Age Child**

**NURSING DIAGNOSIS:** Risk for disproportionate growth (risk factors: caregiver knowledge deficit, frequent illnesses)

**Outcome Identification and Evaluation**

School-age child will demonstrate adequate growth: *appropriate weight gain and increases in height for age and gender*

**Interventions: Promoting Proportionate Growth**

- Assess parent's knowledge of nutritional needs of school-age children *to determine need for further education.*
- Plot out height, weight, and body mass index (BMI) *to detect possible pattern.*
- Determine need for additional caloric intake if necessary *(if very active in sports, if have a chronic illness).*
- Educate parent about appropriate serving sizes and foods *so that parent is aware of what to expect for school-age children.*

**NURSING DIAGNOSIS:** Ineffective Health Maintenance related to lack of exercise, increased caloric intake, poor food choices

**Outcome Identification and Evaluation**

School-age child will engage in health maintenance behaviors and lose weight at an appropriate rate: *increase amount of exercise, make appropriate eating choices, decrease caloric intake to appropriate amount for age and gender*

**Interventions: Promoting Appropriate Health Maintenance Behaviors**

- Assess knowledge of parents and child about nutritional needs of school-age children *to determine deficits in knowledge.*
- Plot out height, weight, and BMI *to detect weight loss or weight gain.*
- Have child keep food and exercise diary for 1 week *to determine current patterns of eating and exercise.*
- Interview parents in relationship to their eating habits and exercise habits *to determine where adjustments might need to be made.*
- Analyze preceding data, and base recommendations for changes on these data.
- Discuss ways to decrease temptation to overeat and to make good meal choices (see Teaching Guideline 28.2).
- Have child assist in meal planning and grocery shopping *to allow him or her some sense of control in process.*
- Incorporate increase in daily exercise, which will stress sense of self-improvement, *to increase caloric expenditure and self-esteem.*
- Decrease TV/computer time *to increase caloric expenditure.*
- Develop reward system *to increase self-esteem.*
- Investigate joining weight-loss program for school-age children *to increase self-esteem and to increase awareness that other children have the same problem.*

**NURSING DIAGNOSIS:** Growth and development, delayed related to speech, motor, psychosocial, or cognitive concerns as evidenced by delay in meeting expected school performances

## NURSING CARE PLAN 28.1

**Growth and Development Issues of the School-Age Child** (continued)**Outcome Identification and Evaluation**

*Development will be maximized:* School-age child will make continued progress toward attainment of expected school performances.

**Interventions: Promoting Growth and Development**

- Perform scheduled evaluation of the school-age child by school and physician *to determine current functioning.*
- Develop realistic multidisciplinary plan *to ensure maximizing resources.*
- Carry out interventions as prescribed by developmental specialist, physical therapist, occupational therapist, or speech therapist at home and at school *to maximize benefit of interventions.*
- Have scheduled evaluation meetings *to be able to adapt interventions as soon as possible.*

**NURSING DIAGNOSIS:** Caregiver role strain, risk for (risk factors: new sibling in household, knowledge deficit about school-age issues, lack of prior exposure, fatigue, ill or developmentally delayed child)

**Outcome Identification and Evaluation**

Parent will experience competence in role: *will demonstrate appropriate caretaking behaviors and verbalize comfort in caring for a school-age child*

**Interventions: Preventing Caregiver Role Strain**

- Assess parents' knowledge of school-age children and the issues that arise as a part of normal development *to determine parents' needs.*
- Provide education on normal issues of school-age children so that parents are armed with the knowledge they need *to appropriately care for their school-age child.*
- Provide anticipatory guidance related to upcoming expected issues related to school-age development *to prepare parents for what to expect next and how to intervene.*

**NURSING DIAGNOSIS:** Injury, risk for (risk factors: curiosity, increasing cognitive skills and motor abilities)

**Outcome Identification and Evaluation**

School-age child's safety will be maintained: *will remain free from injury*

**Interventions: Preventing Injury**

- Discuss safety measures needed for the following: bikes, scooters, guns, skateboards, cars, water, and playground *to decrease risk of injury related to those areas.*
- Discuss and develop a fire safety plan *to decrease risk of injury related to fire.*
- Discuss appropriate safety equipment needed for each sport *to decrease risk of injury.*
- Discuss appropriate sports to participate in depending on age, sex, and maturity of child *to prevent possible injury and to promote child's self-esteem.*
- Instruct parents to post the Poison Control Center phone number *(in the event of accidental ingestion, Poison Control can give parents the best advice for appropriate intervention).*
- Teach parents and child first-aid measures and child cardiopulmonary resuscitation (CPR) *to minimize consequences of injury should it occur.*
- Discuss influence of peers on actions of school-age children *to prevent possible injury due to mimicking behavior.*

**FIGURE 28.6** This school-age girl enjoys solitary play with her dollhouse and dolls.

School-age children also enjoy solitary activities including board, card, video, and computer games, and dollhouse and other small-figure play (Fig. 28.6). Many school-agers start collections of stamps, cars, or other valuable or not-so-valuable items. During the school-age years, children may also begin a scrapbook or keep a diary. They may participate in activities such as dance or karate. Girls and boys may join clubs, gangs, or special interest groups.

Active play has decreased in recent years as television viewing and computer games have increased. This trend has resulted in health risks such as obesity, type 2 diabetes, and cardiovascular problems.

## Promoting Learning

School attendance and learning are very important to the school-age child. Parent–child, child–teacher, and child–peer relationships and activities influence the school-age child’s learning.

### Formal Education

Most children are excited about starting school and making new friends. They like the notion of getting books, having book bags, and having homework assignments. The reality of the work involved with school and homework may decrease the enthusiasm about school.

Peers are very important within this age group. Both peers and teachers influence children. Attending school may be their first experience interacting with a large number of children their own age. Through this interaction, children learn cooperation, competition, and the importance of following the rules. Peer approval and influences grow as the child matures. Teachers have significant influences on children. They help to guide the child’s intellectual development by rewarding successes and helping the child deal with failures. The student–teacher relationship is a key to success. Teachers play a role in fostering feelings of industry and preventing feelings of inferiority (Fig. 28.7). School-age children also

**FIGURE 28.7** School is important to the school-age child.

learn skills, rules, values, and other ways to work with peers and other authority figures.

Parental support is important for school adjustment and achievement. Parents must collaborate with teachers and school personnel to ensure that the child is fulfilling the expectations and requirements for this age group in school. Parents must monitor the child’s homework assignments and friends, and observe for any changes in behavior that would indicate school or behavioral problems.

### Reading

Encouraging reading is an excellent way to promote learning in the school-age child. Trips to the library and purchasing books help to promote a love of reading. School-age children enjoy being read to as well as reading on their own. Younger school-age children (6 to 8 years) enjoy books that are simple to read with few words on a page, such as the Dr. Seuss books. They enjoy books about animals and trains and simple mysteries. Children 8 to 10 years of age have more advanced reading skills and enjoy those books from early childhood, plus more classic novels and adventures such as the Harry Potter series. Older children enjoy horror stories, mysteries, romances, and adventure stories as well as classic novels. School-age children of all ages benefit from books on topics related to things they may be experiencing, such as a visit to the hospital for a surgical procedure. See Box 28.1 for ideas for parents to promote reading in the school-age child.

## Promoting Safety

School-age children become more independent with age. This independence leads to an increased self-confidence and decreased fears, which may contribute to accidents and injuries. School age is a time that the child may walk to school with peers who may influence his or her behavior. Increased independence may also increase exposure to dangerous situations such as the approach of strangers or unsafe streets. Promotion of safe habits

## BOX 28.1

**PROMOTION OF READING IN SCHOOL-AGE CHILDREN**

- Parents, read to and with your children.
- Ask teachers and librarians for advice on books appropriate for your child.
- Choose stories that the child can relate to if the child has difficulty reading.
- Choose books with movement if the child has a short attention span.
- Take advantage of all reading opportunities (cereal boxes, road signs).
- Provide choices for the child to select a book of interest.
- Talk about the text and ask questions to improve understanding.
- Keep a record of what the child is reading.
- Visit a library, get a library card, and check out books.
- Parents, demonstrate role modeling through reading books.

during the school-age years is important for parents and nurses. See Teaching Guidelines 28.1 for additional information on safety education for nurses and parents.

**Teaching Guidelines 28.1****SAFETY ISSUES AND INTERVENTIONS OF THE SCHOOL-AGE CHILD****Issue****Interventions**

Car safety

- Seat belt or age- and weight-appropriate booster seat (usually until 80 pounds and about 4 feet 9 inches) should be used at all times.
- Seat belts should be fastened before car is started.
- Children under 12 years must sit in back seat.
- Childproof locks should be used in back seat.
- Rules of conduct for car rides must be established.
- Remind child to wear seat belt and use appropriate booster if needed when riding with others.

Pedestrian safety

- Child should be instructed on looking right, left, then right again before crossing the street; and crossing only at safe crossings.
- Older children and adults should provide supervision of younger children.
- Walking should only be done on sidewalks.

Bike safety:  
general

- In parking lots, children should know to watch for cars backing up and not dart out between parked cars.
- If children are playing outside, drivers should be aware of their presence before backing up.
- Bikes should be well-maintained and appropriately sized.
- Child should be oriented to bike and demonstrate ability to ride bike safely before being allowed to ride on street.
- Safe areas for bike riding should be established as well as routes to and from area of activities.
- Riding bike barefoot, with someone else on bike, or with clothing that might get entangled in the bike should be prohibited.
- Child should know to wear sturdy, well-fitting shoes.
- Child should know to wear ANSI-approved helmets.
- Bike should be inspected often to ensure it is in proper working order.
- A basket should be used to carry heavy objects.

Bike safety in  
traffic

- All traffic signs and signals must be observed.
- If riding at night, the bike should have lights and reflectors and the rider should wear light-colored clothes.
- Child should know to ride on the side of the road traveling with traffic, and keep close to the side of the road in single file.
- Child should learn to watch and listen for cars.
- Headphones should not be used while riding a bike.
- Never hitch a ride on any vehicles.

Sports safety

- Sports should be matched to child's ability and desire.
- Sports program should have warm-up procedure.
- Coaches should be trained in cardiopulmonary resuscitation (CPR) and first aid.
- Appropriate protection devices should be used for individual sport.

- Skateboarding and inline skating safety
  - Child should wear helmet, and protective padding on knees, elbows, and wrists
  - Child should know not skate in traffic or on streets or highways.
  - Homemade ramps should be assessed for hazards before skating.
- All-terrain vehicle safety
  - Child should be at least 16 years of age to operate vehicle.
  - Helmets must be worn in addition to protective coverings.
  - No nighttime riding.
  - Use should be avoided on public roads.
  - Never stand up in the vehicle or ride in a person's lap.
- Fire safety
  - All homes should have working smoke detectors and fire extinguishers. Change the batteries at least twice a year.
  - Have a fire-escape plan.
  - Practice fire-escape plan routinely.
  - Nobody should smoke in the home.
  - Teach what to do in case of a fire: use fire extinguisher, call 911, and how to put out clothing fire.
  - Use stove and other cooking facilities under adult supervision.
  - All flammable materials and liquids should be stored safely.
  - Fireplaces should have protective gratings.
  - Teach children to avoid touching wires they might encounter while playing.
- Water safety
  - Teach children how to swim.
  - If swimming skill is limited, child must wear life preserver at all times.
  - Child should know never swim alone—if at all possible, swim only where there is a life guard.
  - Understand basic CPR.
  - Teach child to never run or fool around at edge of pool.
  - Drains in pool should be covered with appropriate cover.
  - Life jackets should be worn when on boat.
  - Make sure water is deep enough to support diving.
- Firearm safety
  - Teach child never to touch gun—tell adult.

#### Toxin safety

- If have guns in household, need to secure them in safe place, store them unloaded, use gun safety locks, store bullets in separate place.
- Never point a gun at a person.
- Teach child the hazards of accepting illegal drugs, alcohol, or dangerous drugs.
- Store potential dangerous material in safe place.

Retrieved June 30, 2012, from <http://www.healthychildren.org/English/tips-tools/Pages/Safety-for-Your-Child-6-Years.aspx>; American Academy of Pediatrics, The Injury Prevention Program. (2012b). *Safety for your Child: 8 years*. Retrieved June 30, 2012 from <http://www.healthychildren.org/English/tips-tools/Pages/Safety-for-Your-Child-8-Years.aspx>; American Academy of Pediatrics, The Injury Prevention Program. (2012c). *Safety for your Child: 10 years*. Retrieved June 30, 2012 from <http://www.healthychildren.org/English/tips-tools/Pages/Safety-for-Your-Child-10-Years.aspx>; Centers for Disease Control and Prevention (2010). *Unintentional drowning: Fact sheet*. Retrieved March 23, 2011, from <http://www.cdc.gov/HomeandRecreationalSafety/Water-Safety/waterinjuries-factsheet.html>; and Hagan, J. F., Shaw, J. S., & Duncan, P. (2008). *Bright futures guidelines for health supervision of infants, children, and adolescents* (3rd ed.). Elk Grove Village, IL: American Academy of Pediatrics.

Unintentional injuries are the leading cause of death in children between 1 and 21 years of age (Centers for Disease Control and Prevention [CDC], 2009). Each year, 20 million children sustain an injury sufficiently severe to seek medical attention (Borse et al., 2008; CDC, 2008). School-age children are very active at home, in the community, and at school. This increased mobility, activity, and time away from parents increases the risk for unintentional injuries. School-age children continue to need supervision and guidance. They need information and rules about car safety, pedestrian safety, bicycle and other sport safety, fire safety, and water safety.

#### Car Safety

Motor vehicle accidents are a common cause of injury in the school-age child. While traveling in the car, school-age children should always sit in the rear seat. The front seat is dangerous because of passenger-side airbags in most new-model cars. The school-age child should use a three-point restraint system in the rear seat of the car with the shoulder strap and lap belt fitted snugly. In addition, a school-age child over 40 pounds (generally 4 to 8 years of age) should use a belt-positioning, forward-facing booster seat using both lap and shoulder belts (National Highway Traffic Safety Administration [NHTSA], 2008). School-age children who outgrow the convertible restraint can sit in a booster seat until their head is higher than the vehicle seat back (usually 4'9" and taller) (NHTSA, 2008). Children younger than 12 years of age should not ride in the front seat of a vehicle with an airbag (NHTSA, 2008).

## Pedestrian Safety

Twenty percent of fatal crashes in children between the ages of 5 and 9 involve pedestrian-related fatalities (Percer, 2009). Children younger than 10 years of age should not cross the street alone (Percer, 2009). Young school-age children therefore should walk to school or the bus with an older friend, sibling, or parent. Darting out into the street without looking both ways or from between cars is a common occurrence in the school-age years. Teach children safe street and pedestrian practices.

## Bicycle and Sport Safety

Bicycling, riding scooters, skateboarding, and inline skating or rollerskating are common activities of school-age children. Laws in most states require helmets for riding bicycles and scooters. In addition, when skating or skateboarding, school-age children should wear a helmet, kneepads, and elbow pads.

Research has shown that head injuries due to bicycle accidents have been reduced by 85% by wearing a well-fitting helmet (Bicycle Helmet Safety Institute, 2009). National estimates of bicycle helmet ownership and use varies greatly among different areas and sectors of the U.S., but overall it is estimated at about 25% (Bicycle Helmet Safety Institute, 2009) (see Healthy People 2020). It is important for children to wear helmets that fit and that do not obstruct their vision or hearing. Because school-age children have completed most of their skull growth, a helmet can be worn into adolescence. It is important for the child to have a bicycle that is appropriate for his or her size and age. The child should be able to plant both feet on the ground when sitting on the seat of the bike (Fig. 28.8). It is important to stress to parents the importance of appropriate size and not to get a bike for the child to “grow into.” If older school-agers are using the bike for transportation on busy streets, they should be taught to use bike lanes and to give appropriate hand signals for turning. Nonmotorized and motorized scooters also place children at risk for injury, so counsel families

**FIGURE 28.8** Wearing the appropriate safety equipment and having an appropriately sized bicycle are important to prevent injuries in school-age children.

about the use of protective gear, including helmets, elbow pads, and kneepads.

## Fire Safety

School-age children are eager to help parents with cooking and ironing. They are curious about fire and are drawn to play with fire, matches, and fireworks. Serious burns can occur from any exposure to fire. Educate children about the hazards of fire. In addition, teach children proper behavior around fires at home and outdoors. Always supervise children in the use of matches. In the home setting, parents should develop a fire safety plan with their children, teach children what to do if their clothes catch on fire, and practice evacuating the house in the event of a fire. In the school setting, children should be aware of the appropriate response to fire drills and fire drills should be conducted on a regular basis.

## Water Safety

Teach school-age children swim and water safety. An adult should always supervise children when they are swimming to prevent water-related accidents.

## Abuse in Children

Child abuse, including physical abuse and sexual abuse, is a common crime of violence against children. An

### HEALTHY PEOPLE 2020

Objective	Nursing Significance
Reduce fatal and nonfatal traumatic brain injuries.	<ul style="list-style-type: none"> <li>• Provide education to children and their parents about avoiding head injury through helmet use.</li> <li>• Encourage child to choose a helmet that appeals to him or her (one that looks “cool”).</li> </ul>

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

estimated 3.3 million reports of child abuse are made annually to child protective services in the United States (CDC, 2010c). Over 772,000 cases were substantiated in 2008, with 71% being victims of neglect, 16% victims of physical abuse, 9% victims of sexual abuse, and 7% victims of emotional or psychological abuse (CDC, 2010c). The abusers of children are family, friends, and strangers. It is important for parents to teach children the concept of “good touch” versus “bad touch” prior to school-age years. Whenever the school-age child’s behavior yields suspicion of physical or sexual abuse, the nurse should report to the appropriate authorities in his or her state. These topics will be discussed in more depth in Chapter 52.

*Remember Lawrence Jones, the 10-year-old presented in the case study? What anticipatory guidance related to safety should you provide to his mother?*

## Promoting Nutrition

Growth, body composition, and body shape remain constant during late school-age years. Needed calories decrease while the appetite increases. In preparation for adolescence, the body fat composition of school-age children increases. This tendency toward increased body fat

occurs earlier in girls than in boys, with the amount of increase greater in girls. Boys have more lean body mass per inch of height than girls.

Diet preferences established in the preschool years continue during the school-age period. As the child grows older, influences of family, media, and peers can impact the eating habits of this age group. Some of these influences are parents’ work schedule, outside activities, and exercise level of the child. Decreased exercise levels and poor nutritional choices lead to the mounting problem of obesity seen in this age group. See Box 28.2 for appropriate questions to ask the child and parent regarding nutritional status. Healthy People 2020 provides objectives and actions to improve the nutritional health of children.

### BOX 28.2

#### DIETARY QUESTIONS

##### Questions for the Child

- How often do you eat together as a family?
- What are the usual mealtimes?
- How often does the family eat out?
- Do you eat breakfast regularly?
- Where do you eat lunch?
- What do you drink/how much?
- What foods do you eat most often?
- What is your favorite food?
- How often do you eat fast foods?
- What type of exercise do you do?

##### Questions for the Parents

- How would you describe your child’s usual appetite?
- Do you have any special cultural/religious practices regarding food?
- Has your child gained or lost weight recently?
- Do you have any concerns about his or her eating behaviors?
- How does your child exercise? Your family?
- Is there a family history of cancer, hypertension, diabetes, obesity, or heart disease?

### HEALTHY PEOPLE 2020

#### Objective

#### Nursing Significance

Increase the contribution of fruits to the diets of the population aged 2 years and older.

- Educate families about the importance of whole grains, fruits, and vegetables in the diet.

Increase the contribution of total vegetables to the diets of the population aged 2 years and older.

- Encourage the child to choose fruits and vegetables that appeal to him or her.

Increase the contribution of dark green vegetables, orange vegetables, and legumes to the diets of the population aged 2 years and older.

- Provide creative suggestions for vegetable preparation to make them more appealing to children.

Increase the contribution of whole grains to the diets of the population aged 2 years and older.

- Educate families about saturated fat-containing foods.

Reduce consumption of calories from solid fats.

- Offer suggestions for alternate sources of proteins and fats (chicken or fish, olive oil).

Reduce consumption of calories from added sugars.

Reduce consumption of calories from solid fats and added sugars.

Reduce consumption of saturated fat in the population aged 2 years and older.

Reduce consumption of sodium in the population aged 2 years and older.

Increase consumption of calcium in the population aged 2 years and older.

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

## Nutritional Needs

The school-age child's calorie needs vary based on age, gender, and activity level. In general, children with higher activity levels and male gender have higher calorie needs (U.S. Department of Agriculture and U.S. Department of Health and Human Services, 2010). Boys and girls 4 to 8 years old who are moderately active will need about 1,400 to 1,600 calories a day (U.S. Department of Agriculture and U.S. Department of Health and Human Services, 2010). Boys 9 to 13 years old who are moderately active need about 1,800 to 2,000 calories a day, while girls this age who are moderately active need about 1,600 to 2,000 calories a day (U.S. Department of Agriculture and U.S. Department of Health and Human Services, 2010). Of these calories, 45% to 65% should come from carbohydrates, 10% to 30% from protein, and 25% to 35% from fat (U.S. Department of Agriculture and U.S. Department of Health and Human Services, 2010). The 4- to 8-year-old child needs 800 to 1,000 mg of calcium, while the 9- to 13-year-old needs 1,300 mg of calcium for maintenance of growth and good nutrition (Krebs, Primark, & Haemer, 2011). Calcium is needed for the development of strong bones and teeth. Milk, yogurt, and cheese provide protein, vitamins, and minerals and are an excellent source of calcium. Meats, poultry, fish, and eggs provide protein, vitamins, and minerals.

## Promoting Healthy Eating Habits

School-age children should choose culturally appropriate foods and snacks from the U.S. Department of Agriculture's MyPyramid (Fig. 28.9). MyPyramid.gov offers many tools for the child to use including development of personalized goals and menus, online dieting and physical activity assessment tools, games, activities, and tips for parents. School-age children need to limit intake of fat and processed sugars. A prudent diet limits the use of fatty meats, high-fat dairy products, eggs, and hydrogenated shortenings and promotes the consumption of fish and the substitution of polyunsaturated vegetable oils and margarines. The American Heart Association has endorsed a diet for school-age children that includes the recommendations listed in Box 28.3.

## Preventing the Development of Overweight and Obesity

The National Health and Nutrition Examination Survey (NHANES) found that more and more children are overweight. Over the past three decades the number of overweight children and adolescents more than tripled. Thirty percent of 6- to 11-year-olds are overweight or at risk for overweight (CDC, 2012). Overweight is classified as a body mass index (BMI) greater than 85% and obese is classified as a BMI greater than 95% (Krebs et al., 2011;

### BOX 28.3

#### AMERICAN HEART ASSOCIATION'S DIET RECOMMENDATIONS FOR SCHOOL-AGE CHILDREN

- A high-quality protein with every meal
- Milk with added vitamin D and other low-fat dairy products
- Vegetables high in vitamin A
- Fruits high in vitamin C
- Whole-grain or enriched breads or cereals
- Vegetable oils high in polyunsaturated fats
- Meats (4 servings per week of 4 ounces each)
- Fish (1–2 times per week)
- Poultry (1–2 times per week)
- Dark green, leafy, or deep yellow vegetables (at least 4 times per week)
- Eggs (4 times per week)

Adapted from American Heart Association, Gidding, S. S., Dennison, B. A., Birch, L. L., Daniels, S. R., Gilman, M. W., et al. (2006). Dietary recommendations for children and adolescents: A guide for practitioners. *Pediatrics*, 117(2), 544–559.

U.S. Department of Agriculture and U.S. Department of Health and Human Services, 2010) (see Healthy People 2020).

### HEALTHY PEOPLE 2020

Objective	Nursing Significance
Reduce the proportion of children and adolescents who are considered obese.	<ul style="list-style-type: none"> <li>• Screen all children for the development of overweight as indicated by an increasing body mass index (BMI) for their age.</li> <li>• Provide accurate diet counseling.</li> </ul>
Prevent inappropriate weight gain in youth.	<ul style="list-style-type: none"> <li>• Encourage daily physical activity.</li> <li>• Counsel parents to limit television/computer time daily.</li> </ul>

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

Obesity occurs when the intake of calories and food exceeds the expenditures. Some factors linked to causing obesity include family role modeling, lack of exercise, unstructured meals, consumption of sugar-sweetened beverages, large portion sizes, television viewing, and video gaming as well as cultural, genetic, environmental, and socioeconomic factors. Some factors that influence lack of exercise include the decreased number of days that school systems offer physical education programs and recess. Also, some children live in unsafe neighborhoods or in a community that lacks sidewalks or parks

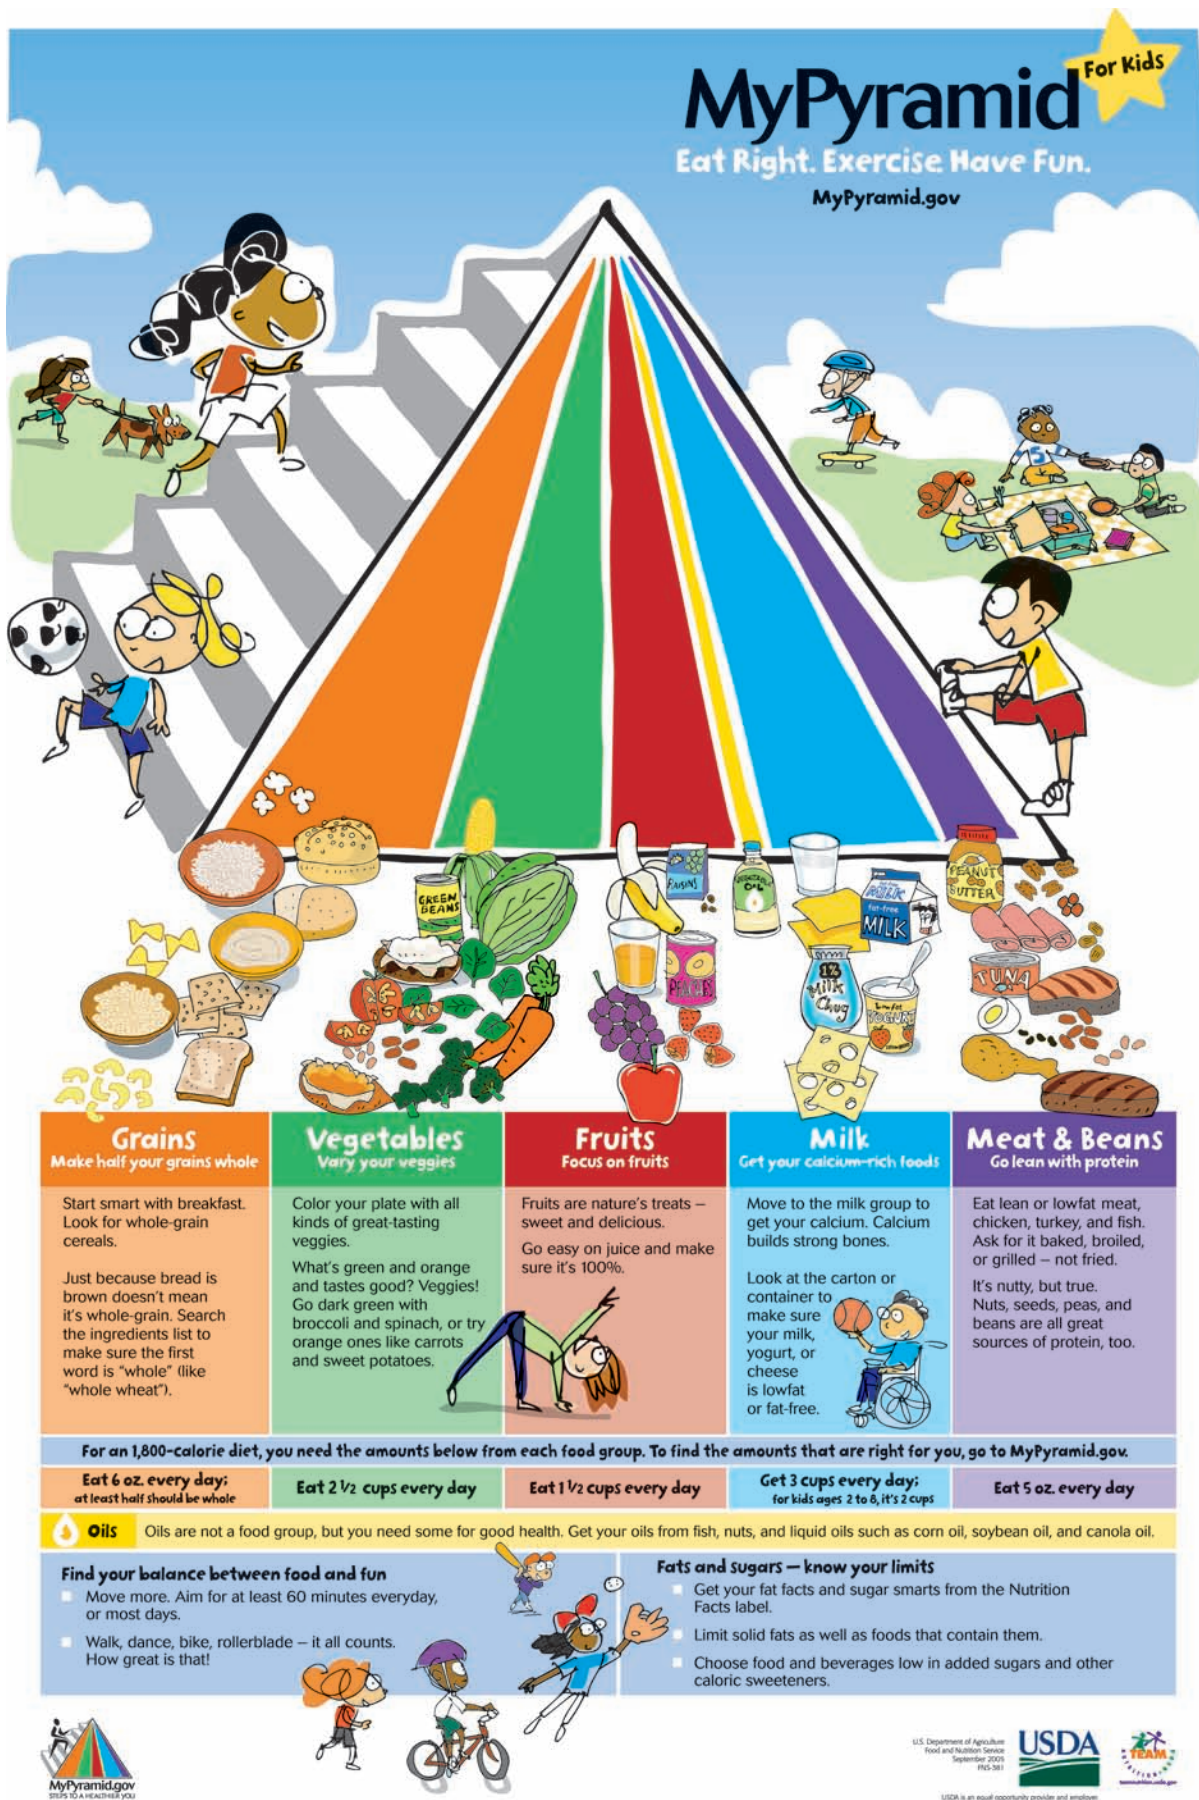

FIGURE 28.9 MyPyramid for kids. Eat foods from each color every day; choose more foods from the food groups with the wider stripes. (From U.S. Department of Agriculture [2005]. *My pyramid for kids*. Retrieved March 21, 2011, from [http://teamnutrition.usda.gov/Resources/mpk\\_poster2.pdf](http://teamnutrition.usda.gov/Resources/mpk_poster2.pdf))

and have no safe place to play outside; therefore, they spend time doing sedentary activities such as watching TV or playing video or computer games (U.S. Department of Agriculture and U.S. Department of Health and Human Services, 2010). Obese children are at risk for cardiovascular diseases such as high cholesterol and hypertension, type 2 (non-insulin-dependent) diabetes, respiratory complications such as obstructive sleep apnea, mental health issues such as depression, anxiety and eating disorders, and orthopedic problems (Krebs et al., 2011; U.S. Department of Agriculture and U.S. Department of Health and Human Services, 2010). When parents do not have knowledge of nutrition, do not monitor snacks or meals, and have unstructured meals, habits are established that lead to obesity.

Preventing obesity in childhood is important because the fat cells of childhood are carried into adulthood obesity and contribute to disease. Due to the risk of obesity, encourage parents to never use food as a reward. To prevent obesity, establish regular mealtimes and offer healthy foods and snacks. Encourage parents to praise their child's good food choices and to role model appropriate eating and exercise.

*Regarding Lawrence Jones, what questions should you ask Lawrence's mother related to nutritional intake? What anticipatory guidance related to nutrition would be appropriate?*

## Promoting Healthy Sleep and Rest

The number of hours of sleep required for growth and development decreases with age. Children between the ages of 6 and 8 years require about 12 hours of sleep per night, children between 8 and 10 years of age require 10 to 12 hours of sleep per night, and children between 10 and 12 years of age need 9 to 10 hours of sleep per night. Young school-age children may need an occasional brief nap for an energy boost after being in school for most of the day. Bedtime rituals and consistent schedules continue to be important throughout the school-age years. Parents must facilitate the bedtime schedule and quiet time before bed. Bedtime is a special time for parents and children to read together, listen to stories or soothing music, share events of the day, and exchange expressions of affection (American Academy of Pediatrics, 2011). Children should have bedtime expectations as well as wake-up times and methods for waking up (alarm, calling by parent, and so forth).

Night terrors or sleepwalking may occur in 6- to 8-year-olds but should be resolved between the ages of 8 and 10 years. In the older school-age child (11 to 12 years), encourage parents to allow a variation in the sleep schedule on the weekends and a regular schedule on weekdays.

*Provide anticipatory guidance to Lawrence Jones's mother in relation to proper sleep for her 10-year-old son.*

## Promoting Healthy Teeth and Gums

Dental **caries** remains a leading chronic disease in the United States (CDC, 2010a; Peterson-Sweeney & Stevens, 2010). The incidence declined from the 1970s to the early 1990s, mostly due to the introduction of fluoride (National Institutes of Dental and Craniofacial Research, National Institutes of Health, 2008). Since then there has been a small but significant increase in the incidence of dental caries. Recent statistics show that 51% of children between the ages of 6 and 11 have dental caries in their primary teeth and 21% have dental caries in their permanent teeth (National Institutes of Dental and Craniofacial Research, National Institutes of Health, 2008).

Dental care with emphasis on prevention of caries is important in this age group. School-age children need to brush their teeth two to three times per day for 2 to 3 minutes each time with fluorinated toothpaste (Hirsch, 2009; American Academy of Pediatrics, 2012a) (Fig. 28.10). Parents should replace the toothbrush (soft) every 3 to 4 months (Peterson-Sweeney & Stevens, 2010). Flossing the teeth at least once daily is recommended along with limiting the intake of sugar to aid in the prevention of cavities

**FIGURE 28.10** Using correct technique to brush the teeth is important in the prevention of cavities.

and improved oral health (American Academy of Pediatrics, 2012). Parents must monitor teeth brushing, observe for abnormal alignment of their child's teeth, and schedule regular dental examinations every 6 months to ensure good dental health and prevent dental problems. Children may need help with brushing teeth until they are between 7 and 10 years of age.

Dental sealants are recommended for all school-age children (CDC, 2010a). The sealant is a plastic coating applied to biting surfaces to seal out tooth decay on permanent back teeth. In addition, parents should give a fluoride supplement (as directed by the dentist) to their children if fluoride is not in the town's water supply (American Academy of Pediatric Dentistry, 2008). The school-age child should have an established dental home; if not, provide appropriate resources to establish one (Hagan, Shaw, & Duncan, 2008).

Sometimes dental care is not considered to be important by parents of young children because the primary teeth will be replaced by permanent teeth. This perception leads to complications of permanent teeth such as **malocclusion**, a condition in which the teeth are crowded, crooked, or misaligned (see Healthy People 2020).

### HEALTHY PEOPLE 2020

#### Objective

#### Nursing Significance

Reduce the proportion of children and adolescents who have dental caries in their primary or permanent teeth.

Reduce the proportion of children and adolescents with untreated dental decay.

Increase the proportion of children who have received dental sealants to their molar teeth.

- Encourage appropriate toothbrushing and flossing.
- Educate child and family about fluoride use.
- Refer school-age children to dentist for regular check-ups and interventions such as molar sealants.
- Assist families lacking dental insurance to find resources for the provision of dental care.

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

Proper alignment of teeth is important to tooth formation, speech development, and physical appearance. Many school-age children need braces or other orthodontic devices to correct malocclusion, a condition in which the teeth are crowded, crooked, or misaligned. **Bruxism** or teeth grinding while asleep may continue in the school-age years. Bruxism may result in grinding away of tooth enamel. Teeth grinding may be due to malalignment. A dental evaluation should be scheduled if consistent teeth grinding occurs.

Children wearing braces are more prone to cavities; encourage them to brush their teeth after meals and snacks. School nurses can assist these children with brushing after lunch. In addition, the school nurse should promote dental health through education on dental care and gum problems that result from lack of proper dental care. Diet can play a part in dental health. Limiting sticky, high-sugar, and high-carbohydrate foods will decrease the possibility of cavities.

## Promoting Appropriate Discipline

Because of the increasing ability of the school-age child to view situations from different angles, the school-age child should be able to see how his or her actions affect others. The school-age child is aware of the cause and effect of his or her behaviors and realizes that his or her behaviors have consequences. School-age children should be able to express emotions without using violence. Discipline techniques with consequences have both *natural* and *logical* consequences (Allen & Boelter, 2008). Natural consequences allow the child to learn the results of his or her actions. For example, if the child throws a toy out of the window, then he or she cannot play with the toy anymore. In logical consequences, if the child does not put away his or her bike, he or she does not get to ride the bike for the rest of the day.

In disciplining children, parents should teach children the rules established by the family, values, and social rules of conduct. Rules should provide the school-age child with guidelines about behavior that is acceptable and unacceptable. School-age children look to their parents for guidance and as role models. Parents should role model appropriate expressions of feelings and emotions and allow the child to express emotions and feelings. Discuss the effects of the child's temperament on his or her behavior, as well as what constitutes age-appropriate behavior. Include how the parents' temperament can influence the child's temperament.

Effective guidance and discipline focus on the development of the child. They can preserve the child's self-esteem and dignity. Discuss with parents guidelines regarding discipline. Explain to parents that they should never belittle the child. Children may view parents and caretakers negatively if they are consistently belittled or insulted. These negative actions can inhibit learning and teach the child to react unkindly to others. Instead, parents should discipline with praise. Positive acknowledgements of progress are likely to encourage healthy development and appropriate behavior (American Academy of Pediatrics, 2012b). Discuss with parents how to be realistic when planning activities so as to not overwhelm the child, resulting in misbehavior. Encourage parents to say "no" only when they mean it, to avoid a negative atmosphere in the home, and to avoid inconsistency.

When misbehaviors occur, the type and amount of discipline are based on different factors:

- Developmental level of both the child and the parents
- Severity of the misbehavior
- Established rules of the family
- Temperament of the child
- Response of the child to rewards

Keep in mind that school-age children should participate in developing a plan of action for their misbehavior. Whatever methods of discipline are chosen, it is important that parents are consistent in providing discipline in a nurturing environment.

## Addressing Common Developmental Concerns

The developmental task (according to Erikson) of the school-age child is industry (Erikson, 1963; Feigelman, 2011a). The school-age child is busy learning, achieving, and exploring. As the school-age child becomes more independent, forces other than the family such as television, video games, and peers influence him or her. Some of these influences are positive and others are negative. Some of the common developmental concerns for the school-age child are discussed in the following sections. Guidelines to assist the parents and nurses when encountering these concerns are included in Teaching Guidelines 28.2.

### Teaching Guidelines 28.2

#### ADDRESSING COMMON DEVELOPMENTAL CONCERNS

##### Television and Video Games

- Limit television watching and video-game playing to 2 hours per day.
- Monitor television programs.
- Prohibit television or video games with violence.
- Do not put television or video games in children's bedrooms.
- Provide a schedule of accepted television programs for viewing each week.
- Co-view television and video games with the child.
- Encourage sports, interactive play, and reading.

##### Obesity

- Provide healthy meals and snacks.
- Schedule and encourage daily exercise.
- Encourage involvement in sports.
- Restrict TV and computer-game use.
- Limit the amount of fast-food intake.
- Provide education about healthy nutrition.
- Never use food as a reward.
- Be a good role model.

##### School Phobia

- Return child to school.
- Investigate cause of the fear.
- Support child.
- Collaborate with teachers.
- Praise success in school attendance.

##### Latchkey Kids

- Provide rules to follow and expectations, such as:
  - Not answering the door or phone
  - No friends in the house when parents are not home
  - No playing with fire
- Teach child to call a trusted neighbor when help is needed and 911 in the event of emergency.
- Post all resource numbers (even numbers you think your child may have memorized), including after-school help lines if available, in a clearly viewable spot.
- Purchase caller ID for the phone system.
- Enroll the child in an after-school program if available.
- Discuss limitations of outside play.
- Discuss limitations of television viewing and video-game use.
- Make sure the child knows how to contact the parent.
- Set clear homework expectations.
- DO NOT keep guns in the home.

##### Stealing

- Educate parents about possibility of stealing.
- Discuss ways to teach concept of ownership and property rights.
- Handle situation openly.
- Assist child in developing and enacting a plan to return what was stolen.
- Make sure the punishment is appropriate for the action.

##### Lying

- Help parents in understanding why the child is lying.
- When the child lies, calmly confront the child and explain why the behavior is not acceptable.
- Educate parents that their behavior should reflect what they teach and expect from their child.
- Educate parents that too-rigid or severe punishments can decrease the child's sense of worth.
- Seek professional help if lying persists in the older school-age child, to rule out underlying problems.

##### Cheating

- Educate parents that the child must be mature enough to understand the concept of rules.
- Handle cheating situations openly.
- Help parents to understand why their child is cheating and to modify the trigger.
- Develop appropriate punishment; inappropriate punishment could undermine the child.
- Educate parents that their behavior should reflect what they expect from their child.
- Seek professional help if cheating persists in the older school-age child, to rule out underlying problems.

**Bullying****The Bullied Child**

- Educate parents whose children are at risk for being bullied, such as:
  - Children who appear different from the majority
  - Children who act different from the majority
  - Children who have low self-esteem
  - Children with a mental or psychological problem
- Teach parents to role-play different scenarios the child may face at school; show the child different ways to react to being bullied.
- Impress upon the child that he or she did not cause the bullying.
- Develop ways to increase the child's self-esteem at home.
- Discuss the situation with the teacher and develop a plan of care.

**The Bullying Child**

- Educate parents on reasons why it is important to correct the behavior.
- Discuss ways the child can appropriately show his or her anger and feelings.
- Have parents help the child to see how it feels to be bullied.
- Do not allow fighting at home.
- Reward settling of conflicts without violence.

**Tobacco and Alcohol Education**

- Inquire about tobacco and alcohol use.
- Discuss the physical and social dangers of tobacco and alcohol use.
- Urge parents to be good role models.
- Limit reading and media materials about alcohol and tobacco use.
- Discuss the influences of tobacco and alcohol use by peers.
- Educate the child on spit tobacco. Let them know it is just as dangerous as smoking tobacco.
- Advocate for a smoke-free environment in the home and other places frequented.
- Avoid having tobacco and alcohol products readily available in the home.

**Television and Video Games**

The influence of television and video games upon the school-age child is a growing concern for parents and child specialists. Children, 8 to 18 years of age, in the United States spend about 4 hours a day either watching TV or playing video games and another 2 hours on the computer outside of school work (Gavin, 2008). During that time, a child by the age of 18 will see 200,000 violent acts (Gavin, 2008). Although a school-age child can determine what is real from what is fantasy, research has shown that this amount of time in front of the TV—watching it or playing video games—can lead to aggressive behavior, less physical activity, and obesity (Gavin, 2008) (see Healthy People 2020).

**HEALTHY PEOPLE 2020****Objective**

Increase the proportion of children and adolescents who do not exceed recommended limits for screen time.

Increase the proportion of children and adolescents aged 2 years through 12th grade who view television or videos or play video games for no more than 2 hours a day.

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

**Nursing Significance**

- Assist families to identify activities other than television or video games for the child to participate in.
- Praise craft, music, and sports participation.

Although some television shows and video games can have positive influences on children, teach parents guidelines on the use of TV and video games. Parents should set limits on how much TV watching the child can have. The American Academy of Pediatrics recommends 2 hours or less of television viewing per day (Gavin, 2008). The parent should establish guidelines on when the child can watch TV, for example, after homework or when chores are completed (Gavin, 2008). Television watching should not be used as a reward. The parents should be aware of what the child is watching. Watch the programs together and use that opportunity to discuss the subject matter with the child. There should be no TV during dinner and no TV in the child's room. The parents need to set an example for the child. Read instead of watching TV or do a physical activity together as a family. If the TV causes fights or arguments, it should be turned off for a period of time.

**School Phobia**

**School refusal** (also called *school phobia* or *school avoidance*) has been defined as a refusal to attend school or difficulty remaining in school for an entire day. Behaviors include frequent absences, skipping classes, chronically late for school, severe misbehavior before school, or attending school with great fear. School phobia needs to be defined both symptomatically and operationally as the cause for the anxiety. School avoidance occurs in approximately 8.2% of children and adolescents (Kearney & Chapman, 2008).

Some of the fears expressed by school-refusing children include separating from parents, riding the bus, tests, bullying, teacher reprimands, anxieties over toileting in a public bathroom, physical harm, or undressing in the locker room. Due to the emotional distress caused in these children when attending school, they are frequently classified as having school phobia. Young children may

complain of stomachache or headache and older children may complain of palpitations or feeling faint.

It is important to investigate specific causes of school refusal/school phobia and take appropriate actions. Many times school phobia is a symptom of deeper problems. Children with extensive school refusal are at risk for dropping out of school, delinquency, and social and occupational problems in adulthood (Kearney & Chapman, 2008). The physician or nurse practitioner should conduct a physical examination of the child to rule out any physical illness. After these measures are taken, the parent, teacher, school counselor, and school administrator may devise a plan to assist the student to overcome a specific fear. In uncomplicated cases, parents must return the child to school as soon as possible. There may be altered schedules (partial days or decreased hours) to help promote a successful transition back to school. Another idea to help desensitize the child may be to have him or her spend part of the day in the counselor's or school nurse's office.

## Latchkey Children

With the increasing incidence of both parents in the workforce and many children living with just one parent, often times children return home alone without adult supervision for a number of hours. Most young children are not capable of handling stress or making decisions on their own before 11 or 12 years of age. However, some school-age children are more mature and can be left alone by 8 to 10 years of age; maturity is the key, not the age. Parents not only need to consider their child's maturity and readiness to be home alone but also must comply with legal requirements if present. Laws regarding the age at which it is legal to leave a child home alone vary by state; therefore, the nurse needs to be familiar with the state and local laws in order to assist parents in making decisions about when it is appropriate for their child to be home alone (Kroll & Nield, 2010). The American Academy of Pediatrics recommends that a school-age child come home to a parent or another responsible adult (American Academy of Pediatrics, 2009a).

Despite the level of maturity, children who are unsupervised are more likely to participate in risky behaviors such as smoking, drinking, and doing drugs (Kroll & Nield, 2010). Children left alone have a higher incidence of injuries such as burns, falls, and poisoning than children who are supervised (Kroll & Nield, 2010). In addition, latchkey children may feel anxiety, fear, boredom, or loneliness (Kroll & Nield, 2010).

If children come home to no supervision, they should know the names, addresses, and phone numbers of parents and a neighbor, as well as emergency numbers. They should be given rules about answering the door and the phone. They should tell anyone who comes to the door or who calls that mom is home but busy at this time. Directions as to the handling of the house key

and fire safety should be taught and demonstrated (see Teaching Guidelines 28.2).

## Stealing, Lying, and Cheating

It is during the school-age years that antisocial behaviors can emerge. Children who were previously well behaved may now exhibit behaviors such as stealing, lying, and cheating (Mannheim & Zieve, 2010). Parents are usually disturbed by this change in behavior. In turn, they have difficulty in addressing these issues and need help in providing appropriate interventions.

Children between 6 and 8 years old do not fully understand the concept of ownership and property rights. These children may steal things because they like the look of the item. By the age of 9, the child should respect others' possessions and property and understand that stealing is wrong (Children's Hospital of Boston, 2010). The school-age child may steal because he or she desires the item, feels peer pressure and is trying to impress his or her peers, or has a sense of low self-esteem (Children's Hospital of Boston, 2010). Stealing becomes a concern if the child steals and does not have remorse or continuously steals, or if stealing is accompanied by other behavior problems (Children's Hospital of Boston, 2010).

Lying is more common in boys and in children between 5 and 8 years old (Children's Hospital of Boston, 2010). It is acceptable for these children to tell tall tales, but they should know what truth is and what make-believe is. These younger children typically lie to avoid punishment. However, they do not like others to lie and will tell on them if they lie. Children between 8 and 12 years old typically lie because they are unable to meet expectations of family and peers, they are testing the rules and limits placed on them, or they are unable to explain bad behavior (Children's Hospital of Boston, 2010). If lying persists in older school-age children, parents should discuss the matter with a physician because the lying may be evidence of underlying problems.

The concept of cheating is not well understood until the child is 7 years old. Before this age, the desire to "win" is most important and rigid rules are hard to understand. In children between 8 and 12 years old, the concept of cheating is fully understood and following of rules becomes more important (Children's Hospital of Boston, 2010). Cheating is usually done because of competition and strong pressure placed on the child to succeed (American Academy of Pediatrics, 2010). If cheating persists in older school-age children, parents should discuss the matter with a physician because the behavior may indicate underlying problems.

In dealing with children who exhibit stealing, lying, or cheating behaviors, parents must first realize the importance of their own behaviors in those areas. Parents are role models to the school-age child. Therefore, when the child sees or hears that parents lie, steal, or cheat (e.g., parents

bragging about cheating on their taxes), they think it is all right to mimic those behaviors. Secondly, parents must directly confront any stealing, lying, or cheating behaviors and discuss (and follow through consistently with) the consequences of such behaviors (see Teaching Guideline 28.2).

## Bullying

Bullying, which is inflicting repeated verbal, emotional, or physical abuse upon others, is on the rise (Schoen & Schoen, 2010). Utilizing email, text messages, social networking, and instant messaging, often referred to as cyberbullying, is a growing concern. Bullies often look for victims who appear shy, weak, and defenseless. Children with disabilities are at an increased risk of being bullied (Schoen & Schoen, 2010).

In general, about 10% of all children attending school are frightened and afraid most of the day (American Academy of Child and Adolescent Psychiatry, 2008). Thirty percent of children in 6th to 10th grades bully or have been bullied (American Academy of Pediatrics, 2009b). Most of the bullying occurs at school (Augustyn & Zuckerman, 2011). Both boys and girls are bullied and can bully others; however, boys are twice as likely to be bullies and victims of bullying (Augustyn & Zuckerman, 2011). Boys usually bully other boys and use force more often, while girls can be bullied by both sexes using mainly verbal bullying, like social alienation and intimidation (Schoen & Schoen, 2010). Being bullied can have negative results on children throughout life. These children often have increased episodes of headaches, stomachaches, sleep problems, anxiety, loneliness, depression, and suicidal

tendencies (Schoen & Schoen, 2010). After the problem of either being bullied or being the bully has been identified, parents must work with the child, the school, and the physician to solve the problem (see Teaching Guidelines 28.2 and Evidence-Based Practice 28.1).

## Tobacco and Alcohol Education

School-age children are eager to grow up and be independent. Peers and acceptance are very important at this time. School-age children may be exposed to messages that are in conflict with their parents' values regarding smoking and alcohol. Peers often exert pressure for children to experiment with tobacco and alcohol (see Healthy People 2020).

### HEALTHY PEOPLE 2020

#### Objective

Reduce initiation of tobacco use among children and adolescents.

#### Nursing Significance

- Educate children and families about the dangers of tobacco use.

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

School-age children are ready to absorb information that deals with drugs and alcohol. Information from parents or other adults who are major influences in the child's life is essential at this time to set clear rules and

### EVIDENCE-BASED PRACTICE 28.1

#### DOES BEING INVOLVED IN BULLYING LEAD TO AN INCREASED RISK OF PSYCHOSOMATIC COMPLAINTS IN CHILDREN?

##### STUDY

In recent years health professionals and educators have become aware of the long term, adverse consequences of being involved in school bullying. Victimization can lead to low self-esteem, loneliness, depression and anxiety. Bullies are likely to display anti-social behavior, poor school adjustment, and substance use. A quantitative meta-analysis was performed to look at the association with being involved with bullying and psychosomatic complaints (such as headache, backache, abdominal pain). Eleven studies were found to meet the study inclusion criteria.

##### Findings

Upon analysis of the literature, the researchers found the bullying victims had a significantly higher risk for psychosomatic problems compared with uninvolved children. Bullies were also at risk although at a lower risk than victims.

##### Nursing Implications

Health care providers need to identify children at risk for being involved in bullying due to the long-term, negative consequences. Providers should be encouraged to incorporate questions that will allow them to assess the emotional functioning of the child and peer experiences of the child to help identify those at risk.

Adapted from Gini, G. & Pozzoli, T. (2009). Association Between Bullying and Psychosomatic Problems: A Meta-analysis. *Pediatrics*, 123(3), 1059-1065:doi:10.1542/peds.2008-1215.

model behaviors for children to embrace. Discussions with children need to be based on facts and focused on the present. Some topics for discussion include:

- What alcohol and drugs are like and how they harm you
- Differences in medical use versus illegal use of drugs
- How to think critically to interpret messages seen in advertising, media, sports, and entertainment personalities

See Teaching Guidelines 28.2.

*Recall Lawrence Jones, the 10-year-old presented at the beginning of the chapter. List potential developmental problems he may experience. What anticipatory guidance related to these concerns should you provide to his mother?*

## KEY CONCEPTS

- Physical growth is slow and steady, with social and cognitive development progressing rapidly, during the school-age years of 6 to 12. Height increases approximately 2.5 inches (6 to 7 centimeters) per year and weight gain is 3 to 3.5 kilograms (7 pounds) per year. Boys are taller and heavier than girls during this time period (Feigelman, 2011a).
- With entrance into the school system, school-age children have the influences of peers and teachers.
- With the development of gross motor skills and involvement in sports at school and in the community, safety education and practices are required. Also, with the participation in cooperative sports, injuries occur.
- Visual acuity is reaching maturation and 20/20 vision is expected by 7 years of age (Jarvis, 2008).
- Increased independence leads to increased exposure to safety hazards.
- The school-age child develops the cognitive ability to classify objects and to identify relationships among objects.
- Dental care is very important to prevent dental caries, malocclusion, and other problems. In early school age, the first primary teeth will be lost.
- The onset of puberty may occur by the later school-age years.
- Erikson's (1963) developmental task for the age group is the development of a sense of industry.
- Peers are very important, especially peers of the same sex. School-age children usually have a best friend and belong to clubs. They have collections of nonvaluable items such as rocks, clips, and so forth.
- School-age children are capable of concrete operations, solving problems, and making decisions. They continue to need guidance, rules, and direction from parents.
- The school-age child develops a conscience and knows cultural and social values. He or she can understand and obey rules.
- The school-age child incorporates religious practices into his or her life, which may be a source of comfort during stressful times.
- The nurse's role includes educating parents and school-age children in promoting health and safety.
- Nurses should inform the school-age child about expected developmental changes in the body to promote self-esteem and self-confidence.

## MULTIPLE CHOICE QUESTIONS

- The successful resolution of developmental tasks for the school-age child, according to Erikson, would be identified by:
  - Learning from repeating tasks
  - Developing a sense of worth and competence
  - Using fantasy and magical thinking to cope with problems
  - Developing a sense of trust
- Which of the following are reasons that stealing occurs in school-age children? (Choose all that apply.)
  - To escape punishment
  - High self-esteem
  - Low expectations of family/peers
  - Lack of sense of propriety
  - Strong desire to own something
- Which activities will promote weight loss in an obese school-age child? (Choose all that apply.)
  - Unlimited computer and TV time
  - Role modeling by family
  - Becoming active in sports
  - Eating unstructured meals
  - Involving child in meal planning and grocery shopping
  - Drinking three glasses of water per day
- As the school nurse conducting screening for vision in a 6-year-old child, you would refer the child to a specialist if the visual acuity in both eyes is:
  - 20/20
  - 20/25
  - 20/30
  - 20/50
- The mother of two sons, ages 6 and 9, states they want to play on the same baseball team. As the school nurse, what advice would you give their mother?
  - Having the boys on the same team will make it more convenient for the mother.
  - Levels of coordination and concentration differ, so the boys need to be on different teams.
  - Put the boys on the same team because they are both school-age children.
  - It is best to avoid putting the boys on the same team to prevent sibling rivalry.

## CRITICAL THINKING EXERCISES

- Ms. Sams brings her 8-year-old son, Frank, to the physician's office for his annual exam. She states that she is concerned about his recent behavior. He went to the grocery store with his friend and his friend's mother and he came home with a Matchbox car. The friend's mother stated she had not purchased the car.
  - What would be your response to Ms. Sams?
  - Ms. Sams said she still has the car. What would you advise Ms. Sams to do to make Frank aware of the consequences of his actions?
- Sally's mother is asking the nurse for advice about purchasing a two-wheeled bike for her 7-year-old. What guidance should the nurse offer this parent?
- Ms. Shaw brings in her 11-year-old daughter for a well-child check-up. The school-ager says to the nurse, "I look different from my friends. I do not wear bras and my friends are already wearing bras." What would be an appropriate response to this school-ager?
- Johnny is a 9-year-old whose mother and father both work during the day. He returns home after school. How should the parents prepare Johnny for this experience? What safety rules would be included in the education for Johnny?

## STUDY ACTIVITIES

- Attend a sporting event (such as soccer or baseball) with school-age teams. Describe the coordination and gross motor functioning of this group.
- Attend a first-grade class. Observe the behaviors exhibited by the school-age children in this class. How do these behaviors compare with normal values for this age group?

**KEY TERMS**

adolescence  
menarche  
peer groups  
puberty  
risk-taking behaviors  
sexuality

# Growth and Development of the Adolescent

## Learning Objectives

*Upon completion of the chapter, you will be able to:*

1. Define the key terms used in this chapter.
2. Identify normal physiologic changes, including puberty, occurring in the adolescent.
3. Discuss psychosocial, cognitive, and moral changes occurring in the adolescent.
4. Identify changes in relationships with peers, family, teachers, and community during adolescence.
5. Describe interventions to promote safety during adolescence.
6. Demonstrate knowledge of the nutritional requirements of the adolescent.
7. Demonstrate knowledge of the development of sexuality and its influence on dating during adolescence.
8. Identify common developmental concerns of the adolescent.
9. Demonstrate knowledge of the appropriate nursing guidance for common developmental concerns.

*Cho Chung is a 15-year-old girl brought to the clinic by her mother for her annual school check-up. During your assessment you measure Cho's weight at 110 pounds and her height at 60 inches. As the nurse caring for her, assess Cho's growth and development, and then provide appropriate anticipatory guidance to her and her mother.*

### **Words of Wisdom**

The only way to grow is to let go...

**Adolescence** spans the years of transition from childhood to adulthood, which is usually between the ages of 11 and 20 years. There is some overlap between late school age and adolescence. The adolescent experiences drastic changes in the physical, cognitive, psychosocial, and psychosexual areas. With this rapid growth during adolescence, the development of secondary sexual characteristics, and interest in the opposite sex, the adolescent needs the support and guidance of parents and nurses to facilitate healthy lifestyles and to reduce **risk-taking behaviors**.

## GROWTH AND DEVELOPMENT OVERVIEW

Adolescence is a time of rapid growth with dramatic changes in body size and proportions. The magnitude of these changes is second only to the growth in infancy. During this time sexual characteristics develop and reproductive maturity is achieved. The age of onset and the duration of the physiologic changes vary from individual to individual. Generally girls enter **puberty** earlier (at 9 to 10 years of age) than boys (at 10 to 11 years). Adolescents will represent varying levels of identity formation and will offer unique challenges to the nurse (Table 29.1).

## Physiologic Changes Associated with Puberty

The secretion of estrogen in girls and testosterone in boys stimulates the development of breast tissue in girls, pubic hair in both sexes, and changes in male genitalia. These biological changes that occur during adolescence are known as *puberty*. Puberty is the result of triggers among the environment, the central nervous system, the hypothalamus, the pituitary gland, the gonads, and the adrenal glands. Gonadotropin-releasing hormone (GnRH), produced by the hypothalamus, travels to the anterior pituitary gland to stimulate the production and secretion of follicle-stimulating hormone (FSH) and luteinizing hormone (LH). The increased levels of FSH and LH stimulate the gonadal response. LH stimulates ovulation in girls and acts on testicular Leydig cells in boys, prompting maturation of the testicles and testosterone production. FSH with LH stimulates sperm production. Estrogen, progesterone, and testosterone and other androgens are released from the gonads and affect biological changes and changes in various organs, including alterations in muscles, bones, skin, and hair follicles.

Adolescents experience physical development, hormonal changes, and sexual maturation during puberty that correlate to Freud's genital stage of psychosexual

**TABLE 29.1** PHYSIOLOGIC CHANGES OF ADOLESCENCE

Stage of Adolescence	Changes in Females	Changes in Males
Early adolescence (10–13 years)	Pubic hair begins to curl and spread over mons pubis; genitalia pigmentation increases. Breast bud and areola continue to enlarge; no separation of breasts First menstrual period (average 12 years, normal range 9–16 years)	Pubic hair spreads laterally, begins to curl; pigmentation increases. Growth and enlargement of testes in scrotum (scrotum reddish in color) and continued lengthening of penis Leggy look due to extremities growing faster than the trunk
Middle adolescence (14–16 years)	Pubic hair becomes coarse in texture and continues to curl; amount of hair increases. Areola and papilla separate from the contour of the breast to form a secondary mound.	Pubic hair becomes coarser in texture and takes on adult distribution. Testes and scrotum continue to grow; scrotal skin darkens; penis grows in width, and glans penis develops. May experience breast enlargement Voice changes; more masculine due to rapid enlargement of the larynx and pharynx as well as lung changes
Late adolescence (17–20 years)	Mature pubic hair distribution and coarseness	Mature pubic hair distribution and coarseness Breast enlargement disappears. Adult size and shape of testes, scrotum, and penis; scrotal skin darkening

Adapted from Cromer, B. (2011). Adolescent Development. In R. M. Kliegman, B. F. Stanton, St. Geme, J. W., Schor, N. F., & Behrman, R. E. (Eds.), *Nelson's textbook of pediatrics* (19th ed., p. 649–59). Philadelphia: Saunders.

development. The genital stage begins with the production of sex hormones and maturation of the reproductive system.

Girls reach physical maturity before boys and **menarche**, the first menstrual period, usually begins between the ages of 9 and 15 years (average 12.8 years). Breast budding (thelarche) occurs at approximately age 9 to 11 years and is followed by the growth of pubic hair.

### Take Note!

African-American girls on average reach menarche slightly earlier than Caucasian girls (Hirsch, 2008).

The first sign of pubertal changes in boys is testicular enlargement in response to testosterone secretion, usually occurring in Tanner stage 2. As testosterone levels increase, the penis and scrotum enlarge, hair distribution increases, and scrotal skin texture changes. During late puberty, boys will typically experience their first ejaculation, which may occur while they are sleeping (nocturnal emissions). Nurses should provide anticipatory guidance to adolescent males regarding involuntary nocturnal emissions (wet dreams) to assure them that this is a normal occurrence.

Tanner stages 3 to 5 usually occur during adolescence. Refer to Figures 32.28, 32.34, and 32.36 for an illustration of the increase in breast tissue and pubic hair distribution in girls, and scrotal and penile changes as well as hair distribution changes in boys. The nurse should provide guidance to adolescents about the normalcy of the sexual feelings and evolving body changes that occur during puberty.

## Physical Growth

Diet, exercise, and hereditary factors influence the height, weight, and body build of the adolescent. Over the past three decades, adolescents have become taller and heavier than their ancestors and the beginning of puberty is earlier. During the early adolescent period, there is an increase in the percentage of body fat and the head, neck, and hands reach adult proportions.

The rapid growth during adolescence is secondary only to that of the infant years and is a direct result of the hormonal changes of puberty. Both girls and boys experience changes in appearance and size. Height in girls increases rapidly after menarche and usually ceases 2 to 2½ years after menarche. Boys' growth spurt occurs later than girls' and usually begins between the ages of 10½ and 16 years and ends sometime between the ages of 13½ and 17½ years. Peak height velocity (PHV) occurs at approximately 12 years of age in girls or at about 6 to 12 months after menarche. Boys reach PHV at about 14 years of age. Peak weight velocity (PWV) occurs about 6 months after menarche in girls and at about 14 years of age in boys. Muscle mass increases in boys and fat deposits increase in girls (Fig. 29.1).

During early adolescence growth is rapid, but it decreases in middle and late adolescence. Height for adolescent boys who are between the 50th and 95th percentile ranges from 52½ inches (132 centimeters) to 69½ inches (176.8 centimeters). Weight of boys in these percentiles ranges from 77¼ pounds (35.3 kilograms) to 211 pounds (95.76 kilograms). On average, boys will gain 10 to 30 centimeters (4 to 12 inches) in height and 7 to 30 kilograms (15 to 65 pounds) in weight.

**FIGURE 29.1** These adolescents reflect the differences in sizes and shapes seen in adolescents of the same age.

Height for girls who are between the 50th and 95th percentile ranges from 57 inches (144.8 centimeters) to 68½ inches (173.6 centimeters), with weight ranging from 60 pounds (27.24 kilograms) to 181 pounds (82.47 kilograms). On average, girls will gain 5 to 20 centimeters (2 to 8 inches) in height and 7 to 25 kilograms (15 to 55 pounds) in weight during adolescence. See Appendix F for growth charts for this age group. Refer to Chapter 32, Box 32.1, for instructions for calculating body mass index (BMI).

### Organ System Maturation

Adolescence is a time of metabolic slowing and of increasing size of some organs. The basal metabolic rate (BMR) reaches the adult level during late adolescence.

### Neurologic System

During adolescence there is continued brain growth, although the size of the brain does not increase significantly. Neurons do not increase in number, but growth of the myelin sheath enables faster neural processing.

### Respiratory System

The adolescent years see an increase in diameter and length of the lungs. Respiratory rate decreases and reaches the adult rate of 15 to 20 breaths per minute. Respiratory volume and vital capacity increase. Volume and capacity are greater in boys than girls, which may be associated with increased chest and shoulder size in boys. The growth of the laryngeal cartilage, larynx, pharynx, vocal cords, and lungs produces the voice changes experienced in adolescence. These changes in the quality of the child's voice are often preceded with some voice instability where voice cracking is heard. Deepening of both male and female voices occurs but is more pronounced in boys.

### Cardiovascular System

There is an increase in size and strength of the heart. Systolic blood pressure increases and heart rate decreases. Blood volume reaches higher levels in boys than girls, which may be due to boys' greater muscle mass.

### Gastrointestinal System

The adolescent has a full set of permanent teeth with the exception of the last four molars (wisdom teeth), which may erupt between the ages of 17 and 20 years. The liver, spleen, kidneys, and digestive tract enlarge during the growth spurt in early adolescence, but do not change in function. These systems are mature in early school age.

## Musculoskeletal System

The ossification of the skeletal system is incomplete until late adolescence in boys. Ossification is more advanced in girls and occurs at an earlier age. During the growth spurt, muscle mass and strength increase. At similar stages of development, muscle development is generally greater in boys. Estrogen, progesterone, and testosterone (sex steroids) and other androgens are released from the gonads and affect changes in the muscles and bones. Low estrogen levels tend to stimulate skeletal growth, while higher levels inhibit growth. During middle adolescence, shoulder, chest, and hip breadth increase.

## Integumentary System

During adolescence the skin becomes thick and tough. Under the influence of androgens, the sebaceous glands become more active, particularly on the face, back, and genitals. Due to the increased levels of testosterone during Tanner stages 4 and 5 in both boys and girls, both sexes may have increased sebum production, which may lead to the development of acne and oily hair.

The exocrine and apocrine sweat glands function at adult levels during adolescence. The exocrine glands are all over the body and they produce sweat that helps to eliminate body heat through evaporation. The apocrine glands are found in the axillae, genital, and anal areas and around the breasts. The apocrine sweat glands produce sweat in response to hair follicles. This sweat is produced continuously and is stored and released in response to emotional stimuli.

### Psychosocial Development

According to Erikson, it is during adolescence that teenagers achieve a sense of identity (Erikson, 1963). As the adolescent is trying out many different roles in regard to his or her relationships with peers, family, community, and society, he or she is developing his or her own individual sense of self. If the adolescent is not successful in forming his or her own sense of self, he or she develops a sense of role confusion or diffusion. The adolescent culture becomes very important to the teenager. It is through his or her involvement with teenage groups that the adolescent finds support and help with developing his or her own identity.

Erikson (1963) believed that during the task of developing his or her own sense of identity, the adolescent revisits each of the previous stages of development. The sense of trust is encountered as the adolescent strives to find out whom and what ideals he or she can have faith in. In revisiting the stage of autonomy, the adolescent is seeking out ways to express his or her individuality in an effective manner. The adolescent

would avoid behaviors that would “shame” or ridicule him or her in front of his or her peers. The sense of initiative is revisited as the adolescent develops his or her vision for what he or she might become. And the sense of industry is again encountered as the adolescent makes his or her choice to participate in different activities at school, in the community, at church, and in the workforce.

The ability of the adolescent to successfully form a sense of self is dependent upon how well the adolescent successfully completed the former stages of development. Erikson (1963) believed that if the adolescent has been successful, he or she can develop resources during adolescence to overcome any gaps in previous developmental stages. If the adolescent believes that he or she cannot express himself or herself in any manner due to societal restrictions, he or she will develop role confusion. See Table 29.2 for additional information.

### Cognitive Development

According to Piaget, the adolescent progresses from a concrete framework of thinking to an abstract one (Piaget, 1969). It is the formal operational period. During this period, the adolescent develops the ability to think outside of the present; that is, he or she can incorporate into thinking concepts that do exist as well as concepts that might exist. The adolescent’s thinking becomes logical, organized, and consistent. He or she is able to think about a problem from all points of view, ranking the possible solutions while solving the problem. Not all adolescents achieve formal operational reasoning at the same time.

In the early stages of formal operational reasoning, the adolescent’s thinking is egocentric. The adolescent is very idealistic, constantly challenging the way things are and wondering why things cannot change. These activities lead to the adolescent’s feeling of being omnipotent. The adolescent must undergo this way of thinking, even though it can frustrate adults, in his or her quest to reach formal operational reasoning. As the teenager progresses toward middle adolescence, his or her thinking becomes very introspective. He or she assumes others are just as interested in what interests him or her, which leads him or her to feel unique, special, and exceptional. That feeling of “being exceptional” leads to the risk-taking behaviors of which teenagers are well known. Also, the teenager feels very committed to his or her viewpoints. He or she tries very hard to convince others of his or her viewpoints and embraces strongly those causes that support his or her opinions. This idealism can cause the adolescent to reject his or her family, culture, church, and community beliefs, which can cause conflict with his or her family, culture, church, and community. See Table 29.2 for additional information.

### Moral and Spiritual Development

It is during the adolescent years that teenagers develop their own set of values and morals. According to Kohlberg, adolescents are experiencing the postconventional stage of moral development (Kohlberg, 1984). It is only because adolescents are developing their formal operational way of thinking that they can experience the postconventional stage of moral development. At the beginning of this stage, teenagers begin to question the status quo. The majority of their choices are based on emotions while they are questioning societal standards. As they progress to developing their own set of morals, adolescents realize that moral decisions are based on rights, values, and principles that are agreeable to a given society. They also realize that those rights, values, and principles can be in conflict with the laws of the given society, but they are able to reconcile the differences. Because adolescents undergo the process of developing their own set of morals at different rates, they might find that their friends view a situation differently. This difference can lead to conflicts and the forming of different friendships. See Table 29.2 for additional information.

Adolescents also may begin to question their formal religious practices or in some cases cling to them (King & Roeser, 2009). As they progress through adolescence, teenagers become more interested in the spiritualism of their religion than in the actual practices of their religion. Adolescents are searching for ideals and may exhibit intense emotions along with introspection and self reflection (Cromer, 2011). Increased spirituality and religious activities are related to increased healthy behaviors and decreased high-risk behaviors (King & Roeser, 2009).

*Referring back to Cho Chung, identify the stage of psychosocial development that she should be in according to Erikson. What approaches for assessment and teaching would be most effective based on the stage you identified?*

### Motor Skill Development

During adolescence, the teenager refines and continues to develop his or her gross and fine motor skills. Because of this period of rapid growth spurts, teenagers may experience times of decreased coordination and have a diminished ability to perform previously learned skills, which can be worrisome for the teenager.

### Gross Motor Skills

It is usually during early adolescence that teenagers begin to develop endurance. Their concentration has increased

**TABLE 29.2**      **DEVELOPMENTAL THEORIES**

Theories	Stages	Activities
Erikson (psychosocial)	<p>Identity vs. role confusion or diffusion Early (11–14 years)</p> <p>Middle (14–16 years)</p> <p>Late (17–20 years)</p>	<p>Focuses on bodily changes</p> <p>Experiences frequent mood changes</p> <p>Importance placed on conformity to peer norms and peer acceptance</p> <p>Strives to master skills within peer groups</p> <p>Defining boundaries with parents and authority figures</p> <p>Early stage of emancipation—struggles to separate from parents while still desiring dependence upon them</p> <p>Identifies with same-sex peers</p> <p>Takes more responsibility for own behaviors</p> <p>Continues to adjust to changed body image</p> <p>Tries out different roles within peer groups</p> <p>Need for acceptance by peer group at the highest level</p> <p>Interested in attracting opposite gender</p> <p>Time of greatest conflict with parents/authority figures</p> <p>Able to understand implications of behavior and decisions</p> <p>Roles within peer groups established</p> <p>Feels secure with body image</p> <p>Has matured sexual identity</p> <p>Has idealistic career goals</p> <p>Importance of individual friendships emerges</p> <p>Process of emancipation from family almost complete</p>
Piaget (cognitive)	<p>Formal operations Early (11–14 years)</p> <p>Middle (14–17 years)</p> <p>Late (17–20 years)</p>	<p>Limited abstract thought process</p> <p>Egocentrically thinking</p> <p>Eager to apply limited abstract process to different situations and to peer groups</p> <p>Increased ability to think abstractly or in more idealistic terms</p> <p>Able to solve verbal and mental problems using scientific methods</p> <p>Thinks he or she is invincible—risky behaviors increase</p> <p>Likes making independent decisions</p> <p>Becomes involved/concerned with society, politics</p> <p>Abstract thinking is established</p> <p>Develops critical thinking skills—tests different solutions to problems</p> <p>Less risky behaviors</p> <p>Develops realistic goals and career plans</p>
Kohlberg	<p>Postconventional level III</p> <p>Early (11–14 years)</p> <p>Middle (14–17 years)</p> <p>Late (17–20 years)</p>	<p>Morals based on peer, family, church, and societal morals</p> <p>Asks broad, usually unanswerable questions about life</p> <p>Developing own set of morals—evaluates individual morals in relation to peer, family, and societal morals</p> <p>Internalizes own morals and values</p> <p>Continues to compare own morals and values to those of society</p> <p>Evaluates morals of others</p>

Adapted from Erikson, E. (1963). *Childhood and society* (2nd ed.). New York: Norton; Kohlberg, L. (1984). *Moral development*. New York: Harper & Row; and Piaget, J. (1969). *The theory of stages in cognitive development*. New York: McGraw-Hill.

**FIGURE 29.2** Adolescents become involved in competitive sports, which draw upon their gross motor skills.

so they can follow complicated instructions. Coordination can be a problem because of the uneven growth spurts. During middle adolescence, speed and accuracy increase while coordination also improves. Teenagers become more competitive with each other (Fig. 29.2). During late adolescence, the teenager usually narrows his or her areas of interest and concentrates on the needed relevant skills.

### Fine Motor Skills

The use of computers has greatly increased the fine motor skills of teenagers (Fig. 29.3). In the early adolescent years, the teenager increases his or her ability to manipulate objects. The adolescent's handwriting is neat and he or she increases his or her finger dexterity. The middle adolescent years see the teenager refining his or her dexterity skills. By late adolescence, the teenager has developed precise eye–hand coordination and finger dexterity.

**FIGURE 29.3** Using computers has increased the fine motor skills of adolescents.

## Communication and Language Development

Language skills continue to develop and be refined during adolescence. Adolescents have improved communication skills, using correct grammar and parts of speech. Vocabulary and communication skills continue to develop during middle adolescence. However, the usage of colloquial speech (slang) increases, causing communication with people other than peers to be difficult at times. By late adolescence, language skills are comparable to those of adults.

## Emotional and Social Development

Adolescents undergo a great deal of change in the areas of emotional and social development as they grow and mature into adults. Areas that are affected include the adolescent's relationship with parents; self-concept and body image; importance of peers; and **sexuality** and dating.

### Relationship With Parents

Families and parents of adolescents experience changes and conflict that require adjustments and the understanding of adolescent development. The adolescent is striving for self-identity and increased independence. He or she spends more time with peers and less time with family and attending family functions. Parents sense that they have less influence on the adolescent as the teen questions family values and becomes more mobile. This may lead to a family crisis, and the parents may respond by setting stricter limits or asking questions about the teen's activities and friends. Other parents may drop all rules and assume that the adolescent can manage himself or herself. Both of these responses increase tension in the family.

With the adolescent attempting to establish some level of independence—and the family learning to let go while focusing on aging parents, their marriage, and other children—a state of disequilibrium occurs. The family may experience more stress than at any other time.

Some families have better outcomes with their adolescents than others. Families who listen to and continue to demonstrate affection for and acceptance of their adolescent have a more positive outcome. This does not mean that the family accepts all of the teen's ideas or actions, but they are willing to listen and attempt to negotiate some limits. For tips to improve communication with teenagers, see Box 29.1.

Siblings experience changes in the relationship with the adolescent brother or sister; the older sibling may attempt to parent and the younger sibling may regress

## BOX 29.1

**WAYS TO IMPROVE COMMUNICATION WITH TEENS**

- Set aside appropriate amount of time to discuss subject matter without interruptions.
- Talk face to face. Be aware of body language.
- Ask questions to see why he or she feels that way.
- Ask him or her to be patient as you tell your thoughts.
- Choose words carefully so he or she understands you.
- Tell him or her exactly what you mean.
- Give praise and approval to your teenager often.
- Speak to your teenage as an equal—don't talk down to him or her.
- Be aware of your tone of voice and body language.
- Don't pretend you know all the answers.
- Admit that you do make mistakes.
- Set rules and limits fairly.

in an attempt to avoid the family conflict. Understanding the status of the adolescent–family relationship is essential for the nurse.

## Self-Concept and Body Image

Self-concept and self-esteem are often tied to body image. Adolescents who perceive their body as being different than peers or as less than ideal may view themselves negatively. Adolescent girls often are influenced by peers and the media and want to weigh less and have smaller hips, waist, or thighs. Boys tend to view themselves as being too thin or not muscular enough.

Sexual characteristics are important to the adolescent's self-concept and body image. Boys are concerned about the size of their penis and facial hair while girls are concerned about breast size and the onset of menstruation. Larger breasts are considered more feminine and menstruation is considered the right of passage into adulthood. All of these body changes are important to the adolescent's self-concept.

## Importance of Peers

**Peer groups** play an essential role in the identity of the adolescent (Cromer, 2011). Adolescent peer relationships are very important in providing opportunities to learn about negotiating differences; for recreation, companionship, and someone to share problems with; for learning peer loyalty; and for creating stability during transitions or times of stress. Learning to work out differences with peers is a skill that is important throughout life. Peers serve as someone safe to discuss family issues

**FIGURE 29.4** Peers play an important role in shaping the adolescent's identity.

with, as the teen emotionally moves away from the family while trying to find his or her identity. Due to changes that have taken place within family systems in society, peer groups play a significant role in the socialization of adolescents (Fig. 29.4).

Peers serve as credible sources of information, role model social behaviors, and act as sources of social reinforcement. Friends provide an opportunity for fun and excitement. Peers impact teens' appearance, dress, social behavior, and language. Peers also can have positive influences on each other, such as promoting college attendance, or negative influences, such as involvement with alcohol, drugs, or gangs. Early and middle adolescence are periods when teens are prone to join gangs. Peer role modeling and peer acceptance may lead to the formation of a gang that provides a collective identity and gives a sense of belonging. Peer pressure, companionship, and protection are the most frequent reasons given for joining gangs, particularly those associated with criminal activity.

Parents must know their teen's friends and continue to be aware of potential problems while allowing the teen the independence to become his or her own person. Nurses must remind parents of the importance of peers and the impact they have on the teen's decisions and life choices. The transition to greater peer involvement requires guidance and support. Adolescents who do not have parental or adult supervision and opportunities for conversation with adults may be more susceptible to peer influences and at higher risk for poor peer selections.

## Sexuality and Dating

Adolescence is a critical time in the development of sexuality. Sexuality includes the thoughts, feelings, and behaviors related to the adolescent's sexual identity. Adolescents usually begin experimentation with heterosexual and homosexual behaviors, although these behaviors may occur earlier in some cultures.

**FIGURE 29.5** Dating becomes an important aspect of the teenager's life.

An interest in the opposite sex occurs during adolescence (Fig. 29.5). Some of the reasons cited for this developing interest are physical development and body changes, peer-group pressure, and curiosity. During the past couple of decades, the percentage of 8th through 12th graders that have dated has declined. Thirty percent of 12th graders have never dated, while 21% reported going on a date one or more times a week (Child Trends, 2012). Teen dating can range from group dating to single dating to serious relationships. Most early adolescents spend more time in activities with mixed-sex groups, such as dances and parties, than they do dating as a couple. Popular dating activities today include going out to dinner or the movies, “hanging out” at the mall, or visiting each other's home. During early adolescence, teens tend to date for fun and recreation. Also, they may see dating as a way to upgrade social standing by being seen with a popular boy or an attractive girl.

Middle and late adolescents have group and single dates. Romantic relationships are central to the social life of this age group. Most teens have been involved in at least one romantic relationship by middle adolescence (Child Trends, 2012). Dating or spending time with a potential romantic partner is viewed as a major developmental marker for teens and is one of the most challenging adjustments. Teens that date frequently report slightly higher levels of self-esteem and increased autonomy and perceive themselves as more popular. However, they frequently have lower academic success and motivation, have higher depression rates, and experience a higher level of parental conflict.

Trends in dating are changing, but dating remains a developmental milestone for the adolescent. Adolescents may experiment with homosexual behavior, though homosexual behavior as a teen does not necessarily indicate that the adolescent will maintain a homosexual orientation (Sass & Kaplan, 2011). Gay and lesbian adolescents face many challenges due to society's nonacceptance and peer insensitivity. Teens who self-declare as homosexual during high school are at increased risk for such problems as depression, suicide, victimization, school avoidance, risky sexual behaviors, and substance abuse (Friedman, 2008; Sass & Kaplan, 2011).

Early romantic relationships play a critical role in the development capacity for long-term committed relationships in adulthood (Child Trends, 2012). Healthy romantic relationships in adolescence can assist the teen in developing a strong sense of self-identity and developing interpersonal skills, such as empathy. The emotional ups and downs that accompany dating can help develop emotional resilience and coping skills. Romantic relationships at this stage are a great source of emotional support. Risks of being involved in unhealthy romantic relationships include dating violence and risky sexual activity such as sexually transmitted infections (STIs) and premature pregnancy. Adolescents do not automatically know what makes for a healthy relationship. They need to be educated on the right and wrong behaviors of dating and what behaviors make up a healthy relationship, such as open communication, honesty, and trust. They need to know the signs of an unhealthy relationship and how to seek help if needed.

*Cho Chung's mother states that she is concerned about the changes that have occurred in her and Cho's relationship over the past year. Cho seems much more self-centered, always wants to be with her friends, is very critical of her mother and father, and seems to be constantly in conflict with them. Based on what you know about this stage of development, what guidance, including approaches and techniques, can you discuss with Mrs. Chung to address her concerns?*

### Cultural Influences on Growth and Development

Although the adolescent's culture continues to influence him or her, the desire to be in harmony with peers becomes paramount. That desire can cause conflict with the adolescent's family and culture. Today's adolescents live in a rapidly changing, increasingly culturally diverse world. They are exposed to many different cultures and

ethnic groups. In 2007, over 40% of children and adolescents in the United States were minorities (Federal Inter-agency Forum on Child and Family Statistics, 2008).

Attitudes regarding adolescence vary among different cultures. Certain cultures may have more permissive attitudes toward issues facing adolescents, while others are more conservative (e.g., toward sexuality). Experiencing a rite-of-passage ceremony to signal the adolescent's movement to adult status varies among cultures. The American culture does not universally have a rite of passage for teenagers. Some religious and social groups do have ceremonies that signal a movement toward the maturity of adulthood (e.g., the Jewish bar or bat mitzvah, the Catholic confirmation, and social debuts). In many parts of the world, separate "youth cultures" have developed in an attempt to blend traditional and modern worlds for the adolescent.

It is important for the nurse to recognize the ethnic background of each adolescent. Research has shown that certain ethnic groups are at higher risk for certain diseases. For example, adolescent African Americans are at higher risk for developing hypertension (American Heart Association, 2011). But the major barrier to the adolescent's health and successful achievement of the tasks of adolescence is socioeconomic status. Adolescents at a lower socioeconomic level are at higher risk for developing health care problems and risk-taking behaviors; this may be due to their inability to access health care and to obtain needed services (National Institute for Health Care Management [NIHCM], 2007). In caring for adolescents, recognize the influence of their culture, ethnicity, and socioeconomic level upon them.

## THE NURSE'S ROLE IN ADOLESCENT GROWTH AND DEVELOPMENT

Growth and development in the adolescent is rapid. Nurses must be aware of the usual growth and development patterns for this age group so that they can assess the adolescent appropriately and provide guidance to the adolescent and his or her family. During adolescence, the teenager faces many challenges. His or her fluctuating relationships with parents and other adult figures may limit the teen from seeking assistance in dealing with the common issues of adolescence. In dealing with adolescents, be aware that they behave unpredictably, are inconsistent with their need for independence, have sensitive feelings, may interpret situations differently from what they are, think friends are extremely important, and have a strong desire to belong. During health care visits the adolescent or parent may have concerns that they are hesitant or uncomfortable talking about in front of each other. Try to provide an opportunity for them to have private time with a health care provider to discuss issues. The adolescent may greatly appreciate the

opportunity for time to discuss concerns with a nonjudgmental informed adult.

If the adolescent is hospitalized, growth and development may be altered. The adolescent is concerned about how the illness or injury will affect his or her body and body image. He or she fears pain and loss of privacy. The adolescent may experience anxiety about being separated from friends and loss of control.

When caring for the hospitalized adolescent, the nurse must use knowledge of normal growth and development to recognize potential delays, promote continued appropriate growth and development, and interact successfully with the teen. Provide opportunities for them to maintain independence, participate in decisions, and encourage socialization with friends through phone, e-mail, and visits when possible. The following Nursing Process Overview will address promoting healthy growth and development and dealing with common developmental concerns.

## NURSING PROCESS OVERVIEW

Upon completion of assessment of the adolescent's current growth and development status, problems or issues related to growth and development may be identified. The nurse may then identify one or more nursing diagnoses, including:

- Risk for disproportionate growth
- Imbalanced nutrition: more than body requirements
- Delayed growth and development
- Risk for caregiver role strain
- Risk for injury
- Ineffective coping

Nursing care planning for the adolescent with growth and development issues should be individualized based on the adolescent's and family's needs. Nursing Care Plan 29.1 can be used as a guide in planning nursing care for the adolescent with a growth and development concern. The nurse may choose the appropriate nursing diagnoses from this plan and individualize them as needed. The nursing care plan is intended to serve as a guide, not to be an all-inclusive growth and development care plan.

## Promoting Healthy Growth and Development

It takes multiple groups who address multiple issues to promote healthy growth and development in the adolescent. Some of these groups include sports teams in the school or the community, peers, teachers, band and choir members, and so forth. Also, the family's support and love will influence growth and development.

## NURSING CARE PLAN 29.1

## Growth and Development of the Adolescent

**NURSING DIAGNOSIS:** Risk for disproportionate growth (risk factors: caregiver and adolescent knowledge deficit, low self-esteem, frequent illnesses)

### Outcome Identification and Evaluation

Adolescent will demonstrate adequate growth: *appropriate weight gain and increase in height for age and sex*

### Intervention: Promoting Appropriate Physical Growth

- Assess parents' and adolescent's knowledge of nutritional needs of adolescents *to determine need for further education.*
- Educate parents and adolescent about appropriate serving sizes and foods *so that they are aware of what to expect for adolescents.*
- Determine need for additional caloric intake if necessary *(if very active in sports, if have a chronic illness).*
- Plot out height, weight, and body mass index (BMI) *to detect possible pattern.*
- Assess for risk factors for developing eating disorder *to refer to if needed and plan interventions.*

**NURSING DIAGNOSIS:** Ineffective health maintenance related to lack of exercise, increased caloric intake, poor food choices, and stresses of adolescence

### Outcome Identification and Evaluation

Adolescent will engage in health maintenance behaviors and lose weight at an appropriate rate: *increase amount of exercise, make appropriate eating choices, decrease caloric intake to appropriate amount for age and sex*

### Intervention: Promoting Appropriate Health Maintenance Behaviors

- Assess knowledge of parents and adolescent about nutritional needs of teenagers *to determine deficits in knowledge.*
- Have adolescent keep a detailed food and exercise diary for 1 week *to determine current patterns of eating and exercise.*
- Interview family in relationship to their eating habits and exercise habits *to determine where adjustments might need to be made.*
- Discuss changes in a positive manner—talk about developing healthy eating habits instead of dieting *to promote compliance.*
- Analyze preceding data, and base recommendations for changes on these data *to promote compliance and to prioritize recommendations.*
- Discuss ways to decrease temptation to overeat, for example, eat slowly, put down the fork between bites, serve food on smaller plates, and count mouthfuls, *to allow time to realize that you are full.*
- Have adolescent create meal plans and grocery shop *to allow him or her some sense of control and decision making.*
- Incorporate increase in daily exercise, which will stress sense of self-improvement *to increase caloric expenditure and self-esteem.*
- Decrease TV/computer time *to increase caloric expenditure.*
- Encourage peer exercise activities *to increase peer interactions and to help teen to realize that others are like him or her.*
- Develop reward system *to increase self-esteem.*
- Investigate joining weight loss program for adolescents *to increase self-esteem and encourage weight loss.*

(continued)

## NURSING CARE PLAN 29.1

**Growth and Development of the Adolescent** (continued)

**NURSING DIAGNOSIS:** Growth and development, delayed, related to speech, motor, psychosocial, or cognitive concerns as evidenced by delay in meeting expected school performances

**Outcome Identification and Evaluation**

Development will be maximized: Adolescent will make continued progress toward attainment of expected school performance.

**Interventions: Promoting Growth and Development**

- Perform scheduled evaluation of the adolescent by school and health care provider *to determine current functioning.*
- Develop realistic multidisciplinary plan *to ensure maximizing resources.*
- Carry out interventions as prescribed by developmental specialist, physical therapist, occupational therapist, or speech therapist at home and at school *to maximize benefit of interventions.*
- Have scheduled evaluation meetings *to be able to adapt interventions as soon as possible.*

**NURSING DIAGNOSIS:** Caregiver role strain, risk for (risk factors: knowledge deficit about adolescent issues, lack of prior exposure, fatigue, ill or developmentally delayed child)

**Outcome Identification and Evaluation**

Parent will experience competence in role: *will demonstrate appropriate caretaking behaviors and verbalize comfort in caring for an adolescent*

**Interventions: Preventing Caregiver Role Strain**

- Assess parents' knowledge of adolescents and the issues that arise as a part of normal development *to determine parents' needs.*
- Provide education on normal issues of adolescence *so that parents are armed with the knowledge they need to appropriately care for their adolescents.*
- Provide anticipatory guidance related to upcoming expected issues related to adolescent development *to prepare parents for what to expect next and how to intervene in an appropriate manner.*

**NURSING DIAGNOSIS:** Injury, risk for (risk factors: increased motor and cognitive skills and feeling of invincibility)

**Outcome Identification and Evaluation**

Adolescent's safety will be maintained: *will remain free from injury*

**Interventions: Preventing Injury**

- Discuss safety measures needed for the following: bikes, scooters, guns, skateboards, cars, and water *to decrease risk of injury related to those areas.*
- Discuss and develop a fire safety plan *to decrease risk of injury related to fire.*
- Discuss appropriate safety equipment needed for each sport *to decrease risk of injury.*
- Discuss appropriate sports to participate in depending on age, sex, and maturity of adolescent *to prevent possible injury.*
- Teach parents and adolescent first-aid measures and cardiopulmonary resuscitation (CPR) *to minimize consequences of injury should it occur.*
- Discuss influence of peers upon actions of adolescents *to prevent possible injury due to mimicking behavior.*

## NURSING CARE PLAN 29.1

**Growth and Development of the Adolescent** (continued)

**NURSING DIAGNOSIS:** Coping, ineffective (risk factors: low self-esteem, poor relationship with parents and peers, participating in risk-taking behaviors)

**Outcome Identification and Evaluation**

Adolescent will demonstrate adequate coping abilities *as evidenced by management of stress of adolescence and no evidence of participating in risk-taking behaviors.*

**Interventions: Promoting Effective Coping**

- Assess adolescent's knowledge of normal stress facing teenagers *to determine current knowledge.*
- Assess adolescent's present coping skills *to determine areas for improvement/support.*
- Encourage parents to accept teenager as a unique individual *to improve self-esteem.*
- Discuss with parents and adolescent normal developmental issues facing teens *to give them knowledge needed to cope.*
- Provide different situations the teen might be faced with and encourage teen to develop different solutions.
- Allow for increasing independence and opportunities to solve own problems *to improve coping skills.*
- Encourage parents to provide unconditional love *to improve self-esteem.*
- Assess for any evidence of any risk-taking behaviors (drugs, smoking, suicide) *to identify need for early interventions.*

## Promoting Growth and Development Through Sports and Physical Fitness

Many adolescents are involved in team sports that provide avenues for exercise. High levels of physical activity may reduce cardiovascular disease risk factors and provide disease prevention against cancer, obesity, osteoporosis, and depression (Kelly, 2010). Also, physical activity may contribute to higher academic performance and achievement (National Center for Chronic Disease Prevention and Health Promotion, Division of Adolescent and School Health, 2010). Adolescents probably spend more time and energy participating in sports than any other age group. Participation in sports contributes to the adolescent's development, educational process, and better health. Sports and games provide an opportunity to interact with peers while enjoying socially accepted stimulation and conflict. Competition in sports activities helps the teenager in processing self-appraisal and in developing self-respect and concern for others.

Every sport has some potential for injury. Rapidly growing bones, muscles, joints, and tendons are more vulnerable to unusual strains and fractures. Parents, coaches, and the adolescent himself need to be aware of early warning signs of fatigue, dehydration, and injury (Hagan, Shaw, & Duncan, 2008). See Chapter 45 for a discussion of sports injuries.

In relation to youth sports, the role of the nurse is to educate to prevent injuries (Fig. 29.6). This education should include discouraging participation when the teen is tired or has an existing injury.

Additionally, adolescence is a good time to develop an exercise program. The U.S. Department of Health and Human Services (2008) recommends that adolescents participate in 60 minutes of moderate to vigorous physical activity each day. Nurses should encourage all adolescents to be physically active daily.

**FIGURE 29.6** Stretching before exercise is an important part of exercise.

## Promoting Learning

School, teachers, family, and peers influence education and learning for the adolescent. Also, activities such as athletics and club membership enhance learning through interactions with peers, coaches, club leaders, and others.

### School

School plays an essential part in preparing adolescents for the future. Completing school prepares the adolescent for college or employment to make an adequate income. Schools in the United States may not meet the developmental needs of all adolescents. Minority students may not be at the appropriate grade level and the dropout rate may be higher than in nonminority students. Dropout rates have declined since the 1970s but still remain a concern. Dropout rates are highest among Hispanic students (Child Trends Data Bank, 2008). Those who drop out of school may lack skills needed to function in today’s society. They are more likely to be unemployed and have lower income levels and occupational status than those with a high school diploma (Child Trends Data Bank, 2008) (see Healthy People 2020). Another influencing factor is a lack of parental involvement. Due to single-parent families and both parents being in the workforce, parents have less time to devote to involvement in their child’s school activities.

#### HEALTHY PEOPLE 2020

Objective	Nursing Significance
Increase educational achievement of adolescents.	<ul style="list-style-type: none"> <li>• Encourage school attendance and completion when encountering teens for well-child or sick visits.</li> <li>• Refer children who have difficulty concentrating or learning for further evaluation.</li> <li>• Praise school accomplishments.</li> </ul>

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

There is evidence that the transition from elementary school to middle school at age 12 or 13, and then the transition to high school, both of which occur at the time of physical changes, may have a negative effect on teens. It is important to observe for transition problems into middle or high school, which may be exhibited by failing grades or behavior problems. Also, students who experience difficulties in school, resulting in negative evaluations and failing grades,

may feel alienated from school. Students with failing grades and those repeating grades exhibit more emotional behavior such as violence and are more likely to engage in risky behaviors such as tobacco and alcohol use (National Center for Chronic Disease Prevention and Health Promotion, Division of Adolescent and School Health, 2010). Schools that support peer-group relationships, promote health and fitness, encourage parental involvement, and strengthen community relationships have better student outcomes. Parents, teachers, and health care providers should provide guidance and support.

### Other Activities

Adolescents are involved in many other activities that influence learning. Some of these activities include (1) school activities such as band, choir, or clubs requiring high achievement; (2) athletic activities in the school and community and sometimes in the state or region; (3) art, sewing, and building classes; and (4) work activities when the late adolescent has a part-time job. These activities all contribute to the growth, development, and education of the adolescent.

### Promoting Safety

Unintentional injuries are the leading causes of death in adolescents with homicide, suicide, cancer, and heart disease following. (U.S. Department of Health and Human Services, Health Resources and Services Administration, Maternal and Child Health Bureau, 2011). Injuries kill more adolescents than all diseases combined with 70.7% of unintentional injury related deaths due to motor vehicle accidents followed by poisonings. Males are more likely than females to die of any type of injury (Centers for Disease Control and Prevention [CDC], 2008d).

Influencing factors related to the prevalence of adolescent injuries include increased physical growth, insufficient psychomotor coordination for the task, abundance of energy, impulsivity, peer pressure, and inexperience. Impulsivity, inexperience, and peer pressure may place the teen in a vulnerable situation between knowing what is right and wanting to impress peers. On the other hand, teens have a feeling of invulnerability, which may contribute to negative outcomes. Alcohol and other drugs are contributing factors in automobile and firearm accidents among adolescents. Most of the serious or fatal injuries in adolescents are preventable (Fig. 29.7). Nurses must educate parents and adolescents on car, gun, and water safety to prevent unintentional injuries. See Teaching Guidelines 29.1 for information on promoting safety.

FIGURE 29.7 Wearing appropriate safety equipment can prevent injuries.

### Teaching Guidelines 29.1

#### PROMOTING SAFETY

##### Safety Issue

##### Motor vehicle

##### Activity

- Wear seat belt at all times.
- Do not drive with someone who is impaired.
- Take driver-education course.
- Establish driving rules between parent and adolescent prior to getting license.
- Have all passengers wear seat belts.
- Do not use cell phone while driving, drink and drive, or drive when tired.
- Maintain car in good condition.
- Drive with adult supervision for period of time after receiving license.

##### Bike: General

- Have a well-maintained and appropriate-size bike for adolescent.
- Adolescent should demonstrate his or her ability to ride bike safely before being allowed to ride on street.
- Safe areas for bike riding should be established as well as routes to and from area of activities.

##### Bike: In traffic

- Should not ride bike barefoot, with someone else on bike, or with clothing that might get entangled in the bike.
- Should wear sturdy, well-fitting shoes and American National Standards Institute (ANSI)-approved helmets.
- Bike should be inspected often to ensure it is in proper working order.
- A basket should be used to carry heavy objects.
- All traffic signs and signals must be observed.
- If adolescent is riding at night, the bike should have lights and reflectors and the rider should wear light-colored clothes.
- Should ride on the side of the road traveling with traffic and keep close to the side of the road in single file.
- Should watch and listen for cars and never hitch a ride on any vehicle.

##### All-terrain vehicles

- Should not wear headphones while riding a bike.
- Should not be operated by adolescent younger than 16 years of age.
- Helmet and protective coverings required.
- No nighttime riding.
- Not for use on public roads or if teen has been drinking or using drugs.

##### Skateboards/ skates

- Do not stand up in the vehicle or ride in a person's lap.
- Wear helmet, and protective padding on knees, elbows, and wrists.
- Do not skate in traffic or on streets or highways.
- Skating on homemade ramps could be dangerous—assess ramps for any hazards before skating.

##### Water safety

- Learn how to swim; if swimming skill is limited, must wear life preserver at all times.
- Never swim alone—should, if at all possible, swim only where there is a life guard.
- Learn basic cardiopulmonary resuscitation (CPR).
- Do not run or fool around at edge of pool.
- Drains in pool should be covered with appropriate cover.

- Firearms
  - Wear life jacket when on boat.
  - Make sure there is enough water to support diving.
  - Do not swim if drinking alcohol or using drugs.
  - If guns are in household, should take firearm safety class, secure guns in safe place, use gun safety locks, and store bullets in separate place.
- Fire safety
  - Never point a gun at a person.
  - All homes should have working smoke detectors and fire extinguishers. Change the batteries at least twice a year.
  - Have fire-escape plan and practice the plan routinely.
  - No smoking in bed.
  - Teach what to do in case of a fire—use fire extinguisher, call 911, how to put out clothing fire.
  - All flammable materials and liquids should be stored safely.
  - Fireplaces should have protective gratings.
  - Avoid touching any downed power lines.
- Machinery
  - Use safety devices.
  - Receive training on how to use equipment.
- Sports
  - Do not use when alone.
  - Match sport to adolescent’s ability and desire.
  - Sports program should have warm-up procedure and hydration policy.
  - Undergo sports physical before start of activity.
  - Coaches should be trained in CPR and first aid.
- Sun
  - Wear appropriate protection devices for individual sport.
  - Use sunscreen with both ultraviolet A (UVA) and ultraviolet B (UVB) protection.
  - Apply sunscreen prior to going out and reapply sunscreen often.
  - Limit sun exposure, especially between 10 a.m. and 2 p.m.
  - Wear hat and sunglasses while outside.
- Personal safety
  - Never go with a stranger.
  - Do not enter a car when the driver has been drinking.
  - Notify adult where you are when out after dark.

- Toxins
  - Keep cell phone fully charged.
  - Never give out personal information over the Internet.
  - Say “no” to drugs, alcohol, or smoking, or to being touched when you do not want to be touched.
  - Teach the hazards of accepting illegal drugs, alcohol, dangerous drugs.
  - Decrease the misuse of prescription drugs, discourage medication sharing
  - Store potential dangerous material in safe place. and dispose of appropriately

Elk Grove Village, IL: American Academy of Pediatrics; American Academy of Pediatrics, Council on Environmental Health and Section on Dermatology. (2011). Policy statement—Ultraviolet radiation: A hazard to children and adolescents. *Pediatrics*, online. Retrieved March 26, 2011, from <http://pediatrics.aappublications.org/cgi/content/abstract/peds.2010-3501v1>

### Motor Vehicle Safety

The largest numbers of adolescent injuries are due to motor vehicle crashes. When the adolescent passes his or her driving test, he or she is able to drive legally. However, driving is complex and requires judgments that the teen is often incapable of making. Also, the typical adolescent is opposed to authority and is interested in showing peers and others his or her independence. Teenagers are the least likely age group to wear a seat belt, with males less likely than females and African American and Hispanic teens less likely than Caucasian teens (CDC, 2010f). Crashes involving adolescents are more likely to involve speeding or driving too fast for conditions (National Highway Traffic Safety Association [NHTSA], 2008). More accidents occur when passengers, mostly other teenagers, are present in the car, during driving at night or driving under the influence of alcohol (NHTSA, 2008).

It is essential to promote driver education, to teach about the importance of wearing seat belts, and to explain laws about teen driving and curfews (Fig. 29.8). See Teaching Guidelines 29.1 for additional information.

#### Take Note!

Many states have enacted a Graduated Driving License (GDL) program, which allows teens to gain driving experience and limits risky circumstances (such as nighttime driving and driving with passengers) by providing a license in three stages (learners permit, provisional license, and full license) (NHTSA, 2008). Studies have shown this program to be highly effective in reducing teen driver crashes (NHTSA, 2008).

**FIGURE 29.8** The use of seat belts has led to fewer fatal injuries in car accidents.

### Firearm Safety

The risk of dying from a firearm injury among 15- to 19-year-olds has been rising. In 2007, 85% of homicides and 42.5% of suicides in children and adolescents were caused by a firearm (U.S. Department of Health and Human Services, Health Resources and Services Administration, Maternal and Child Health Bureau, 2011). Provide education about gun safety. Guns in the home must be kept and locked in a safe location, with ammunition kept separately. Parents must teach adolescents about the dangers of playing with firearms. See Teaching Guidelines 29.1 for additional information on gun safety.

### Water Safety

Drowning is a needless cause of death in adolescents. Many drownings are a result of risk-taking behaviors. With the independence of the adolescent, many times adult supervision is not prevalent and the teen takes a dare that results in drowning. Provide water safety education and proper supervision to decrease the incidence of risk taking. Teach about swimming lessons for nonswimmers. See Teaching Guidelines 29.1 for additional information.

*Remember Cho Chung, the 15-year-old presented at the beginning of the chapter? What anticipatory guidance related to safety should you provide to Cho and her mother?*

#### BOX 29.2

##### FACTORS INFLUENCING THE ADOLESCENT'S DIET

- Peer pressure
- Busy schedules
- Concern about weight control
- Convenience of fast food

### Promoting Nutrition

Nutritional needs are increased during adolescence due to accelerated growth and sexual maturation. Adolescents may appear to be hungry constantly and need regular meals and snacks with adequate nutrients to meet the body's anaerobic requirements. Multiple factors influence the adolescent's diet and eating habits (Box 29.2).

According to CDC data, in 12- to 19-year-olds, the obesity rate has more than tripled (CDC, 2012a). Poor diet and physical inactivity have led to the mounting problem of obesity in this age group. Obesity in adolescence is associated with obesity in adulthood along with numerous adverse health conditions such as diabetes, hypertension, high cholesterol, and overall poorer health (CDC, 2012a).

### Nutritional Needs

Teenagers have a need for increased calories, zinc, calcium, and iron for growth. However, the number of calories needed for adolescence depends on the teen's age and activity level as well as growth patterns. Teenage girls who are moderately active require about 2,000 calories per day (U.S. Department of Agriculture and U.S. Department of Health and Human Services, 2010). Teenage boys who are moderately active require between 2,400

#### BOX 29.3

##### FOODS HIGH IN IRON

- Beef, chicken, fish
- Liver
- Peanut butter
- Nuts and seeds
- Green peas, lima beans
- Spinach
- Strawberries
- Tomato juice
- Whole-grain bread
- Raisins
- Watermelon

**HEALTHY PEOPLE 2020****Objective**

Reduce iron deficiency among young children and females of childbearing age.

**Nursing Significance**

- Educate parents and teens about iron-containing foods.
- Encourage adolescent females to consume a diet high in iron-rich foods.

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

and 2,800 calories per day (U.S. Department of Agriculture and U.S. Department of Health and Human Services, 2010). Of these calories, 45% to 65% should come from carbohydrates, 10% to 30% from protein, and 25% to 35% from fat (U.S. Department of Agriculture and U.S. Department of Health and Human Services, 2010). Adolescents require about 1,300 milligrams of calcium each day (Krebs, Primark, & Haemer, 2011). Adolescents should be made aware of foods high in calcium, including milk, white beans, broccoli, cheese, and yogurt. Adolescent males require 11 milligrams of iron each day and females require 15 milligrams each day (Krebs et al., 2011). Advise adolescents about foods high in iron (Box 29.3; see Healthy People 2020). Protein requirements for adolescent girls, 14 to 18 years of age, are 46 grams per day, and for adolescent boys, 14 to 18 years of age, 52 grams per day (U.S. Department of Agriculture and U.S. Department of Health and Human Services, 2010). Some foods high in protein are meats, fish, poultry, beans, and dairy products.

**Promoting Healthy Eating Habits**

The nurse must understand normal growth and development of the adolescent in order to provide guidance that fits the quest for independence and the need for teens to make their own choices. Assess the eating habits and diet preferences of the adolescent. The assessment should include an evaluation of foods from the different food groups that the adolescent eats each day. Also, assess the number of times that fast foods, snacks, and other junk food are eaten per week. This assessment will help the nurse to guide the adolescent in making better food choices at home and in fast-food establishments. Many fast-food restaurants offer baked chicken sandwiches and salads with fewer calories and less fat. Adolescents may be guided in alternating hamburgers and fries with more nutritious choices. Remember that planning should always include the adolescent.

The U.S. Department of Agriculture provides a personalized food pyramid called MyPyramid Plan based on an individual's age, sex, weight, height, and amount of physical activity. Refer to Figure 29.9 for an example. At <http://www.mypyramid.gov>, the adolescent can create his or her customized food pyramid plan. Table 29.3 outlines daily

serving recommendations based on caloric requirements (lower, moderate, or higher). Nurses may use the information in Table 29.3 to help teens plan a healthy diet for themselves. Active teenage girls should eat the number of servings recommended in the “Moderate” column of Table 29.3. Active teenage boys should eat the number of servings recommended in the “Higher” column. Adolescents who are overweight and dieting should base their daily intake on the serving recommendations in the “Lower” column.

**Preventing the Development of Overweight and Obesity**

Over the past 30 years, the number of overweight adolescents has more than tripled from 5% to 18% (CDC, 2012a). Although obesity has increased in all segments of the US population, there are differences specific to race, ethnicity, and socioeconomic status. The prevalence of obesity is highest in Hispanic and African American teens between the ages of 12 and 19 years (Ogden & Carroll, 2010).

This increase in obesity in adolescents has led to increases in hypertension, heart disease, and type 2 diabetes. Influential factors causing obesity include food choices, eating practices, and lack of exercise. Research indicates that the percentage of children that eat breakfast decreases with age and that by adolescence only 77% of 12 to 19 years old eat breakfast (CDC, 2008f). Also, fewer than 20% of adolescents ages 12 to 19 years meet the daily dietary requirement of vegetables and fruits while less than 40% meet the guidelines for saturated fats (CDC, 2008f). Adolescents are busy and eat on the run, with many meals from fast-food facilities. In addition, many schools have decreased or discontinued physical education, which has resulted in a more sedentary lifestyle, leading to weight gain. Interest in computer games and television watching at home has decreased physical activity and exercise and further contributed to weight gain and obesity (see Healthy People 2020).

**HEALTHY PEOPLE 2020****Objective**

Increase the proportion of adolescents who meet current federal physical activity guidelines for aerobic physical activity and for muscle-strengthening activity.

**Nursing Significance**

- For the nonexercising teen, advise to start slowly by walking.
- Work with the teen to identify physical activities that interest the teen.
- Praise efforts to participate in a routine exercise plan.
- Identify an athletic individual that the teen identifies with and encourage similar activities in the teen.

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

Based on the information you provided, this is your daily recommended amount from each food group.

<b>GRAINS</b> 10 ounces  <b>Make half your grains whole</b>  Aim for at least <b>5 ounces</b> of whole grains a day	<b>VEGETABLES</b> 3 1/2 cups  <b>Vary your veggies</b> Aim for these amounts <b>each week:</b> <b>Dark green veggies</b> = 3 cups <b>Orange veggies</b> = 2 1/2 cups <b>Dry beans &amp; peas</b> = 3 1/2 cups <b>Starchy veggies</b> = 7 cups <b>Other veggies</b> = 8 1/2 cups	<b>FRUITS</b> 2 1/2 cups  <b>Focus on fruits</b>  Eat a variety of fruit  Go easy on fruit juices	<b>MILK</b> 3 cups  <b>Get your calcium-rich foods</b>  Go low-fat or fat-free when you choose milk, yogurt, or cheese	<b>MEAT &amp; BEANS</b> 7 ounces  <b>Go lean with protein foods</b>  Choose low-fat or lean meats and poultry  Vary your protein routine—choose more fish, beans, peas, nuts, and seeds
<b>Find your balance between food and physical activity</b> Be physically active for at least <b>60 minutes</b> every day, or most days.		<b>Know your limits on fats, sugars, and sodium</b> Your allowance for oils is <b>8 teaspoons a day.</b>  Limit extras—solid fats and sugars—to <b>425 calories a day.</b>		

**Your results are based on a 2800 calorie pattern.**

**Name:** \_\_\_\_\_

This calorie level is only an estimate of your needs. Monitor your body weight to see if you need to adjust your calorie intake.

**FIGURE 29.9** MyPyramid Plan for a 15-year-old boy, 140 pounds, 5 feet 4 inches, 30 to 60 minutes of exercise daily. Retrieved March 21, 2011, from [http://mypyramid.gov/downloads/results/results\\_2800\\_under18.pdf](http://mypyramid.gov/downloads/results/results_2800_under18.pdf)

Calories for Three Caloric Levels	Lower (About 1,600 Calories)	Moderate (About 2,200 Calories)	Higher (About 2,600 Calories)
Grain group servings	6	6–8	10–11
Vegetable group servings	3–4	4–5	5–6
Fruit group servings	4	4–5	5–6
Milk group servings	2–3	2–3	3
Meat group (ounces)	3–4	6	6

Adapted from U.S. Department of Agriculture and U.S. Department of Health and Human Services (2010). *Dietary guidelines for Americans, 2010* (7th ed.). Washington, DC: U.S. Government Printing Office. Retrieved March 21, 2011, from <http://www.cnpp.usda.gov/DGAs2010-PolicyDocument.htm>

Nurses must make parents and adolescents aware of factors leading to obesity. Nurses should recommend:

- Proper nutrition and healthy food choices
- Good eating habits
- Decreased fast-food intake
- Participation in physical activity daily
- Parents/adolescents exercising more at home
- Decreased computer use and television watching

*What questions should you ask Cho Chung and her mother related to nutritional intake? What anticipatory guidance related to nutrition would be appropriate?*

## Promoting Healthy Sleep and Rest

The average number of hours of sleep that teens require per night is 8.5 to 9.5 (Gavin, 2011). The adolescent often experiences a change in sleep patterns that leads to feeling more awake at night and the desire to sleep later in the morning (Gavin, 2011). Also, in this independence-seeking phase of adolescence, the teen may stay up later to do homework or to complete projects and may have difficulty awakening in the morning. Due to early school schedules and activities the teen will often try to make up for needed sleep by sleeping longer hours on the weekend. Rapid growth and increased activities may produce fatigue and the need for more rest. Parents may relate that the teen sleeps all the time and never has the time or energy to help with household chores. Explain to parents the need to discourage late hours on school nights because they may affect school performance. Encourage the teen to go to bed at the same time at night and awaken at the same time in the morning, even on weekends (Gavin, 2011). Provide advice to teens and parents about having realistic expectations; encourage them to agree on a level of normalcy and adequate rest for the teen so that he or she can still fulfill responsibilities in the home.

*Provide anticipatory guidance to Cho Chung and her mother in relation to sleep during the adolescent years.*

## Promoting Healthy Teeth and Gums

Most permanent teeth have erupted with the possible exception of the third molars (wisdom teeth). These molars may become impacted and require surgical removal. The rate of cavities decreases but the need for

routine dental visits every 6 months and brushing two to three times per day is very important. Some of the conditions that occur during adolescence include malocclusion, gingivitis, and tooth avulsion. Malocclusion occurs in approximately 45% of adolescents, resulting from facial and mandibular bone growth (Tinanoff, 2011). It is the most common reason for referral to an orthodontist. The treatment includes braces and other dental devices. Teach the adolescent to brush the teeth more frequently if he or she has braces or other dental devices. Gingivitis is inflammation of the gums and breakdown of gingival epithelium due to diet and hormonal changes. The use of dental devices/braces makes cleaning more difficult and contributes to gingivitis. Tooth avulsion (knocked-out teeth) may occur during sports and other activities such as falls. The avulsed tooth should be reimplanted as soon as possible. The nurse may see the teen first so it is important that nurses know the proper procedure, which is to reinsert the tooth into its socket if possible or to store it in cool milk or normal saline for transport to the dentist.

## Promoting Personal Care

Promotion of personal care during adolescence is an important topic to cover with the adolescent and his or her parents. Topics to discuss include general hygiene tips, caring for body piercings and tattoos, preventing suntanning, and promoting a healthy sexual identity.

### General Hygiene Tips

Adolescents find that frequent baths and deodorant use are important due to apocrine sweat gland secretory activity. Also, to decrease oily skin due to sexual steroids and hormones, teach the adolescent to wash his or her face two to three times per day with plain unscented soap. Vigorous scrubbing should be discouraged because it could irritate the skin and lead to follicular rupture. The hair should be shampooed daily to remove excess oil from the hair and scalp. Many over-the-counter medications are available for beginning acne or acne with a few lesions. These preparations may cause drying or redness. Discourage adolescents from squeezing acne lesions to prevent further irritation and permanent scarring. If the adolescent has severe acne, encourage him or her to ask a parent to make an appointment with a dermatologist.

### Caring for Body Piercings and Tattoos

It is not uncommon for a teen to experiment with body piercing on areas such as the tongue, lip, eyebrow, navel, and nipple (Fig. 29.10). Other sites such as the genitals, chin cleft, knuckles, and even the uvula have been used.

**FIGURE 29.10** Having multiple piercings and tattoos can lead to certain health risks.

Generally, body piercing is harmless, but nurses should caution teens about performing these procedures under nonsterile conditions and should educate them about complications. Qualified personnel using sterile needles should perform the procedure. Teach the adolescent to cleanse the pierced area twice a day and more often at some sites.

The complications of body piercing vary by site. Infections from body piercing usually result from unclean tools of the trade. Some of the infections that may occur as a result of unclean tools include hepatitis, tetanus, tuberculosis, and HIV. Also, keloid formation and allergies to metal may occur. The navel is an area prone to infection because it is a moist area that endures friction from clothing. After a navel infection occurs, it may take up to a year to heal. Pierced ear cartilage also heals slowly and is prone to infection. Tongue piercings heal very quickly, usually within 4 weeks, probably due to the antiseptic effects of saliva. Other concerns with tongue piercing include tooth damage from biting on the jewelry or partial paralysis if the jewelry pierces a nerve.

Tattoos are continuing to grow in popularity among adolescents (U.S. Food and Drug Administration, 2009). Tattoos serve to define one's identity and are a form of self-expression (see Fig. 29.10). Because of the invasiveness of the tattooing procedure, it should be considered a health-risk situation. Like piercings, tattoos are open wounds predisposing to infection.

Nurses should educate adolescents about the risk of bloodborne infections, such as hepatitis B and C, HIV, skin infections, scarring, and allergic reactions to dyes used in the tattoo process (U.S. Food and Drug Administration, 2009). They need to encourage the teen to go to a licensed facility and to double check that needles are new and sterilized (American Academy of Pediatrics, 2010). Teach teens to cleanse tattoos with an antibacterial soap and water several times a day and to keep the area moist with an ointment to prevent scab formation. Refer to Box 29.4 for additional information about tattoos.

#### BOX 29.4

#### WHAT ADOLESCENTS NEED TO KNOW ABOUT TATTOOING

- Infections occur as a result of nonsterile equipment used in the procedure.
- Tattoos are open wounds predisposing to infection; sites require proper care with antibacterial soap and water several times per day and application of ointment.
- For most people a tattoo is permanent; new procedures for removal are painful and expensive.

#### Preventing Suntanning

Suntanning is popular among adolescents and is influenced by the media, which promotes a link between tan skin and beauty. There is no such thing as a good tan (American Academy of Pediatrics, 2011). Most exposure to ultraviolet rays occurs during childhood and adolescence, thereby putting people at risk for the development of skin cancer. However, it is difficult to convince adolescents that tanning is harmful to their skin and puts them at risk for skin cancer later in life (see Healthy People 2020).

#### HEALTHY PEOPLE 2020

##### Objective

##### Nursing Significance

Increase the proportion of persons who participate in behaviors that reduce their exposure to harmful ultraviolet (UV) irradiation and avoid sunburn.

Reduce the proportion of adolescents in grades 9 through 12 who report using artificial sources of UV light for tanning.

Increase the proportion of adolescents in grades 9 through 12 who follow protective measures that may reduce the risk of skin cancer.

- Encourage female teens to use sunscreen-containing makeup.
- Discourage teen use of tanning beds.
- Remind students to use sunscreen during outdoor organized-sports practice.
- Educate teens and families about the risks associated with sun exposure.
- Educate teens and their families to avoid the sun between 10 a.m. and 4 p.m., wear sun-protective clothing when exposed to sunlight, use sunscreen with a sun protection factor (SPF) of 15 or higher, and avoid artificial sources of UV light.

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

Educate teens about the benefits and effects of different sun protection products. Explain to them that sun damage and skin cancers can be prevented if sunscreens are used as directed on a regular basis. Encourage sunscreen or sunblock use for water sports, beach activities, and participation in outdoor sports. Also, make adolescents aware of allergies to some sunscreen products. See Teaching Guidelines 29.1 for additional information.

### *Promoting a Healthy Sexual Identity*

Encourage parents and teens to have discussions about sexuality. In addition, nurses should ensure that adolescents have the knowledge, skills, and opportunities that enable them to make responsible decisions regarding sexual behaviors and sexual orientation. Education for the adolescent should include a discussion about media influences and the use of sexuality to promote products. This discussion should make the adolescent aware of the motives of the media and the need to be an individual and not be influenced by television, magazines, and other forms of advertisement. Encourage parents to be aware of who their adolescents are dating and where they go on their dates. Refer to Teaching Guidelines 29.2 for information on counseling related to adolescent sexuality.

### **Promoting Appropriate Discipline**

Adolescents naturally misbehave or do not follow the rules of the house, and parents must determine how to respond. Adolescents need to know the rules and expectations. After rules are established, parents must explain to the adolescent the consequences of breaking the rules.

#### Teaching Guidelines 29.2

#### **ADOLESCENT SEXUALITY**

- It should be your choice to engage in sexual relations. Do not be influenced by peers. When you say “no,” be firm and clear about your position.
- Pregnancy, sexually transmitted infections, and HIV infection can occur with any sexual encounter without the use of barrier methods of contraception. Use appropriate contraception if sexually active. Discuss abstinence as a contraceptive method.
- Sexual activity in a mature relationship should be pleasurable to both parties. If your sexual partner is not interested in your pleasure, you need to reconsider the relationship.

Offer guidance to parents related to disciplining teens. The parent and the teen should collaborate on what the consequences will be if the rules are broken. Parents must acknowledge and offer reinforcement and support when the teen follows the rules. Consistency and predictability are the cornerstones of discipline, and praise is the most powerful reinforcer of learning.

### **Addressing Common Developmental Concerns**

Adolescence is a time of rapid growth and development with maturation of sexuality. The adolescent period begins with a child and ends with the expectation of adulthood. There are many developmental concerns that present during this period, including violence, suicide, homicide, and substance use. The following is an overview of some of these concerns.

### **Violence**

The CDC’s Injury Center defines violence as threatened or actual physical force or power initiated by an individual that results in or has a high likelihood of resulting in physical or psychological injury or death (Centers for Disease Control and Prevention [CDC], 2010b). More than 656,000 adolescents and young adults between 10 and 24 years of age were injured and treated in an emergency department as a result of violence in 2008 (Centers for Disease Control and Prevention [CDC], 2010a). The issue of youth violence is a growing concern in America’s communities. The health and well-being of adolescents and society are threatened by this violence. See Box 29.5 for factors contributing to adolescent violence. Health care providers need to provide education on the effects and ways to prevent youth violence along

#### BOX 29.5

#### **FACTORS CONTRIBUTING TO ADOLESCENT VIOLENCE**

- Crowded conditions/housing
- Low socioeconomic status
- Limited parental supervision
- Single-parent families/both parents in workforce
- Access to guns or cars
- Drug or alcohol use
- Low self-esteem
- Racism
- Peer or gang pressure
- Aggression

with supporting programs developed to curb youth violence.

### Homicide

Homicide is the second leading cause of death in children between 10 and 24 years old, with the majority of victims being male and killed by firearms (CDC, 2010a). It is the leading cause of death in African Americans 10 to 24 years old (CDC, 2010a). Refer to Box 29.5 for factors that contribute to violence among adolescents. In a nationwide survey conducted in 2009, 17.5% of youth reported carrying a weapon (gun, club, or knife) on one or more days within the past 30 days (CDC, 2010a) (see Healthy People 2020).

#### HEALTHY PEOPLE 2020

Objective	Nursing Significance
Reduce homicides, physical fighting, and bullying among adolescents and weapon carrying by adolescents on school property.	<ul style="list-style-type: none"> <li>• Screen teens at all encounters for indications of violent behaviors.</li> <li>• Provide education related to decreasing school violence at middle and high schools.</li> <li>• Encourage alternate, appropriate methods for dispelling anger.</li> </ul>
Reduce suicide attempts by adolescents.	<ul style="list-style-type: none"> <li>• Screen teens at all encounters for indications of depression.</li> </ul>

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

### Suicide

Suicide is the third leading cause of death in adolescents 15 to 19 years old (CDC, 2008b). In a nationwide CDC study, 15% of adolescents surveyed reported that they had seriously considered suicide within the past 12 months, with 11% creating a plan and 7% attempting to take their own life (CDC, 2008b). Certain factors can put youth at risk for suicide, but having these risk factors does not mean suicide will occur. Refer to Box 29.6 for risk factors for suicide in adolescents (see Healthy People 2020). Most people are not comfortable discussing the topic of suicide and therefore do not communicate openly about it. It is important that health care providers address this important health problem and work to prevent suicide. The National Center for Injury Prevention and Control (NCIPC) is working to create awareness of suicide as a serious public health problem and is developing strategies to reduce injuries and deaths due to suicide.

#### BOX 29.6

#### RISK FACTORS FOR SUICIDE IN ADOLESCENTS

- Depression or other mental illness
- Mental health changes
- History of previous suicide attempt
- Family history of suicide
- Poor school performance
- Family disorganization
- Substance abuse
- Homosexuality
- Giving away valued possessions
- Being a loner/having no close friends
- Changes in behavior
- Incarceration

### Dating Violence

Violent behavior that takes place in a context of dating or courtship is not a rare event. It is estimated that approximately 10% of teens in the U.S. are victims of dating violence (CDC, 2012b). Females are victims of dating violence more often than males and suffer more injuries than males. Dating violence in the teen years is a risk factor for continued violence exposure in adulthood. Risk factors for dating violence include inadequate parental supervision, depression or anxiety, learning difficulties, trouble at school, history of or hanging out with friends who have aggressive or bullying behavior, condoning or witnessing violence, prior victimization, and risky sexual practices (CDC, 2012b). Nurses need to assess for and provide interventions to those teens experiencing dating violence or those at risk for being a victim or perpetrator.

### Gangs

Much of youth violence is a result of the behavior of adolescent gangs. Nationwide there are an estimated 27,000 gangs with 788,000 members, with more males joining gangs than females (Egley, Jr., & O'Donnell, 2009). The risk factors for gang involvement relate to the adolescent, family, school, community, and peers. See Box 29.7 for risk factors for adolescent gang involvement. Gang membership occurs in cities and in suburban areas, but may differ in composition. All socioeconomic groups are represented in gang membership. Gang membership may aid in the formation of identity by providing status and a sense of belonging. However, adolescents who are gang members are more likely to commit serious and violent crimes.

## BOX 29.7

**RISK FACTORS FOR GANG INVOLVEMENT****Individual**

- Few social ties
- Delinquency involvement
- Drug dealing
- Physical violence or aggression
- Mental health problems, including depression
- Authority conflicts, rebellion, conduct problems
- Illegal gun ownership
- Precocious sexual activity
- Alcohol and drug use
- Increased life stressors, such as failing at school, fights with friends, or death of someone close

**Family**

- Poor family relationship
- Antisocial parents
- Broken home
- Poverty/low socioeconomic status
- Family with criminal history, drug or alcohol problems
- Young mother
- Poor parental supervision or involvement
- Low parental education
- Child maltreatment

**School**

- Academic failure
- Low academic motivation
- Truancy and dropping out of school
- Frequent school transitions
- Negative labeling by teachers (as disturbed, disruptive)

**Community**

- Poverty
- Poor housing conditions
- High availability and use of drugs in neighborhood
- Exposure to violence and racial prejudice
- High crime area
- Availability of guns

**Peer**

- Antisocial peers
- Association with delinquent, aggressive peers
- Peer drug use
- Peer gang membership

Adapted from Howell, J.C. (2010). Gang Prevention: An Overview of Research and Programs, *Office of Juvenile Justice and Delinquency Prevention, Juvenile Justice Bulletin*. Retrieved August 25, 2011 from <https://www.ncjrs.gov/pdffiles1/ojjdp/231116.pdf>

**Nursing Interventions to Decrease Youth Violence**

Nurses working with adolescents should include violence prevention in anticipatory guidance. Violence is a learned behavior. It is often reinforced by the media, television, music, and personal example. Explain to parents, teachers, and peers the importance of being good role models. Parents should monitor video games, music, television, and other media to decrease exposure to violence. Parents need to know who their adolescent's friends are and monitor for negative behaviors and actions. Pediatric nurses play a key role in identifying at-risk youth and developing, planning, implementing, and evaluating interventions to prevent youth violence.

**Substance Use**

Agents commonly abused by children and adolescents include alcohol, prescribed medications such as Ritalin and OxyContin, hallucinogens, sedatives, analgesics, anxiolytics, steroids, inhalants (inhaling fumes of common household products), stimulants, opiates, and various club drugs such as ecstasy, gamma-hydroxybutyrate (GHB), and lysergic acid diethylamide (LSD). The substance abused is related to its availability and cost. Two common substances that are more accessible and have the highest incidence of use are tobacco and alcohol. A national survey found that 66% of high school students and 32% of middle school students attend a school where they have witnessed drugs used, kept or sold (National Center on Addiction and Substance Abuse at Columbia University, 2010). Drug use progresses from beer or wine to cigarettes or hard liquor and then to marijuana, followed by illicit drugs.

Some of the long-term effects and consequences of drug and alcohol use include possibility of overdose and death, unintentional injuries, irrational behaviors, inability to think clearly, unsafe driving and legal consequences, problems with relationships with family and friends, sexual activity and STIs, and health problems such as liver problems (hepatitis) and cardiac problems (sudden death with cocaine). Refer to Table 29.4 for commonly abused drugs and behaviors exhibited (see Healthy People 2020) (see Evidence-Based Practice 29.1).

**Take Note!**

African Americans have lower rates of most licit and illicit drug use than Caucasians (Johnston, O'Malley, Bachman, & Schulenberg, 2011)

**EVIDENCE-BASED PRACTICE 29.1****PREDICTING INFLUENCES ON ADOLESCENT ALCOHOL AND OTHER DRUG USE OUTCOMES****STUDY**

Peers and family play an important role in an adolescent's development. Substance use, abuse and treatment outcomes are also greatly influenced by family and friends. Peer influence increases and the importance of friends continues to rise as the adolescent matures. Research suggests that having friends that use alcohol and other drugs (AOD) greatly influences whether or not the teen will use AOD. The authors surveyed 419 adolescents age 13 to 18 years of age who were admitted into 4 different AOD treatment programs. They followed up with a telephone survey a year later. The purpose of the study was to examine characteristics that predict 1 year abstinence, mainly looking at family environment and peer networks.

**Findings**

This study indicated that peer networks were related to abstinence outcomes but family environment (such as family conflict, limit setting, and positive family experiences) was not. Positive peer influences predicted 1 year abstinence. Teens with fewer friends (less than 4) who use AOD were more likely to be abstinent than those with four or more friends that used AOD.

**Nursing Implications**

Nurses need to recognize and respect the important role friends and peer acceptance plays in the adolescent's life. Family has long been involved in treatment programs and nurses need to involve positive peer influences and provide support, encouragement, and education on how to change peer networks and to develop positive peer groups.

Adapted from Ramirez, R., Hinman, A., Sterling, S., Weisner, C. & Campbell, C. (2012). Peer Influences on Adolescent Alcohol and Other Drug Use Outcomes. *Journal of Nursing Scholarship*, 44(1), 36-44.

**HEALTHY PEOPLE 2020****Objective**

Reduce the proportion of adolescents who report that they rode, during the previous 30 days, with a driver who had been drinking alcohol.

Reduce steroid use among adolescents.

Increase the proportion of adolescents who disapprove of substance abuse.

Increase the proportion of adolescents never using substances.

Reduce the past-year non-medical use of prescription drugs.

Reduce the proportion of adolescents who use inhalants.

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

**Nursing Significance**

- Provide education in the office, hospital, or school related to adverse effects of tobacco, alcohol, and illicit substance use.
- Educate families, teens, and coaches about the negative effects of anabolic steroids.
- Praise teens for abstaining from the above substances and rising above peer pressure.

**Tobacco**

Tobacco use remains the leading preventable cause of death in the United States, causing more than 440,000 deaths each year (CDC, 2011b). Long-term consequences of youth smoking are reinforced by the fact that most young people who smoke regularly continue to smoke throughout adulthood. Each day in the United States, approximately 3,900 children less than 8-year-olds try their first cigarette, with 950 becoming regular smokers; 90% of adult smokers started smoking before age 19 (American Cancer Society, 2008; American Lung Association, 2010). Half of these smokers will die from the effects of smoking (American Lung Association, 2010). An estimated 6.4 million people will die prematurely because of smoking as adolescents (American Lung Association, 2010). Although the overall rate of smoking has declined since 1999, rates over the past several years have remained stable but still are high, with 19% of high school students reporting current cigarette use (CDC, 2010c). Approximately 8% of high school students use smokeless tobacco (American Lung Association, 2010). Teens who smoke are 3 times more likely than nonsmokers to use alcohol, 8 times more likely to use marijuana, and 22 times more likely to use cocaine (Focus Adolescent Services, 2008b). Smoking is associated with other risky behaviors, including fighting and

**TABLE 29.4** DRUGS COMMONLY ABUSED

Drug	Manifestations	Considerations
Marijuana	Red eyes, dry mouth, euphoria, relaxation, decreased motivation, loss of inhibition, appetite stimulation	Considered a gateway drug
Cocaine	Weight loss, euphoria, elation, agitation, increased motor activity, pressured speech, tachycardia, hypertension, anorexia, insomnia	Psychotic behavior with large doses; if combined with other drugs can be fatal
Opiates	Elation, euphoria, detachment, drowsiness, constricted pupils, slurred speech, impaired judgment	Self-neglect with malnutrition and dehydration; criminal behaviors to get drugs; infections at injection sites
Amphetamines	Euphoria, agitation, weight loss, insomnia, tachycardia, hypertension	Possible paradoxical effect of depression in children
Hallucinogens	Hallucinations, illusions, depersonalization, heightened awareness, dilated pupils, hypertension, increased salivation, distorted perceptions	Panic flashbacks long after use of drugs; psychotic behaviors
Phencyclidine hydrochloride (PCP)	Euphoria, distorted perceptions, agitation, violence, antisocial behaviors, hypertension, increased salivation, increased pain response	Irrational behaviors, panic, psychosis
Barbiturates	Euphoria followed by depression or hostility; impaired judgment; decreased inhibitions; slurred speech; incoordination	Often used with stimulants; may have a paradoxical effect of hyperactivity in children

Adapted from Stager, M.M. (2011). Substance Abuse. In R. M. Kliegman, B. F. Stanton, J.W. St. Geme, N.F. Schor, & R.E. Behrman, (Eds.), *Nelson's textbook of pediatrics* (19th ed., p. 671-85). Philadelphia: Saunders.

engaging in unprotected sex. The short-term health effects of smoking include damage to the respiratory system, addiction to nicotine, and the associated risk of other drug use. Smoking negatively impacts physical fitness and lung growth and increases the potential for addiction in adolescents. Smokeless tobacco may also cause many problems. It can lead to bleeding gums and sores in the mouth that never heal. Smokeless tobacco use leads to discoloration of the teeth and eventually may lead to cancer.

### Alcohol

In the United States alcohol is one of the most abused drugs, though many do not consider it a drug at all. It is estimated that 80% of adolescents have tried alcohol by the time they reach adulthood (Dowshen, 2009). A national survey on drug use found that nearly three quarters of students have consumed alcohol by the end of high school, with 36% consuming alcohol by the end

of 8th grade (Johnston et al., 2011). More than half of 12th graders and 16% of 8th graders reported having been drunk at least once (Johnston et al., 2011). The findings revealed that there were no substantial differences among various sociodemographic subgroups with respect to drinking rates, although alcohol use is lowest in African Americans and highest in Caucasians. The incidence of alcohol use increases throughout adolescence. Adolescents who begin drinking before the age of 15 are five times more likely to develop alcohol dependence than those who begin drinking at the age of 21 (Focus Adolescent Services, 2008a). Alcohol use in adolescence can lead to prevailing alcohol use in adulthood and contribute to physical health problems. It may also precede other drug abuse.

### Illicit Drugs

Adolescents may also experiment with or abuse illicit drugs. Substance abuse remains a widespread problem

among American adolescents. A national survey on drug use showed the prevalence rate for 12th graders for marijuana use to be 34.8%, amphetamines 7.4%, ecstasy 4.5%, Salvia 5.5%, cocaine 2.9%, LSD 2.6%, inhalants 3.6%, over-the-counter medications (such as cold medicines) 5.8%, Vicodin 8%, OxyContin 5.1%, and steroids 1.5% (Johnston et al., 2011).

Factors that primarily affect drug use include the psychoactive potential and benefits reported, how risky the drug is to use, how acceptable it is to peer groups, and the accessibility and availability of the drug. The more risky or less accepted a drug is by peers, the less likely the adolescent will use it.

### Nursing Interventions to Decrease Substance Use Among Teens

Substance use in adolescence is related to poorer health outcomes; therefore, it is important that nurses are aware of interventions to decrease these behaviors. Based on reviews of programs and interventions, it has been found that certain methods work. Programs that reach children and adolescents through a variety of sources such as school, family, community, and media campaigns are more successful. Programs that address all forms of drug use (alcohol, tobacco, and illicit drugs) tend to work well. Programs that focus on increasing awareness of the risks and health consequences of substance use are important. Initial research suggests that peer teaching with adult facilitation is successful (Bandy & Moore, 2008). Programs that focus on anti-drug attitudes and drug resistance along with enhancing self-esteem, social support, and stress-specific coping skills are beneficial. Topics that should be discussed include:

- Short- and long-term effects of alcohol, tobacco, and drugs on health
- Risk factors and implications for unintentional injuries and sexual activity
- Short- and long-term effects of alcohol, tobacco, and drugs on relationships and school performance and progression
- The how and why of chemical dependency
- Impact of substance abuse on society
- Importance of maintaining a healthy lifestyle
- Importance of resisting peer pressure to use drugs and alcohol
- Importance of having confidence in one's own judgment

*Think back to Cho, who was introduced at the beginning of the chapter. List common developmental concerns of the adolescent. What anticipatory guidance related to these concerns would you provide?*

### KEY CONCEPTS

- Adolescence is a period of rapid and variable growth in the areas of physical, psychosocial, cognitive, and moral development.
- The adolescent is developing his or her own identity, becoming an abstract thinker, and developing his or her own set of morals and values. Inability to successfully develop an individual identity leads to poor preparation for the challenges of adulthood.
- Relationships with parents fluctuate widely during adolescence. The teenager eventually becomes emancipated from his or her parents.
- Peers become most important—guiding mainly the early and middle adolescent in his or her decisions, while the late adolescent can usually formulate his or her own decisions.
- Adolescence is a critical time in the development of sexuality. Sexuality includes the thoughts, feelings, and behaviors surrounding the adolescent's sexual identity.
- The egocentric and invincible thought processes of the adolescent can lead to injuries. Health care providers must emphasize safety regarding cars, bikes, water, firearms, and fire.
- Motor vehicle accidents are the number one cause of death in adolescents (CDC, 2010d).
- Nutritional habits of the adolescent lead to deficiency in vitamins and minerals needed for the rapid growth during this period.
- Obesity in adolescents is a growing health concern. Health care providers are facing increased numbers of adolescents with hypertension, type 2 diabetes, and hyperlipidemia.
- Substance abuse and experimentation is common during adolescence; it is associated with other risk-taking behaviors such as injuries and sexual activity.
- Health care providers must work collaboratively with the adolescent in the development of interventions to promote health.

## MULTIPLE CHOICE QUESTIONS

- When giving parents guidance for the adolescent years, the nurse would advise the parents to: (Choose all that apply.)
  - Accept the adolescent as a unique individual
  - Provide strict, inflexible rules
  - Listen and try to be open to the adolescent's views
  - Screen all of his or her friends
  - Respect the adolescent's privacy
  - Provide unconditional love
- In developing a weight-loss plan for an adolescent, which would the nurse include? (Choose all that apply.)
  - Have parents make all of the meal plans.
  - Eat slowly and place the fork down between each bite.
  - Have the family exercise together.
  - Refer to an adolescent weight-loss program.
  - Keep a food and exercise diary.
- Which is associated with early adolescence? (Choose all that apply.)
  - Uses scientific reasoning to solve problems
  - Still at times wants to be dependent upon parents
  - Incorporates own set of morals and values
  - Is influenced by peers and values memberships in cliques
- What has the most influence in deterring an adolescent from beginning to drink alcohol?
  - Drinking habits of parents
  - Drinking habits of peers
  - Drinking philosophy of adolescent's culture
  - Drinking philosophy of adolescent's religion

## CRITICAL THINKING EXERCISES

- During a sports physical examination, Susan, a 16-year-old, tells her physician that she is overweight. What additional information would the physician obtain?

- The parents of Joe, a 14-year-old, talk to the school nurse about Joe's behavior at home. He is moody, fights with his younger siblings, only wants to be on his computer, and does not want to go on the family vacation. What advice would the nurse give the parents?
- Jane tells the school nurse that she might be homosexual. What additional information would the nurse obtain?
- Alicia's parents are worried because all of Alicia's friends wear heavy makeup and have multiple piercings and hair colors. What advice would the nurse give Alicia's parents?

## STUDY ACTIVITIES

- Talk to an early, middle, and late adolescent. Compare and contrast their interactions with you. Identify what psychosocial, cognitive, and moral stage they are in, using examples from their conversations with you.
- Have an adolescent keep a food and exercise diary for 1 week. Analyze the information. Develop with the adolescent any interventions needed to promote healthy eating and exercise habits.
- Plan a class on the dangers of smoking for 15-year-olds.
- Plan a class for parents on how to keep the lines of communication open for adolescents.
- Go to <http://www.mypyramid.gov> and create and compare a customized meal plan for a healthy adolescent versus an obese adolescent.

# Atraumatic Care of Children and Families

## Learning Objectives

*Upon completion of the chapter, you will be able to:*

1. Define the key terms used in this chapter.
2. Describe the major principles and concepts of atraumatic care.
3. Incorporate atraumatic care to prevent and minimize physical stress for children and families.
4. Discuss the major components and concepts of family-centered care
5. Utilize excellent therapeutic communication skills when interacting with children and their families.
6. Describe the process of health teaching as it relates to children and their families.

*Emma Moore, 4 years old, is admitted to the pediatric unit with a suspected head injury from a fall. She was playing at a playground with her babysitter and fell from the top of the slide.*

### **Words of Wisdom**

Children need to be seen for who they really are.

**Atraumatic care** is defined as therapeutic care that minimizes or eliminates the psychological and physical distress experienced by children and their families in the health care system (Hockenberry & Wilson, 2009; Wong, n.d.). This concept is based on the underlying premise of “do no harm.” Box 30.1 highlights the major principles of atraumatic care.

Pediatric nurses must be vigilant for any situation that may cause distress and must be able to identify potential stressors. It is important to provide nursing care that decreases the child’s exposure to stressful situations and prevents or minimizes pain and bodily injury; take steps to minimize separation of the child from the family; and utilize techniques of communication and provide teaching that promotes a sense of control.

### BOX 30.1

#### PRINCIPLES OF ATRAUMATIC CARE

- Prevent or minimize physical stressors, including pain, discomfort, immobility, sleep deprivation, inability to eat or drink, and changes in elimination.
- Avoid or reduce intrusive and painful procedures, such as injections, multiple punctures, urethral catheterization.
- Avoid or reduce other kinds of physical distress, such as noise, smells, shivering, nausea and vomiting, sleeplessness, restraints, skin trauma.
- Control pain via frequent assessments and use of pharmacologic and nonpharmacologic interventions.
- Prevent or minimize parent–child separation.
  - Promote family-centered care, treating the family as the client.
  - Use core primary nursing.
  - Consider research findings related to preferences of parents and children and whether or not to be together.
- Promote a sense of control.
  - Elicit the family’s knowledge about the child and his or her health condition, promoting partnerships, empowerment, and enabling.
  - Reduce fear of the unknown through education, familiar articles, and decreasing the threat of the environment.
  - Provide opportunities for control, such as participating in care, attempting to normalize daily schedule, and providing direct suggestions.

Adapted from Wong, D. L. (n.d.). Innovative Approaches for Atraumatic Cancer Care. Retrieved on May 3, 2009, at <http://www.authorstream.com/presentation/Carolina-48857-op077-INNOVATIVE-APPROACHES-ATRAUMATIC-CANCER-CARE-DEFINITION-SOURCES-PATIENT-FAMILY-STRESSORS-as-Entertainment-ppt-powerpoint/>

Atraumatic care involves guiding children and their families through the health care experience using a family-centered approach by promoting family roles, fostering family support of the child, and providing appropriate information. Help children cope with this experience by using age-appropriate and child-specific interventions. Preparation can help children and their families to adjust to illness and hospitalization. Use appropriate techniques for therapeutic communication (goal-directed, focused, purposeful communication), therapeutic play (type of play that provides an emotional outlet or improves the child’s ability to cope with the stress of illness and hospitalization), and client education to help the child and family understand the reason for the hospitalization and the necessary tests and procedures. In addition, help the family and other health care personnel to obtain the resources and relationships they need for optimal care.

The best pediatric nursing care encompasses the concepts of atraumatic care. Minimizing physical stressors during procedures, providing family-centered care, and utilizing excellent communication skills on the part of the nurse enhance the health care experience for the child and family. Having an informed and educated family is the best way to provide optimal health care for children.

Table 30.1 gives suggestions for incorporating the principles of atraumatic care into nursing care for the child and family. Look for tips on atraumatic care as it relates to specific topics throughout the text.

#### PREVENTING/MINIMIZING PHYSICAL STRESSORS

The health care facility or hospital is an unfamiliar environment for children and parents and may upset or intimidate them. They may feel anxiety, fear, helplessness, anger, or loss of control. Even health care procedures performed in the home or school may be perceived as threatening to children. To prevent and minimize the physical stress experienced by children and their families in relation to health care, pediatric nurses, child life specialists, and other health care professionals recommend the use of atraumatic care.

#### Utilizing the Child Life Specialist

The **child life specialist (CLS)** is a specially trained individual who provides programs that prepare children for hospitalization, surgery, and other procedures that could be painful (Child Life Council, 2010). The CLS is a member of the multidisciplinary team and works in conjunction with the health care providers and parents

**TABLE 30.1** SUGGESTIONS FOR ATRAUMATIC CARE

Principle	Suggestions for Nursing Care
Preventing or minimizing physical stressors	<ul style="list-style-type: none"> <li>• For painful injections, blood draws, or IV insertion, use numbing techniques (see Chapter 35).</li> <li>• During painful or invasive procedures, avoid traditional restraint or “holding down” of the child. Use alternative positioning such as “therapeutic hugging.”</li> <li>• If the above-mentioned positions are not an option, have the parent stand near the child’s head to provide comfort.</li> <li>• Insert a saline lock if the child will require multiple doses of parenteral medications.</li> <li>• Advocate for minimal laboratory blood draws.</li> <li>• Minimize intramuscular or subcutaneous injections.</li> <li>• Provide appropriate pain management (refer to Chapter 36).</li> </ul>
Preventing or minimizing child and family separation	<ul style="list-style-type: none"> <li>• Promote family-centered care.</li> <li>• In the hospital, provide comfortable accommodations for the parent.</li> <li>• Allow the family the choice about whether to stay for an invasive procedure, and support them in their decision.</li> </ul>
Promoting a sense of control	<ul style="list-style-type: none"> <li>• Maintain child’s home routine related to activities of daily living.</li> <li>• In the hospital, use primary nursing.</li> <li>• Encourage the child to have a security item present if desired.</li> <li>• Involve the child and family in planning care from the moment of the first encounter.</li> <li>• Empower the family and child by providing knowledge.</li> <li>• Allow the child and family choices when they are available.</li> <li>• Make the environment more inviting and less intimidating.</li> </ul>

to foster an atmosphere that promotes the child’s well-being. Services provided by a CLS include:

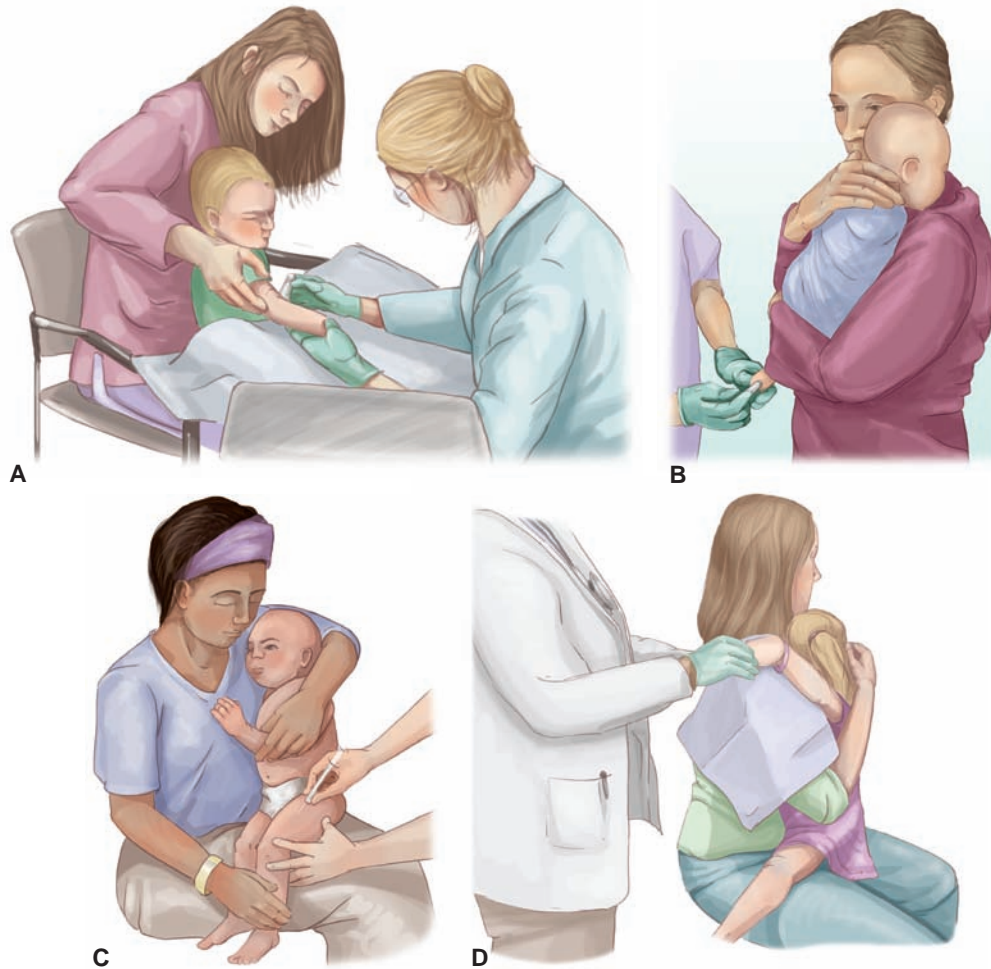

- Nonmedical preparation for tests, surgeries, and other medical procedures
- Support during medical procedures
- Therapeutic play
- Activities to support normal growth and development
- Sibling support
- Advocate for the child and family
- Grief and bereavement support
- Emergency room interventions for children and families
- Hospital preadmission tours and information programs
- Outpatient consultation with families (Child Life Council, 2012)

The goal of the CLS is to decrease the anxiety and fear of the child while improving and encouraging understanding and cooperation of the child. The CLS considers the needs of siblings or other children who may

be affected by the child’s illness or trauma. The CLS provides engaging and uplifting events by coordinating special entertainment and activities. The CLS is an excellent resource and provides education to health care providers and families. The American Academy of Pediatrics recommends child life services as “an essential component of quality pediatric health care and are integral to family-centered care and best practice models of health care delivery for children” (American Academy of Pediatrics, Child Life Council, and Committee on Hospital Care [AAP], 2006, p. 1760).

## Minimizing Physical Stress During Procedures

Children undergo numerous diagnostic and therapeutic procedures in a wide range of settings during their development. These procedures may be performed in the community or outpatient setting or in a care facility.

**FIGURE 30.1** Positioning a child for comfort during a painful procedure. **(A)** Sitting on the parent's lap while undergoing allergy testing provides this toddler with a sense of comfort. **(B)** Position the infant cuddled over the parent's (preferable) or the nurse's shoulder when obtaining a heelstick. **(C)** Use "therapeutic hugging" to maintain a child's position when the child is receiving an IM injection. **(D)** Use "therapeutic hugging" to position a child while the child is having an IV line inserted.

Regardless of the procedure to be performed and the setting, children, like adults, need thorough preparation before the procedure and support during and after the procedure, to promote the best outcome and to ensure atraumatic care.

Using positions that are comforting to the child during painful procedures is an important aspect of atraumatic care (see Fig. 30.1). **Therapeutic hugging** (a holding position that promotes close physical contact between the child and a parent or caregiver) may be used for certain procedures or treatments where the child must remain still. For example, the parent can hold the child in his or her lap snugly to prevent the child from moving during an injection or venipuncture. When using this technique, make sure the parent understands his or her role and knows which body parts to hold still in a safe manner. Alternatively, distraction or stimulation (such as

with a toy) can help to gain the child's cooperation. Refer to Box 30.2 for distraction methods.

#### BOX 30.2

##### DISTRACTION METHODS

- Have the child point toes inward and wiggle them.
- Ask the child to squeeze your hand.
- Encourage the child to count aloud.
- Sing a song and have the child sing along.
- Point out the pictures on the ceiling.
- Have the child blow bubbles.
- Play music appealing to the child.

## Before the Procedure

Appropriate preparation for procedures helps to decrease the child's and family's anxiety level, promote the child's cooperation, and support the child's and family's coping skills, improve recovery, and increase trust between the child, their family, and the health care providers (LeRoy et al., 2003). Adequate preparation also helps to foster the child's feeling of mastery over a potentially stressful event (e.g., undergoing invasive procedures in particular is extremely distressing for children) (LeRoy et al., 2003).

Preparation may include psychological preparation (including explanation and education) as well as preparing the child physically. It is very important to employ the concepts of atraumatic care when preparing children for a procedure. General guidelines for preparation include the following:

- Provide a description of and the reason for the procedure using age-appropriate language (e.g., "The doctor will look at your blood to see why you are sick.>").
- Describe where the procedure will occur (e.g., "The x-ray department has big machines that won't hurt you; it's a little cold there too.>").
- Introduce strange equipment the child may see (e.g., "You will lie on a special bed that moves in the big machine, but you can still see out.>").
- Describe how long the procedure will last (e.g., "You will be in the x-ray department until lunchtime.>").
- Identify unusual sensations that may occur during the procedure (e.g., "You may smell something different, like an alcohol smell." or "The MRI machine makes loud noises.>").
- Inform the child if any pain is involved.
- Tell the child it is okay to cry or yell
- Identify any special care required after the procedure (e.g., "You will need to lie quietly for 15 minutes afterward.>").
- Discuss ways that may help the child stay calm, such as using distraction methods or relaxation techniques (e.g., "During the procedure you may want to count from 1 to 100 or sing your favorite song.") (Justus et al., 2006).

### Take Note!

In the hospital, perform all invasive procedures in the treatment room or a room other than the child's room. The child's room should remain a safe and secure area (Leahy et al., 2008).

A major aspect of preparation involves play. In general, young children respond better to play materials and older children benefit more from viewing peer modeling films (LeRoy et al., 2003). However, consider the child's temperament, coping strategies, and previous experiences as well as developmental needs and cognitive abilities. First, gain trust and provide support. Include

the child's parents, because parents are usually the greatest source of comfort for the child. Be short, simple, and appropriate in explaining situations at the child's level of development. Explain what is to be done and what is expected of the child. Avoid terms that have double meanings or might be confusing. Table 30.2 lists alternative words or phrases to use for terms that may be confusing or misunderstood.

## During the Procedure

Use a firm, positive, confident approach that provides the child with a sense of security. Encourage cooperation by involving the child in decision making and allowing the child to select from a list or group of appropriate choices. Allow the child to express feelings of anger, anxiety, fear, frustration, or any other emotions. Often this is how a child communicates and copes with the situation. Remind the child that it is okay to scream or cry, but that it is very important to hold still. Use distraction methods such as those listed in Box 30.2.

Toddlers and preschoolers often resist procedures despite preparation for them. Being held down or restrained is often more traumatizing to the young child than the procedure itself. Use alternative methods (positions that provide comfort for the child) to keep the child still during the procedure (refer back to Fig. 30.1). The older child can be held while using a book or story for distraction.

## After the Procedure

After the procedure, hold and comfort the child. Cuddle and soothe infants. Encourage children to express their feelings through play, such as dramatic play or use of puppets. Gross motor activities such as pounding or throwing are also helpful for children to discharge pent-up feelings and energy. School-age children and adolescents may not outwardly demonstrate behavior indicating the need for comforting; however, provide them with opportunities to express their feelings and be comforted. Remember to praise children for appropriate behavior during the procedure and after all interventions are completed.

### Take Note!

Remember to utilize child life specialists when available.

*The physician's orders for Emma include starting intravenous fluids and obtaining blood work upon arrival to the unit. As the admitting nurse, how will you provide atraumatic care?*

TABLE 30.2

## ALTERNATIVES FOR CONFUSING OR MISUNDERSTOOD TERMS

Term to Avoid	How Children Might Interpret It	Use These Terms Instead
Catheter	Too technical	Tube
Deaden	Kill?	Make sleepy
Dye	“Die”	Special medicine to help the doctor see _____ (part of the body) better
Electrodes	Too technical	Stickers, ticklers, snaps
ICU	“I see you”	Special room with your own nurse
Incision, cut open, make a hole	Too explicit	Special or small opening
Monitor	Too technical	TV screen
Organ	Like a piano?	Special place in the body
Pain	May be too explicit	Child’s word for hurt; “boo-boo”
Put to sleep, anesthesia	May confuse with putting a pet to sleep	Special kind of sleep
Shot	Children are scared of shots	Medication under the skin
Stool	Like you sit on?	“Poop” or child’s word for it
Stretcher or gurney	“Stretch her”	Rolling bed or special bed on wheels
Take your temperature/BP	Where are you going to “take” them?	See how warm you are/hug your arm
Test	Like at school? (the child will need to perform)	See how your heart is working
Tourniquet	Too technical	Special kind of rubber band
Urine	“You’re in?”	“Pee” or child’s word for it
X-ray	Don’t understand	Picture or big camera to take pictures of the inside of your body

Partially adapted from Florida Children’s Hospital, Child Life Department. (n.d.). *Suggested vocabulary to use with children.*

## PREVENTING OR MINIMIZING CHILD AND FAMILY SEPARATION: PROVIDING CLIENT- AND FAMILY-CENTERED CARE

**Family-centered care** involves a partnership between the child, family, and health care providers in planning, providing, and evaluating care (O’Malley, Brown, & Krug, 2008). It works well for children of any age and in all arenas of health care, from preventive care of the healthy child to long-term care of the chronically or terminally ill child. Family-centered care enhances parents’ and caregivers’ confidence in their own skills and also prepares children and young adults for assuming responsibility for their own health care needs. It is based on the

concept that the family is the constant in the child’s life and the primary source of strength and support for the child (AAP, 2007; Harrison, 2010).

According to the American Academy of Pediatrics (2007), family-centered care focuses on several core principles:

- Respect for the child and family
- Recognition of the effects of cultural, racial, ethnic, and socioeconomic diversity on the family’s health care experience
- Identification of and expansion of the family’s strengths
- Support of the family’s choices related to the child’s health care
- Maintenance of flexibility
- Provision of honest, unbiased information in an affirming and useful approach

- Assistance with the emotional and other support the child and family require
- Collaboration with families
- Empowerment of families

When children's health care is provided through a family-centered approach, many positive outcomes are possible, including (AAP, 2007):

- Anxiety is decreased.
- Children are calmer and pain management is enhanced.
- Recovery times are shortened.
- Families' confidence and problem-solving skills are improved.
- Communication between the health care team and the family is also improved, leading to greater satisfaction for both health care providers and health care consumers (families).
- A decrease in health care costs is seen and health care resources are used more effectively.

Ways to increase collaboration between the family and the health care team may include a family advisory board, newsletter, client conferences, or parent resource notebooks. Methods for increasing communication between the health care team and the family may include the use of mailboxes or dry-erase boards for updating the daily plan of care, including the parents' participation in rounds, or through a daily assessment of health status by the child or family.

Vigilant parents are committed to their child's care and most want to be present for all aspects of their child's care. They want to be part of the decision-making process regarding their child's care; they want to be heard and develop a rapport with the health care professionals caring for their child. They demonstrate resilience in their ability to make it through the emotional upheaval associated with an illness. It is important to be sensitive to the inconveniences that their child's illness may impose on the family. Address the family's emotional and spiritual needs, attend to their concerns, and provide the best accommodations possible (when the child is hospitalized) (Fig. 30.2). Practicing true family-centered care may empower the family, strengthen family resources, and help the child and family feel more secure and supported throughout the process.

#### Take Note!

Some parents will not know how to advocate or speak up for their child. As a nurse you must help open this door for them.

*How could family-centered care help the Moore family described at the beginning of the chapter?*

**FIGURE 30.2** Providing a comfortable area for the parent to rest is an important component of family-centered care.

## PROMOTING A SENSE OF CONTROL

During times of illness, hospitalization, or health-related interventions, the child and family can experience an extreme sense of loss of control. Providing effective communication and teaching can help foster feelings of control and improve the child and family's ability to cope. Assisting the family to obtain necessary information, resources, and relationships attributes to optimal health care for the child and family. Communication and teaching are skills that are used continuously in pediatric nursing, no matter what the setting or the child's state of health.

## Enhancing Communication

**Effective communication** with children and their parents is critical to providing atraumatic quality nursing care. Child- and parent-centered communication enhances client outcomes and child and family satisfaction with nursing care. Effective communication is the foundation of the therapeutic relationship and leads to increased knowledge and health care behaviors on the part of the child and family (Levetown & Committee on Bioethics, 2008). Nurses are in an ideal position to improve communication in the health care environment. They need to ensure inclusion of the child and family in health conversations and to clarify misconceptions following medical encounters.

Children are often socialized to be passive participants in health care, doing as they are told, with or without protests. "As pediatric nurses, we have an obligation to listen, to hear, and to feel the voices of the children in our care" (McPherson & Thorne, 2000). Children can inform nurses of their experiences in an accurate fashion, and nurses need to be able to discern this information from communication with the child.

**HEALTHY PEOPLE 2020****Objective**

Increase the proportion of persons who report that their health care providers have satisfactory communication skills

**Significance**

- Develop effective child- and parent-centered communication skills.
- Ensure inclusion of children and families in health conversations.
- Clarify any misconceptions following medical encounters.
- Adapt communication style based on developmental age of child.

Communication patterns can vary greatly from one child to the next. Some children are very talkative while others are quiet. Children may be more apt to communicate if they are engaged in another activity. Children often use fewer words than adults and may rely more on nonverbal communication and silence. Parents more often require neutral communication (i.e., verbal communication that is related to assessing and solving problems), whereas children more often desire affective communication (establishment of rapport and trust, giving comfort). The best communicators in pediatric nursing find a balance between neutral and affective communication (Shin & White-Traut, 2005). Communicating in the pediatric setting can be more difficult than in the adult setting. The pediatric nurse must communicate with different ages of children, as well as on a supportive level with adolescents and parents (Shin & White-Traut, 2005).

### **Developmental Techniques for Communicating With Children**

Effective communication with children involves a variety of age-appropriate methods. Encouraging children to participate actively gives them some control over the interaction (Shin & White-Traut, 2005). If the child is shy, talk to the parents first to give the child time to “warm up” to you. Use specific and clear phrases in an unhurried, quiet, yet confident manner. Communicate at the child’s eye level (Fig. 30.3). Spending time and incorporating play with younger children, even just a few moments, may help them feel more at ease with you. Instead of direct questioning, use dolls, puppets, or stuffed animals with younger children (Fig. 30.4). The use of metaphors (e.g., referring to white blood cells as “bad guy fighters”) and stories can help to illustrate concepts to young and school-age children.

Older children need privacy. Provide the child or adolescent with honest answers at a developmentally appropriate level. Allow children to express their thoughts

**FIGURE 30.3** Sitting at the child’s level and allowing the child time for self-expression are steps that improve therapeutic communication.

and feelings. Offer the child choices when possible but only when they truly exist. Encourage children to write and draw about their experiences. This may increase their understanding and also draw attention to any misconceptions or fears. Box 30.3 lists requirements for communication with children and adolescents.

Children feel empowered when health care professionals communicate directly with them. Include children in discussions and avoid talking about them in their presence. Children may also desire advice about their health care and reassurance about their health status. To be effective when communicating with children of different developmental stages, the nurse must become familiar with how children of different ages communicate and then use age-appropriate techniques for effective communication:

- Infants primarily communicate through touch, sight, and hearing. Communication with the infant can occur by cuddling, holding, rocking, and singing to the

**FIGURE 30.4** Communication or teaching with dolls may be useful with younger children.

## BOX 30.3

**BASICS FOR COMMUNICATING WITH CHILDREN**

- Introduce yourself and explain your role.
- Position yourself at the child's level.
- Allow the child to remain near the parent if needed, so the child can remain comfortable and relaxed.
- Smile and make eye contact with the child if culturally appropriate.
- Direct your questions and explanations to the child.
- Listen attentively and pause to allow time for the child to formulate his or her thoughts.
- Use the child's or family's terms for body parts and medical care when possible.
- Speak in a calm, quiet, confident, and unhurried voice.
- Use positive rather than negative statements and directions.
- Encourage the child to express his or her feelings and ask questions.
- Observe for nonverbal cues.
- Ask for permission if you need to approach the child to avoid appearing threatening.

infant. Communication through play may be helpful in the older infant. Playful persuasion may help to distract the infant. When interacting with the infant be alert for signs of over stimulation, such as yawning, turning away, decreased eye contact, and increasing irritability (Deering & Cody, 2002).

- When working with toddlers and preschoolers, allow them time to complete their thoughts. Though language acquisition at this age is exponential, it often takes longer for the young child to find the right words, particularly in response to a query. When possible give this age group choices, ask specific questions, and respond to queries with simple answers. Participating in parallel play with toddlers, imaginative play with preschoolers or commenting on the child's toy or activity can open the door for communication with this age group (Deering & Cody, 2002).
- School-age children are very interested in learning and appreciate simple but honest and straightforward responses. When addressed first and allowed to respond, the school-age child may be eager to communicate. The school-age child may respond well to the use of a third-person conversation (e.g., "Some children feel anxious when entering the hospital."). It is also important to understand how the child views a situation before explaining or discussing it with him or her (Deering & Cody, 2002).
- Adolescents tend to experience strong feelings and emotions and perceive situations in extreme terms.

Building a trusting, respectful rapport is essential. When communicating with teenagers, remain non-judgmental, listen attentively, and do not force them to talk, to avoid alienating them and to keep lines of communication open (Deering & Cody, 2002).

For communication tips related to the child's age, see Table 30.3.

**Tips for Communicating with Parents**

When communicating with parents, be honest. Parents want to feel valued and should be equal partners in the health care team. Allow the parent to express concerns and ask questions. Explain equipment and procedures thoroughly. Help the parents to understand the long-term as well as short-term effects of the treatment. Teach the parents what the child will feel like and how he or she will look during a procedure. Teach and encourage the parent to perform as much of the child's care as is reasonable and permitted. Ask the parent about his or her perception of the child's progress. Allowing the parents to be involved in the care of their child gives them a sense of control and lets them know they are valued by the health care team. Provide parents with positive reinforcement, reassurance, guidance, and support.

*In the beginning of the chapter you were introduced to Emma Moore. Discuss ways to facilitate communication with Emma and her family/caregiver.*

**Teaching Children and Families**

Regardless of the type of practice or health care setting, nurses are in a unique position to help families manage the health care needs of their child. Indeed, the family has a right and a responsibility to participate fully in making decisions about health care processes for their child. This is true whether the child is hospitalized with a long-term, devastating illness or needs only health maintenance activities. To accomplish this, families need to be knowledgeable about such things as their child's condition, the health care management plan, and when and how to contact health care providers. With the limited time available in all health care arenas and shortened stays in inpatient facilities, the pediatric nurse must focus on teaching goals and begin teaching at the earliest opportunity.

**Goals of Child and Family Education**

The goal of child and family education is to:

- Improve the child and family's health literacy
- Encourage communication with health care providers

TABLE 30.3

## COMMUNICATING EFFECTIVELY WITH CHILDREN

Age	Techniques
Infants	<ul style="list-style-type: none"> <li>• Respond to crying in a timely fashion.</li> <li>• Allow the infant time to warm up to you.</li> <li>• Use a soothing and calming tone when speaking to the infant.</li> <li>• Talk to the baby directly.</li> </ul>
Toddlers	<ul style="list-style-type: none"> <li>• Approach toddlers carefully; they are often not only fearful but also quite resistant.</li> <li>• Use the toddler's preferred words for objects or actions so he or she is better able to understand.</li> <li>• Toddlers enjoy stories, dolls, and books.</li> <li>• Prepare toddlers for procedures just before they are about to occur.</li> </ul>
Preschoolers	<ul style="list-style-type: none"> <li>• Use play, puppets, or storytelling via a third-party approach.</li> <li>• Speak honestly.</li> <li>• Use simple, concrete terms.</li> <li>• Allow the child to have choices as appropriate.</li> <li>• Prepare preschoolers about 1 hour prior to a procedure.</li> </ul>
School-age children	<ul style="list-style-type: none"> <li>• Use diagrams, illustrations, books, and videos.</li> <li>• Allow the child to honestly express feelings.</li> <li>• Use third-party stories to elicit desired information.</li> <li>• Allow the child to ask questions related to care and treatment. Give the child adequate time for all of the questions to be answered.</li> <li>• Prepare the child a few days in advance for a procedure.</li> </ul>
Adolescents	<ul style="list-style-type: none"> <li>• Always respect the teenager's need for privacy.</li> <li>• Ensure confidentiality.</li> <li>• Use appropriate medical terminology, defining words as necessary.</li> <li>• Use creativity.</li> <li>• Prepare the teen up to 1 week prior to a procedure.</li> </ul>

- Improve health outcomes and promote healthy lifestyles
- Encourage involvement of child and family in care, and in decision making about care
- Improve compliance with care and treatment plan
- Promote a sense of autonomy and control

Overall goals for the child and family include the ability of children and families to make informed decisions, to perform basic health care skills, to recognize when the child has a problem and know how to respond to the problem, and when questions arise how to get answers.

### Teaching Children and Adolescents

Teaching children and adolescents is a vital part of pediatric nursing practice. Children and adolescents have

a great need for information about their illness as they attempt to master their anxiety and restore feelings of competency, self-confidence, and hope. As with adults, they learn best when their input is valued and they are actively involved in the learning process. The age and developmental level of the child will determine the amount, format, and timing of the information given. Before beginning to teach a child, it is important to establish rapport and lay the foundation for good communication. Refer back to “Developmental Techniques for Communicating With Children” and Table 30.3 for additional information related to communicating well with children and adolescents.

### TEACHING PRESCHOOL CHILDREN

When teaching young children, the nurse or family assumes part or all of the responsibility for what is learned, how it is learned, and when it is learned. Because they

have vivid imaginations, young children often attempt to invent pieces of information, or they pick up bits and pieces of misinformation that can lead to false assumptions. Skillfully delivered and timed information can promote trust, calmness, and control in an otherwise apprehensive and uncooperative preschooler. Table 30.4 presents some general guidelines for teaching young children.

### TEACHING SCHOOL-AGE CHILDREN

Unless they are quite ill, school-age children usually want to participate in their care. They have a need to cooperate and achieve. When teaching, speak directly to them and include them in the education plan. Parents can often learn by observing the care being given and taught to their child (Fig. 30.5). Table 30.5 provides some general guidelines to keep in mind when teaching school-age children.

### TEACHING ADOLESCENTS

Adolescents are particularly sensitive about maintaining body image and feelings of control and autonomy. This

is especially important with health care processes and decisions that affect them. Table 30.6 gives guidelines to use when teaching adolescents.

**FIGURE 30.5** Nurses need to adapt teaching to the child's developmental level. For the school-age child, teaching the child and parents together fosters the child's need for achievement.

**TABLE 30.4** GENERAL TEACHING TIPS FOR YOUNG CHILDREN

Teaching Tips	Practical Application
Offer simple, concise, concrete explanations based on the assessed needs, questions, and developmental level of the child.	Use a child's senses and relate what a procedure will look, sound, smell, taste, or feel like (e.g., "The MRI machine will sound very loud, like a big train.").
Be honest, even when the information you need to convey is not positive. This helps the child to form a bond of trust and confidence with caregivers.	Use the family's words that the child understands; use "soft words" (e.g., "This will feel warm" instead of "This will burn.>").
Time explanations to decrease anxiety and excess worry before the event. Avoid telling unpleasant news close to bedtime.	As a general rule, give toddlers information about procedures, medicines, and other interventions immediately beforehand; give 4- to 7-year-olds information 1 or 2 days in advance.
Parents know their child best. Eliciting information from them about their child's past behaviors and coping skills can often mean the difference between a positive and negative experience for their child.	Teach parents how to coach their child with pain management, visualization, or other methods of distraction when appropriate (e.g., "Remember when we went to the beach...?").
Provide an active role for the child. This helps to foster a child's sense of self-confidence and control over the situation.	Allow the child to help with simple self-care activities such as holding a dressing or piece of tape. Provide props and dolls to touch and feel as much as possible (e.g., "Your job is to keep your hands still.>").
Children's wishes must be respected when they verbalize or demonstrate that they do not want more information.	Keep explanations short and simple; know when to stop teaching.
Praise the child and let him or her know how much you appreciate his or her help and cooperation.	Use "please" and "thank you" often (e.g., "Thank you. I like the way you held still for me.>").

TABLE 30.5

## GENERAL GUIDELINES WHEN TEACHING SCHOOL-AGE CHILDREN

Teaching Tips	Practical Application
Allow the child some control and involvement in the decision-making process.	Offer choices whenever possible (taking the medicine with juice or milk), but don't offer choices when there are no alternatives (taking the medicine).
Children can relate present-day happenings to past experiences.	Use examples and past experiences that are familiar to the child (e.g., "Remember when you were first learning to swim...?").
Achievement and accomplishment are very important to children at this age, so anything they can be actively involved in will help them adjust and learn.	Provide an active role and allow the child to do as much of his or her care as possible. Use props, dolls, games, and computers to enhance learning.
At this age, most children are able to sequence, understand cause-and-effect, and make sense of time.	Teach children the steps involved and how long it will take (e.g., "Today I'm going to teach you how to change your dressing. This will help keep your cut clean. First, wash your hands...").
Gaining control over the situation and preparing mentally is important for their self-confidence.	Provide information 3 to 7 days in advance, depending on the child's age and developmental level.
Praise the child and let him or her know how much you appreciate his or her help and cooperation.	Use "please" and "thank you" often (e.g., "Thanks! You did a great job using your inhaler.>").

TABLE 30.6

## GENERAL GUIDELINES WHEN TEACHING ADOLESCENTS

Teaching Tips	Practical Application
Allow teens to be in control and involved in the decision-making process.	Speak directly to teens; consider their input in all decisions about their care and education.
Adolescents can process abstract information and understand how their actions affect long-term outcomes.	Provide reasons why something is important and discuss how their lives will be affected by their decision to take care of their health needs (e.g., "If you take your asthma medicine, you'll be better able to play tennis.>").
Adolescents are very concerned about how they look and how they fit in with peers.	Collaborate with the teen to develop acceptable solutions and strategies for dealing with health issues that affect personal appearance and peer acceptance (e.g., wig versus head scarves for hair loss from chemotherapy).
Adolescents strive for independence and have personal values and ideologies that may conflict with those of parents and the medical community.	Expect some noncompliance with care, despite your best educational efforts. Work together to achieve win-win outcomes of educational goals.

## MULTIPLE-CHOICE QUESTIONS

1. When providing atraumatic care to a child, which action would be most appropriate?
  - a. Applying restraints for any procedure that would be uncomfortable
  - b. Keeping the lights on in the child's room throughout the day and night
  - c. Limiting the use of topical anesthetics for painful injections
  - d. Allowing parents and children an informed choice about being together
2. When caring for children, how does the nurse best incorporate the concept of family-centered care?
  - a. Encourages the family to allow the physician to make health care decisions for the child
  - b. Uses the concepts of respect, family strengths, diversity, and collaboration with family
  - c. Advises the family to choose a pediatric provider who is on the child's health care plan
  - d. Recognizes that families undergoing stress related to the child's illness cannot make good decisions
3. When working with children and families, which is a critical strategy for promoting therapeutic communication?
  - a. Detailed explanations
  - b. Attentive listening
  - c. Comforting touch
  - d. Closed-ended questions
4. The nurse is caring for a 2-year-old in the hospital, and the mother expresses concern that the toddler will be scared. Which response by the nurse would be most appropriate?
  - a. "Don't worry; we practice family-centered and atraumatic care here."

- b. "We will do our best to minimize the stress that your child experiences."
- c. "It will probably be upsetting for you as well, so you should stay home."
- d. "Our practice of atraumatic care will eliminate all pain and stress for your child."

## CRITICAL THINKING EXERCISES

1. A 5-year-old boy is being admitted to your unit. The physician has ordered IV fluids along with laboratory work including a complete blood count, electrolytes, and a urine culture. As his nurse, how will you prepare him and his family before the procedure and support them during and after the procedure, to promote the best outcome and to ensure atraumatic care?
2. An 8-year-old girl is admitted to your nursing unit. Please describe the steps the nurse should take to provide health care teaching to this child.
3. A 3-year-old girl from Saudi Arabia has become seriously ill while visiting the United States. She will require a lengthy hospital stay. Describe the steps the nurse should take to communicate effectively with and provide extensive health care teaching to this child's family, including developmentally appropriate communication and teaching.

## STUDY ACTIVITIES

1. Interview a child life specialist about the effects that the traditional (not atraumatic) approach to restraining a child for procedures might have on a child of various ages.

## Health Supervision

### Learning Objectives

Upon completion of the chapter, you will be able to:

1. Define the key terms used in this chapter.
2. Describe the principles of health supervision.
3. Identify challenges to health supervision for children with chronic illnesses.
4. List the three components of a health supervision visit.
5. Use instruments appropriately for developmental surveillance and screening of children.
6. Demonstrate knowledge of the principles of immunization.
7. Identify barriers to immunization.
8. Identify the key components of health promotion.
9. Describe the role of anticipatory guidance in health promotion.

*Three-year-old Maya Randall and 9-month-old Evan Randall are brought to the clinic by their father. Maya was last seen in the clinic when she was 1 year old and Evan has never been seen. The father says that they have both been healthy so they did not need to come to the clinic before this. Maya is complaining of a sore throat, which is what prompted today's visit.*

### Words of Wisdom

It is never too late to start prevention. It begins with a genuine desire for health improvement.

## PRINCIPLES OF HEALTH SUPERVISION

Health supervision involves providing services proactively, with the goal of optimizing the child's level of functioning. It ensures the child is growing and developing appropriately and it promotes the best possible health of the child by teaching parents and children about preventing injury and illness (e.g., proper immunizations and anticipatory guidance). This chapter is organized around the three components of health supervision: developmental surveillance and screening; injury and disease prevention; and health promotion. Health supervision of the child begins at birth and continues through adolescence. It is vital to every child and is most effective when the child has a centralized source of health care. Any place publicly accessible by children and families can be an appropriate setting for health supervision services—private physicians' offices, community health departments, sliding-scale clinics, homeless shelters, day care centers, and schools. The framework for the health supervision visit is developed from national guidelines available through the U.S. Department of Health and Human Services (DHHS), the American Medical Association (AMA), and the American Academy of Pediatrics (AAP). These organizations also provide guidelines for children with chronic health problems and services and information regarding unique situations such as the internationally adopted child.

### Wellness

The focus of pediatric health supervision is wellness. The health supervision visit provides an opportunity to maximize health promotion for the child, family, and community. Nurses have the ability to promote optimal health during these encounters. Health supervision visits must be viewed as part of a continuum of care, not as the accomplishment of isolated tasks.

### Medical Home

A **medical home** is the primary physician who has a long-term and comprehensive relationship with the family. This continuing relationship promotes trust between the provider and the family and leads to comprehensive, continuous, coordinated, and cost-effective care. The medical home is the setting that allows the highest level of health supervision. To be effective, the medical home must be accessible, family centered, culturally effective, and community based. It must be integrated into the child's world, not adjacent to it. Characteristics of a medical home are displayed in Box 31.1.

### Partnerships

The child is the focus of the health supervision visit. However, the child's health is linked to the needs and resources

of his or her family and community. For instance, if the family is in turmoil because of divorce, drug abuse, or parental health problems, the child is less likely to receive the attention and energy that he or she needs to thrive. Likewise, a community with high levels of poverty, poor infrastructure, and lack of resources will not be able to provide the support services needed to allow children to reach their full potential. To be effective, the nurse must offer commitment and develop an ongoing partnership with the child, family, and community. These partnerships allow for mutual goal setting, marshalling of resources, and development of optimal health practices.

The partnership between the child and the health supervision team develops over time. In infancy the family is the surrogate for the child in the partnership. The child's participation in the partnership increases at a rate that is developmentally appropriate. The child's increasing influence in the partnership allows the nurse to tailor health supervision to the child's needs. The partnership allows the child to take increasing responsibility for his or her personal health and optimizes health promotion.

#### BOX 31.1

#### CHARACTERISTICS OF A MEDICAL HOME

- Care accessible and in the child's community
- All insurance, including Medicaid, accepted
- Family-centered care provided
- Child or family able to speak directly to the physician when needed
- Partnership based on mutual trust and respect between the family and physician
  - Preventive care activities provided
  - Ambulatory and inpatient care available 24 hours a day
  - Continuity of care from infancy through adolescence
- Coordinated care with other care providers
  - Availability of subspecialty consultation and referrals
- Work with family to meet the nonmedical and medical needs of the child and family
  - Interactive relationships with school and community agencies
  - A centralized database containing all pertinent information
- Concern for the well-being of the child and family expressed
- Respect for family's cultural and religious beliefs

Adapted from American Academy of Pediatrics, Medical Home Initiatives for Children With Special Needs Project Advisory Committee. (2008). *The medical home*. Retrieved April 17, 2011, from <http://aappolicy.aappublications.org/cgi/content/full/pediatrics;110/1/184#T1>

Nurses must validate and enhance the role of family members as they influence and inform the child's concept of wellness. The health care community must involve the family to have a significant impact on a child's health. The family wants the best possible outcome for their child, and health care decisions are based on the knowledge they possess. The nurse can greatly facilitate trust by acknowledging that the family has unique insights to offer on their child's health. Nurses can also strengthen the partnership between the family and the health care community by recognizing the family's healthy practices, addressing their health issues, and strengthening their skills. By contributing to the partnership, both the nurse and the family enhance the chance of success for health care plans, but families are the ones who must implement any health care strategy and know what expected outcomes are reasonable. Their feedback is invaluable to formulating an effective long-term health supervision plan that optimizes their child's wellness.

### Take Note!

Observe the parent-child interaction during the health supervision visit. The nurse can learn much about the family dynamic by observing the family for behavioral clues:

- Does the parent make eye contact with the infant?
- Does the parent anticipate and respond to the infant's needs?
- Are parents effective when dealing with a toddler's temper tantrum?
- Do the parents' comments increase the school-age child's sense of self-worth?

Behavioral observations are crucial to the proper assessment of the family's needs and issues.

Partnerships between the community and the health promotion team benefit the community as well as individual children. When nurses develop partnerships with community agencies such as schools, churches, and ancillary health facilities, barriers to care can be overcome. The nurse becomes aware of available resources in the community that can benefit an individual family. With input from community partners, the nurse can perform an assessment of the community's needs. The assessment then provides the foundation for the development of community-based health promotion programs. These programs expand the resources of the community, which in turn enhances the health of its members.

## Special Issues in Health Supervision

Special issues in health supervision include cultural influences, community influences, health supervision and the

chronically ill child, and health supervision and the internationally adopted child.

### Cultural Influences on Health Supervision

A person's definition of health is influenced by his or her culture. Successful interactions result when the nurse is aware of the beliefs and interactive styles that are often present in members of a specific culture. If the goals of the health care plan are not consistent with the health belief system of the family, the plan has little chance for success. Optimal wellness for the child requires the nurse and the family to negotiate a mutually acceptable plan of care. A plan must balance the cultural beliefs and practices of the family with those of the health care establishment. The nurse must possess cultural competence and sensitivity for the partnership to be successful.

Most health promotion and disease prevention strategies in the United States have a future-based orientation and view the child as an active and controlling agent in his or her own health. This reflects the dominant culture; however, the challenge to the nurse is to develop strategies that are meaningful to children from other cultures. Significant numbers of children belong to cultures with a present-based orientation. These cultures are more concerned about what is going on now. For these children, health promotion activities need shorter-term goals and outcomes to be useful. Children with a fatalistic worldview will see any actions on their part as ineffective. They may feel that a god figure or supernatural forces control their fate and that health is a gift to be appreciated, not a goal to be pursued. Certain cultures believe health is the result of being in harmony within oneself and the larger universe. From this viewpoint, taking a medication or receiving a treatment may not be an effective way to restore health because it does not address the problem of being "out of harmony."

However, just because an individual belongs to a certain culture does not guarantee that he or she subscribes to all of its values. The nurse should explore each child's specific beliefs during the health interview.

### Community Influences on Health Supervision

The child is a member of a community as well as a family and a culture. Each community has unique strengths, weaknesses, and values. A community can be a contributor to a child's health or be the cause of his or her illnesses. The child's health cannot be totally separated from the health of the surrounding community.

Ideally the child's medical home is within the family's community. If home and access to medical care are close, barriers such as lack of transportation, expense of travel, and time away from the parents' workplace are reduced. Having the medical home within the community

facilitates bonds between the health team and schools, churches, and support services and agencies. Community support and resources are necessary for children with significant problems. A close working relationship between the child's physician and community agencies is an enormous benefit to the child (see the earlier section on partnerships).

The community assessment may reveal problems that are causing or contributing to the child's health problems. A deteriorating infrastructure can contribute to decreased access to care and increased risk of injury or illness. Poverty has been linked to low birthweight and premature birth, among other health problems (Shore & Shore, 2009). Substandard housing can be directly related to lead poisoning and asthma (Centers for Disease Control and Prevention [CDC], 2009a). A thorough knowledge of the family's community is needed before a health surveillance program can be effective.

### Health Supervision and the Child With Chronic Illness

Effective health supervision must be responsive to the individual child's situation. The child with a chronic illness needs to be assessed repeatedly to determine his or her health maintenance needs. These assessments determine the frequency of visits and types of interventions needed. The impact of the illness on the child's functional health patterns determines whether standard health supervision visits need to be augmented.

An effective partnership among the child's medical home, family, and community is vital for a child with a chronic illness. Coordination of specialty care, community agencies, and family support networks enhances the quality of life and health of these children. Access to care and services minimizes the risk of injury from the illness. Support groups and community-based resources optimize the family's adaptation to the stressors of chronic illness.

Comprehensive health supervision includes frequent psychosocial assessments. Issues to be covered include:

- Health insurance coverage
- Transportation to health care facilities
- Financial stressors
- Family coping
- School's response to the chronic illness

These are often stressful and emotionally charged issues. The nurse with a trusting and ongoing relationship with the child and family is in the best position to help with these issues. The nurse can assist the family to find financial and medical assistance programs, take advantage of community resources, and participate in support groups. The nurse can also educate school personnel about the child's illness and assist them in maximizing the child's potential for academic success.

### Health Supervision and the Child Adopted Internationally

Health supervision of the internationally adopted child must include comprehensive screening for infectious disease. In 2010, approximately 11,050 children were adopted from countries outside the United States, many from areas with a high prevalence of infectious diseases (Intercountry Adoption, Office of Children's Issues, U.S. Department of State, 2010a). China, Ethiopia, and Russia supplied over half of all international adoptees in 2010, followed by South Korea and the Ukraine (Intercountry Adoption, Office of Children's Issues, U.S. Department of State, 2010b). Proper screening is important not only to the child's health but also to the adopting family and the larger community. Screening is recommended within the first few weeks of the child's arrival into the United States.

Intestinal parasites are a common problem with *Giardia lamblia*, the most common pathogen (Miller, 2008). Infected children are frequently symptom-free, so universal screening is recommended (Simms & Wilson, 2011).

Latent tuberculosis is also common. Though active tuberculosis infection has been rarely reported, an extensive outbreak of tuberculosis occurred in a North Dakota community in 1998. The index case was an internationally adopted child from the Marshall Islands (Curtis et al., 1999; Miller, 2008). Universal screening is recommended for this high-risk population (Shetty, 2010).

Universal screening for hepatitis B, HIV, and syphilis infections is recommended (Shetty, 2010). Due to lack of resources in the home country, screening and treatment for these diseases are sporadic and ineffective. If testing is documented, it is likely to be unreliable. Testing supplies may have been outdated or improperly stored. Also, the test may have been performed before the child's seroconversion occurred.

## COMPONENTS OF HEALTH SUPERVISION

Developmental surveillance and screening, injury and disease prevention, and health promotion are the critical components of health supervision for children. Health supervision visits for children without health problems and appropriate growth and development are recommended at birth, within the first week of life, by 1 month, then at 2 months, 4 months, 6 months, 9 months, 12 months, 15 months, 18 months, 24 months, 30 months, and then yearly until age 21 (Hagan, Shaw, & Duncan, 2008). Children with special needs or concerns will have more frequent and intensive visits. Health supervision visits include assessment of physical health along with intellectual and social development and parent-child interaction.

Each health supervision visit will include (Hagan et al., 2008):

- A history and physical assessment, including head circumference (until 2 years of age), height, and weight
- Developmental/behavioral assessment
- Sensory screening (vision and hearing)
- Appropriate at-risk screening (such as lead screening, anemia screening, tuberculin test, hypertension screening, cholesterol screening)
- Immunizations
- Health promotion/anticipatory guidance (injury prevention, violence prevention, nutrition counseling)

Disease prevention and health promotion are concepts well established in adult health supervision. Injury prevention and developmental surveillance/screening are additional components of pediatric health supervision visits that help every child achieve his or her optimal state of wellness.

## Developmental Surveillance and Screening

**Developmental surveillance** is an ongoing collection of skilled observations made over time during health care visits. Components include:

- Noting and addressing parental concerns
- Obtaining a developmental history
- Making accurate observations
- Consulting with relevant professionals

**Developmental screenings** are brief assessment procedures that identify children who warrant more intensive assessment and testing. Developmental screening assessments may be observational or by caregiver report (Fig. 31.1).

Development, or the emergence of the child's abilities, is a longitudinal process. Within the trust and security of the medical home, family and physicians can share observations and concerns. In collaboration, the family and the physician observe the child's accomplishments or milestones over time. Data collection for developmental surveillance of infants and young children is performed through developmental questionnaires, physician observations, and a thorough physical examination. School records and test results can provide academic performance data for the older child. Input from teachers, coaches, and other adults involved with the child can give insight into the child's emotional and social development.

When developmental delay is suspected, frequent developmental surveillance is warranted. Reemphasizing parental roles and responsibilities fosters cooperation and compliance. It is therefore crucial that parents understand the need for frequent assessments. A pattern of developmental delays warrants a formal evaluation.

The pediatric nurse must understand normal growth and development and become proficient at screening for problems related to development. The historical

**FIGURE 31.1** Developmental screening provides the opportunity for the nurse to identify problems in the child's development.

information obtained from the parent or primary caregiver about developmental milestones may indicate warning signs or identify risks for developmental delay (Table 31.1). Factors placing the infant or toddler at risk for developmental problems include:

- Birthweight less than 1,500 g
- Gestational age less than 33 weeks
- Central nervous system abnormality
- Hypoxic ischemic encephalopathy
- Maternal prenatal alcohol or drug abuse
- Hypertonia
- Hypotonia
- Hyperbilirubinemia requiring exchange transfusion
- Kernicterus
- Congenital malformations
- Symmetric intrauterine growth deficiency
- Perinatal or congenital infection
- Suspected sensory impairment
- Chronic (more than 3 months) otitis media with effusion
- Inborn error of metabolism
- HIV infection
- Lead level above 19 mg/dL
- Inappropriate parental concern about developmental issues (e.g., not allowing a developmentally appropriate 3-year-old feed him- or herself)
- Parent with less than high school education
- Single parent
- Sibling with developmental problems
- Parent with developmental disability or mental illness

Infants or children with any of these risk factors should be screened carefully for developmental delays. This screening should occur in a prospective manner, with screenings occurring at frequent intervals to identify concerns early.

TABLE 31.1

## EARLY CHILDHOOD DEVELOPMENTAL WARNING SIGNS

Age	Warning Sign
Any age	No response to environmental stimulus
Any age	Persistently up on toes (longer than 30 seconds) in supported standing position
Before 3 months	Rolls over
After 2–3 months	Persistent fisting
After 4 months	Persistent head lag
5 months	Not reaching for toys
6 months	<ul style="list-style-type: none"> <li>• Lack of tripod sitting</li> <li>• Not smiling</li> <li>• Primitive reflex persistence</li> <li>• Not babbling</li> </ul>
9 months	No reciprocal vocalizations or facial expressions
12 months	No spoon or crayon use
15–18 months	<ul style="list-style-type: none"> <li>• Not walking</li> <li>• No first word</li> </ul>
Prior to 18 months	Hand dominance present
By 18 months	<ul style="list-style-type: none"> <li>• Not walking</li> <li>• Not speaking 15 words</li> <li>• Does not understand function of common household items</li> <li>• No imitative play</li> </ul>
After independent walking for several months	<ul style="list-style-type: none"> <li>• Persistent tiptoe walking</li> <li>• Failure to develop a mature walking pattern</li> </ul>
By 2 years	<ul style="list-style-type: none"> <li>• Does not use two-word sentences</li> <li>• Does not imitate actions</li> <li>• Does not follow basic instructions</li> <li>• Cannot push a toy with wheels</li> <li>• Echolalia (repetitive speech)</li> </ul>
By 3 years	<ul style="list-style-type: none"> <li>• Difficulty with stairs</li> <li>• Frequent falling</li> <li>• Cannot build tower of more than four blocks</li> <li>• Difficulty manipulating small objects</li> <li>• Extreme difficulty in separation from parent or caregiver</li> <li>• Cannot copy a circle</li> <li>• Does not engage in make-believe play</li> <li>• Cannot communicate in short phrases</li> <li>• Does not understand simple instructions</li> <li>• Little interest in other children</li> <li>• Unclear speech, persistent drooling</li> </ul>
4 years	<ul style="list-style-type: none"> <li>• Cannot jump in place or ride a tricycle</li> <li>• Cannot stack four blocks</li> <li>• Cannot throw ball overhand</li> <li>• Does not grasp crayon with thumb and fingers</li> <li>• Difficulty with scribbling</li> <li>• Cannot copy a circle</li> <li>• Does not use sentences with three or more words</li> <li>• Cannot use the words “me” and “you” appropriately</li> <li>• Ignores other children or does not show interest in interactive games</li> <li>• Will not respond to people outside the family; still clings or cries if parents leave</li> <li>• Resists using toilet, dressing, sleeping</li> <li>• Does not engage in fantasy play</li> </ul>

TABLE 31.1

EARLY CHILDHOOD DEVELOPMENTAL WARNING SIGNS (continued)

Age	Warning Sign
By 5 years	<ul style="list-style-type: none"> <li>• Unhappy or sad often</li> <li>• Little interest in playing with other children</li> <li>• Unable to separate from parent without major protest</li> <li>• Is extremely aggressive</li> <li>• Is extremely fearful or timid, or unusually passive</li> <li>• Cannot build tower of six to eight blocks</li> <li>• Easily distracted; cannot concentrate on single activity for 5 minutes</li> <li>• Rarely engages in fantasy play</li> <li>• Trouble with eating, sleeping, or using the toilet</li> <li>• Cannot use plurals or past tense</li> <li>• Cannot brush teeth, wash and dry hands, or undress efficiently</li> </ul>

**Take Note!**

Any child who “loses” a developmental milestone—for example, the child able to sit without support who now cannot—needs an immediate full evaluation, since this may indicate a significant neurologic problem.

A number of developmental screening tools are available to guide the nurse in assessing development (Table 31.2). The Denver II is a frequently used tool (see Appendix G). The Denver II should be used for diagnostic purposes only when administered by specifically trained personnel. Nurses not trained in the use of the Denver II should use screening tools based on the Denver II. Many screening methods assist the nurse in identifying infants and children who may have developmental delays, thus allowing for prompt identification and referral for evaluation. Additional data can be used to determine a school-age child’s developmental level, include handwriting samples, ability to draw, school performance, and social skills.

## Injury and Disease Prevention

Disease prevention is defined as interventions performed to protect children from a disease or to identify it at an early stage and lessen its consequences. These interventions are determined by the results of the nurse’s assessment, nationally accepted practice guidelines, and the family’s goals. Components of disease prevention include screening tests and immunizations.

Injury prevention is primarily accomplished through education, anticipatory guidance, and physical changes in the environment. Injuries can be unintentional (poisoning, falls, or drowning) or intentional (child abuse, homicide, or suicide). The types of injuries a child is most likely to encounter vary greatly among age groups. Although aggressive public health initiatives have decreased mortality rates of childhood unintentional injuries significantly in the past 50 years,

continued vigilance and innovation are needed (Singh, 2010). The nurse, in partnership with the family and the community, can have an enormous impact on child safety. Specific interventions are discussed in Chapters 25 through 29.

## Screening Tests

**Screening tests** are procedures or laboratory analyses used to identify children with a certain condition. These tests are done to ensure that no child with the disorder is missed. They have a high sensitivity (a high false-positive rate) and a low specificity (a low false-negative rate). If a screening test is positive, follow-up tests with higher specificity are performed. A **risk assessment** is performed by the physician in conjunction with the child and includes objective as well as subjective data to determine the likelihood that the child will develop a condition.

In **universal screening**, an entire population is screened regardless of the child’s individual risk. This type of screening is performed when a reliable risk assessment procedure is not available. In contrast, **selective screening** is done when a risk assessment indicates the child has one or more risk factors for the disorder.

**Take Note!**

To increase cooperation from young children during screenings, set up a reward system. Easy-to-do rewards include:

- Stamping the back of the child’s hand with a “smiley face”
- Making an eye cover by placing two stickers back to back over a tongue blade and letting the child keep the cover after the screening
- Copying a design onto a sheet of paper and letting the child take it home to color
- Letting the child play with a simple device such as a penlight or stethoscope

**TABLE 31.2** DEVELOPMENTAL SCREENING TOOLS

Age	Screening Tool	Definition	Nursing Implications
Birth–6 years	Denver II	Assesses personal–social, fine motor–adaptive, language, and gross motor skills	Administered by nurse. Requires props (e.g., ball, crayon, doll), available in the Denver II kit. Simple to learn to administer
Birth–6 years	Denver PRQ	Assesses personal–social, fine motor–adaptive, language, and gross motor skills	Parental report of all items on the Denver II
Birth–6 years	Child Development Inventory (CDI)	Simple questions about infant, toddler, or preschooler behaviors. Measures social, self-help, gross motor, fine motor, expressive language, language comprehension, letters, numbers, and general development as appropriate	A parental-report screening tool
Birth–6 years	Ages and Stages Questionnaire (ASQ)	Assesses communication, gross motor, fine motor, personal–social, and problem-solving skills	A parental-report screening tool, scored by the nurse after completion to determine child's progress in each of the developmental areas
Birth–8 years	Parents' Evaluation of Developmental Status (PEDS)	Screens for a wide range of developmental, behavioral, and family issues	A parental-report screening tool that can also be used in nurse interview format. Also available in Spanish.
12–96 months	Batelle Developmental Inventory Screening Test	Assesses fine and gross motor, adaptive, personal–social, receptive and expressive language, and cognitive skills	Direct elicitation, parental description, and examiner observation. Requires special training
1–42 months	Bayley Scales of Infant Development II	Provides a mental and motor scale for assessment of cognitive, language, personal–social, and fine and gross motor development. A behavior rating scale is obtained during the testing.	Direct elicitation. Thorough. Requires special training
Birth–3 years	Early Language Milestone Scale	Screens for auditory expressive and receptive, visual components of speech	Requires standardized kit
2½–7 years	Denver Articulation Screening	Screens for articulation disorders	5 minutes to administer. Does not evaluate language ability
5–17 years	Goodenough-Harris Drawing Test	A nonverbal screen for mental ability (intelligence)	Child draws a person, which is analyzed for body parts, clothing, proportion, and perspective.

## METABOLIC SCREENING

State law determines which metabolic screening tests are mandatory in that state. In some states, mandatory screening is limited to as few as four diseases. In addition to screening for hearing loss, the March of Dimes currently recommends universal newborn metabolic screening tests for 29 disorders for which effective treatment is available (March of Dimes, 2010):

- Amino acid metabolism disorders: phenylketonuria, maple syrup urine disease, homocystinuria, citrullinemia, argininosuccinic acidemia, tyrosinemia type I
- Organic acid metabolism disorders: isovaleric acidemia, glutaric acidemia type I, hydroxymethylglutaric aciduria, multiple carboxylase deficiency, methylmalonic acidemia due to mutase deficiency, methylmalonic acidemia cblA and cblB forms, 3-methylcrotonyl-CoA carboxylase deficiency, propionic acidemia,  $\beta$ -ketothiolase deficiency
- Fatty acid oxidation disorders: medium-chain acyl-CoA dehydrogenase deficiency, very-long-chain acyl-CoA dehydrogenase deficiency, long-chain 3-OH acyl-CoA dehydrogenase deficiency, trifunctional protein deficiency, carnitine uptake defect
- Hemoglobinopathies: sickle cell anemia, HbS/ $\beta$ -thalassemia, HbS/C disease
- Others: congenital hypothyroidism, biotinidase deficiency, congenital adrenal hyperplasia, classical galactosemia, cystic fibrosis, and severe combined immunodeficiency (SCID)

During the initial health supervision visit, the nurse should confirm that newborn metabolic screening was performed prior to discharge from the birthing unit. If the test was not performed or was performed at younger than 24 to 48 hours of age, the screening should be performed at that visit. The metabolic screening results need to be noted in the child's permanent record at the medical home.

## HEARING SCREENING

The AAP recommends hearing screening of all infants. Hearing loss is a common condition in newborns, and even mild hearing loss can cause serious delays in social and emotional development, language acquisition, and cognitive function (De Michele & Meyers, 2010). Identification of hearing loss by 6 months of age is crucial to reduce the impact on the child's development (De Michele & Meyers, 2010). Refer to Healthy People 2020. Targeted screening based on risk factors will identify only 50% of infants with hearing loss, and with reliable screening tests available, universal screening has been implemented (De Michele & Meyers, 2010). Screening should be done before discharge from the birthing unit; if not, the newborn needs to be screened before 1 month of age. Behavioral observations of the infant's response to sounds, such as a ringing bell or clapping hands, are not sensitive enough to preclude mild to moderate hearing loss (De Michele & Meyers, 2010).

## HEALTHY PEOPLE 2020

### Objective

### Nursing Significance

Increase the proportion of newborns who are screened for hearing loss by age 1 month, have audiologic evaluation by age 3 months, and are enrolled in appropriate intervention services by age 6 months.

Increase the proportion of persons who have had a hearing examination on schedule.

- Determine results of newborn hearing screening at first newborn check-up.
- Refer any infant with possible hearing deficit for further evaluation.
- Ensure infants with hearing impairment receive appropriate augmentation (hearing aids).
- Ensure all children and adolescents receive hearing screenings with well-child check-ups as appropriate.

*Healthy People Objectives based on data from <http://www.healthypeople.gov>.*

Accepted methodologies for screening newborn hearing are displayed in Table 31.3.

Screening for hearing loss in older children begins with a history from the primary caregivers. If any problems are noted, audiometry should be performed. When the child is capable of following simple commands reliably, the nurse can perform some basic procedures to screen for hearing loss. The whisper test is easy to perform but to be valid requires a quiet room that is away from distractions. The Weber and Rinne tests can be used to screen for sensorineural or conductive hearing loss (Fig. 31.2).

Universal hearing screening with objective testing is recommended at ages 4, 5, 6, 8, and 10 (Hagan et al., 2008). At the ages of 7, 9, and 11 through 21 years, age-appropriate risk assessment should be performed (Hagan et al., 2008). See Box 31.2 for examples of risk

### BOX 31.2

#### HEARING RISK ASSESSMENT

##### Ages 3 months to 4 years

- Auditory skill monitoring
- Developmental surveillance
- Assessment of parental concerns

##### Age 4 years

- Difficulty hearing on the telephone
- Difficulty hearing people in a noisy background
- Frequent asking of others to repeat themselves
- Turning the television up too loudly

**TABLE 31.3** HEARING SCREENING METHODS

Test Name	Age Group	Characteristics	Nursing Implications
Auditory brain stem response (ABR)	Newborn–6 months	Measures electroencephalographic waves Test results may be affected by ear debris	Infant must be quiet (sedation may be needed).
Evoked otoacoustic emissions (EOAE)	Newborn–6 months or developmentally delayed children at the infant's level of functioning	The machine produces clicks that stimulate cilia in the cochlea and measures the response.	Infant must be quiet. Test results may be inaccurate in first 24 hours of life.
Visual reinforcement audiometry (VRA)	6 months–2 years	Visual reward is linked to a tone signal. Child looks to the visual reward in response to the tone. Reward is activated, reinforcing the response.	Child must be alert and happy for best results. Schedule for after sleep/rest period. Allow child to sit in parent's lap.
Tympanometry	Over 7 months	Measures tympanic membrane mobility and determines middle ear pressure	The probe must form a seal with the canal. The child must remain still to obtain a valid result.
Conditioned play audiometry (CPA)	2–4 years	Similar to VRA except uses “listening games” Child does listening game at the tone and receives social reward. May be used when developmental age is 2 years	See Nursing Implications for VRA.
Pure-tone (conventional) audiometry	4 years and older	Measures hearing acuity through a range of frequencies and intensities Child must wear earphones. Performed in a soundproof room if possible	Teach the child the desired motor response before screening. Administer conditioning trials. Offer two presentations of stimulus to ensure reliability. At a minimum, screen 1,000-, 2,000-, and 4,000-hertz levels at 20 decibels.
Whisper test	4 years and older	One ear is occluded. Examiner stands behind the child and whispers a word. The child must accurately repeat the whispered word.	The child must be in a quiet room and away from distractions. The child should be alert and well rested for accurate results. Consider a reward system to increase compliance.
Weber test	6 years and older	Place a vibrating tuning fork in the middle of the top of the head. Ask if the sound is in one ear or both ears. The sound should be heard in both ears.	The child must understand the instructions and be able to cooperate.

**TABLE 31.3** HEARING SCREENING METHODS (continued)

Test Name	Age Group	Characteristics	Nursing Implications
Rinne test	6 years and older	Place a vibrating tuning fork on the mastoid process to assess bone conduction. The child signals when the sound is gone. Next place a vibrating tuning fork outside the ear to test air conduction. The child signals when the sound is gone. For a passing test, air conduction time should be twice as long as bone conduction time.	The child must understand the instructions and be able to cooperate.

assessment. More frequent screening is recommended if there is any behavior that indicates the child's hearing may be impaired. Repeated hearing screenings are recommended if a child has risk factors for acquired hearing loss such as those listed in Box 31.3.

#### VISION SCREENING

Newborns with ocular structural abnormalities are at high risk for vision impairment. Vision screening is performed at every scheduled health supervision visit. The screening procedures for children younger than 3 years of age or for nonverbal children involve evaluating the child's ability to fixate on and follow objects. The neonate should be able to fixate on an object 10 to 12

inches from the face. After fixation, the infant should be able to follow the object to the midline. By 2 months of age, the infant should be able to follow the object 180 degrees. The technique of photoscreening can help identify problems such as ocular malalignment, refractive error, and lens and retinal problems.

#### Take Note!

Use objects with black-and-white patterns when performing vision screening on an infant younger than 6 months of age. The infant's vision at this age is more attuned to high-contrast patterns than to colors. Try checkerboard patterns or concentric circles. Animal figures like pandas and dalmatians also work well.

**FIGURE 31.2** (A) The Weber test screens for hearing by assessing sound conducted via bone. (B) The Rinne test screens for hearing by comparing sound conduction via bone to sound conduction via air.

BOX 31.3

**RISK FACTORS FOR HEARING IMPAIRMENT**

- Family history of hearing loss
- Prenatal infection
- Anomalies of the head, face, or ears
- Low birthweight (<1,500 g)
- Hyperbilirubinemia requiring exchange transfusion
- Ototoxic medications
- Low Apgar scores: 4 or less at 1 minute, or 6 or less at 5 minutes
- Mechanical ventilation lasting 5 days
- Syndrome associated with hearing loss
- Head trauma
- Bacterial meningitis
- Neurodegenerative disorders
- Persistent pulmonary hypertension
- Otitis media with effusion for 3 months

Adapted from De Michele, A. M., & Meyers, A. D. (2010). Newborn hearing screening. *eMedicine*. Retrieved April 12, 2011, from <http://emedicine.medscape.com/article/836646-overview>

After the age of 3 years, a variety of standardized age-appropriate vision screening charts are available. These charts include the “tumbling E” and Allen figures (Fig. 31.3A, B). These charts allow for a more precise vision

assessment and aid the nurse in identifying preschool children with visual acuity problems. By age 5 or 6, most children know the alphabet well enough to use the traditional Snellen chart for vision screening (see Fig. 31.3C). Refer to Healthy People 2020. Table 31.4 gives further information about vision screening tools.

**HEALTHY PEOPLE 2020**

Objective	Nursing Significance
Increase the proportion of preschool children age 5 years and younger who receive vision screening.	<ul style="list-style-type: none"> <li>• Use a preschool-appropriate vision screening tool to assess vision.</li> <li>• Ensure screening begins at age 3 years.</li> </ul>

*Healthy People* Objectives based on data from <http://www.healthypeople.gov>.

Screenings should be performed when children are alert, as fatigue and lack of interest can mimic poor vision. When using any vision screening chart, several simple steps need to be followed (Bowden & Greenburg, 2008):

- Place the chart at the child’s eye level.
- Make sure there is sufficient lighting.

**FIGURE 31.3** (A) The “tumbling E” chart is appropriate for children who do not yet know the alphabet but who can follow instructions to indicate the direction that the arms of the “E” are pointing. (B) A picture chart similar to the Allen object recognition chart is appropriate for vision screening in the preschool-age child. (C) The Snellen eye chart may be used for children age 6 or older who know the alphabet. The test can be obtained at [www.preventblindness.org/children](http://www.preventblindness.org/children) or by calling 1-800-331-2020.

**TABLE 31.4** VISION SCREENING TOOLS

Screening Tool	Age	Nursing Implications
Snellen letters or numbers	School-age	The child must know his or her letters or numbers for the test to be valid.
“Tumbling E”	Preschool	The child points in the direction that the “E” is facing.
LEA symbols or Allen figures	Preschool	The child should first identify the pictures with both eyes at a comfortable distance prior to monocular testing to ensure validity of the test.
Ishihara	School-age	Screens for color discrimination (numbers composed of dots, hidden within other dots)
Color Vision Testing Made Easy (CVTME)	Preschool	Uses dot pictures like the Ishihara, but instead of numbers has easily identified shapes imbedded in the dots

- Place a mark on the floor 10 to 20 feet from the chart (distance depends on what the tool is calibrated for).
- Align the child’s heels on the mark.
- Have the child read each line with one eye covered and then with the other eye covered. Explain to the child to keep the eye covered but open (Fig. 31.4).
- Have the child read each line with both eyes.

In addition to visual acuity screening, children should also be screened for color discrimination. Any child with eye abnormalities or who has failed visual screening needs to be evaluated by a specialist appropriately trained to treat children.

#### IRON-DEFICIENCY ANEMIA SCREENING

Iron deficiency is the leading nutritional deficiency in the United States (CDC, 2011a). Iron deficiency can cause cognitive and motor deficits resulting in developmental delays and behavioral disturbances. The increased incidence of iron-deficiency anemia is directly associated

**FIGURE 31.4** One eye must be covered while the other is tested in order to detect discrepancies in visual acuity between the two eyes and identify amblyopia early.

with periods of diminished iron stores, rapid growth, and high metabolic demands. At 6 months of age, the in utero iron stores of a full-term infant are almost depleted (Baker, Greer, & The Committee on Nutrition, 2010). The adolescent growth spurt warrants constant iron replacement. Pregnant adolescents are at even higher risk for iron deficiency due to the demands of the mother’s growth spurt and the needs of the developing fetus (CDC, 2011a).

Guidelines for universal iron-deficiency anemia screening vary. It is important for the nurse to assess for risk factors related to iron-deficiency anemia at each health supervision visit. Refer to Box 31.4 for Bright Future Guidelines and Box 31.5 for risk factors for iron-deficiency anemia.

#### LEAD SCREENING

Elevated blood lead levels (10 mcg/dL or higher) remain a preventable environmental health threat. Approximately 25% of children live in housing with lead-based paint, therefore leading to a risk of lead exposure and resulting cognitive impairments (American Academy of Pediatrics, 2009). Although the prevalence of elevated lead levels has declined significantly over the past two decades, certain communities still possess a high level of lead exposure. A shift to targeted screening has occurred, with criteria continuing to develop. In the past, 80% of children on Medicaid were found to have an increased blood lead concentration (American Academy of Pediatrics, 2009). Therefore, screening of all children eligible for Medicaid was recommended and even required by federal Medicaid. Recent research has shown that blood lead levels have decreased in certain enrolled Medicaid children and in response the CDC Advisory Committee on Childhood Lead Poisoning Prevention is updating their recommendations to targeted screenings of specific groups of children that state and local officials deem to be living in areas of higher risk (Wengrovitz &

BOX 31.4

**GUIDELINES FOR IRON-DEFICIENCY ANEMIA SCREENING**

**Universal Screening**

- Screen all full-term infants at 9–12 months.

**Selective Screening**

- 4 months: Screen children with risk factors of prematurity, with low birthweight, on low-iron formula or not receiving iron-fortified formula or foods, and with early introduction of cow’s milk.
- 18 months and annually beginning at 2 years: Screen children with special health needs that put them at risk for iron-deficiency anemia, on low-iron diets such as nonmeat, with environmental factors such as poverty, and with limited access to food.
- 6–10 years: Screen children on a strict vegetarian diet and not receiving iron supplementation.
- 11–21 years: Screen all nonpregnant females every 5 to 10 years throughout childbearing years at routine health care visits. Annually screen females with risk factors such as extensive menstrual flow, low iron intake, or previous diagnosis of iron-deficiency anemia.

Adapted from Hagan, J. F., Shaw, J. S., & Duncan, P. M. (Eds.). (2008). *Bright futures: Guidelines for health supervision of infants, children, and adolescents* (3rd ed., rev.). Elk Grove Village, IL: American Academy of Pediatrics. Retrieved August 23, 2009, from [http://brightfutures.aap.org/pdfs/Guidelines\\_PDF/13-Rationale\\_and\\_Evidence.pdf](http://brightfutures.aap.org/pdfs/Guidelines_PDF/13-Rationale_and_Evidence.pdf)

Brown, 2009). Until these recommendations are finalized, the CDC and AAP continue to support universal screening of Medicaid-eligible children (American Academy of Pediatrics, 2009).

For children not eligible for Medicaid some states have developed targeted screening based on risk assessment by the CDC or their own data (American Academy of Pediatrics, 2009). Targeted screening is recommended at 9 to 12 months with a repeat screening at 24 months (Hagan et al., 2008). For children who live in areas where health authorities have not made clear recommendations on risk, screening guidelines are less clear and therefore universal screening is currently recommended. Refer to Healthy People 2020.

**HEALTHY PEOPLE 2020**

**Objective**

Eliminate elevated blood lead levels in children.

**Nursing Significance**

- Screen for lead exposure.
- Ensure that high-risk children have blood lead levels measured.

*Healthy People* Objectives based on data from <http://www.healthypeople.gov>.

BOX 31.5

**RISK FACTORS FOR IRON-DEFICIENCY ANEMIA**

- Periods of rapid growth
- Low-birthweight or preterm infants
- Low dietary intake of meat, fish, poultry, and ascorbic acid
- Macrobiotic diets
- Inappropriate consumption of cow’s milk
- Use of infant formula not fortified with iron
- Exclusive breastfeeding after age 4 months without iron-fortified supplemental foods
- Meal skipping, frequent dieting
- Exposure to lead
- Feeding problems
- Pregnancy or recent pregnancy
- Intensive physical training
- Recent blood loss, heavy/lengthy menstrual periods
- Chronic use of aspirin or nonsteroidal anti-inflammatory drugs
- Parasitic infections

**Children at High Risk for Iron-Deficiency Anemia**

- Low-income families
- Those eligible for the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC)
- Migrants or recently arrived refugees

Adapted from Baker, R. D., Greer, F. R., & The Committee on Nutrition. (2010). Clinical report. Diagnosis and prevention of iron deficiency and iron-deficiency anemia in infants and young children (0–3 years of age). *Pediatrics*, 126(5), 1040–1050. Retrieved April 13, 2011, from <http://aappolicy.aappublications.org/cgi/content/full/pediatrics;126/5/1040>

**Take Note!**

Many cases of elevated blood lead levels have been reported in children who are recent immigrants, refugees, or international adoptees. The CDC recommends blood lead testing for these children upon entering the United States and a repeat test 3 to 6 months after placement in a permanent residence (American Academy of Pediatrics, 2009).

**HYPERTENSION SCREENING**

Obesity and resulting hypertension have been on the rise in children and can lead to adult cardiovascular disease. Universal hypertension screening for children beginning at 3 years of age is recommended (Hagan et al., 2008). If the child has risk factors for systemic hypertension, such as preterm birth, very low birthweight, renal disease, organ transplant, congenital heart disease, or other illnesses associated with hypertension, then screening begins when the risk factor becomes apparent (Hagan et al., 2008).

## BOX 31.6

**PREADOLESCENT CHILDHOOD HYPERTENSION GUIDELINES**

Optimal/normal	<90th percentile for sex, age, and height
Prehypertension	≥90th or 120/80 mmHg but <95th percentile for sex, age, and height
Stage I Hypertension	BP ≥95th percentile but < or equal to 99th percentile + 5 mmHg for sex, age, and height
Stage II Hypertension	≥99th percentile + 5 mmHg for sex, age, and height on three separate occasions

Adapted from National Heart, Lung, and Blood Pressure Institute (2011). Integrated Guidelines for Cardiovascular Health and Risk Reduction in Children and Adolescents: The Report of the Expert Panel. Retrieved on July 1, 2012 at [http://www.nhlbi.nih.gov/guidelines/cvd\\_ped/index.htm](http://www.nhlbi.nih.gov/guidelines/cvd_ped/index.htm)

The guidelines for determining hypertension in children and adolescents utilize body size in order to be more precise. Gender and age are used to determine specific systolic and diastolic blood pressure percentiles. Refer to Appendix H for Blood Pressure Charts for Children and Adolescents. Auscultation is the preferred method of measuring blood pressure in children, and an elevated blood pressure must be confirmed on repeated visits before a diagnosis of hypertension is given. Refer to Box 31.6 for hypertension guidelines. Anticipatory guidance on diet and lifestyle changes is appropriate for any child with prehypertension (National Heart, Lung, and Blood Institute, 2011). Refer to Chapter 41 for additional information on hypertension.

**HYPERLIPIDEMIA SCREENING**

Atherosclerosis has been documented in children, and a link exists between high lipid levels and the development of these lesions. Bright Futures Guidelines recommend universal screening for dyslipidemia once in late adolescence (Hagan et al., 2008). Selectively screening children at high risk for hyperlipidemia can reduce their lifelong risk of coronary artery disease.

The risk assessment focuses on the child's family history. Refer to Box 31.7 for details regarding screening for hyperlipidemia.

*Remember Maya and Evan, the children introduced at the beginning of the chapter? How would you assess their growth and development? Which screening tests are warranted for them, and why? What further information would you need to determine which tests should be performed?*

## BOX 31.7

**HYPERLIPIDEMIA SCREENING**

Screen if parents or grandparents, at <55 years of age, have/had documented:

- Coronary atherosclerosis
- Myocardial infarction
- Angina pectoris
- Peripheral vascular disease
- Cerebrovascular disease
- Sudden cardiac death

Screen if a parent's blood cholesterol level is 240 mg/dL or higher.

Screen at physician's discretion:

- Parental history is unobtainable.
- Child has diabetes or hypertension.
- Child has lifestyle risk factors:
  - Cigarette smoking
  - Obesity
  - Sedentary lifestyle
  - High-fat dietary intake

Adapted from Hagan, J. F., Shaw, J. S., & Duncan, P. M. (Eds.). (2008). *Bright futures: Guidelines for health supervision of infants, children, and adolescents* (3rd ed., rev.). Elk Grove Village, IL: American Academy of Pediatrics. Retrieved April 17, 2011, from [http://brightfutures.aap.org/pdfs/Guidelines\\_PDF/13-Rationale\\_and\\_Evidence.pdf](http://brightfutures.aap.org/pdfs/Guidelines_PDF/13-Rationale_and_Evidence.pdf)

**Immunizations**

Immunization is the key disease prevention activity during childhood health supervision visits. The development of effective vaccines, beginning in the 1940s, revolutionized children's health care. Immunization allowed the focus to shift from disease treatment to disease prevention. The nurse needs to understand the principles of immunizations, the proper use of vaccines, and barriers to immunization. Armed with this knowledge, the nurse can partner with families to provide the highest level of disease protection to children (Fig. 31.5). Refer to Healthy People 2020.

**HEALTHY PEOPLE 2020****Objective**

Achieve and maintain effective vaccination coverage levels for universally recommended vaccines among young children.

**Nursing Significance**

- Immunize at every opportunity. If a child is due or past due for vaccinations, provide them at a sick visit if not contraindicated.
- Educate families about the benefits and risks of immunization.

*Healthy People* Objectives based on data from <http://www.healthypeople.gov>.

**FIGURE 31.5** Nurse administering intramuscular injection into the vastus lateralis of an infant.

### PRINCIPLES OF IMMUNIZATION

The immune system has the ability to recognize materials present in the body as “self” or “non-self.” Foreign materials (non-self) are called antigens. When an antigen is recognized by the immune system, the immune system responds by producing antibodies (immunoglobulins) or directing special cells to destroy and remove the antigen.

**Immunity** is the ability to destroy and remove a specific antigen from the body. The acquisition of immunity can be active or passive. **Passive immunity** is produced when the immunoglobulins of one person are transferred to another. This immunity lasts only weeks or months. Passive immunity can be obtained by injection of exogenous immunoglobulins. It can also be transferred from mothers to infants via colostrum or the placenta. **Active immunity** is acquired when a person’s own immune system generates the immune response. Active immunity lasts for many years or for a lifetime. This long-term protection is the result of immunologic memory. After the initial immune response, specialized cells for that antigen continue to exist. When an antigen returns, these memory cells very rapidly produce a fresh supply of antibodies to reestablish protection. This immunity can occur after exposure to natural pathogens or after exposure to vaccines. Vaccines mimic the characteristics of the natural antigen. The immune system mounts a response and establishes an immunologic memory as it would for an infection.

The classification of vaccines is based on the characteristics of the antigen present. The antigen may be

viral or bacterial. It may be live attenuated (weakened) or killed. It may be the whole antigen or a portion of it (fractional).

- Live attenuated vaccines are modified living organisms that are weakened. The organism can produce an immune response but does not produce the complications of the illness.
- Killed vaccines contain whole dead organisms; they are incapable of reproducing but are capable of producing an immune response.
- Toxoid vaccines contain protein products produced by bacteria called toxins. The toxin is heat-treated to weaken its effect, but it retains its ability to produce an immune response.
- Conjugate vaccines are the result of chemically linking the bacterial cell wall polysaccharide (sugar-based) portions with proteins. This dramatically increases the immune response compared to presenting the polysaccharide portion alone.
- Recombinant vaccines use genetically engineered organisms. For example, the hepatitis B vaccine is produced by splicing a gene portion of the virus into a gene of a yeast cell. The yeast cell is then able to produce hepatitis B surface antigen to use for vaccine production.

The safety and efficacy of existing vaccines are constantly being reviewed, and research to improve vaccines is ongoing. The goal is to refine vaccines so that a maximum immune response is produced with the least amount of risk for the child.

### IMMUNIZATION MANAGEMENT

The Advisory Committee on Immunization Practices (ACIP), a branch of the CDC, reviews the recommended immunization schedules at least yearly and updates the schedule to ensure that it reflects current best practices (Tables 31.5 and 31.6). In addition to the recommended schedule, the ACIP publishes a “catch-up” schedule for children who have not been adequately immunized (Table 31.7). The child’s immunization record must be compared with the latest edition of these schedules when assessing the need for immunization.

#### *Take Note!*

When obtaining an immunization history from the parent, ask, “When and where did your child receive his (or her) last immunization?” The answer will provide more information than simply asking, “Are your child’s immunizations up to date?” The nurse can compare this information with that on the immunization record, discover in what settings the child is getting health care, and use the information as a starting point in a discussion of any reactions to previous immunizations.

TABLE 31.5

CDC-RECOMMENDED IMMUNIZATION SCHEDULE FOR PERSONS AGED 0–6 YEARS—UNITED STATES, 2011

FIGURE 1: Recommended immunization schedule for persons aged 0 through 6 years—United States, 2012 (for those who fall behind or start late, see the catch-up schedule [Figure 3])

Vaccine ▼	Age ►	Birth	1 month	2 months	4 months	6 months	9 months	12 months	15 months	18 months	19–23 months	2–3 years	4–6 years	
Hepatitis B <sup>1</sup>	Hep B	HepB	HepB			HepB		HepB						Range of recommended ages for all children
Rotavirus <sup>2</sup>				RV	RV	RV <sup>2</sup>								
Diphtheria, tetanus, pertussis <sup>3</sup>				DTaP	DTaP	DTaP	see footnote <sup>3</sup>		DTaP				DTaP	
<i>Haemophilus influenzae</i> type b <sup>4</sup>				Hib	Hib	Hib <sup>4</sup>		Hib						Range of recommended ages for certain high-risk groups
Pneumococcal <sup>5</sup>				PCV	PCV	PCV		PCV				PPSV		
Inactivated poliovirus <sup>6</sup>				IPV	IPV			IPV					IPV	
Influenza <sup>7</sup>								Influenza (Yearly)						
Measles, mumps, rubella <sup>8</sup>								MMR		see footnote <sup>8</sup>			MMR	Range of recommended ages for all children and certain high-risk groups
Varicella <sup>9</sup>								Varicella		see footnote <sup>9</sup>			Varicella	
Hepatitis A <sup>10</sup>								Dose 1 <sup>10</sup>					HepA Series	
Meningococcal <sup>11</sup>								MCV4 — see footnote <sup>11</sup>						

This schedule includes recommendations in effect as of December 23, 2011. Any dose not administered at the recommended age should be administered at a subsequent visit, when indicated and feasible. The use of a combination vaccine generally is preferred over separate injections of its equivalent component vaccines. Vaccination providers should consult the relevant Advisory Committee on Immunization Practices (ACIP) statement for detailed recommendations, available online at <http://www.cdc.gov/vaccines/pubs/acip-list.htm>. Clinically significant adverse events that follow vaccination should be reported to the Vaccine Adverse Event Reporting System (VAERS) online (<http://www.vaers.hhs.gov>) or by telephone (800-822-7967).

- Hepatitis B (HepB) vaccine.** (Minimum age: birth)
  - At birth:**
    - Administer monovalent HepB vaccine to all newborns before hospital discharge.
    - For infants born to hepatitis B surface antigen (HBsAg)-positive mothers, administer HepB vaccine and 0.5 mL of hepatitis B immune globulin (HBIG) within 12 hours of birth. These infants should be tested for HBsAg and antibody to HBsAg (anti-HBs) 1 to 2 months after completion of at least 3 doses of the HepB series, at age 9 through 18 months (generally at the next well-child visit).
    - If mother's HBsAg status is unknown, within 12 hours of birth administer HepB vaccine for infants weighing ≥2,000 grams, and HepB vaccine plus HBIG for infants weighing <2,000 grams. Determine mother's HBsAg status as soon as possible and, if she is HBsAg-positive, administer HBIG for infants weighing ≥2,000 grams (no later than age 1 week).
  - Doses after the birth dose:**
    - The second dose should be administered at age 1 to 2 months. Monovalent HepB vaccine should be used for doses administered before age 6 weeks.
    - Administration of a total of 4 doses of HepB vaccine is permissible when a combination vaccine containing HepB is administered after the birth dose.
    - Infants who did not receive a birth dose should receive 3 doses of a HepB-containing vaccine starting as soon as feasible (Figure 3).
    - The minimum interval between dose 1 and dose 2 is 4 weeks, and between dose 2 and 3 is 8 weeks. The final (third or fourth) dose in the HepB vaccine series should be administered no earlier than age 24 weeks and at least 16 weeks after the first dose.
- Rotavirus (RV) vaccines.** (Minimum age: 6 weeks for both RV-1 [Rotarix] and RV-5 [Rota Teq])
  - The maximum age for the first dose in the series is 14 weeks, 6 days; and 8 months, 0 days for the final dose in the series. Vaccination should not be initiated for infants aged 15 weeks, 0 days or older.
  - If RV-1 (Rotarix) is administered at ages 2 and 4 months, a dose at 6 months is not indicated.
- Diphtheria and tetanus toxoids and acellular pertussis (DTaP) vaccine.** (Minimum age: 6 weeks)
  - The fourth dose may be administered as early as age 12 months, provided at least 6 months have elapsed since the third dose.
- Haemophilus influenzae* type b (Hib) conjugate vaccine.** (Minimum age: 6 weeks)
  - If PRP-OMP (PedvaxHIB or Comvax [HepB-Hib]) is administered at ages 2 and 4 months, a dose at age 6 months is not indicated.
  - Hiberix should only be used for the booster (final) dose in children aged 12 months through 4 years.
- Pneumococcal vaccines.** (Minimum age: 6 weeks for pneumococcal conjugate vaccine [PCV]; 2 years for pneumococcal polysaccharide vaccine [PPSV])
  - Administer 1 dose of PCV to all healthy children aged 24 through 59 months who are not completely vaccinated for their age.
  - For children who have received an age-appropriate series of 7-valent PCV (PCV7), a single supplemental dose of 13-valent PCV (PCV13) is recommended for:
    - All children aged 14 through 59 months
    - Children aged 60 through 71 months with underlying medical conditions.
  - Administer PPSV at least 8 weeks after last dose of PCV to children aged 2 years or older with certain underlying medical conditions, including a cochlear implant. See *MMWR* 2010;59(No. RR-11), available at <http://www.cdc.gov/mmwr/pdf/rr/r11.pdf>.
- Inactivated poliovirus vaccine (IPV).** (Minimum age: 6 weeks)
  - If 4 or more doses are administered before age 4 years, an additional dose should be administered at age 4 through 6 years.
  - The final dose in the series should be administered on or after the fourth birthday and at least 6 months after the previous dose.
- Influenza vaccines.** (Minimum age: 6 months for trivalent inactivated influenza vaccine [TIV]; 2 years for live, attenuated influenza vaccine [LAIV])
  - For most healthy children aged 2 years and older, either LAIV or TIV may be used. However, LAIV should not be administered to some children, including 1) children with asthma, 2) children 2 through 4 years who had wheezing in the past 12 months, or 3) children who have any other underlying medical conditions that predispose them to influenza complications. For all other contraindications to use of LAIV, see *MMWR* 2010;59(No. RR-8), available at <http://www.cdc.gov/mmwr/pdf/rr/r8.pdf>.
  - For children aged 6 months through 8 years:
    - For the 2011–12 season, administer 2 doses (separated by at least 4 weeks) to those who did not receive at least 1 dose of the 2010–11 vaccine. Those who received at least 1 dose of the 2010–11 vaccine require 1 dose of the 2011–12 season.
    - For the 2012–13 season, follow dosing guidelines in the 2012 ACIP influenza vaccine recommendations.
- Measles, mumps, and rubella (MMR) vaccine.** (Minimum age: 12 months)
  - The second dose may be administered before age 4 years, provided at least 4 weeks have elapsed since the first dose.
  - Administer MMR vaccine to infants aged 6 through 11 months who are traveling internationally. These children should be revaccinated with 2 doses of MMR vaccine, the first at ages 12 through 15 months and at least 4 weeks after the previous dose, and the second at ages 4 through 6 years.
- Varicella (VAR) vaccine.** (Minimum age: 12 months)
  - The second dose may be administered before age 4 years, provided at least 3 months have elapsed since the first dose.
  - For children aged 12 months through 12 years, the recommended minimum interval between doses is 3 months. However, if the second dose was administered at least 4 weeks after the first dose, it can be accepted as valid.
- Hepatitis A (HepA) vaccine.** (Minimum age: 12 months)
  - Administer the second (final) dose 6 to 18 months after the first.
  - Unvaccinated children 24 months and older at high risk should be vaccinated. See *MMWR* 2006;55(No. RR-7), available at <http://www.cdc.gov/mmwr/pdf/rr/r7.pdf>.
  - A 2-dose HepA vaccine series is recommended for anyone aged 24 months and older, previously unvaccinated, for whom immunity against hepatitis A virus infection is desired.
- Meningococcal conjugate vaccines, quadrivalent (MCV4).** (Minimum age: 9 months for Menactra [MCV4-D], 2 years for Menveo [MCV4-CRM])
  - For children aged 9 through 23 months 1) with persistent complement component deficiency; 2) who are residents of or travelers to countries with hyperendemic or epidemic disease; or 3) who are present during outbreaks caused by a vaccine serogroup, administer 2 primary doses of MCV4-D, ideally at ages 9 months and 12 months or at least 8 weeks apart.
  - For children aged 24 months and older with 1) persistent complement component deficiency who have not been previously vaccinated; or 2) anatomic/functional asplenia, administer 2 primary doses of either MCV4 at least 8 weeks apart.
  - For children with anatomic/functional asplenia, if MCV4-D (Menactra) is used, administer at a minimum age of 2 years and at least 4 weeks after completion of all PCV doses.
  - See *MMWR* 2011;60:72–6, available at <http://www.cdc.gov/mmwr/pdf/wk/mm6003.pdf>, and Vaccines for Children Program resolution No. 6/11-1, available at <http://www.cdc.gov/vaccines/programs/vfc/downloads/resolutions/06-11mening-mcv.pdf>, and *MMWR* 2011;60:1391–2, available at <http://www.cdc.gov/mmwr/pdf/wk/mm6040.pdf>, for further guidance, including revaccination guidelines.

TABLE 31.6

## RECOMMENDED IMMUNIZATION SCHEDULE FOR PERSONS AGED 7–18 YEARS—UNITED STATES, 2011

**FIGURE 2: Recommended immunization schedule for persons aged 7 through 18 years—United States, 2012** (for those who fall behind or start late, see the schedule below and the catch-up schedule [Figure 3])

Vaccine ▼	Age ►	7–10 years	11–12 years	13–18 years	
Tetanus, diphtheria, pertussis <sup>1</sup>		1 dose (if indicated)	1 dose	1 dose (if indicated)	Range of recommended ages for all children
Human papillomavirus <sup>2</sup>		see footnote <sup>2</sup>	3 doses	Complete 3-dose series	
Meningococcal <sup>3</sup>		See footnote <sup>3</sup>	Dose 1	Booster at 16 years old	Range of recommended ages for catch-up immunization
Influenza <sup>4</sup>		Influenza (yearly)			
Pneumococcal <sup>5</sup>		See footnote <sup>5</sup>			Range of recommended ages for certain high-risk groups
Hepatitis A <sup>6</sup>		Complete 2-dose series			
Hepatitis B <sup>7</sup>		Complete 3-dose series			
Inactivated poliovirus <sup>8</sup>		Complete 3-dose series			
Measles, mumps, rubella <sup>9</sup>		Complete 2-dose series			
Varicella <sup>10</sup>		Complete 2-dose series			

This schedule includes recommendations in effect as of December 23, 2011. Any dose not administered at the recommended age should be administered at a subsequent visit, when indicated and feasible. The use of a combination vaccine generally is preferred over separate injections of its equivalent component vaccines. Vaccination providers should consult the relevant Advisory Committee on Immunization Practices (ACIP) statement for detailed recommendations, available online at <http://www.cdc.gov/vaccines/pubs/acip-list.htm>. Clinically significant adverse events that follow vaccination should be reported to the Vaccine Adverse Event Reporting System (VAERS) online (<http://www.vaers.hhs.gov>) or by telephone (800-822-7967).

- Tetanus and diphtheria toxoids and acellular pertussis (Tdap) vaccine.** (Minimum age: 10 years for Boostrix and 11 years for Adacel)
  - Persons aged 11 through 18 years who have not received Tdap vaccine should receive a dose followed by tetanus and diphtheria toxoids (Td) booster doses every 10 years thereafter.
  - Tdap vaccine should be substituted for a single dose of Td in the catch-up series for children aged 7 through 10 years. Refer to the catch-up schedule if additional doses of tetanus and diphtheria toxoid-containing vaccine are needed.
  - Tdap vaccine can be administered regardless of the interval since the last tetanus and diphtheria toxoid-containing vaccine.
- Human papillomavirus (HPV) vaccines (HPV4 [Gardasil] and HPV2 [Cervarix]).** (Minimum age: 9 years)
  - Either HPV4 or HPV2 is recommended in a 3-dose series for females aged 11 or 12 years. HPV4 is recommended in a 3-dose series for males aged 11 or 12 years.
  - The vaccine series can be started beginning at age 9 years.
  - Administer the second dose 1 to 2 months after the first dose and the third dose 6 months after the first dose (at least 24 weeks after the first dose).
  - See *MMWR* 2010;59:626–32, available at <http://www.cdc.gov/mmwr/pdf/wk/mm5920.pdf>.
- Meningococcal conjugate vaccines, quadrivalent (MCV4).**
  - Administer MCV4 at age 11 through 12 years with a booster dose at age 16 years.
  - Administer MCV4 at age 13 through 18 years if patient is not previously vaccinated.
  - If the first dose is administered at age 13 through 15 years, a booster dose should be administered at age 16 through 18 years with a minimum interval of at least 8 weeks after the preceding dose.
  - If the first dose is administered at age 16 years or older, a booster dose is not needed.
  - Administer 2 primary doses at least 8 weeks apart to previously unvaccinated persons with persistent complement component deficiency or anatomic/functional asplenia, and 1 dose every 5 years thereafter.
  - Adolescents aged 11 through 18 years with human immunodeficiency virus (HIV) infection should receive a 2-dose primary series of MCV4, at least 8 weeks apart.
  - See *MMWR* 2011;60:72–76, available at <http://www.cdc.gov/mmwr/pdf/wk/mm6003.pdf>, and Vaccines for Children Program resolution No. 6/11-1, available at <http://www.cdc.gov/vaccines/programs/vfc/downloads/resolutions/06-11mening-mcv.pdf>, for further guidelines.
- Influenza vaccines (trivalent inactivated influenza vaccine [TIV] and live, attenuated influenza vaccine [LAIV]).**
  - For most healthy, nonpregnant persons, either LAIV or TIV may be used, except LAIV should not be used for some persons, including those with asthma or any other underlying medical conditions that predispose them to influenza complications. For all other contraindications to use of LAIV, see *MMWR* 2010;59(No. RR-8), available at <http://www.cdc.gov/mmwr/pdf/rr/rr5908.pdf>.
  - Administer 1 dose to persons aged 9 years and older.
  - For children aged 6 months through 8 years:
    - For the 2011–12 season, administer 2 doses (separated by at least 4 weeks) to those who did not receive at least 1 dose of the 2010–11 vaccine. Those who received at least 1 dose of the 2010–11 vaccine require 1 dose for the 2011–12 season.
    - For the 2012–13 season, follow dosing guidelines in the 2012 ACIP influenza vaccine recommendations.
- Pneumococcal vaccines (pneumococcal conjugate vaccine [PCV] and pneumococcal polysaccharide vaccine [PPSV]).**
  - A single dose of PCV may be administered to children aged 6 through 18 years who have anatomic/functional asplenia, HIV infection or other immunocompromising condition, cochlear implant, or cerebral spinal fluid leak. See *MMWR* 2010;59(No. RR-11), available at <http://www.cdc.gov/mmwr/pdf/rr/rr5911.pdf>.
  - Administer PPSV at least 8 weeks after the last dose of PCV to children aged 2 years or older with certain underlying medical conditions, including a cochlear implant. A single revaccination should be administered after 5 years to children with anatomic/functional asplenia or an immunocompromising condition.
- Hepatitis A (HepA) vaccine.**
  - HepA vaccine is recommended for children older than 23 months who live in areas where vaccination programs target older children, who are at increased risk for infection, or for whom immunity against hepatitis A virus infection is desired. See *MMWR* 2006;55(No. RR-7), available at <http://www.cdc.gov/mmwr/pdf/rr/rr5507.pdf>.
  - Administer 2 doses at least 6 months apart to unvaccinated persons.
- Hepatitis B (HepB) vaccine.**
  - Administer the 3-dose series to those not previously vaccinated.
  - For those with incomplete vaccination, follow the catch-up recommendations (Figure 3).
  - A 2-dose series (doses separated by at least 4 months) of adult formulation Recombivax HB is licensed for use in children aged 11 through 15 years.
- Inactivated poliovirus vaccine (IPV).**
  - The final dose in the series should be administered at least 6 months after the previous dose.
  - If both OPV and IPV were administered as part of a series, a total of 4 doses should be administered, regardless of the child's current age.
  - IPV is not routinely recommended for U.S. residents aged 18 years or older.
- Measles, mumps, and rubella (MMR) vaccine.**
  - The minimum interval between the 2 doses of MMR vaccine is 4 weeks.
- Varicella (VAR) vaccine.**
  - For persons without evidence of immunity (see *MMWR* 2007;56[No. RR-4], available at <http://www.cdc.gov/mmwr/pdf/rr/rr5604.pdf>), administer 2 doses if not previously vaccinated or the second dose if only 1 dose has been administered.
  - For persons aged 7 through 12 years, the recommended minimum interval between doses is 3 months. However, if the second dose was administered at least 4 weeks after the first dose, it can be accepted as valid.
  - For persons aged 13 years and older, the minimum interval between doses is 4 weeks.

TABLE 31.7

**CATCH-UP IMMUNIZATION SCHEDULE FOR PERSONS AGED 4 MONTHS–18 YEARS WHO START LATE OR WHO ARE ≥1 MONTH BEHIND—UNITED STATES, 2011**

**FIGURE 3. Catch-up immunization schedule for persons aged 4 months through 18 years who start late or who are more than 1 month behind —United States • 2012**  
The figure below provides catch-up schedules and minimum intervals between doses for children whose vaccinations have been delayed. A vaccine series does not need to be restarted, regardless of the time that has elapsed between doses. Use the section appropriate for the child's age. **Always use this table in conjunction with the accompanying childhood and adolescent immunization schedules (Figures 1 and 2) and their respective footnotes.**

Persons aged 4 months through 6 years					
Vaccine	Minimum Age for Dose 1	Minimum Interval Between Doses			
		Dose 1 to dose 2	Dose 2 to dose 3	Dose 3 to dose 4	Dose 4 to dose 5
Hepatitis B	Birth	4 weeks	8 weeks and at least 16 weeks after first dose; minimum age for the final dose is 24 weeks		
Rotavirus <sup>1</sup>	6 weeks	4 weeks	4 weeks <sup>1</sup>		
Diphtheria, tetanus, pertussis <sup>2</sup>	6 weeks	4 weeks	4 weeks	6 months	6 months <sup>2</sup>
<i>Haemophilus influenzae</i> type b <sup>3</sup>	6 weeks	4 weeks if first dose administered at younger than age 12 months 8 weeks (as final dose) if first dose administered at age 12–14 months No further doses needed if first dose administered at age 15 months or older	4 weeks <sup>3</sup> if current age is younger than 12 months 8 weeks (as final dose) <sup>3</sup> if current age is 12 months or older and first dose administered at younger than age 12 months and second dose administered at younger than 15 months No further doses needed if previous dose administered at age 15 months or older	8 weeks (as final dose) This dose only necessary for children aged 12 months through 59 months who received 3 doses before age 12 months	
Pneumococcal <sup>4</sup>	6 weeks	4 weeks if first dose administered at younger than age 12 months 8 weeks (as final dose for healthy children) if first dose administered at age 12 months or older or current age 24 through 59 months No further doses needed for healthy children if first dose administered at age 24 months or older	4 weeks if current age is younger than 12 months 8 weeks (as final dose for healthy children) if current age is 12 months or older No further doses needed for healthy children if previous dose administered at age 24 months or older	8 weeks (as final dose) This dose only necessary for children aged 12 months through 59 months who received 3 doses before age 12 months or for children at high risk who received 3 doses at any age	
Inactivated poliovirus <sup>5</sup>	6 weeks	4 weeks	4 weeks	6 months <sup>5</sup> minimum age 4 years for final dose	
Meningococcal <sup>6</sup>	9 months	8 weeks <sup>6</sup>			
Measles, mumps, rubella <sup>7</sup>	12 months	4 weeks			
Varicella <sup>8</sup>	12 months	3 months			
Hepatitis A	12 months	6 months			
Persons aged 7 through 18 years					
Tetanus, diphtheria/ tetanus, diphtheria, pertussis <sup>9</sup>	7 years <sup>9</sup>	4 weeks	4 weeks if first dose administered at younger than age 12 months 6 months if first dose administered at 12 months or older	6 months if first dose administered at younger than age 12 months	
Human papillomavirus <sup>10</sup>	9 years		Routine dosing intervals are recommended <sup>10</sup>		
Hepatitis A	12 months	6 months			
Hepatitis B	Birth	4 weeks	8 weeks (and at least 16 weeks after first dose)		
Inactivated poliovirus <sup>5</sup>	6 weeks	4 weeks	4 weeks <sup>5</sup>	6 months <sup>5</sup>	
Meningococcal <sup>6</sup>	9 months	8 weeks <sup>6</sup>			
Measles, mumps, rubella <sup>7</sup>	12 months	4 weeks			
Varicella <sup>8</sup>	12 months	3 months if person is younger than age 13 years 4 weeks if person is aged 13 years or older			

- Rotavirus (RV) vaccines (RV-1 [Rotarix] and RV-5 [Rota Teq]).**
  - The maximum age for the first dose in the series is 14 weeks, 6 days; and 8 months, 0 days for the final dose in the series. Vaccination should not be initiated for infants aged 15 weeks, 0 days or older.
  - If RV-1 was administered for the first and second doses, a third dose is not indicated.
- Diphtheria and tetanus toxoids and acellular pertussis (DTaP) vaccine.**
  - The fifth dose is not necessary if the fourth dose was administered at age 4 years or older.
- Haemophilus influenzae* type b (Hib) conjugate vaccine.**
  - Hib vaccine should be considered for unvaccinated persons aged 5 years or older who have sickle cell disease, leukemia, human immunodeficiency virus (HIV) infection, or anatomic/functional asplenia.
  - If the first 2 doses were PRP-OMP (PedvaxHIB or Comvax) and were administered at age 11 months or younger, the third (and final) dose should be administered at age 12 through 15 months and at least 8 weeks after the second dose.
  - If the first dose was administered at age 7 through 11 months, administer the second dose at least 4 weeks later and a final dose at age 12 through 15 months.
- Pneumococcal vaccines.** (Minimum age: 6 weeks for pneumococcal conjugate vaccine [PCV]; 2 years for pneumococcal polysaccharide vaccine [PPSV])
  - For children aged 24 through 71 months with underlying medical conditions, administer 1 dose of PCV if 3 doses of PCV were received previously, or administer 2 doses of PCV at least 8 weeks apart if fewer than 3 doses of PCV were received previously.
  - A single dose of PCV may be administered to certain children aged 6 through 18 years with underlying medical conditions. See age-specific schedules for details.
  - Administer PPSV to children aged 2 years or older with certain underlying medical conditions. See *MMWR* 2010;59(No. RR-11), available at <http://www.cdc.gov/mmwr/pdf/rrrr5911.pdf>.
- Inactivated poliovirus vaccine (IPV).**
  - A fourth dose is not necessary if the third dose was administered at age 4 years or older and at least 6 months after the previous dose.
  - In the first 6 months of life, minimum age and minimum intervals are only recommended if the person is at risk for imminent exposure to circulating poliovirus (i.e., travel to a polio-endemic region or during an outbreak).
  - IPV is not routinely recommended for U.S. residents aged 18 years or older.
- Meningococcal conjugate vaccines, quadrivalent (MCV4).** (Minimum age: 9 months for Menactra [MCV4-D]; 2 years for Menvex [MCV4-CRM])
  - See Figure 1 ("Recommended immunization schedule for persons aged 0 through 6 years") and Figure 2 ("Recommended immunization schedule for persons aged 7 through 18 years") for further guidance.
- Measles, mumps, and rubella (MMR) vaccine.**
  - Administer the second dose routinely at age 4 through 6 years.
- Varicella (VAR) vaccine.**
  - Administer the second dose routinely at age 4 through 6 years. If the second dose was administered at least 4 weeks after the first dose, it can be accepted as valid.
- Tetanus and diphtheria toxoids (Td) and tetanus and diphtheria toxoids and acellular pertussis (Tdap) vaccines.**
  - For children aged 7 through 10 years who are not fully immunized with the childhood DTaP vaccine series, Tdap vaccine should be substituted for a single dose of Td vaccine in the catch-up series; if additional doses are needed, use Td vaccine. For these children, an adolescent Tdap vaccine dose should not be given.
  - An inadvertent dose of DTaP vaccine administered to children aged 7 through 10 years can count as part of the catch-up series. This dose can count as the adolescent Tdap dose, or the child can later receive a Tdap booster dose at age 11–12 years.
- Human papillomavirus (HPV) vaccines (HPV4 [Gardasil] and HPV2 [Cervarix]).**
  - Administer the vaccine series to females (either HPV2 or HPV4) and males (HPV4) at age 13 through 18 years if patient is not previously vaccinated.
  - Use recommended routine dosing intervals for vaccine series catch-up; see Figure 2 ("Recommended immunization schedule for persons aged 7 through 18 years").

Clinically significant adverse events that follow vaccination should be reported to the Vaccine Adverse Event Reporting System (VAERS) online (<http://www.vaers.hhs.gov>) or by telephone (800-822-7967). Suspected cases of vaccine-preventable diseases should be reported to the state or local health department. Additional information, including precautions and contraindications for vaccination, is available from CDC online (<http://www.cdc.gov/vaccines>) or by telephone (800-CDC-INFO [800-232-4636]).

BOX 31.8

**VACCINE ADMINISTRATION ROUTES**

Intramuscular	Subcutaneous
DTaP, DT, Tdap	IPV
Hepatitis A, hepatitis B	MMR
Hib	Varicella
Influenza (trivalent)	MPSV4
Pneumococcal	
HPV	
MCV4	

Adapted from Immunization Action Coalition. (2009). *Administering vaccines: Dose, route, site, and needle size*. Retrieved April 17, 2011, from <http://www.immunize.org/catg.d/p3085.pdf>. We thank the Immunization Action Coalition.

Vaccine storage and administration affect the efficacy of a vaccine. Improperly stored or reconstituted vaccines can be ineffective (CDC, 2011c). The vaccine must be given by the correct route; not all vaccines are given intramuscularly (Box 31.8, Table 31.8). The manufacturer’s package insert is the best reference source for any vaccine.

**Take Note!**

Proper vaccine storage is critical to vaccine efficacy. If you suspect that a vaccine was not maintained at the proper storage temperature, do not use it! An ineffective vaccine is of no use in preventing disease.

The National Childhood Vaccine Injury Act (NCVIA) requires that Vaccine Information Statements (VIS; Fig. 31.6) be provided to parents before an immunization is given (CDC, 2010b). In accordance with the concept of partnership with the parents, allow ample time for them to read the VIS and to discuss their concerns. If the parents do not understand the information presented, they should feel comfortable asking questions. If the parents are illiterate, present the information orally and verify that the parents understand it. If the information in the VIS is not in the parent’s native language, have a translator present the information.

At this time, ask the parents about the child’s reactions to previous immunizations, and screen for precautions and contraindications for each vaccine to be administered. Before the vaccine is given, the parents must sign consent forms.

Any clinically significant adverse event that occurs after an immunization should be reported to the Vaccine Adverse Event Reporting System (VAERS), which is a cosponsored surveillance program by the CDC and the U.S. Food and Drug Administration (FDA) (Vaccine Adverse Event Reporting System, n.d.). For assistance in obtaining and completing a VAERS form, call 800-822-7967 or visit [www.vaers.hhs.gov](http://www.vaers.hhs.gov).

Documentation in the child’s permanent record includes the following:

- Date the vaccine was administered
- Name of vaccine (commonly used abbreviation is acceptable)

**TABLE 31.8 VACCINE ADMINISTRATION: NEEDLE AND SITE SELECTION**

Child	Needle Size	Needle Length (Inches)	Site
<b>Intramuscular</b>			
Birth–28 days	25 gauge	5/8	Anterolateral thigh
1–12 months	23–25 gauge	1	Anterolateral thigh
1–2 years	23–25 gauge	1–1.25 5/8–1	Anterolateral thigh Deltoid
3–18 years	22–25 gauge	1–1.25 5/8–1	Anterolateral thigh Deltoid
<b>Subcutaneous</b>			
1–12 months	23–25 gauge	5/8	Fat of anterolateral thigh
>12 months	23–25 gauge	5/8	Fatty tissue over triceps

A 5/8-length needle should only be used if skin is stretched tight, subcutaneous tissue is not pinched, and a 90-degree angle is used.

Adapted from Immunization Action Coalition. (2009). *Administering vaccines: Dose, route, site, and needle size*. Retrieved April 17, 2011, from <http://www.immunize.org/catg.d/p3085.pdf>. We thank the Immunization Action Coalition.

# DIPHTHERIA TETANUS & PERTUSSIS VACCINES

## WHAT YOU NEED TO KNOW

### 1 Why get vaccinated?

**Diphtheria, tetanus, and pertussis are serious diseases caused by bacteria.** Diphtheria and pertussis are spread from person to person. Tetanus enters the body through cuts or wounds.

**DIPHTHERIA** causes a thick covering in the back of the throat.

- It can lead to breathing problems, paralysis, heart failure, and even death.

**TETANUS (Lockjaw)** causes painful tightening of the muscles, usually all over the body.

- It can lead to “locking” of the jaw so the victim cannot open his mouth or swallow. Tetanus leads to death in about 1 out of 10 cases.

**PERTUSSIS (Whooping Cough)** causes coughing spells so bad that is hard for infants to eat, drink, or breathe. These spells can last for weeks.

- It can lead to pneumonia, seizures (jerking and staring spells), brain damage, and death.

**Diphtheria, tetanus, and pertussis vaccine (DTaP) can help prevent these diseases.** Most children who are vaccinated with DTaP will be protected throughout childhood. Many more children would get these diseases if we stopped vaccinating.

DTaP is a safer version of an older vaccine called DTP. DTP is no longer used in the United States.

### 2 Who should get DTaP vaccine and when?

**Children** should get 5 doses of DTaP vaccine, one dose at each of the following ages:

- ✓ 2 months
- ✓ 4 months
- ✓ 6 months
- ✓ 15-18 months
- ✓ 4-6 years

DTaP may be given at the same time as other vaccines.

### 3 Some children should not get DTaP vaccine or should wait.

- Children with minor illnesses, such as a cold, may be vaccinated. But children who are moderately or severely ill should usually wait until they recover before getting DTaP vaccine.
- Any child who had a life-threatening allergic reaction after a dose of DTaP should not get another dose.
- Any child who suffered a brain or nervous system disease within 7 days after a dose of DTaP should not get another dose.
- Talk with your doctor if your child:
  - had a seizure or collapsed after a dose of DTaP,
  - cried non-stop for 3 hours or more after a dose of DTaP,
  - had a fever over 105°F after a dose of DTaP.

Ask your health care provider for more information. Some of these children should not get another dose of pertussis vaccine, but may get a vaccine without pertussis, called **DT**.

### 4 Older children and adults

DTaP should not be given to anyone 7 years of age or older because pertussis vaccine is only licensed for children under 7.

But older children, adolescents, and adults still need protection from tetanus and diphtheria. A booster shot called **Td** is recommended at 11-12 years of age, and then every 10 years. There is a separate Vaccine Information Statement for Td vaccine.

Diphtheria/Tetanus/Pertussis

7/30/2001

**FIGURE 31.6** Federal law mandates the use of Vaccine Information Statements (VISs). These should be given to the parent or primary caregiver for each vaccine the child receives. (Obtained from Centers for Disease Control and Prevention. [2010]. *Pneumococcal conjugate vaccine: What you need to know*. Retrieved April 19, 2011 at, from <http://www.cdc.gov/vaccines/pubs/vis/downloads/vis-pcv.pdf>) (continued)

## 5

**What are the risks from DTaP vaccine?**

Getting diphtheria, tetanus, or pertussis disease is much riskier than getting DTaP vaccine.

However, a vaccine, like any medicine, is capable of causing serious problems, such as severe allergic reactions. The risk of DTaP vaccine causing serious harm, or death, is extremely small.

**Mild Problems (Common)**

- Fever (up to about 1 child in 4)
- Redness or swelling where the shot was given (up to about 1 child in 4)
- Soreness or tenderness where the shot was given (up to about 1 child in 4)

These problems occur more often after the 4th and 5th doses of the DTaP series than after earlier doses. Sometimes the 4th or 5th dose of DTaP vaccine is followed by swelling of the entire arm or leg in which the shot was given, lasting 1-7 days (up to about 1 child in 30).

**Other mild problems include:**

- Fussiness (up to about 1 child in 3)
- Tiredness or poor appetite (up to about 1 child in 10)
- Vomiting (up to about 1 child in 50)

These problems generally occur 1-3 days after the shot.

**Moderate Problems (Uncommon)**

- Seizure (jerking or staring) (about 1 child out of 14,000)
- Non-stop crying, for 3 hours or more (up to about 1 child out of 1,000)
- High fever, over 105°F (about 1 child out of 16,000)

**Severe Problems (Very Rare)**

- Serious allergic reaction (less than 1 out of a million doses)
- Several other severe problems have been reported after DTaP vaccine. These include:
  - Long-term seizures, coma, or lowered consciousness
  - Permanent brain damage.

These are so rare it is hard to tell if they are caused by the vaccine.

Controlling fever is especially important for children who have had seizures, for any reason. It is also important if another family member has had seizures. You can reduce fever and pain by giving your child an *aspirin-free* pain reliever when the shot is given, and for the next 24 hours, following the package instructions.

FIGURE 31.6 (Continued)

## 6

**What if there is a moderate or severe reaction?****What should I look for?**

Any unusual conditions, such as a serious allergic reaction, high fever or unusual behavior. Serious allergic reactions are extremely rare with any vaccine. If one were to occur, it would most likely be within a few minutes to a few hours after the shot. Signs can include difficulty breathing, hoarseness or wheezing, hives, paleness, weakness, a fast heart beat or dizziness. If a high fever or seizure were to occur, it would usually be within a week after the shot.

**What should I do?**

- **Call** a doctor, or get the person to a doctor right away.
- **Tell** your doctor what happened, the date and time it happened, and when the vaccination was given.
- **Ask** your doctor, nurse, or health department to report the reaction by filing a Vaccine Adverse Event Reporting System (VAERS) form.

Or you can file this report through the VAERS website at [www.vaers.org](http://www.vaers.org), or by calling 1-800-822-7967.

VAERS does not provide medical advice.

## 7

**The National Vaccine Injury Compensation Program**

In the rare event that you or your child has a serious reaction to a vaccine, a federal program has been created to help pay for the care of those who have been harmed.

For details about the National Vaccine Injury Compensation Program, call **1-800-338-2382** or visit the program's website at [www.hrsa.gov/osp/vicp](http://www.hrsa.gov/osp/vicp)

## 8

**How can I learn more?**

- Ask your health care provider. They can give you the vaccine package insert or suggest other sources of information.
- Call your local or state health department's immunization program.
- Contact the Centers for Disease Control and Prevention (CDC):
  - Call **1-800-232-4636 (1-800-CDC-INFO)**
  - Visit the National Immunization Program's website at [www.cdc.gov/nip](http://www.cdc.gov/nip)

U.S. DEPARTMENT OF HEALTH & HUMAN SERVICES  
Centers for Disease Control and Prevention  
National Immunization Program

Vaccine Information Statement

DTaP (7/30/01)

42 U.S.C. § 300aa-26

- Lot number and expiration date of vaccine
- Manufacturer's name
- Site and route by which vaccine was administered (e.g., left deltoid, intramuscularly)
- Edition date of VIS given to the parents
- Name and address of the facility administering the vaccine (where the permanent record will be kept)
- Name of the person administering the immunization

Families should be provided with a copy of the child's immunizations. This reinforces the importance of the procedure and reminds the parents to keep the child's immunizations up to date.

Figure 31.7 shows a typical vaccine administration record.

### VACCINE DESCRIPTIONS

This section reviews the most commonly used vaccines. These immunizations are recommended by the ACIP and the AAP. Each state has laws that determine which immunizations are required for school admittance. These requirements can be waived if a contraindication or precaution to the vaccine exists. *Contraindications* are conditions that justify withholding an immunization either permanently or temporarily. The only permanent contraindication to all vaccines is an anaphylactic or systemic allergic reaction to a vaccine component (Kroger, Sumaya, Pickering, & Atkinson, 2011). Children who are severely immunocompromised or women who are pregnant should not receive live vaccines (such as MMR and varicella, see below); with pertussis immunization (DTP, DTaP, or Tdap, see below), encephalopathy without an identified cause within 7 days of the immunization permanently contraindicates further immunization with pertussis-containing vaccine (Kroger et al., 2011). Temporarily postponing vaccinations is recommended for moderate to severe illness, immunosuppression, pregnancy, or recently received blood products or other antibody-containing products (Kroger et al., 2011). Vaccination should not be postponed because of a minor respiratory illness or a low-grade fever (Kroger et al., 2011). *Precautions* are conditions that increase the risk of an adverse reaction or may impair the child's ability to acquire immunity from the vaccine. On an individualized basis, providers must weigh the benefits of immunization against the likelihood of an adverse event.

**DIPHTHERIA, TETANUS, AND PERTUSSIS VACCINES.** Immunization against diphtheria, tetanus, and pertussis diseases is given via a combination vaccine. The vaccine currently used for children younger than age 7 is diphtheria, tetanus, acellular pertussis (DTaP). It contains diphtheria and tetanus toxoids and pertussis cell wall proteins. The older version of this vaccine—diphtheria, tetanus, pertussis (DPT)—contained killed whole cells of

pertussis bacteria and caused more frequent and severe adverse reactions than DTaP. Diphtheria and tetanus (DT) vaccine is used for children younger than age 7 who have contraindications to pertussis immunization. Full-strength diphtheria toxoid causes significant adverse reactions in people older than age 7 years. For this group, the Tdap adolescent preparation vaccine is used: it contains tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis vaccine. The lowercase “d” is used to designate the lower dose of diphtheria toxoid. The ACIP recommends that Tdap be used for all tetanus boosters in older children (11 to 12 years) and adolescents, because Tdap provides a boost to diphtheria and pertussis immunization.

#### Take Note!

An increase in cases of pertussis have been seen in recent years especially in children 7 to 10 years of age (CDC, 2012). Pertussis can cause serious illness in children, especially children < 1 year old. The best prevention against pertussis is vaccination in infants, children, adolescents and adults (protection from the childhood vaccine fades with time) (CDC, 2012).

### HAEMOPHILUS INFLUENZAE TYPE B VACCINES.

*Haemophilus influenzae* type B is a bacterium that causes several life-threatening illnesses in children younger than 5 years of age. These infections include meningitis, epiglottitis, and septic arthritis. *H. influenzae* type B conjugate vaccines (Hib) have been extremely effective in cutting the rates of these diseases in children. There are several different types of Hib conjugate vaccines. HibTITER (HbOC) and ActHib (PRP-T) require three doses for the primary infant series, while PedvaxHIB and Comvax (PRP-OMP) require two doses. These vaccines are interchangeable, but if different brands are administered to a child, then a total of three doses are necessary to complete the primary series in infants. Hib vaccine is not given to children 5 years of age or older and is contraindicated in children younger than 6 weeks (Kroger et al., 2011).

**POLIO VACCINE.** Inactivated polio vaccine (IPV) is the only polio vaccine currently recommended in the United States (AAP, 2012b; ACIP, 2000). It is a killed virus vaccine that poses no risk for vaccine-acquired disease. Oral polio vaccine (OPV), a live attenuated virus vaccine, was the preferred polio vaccine until 2000. At that time it became apparent that the only victims of poliomyelitis were people who had acquired it from OPV. The ACIP determined that in this country the risks of OPV outweighed the benefits and withdrew its recommendation of OPV (AAP, 2012b; ACIP, 2000).

**MEASLES, MUMPS, AND RUBELLA VACCINES.** Measles, mumps, and rubella (MMR) is a live attenuated virus combination vaccine. It is the one most commonly used

in childhood immunizations. MMR can be given the same day as other live attenuated virus vaccines such as varicella vaccine. However, if not given on the same day, the immunizations should be spaced at least 28 days apart (Kroger et al., 2011). Anaphylactic reactions are believed to be associated with the neomycin or gelatin components of the vaccine rather than the egg component. The vaccine is not prepared from the allergenic albumen portion of the egg, so egg allergy is no longer a contraindication for measles vaccine (Kroger et al., 2011). Pregnancy in a child's mother is not a contraindication to the vaccination of the child (Kroger et al., 2011). Individual measles, mumps, and rubella vaccines are available if needed.

**HEPATITIS A VACCINE.** Hepatitis A vaccine (HepA) is an inactivated whole virus vaccine. Hepatitis A is spread through close physical contact and by eating or drinking contaminated food or water. It is one of the most frequently reported vaccine-preventable diseases in the United States. Young children are particularly susceptible to hepatitis A because of their close contact with other children, inadequate hygiene practices, and tendency to place everything in their mouth. Hepatitis A vaccine is recommended to be given to all children at age 12 months, followed by a repeat dose in 6 to 12 months.

**HEPATITIS B VACCINE.** Hepatitis B vaccine (HepB) is a recombinant vaccine. For infants, the mother's HBsAg status determines when immunization for hepatitis B begins. If the mother's status is positive or unknown, the neonate is immunized within the first 12 hours of life, at 1 to 2 months of age, and at 6 months of age. This is vital, because up to 90% of infected neonates develop chronic carrier status and will be predisposed to cirrhosis and hepatic cancer (CDC, 2010e). If the mother's status is negative, immunizations are given routinely at 2, 4, and 6 months of age. Because hepatitis B is a sexually transmitted infection, it is important to verify the immunization status of all adolescents.

**VARICELLA VACCINE.** Varicella vaccine (Var) is a live attenuated virus vaccine. All children age 12 to 15 months who have not had varicella (chickenpox) should be immunized. A second dose is recommended at age 4 to 6 years. The vaccine provides effective postexposure prophylaxis if administered within 3 to 5 days after exposure. Varicella vaccine may be given the same day as other live attenuated virus vaccines. However, if not given on the same day, the immunizations should be spaced at least 28 days apart. Pregnancy in a child's mother is not a contraindication to the vaccination of the child.

**PNEUMOCOCCAL VACCINES.** *Streptococcus pneumoniae* (pneumococcus) is the most common cause of pneumonia, sepsis, meningitis, and otitis media in young children (CDC, 2011d). The two available pneumococcal vaccines are pneumococcal conjugate vaccine (PCV) and

pneumococcal polysaccharide vaccine (PPSV). Beginning in 2010, PCV13, which contains 13 strains of *S. pneumoniae*, replaced PCV7, which only contained 7 strains, for use in routine vaccination for children (CDC, 2010d). It stimulates an immune response in infants and is given at 2 months of age as part of the initial immunization series but can be given as early as 6 weeks of age (CDC, 2010d). PPSV contains 23 strains of *S. pneumoniae*. It does not provoke an immune response in children younger than 2 years of age (CDC, 2010d). PPSV is given to children older than 2 years of age who are at high risk for pneumococcal sepsis. This group includes children with anatomic/functional asplenia; sickle cell disease; chronic cardiac, pulmonary, or renal disease; diabetes mellitus; or HIV infection; children getting or who have cochlear implants; and children with immunosuppression (CDC, 2010d).

**INFLUENZA VACCINES.** Influenza immunization is recommended yearly for healthy and high-risk children 6 months of age or older. Caregivers and household contacts of these children should also be immunized. In 2009–2010, in addition to the seasonal influenza vaccinations, the CDC began recommending vaccination against H1N1 influenza due to the influenza pandemic that was occurring worldwide (American Academy of Pediatrics, 2010). In the 2010–2011 influenza season, one vaccine was recommended, which protects against three strains of influenza, including the 2009 H1N1 (American Academy of Pediatrics, 2010). For children younger than 9 years old who are receiving their first influenza vaccination, who were immunized for the first time last season but did not receive two doses, or who did not receive two doses of the 2009 H1N1 vaccine, the CDC recommends two doses separated by 4 weeks (American Academy of Pediatrics, 2010).

There are two influenza vaccines available, the live attenuated influenza vaccine (LAIV) and the trivalent inactivated influenza vaccine (TIV). LAIV is given intranasally and is indicated for healthy persons between the ages of 2 and 49 years (American Academy of Pediatrics, 2010). The virus in LAIV can replicate, and a person who has received LAIV can shed virus for a week (American Academy of Pediatrics, 2010). LAIV should not be given to anyone who will be in contact with an immunosuppressed person requiring a protected environment. TIV is suitable for any eligible person age 6 months or older. TIV is not capable of causing disease and is given by intramuscular injection (American Academy of Pediatrics, 2010).

**ROTAVIRUS VACCINE.** Rotavirus is the most common cause of severe gastroenteritis among young children (Cortese & Parashar, 2009). The virus is shed in the stool and easily spreads via the fecal–oral route. Rotavirus accounts for about 30% to 50% of annual hospitalizations for gastroenteritis in children younger than 5 years of age (Cortese & Parashar, 2009). Severe, watery, crampy

diarrhea quickly leads to dehydration in the infected child. The most severe disease occurs in children ages 4 to 23 months (Cortese & Parashar, 2009). The rotavirus vaccine is a live vaccine targeting five strains of rotavirus and is given via the oral route to infants younger than 32 weeks of age. Recently, administration of rotavirus vaccine to children with severe combined immunodeficiency (SCID) was contraindicated (Centers for Disease Control and Prevention, 2010f).

**HUMAN PAPILLOMAVIRUS VACCINE.** Human papillomavirus (HPV) is a DNA tumor virus transmitted through direct skin-to-skin contact. HPV is contracted most often during vaginal or anal penetrative sexual acts. HPV infection is most common in adolescents and young adults aged 15 to 24 years who are sexually active. HPV causes genital warts and is responsible for the development of cervical cancer. For these reasons, the ACIP and AAP have recommended that HPV vaccination occur in preadolescent girls (CDC, 2010g). Two vaccines have been licensed: Cervarix, or HPV2, and Gardasil, or HPV4. The three-vaccine series of either HPV2 or HPV4 is recommended to be given at 11 to 12 years of age but can be given as early as 9 years of age (CDC, 2010g). The vaccine is anticipated to prevent most cases of genital warts and cervical cancer. HPV4 has been licensed for use in males to prevent genital warts. Routine immunization has not been recommended, but it may be offered to adolescent males ages 9 to 26 years of age (CDC, 2010h).

**MENINGOCOCCAL VACCINE.** Meningococcal disease may manifest as meningitis or as a deadly blood infection (meningococemia). It is caused by the bacterium *Neisseria meningitidis*, which is spread through direct contact or by air droplets. The incidence of meningococcal disease has decreased since 2000 but a peak in cases still is seen around the age of 18 years (CDC, 2011h). About 10% to 14% of infected persons die; of the remaining victims, about 11% to 19% suffer severe long-term consequences (CDC, 2009b). For these reasons, the meningococcal vaccine is recommended for all previously unvaccinated children at age 11 to 12 years

*Recall the Randall children, introduced at the beginning of the chapter. What immunizations would be appropriate for them to receive? Explain how you would administer the injections, and discuss any contraindications or precautions.*

with a booster dose at the age of 16 years (CDC, 2011h). These children should receive the meningococcal conjugated vaccine (MCV4). Certain high-risk groups may be vaccinated at 2 years of age (through age 10) with the meningococcal polysaccharide vaccine (MPSV4).

## BARRIERS TO IMMUNIZATION

A fully immunized child is protected from the discomforts and complications of many infectious diseases. Disease prevention spares the family the emotional and financial burdens that serious illnesses can cause. Immunization programs prevent devastating epidemics in a community. Health care dollars not spent treating preventable diseases can be used for other urgent issues. Despite the numerous advantages of immunization and improved immunization rates, some communities in this country continue to have high numbers of undervaccinated or unvaccinated children (CDC Online Newsroom, 2010).

Many factors lead to children not being fully immunized. Parental concerns about vaccine safety are a significant cause of inadequate immunization (CDC Online Newsroom, 2010). See Evidenced-Based Practice 31.1. Misconceptions of what constitutes a contraindication to vaccination and having more than one physician are major contributors to inadequate immunization status. The more children in a family, the less likely the children are to be fully vaccinated. The costs for vaccines can also deter families from obtaining immunizations. Parents may want to postpone some of the scheduled immunizations because they are concerned about the effects of multiple injections on their child. Postponing a portion of the immunizations puts the child at risk for contracting disease. Disrupting the optimal spacing of the immunizations can decrease the efficacy of vaccine, further putting the child at risk.

## OVERCOMING BARRIERS TO IMMUNIZATION

The AAP recommends the use of a manufacturer-produced combination vaccine whenever it will reduce the number of injections at a visit (CDC, 2011j; Freed, Cowan, Clark, Santoli, & Bradley, 2006). These combination vaccines have been studied and approved by the FDA. The nurse should never mix separate vaccines in the same syringe unless expressly permitted in the product insert for all vaccines involved. Examples of combination vaccines are:

- MMR: measles, mumps, rubella
- Comvax: HepB–Hib
- Pediarix: DTaP–Hep B–IPV
- Pentacel: DTaP–IPV/Hib

The Vaccines for Children (VFC) program was implemented in 1994 (Ching, 2007). Prior to this program, free vaccines were available only through public health agencies. By providing free vaccines to low-income and uninsured families through their private physicians, immunization rates have improved (Ching, 2007). Additional information on the VFC program is available at <http://www.cdc.gov/vaccines/programs/vfc/>.

Establishing a medical home for every child will alleviate many of the factors associated with lack of immunization. Parents who have a long-term, trusting relationship with a physician are more likely to have

**EVIDENCE-BASED PRACTICE 31.1****WHICH INTRAMUSCULAR VACCINATION TECHNIQUE RESULTS IN THE FEWEST ADVERSE REACTIONS IN CHILDREN?****STUDY**

The incidence of vaccine-preventable diseases is decreasing, yet concern remains about adverse reactions following intramuscular immunizations. Also, inconsistencies in recommendations and practice exist. This study conducted a literature review of clinical trials and studies on intramuscular vaccine administration technique primarily in the pediatric population. Databases searched included the Cochrane Database of Systematic Review, Medline, and Embase. Prior to 2002, there are almost no published studies investigating the best technique for administering intramuscular injections, which has led to the wide variation in recommendations and techniques.

**Findings**

Existing evidence supports fewer reactions noted when the buttock versus the thigh is used as the site of injection and fewer reactions when the vaccine is administered intramuscularly versus subcutaneously. Longer needles and a 90-degree angle are associated with fewer

reactions. Existing research did not provide evidence to support reactogenicity for aspiration, speed of injection, age/size of vaccine, experience of nurse, and pain on injection.

**Nursing Implications**

Parents often have concerns about adverse reactions associated with immunization. Current recommendations and techniques vary greatly internationally. Existing research supports the use of longer needles and a 90-degree angle, which is the technique supported by the World Health Organization. This technique decreases the potential of administering an intramuscular injection into the subcutaneous tissue along with decreasing the incidence of adverse reactions. The amount of muscle varies with the size of the infant and toddler, so the nurse must ensure that the needle chosen is long enough to place the medication intramuscularly. When appropriate, the buttocks as a site of injection needs to be considered.

Adapted from Perousis-Harris, H. (2008). Vaccine injection technique and reactogenicity-Evidence for practice. *Vaccine*, 26(50), 6299–6304.

their concerns about vaccine safety discussed and removed. Missed opportunities for immunizations can be reduced by:

- Maintaining a centralized immunization record
- Verifying immunization status at every visit, not just health supervision visits
- Verifying the status of siblings accompanying the child to the appointment
- Providing parents with up-to-date information on vaccines geared to their concerns and needs

Two excellent resources for vaccination recommendations in the United States are the CDC's Vaccines and Immu-

*Discuss potential barriers to the Randall children being fully immunized. As a nurse, how can you help overcome these barriers?*

nizations website (<http://www.cdc.gov/vaccines/default.htm>) and the CDC Hotline (800-232-4636 or 800-CDC-INFO).

**Health Promotion**

Health promotion focuses on maintaining or enhancing the physical and mental health of children. The principal components of health promotion are identifying risk factors for a disease, facilitating lifestyle changes to eliminate or reduce those risk factors, and empowering children at the individual and community level to develop resources to optimize their health. The nurse implements health promotion through education and anticipatory guidance.

Partnership development is the key strategy for success when implementing a health promotion activity. Identifying key stakeholders from the community allows problems to be solved and provides additional venues for disseminating information. Health promotion messages can be reinforced at schools, day care centers, community agencies, and churches. If families have difficulty getting to health care facilities, the community arenas may be the primary source of health promotion.

**Providing Anticipatory Guidance**

Anticipatory guidance is primary prevention. The nurse partners with the parents to create a “road map” to optimal health for the child. Healthy People 2020 provides a framework for determining health promotion goals. *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents* (Hagan et al., 2008) is another valuable resource.

The “skeleton” of the guidance provided involves common childhood health problems. The nurse fleshes out that information using the results of risk assessments and screening tests, health concerns unique to the child, and the interests and concerns of the parents. Age-related anticipatory guidance information is provided in Chapters 25 through 29.

*Provide appropriate anticipatory guidance for 3-year-old Maya and 9-month-old Evan.*

### Promoting Oral Health Care

Effective oral health practices are essential to the overall health of children and adolescents. Dental caries are the most common chronic illness seen in children, and 19.5% of children ages 2 to 5 years and about 23% of children ages 6 to 19 years have untreated dental caries (CDC, 2011i; Hagan et al., 2008; The Kaiser Commission on Medicaid and the Uninsured, 2008). Poor oral health can have significant negative effects on systemic health. Children who suffer from untreated dental caries have an increased incidence of pain and infections and may have problems with eating and playing, difficulty at school, and sleep pattern disturbances (CDC, 2011i). Refer to Healthy People 2020.

#### HEALTHY PEOPLE 2020

Objective	Nursing Significance
Reduce the proportion of children and adolescents who have dental caries in their primary or permanent teeth.	<ul style="list-style-type: none"> <li>• Teach children and adolescents appropriate toothbrushing and flossing techniques.</li> <li>• Encourage use of fluoride-containing toothpastes.</li> <li>• Encourage routine dental visits.</li> </ul>

*Healthy People* Objectives based on data from <http://www.healthypeople.gov>.

Optimal oral health is not limited to the prevention and treatment of dental caries. It includes anticipatory guidance about nonnutritive sucking habits, injury prevention, oral cancer prevention, and tongue and lip piercing. Preventing and treating malocclusion can have a significant benefit for children. Comprehensive health care is not possible if oral health is not a priority in the health delivery system.

Optimizing oral health can benefit the community as well as the individual child. There has been a 60% reduction in early childhood caries over the past 50 years since community water supplies were fluoridated at optimal levels (American Academy of Pediatric Dentistry [AAPD], 2008). The cost of pediatric oral health care could be reduced by 50% with the proper use of fluoride treatments coupled with other preventive measures (AAPD, 2008). These health care dollar savings will enhance community resources.

Having a dental home enhances the likelihood that the child will obtain appropriate preventive and routine care. The AAPD adopted the policy of the dental home in 2001 (AAPD, 2010). It is modeled on the AAP medical home policy. The dental home provides the same benefits to the child as the medical home. Characteristics of a dental home are listed in Box 31.9. The AAPD (2010)

#### BOX 31.9

#### CHARACTERISTICS OF THE DENTAL HOME

- Preventive health program based on risk assessment
- Anticipatory guidance on oral health developmental issues, including dietary counseling related to oral health
- Plans for emergency dental trauma
- Anticipatory guidance on oral hygiene
- Comprehensive dental care (acute and preventative services)
- Referral to specialists for care not available at the dental home

Adapted from American Academy of Pediatric Dentistry. (2010). *Policy on the dental home*. Retrieved April 17, 2011, from [http://www.aapd.org/media/Policies\\_Guidelines/P\\_DentalHome.pdf](http://www.aapd.org/media/Policies_Guidelines/P_DentalHome.pdf)

recommends that the dental home be established by the infant's first birthday.

### Promoting Healthy Weight

Childhood obesity is a growing problem. The number of overweight children has doubled since 1980; the rate for teens has tripled (CDC, 2008). The principal causes of this increase in obesity are unhealthy eating habits and decreased physical activity. Weight is best managed by balancing calories with a combination of diet and exercise (U.S. Department of Agriculture and U.S. Department of Health and Human Services, 2010). Nurses can have the maximum effect in promoting healthy weight in children by encouraging activities that address both healthy eating patterns and physical fitness. Children, parents, and communities are all targets for healthy weight promotion by nurses. Refer to Healthy People 2020.

#### HEALTHY PEOPLE 2020

Objective	Nursing Significance
Reduce the proportion of children and adolescents who are obese.	<ul style="list-style-type: none"> <li>• Screen all children for the development of overweight as indicated by an increasing body mass index (BMI) for their age.</li> <li>• Provide accurate diet counseling.</li> <li>• Encourage daily physical activity.</li> <li>• Counsel parents to limit television/computer time daily.</li> </ul>

*Healthy People* Objectives based on data from <http://www.healthypeople.gov>.

The focus of healthy weight promotion should be health centered, not weight centered. Linking success to numbers on a scale increases the possibility of developing eating disorders, nutritional deficiencies, and body hatred. Instead, emphasizing the benefits of health through an active lifestyle and nutritious eating creates a nurturing environment for the child. This allows the child to maintain his or her self-esteem. In addition, a health-centered orientation also allows the family to develop a lifestyle that incorporates its cultural food patterns and traditions.

The nurse can stress the benefits of the mother's healthy nutritional habits on the fetus at prenatal visits. Parents who have a healthy eating pattern are likely to maintain and encourage those patterns in their children. The nurse provides parents with anticipatory guidance about age-related eating patterns during each health supervision visit. Parents with toddlers and preschoolers may need training in ways to cope with the child's growing autonomy while providing a variety of nutritious options.

The nurse can begin directly advising the young child on healthy foods. Information and teaching modalities need to be age appropriate. With colorful posters and games, the nurse can teach the preschool child the difference between healthy and unhealthy food choices. As children enter school, group and peer-led activities can be very effective. The nurse must gear material toward the teen's growing autonomy in making self-care decisions.

Before providing education to school-age and teenage children, it is important to obtain nutritional histories directly from them because increasingly they are eating meals away from the family table. As they spend more time away from their parents, they need to develop the ability to make nutritious choices. The goal is to help older children develop strategies for making healthy choices as part of their increasingly independent lifestyle. Detailed anticipatory guidance is provided in Teaching Guidelines 31.1 and in Chapters 25 through 29.

### Teaching Guidelines 31.1

#### HEALTHY EATING

##### Breakfast

1. Don't skip breakfast. You will not have enough energy to play well later in the day. Skipping breakfast can also lower your grades in school.
2. Avoid eating high-sugar foods at breakfast. They will make you sleepy during the day.
3. Start your breakfast with some fruit. A small glass of juice, berries on your cereal, or a banana is a good choice.

4. Protein is important at breakfast. Milk, either in a glass or on cereal, is a good source of protein; so is yogurt or peanut butter.

##### Lunch

1. Check the quality of school-provided lunches. If they are high in fat or sugar, bring your lunch. Many schools publish their daily menus in advance. Check the newspaper or ask the school for a copy.
2. Add a variety of healthy alternatives to your lunches.
  - a. Try different types of breads. Pitas, wraps, bagels, and taco shells can be a good change of pace in the sandwich routine.
  - b. Freeze fruits before putting them in the lunch box. This will keep the lunch items cool and the fruit fresh tasting. Canned pineapple and grapes freeze well; so do bananas.
  - c. Try alternatives to high-fat chips. Dried fruits, baked pretzels, and animal crackers are a few examples of tasty, healthy treats.
  - d. Low-fat chocolate milk is more nutritious than prepackaged juice boxes, which have high sugar concentrations.

##### Snacks

1. Limit snacks to after school and bedtime. Light snacks such as yogurt or fruit provide good hunger management. A very hungry child will tend to overeat at meals.
2. Children need to learn to eat only when they are hungry. Children often eat out of boredom. Discourage nonstop grazing by planning activities to occupy the child.
3. A small bedtime snack is OK if the child is hungry but should not become a habit. A light carbohydrate such as graham crackers or a piece of fruit works well.

##### Dinner

1. Plan your menu a week ahead. Planning ahead reduces the likelihood of eating out or getting take-out food. Restaurant foods are more likely to be high in fats and carbohydrates.
2. Prepare homemade healthy versions of take-out favorites. Top prepared pizza crust with cooked chicken, vegetables, mushrooms, and cheese. Serve the pizza with a salad for a complete and healthy meal. "Make your own tacos" nights, using lean hamburger and low-fat sour cream, can be a lot of fun for children.
3. Don't turn dinner into a battle zone. Forcing children to eat foods they do not like will only deepen their dislike of them. Give them the healthy foods they do enjoy and eventually they will explore more options.
4. Lead by example. Children eventually adopt the eating patterns of their parents. If they see their parents eat vegetables, they will eventually try them.

## Promoting Healthy Activity

Healthy physical activity can take many forms. During the preschool years, encourage parents to provide a wide variety of physical activities. This exposure to multiple types of exercise allows the child to find the one that is most enjoyable and increases the chances that he or she will maintain an active lifestyle. The focus should be on noncompetitive, fun activities. When the child enters school, the lure of television and computers can significantly diminish the amount of time spent in physical activity. Parents can encourage their children to stay physically active in several ways. They can limit the amount of time spent in sedentary activities and actively encourage the child to pursue any exercise that he or she enjoys. In addition to verbal encouragement, parents can promote exercise by participating in exercise with the child. A simple family walk can increase physical fitness while providing time for interaction between parent and child. Refer to Healthy People 2020. Teaching Guidelines 31.2 gives additional suggestions for promoting physical activity.

### HEALTHY PEOPLE 2020

#### Objective

Increase the proportion of adolescents who meet current federal physical activity guidelines for aerobic physical activity and for muscle-strengthening activity.

#### Nursing Significance

- For the nonexercising teen, advise him or her to start slowly by walking.
- Work with the teen to identify physical activities that interest him or her.
- Praise efforts to participate in a routine exercise plan.
- Identify an athletic individual with whom the teen identifies, and encourage similar activities in the teen.

*Healthy People Objectives based on data from <http://www.healthypeople.gov>.*

### Teaching Guidelines 31.2

#### HEALTHY ACTIVITY

1. Plan physical activities that your family can do as a group.
2. Write exercise activities on your family's daily schedule.
3. Look for activities that appeal to your child's interest, such as dance, team sports, or swimming.
4. Place value on noncompetitive as well as competitive activities.
5. Show your child you believe exercise is important. Exercise daily yourself.
6. Encourage the community to develop safe areas for spontaneous games and activities.

## Promoting Personal Hygiene

Handwashing is the first personal hygiene topic that needs to be introduced to children. Handwashing prevents disease by limiting a child's exposure to pathogens. The nurse can introduce the topic to preschool children using cartoons and games. Have the child sing "Twinkle, Twinkle Little Star" while washing his or her hands; this encourages adequate cleansing time. Use soap containers and towels with colorful characters to make the experience more fun. The school-age child can understand the concepts of germs and disease. Slogans such as "Let's drown a germ" can serve as a reminder of the importance of handwashing. The "Glo-germ" program (n.d.) (see websites on [thePoint](#)) is very effective in this age group. A nontoxic substance that shines under a black light is placed on the children's hands. The children can follow how germs travel from object to object. After washing their hands, the children can see if they did a good job (Glo-germ program, n.d.).

In response to peer pressure, teenagers are usually stringent about personal hygiene. Young teens may need guidance in dealing with pubescent body changes such as body odor, fungal infections such as tinea pedis (athlete's foot), and acne.

## Promoting Safe Sun Exposure

Skin cancer is a significant health problem in the United States. Blistering sunburns in children substantially increase the risk of melanoma and other skin cancers (National Cancer Institute, 2011). People with fair skin are at highest risk for skin cancers, but anyone can become sunburned and develop skin cancer. When teaching children about safe sun exposure, remind them that harmful ultraviolet (UV) rays can reflect off water, snow, sand, and concrete, so being in the shade or under an awning does not guarantee protection. Adequate sun protection requires using sunscreen, avoiding peak sun hours, and wearing proper clothing. Teaching Guidelines 31.3 gives more detailed instructions.

### Teaching Guidelines 31.3

#### SAFE SUN EXPOSURE

#### Sunscreen

1. Use sunscreen lotions every day. Harmful ultraviolet (UV) rays penetrate clouds and cause damaging sunburns.
2. Use sunscreens with a sun protection factor (SPF) of 15 or higher. An adequate amount for an average-sized child is half an ounce.
3. Apply sunscreens half an hour before sun exposure.
4. Reapply every hour if the child is perspiring heavily.
5. Reapply immediately after swimming.

6. Infants 6 months old or younger should not use sunscreens. Take steps to avoid sun exposure completely with this age group.

#### Clothing

1. Wear hats. The brim of the hat should be 4 inches or more and should shade the ears. Straw hats need to have a sun proof liner to be effective. Children introduced to hats as infants usually accept hats as part of the “outfit.”
2. Wear UV-blocking sunglasses. The eye is the second most common site for melanoma.
3. Wear long, loose, and lightweight clothing for maximum sun protection.

#### Lifestyle

1. Avoid sun exposure between 10 a.m. and 4 p.m. This is when UV rays are strongest.
2. Ask your physician if your medication will increase your sensitivity to UV rays. If the answer is yes, take extra precautions to reduce sun exposure.
3. Avoid tanning parlors. The devices emit UV rays just like the sun and can cause damage.
4. Check the UV index before going out. The higher the index, the more precautions you should take. UV index figures are available in newspaper, TV, and radio weather reports and on the Internet.
5. Advocate for safe-sun scheduling of recreational activities. Talk to others about scheduling outdoor activities before 10 a.m., after 4 p.m., or in the shade.
6. Consider UV-blocking plastic film for your house and car windows.

#### Take Note!

Give children the following physical reference when doing health promotion on safe sun exposure. Tell the child, “Play outside only when your shadow is taller than you are.” The child’s shadow will be “taller” before 10 a.m. and after 2 p.m. The nurse can demonstrate this concept by placing a ruler on end and shining a bright light over it. As the nurse moves the light, the child will see the ruler’s shadow lengthen.

#### KEY CONCEPTS

- Health supervision for children is a dynamic process. Optimal wellness for the child can only occur if the nurse forms meaningful partnerships with the child, the family, and the community. These partnerships allow for free exchange of information and the establishment of mutually agreed upon goals. The medical home exists when there is a single primary care provider for the child. The medical home establishes a trusting long-term relationship with the child and family. This relationship

leads to comprehensive, coordinated, and cost-effective care for the child.

- Children with chronic illnesses have a critical need for comprehensive and coordinated health supervision. Children with chronic illnesses require more frequent health supervision assessments. These children must have a medical home. The location of that medical home may be with a knowledgeable primary physician or at a multidisciplinary specialty facility. The location is determined by the child’s needs and the family’s preferences.
- The nurse incorporates frequent assessments of the many psychosocial stressors faced by families of children with chronic illnesses when establishing health care plans for them.
- Health supervision has three components: developmental surveillance and screening; injury and disease prevention; and health promotion.
- Developmental surveillance is an ongoing process requiring a skilled observer and interviewer. To be effective, the nurse must understand normal growth and development expectations and be proficient at developmental screening procedures and techniques. Caregivers are most likely to reveal risk factors or warning signs for developmental delay when the nurse has a long-term and trusting relationship with the family.
- Screening tests are part of injury and disease prevention. They are modalities that identify treatable disease in an early or asymptomatic state and allow for cure or lessening of the disease’s injury.
- Vision and hearing screening are functional testing modalities that the nurse must be proficient in administering in order for the child’s results to be valid.
- Immunizations are a cornerstone of pediatric disease prevention. The nurse increases the effectiveness of immunization by understanding the principles of immunization and applying them to the child’s individual circumstances. Adhering to good immunization management practices, as outlined by the ACIP and the AAP, enhances the benefits and reduces the risks of immunization.
- Barriers to full immunization include fragmentation of health care, concerns about vaccine safety, financial constraints, and lack of knowledge. The nurse can be pivotal in ensuring that children and adolescents are fully immunized by serving as child educator and advocate.
- The principal components of health promotion are identifying risk factors for a disease, facilitating lifestyle changes to eliminate or reduce those risk

factors, and empowering children at the individual and community level to develop resources to optimize their health.

- The nurse implements health promotion through education and anticipatory guidance.
- Anticipatory guidance provided involves common childhood health problems and seeks to prevent or improve the health of children.
- The nurse uses the results of risk assessments and screening tests, health concerns unique to the child, and the interests and concerns of the parents to develop appropriate anticipatory guidance for each child and family.

## MULTIPLE CHOICE QUESTIONS

1. During the health interview, the mother of a 4-month-old says, "I'm not sure my baby is doing what he should be." What is the nurse's best response?
  - a. "I'll be able to tell you more after I do his physical."
  - b. "Fill out this developmental screening questionnaire and then I can let you know."
  - c. "Tell me more about your concerns."
  - d. "All mothers worry about their babies. I'm sure he's doing well."
2. An infant boy is at your facility for his initial health supervision visit. He is 2 weeks old and responds to a bell during his examination. You review all his birth records and find no documentation that a newborn hearing screening was performed. What is the best action by the nurse?
  - a. Do nothing; responding to the bell proves the infant does not have a hearing deficit.
  - b. Schedule the infant immediately for newborn hearing screening.
  - c. Ask the mother to observe for signs that the infant is not hearing well.
  - d. Screen again with the bell at the infant's 2-month health supervision visit.
3. A 15-month-old girl is having her first health supervision visit at your facility. Her mother has not brought a copy of the child's immunization record but believes she is fully immunized: "She had immunizations 3 months ago at the local health department." Which would be the best action by the nurse?
  - a. Ask the mother to bring the records to the 18-month health supervision visit.
  - b. Start the "catch-up" schedule because there are no immunization records.
  - c. Keep the child at the facility while the mother returns home for the records.
  - d. Call the local health department and verify the child's immunization status.
4. A 4-year-old child is having a vision screening performed. Which screening chart would be best for determining the child's visual acuity?
  - a. Snellen
  - b. Ishihara
  - c. Allen figures
  - d. CVTME

5. Which facility fulfills the characteristics of a medical home?
  - a. An urgent care center
  - b. A primary care pediatric practice
  - c. A mobile outreach immunization program
  - d. A dermatology practice
6. When should the child's first examination by a dentist occur?
  - a. By the first birthday
  - b. By the second birthday
  - c. By entry into kindergarten
  - d. By entry into first grade

## CRITICAL THINKING EXERCISES

1. During a health supervision visit for a 5-year-old boy, the mother tells you she is worried about his hearing. Your facility has been his medical home since birth. He was the product of a normal pregnancy and delivery. He has had frequent ear infections since the age of 8 months. Six months ago he had a ruptured appendix. He was treated with an aminoglycoside. He has been fully recovered for 4 months.
  - a. During the health interview, what information should the nurse elicit from the mother?
  - b. What information should the nurse verify from the permanent medical record?
  - c. What risk factors for hearing loss does this child have?
  - d. What is the best course of action at this time?
2. The nurse is examining a 4-year-old to determine his readiness for school. Describe the developmental, vision, and hearing screening tools that will help the nurse to identify any problems.

## STUDY ACTIVITIES

1. Develop an immunization plan for the following well children: a 2-month-old, an 18-month-old who has never been immunized, and a 5-year-old who was current with all immunizations at age 2.
2. This is the first health supervision visit, since arriving in this country 1 week ago, for a 3-year-old international adoptee from Russia. Develop a plan for this visit.
3. Develop a healthy weight program for the following: a preschool class, a family in which the parents and the two school-age children are mildly overweight, and a teenage girl who is of normal weight but fears "getting fat."

#### KEY TERMS

accommodation  
 acrocyanosis  
 body mass index (BMI)  
 chief complaint  
 fontanel  
 lanugo  
 obligate nose breathing  
 palpation  
 PERRLA  
 point of maximal impulse (PMI)  
 stadiometer  
 Tanner stages  
 Tympanometer

## Health Assessment of Children

### Learning Objectives

*Upon completion of the chapter, you will be able to:*

1. Define the key terms used in this chapter.
2. Demonstrate an understanding of the appropriate health history to obtain from the child and the parent or primary caregiver.
3. Individualize elements of the health history depending on the age of the child.
4. Discuss important concepts related to health assessment in children.
5. Perform a health assessment using approaches that relate to the age and developmental stage of the child.
6. Describe the appropriate sequence of the physical examination in the context of the child's developmental stage.
7. Distinguish normal variations in the physical examination from differences that may indicate serious alterations in health status.
8. Determine the sexual maturity of females and males based on evaluation of the secondary sex characteristics.

*Elliot Simmons, 3 years old, is brought to the clinic for his annual examination. His mother states that he is very fearful and anxious about this visit.*

#### **Words of Wisdom**

Astute nursing assessment of the child provides a snapshot of the child's overall health, growth, and development.

**Assessment** of the child's health status involves many components: the health interview and history; observation of the parent–child interaction; assessment of the child's emotional, physiologic, cognitive, and social development; and physical examination. The nurse's skills are vital to the success of the assessment process. The nurse must (Chiocca, 2011):

- Establish rapport and trust
- Demonstrate respect for the child and the parent or caregiver
- Communicate effectively by listening actively, demonstrating empathy, and providing feedback
- Observe systematically
- Obtain accurate data
- Validate and interpret data accurately

The focus of the assessment process depends on the purpose of the visit and the needs of the child. Assessment is an ongoing process and is repeated to varying degrees at every encounter. The expert nurse is constantly evaluating the children in his or her care, whether directly or indirectly as part of conversation and play. Indeed, some of the subtlest developmental signs may express themselves only during relaxed and casual interaction with a child (Burns, Dunn, Brady, Starr, & Blosser, 2009). The nurse may observe gait while watching a child run down the hall, assess fine motor skills and social adaptation while the child is playing a board game, or observe balance and coordination while the child is bouncing a ball. Playful activities such as tickling a child can give the nurse feedback related to upper body strength when the child attempts to push the nurse's arms away. The nurse must also learn to perform a comprehensive and thorough examination of a child in an efficient manner.

A thorough and thoughtful assessment of a child is the foundation upon which the nurse determines the needs of the child. A comprehensive history, a thorough examination, and developmental or cognitive testing as appropriate will provide practical information about the health of a child and guide the nurse's plan of care (developmental testing is covered in Chapter 31). The history and physical examination also provide a time for health education, teaching about expected growth and development, and discussing healthy lifestyle choices. The nurse uses critical thinking skills to analyze the data and establish priorities for nursing intervention or follow-up care (Burns et al., 2009).

The health assessment may be documented using a number of formats such as a written narrative, a written flow sheet, or an electronic health record. The information should be easily retrievable and available to all members of the child's health care team.

## HEALTH HISTORY

The health history provides the nurse with an overall picture of what the child has experienced, highlighting areas of concern such as recurrent upper respiratory

infections or headaches. This not only helps the nurse to assess those specific areas more comprehensively but also provides the opportunity to ask focused questions and identify areas where education may be needed. The time used to obtain the health history also gives the nurse an opportunity to interact with the child in a nonthreatening manner while the child watches the interactions between the nurse and the primary caregiver (Burns et al., 2009; Miller, 2011).

## Preparing for the Health History

Appropriate materials and a suitable environment are needed when performing a thorough health history. Take into account family roles and values. Consider the age and developmental stage of the child in order to approach the child appropriately and possibly involve him or her in the health history. Observe the child–parent interaction. Determine the extent of the health history that is needed in a given situation. Being well organized and staying flexible will help ensure success (Burns et al., 2009).

### Gathering Materials

Before beginning, make sure the following are available: materials to record the history data (either a computer or chart paper and a pen), a private space with adequate lighting, chairs for adults and the nurse, and a bed or examination table for the child. The space should be safe for the child's developmental stage. Sit down for as much of the history taking as possible to demonstrate a relaxed and welcoming manner (Burns et al., 2009).

### Approaching the Parent or Caregiver

Greet the parent or caregiver by name. While interviewing the parent, provide toys or books to occupy the child, allowing the parent to concentrate on the questions. Use open-ended questions and avoid making judgmental comments. Show respect by remaining approachable. Remember that the structure of the family and its roles and dynamics will affect how the family communicates and how they make decisions about health care. Demonstrate patience and help the parent stay on track when there are several children in the family. Throughout the interview, refer to the child by name and use the correct gender when referring to the child, demonstrating interest and competence.

#### Take Note!

*Illness can cause great stress in families and individuals, so nurses must remember to protect themselves from potentially threatening behavior on the part of the family. Sit close to the door, and if uncomfortable with a family member, ask for assistance. The nurse may need to alert security personnel in certain cases (Griffin, 2003).*

## Approaching the Child

Show a professional demeanor while still being warm and friendly to the caregivers and child. A white examination coat or all-white uniform may be frightening to children, who may associate the uniform with painful experiences or find it too unfamiliar (Roohafza et al., 2009). The nurse can wear a variety of professional-looking outfits, whether colorful uniform tops, aprons, or smocks worn over white uniforms, or everyday clothing, depending on the setting of the nurse's practice. Make eye contact if possible and address the child by name. Use slow deliberate gestures rather than very quick or grand ones, which may be frightening to shy children.

Some young children will warm up when given time to be invisible in the room, such as hiding behind a parent before they tentatively appear. Make physical contact with the child in a nonthreatening way at first. Briefly cuddling a newborn before returning him or her to the caregiver, laying a hand on the head or arm of toddlers and preschoolers, and warmly shaking the hand of older children and teens will convey a gentle demeanor. A joke, a puppet, a silly story, or even a simple magic trick may coax the child into warming up. Being at the same eye level as the child can also be more reassuring than standing over the child (Miller, 2011). This may require having extra seating for the nurse at the same level as the child and parent/caregiver. Aim to be seen as a trustworthy adult who is the child's partner in feeling better and staying healthy.

Elicit the child's cooperation by allowing him or her control over the pace and order of the health history, or anything else that the child can control while still allowing the nurse to obtain the information needed. All of this establishes a personal relationship with the child and helps gain his or her cooperation (Miller, 2011).

## Communicating With the Child During the Health History

Give the child opportunities to actively participate in the health history and assessment process. For young children, such as toddlers and preschoolers, ask them to point to where it hurts and allow them to answer questions. Validation of the information by the parent/caregiver is essential because of the limited comprehension and language use of children at these ages. The school-aged child can answer more accurately because of his or her increased language skills and maturity level.

Initially, address the child and obtain as much information from him or her as possible. School-aged children should be able to answer questions about interactions with friends and siblings and school and activities they enjoy or in which they are involved. Ask the parent/

caregiver if any additional information or observations should be included.

Adolescents may not feel comfortable addressing health issues, answering questions, or being examined in the presence of the parent/caregiver. The nurse must establish a trusting relationship with the adolescent to provide him or her with optimal health care. Ask adolescents whether they would be more comfortable answering questions alone in the examination area or whether they prefer their parents to be present. Either way, the parent/caregiver will have an opportunity to talk with the nurse after the health history and assessment are completed (Burns et al., 2009).

Demonstrate an interest in the teen by asking questions about school, work, hobbies or activities, and friendships. Begin with these topics to make the teen feel comfortable in communicating with the nurse. Communicate honestly with the adolescent and explain the rationale for various aspects of the health history. Teens are very sensitive to nonverbal communication, so be very aware of gestures and expressions (Sass & Kaplan, 2011). Once a rapport has been established, move on to more emotionally charged questions that relate to sexuality, substance use, depression, and suicide.

Always assure the teen that complete confidentiality will be maintained to the extent possible. Current state law will determine the types of information that may be withheld from parents. If the information that the nurse receives indicates that the teen may be in danger, then the nurse must inform the teen that the information will be shared with other providers and/or the parents (Burns et al., 2009).

### Take Note!

Do not try to become the adolescent's peer. Remain in the role of the nurse while demonstrating respect and acceptance toward the teen. Clarify the meaning of jargon or slang that the teen uses, but do not use these words yourself; the teen will simply not accept the nurse as a peer.

## Observing the Parent–Child Interaction

Observation of the parent–child interaction begins during the focused conversation of the health interview and continues throughout the physical examination. Explore the family dynamics, not only through questions but also by observing the family for behavioral clues. Does the parent make eye contact with the infant? Does the parent anticipate and respond to the infant's needs? Are the parents ineffective when dealing with a toddler's temper tantrum? The plan of care may need to be adjusted to teach appropriate responses to the infant's needs or toddler's behavior. Do the parents' comments increase the school-age child's sense

of self-worth? Behavioral observations are crucial to proper assessment of the family's needs (Burns et al., 2009; Columbia University, 2011).

Further observe the parent-child interaction to determine if the parent appears to be overwhelmed and if his or her behavior seems appropriate (Burns et al., 2009). Monitor the child's behavioral cues. Does the child look at the parent/caregiver before answering? Does the child seem relaxed and happy with the parent/caregiver, or is the child tense? The infant will appear calm and relaxed if his or her needs are generally met. Crying may occur when the baby is ill or frightened, but may also indicate discomfort with the parent or caregiver. Use a calm and comforting voice with the infant. Infants respond well to higher-pitched and soothing voices.

When observing the relationship between the adolescent and the parent/caregiver, does the parent/caregiver allow the adolescent to speak, or does he or she frequently interrupt? Does the parent/caregiver contradict what is being said? Observe the body language of the adolescent: does the teen seem relaxed or tense? Since adolescents are between childhood and adulthood, they have unique needs. They are experiencing a time of multiple physical and emotional changes, many of which they cannot control. They need to know that the nurse is interested in what they have to say (Sass & Kaplan, 2011). The use of open-ended questions allows the adolescent to talk. "Tell me about your . . ." or "What have you noticed about . . . ?" are comfortable phrases to use to elicit the information needed.

Be aware of your own reactions to the adolescent's questions or behaviors, such as nonverbal and facial expressions. Talk with the adolescent using accurate language that is developmentally and age appropriate.

### **Determining the Type of History Needed**

The purpose of the examination will determine how comprehensive the history must be. If the physician rarely sees the child or if the child is critically ill, a complete and detailed history is in order, no matter what the setting. The child who has received routine health care and presents with a mild illness may need only a problem-focused history. In critical situations, some of the history taking must be delayed until after the child's condition is stabilized. Evaluate the situation to determine the best timing and the extent of the history (Burns et al., 2009). Also, be sensitive to repetitive interviews in hospital situations, and collaborate with physicians or other members of the health care team to ensure that a family already under stress does not need to undergo prolonged or repetitive questioning.

*Remember Elliot, the 3-year-old being seen for his annual examination? When you enter the room, he is hiding behind his mother's legs. Considering his age and developmental level, how will you proceed with obtaining a health history?*

## **Performing a Health History**

The health interview is the foundation of an accurate health assessment. Careful conversation and interview with the child and/or the caregiver will provide important information about the child's health (Burns et al., 2009). Depending on the intent of the health assessment, many of the questions will be direct, and many will require the caregiver or child to answer simply "yes" or "no." In other than emergency situations, though, asking open-ended questions offers an excellent opportunity to learn more about the patient's life. For example, "Are you happy at school?" may elicit a brief nod of the head, whereas "Tell me what it's like on your school playground" may result in a story about the child's friends, the kind of activities the child enjoys, any bullying that goes on, and so forth. These stories will provide the nurse with clues to the child's stage of physical, emotional, and moral development as well as his or her functional status (Burns et al., 2009; Columbia University, 2011).

Establish a therapeutic relationship with the child and family. Without the trust that comes from this therapeutic relationship, the family may not reveal vital information due to fear, embarrassment, or mistrust (Bunik, Brayden, & Fox, 2011). Use therapeutic communication techniques such as active listening, open-ended questions, and eliminating barriers to communication. Establishing a "medical home" where ongoing health supervision occurs encourages trust through continuity of care and the family's continuing relationships with primary care providers (see Chapter 31).

The structure of the health interview is determined by the nature of the visit. At an initial visit, large amounts of historical data are collected. Having the family fill out a questionnaire can save time, but a questionnaire is not a substitute for the health interview. The questionnaire may serve as a springboard to begin structured conversations between the family and the nurse. At subsequent visits the health interview can focus on the pertinent issues of that visit as well as any health issues that are being monitored.

The health history includes demographics, chief complaint and history of present illness, past health history, review of systems, family health history, developmental history, functional history, and family composition, resources, and home environment.

**Take Note!**

Any questionnaires used in the health care setting should be written at a fifth-grade reading level and be in the primary language of the person completing them (The Joint Commission, 2010).

**Demographics**

Initially, questions should be simple and nonintrusive; once a rapport between the nurse and patient has started, sensitive questions can be asked. First obtain data such as the child’s name, nickname, birth date, and gender. Determine the child’s race or ethnicity, the language the child understands, and the language the child speaks. Record the child’s address and home telephone number and the parent’s or caregiver’s work telephone number. Identify who the historian is (the child or the parent or caregiver), and note how reliable this source of information is considered to be. Do not assume that an adult with the child is the child’s parent. Establish the relationship of the adult to the child, and ask who cares for the child if that person does not. Determine the composition of the household, including other children and other family members or other persons who live there.

**Chief Complaint and History of Present Illness**

Next, ask about the **chief complaint** (reason for the visit). The reason may not always be apparent to you. A question such as, “What can I help you with today?” or “What did you notice in your baby/child that you wanted to have checked today?” is very welcoming. The response from the child or parent may be a functional problem, a developmental concern, or a disease. Record the chief complaint in the child’s or parent’s own words.

Next address the history related to the present illness. For each concern, determine its onset, duration, characteristics and course (location, signs, symptoms, exposures, and so on), previous episodes in patient or family, previous testing or therapies, what makes it better or worse, and what the concern means to the child and family. Inquire about any exposure to infectious agents.

**Past Health History**

Ask about the prenatal history (any problems with pregnancy), perinatal history (any problems with labor and delivery), past illnesses, or any other health or developmental problems. Document the child’s prior history of illnesses (recurrent, chronic, or serious) and any accidents or injuries in the past. Inquire about any operations or hospitalizations the child has had. Document the child’s diet. Note the child’s allergies to foods,

medications, animals, environmental or contact agents, or latex products. Determine the child’s reaction to the allergen as well as its severity. Determine the child’s immunization status (refer to Chapter 31 for further information on immunizations). Record any medications the child is taking, the dosage and schedule, as well as when the last dose was given. In preadolescent and adolescent females, determine menstrual history.

**Family Health History**

Obtaining information about the family’s health is a key part of a health interview. Perform a three-generation family health history. This information may be documented in a genogram (Fig. 32.1). Asking about the age and health status of mother, father, siblings, and other family members helps to identify trends and specific health issues (Burns et al., 2009; Hagan, Shaw, & Duncan, 2008). For example, do the grandparents have early-onset coronary artery disease? If they do, the child may benefit from additional health screening. Siblings may exhibit a genetic disease or carry a trait for the disease. This family health information helps to guide future health planning.

**Review of Systems**

Inquire about current or past history of problems related to:

- Growth and development
- Skin
- Head and neck
- Eyes and vision
- Ears and hearing
- Mouth, teeth, and throat
- Respiratory system and breasts
- Cardiovascular system

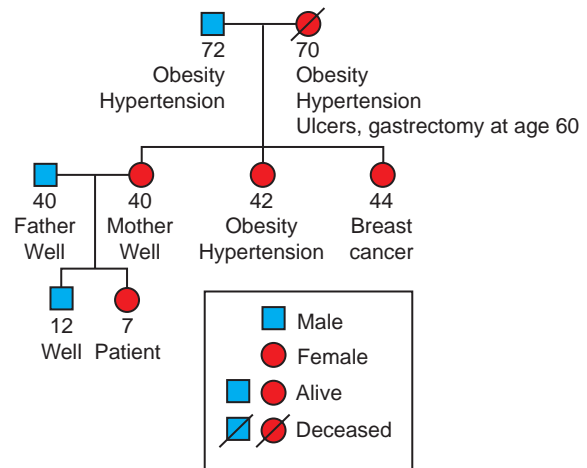

FIGURE 32.1 Genogram.

- Gastrointestinal system
- Genitourinary system
- Musculoskeletal system
- Neurologic system
- Endocrine system
- Hematologic system

Table 32.1 provides specific questions related to each of these systems.

### Developmental History

Determine the age when landmarks in gross motor control were achieved, such as sitting, standing, walking, pedaling, and so on. Ask whether the child has attained fine motor skills such as grasping, releasing, pincer grasp, crayon or utensil use, and handwriting skills. Note the child's age and extent of language acquisition. Document speech problems such as a lisp or stuttering.

**TABLE 32.1** QUESTIONS FOR THE REVIEW OF SYSTEMS

Systems	Has the Child Experienced
Growth and development	Weight loss or gain, appropriate energy and activity levels, fatigue, behavioral changes such as irritability, nervousness, anger, or increased crying
Skin	Easy bruising or bleeding, rash, lesion, skin disease, pruritus, birthmarks, or change in mole, pigment, hair, or nails
Head and neck	Head injury, headache, dizziness, syncope
Eyes and vision	Pain, redness, discharge, diplopia, strabismus, cataracts, vision changes, reading difficulties, need to sit close to the board at school or close to the TV at home
Ears and hearing	Earache, recurrent ear infection, tubes in eardrums, discharge, difficulty hearing, ringing, excess cerumen
Mouth, teeth, and throat	Swollen gums, pain with teething, caries, tooth loss, toothache, sores, difficulty with chewing or swallowing, hoarseness, sore throat, mouth breathing, change in voice
Respiratory system and breasts	Nasal congestion or discharge, cough, wheeze, noisy breathing, snoring, shortness of breath or other difficulty breathing, problems with or changes in breasts
Cardiovascular system	Murmur, color change (cyanosis), exertional dyspnea, activity intolerance, palpitations, extremity coldness, high blood pressure, high cholesterol
Gastrointestinal system	Nausea, vomiting, abdominal pain, cramping, diarrhea, constipation, stool holding, anal pain or itching
Genitourinary system	Dysuria; polyuria; oliguria; narrow urine stream; dark, cloudy, or discolored urine; difficulty with toilet training; bedwetting <i>Boys:</i> undescended testicles, pain in penis or scrotum, sores or lesions, discharge, scrotal swelling when crying, changes in scrotum or penis size, addition of pubic hair <i>Girls:</i> vaginal discharge, itching rash, problems with menstruation or menstrual cycle, development of pubic hair
Musculoskeletal system	Joint or bone pain, stiffness, swelling, injury (e.g., broken bones or sprains), movement limitation, decreased strength, altered gait, changes in coordination, back pain, posture changes or spinal curvature
Neurologic system	Numbness, tingling, difficulty learning, altered mood or ability to stay alert, tremors, tics, seizures
Endocrine system	Increased thirst, excessive appetite, delayed or early pubertal changes, problems with growth
Hematologic system	Swelling of lymph nodes, pale color, excessive bruising

Adapted from Burns, C., Dunn, A., Brady, M., Starr, N., & Blosser, C. (2009). *Pediatric primary care* (4th ed.). Philadelphia: Saunders; and Jarvis, C. (2012). *Physical examination and health assessment* (6th ed.). St. Louis: Saunders.

The rate of developmental skill acquisition may vary from child to child, but the sequence of skill attainment should remain the same. Inquire about self-care ability (e.g., tying shoes, dressing, brushing teeth) and, in the younger child, how toilet training is progressing. Question the parents about the child's feeding skills, including how well the child drinks from a cup and uses utensils or whether the child has any special requirements. Inquire about social skills and comfort articles (e.g., blankets, stuffed animals). Note whether the child has a habit of thumb or finger sucking or using a pacifier. Document day care attendance and preschool or school adjustment and achievements.

### Functional History

The functional history should contain information about the child's daily routine. Inquire about:

- Safety measures (e.g., car seats and their placement, use of seat belts, smoke detectors, bike helmets)
- Routine health care and dental care (including dates of dental care and what was done)
- Nutrition, including a 24-hour dietary recall or week-long food diary, use of supplements and vitamins, feeding pattern and satisfaction with diet, amount of "junk food" consumed, food likes and dislikes, and the parent's perception of the child's nutrition (refer to Chapters 25 through 29 for nutritional needs at various ages)
- Physical activity, recreation, play, and organized sports
- Television and computer habits
- Sleep behavior and bedtime
- Elimination patterns and any concerns
- Hearing or vision problems (dates of last screenings and results)
- Relationships with other family members and friends, coping and temperament, discipline strategies, attention or school behavior problems
- Religious involvement and other spiritual practices
- Use of adaptive and assistive devices such as eyeglasses or contact lenses, hearing aids, walker, braces, wheelchair
- Sexual practices (Burns et al., 2009; Hagan et al., 2008)

### Family Composition, Resources, and Home Environment

Determine the marital status of the parents. Does the child live with the parents, a stepparent, or other family member? Is the child adopted or in foster care? Are the parents the primary caretakers for the child? If not, the primary caretaker should be included in the interview process if possible. Parents may not know some of the child's routines if the child spends much of the time being cared for by someone else. Working parents may

learn about a health or behavior issue only after being alerted by the child's day care center or babysitter. It may be helpful to expand the family history to include the grandparents and their interaction with the child.

Determine the employment status of the parents and their occupations, as this could affect the child's overall well-being; for example, the parents' work schedule may not allow them to spend much time with the child. Assess family income and financial resources, including health insurance and Supplemental Nutrition Assistance Program (formerly food stamps); Aid for Women, Infants, and Children (WIC); or other governmental supplemental income. Major family changes can also affect how the parents and child interact, so evaluate for relationship problems or changes.

Ask about the family's home and its age and environment. Is there a safe outdoor play area? If there is a pool, are safety features in place? Determine whether the home has electricity and an indoor water supply. Also determine whether the home has heating, air conditioning, and refrigeration. What pets does the family have? How are they housed? Are there infestations of insects or rodents in the home?

#### Take Note!

Homes or apartments built prior to 1978 may contain lead-based paint, and children who live there are at an increased risk for the development of lead poisoning (Hagan et al., 2008).

## PHYSICAL EXAMINATION

The next step after the health history is the physical examination. It should focus on the chief complaint or any of the systems that engaged the nurse's critical thinking while obtaining the history. The examination will reflect the nurse's general practice style, the developmental stage and age of the child, the temperament of the child and caregiver, and the health status of the child. For example, a very ill child will not waste energy protesting the examination, so the nurse can move quickly in that situation. A healthy child, however, will express his or her normal developmental stage and will show varying degrees of resistance to the examination (Miller, 2011; Columbia University, 2011).

### Preparing for the Physical Examination

When performing the physical examination, being prepared and organized ensures that the needed information will be obtained efficiently. The appropriate methods to use and ways to approach the child depend on the child's developmental stage.

## Gathering Materials

The examination area should include an examination table or the child's hospital crib or bed. Appropriate lighting is necessary for adequate observation and inspection. Gather the equipment necessary for the examination such as clean gloves, stethoscope, thermometer, sphygmomanometer, tape measure, reflex hammer, penlight, otoscope/ophthalmoscope, tongue depressor, and cotton ball. An infant or adult scale is needed, as well as a **stadiometer** for children capable of standing independently. Young children may be frightened by seeing a large amount of equipment, so take out one piece of equipment at a time. Some children can be very resistant to what they see as a threat or an invasion of their privacy, so it may help to have washable toys in the examination area to use as distractions during the assessment (Burns et al., 2009; Hagan et al., 2008; Miller, 2011).

Children and their parents may be able to sense any frustration or anxiety on the part of the examiner, so display a confident and matter-of-fact approach. If the child is not cooperative, do not become discouraged; more time and explanation will usually do the trick.

Regardless of the child's age, if the examination room is cold, the child will be uncomfortable and possibly less cooperative. Provide appropriate covers to ensure the child's comfort, or have the child remain dressed until the time of the examination (Miller, 2011).

## Approaching the Child

Approach the child according to his or her developmental age and stage. Table 32.2 outlines a general approach to the physical examination in each broad developmental category.

If several children are to be seen at the same time, begin with the child who will be most cooperative. If the other children do not see anything scary and realize that their sibling was examined without a problem, it sets the stage for better cooperation from the younger ones.

### NEWBORNS AND INFANTS

If the infant is asleep, auscultate the heart, lungs, and abdomen first while the baby is quiet. Count the heart rate and respiratory rate before undressing the baby. Completely undress newborns and infants down to their diaper, removing it just at the end to examine the genitalia, anus, spine, and hips. It is best to examine the infant 1 to 2 hours before a feeding. Having the parent or caregiver hold the child during the examination can help to alleviate fears and anxieties (Fig. 32.2). Allow the parent or caregiver to be a nurturer rather than assisting with painful procedures, unless there are no other choices available (Miller, 2011).

Perform the assessment in a head-to-toe manner, leaving the most traumatic procedures, such as

**FIGURE 32.2** The infant or toddler may feel more comfortable and secure being examined while sitting in the parent or caregiver's lap.

examination of the ears, nose, mouth, and throat, until last (Burns et al., 2009; Miller, 2011). Also delay eliciting the Moro reflex until the end of the examination, as the startling sensation may make the infant cry. Use firm, gentle handling while examining the infant. Make sure your hands and the stethoscope are warm. Perform the assessment as quickly and completely as possible. Use a soft and crooning voice, smile, and engage the infant in eye contact. In addition, use brightly colored objects to help distract him or her. If the baby is crying, a pacifier may be useful.

### Take Note!

Many older infants demonstrate stranger anxiety as a normal part of development. If the parent is not holding the infant, make sure the parent is within the infant's view; this will increase the baby's comfort and cooperation (Bickley & Szilagyi, 2009; Burns et al., 2009; Miller, 2011).

### TODDLERS

Toddlers usually prefer to remove their clothing one item at a time as needed for the examination. After one area is examined, the child may feel more comfortable replacing that item of clothing before removing another one (Bunik et al., 2011). An examination gown is usually not necessary before school age. Again, make certain the room temperature is comfortable.

When the nurse enters the room, a child of this age is often sitting or standing by the parent. Incorporate play as appropriate during the health assessment. Remember your own facial expressions and tone. Use little touch at the beginning of the encounter with the child and the caregiver.

TABLE 32.2

## DEVELOPMENTAL CONSIDERATIONS FOR EXAMINATION

	Newborn	Infant	Toddler	Preschool	School-age	Early Teen	Late Teen
<b>Place to perform examination</b>	May lie on examination table or in caregiver's lap.	In caregiver's lap or on examination table with caregiver right beside infant.	Allow some freedom of movement when possible; child may stand between seated caregiver's legs or sit on the lap.	Some may be willing to sit on examination table with caregiver standing close by with hand on the leg.	Sitting on examination table where they still have eye contact with caregiver.	Some may be willing to have their caregiver wait outside the examination room.	Explain to the caregiver that the teen needs privacy and that he or she should wait outside the examination room.
<b>Examination direction</b>	Keep up a running dialog with the caregiver, explaining each step as you do it.	Continue to explain each step to the caregiver; address child by name. Perform most invasive parts last.	Introduce yourself to caregiver and child; explain most steps to the child and all steps to caregiver; allow child to handle instruments. Perform most invasive parts last.	Allow child to decide the order of the examination; explain what the instruments do and let the child try them; speak to the caregiver before and after the examination.	Include the child in all parts of the examination; use head-to-toe approach with genital exam last. Speak to the caregiver before and after the examination.	Speak to the child using mature language; appeal to his or her desire for self-care. Use a head-to-toe approach, with genital examination last.	Explain confidentiality to caregiver and teen; allow time talking with them together and separately. Use a head-to-toe approach, with genital exam last.

**FIGURE 32.3** The preschooler enjoys listening to her mother's heart first.

Introduce the equipment to be used slowly, explaining briefly what is going to happen. Let the child touch and hold the equipment whenever possible, even taking a parent's temperature or putting the blood pressure cuff on a teddy bear (Fig. 32.3). The toddler will prefer to sit on the caregiver's lap. When the toddler must be supine for the abdominal examination, sit in your chair knee-to-knee with the caregiver so the toddler may lie back on the caregiver's and your laps. Praise the child for being cooperative during the examination. "You did such a good job holding still while I listened to your chest" and similar phrases give positive feedback to the child.

If the child is uncooperative, assess as thoroughly as possible and move on to the next area to be assessed. The caregiver may need to place an arm around the toddler's body to provide restraint for invasive procedures. Use short phrases to tell the toddler what you are going to do, rather than asking if it is OK (Miller, 2011; Nettina, 2010).

#### Take Note!

Toddlers are *egocentric*. Telling a toddler how well another child behaved probably will not be helpful in gaining the young child's cooperation.

### PRESCHOOLER

The preschooler may fear body invasion and mutilation and will withdraw from any procedure or assessment that is viewed as intrusive. Otherwise, the sense of initiative often leads the preschooler to be cooperative. Use simple explanations to inform the child about each step of the examination, offering reassurance as appropriate. Allow him or her to "help" by holding the stethoscope or penlight. If choices are available, offer them to the child. Again, always compliment the child on his or her cooperation.

#### Take Note!

Preschoolers like to play games. To encourage deep breathing during lung auscultation, hold up a finger or a lit penlight and instruct the child to "blow it out" (Miller, 2011).

### SCHOOL-AGE CHILDREN

The school-age child's thinking is still very concrete, but he or she can be objective and realistic. Avoid using medical jargon and words that may have a double meaning to a young child. Instead of "take your temperature," "take your blood pressure," "hit your knee," or "test," say, "Let's see how warm you are," "I want to listen to you breathe," and other phrases that describe, in words the child can understand, what you are preparing to do. The school-age child may be very interested in how things work and why certain things need to be done and will be responsive to truthful and simple explanations. Instruments that are colorful or look like toys are very helpful throughout early childhood and the school-age period (Burns et al., 2009; Miller, 2011).

Always respect a child's desire to avoid pain and insult. Allow children to wear their underpants under the examination gown to provide a sense of security until the genitalia need to be examined. Allow the child to replace his or her clothing as soon as possible. Privacy and respect for the child's feelings are important to children of this age (Bunik et al., 2011).

#### Take Note!

Describing and commenting on your findings during the physical examination is interesting to the school-age child, as children of this age like to learn about how the body works (Miller, 2011).

### ADOLESCENTS

Provide privacy while the adolescent is undressing and putting on a gown. Demonstrate an attitude of respect. Perform the assessment in a head-to-toe manner, exposing only the area to be examined. Provide information about physical changes in a matter-of-fact way, such as, "The hair on your legs is what is expected at this time." This provides information related to sensitive areas that the teen may be reluctant to ask about. It also provides the adolescent with information about the sexual development that is normal and expected. Allow opportunities for the teen to ask questions without the caregiver being present. Assure the adolescent that there are no "dumb questions" about the changes being experienced. Teenage girls should remove their bras so that the nurse can perform a breast examination, teach breast self-examination, and check for scoliosis. If the nurse is a male and the patient is an adolescent female, it is appropriate for a female staff member to be present during the breast and genital examination (Sass & Kaplan, 2011).

## Steps of the Physical Examination

The physical examination of children, just as for adults, begins with a systematic inspection: checking color, warmth, characteristics, and texture visually and smelling for any odor. **Palpation** follows inspection to validate your observations. Percussion is a useful tool for determining the location, size, and density of organs or masses. Tapping with the reflex hammer elicits deep tendon reflexes. The stethoscope is used to auscultate the heart, lungs, and abdomen.

## Performing a Physical Examination

A complete examination includes assessment of the general appearance, vital signs, body measurements, and pain, as well as examination of the head, neck, eyes, ears, nose, mouth and throat, skin, thorax and lungs, breasts, heart and peripheral perfusion, abdomen, genitalia and rectum, musculoskeletal system, and neurologic system. The nurse in most settings will not be assessing the breasts, genitalia, or eyes or ears in detail. Be aware of the role of the nurse in different settings and how the nurse can facilitate the assessment process.

### General Appearance

Never discount first impressions. Does the child give an impression of being ill or well? What is the child's expression and energy level? Note lethargy, listlessness, excessive activity, or inappropriate attention span for the child's age. Observe the child's state of alertness and whether he or she is responding appropriately to the stress of the situation. Note the child's posture and positioning:

- The newborn's posture is flexed, with arms and legs tucked in.
- The older infant should have improving head and then trunk control.
- The toddler demonstrates lordosis (swayback) and bowlegs, with a relatively large head and protuberant belly.
- The preschooler is more slender and upright in appearance.
- The school-age child and adolescent should demonstrate an upright, straight, and well-balanced posture.

Note whether the child's development appears appropriate. Observing the child initially may yield a wealth of information about the child's development. Is the child active, moving about the room? Does the child's speech seem appropriate for his or her age? Notice whether the family interacts appropriately with one another and the child. Does the child appear clean and well cared for? Does the child appear well nourished

or small for age or obese? Note the scent of tobacco smoke or alcohol on family members. Notice if the baby bottle or pacifier is nearby and whether the child has a toy or transitional object. Assess whether the siblings appear equally well cared for. Observe for tension in the room between adults or children/adolescents. This initial quick assessment of general appearance will serve the nurse well if it is objective; delay interpretation of this assessment until additional data are gathered.

### Measurement of Vital Signs

Measure, document, and interpret the vital signs of children using age-appropriate equipment and approaches. The child's age and size, as well as knowledge of underlying health conditions, will affect analysis of the vital signs. Vital signs are the temperature, pulse rate, respiratory rate, and blood pressure. These measurements fluctuate normally in children; assessing vital signs while the child is quiet is most appropriate. Comforting an infant or distracting a young child may be necessary while obtaining vital signs. If the child is crying or otherwise active during the assessment, document that fact. Many acute care settings require continuous measurement of vital signs using specific monitoring equipment. Also assess the child's pain level when assessing the vital signs.

#### TEMPERATURE

Temperature is measured as it is in adults. Thermometers are available in glass, electronic, and digital types. Use the same type of equipment consistently to allow reliable comparisons to be made and to permit tracking of temperatures during the course of illness (Bowden & Greenberg, 2008). No matter which type of thermometer is used, ensure accuracy by carefully following the manufacturer's instructions.

The routes for taking the child's temperature are tympanic, temporal, oral, axillary, and rectal. Numerous research studies have been undertaken to determine the best method for temperature assessment in children. Take the child's temperature using the least invasive method that is best accepted by the child, parent, and physician.

#### Take Note!

Glass thermometers are not recommended for use due to the mercury they contain (Bowden & Greenberg, 2008).

Choosing a method of measuring temperature depends on what is available at the facility and the child's age and physical condition. Tympanic temperature reflects the pulmonary artery temperature and can be measured with the tympanic thermometer within seconds. The accuracy of a tympanic temperature reading depends on the

## NURSING PROCEDURE 32.1

**Measuring Tympanic Temperature**

1. Note age of child. If younger than 3 years, pull the earlobe back and down.
2. Insert the tympanic thermometer gently into the ear canal with the infrared sensor beam directed toward the center of the tympanic membrane rather than the sides of the ear canal.
3. Push the button to take the temperature and hold until a reading is obtained. The length of time required for the temperature to register varies per manufacturer but is only a few seconds at most.

user's technique and can be safely and effectively used in children 3 months of age and older (Bowden & Greenberg, 2008). Refer to Nursing Procedure 32.1.

Temporal scanning uses infrared scanning on the skin over the temporal artery combined with a mathematical computation to determine the child's arterial temperature. Temporal artery thermometry may be used with any age child except infants younger than 90 days of age who are ill or have a fever (Asher & Northington, 2008). Measure temperature on the exposed side of the head (not the side that has been lying on a pillow or covered by a hat). Slide the sensor tip externally in a horizontal line across the child's forehead, midway between the eyebrows and hairline and ending at the temporal artery (Fig. 32.4). Hold it there until the device registers the temperature reading, which usually requires 1 second. Accuracy may be affected by excessive sweating (Exergen Corporation, 2007). Oral temperature is highly reliable if the child can cooperate. By 5 years of age, the child can hold an electronic oral thermometer in the mouth well enough to obtain a reading. Place the probe under the tongue and ensure the child's mouth remains closed until the device registers the temperature. Oral intake, oxygen administration, and nebulized medications or treatments may affect oral temperature.

The axillary method may be used for children who are uncooperative, neurologically impaired, or immunosuppressed or have injuries or have had surgery to the oral cavity (Bowden & Greenberg, 2008). Place the tip of the electronic or digital thermometer in the axilla to obtain the reading. Make sure the tip is indeed in the axilla and not just between the arm and the child's side. Hold the thermometer parallel rather than perpendicular

to the child's side to obtain the most accurate reading. Keep the child's arm pressed down to the side until the thermometer registers, which will be as little as 10 seconds with certain electronic models but 2 or 3 minutes with digital models commonly used at home.

Though long considered to reflect core temperature, the rectal route is invasive, not well accepted by children or parents, and probably unnecessary with the modern alternative methods now available. To take the rectal temperature, position the young infant supine with legs flexed. The older infant or child should be prone or side-lying. Small children may lie across the parent's lap for additional comfort. Apply a water-soluble jelly to the covered probe, insert the thermometer past the anal

**FIGURE 32.4** Temporal artery thermometers are noninvasive and well tolerated by young children. For an accurate reading, move hair to expose forehead and hairline.

**EVIDENCE-BASED PRACTICE 32.1****PACIFIER THERMOMETERS****STUDY**

Nurses and parents are concerned with being able to measure temperature accurately with the least invasive method possible. Research trials on pacifier thermometry in the past have been limited. The researchers utilized a convenience sample of children aged 7 days to 24 months in a prospective, cross-sectional study. Subjects were limited to those without gastrointestinal illness or contraindication to either the sublingual or rectal method of temperature measurement. Each child underwent pacifier temperature measurement with recordings at 3 and 6 minutes. The result was adjusted upward 0.5°F as recommended by the thermometer manufacturer. Rectal temperature was then taken.

**Findings**

Analysis of the pairs of recorded temperatures for each subject revealed close agreement between the rectal temperature and the adjusted 6-minute pacifier temperatures. Differences between the two were not statistically

Adapted from Braun, C. A. (2006). Accuracy of pacifier thermometers in young children. *Pediatric Nursing*, 32(5), 413–418.

significant. Variations between measurements are certain to occur when temperature is measured at different sites, so the researcher does not recommend replacing rectal thermometers with pacifier thermometers when a rectal temperature is indicated. Rather, it is the researcher's recommendation to use the pacifier thermometer as a screening tool.

**Nursing Implications**

Pacifier thermometers are an acceptable tool for temperature screening in children 7 days to 24 months of age. Nurses must use the thermometer properly, as well as instruct parents in its appropriate use if it is to be used at home. Consistent use of one particular method is important for tracking trends in temperature management over time. The mathematical upward adjustment of 0.5°F must be included in the reporting of temperatures measured by pacifier thermometry.

sphincter no more than 1 inch (2.5 cm), and hold it there until the temperature registers (as little as 15 seconds with certain electronic models but longer with digital models).

A newer method of temperature measurement is with the pacifier thermometer. See Evidence-Based Practice 32.1.

**Take Note!**

Avoid the rectal route of temperature measurement in the immunosuppressed child as well as the child who has diarrhea, a bleeding disorder, or a history of rectal surgery (Asher & Northington, 2008).

**PULSE**

Assess the heart rate while the child is resting or sleeping. The heart rate in infants is much faster than in adults. It also varies in infants and children who are anxious, fearful, or crying. As the child grows, the heart rate slows and the range of normal values narrows. Table 32.3 lists heart rate ranges according to the child's age. The radial pulse is difficult to palpate accurately in children younger than 2 years of age because the blood vessels lie close to the skin surface and are easily obliterated (Bickley & Szilagyi, 2009). For children younger than 10 years of age, auscultate the apical pulse with the stethoscope for a full minute (Jarvis, 2012). In older children, palpate the radial pulse for a full minute (Fig. 32.5). Note any irregularities in strength or rhythm. Finally, document the method used to obtain pulse measurement as well as

any activity of the child during the assessment and any action taken.

**Take Note!**

In the infant and young child, the heart rate is often quite elevated due to fear or anxiety when the stethoscope is placed on the chest initially. For an accurate heart rate, wait several seconds until the rate slows, and then count for 1 full minute.

**RESPIRATORY RATE**

Assess respirations when the child is resting or sitting quietly, since respiratory rate often changes when

**FIGURE 32.5** Assessing the radial pulse of a young child.

**TABLE 32.3** HEART RATE AND RESPIRATORY RATE RANGES BY AGE GROUP

	Infant	Toddler	Preschooler	School-age	Adolescent
Heart rate	80–150	70–120	65–110	60–100	55–95
Respiratory rate	25–55	20–30	20–25	14–22	12–18

Adapted from Kliegman, R. M., Stanton, B. F., Schor, N. F., St. Geme, J. W. & Behrman, R. E. (2011). *Nelson textbook of pediatrics* (19th ed.). Philadelphia, PA: Saunders. and Chiocca, E. M. (2011). *Advanced pediatric assessment*. Philadelphia, PA: Lippincott Williams & Wilkins.

infants or young children cry, feed, or become more active. They also tend to breathe faster when they are anxious or scared. The most accurate respiratory rate is obtained before disturbing the infant or child (Bowden & Greenberg, 2008). This can often be done easily when the parent/caregiver is holding the child before any clothing is removed. Count the respiratory rate for a full minute to ensure accuracy. Infants' respirations are primarily diaphragmatic, so count the abdominal movements. After 1 year of age, count the thoracic movements. Table 32.3 lists ranges of respiratory rate according to the child's age. Document the rate, activity of the child, any deviations from normal, and any action taken.

### Take Note!

Infants normally display an uneven or irregular breathing pattern, with short pauses between some breaths. This may be accentuated when they are ill (Bickley & Szilagyi, 2009).

## MEASURING OXYGEN SATURATION

Since the incidence of respiratory dysfunction is high in ill children, pulse oximetry is often routinely included in the vital signs assessment. This method is reliable and noninvasive. Pulse oximetry determines the oxygen saturation (SaO<sub>2</sub>) in blood by using a sensor that measures the absorption of light waves as they pass through highly perfused areas of the body. The pulse rate on the oximeter should coincide with the apical pulse rate to ensure that the oxygen saturation reading is accurate. Nursing Procedure 32.2 details how to use the pulse oximeter. Identify whether pulse oximetry monitoring will be continuous or intermittent (as with vital signs).

A few guidelines to follow when using pulse oximetry are as follows:

- The probe may be placed on the finger, toe, ear, or foot. Avoid placing the probe on the same extremity with a blood pressure cuff or an intravenous or other type of line.

- Use the physician's orders or health care agency guidelines to set parameters for high and low pulse rate as well as high and low oxygen saturation. Never turn off the alarm settings.
- Ensure that the probe is not applied too tightly, as this will prevent venous flow and cause inaccurate readings.

Potential sources of errors in pulse oximeter readings include abnormal hemoglobin value, hypotension, hypothermia, ambient light interference, motion artifact, and skin breakdown. Falsely low readings may be associated with a nonsecure connection (movement of child's foot or hand), cold extremities/hypothermia, and hypovolemia. Falsely high readings may be associated with carbon monoxide poisoning and severe anemia (Fouzaz et al., 2011).

## BLOOD PRESSURE

The National Heart, Lung, and Blood Institute (NHLBI) recommends that children older than 3 years of age have their blood pressure measured at least once during every health care episode (U.S. Department of Health and Human Services, National Institutes of Health, National Heart, Lung, and Blood Institute, 2005). Children younger than 3 years old should have blood pressure measured if they have one of the following risk factors:

- History of prematurity, very low birthweight, or other neonatal intensive care complication
- Congenital heart disease
- Recurrent urinary tract infections, hematuria, proteinuria, known renal disease or urologic malformations, family history of congenital renal disease
- Malignancy, bone marrow transplant, or solid organ transplant
- Treatment with medications that raise blood pressure
- Systemic illnesses associated with hypertension such as neurofibromatosis and tuberous sclerosis
- Increased intracranial pressure (U.S. Department of Health and Human Services, National Institutes of Health, National Heart, Lung, and Blood Institute, 2005)

In the hospital or outpatient setting when a child is ill or undergoing surgery or a procedure, the frequency

## NURSING PROCEDURE 32.2

## Pulse Oximetry Monitoring

1. Explain the procedure to the child and family (use a penlight to show how the sensor “looks through the skin”).
2. Attach the probe to the child and connect to the monitor.
3. Set the parameters for the alarm if monitoring pulse oximetry continuously.
4. Observe and record pulse rate and oxygen saturation.
5. Record the activity level of the child and the percentage of oxygen in use.
6. Check skin condition and rotate sensor position every few hours.

## Types of probes

## a. Infant continuous

## b. Finger continuous

## c. Finger intermittent

Adapted from Nellcor Puritan Bennett, Inc. (2011). *Clinician's guide to Nellcor sensors*. Retrieved June 9, 2012, from [http://www.nellcor.com/\\_Catalog/PDF/Product/CliniciansSensorGuide.pdf](http://www.nellcor.com/_Catalog/PDF/Product/CliniciansSensorGuide.pdf)

of blood pressure measurement will depend on the child's physical status. Measurement of blood pressure can be frightening to a young child, so include an age-appropriate explanation and perform the procedure after obtaining the pulse rate and respirations (Fig. 32.6). Accuracy of blood pressure measurement depends on the cuff size, as well as the operator's skill and accurate calibration of an electronic device. The NHLBI recommends that the cuff bladder width be at least 40% of the circumference of the upper arm at its midpoint (U.S. Department of Health and Human Services, National Institutes of Health, National Heart, Lung, and Blood Institute, 2005). The cuff bladder length should cover 80% to 100% of the circumference of the upper arm. Various

pediatric and infant cuffs are available, as well as larger thigh cuffs that may be used on an arm in an obese adolescent.

**Take Note!**

Using an accurate cuff size is important: a wider cuff yields a lower reading and a narrower cuff yields a higher reading.

Measure blood pressure in the upper arm, lower arm, thigh, or calf/ankle. The size of the cuff should match the extremity used. The measurement should be taken in the same limb, at the same place, and in the

**FIGURE 32.6** Allowing children to handle the equipment gives them some control over the situation.

**FIGURE 32.8** Auscultation is the preferred method for measuring blood pressure in children.

same position with each subsequent measurement to ensure consistency in tracking the blood pressure. To measure blood pressure using the upper arm, place the limb at the level of the heart, place the cuff around the upper arm, and auscultate at the brachial artery. When obtaining blood pressure in the lower arm, again, position the limb at the level of the heart, place the cuff above the wrist, and auscultate the radial artery. For measurement in the thigh, place the cuff above the knee and auscultate the popliteal artery. To obtain blood pressure on the calf or ankle, place the cuff above the malleolus or at the midcalf and auscultate the posterior tibial or dorsal pedal artery. Figure 32.7 shows appropriate cuff placement and auscultation points for the various sites.

The NHLBI recommends auscultation as the preferred method of obtaining blood pressure readings in children (U.S. Department of Health and Human Services, National Institutes of Health, National Heart, Lung, and Blood Institute, 2005) (Fig. 32.8). Systolic pressure in children is read at the moment the first Korotkoff

sound is heard as the manometer pressure is lowered. The point at which the sound disappears is the diastolic pressure. The systolic blood pressure sometimes can be heard to a measurement of zero, so document the reading as systolic pressure over “P” for pulse.

Due to the small arm vessels in infants and young children, it may be very difficult to hear the Korotkoff sounds by auscultation (Jarvis, 2012). Alternative methods for obtaining blood pressure measurements in children include the use of Doppler or oscillometric (Dinamap) devices. The Doppler ultrasound method uses high-frequency sound waves that bounce off body parts to obtain blood pressure. Apply the gel to the Doppler end and listen with the Doppler device where Korotkoff sounds would normally be auscultated.

With either the Doppler method or auscultation, inflate the cuff 20 mm Hg past the point where the distal pulse disappears. Oscillometric equipment measures the mean arterial pulse and then calculates the systolic and diastolic readings. The accuracy of this method depends heavily on ongoing validation and calibration.

**FIGURE 32.7** Various positions of cuff placement and auscultation area for obtaining blood pressure. **(A)** Upper arm. **(B)** Lower arm. **(C)** Thigh. **(D)** Calf/ankle.

Also, the cuff inflates to a preset value often far higher than the infant or child's blood pressure, resulting in a tight, uncomfortable cuff being in place for a longer period of time.

### Take Note!

If the oscillometric device yields a blood pressure greater than the 90th percentile for gender and height, repeat the reading using auscultation.

In children older than 1 year, the systolic pressure in the thigh tends to be 10 to 40 mm Hg higher than in the arm; the diastolic pressure remains the same. Refer to Appendix H for the NHLBI blood pressure levels based on gender and height. Systolic blood pressure increases if the child is crying or anxious, so measure the blood pressure with the child quiet and relaxed. If the reading is lower in the leg than in the arm, always consider coarctation of the aorta or interference with circulation to the lower extremities. Also pay attention to the pulse pressure (the difference between the systolic and diastolic readings): unusually wide (more than 50 mm Hg) or narrow (less than 10 mm Hg) pulse pressure readings suggest a congenital heart defect (Burns et al., 2009).

## Pain Assessment

Pain is considered to be the “fifth vital sign” (Jarvis, 2012). Use the FLACC pain scale to measure pain in children who are too young to verbally or conceptually quantify their pain, or when there is a language barrier (Manworren & Hynan, 2003). The FLACC pain scale consists of a possible 10 points, with 0, 1, or 2 points given for each of five clinical signs (see Table 36.7 in Chapter 36).

Children who are older and can express that pain is worsening or improving should use the Pain Faces Scale (see Fig. 36.3 in Chapter 36). Explain that each face represents a person who is happy or sad, depending on how much or how little pain he has: 0 is for a person who is “very happy because he doesn't hurt at all”; 1 means “it hurts just a little bit”; 2, “it hurts a little more”; 3, “it hurts even more”; 4, “it hurts a whole lot”; and 5, “it hurts as much as you can imagine—but you don't have to be crying to feel this bad.” Then ask the child to point to the face that best describes the amount of pain being felt (Wong & Baker, 1988).

For additional information related to pain assessment, refer to Chapter 36.

## Body Measurements

Appropriate growth in children is usually an indicator of good health. A child who is not growing well may be

in poor health, have inappropriate or inadequate dietary intake, or have a chronic disease (Bickley & Szilagyi, 2009). Accurate assessment of growth is a critical skill for the pediatric nurse.

Determine the child's height or length, weight, and weight for length or body mass index (BMI). Measure the head circumference for healthy children younger than age 3. Plot these measurements on a graph so they can be compared with earlier measurements and those of the child's peers. Additional anthropometric measurements used in children may include the chest circumference, mid-upper arm circumference, and skinfold measurement at the triceps, abdomen, or subscapular regions, but these are not performed routinely and are usually used only when a nutritionist consultation is necessary.

The growth chart is a screening tool for nutritional problems as well as a useful screen for chronic illness. Record each measurement in ink with a small dot at the correct location for the child's age and the date of the measurement written above it. Then use a plastic straight-edge to connect the previous measurement to the most current one. Children grow at variable rates; in infancy and prepuberty, the growth velocity is normally more rapid. The growth chart allows the nurse to compare the child to other children of the same age and gender while allowing for normal genetic variation. When measurements fall close to the same percentiles over time, growth is normal for that child. Children whose measurements fall within the 5th and 95th percentiles are generally considered within the normal growth range (Chiocca, 2011).

Sudden or sustained changes in percentile may indicate a chronic disorder, emotional difficulty, or nutritional intake problem (Bickley & Szilagyi, 2009). These findings require further assessment of the physical status of the child as well as other types of evaluations such as dietary intake or serum laboratory measurements.

Appendix F provides growth charts for boys and girls, ages birth to 36 months and 2 to 20 years. The Centers for Disease Control and Prevention (CDC) (2002) recommends the use of these growth charts with all children, though special growth charts are also available for children with specific conditions. Look for a trend over time of healthy growth that is neither too fast nor too slow.

### Take Note!

The most valid and reliable growth charts are those supplied by epidemiologists at the Centers for Disease Control and Prevention.

## LENGTH OR HEIGHT

Calculate the length of the infant and toddler in a lying position until the age of 24 months. Use a measuring

**FIGURE 32.9** The recumbent measuring board is the most accurate method for obtaining a length measurement in infants and very young children.

board (Fig. 32.9) or a cloth or paper measuring tape. Stretch out the legs to get a full extension of the body. Marking the examination paper at the child's head and extended foot is an option. Make sure that the growth chart where the measurement is plotted is marked for length and not height, as the two measurements differ. Document the length in centimeters and inches.

Once the child can cooperate and stand independently, begin measuring the standing height. Using a stadiometer is best (Fig. 32.10), but a cloth or paper

**FIGURE 32.10** Standing height is most accurately measured with the stadiometer.

tape can be used. Ask the child to remove his or her shoes and check that the back, shoulders, buttocks, and heels are against the wall, with the pelvis tucked as much as possible to correct for lordosis. The chin should be parallel to the floor. Plot this measurement on a growth chart marked for height rather than length. Record the height in centimeters as well as feet and inches.

#### **Take Note!**

Cloth and paper measuring tapes may stretch over time. Periodically replace or recalibrate all measuring tools.

## WEIGHT

Measure weight on a scale that is calibrated between every measurement. Just before placing the child on the electronic scale, press the “zero” or “tare” button and make sure the reading is 0. Calibrate the balance-type scale by setting the weight at zero, observing the beam balance, and making adjustments as necessary. Infants and toddlers should be weighed on a platform-type electronic or balance scale, with an examination paper placed between the child and the scale surface. Calibrate the scale with the examination paper in place. Remove the infant's diaper immediately before placing him or her on the scale. Toddlers may sit on the scale with the nurse or caregiver nearby to avoid falls (Fig. 32.11). Weigh older children and adolescents on a standing scale (Fig. 32.12). They may keep their underpants on and wear a lightweight examination gown.

An alternate method for obtaining weight, though much less accurate, is to weigh the caregiver initially and then weigh the caregiver holding the child. The difference between the two weights is the child's weight. Regardless of the method used, weigh the infant to the nearest 10 g (or half-ounce) and the toddler and older child to the nearest 100 g (or quarter-pound). Record the weight in kilograms and in pounds.

## WEIGHT FOR LENGTH

For children between the ages of newborn and 36 months, plot weight on the growth chart in comparison to the child's length. This allows the nurse to determine whether the child is a healthy weight for how long he or she is. Children placing less than the 5th percentile on the weight-for-length chart are considered underweight. Those placing greater than the 95th percentile are considered to be overweight.

## BODY MASS INDEX (BMI)

With the recent increase in obesity in children, BMI is becoming an important measurement. **BMI** is a measure of body fat and is determined by comparing the

**FIGURE 32.11** A nurse or caregiver should remain nearby while weighing the infant or toddler.

**FIGURE 32.12** Children who can stand independently can be weighed on a regular standing balance scale.

### BOX 32.1

#### CALCULATION OF BODY MASS INDEX (BMI)

##### English Formula:

$$\frac{\text{weight in pounds}}{(\text{height in inches}) \times (\text{height in inches})} \times 703$$

##### Metric Formula:

$$\frac{\text{weight in kilograms}}{(\text{height in meters}) \times (\text{height in meters})} \times 10,000$$

child's height and weight (CDC, 2010). Calculate the BMI using the child's weight and height by either the English or metric method. Box 32.1 provides BMI calculation formulas. BMI is included on the charts for children ages 2 to 20 years. Plot the BMI on the growth chart according to the child's age. A child whose BMI for age plots at less than the 5th percentile is considered to be underweight. BMI between the 85th and 95th percentiles indicates risk for overweight. BMI greater than the 95th percentile indicates the child is overweight.

The growth chart can indicate when a child is not growing adequately and can also be used to predict the development of overweight and obesity (CDC, 2010). Refer to Healthy People 2020.

#### HEALTHY PEOPLE 2020

##### Objective

Reduce the proportion of children and adolescents who are considered obese.

##### Nursing Significance

- Screen for overweight in all children by plotting weight for length of children younger than 36 months and body mass index for age for children age 2–20 years.
- Assess dietary intake and activity level in all children at risk for or overweight.
- Provide diet and activity recommendations to attain a healthy weight or BMI.
- Refer significantly overweight children to a pediatric endocrinologist.

*Healthy People* Objectives based on data from <http://www.healthypeople.gov>.

**FIGURE 32.13** Measure occipitofrontal head circumference at the largest point.

### HEAD CIRCUMFERENCE

Measure head circumference at well-child visits and upon hospital admission until the third birthday. Then measure it at the annual well-child visit until 6 years old if there are problems such as microcephaly or macrocephaly present at age 3. Measure the largest point across the skull, not including the ears, with a nonstretching cloth or paper tape. Begin at the forehead just above the eyebrows and bring the tape around the head in a taut circle just above the occipital prominence at the back of the head (Fig. 32.13). Plot this measurement in relation to the child's age on the appropriate standardized growth chart (usual growth charts include head circumference only up to age 3 years).

### Monitoring Equipment

Sometimes children in acute care settings require continuous monitoring of vital signs. This monitoring could be via an apnea monitor or a cardiopulmonary monitor. The apnea monitor measures abnormal or irregular breathing in infants. The cardiopulmonary monitor generally measures heart rate and respiratory rate. Additional equipment on this monitor also allows for blood pressure and temperature monitoring. Set high and low alarm limits according to the health care facility's policies. Figure 32.14 indicates the placement of electrodes for the apnea and cardiopulmonary monitors. Assess the skin where the electrodes are placed to ensure there is no skin breakdown. If the alarm sounds, immediately check the child to ensure the leads are not disconnected or the child is not in distress.

### Skin

The skin is the body's largest organ and reveals information about a child's nutrition, respiratory, cardiac,

**FIGURE 32.14** Placement of cardiac apnea monitor leads: white on the right upper chest, black on the left upper chest, green or red on the abdomen (not over bone).

endocrine, and hydration status at a glance. A careful skin examination provides an invaluable understanding of a child's health (Jarvis, 2012).

### INSPECTION

Inspect the color of the skin. The color should be appropriate to the child's racial or ethnic background, with the nail beds, conjunctivae, soles of the feet, and palms of the hands appearing pink. Normal variations include the following:

- Blueness of the hands and feet, known as **acrocyanosis**, is normal in babies up to several days of age and results from an immature circulatory system completing the switch from fetal to extrauterine life (see Fig. 25.3A in Chapter 25).
- Cooling or warming the newborn and young infant may produce a vasomotor response that causes a mottling of the skin over the trunk and extremities (see Fig. 25.3B).
- Babies of darkly pigmented Native American, African, and Asian parents will be paler than their parents for many months until the melanocytes in the epidermis begin production.
- Dark-skinned infants commonly have hyperpigmented areolas, genitals, and linea nigra.

Other variations related to skin color are discussed in Box 32.2.

Inspect the skin for the presence of **lanugo**. All infants display some degree of lanugo (soft, downy hair on the body, particularly the face and back). Lanugo is more abundant in infants of Hispanic descent and in premature infants and recedes over the first few weeks of life.

Inspect the entire body for nevi and vascular and other lesions. Note their location, size, distribution, characteristics, and color. Pigmented nevi (also termed birthmarks) are indicated by a darker patch of skin and generally do not fade over time. Note the presence of hyperpigmented nevi (formerly called Mongolian spots), which appear as blue or gray, variably and irregularly shaped macules (Fig. 32.15). These are a common finding

## BOX 32.2

**VARIATIONS IN SKIN COLOR AND THEIR CAUSES**

- **Pallor** (defined as decreased pinkness in light-skinned patients, ashy-gray in dark-skinned) is caused by anemia, shock, fever, or syncope.
- **Peripheral cyanosis** (blue discoloration) occurs in nails, soles, and palms and may be caused by anxiety or cold; also associated with central cyanosis.
- **Central cyanosis** (blueness of the lips, tongue, oral mucosa, trunk) is caused by hypoxia or circulatory collapse.
- Overall yellow color (**jaundice**) may be physiologic in the newborn or related to liver or hematopoietic disease in any age child.
- **Yellowing** of nose, palms, and soles may result from excess intake of yellow vegetables.
- **Redness** of the skin results from blushing, exposure to cold, hyperthermia, inflammation (localized), or alcohol ingestion.
- **Lack of color** in skin, hair, and eyes is related to albinism.

Adapted from Bickley, L., & Szilagyi, P. G. (2009). *Bates' guide to physical examination and history taking* (10th ed.). Philadelphia: Lippincott Williams & Wilkins; and Jarvis, C. (2012). *Physical examination and health assessment* (6th ed.). St. Louis: Saunders.

in dark-skinned infants. These nevi fade over months to years as the child's skin pigment darkens. Do not mistake hyperpigmented nevi for bruises. Inspect the skin for vascular lesions. Table 32.4 describes vascular lesions and their significance.

Rashes are common in children and are often associated with communicable diseases. Describe the rash

**FIGURE 32.15** Transient hyperpigmentation most often occurs in darker-skinned infants.

**FIGURE 32.16** Adolescent with multiple piercings.

in detail, noting types of lesions, distribution, drying, scabbing, scaling, and any drainage. The newborn and young infant may display milia (small white papules) on the forehead, chin, nose, and cheeks. These recede spontaneously. In adolescents the skin examination may reveal open or closed comedones (pimples or blackheads) across the face, chest, and back. Teens may sport tattoos, brandings, or various body piercings; inspect these areas for signs of infection such as erythema or drainage (Fig. 32.16).

Document the presence of any lacerations, abrasions, or burns. Note the distribution of the injury and whether it seems consistent with the mechanism described in the health history. Be alert to the possibility of child abuse if the type or number of burns, lacerations, or bruises seems unusual for the situation.

**Take Note!**

Petechiae or ecchymosis may be found over areas traumatized by the birth process; these may take a few weeks to resolve. Certain cultures use “cupping” or “coining” when a child is ill, and these practices may yield bruises or mild burns (International Cupping Therapy Association, 2010).

**PALPATION**

Palpate the skin for temperature, moisture, texture, turgor, and edema. Use the back of your hand to assess the skin's temperature, comparing the right side of the body to the left and the upper body to the lower. The skin should feel uniformly warm. Cool extremities are associated with environmentally cool temperatures as well as impending circulatory collapse and shock. Warm skin may be associated with fever or sunburn, or locally a burn or infectious process. The skin should feel fairly dry, occasionally moister in the creases. Dry, flaking skin may occur in the young

**TABLE 32.4** VASCULAR LESIONS AND THEIR SIGNIFICANCE

Description	Significance
Salmon nevi: light pink macule usually on eyelids, nasal bridge, back of neck (“stork bite”)	Usually fade over time, but may never go away completely. No complications.
Strawberry nevus: raised reddish papule made of blood vessels (hemangiomas)	Present at or develop after birth; recede over time, usually by age 9 years. Usually no complications.
Nevus flammeus: dark purple-red flat patch, grows with the child (“port-wine stain”)	May be associated with Sturge-Weber syndrome. May be disfiguring; may be removed with laser therapy.
Ecchymosis: purplish discoloration, changing to blue, brown, black (bruise)	Common on lower extremities in young children. Should correlate with the injury.
Petechiae: pinpoint reddish purple macules that do not blanch when pressed	Broken tiny blood vessels; occur with coughing, bleeding disorders, meningococemia
Purpura: larger purple macules that do not blanch when pressed	Bleeding under the skin; occur with bleeding disorders, meningococemia

Adapted from Bickley, L., & Szilagy, P. G. (2009). *Bates' guide to physical examination and history taking* (10th ed.). Philadelphia: Lippincott Williams & Wilkins; and Jarvis, C. (2012). *Physical examination and health assessment* (6th ed.). St. Louis: Saunders.

infant, particularly if born postmaturely. Overall skin dryness in the well-hydrated child may occur with excess sun exposure, poor nutrition, or overbathing. Moist skin occurs with perspiration, fever resolution, and shock. The infant's and young child's skin is very soft ordinarily. Older children should continue to have a smooth and even skin texture. The preadolescent and adolescent may have oily-feeling skin on the face, shoulders, or back.

Assess skin turgor by elevating the skin on the abdomen in the infant or on the back of the hand in the older child or teen. The “pinched-up” skin should quickly return to place. Skin that remains tented is strongly suggestive of moderate to severe dehydration. When edema is present, palpate the edematous area to determine its extent. Palpate any lumps or protrusions to determine firmness or tenderness. Palpate lesions or rashes with a gloved hand to document the size and extent of the lesions.

### Hair and Nails

Inspect the hair and scalp, noting distribution of hair as well as color, texture, amount, and quality. The young infant's hair may be absent entirely or quite thick; it will be replaced by hair that is of a texture and color closer to what the child will have throughout childhood. Coarse, dry hair at any age may indicate a thyroid disorder or nutritional deficiency. Inspect the scalp thoroughly; it should be free from lesions and infestations. Note the

presence of a greasy, scaly plaque on the scalp of infants; termed seborrheic dermatitis or cradle cap, it is benign and easily treated.

Inspect the nails for color, shape, and condition. Full-term infants may have long, papery fingernails that can scratch their skin if not trimmed. Children should have healthy nails. Dry, brittle nails may indicate a nutritional deficiency. Inspect the skin around the nails to ensure that it is intact and without signs of infection. Many children (especially school-age children) have a nervous habit of nail biting or hangnail biting or pulling.

Inspect the school-age child's or adolescent's toenails to ensure they are trimmed in a horizontal fashion. Self-trimming of toenails either too low or in a curved fashion places the child at risk for the development of ingrown nails. Clubbing of the nails indicates chronic hypoxemia related to respiratory or cardiac disease. Nails that curve inward or outward may be hereditary or linked with injury, infection, or iron-deficiency anemia.

### Head

Examining the head is critical in the newborn and infant periods but should not be overlooked in older children as an opportunity to check for diseases of the scalp and functional and developmental problems that are reflected in poor hygiene of the head and scalp. Note hair distribution and any bald or thinning areas.

Use of gloves may be indicated, depending on the overall scalp cleanliness and chance of infestation by head lice (seen as small grayish specks near the base of hair shafts).

### INSPECTION

Examine the head and face for shape and symmetry. In newborns, the head may be temporarily misshapen from uterine positioning or a lengthy vaginal delivery. Some infants have a slight flattening of the back of the head since the recommended sleeping position is supine. Note any irregularities or asymmetry. Observe the infant's head shape by looking down on it from above. Observe whether the head appears centered on the neck or tilts to one side. After 4 months of age, the infant should have achieved enough head control to hold the head erect and in midline when placed in a vertical position. Pull the infant from the supine position into sitting to determine the extent of head lag. To determine the extent of head control in older infants and children, ask the child to turn the head in different directions, either by simple commands or by following a colorful object.

Observe the infant's face when crying, smiling, or babbling for symmetry of muscle movement. In children who are old enough to follow directions, a game of "Simon Says" is a playful way to determine facial symmetry and strength; ask them to puff out their cheeks, make kisses, look surprised, stick out their tongue, and so on (effectively testing function of cranial nerve VII [facial]) (Bickley & Szilagy, 2009).

#### Take Note!

When you note a flattened occiput in an infant, encourage the parent or caregiver to allow the infant "tummy time" while awake and observed and to change the infant's head position frequently when upright in an infant seat (Platt, 2011).

### PALPATION

Gently palpate the anterior and posterior **fontanels** (Fig. 32.17). The fontanels are the soft areas on the skull that remain open in infancy to allow for rapid brain growth in the first months of life. Note the size of the fontanels. The anterior fontanel is about the size of a quarter at birth and slowly gets smaller until it can no longer be felt when it is closed by the age of 9 to 18 months. The posterior fontanel is much smaller and may close any time between shortly after birth and approximately 2 months of age. The fontanels should not be depressed or taut and bulging, though it is not uncommon to see them pulsate or briefly bulge if the baby cries. In an acutely ill infant, assess the fontanels while obtaining the vital signs. Dehydration can

**FIGURE 32.17** Note location and size of the fontanels. The anterior fontanel is diamond shaped and closes between the ages of 9 and 18 months.

cause the fontanels to be sunken; increased intracranial pressure and overhydration can cause them to bulge. Palpate the skull for asymmetry, overriding or open sutures, and lumps or other deformities. Palpate the jaw joints as the child bites down to assess cranial nerve V (trigeminal). Use the fingertips to palpate for occipital, postauricular, preauricular, submental, and submandibular lymph nodes, noting their size, mobility, and consistency (Fig. 32.18).

#### Take Note!

Large fontanels may be associated with Down syndrome or congenital hypothyroidism. A fontanel that becomes larger over time rather than smaller may indicate the development of hydrocephalus, especially if accompanied by an accelerated increase in head circumference (Bickley & Szilagy, 2009).

**FIGURE 32.18** Location of lymph nodes.

## Neck

Inspect the neck for symmetry. The infant's neck is short, but by 4 years of age the child's neck should be similar in appearance to the adult's. Webbing or excessive neck skin folds may be associated with Turner syndrome, and lax neck skin may occur with Down syndrome. Assess the flexibility of the neck through a full range of motion. Take younger children through a passive range of motion. Older children will be able to look in all directions on command and stretch their chins to their chests themselves. Test cranial nerve XI (accessory) in the older child by having the child attempt to turn the head against resistance. Assessment of neck mobility is particularly important when infections of the central nervous system are suspected. Pain or resistance to range of motion may indicate meningeal irritation. Do not assess neck mobility in the trauma victim.

### Take Note!

The infant or child who has experienced trauma should have the cervical spine maintained completely immobile until a radiologist has determined that the spinal cord is not damaged.

Palpate the neck for masses and lymph nodes. Palpate the cervical and clavicular lymph nodes with the distal part of the fingers using gentle but firm pressure in a circular motion. Tilt the child's head upward slightly to allow better access. Assess the lymph nodes for swelling, mobility, temperature, and tenderness. In healthy infants and adolescents, the cervical lymph nodes are usually not palpable; in healthy children between 1 and 11 years, the cervical nodes are often found to be small, nontender, and mobile (see Fig. 32.18 for locations of lymph nodes). Enlarged cervical lymph nodes frequently occur in association with upper respiratory infections and otitis media. Report significant enlargement to the physician or nurse practitioner. Palpate the trachea; the thyroid is usually palpable only in older children.

## Eyes

Assessment of the eyes includes evaluation of the external and internal structures as well as screening for visual acuity. Any nurse caring for a child should be adept at examining the external structures. Assessment of the internal structures will also be covered below but is usually performed only by the advanced practitioner. Refer to Chapter 31 for information on vision screening. Determination of visual acuity tests the function of cranial nerve II (optic).

### EXTERNAL STRUCTURES

Observe the eyes for symmetry and spacing, even distribution of eyelashes and eyelids, and presence of

epicanthal folds. Note the child's ability to blink, and report an inability to do so. The eyes should look symmetric and both should be facing forward in the midline when the child is looking directly ahead. The iris should be perfectly round and the sclerae should be clear. The cornea should be uniformly transparent. Inspect the corners of the eye (medial and lateral canthus) and the conjunctiva (lining of the eyelids). They should be free of discharge, inflammation, or swelling. Epicanthal folds may be present in children of Asian descent, children with genetic abnormalities, or those with fetal alcohol spectrum disorder. Using a small penlight or ophthalmoscope, inspect the function and clarity of the pupil by putting your nondominant hand on the child's forehead and moving the light toward and away from each eye. This will elicit the blink reflex. Next observe whether the pupil contracts with the light and expands when the light is removed. Make the same motion with a small toy or object and direct the child to look at it. The eyes demonstrate **accommodation**, or focusing at different distances, if the pupil constricts as the object moves closer. If normal findings are present, report **PERRLA** (pupils are equal, round, reactive to light and accommodation) (Fig. 32.19). This is a particularly important assessment in head and eye injuries, as well as when other neurologic concerns are present. Absence of pupillary reflexive action after age 3 weeks may indicate blindness (Jarvis, 2012).

### Take Note!

The normal infant may exhibit intermittent strabismus (crossing of the eyes) until about 3 months of age. However, persistent strabismus at any age or intermittent strabismus after 6 months of age should be evaluated by a pediatric ophthalmologist (Burns et al., 2009).

**FIGURE 32.19** The pupils should be equal, round, and reactive to light and accommodation (PERRLA).

**FIGURE 32.20** Note reflected light falling symmetrically on each pupil with the Hirschberg test.

Check extraocular muscle motility and function of cranial nerves III and IV (oculomotor and abducens) by instructing the child to follow the light through the six cardinal positions of gaze. Infants and very young children will follow an interesting object. Instruct the older child to look downward and inward (testing cranial nerve IV [trochlear]). Assess eye muscle strength using two tests. Using the Hirschberg test, bring the penlight to the middle of your face and direct the child to look at it. The small dot of reflected light seen in the iris should be placed symmetrically in each eye (Fig. 32.20). The cover test also assesses eye muscle strength. Cover one of the child's eyes and instruct the child to focus on an interesting object. The eye should not waver. While the child is still focusing with the first eye, remove the cover from the second. Observe the uncovered eye for movement. Report any movement or drift.

To test peripheral vision, have the child focus on a specific point or object directly in front. Bring a finger or a small object from beyond the range of vision into the area of the peripheral vision. When the child sees the object from the side, while still focusing on the object or point in front, the child should say "stop." This also tests cranial nerve II (optic).

### INTERNAL STRUCTURES

An advanced practitioner with experience in this type of assessment best accomplishes assessment of the internal structures of the eye. An adequate assessment requires that the child cooperate. Restraint for eye examination does not usually prove fruitful, as movement and tearing of the eyes interfere with the accuracy of the examination. Use the ophthalmoscope to inspect the internal eye structures. Observe the glow of the pupil, which appears red (creamy colored in children with very dark eye color). Inspect the optic disc, macula, fovea, and blood vessels. Refer any child with blurring or bulging of the optic disc or hemorrhage of vessels to a pediatric ophthalmologist for further evaluation.

#### Take Note!

Immediately report absence of the red reflex in one or both eyes, as this may indicate the presence of cataracts (Bickley & Szilagyi, 2009).

## Ears

Assessment of the ears includes evaluation of the external and internal structures as well as screening for hearing. Any nurse caring for a child should be adept at examining the external structures. Assessment of the internal structures will also be covered below but is usually performed only by the advanced practitioner. Refer to Chapter 31 for information on hearing screening. Testing of hearing also tests the function of cranial nerve VIII (acoustic).

### EXTERNAL STRUCTURES

Assess the placement of the external ears on the head. They should be symmetric and placed no lower than the eyes. The pinna should deviate no more than 10 degrees from an imaginary line that is perpendicular to a line drawn between the outer canthus of the eye and the top of the ear. Low-set ears may be associated with genetic abnormalities or syndromes (Fig. 32.21). Note protrusion or flattening of the ears, which may be normal for that child or may indicate inflammation (protrusion) or persistent side-lying (flattening). Note the presence of pits or skin tags in the preauricular area.

**FIGURE 32.21** Low-set ears may be associated with chromosomal or other genetic anomalies.

Observe the exterior ear canal. A waxy cerumen that is soft and an orangish-brown color is normally found lubricating and protecting the external ear canal and should be left in place or washed gently away when bathing. Note drainage from the ear canal, which is always considered abnormal. Pull on the auricle and palpate the mastoid process, neither of which should result in pain in the healthy child.

### Take Note!

Impacted and dry cerumen can be softened with a few drops of mineral or cooking oil and then gently irrigated from the canal with an ear syringe and warm water (Nettina, 2010).

## INTERNAL STRUCTURES

Use a **tympanometer** to assess the mobility of the eardrum (tympanic membrane). Gently pull down on the earlobe of infants and toddlers and up on the outer edge of the pinna in older children to straighten the ear canal, and press the tip of the tympanometer over the external canal. A reading of air pressure is recorded by the instrument, and this is useful to assess middle ear disease. Many tympanometers record a wave pattern that may be printed to include in the child's chart.

A nurse practitioner or physician generally performs inspection of the ear canal and tympanic membrane with an otoscope (Fig. 32.22). The otoscopic examination is usually performed near the end of the physical assessment for infants and young children, as they are often quite resistant to this intrusive procedure. The infant or toddler may require restraint in the parent's lap for the otoscopic evaluation. The preschooler may cooperate if the nurse uses a game

**FIGURE 32.22** Otoscopic examination allows visualization of the internal structures of the ear.

such as looking for pretend puppies or potatoes in the child's ear. As with the tympanometer, gently pull down on the earlobe of the infant or toddler and up on the outer edge of the pinna in older children to straighten the ear canal. Use an otoscopic speculum appropriate to the size of the child's ear canal. Insert the speculum into the ear canal to visualize the canal and the tympanic membrane. The canal should be pink, should have tiny hairs, and should be free from scratches, drainage, foreign bodies, and edema. The tympanic membrane should appear pearly pink or gray and should be translucent, allowing visualization of the bony landmarks. It may be red if the child has been crying recently. Compress the pneumatic insufflator bulb to provide a puff of air; this causes motion of the tympanic membrane when the middle ear is healthy. Note abnormalities such as a fluid level, bubble or pus behind the tympanic membrane, tympanic membrane immobility, holes or perforations in the tympanic membrane, and the presence of tympanostomy tubes, scarring, or vesicles.

### Take Note!

Never attempt to flush a foreign object out with water until it has been identified, because small pieces of sponge, clay, or vegetative material like peas or beans swell with water, further obstructing the ear canal (Nettina, 2010).

## Nose and Sinuses

The nose, as with all facial features in a child, should be symmetric, but it can be displaced temporarily by birth trauma in newborns. Children of Asian or African descent often display a flattened nasal bridge as a normal variation. Ensure that the nares provide unobstructed airflow by alternately occluding one nostril at a time and observing for air movement through the other nostril. If the child is breathing comfortably, there should be little nostril movement visible. Adolescents may have pierced their nose or nasal septum; ensure that the site is free from infection or loose jewelry that could migrate into the sinuses. Ideally the nose should not be draining, though clear mucus may be present if the child has been crying. Assess the amount, color, thickness, and presence of any odor if drainage is present. Inspect the interior of the nose by tilting the child's head backward and pushing the tip of the nose upward. Direct the beam of a penlight in the nostril. The nasal mucosa should be uniformly firm, pink, and free from edema, excoriation, or masses. Test the older child's sense of smell by having the child close the eyes and identify a familiar scent such as peppermint or coffee (cranial nerve I [olfactory]). Palpate the sinuses for tenderness.

### Take Note!

Infants up to 3 to 6 months of age have traditionally been thought to be **obligate nose breathers** because of their long soft palate and relatively large tongue, which allows for swallowing without aspiration during breast or artificial nipple feeding. This lessens with age and as the infant becomes better able to breathe through the mouth when necessary (Bickley & Szilagyi, 2009).

## Mouth and Throat

Wear a powder-free glove to examine the mouth, teeth, and throat. Inspection of the exterior of the mouth may be done at any point in the examination. Infants and young children may find assessment of the mouth and particularly the pharynx and uvula to be quite intrusive, so delay that part of the assessment until the end of the examination, after otoscopic evaluation. Assess the character and quality of the child's voice and the infant's cry. It should be neither too hoarse nor too shrill.

### INSPECTION OF THE MOUTH

Observe the lips for color, symmetry, and absence of inflammation or edema. Salivation in infants begins at about 3 months of age; drooling occurs because the infant does not learn to swallow saliva until several months later. Next, inspect the interior of the mouth. The mouth is the first part of the digestive system, and a pink, moist, healthy mucosal lining is indicative of a healthy gastrointestinal tract. In infants, the tongue should lie within the mouth at rest and should be capable of extending over the lower gum line to help the baby feed. The tongue extrusion reflex is normal in infants up until the age of 6 months and allows the infant to suckle easily from birth. Observe movement of the tongue when the infant or young child babbles or cries. Ask the older child to touch the tongue to the roof of the mouth and then stick out the tongue and move it from side to side (testing cranial nerve XII [hypoglossal]). Full movement should be present and the tongue should be free from lesions or exudate. Visualize the hard and soft palate (which should be intact) or palpate with the gloved finger.

Most infants have no teeth before the fifth to sixth month. When the teeth begin to erupt, they usually erupt symmetrically at the rate of about one a month, until toddlers have 20 teeth by 30 months of age. The infant may drool for several months before teething. During teething the gums will be swollen at the location of the impending tooth. In older children, the secondary teeth replace the primary teeth much more slowly and with little discomfort from the 5th to the 20th year. Figure 32.23 shows the usual permanent tooth eruption pattern.

Look for dental caries or alignment problems and inspect the gums for signs of infection. Test cranial nerve

IX (glossopharyngeal) by having the child identify taste with the posterior portion of the tongue.

### Take Note!

Natal (present at birth) or neonatal (erupting by 30 days of age) teeth should be evaluated by a pediatric dentist for potential extraction, as they may pose an aspiration risk (Bickley & Szilagyi, 2009).

### INSPECTION OF THE THROAT

Inspect the tonsils, uvula, and oropharynx. Assess the infant's throat during a yawn or cry, as any forcible attempt to depress the tongue with a tongue depressor produces a strong reflex elevation of the base of the tongue that completely blocks the view of the pharynx. The young child will require restraint so that the nurse can depress the tongue and visualize the back of the mouth without injuring the child (Fig. 32.24). Asking the older child to open wide, stick out the tongue, and say "aaaah" simultaneously will allow for a quick look at the tonsils and pharynx without the need to use a tongue depressor, but the nurse must be very quick because the tongue rises rapidly after those maneuvers are performed.

Tonsils usually cannot be seen in the infant. As the child becomes a toddler, the tonsils become dramatically larger and then begin to decrease in size again by the ninth year. The tonsils should be pink and often have crypts on their surfaces, which are sometimes filled with debris. Ensure that the uvula is midline and rises if the gag reflex is elicited (cranial nerve X [vagus]). Inspect the oropharynx, which should be pink and free from exudate.

## Thorax and Lungs

Assessment of the thorax and lungs begins by observing the shape and contour of the thorax and determining work of breathing. Accurate auscultation of the lungs is essential, since children often have respiratory infections and disorders and may exhibit alterations in respiratory effort and breath sounds. Note the child's color, which should be pink; cyanosis indicates hypoxia. Listen for audible stridor (inspiratory high-pitched sound), expiratory grunting or snoring, audible wheezing (heard with the naked ear), or cough. Document type and extent of cough. Observe the nail beds for clubbing, which occurs with diseases inducing chronic hypoxic states.

### THORAX

Examine the chest with the head in a midline position to determine size and shape as well as symmetry, movement, and bony landmarks. The newborn's chest should be smooth and round, with the transverse diameter nearly equal to the anterior-posterior diameter. The shape of the chest progresses to that of the adult by age 5 to 6 years.

FIGURE 32.23 Usual sequence of permanent tooth eruption.

At that time the anterior-posterior diameter is about half the transverse diameter (Fig. 32.25). At the point where the xiphoid process and the right and left costal margins meet, the costal angle should measure 90 degrees or less. Inspect for structural deformity such as pectus excavatum (depressed sternum) or pectus carinatum (protuberant sternum) (Fig. 32.26). Note symmetric movement of the chest wall with respiration. Infants and younger

children are primarily diaphragmatic breathers, so the abdomen and chest will rise and fall together. Older children, particularly adolescent females, demonstrate thoracic breathing, yet the abdomen and chest should continue to rise and fall together. Asymmetry of chest wall movement is an abnormal finding.

Observe the depth and regularity of respirations, noting the length of the inspiratory and expiratory phases in relation to each other. The newborn and young infant demonstrate an irregular respiratory pattern. Older infants and children should have a more regular respiratory pattern.

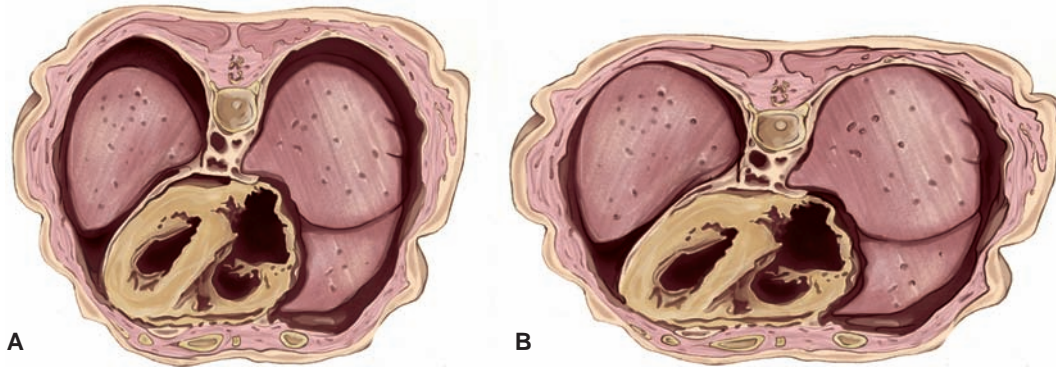

Assess the child's respiratory effort by first observing for nasal flaring, which indicates labored breathing. Observe the chest wall and shoulders for accessory muscle use, which normally is not present. If retractions are present, note their location and severity. Typical locations for retraction include the intercostal, subcostal, substernal, suprasternal, and clavicular regions (Fig. 32.27). Pay attention to the position the child naturally assumes to breathe comfortably; children in respiratory distress often sit forward and are uncomfortable lying down or talking (Jarvis, 2012).

**LUNGS**

Experienced examiners may palpate and percuss the lungs before using auscultation to evaluate the breath sounds.

FIGURE 32.24 The young child may need to be restrained so that the throat examination can be done safely.

**FIGURE 32.25** (A) The newborn's chest is round. (B) The adult chest has an anterior-posterior diameter about half the transverse diameter.

**PALPATION AND PERCUSSION.** Palpate for symmetric respiratory excursion by placing the thumbs and fingers together along the costal margin on the chest or back. Movement should be symmetric with each breath. Palpate for the normal presence of tactile fremitus with the palms or fingertips while the infant is crying or the older child says "99." Indirectly percuss the lungs of older children, noting resonance over lung fields. Hyperresonance may be present in conditions resulting in hyperaeration of the lungs, such as asthma.

**AUSCULTATION.** Use the bell of the stethoscope or switch to a small diaphragm to auscultate lung sounds in the infant or child. The adult-sized diaphragm may be used for the adolescent. Auscultate the lung fields with the infant or child in a sitting position, even if that requires propping the infant in a parent's lap. Infants and young children have loud breath sounds because of their thin chest walls. Breath sounds should be clear with adequate aeration throughout all lung fields. Listen to a full inspiration and expiration at the apices of the

lungs as well as symmetrically across the entire lung field, systematically comparing the right to the left side. Listen on the anterior chest, on the posterior chest, and in the axillary regions.

Playing games may encourage younger children to cooperate with deep breathing during lung assessment. The child can blow a cotton ball up in the air, blow a pinwheel, or "blow out" the light of the penlight (Miller, 2011). Older children are capable of deep breathing when instructed to do so.

The child who has a respiratory disorder or who is experiencing respiratory distress may exhibit diminished breath sounds, most often in the lung bases. Diminished breath sounds are softer and quieter than lung sounds demonstrating adequate aeration. In the healthy infant or child, no adventitious sounds should be heard. If noisy breath sounds are heard in the infant or young child, particularly over all lung fields, compare the sound to the noises heard over the trachea or within the nose. Infants and young children with secretions in the nasopharyngeal area may have those sounds

**FIGURE 32.26** Pectus excavatum: note depression in xiphoid area.

**FIGURE 32.27** Location of retractions.

transmitted over the lung fields. These sounds usually clear with coughing or airway suctioning; they are not true adventitious sounds. Note adventitious breath sounds such as wheezes or crackles, documenting their location and whether they are present on inspiration, expiration, or both. It is most important to describe the abnormal breath sounds being heard rather than attempting to classify the sounds. Adventitious lung sounds are associated with a variety of disorders, and extensive experience is required to appropriately classify lung sounds. Adventitious breath sounds should be reported for further evaluation.

## Breasts

Assess the breasts of children of all ages and both genders. Note the size of the breasts in relation to the age of the child. Palpate the axillary lymph nodes during the breast assessment.

### INSPECTION

Observe the breasts for position, shape, size, symmetry, and color. Newborns of both genders may have swollen nipples from the influence of maternal estrogen, but by several weeks of age the nipples should be flat and should continue to be so in all prepubertal children. In children the nipples are located lateral to the midclavicular line, usually between the fourth and fifth rib. The areola becomes darker in color as the child approaches puberty. Overweight children may appear to have enlarged breasts due to adipose tissue. Note the location of additional (supernumerary) nipples if present (usually located along the mammary ridge); they may appear as darkly pigmented, elevated or nipple-like spots. These are usually of no concern as they do not change over time, but they may be associated with renal disorders.

Inspect the breasts for the current stage of development: widening of the areola, elevation of the nipple, and increase in breast size. Female breast development may begin as early as age 8, but starts by age 13 in most girls. Breast development then continues in a characteristic, but usually asymmetric, pattern, with one breast larger than the other throughout the lifespan. The sexual maturity rating scale developed by Tanner in 1962 is used to describe breast development (**Tanner stages**; Fig. 32.28). Adolescent boys may develop gynecomastia (enlargement of the breast tissue) due to hormonal pubertal changes. When the hormone levels stabilize, male adolescents then have flat nipples. Occasionally gynecomastia is caused by marijuana use, anabolic steroids, or hormonal dysfunction (Jarvis, 2012).

### PALPATION

Palpate the breasts in a systematic fashion. A tender nodule palpated just under the nipple confirms pubertal

changes. This change may be difficult to assess in girls with excessive adipose tissue. Normal breast tissue should feel smooth, firm, and elastic. Note masses or nodules if present. Palpate for axillary lymph nodes with the child's arms relaxed at the side but slightly abducted. Note size and texture of nodes if present.

## Heart and Peripheral Perfusion

The examination of the heart in children is identical to that of adults except for the focus of the examiner's attention. Congenital heart defects are the most common cause of heart problems in children, and children with these defects present differently than adults with heart disease.

### Take Note!

The younger the child, the more responsive the heart rate is to activity changes. It increases with fever, fear, crying, or anxiety and decreases with sleep, sedation, or vagal stimulation (Jarvis, 2012).

### INSPECTION

Observe the child's posture. Note the presence of pallor, cyanosis, mottling, or edema, which may indicate a cardiovascular problem. Inspect the anterior chest from the side or at an angle, noting symmetry in shape as well as movement. Observe for the apical impulse, which is visible in about half of children. It occurs at the **point of maximum intensity (PMI)**, which is located at the third to fourth intercostal space just medial of the child's left midclavicular line until age 4 years, at the fourth intercostal space at the left midclavicular line in children ages 4 to 6 years, and then lateral to the left midclavicular line at the fifth intercostal space in children ages 7 years and older (Fig. 32.29). Note clubbing of the fingertips or distention of neck veins, both of which may be associated with congenital heart disease.

### PALPATION

Using the fingertips, palpate the chest for lifts and heaves or thrills, which are not normal. Palpate the apical pulse in the area of the PMI (see Fig. 32.29). Check the pulses and compare the upper body to lower body pulses, as well as left versus right, noting strength and quality (Fig. 32.30). The pedal, brachial, and femoral pulses are usually easily palpated. The radial pulse is very difficult to palpate in children younger than 2 years of age. Note warmth of the distal extremities. To assess capillary refill time, place slight pressure on the nail beds and quickly release it. Observe the length of time required for refill and return to original color. Compare capillary refill time of the fingers to the toes. A capillary

FIGURE 32.28 Tanner sexual maturity rating for breast development. (Adapted from Tanner, J. M. [1962]. *Growth at adolescence*. Oxford, England: Blackwell Scientific Publications.)

FIGURE 32.29 The point of maximal intensity (PMI) or apical impulse.

FIGURE 32.30 It is important to assess brachial and femoral pulses simultaneously to determine equality or differences in strength and intensity.

**FIGURE 32.31** Auscultating the child's heart.

refill time of less than 3 seconds indicates adequacy of perfusion.

### AUSCULTATION

Perform auscultation of the heart with the child in two different positions, upright and reclined (Fig. 32.31). Auscultate the heart rate in the area of the PMI as this is the point on the chest wall where the heartbeat is heard most distinctly (see Fig. 32.29). As you begin auscultation, listen first for respirations and note their timing so as not to confuse the heart sounds with the lung sounds. A crying infant may help by briefly holding his or her breath between cries. Once you are confident that you are listening to the heart, be sure to listen for 1 full minute because of the irregularity of rhythms in some children. Count the heart rate, which should be consistent with the palpated pulse (either radial or brachial, depending on the child's age).

Develop a systematic approach to auscultation of the heart. Listen over all four valvular areas anteriorly (Fig. 32.32). In the infant or younger child, also auscultate the heart in the axillary region and posteriorly (certain murmurs radiate to these areas). Note  $S_1$ ,  $S_2$ , extra heart sounds, or murmurs.  $S_1$  is usually loudest at the mitral and tricuspid areas and increases in intensity with fever, exercise, and anemia.  $S_2$  is usually most intense at the aortic and pulmonic areas. A split  $S_2$  heard at the apex occurs in many infants and young children.  $S_3$  may be heard in many healthy children and is considered normal, though the child with a chronic cardiac condition may develop an  $S_3$  when congestive heart failure is present.  $S_4$  is usually considered abnormal, most often occurring with cardiac disease.

Sinus arrhythmia is a common and normal finding in children and adolescents. It results in an irregular heart rhythm: the heart rate increases with inhalation and decreases with exhalation. If the child holds his or her breath, the rhythm becomes regular.

**FIGURE 32.32** Areas where the sounds of heart valves radiate. A: Aortic valve—second intercostal space, just right of sternum. P: Pulmonic valve—second intercostal space, just left of sternum. T: Tricuspid valve—fourth intercostal space, just left of sternum. M: Mitral valve—fourth intercostal space at left midclavicular line.

Auscultate for murmurs. Note the location (where it is heard best or loudest) and timing of the murmur. A systolic murmur occurs in association with  $S_1$  (closure of the atrioventricular valves), a diastolic murmur in association with  $S_2$  (closure of the semilunar valves). Also note the duration of murmur. Does it occur early or late in diastole or systole? Does it occur all the way across systole (holosystolic)? Note the intensity of the murmur. Table 32.5 discusses grading of murmur intensity.

Innocent murmurs occur frequently in children as a result of normal blood flow and are easily heard because of the thinner chest wall (Wierwille, 2011). An innocent murmur is most often heard at the second or fourth intercostal space, and its timing is systolic. The innocent murmur is usually medium pitched and musical. Often an innocent murmur disappears when the child changes position. A venous hum that is heard in the supraclavicular area and possibly radiating down the chest is considered an innocent murmur. Refer any child with a murmur to an experienced practitioner for further evaluation.

### Abdomen

The abdomen contains organs related to the genitourinary and lymphatic systems, in addition to the gastrointestinal system. These structures lie within the abdomen in approximately the same location as they do in adults. Dividing the abdomen into quadrants simplifies the description of normal organ location and the reporting of abnormalities. Draw an imaginary vertical line from the xiphoid process to the symphysis pubis. Cross this with an imaginary perpendicular line through the umbilicus.

**TABLE 32.5** GRADING HEART MURMURS IN CHILDREN

Grade	Sound
1	Barely audible; sometimes heard, sometimes not. Usually heard only with intense concentration
2	Quiet, soft; heard each time the chest is auscultated
3	Audible, intermediate intensity
4	Audible, with a palpable thrill
5	Loud, audible with edge of the stethoscope lifted off the chest
6	Very loud, audible with the stethoscope placed near but not touching the chest

Adapted from Wierwille, L. (2011). Pediatric heart murmurs: Evaluation and management in primary care. *The Nurse Practitioner*, 36(3), 22–29.

The sequence of physical examination is altered for the abdominal assessment: auscultation is done before percussion and palpation because manipulation of the lower abdomen may affect the bowel sounds (Bickley & Szilagyi, 2009).

### INSPECTION

Inspect the abdomen for size, shape, and symmetry. The abdomen in the infant and toddler is rounded and protuberant until the abdominal musculature becomes well developed. Though rounded, the abdomen should not be distended (at any age). By adolescence, the stature is more erect and the abdomen begins to appear flat when standing and concave when supine. The thin skin of a young child may allow the visualization of superficial venous circulation across the abdomen. Inspect the abdomen for movement. At eye level with the abdomen, note abdomen and thorax movement occurring simultaneously. Visible peristaltic waves are abnormal and should be reported immediately.

Inspect the newborn's umbilicus for color, bleeding, odor, and drainage. The umbilical stump should slowly dry, become black and hard, and fall away from the cutaneous navel by the end of the second week of life. Note drainage or granulation at the umbilical site indicating delayed drying of the umbilical stump. Inspect the umbilicus in older infants and young children for the presence of umbilical hernia. Because the umbilicus divides the rectus abdominis muscle, it is not uncommon to see an umbilical hernia protrude through and become larger when the infant or toddler strains or cries. This is a benign finding and will usually disappear as the abdomen becomes stronger. Adolescents may have jewelry piercing the umbilicus.

### AUSCULTATION

Auscultate the abdomen using the diaphragm or the bell of the stethoscope pressed firmly against the abdomen.

Count the bowel sounds in each of the four quadrants for a full minute. Bowel sounds should be present by a few hours after birth and should remain active throughout life. Note whether bowel sounds are normally active, hyperactive, hypoactive, or absent. Normal bowel sounds can be described as growls, gurgles, and clicking sounds. Hypoactive bowel sounds may occur postoperatively. Hyperactive bowel sounds are common with diarrhea. Classify bowel sounds as absent after listening for 5 full minutes in each area. Absent bowel sounds may indicate ileus or peritonitis.

### PERCUSSION

Indirectly percuss all areas of the abdomen. Normal findings include dullness along the costal margins and tympany over the remainder of the abdomen. A full bladder may yield dullness to percussion.

### PALPATION

Palpate the abdomen with the child in a supine position. If the child's legs are small enough, the knees may be brought up with the nondominant hand to flex the hips and relax the abdomen. Palpate all four quadrants of the abdomen in a systematic fashion, first lightly and then deeply. Apply light pressure with the fingertips to perform light palpation, assessing for tenderness and muscle tone (Fig. 32.33). Note skin turgor by gently elevating a piece of skin and allowing it to fall back into place. Perform deep palpation to assess the organs and any masses. Place one hand on top of the other and palpate from the lower quadrants to the upper (see Fig. 32.33). The edge of the liver may be felt at the right costal margin, and the tip of the spleen can be felt at the left costal margin. The descending colon may be felt in the left lower quadrant as a small column and the bladder as a soft balloon below the umbilicus. The kidneys are rarely palpable. The abdomen should be soft and nontender to palpation. Report firmness, tenderness, or masses.

**FIGURE 32.33** (A) Light and (B) deep palpation of the abdomen.

Palpate the inguinal area for the presence of hernia or enlarged lymph nodes.

**Take Note!**

To decrease ticklishness with abdominal palpation, place a flat, warm, still hand on the abdomen while distracting the child before palpation begins. An alternate technique is to first palpate with the child's hand under the examiner's hand.

**Genitalia and Anus**

Examination of the genitals should immediately follow the abdominal assessment in the younger child and should be reserved for the end of the assessment in the adolescent. Though the anus is part of the gastrointestinal tract, it is best assessed during the genital examination. Ensure privacy for the older child and adolescent. Keep the child covered as much as possible. Use a casual, matter-of-fact approach to place the child or teen at ease. During the genital examination, teach

the child or adolescent about normal variations and changes with puberty, as well as issues related to health promotion.

**MALE**

Inspect the penis and scrotum for size, color, skin integrity, and obvious masses. The obese boy's penis may appear small because of additional skin folds. Penis size should correlate with pubertal stage (Fig. 32.34). The penis may have

**FIGURE 32.34** Tanner male sexual maturity rating for genitalia and pubic hair. (Adapted from Tanner, J. M. [1962]. *Growth at adolescence*. Oxford, England: Blackwell Scientific Publications.)

a foreskin that covers the glans, protecting and lubricating it. If present, do not forcibly retract the foreskin. In circumcised males the urinary meatus is exposed and should be at the tip of the glans. Assess the meatus for absence of discharge. If possible, observe the stream of urine for strength of flow and patency of the urethral orifice. Skin lesions may indicate sexually transmitted infection. A foreskin that cannot be retracted in a boy older than 3 years of age may indicate phimosis. Report abnormal findings.

### Take Note!

When you first remove a male infant's diaper, this is the ideal time to assess the force of the urine stream and the erection reflex, as the cool air may make the infant void and briefly experience an erection.

Assess the presence and distribution of pubic hair. Inspect the scrotum for size, slight asymmetry, color, and absence of edema. The scrotum may initially be swollen from birth trauma or maternal hormones, but this swelling should decrease in the first few days of life. The scrotum is ordinarily more deeply pigmented than the rest of the boy's skin. Figure 32.34 illustrates scrotal changes that occur with puberty. Assess the testicles by placing one finger over the inguinal canal and palpating the scrotum with the other. This prevents the retractile testes in a young child from slipping back up the inguinal canal. The testicles should be smooth, of similar sizes, and freely moveable. The infant's testicles may be palpated in the scrotum or in the inguinal canal, where they can be easily moved into the scrotum with gentle pressure from the examiner's nondominant hand (Fig. 32.35). Beyond infancy, allow the boy to sit cross-legged to reduce the cremasteric reflex that retracts the testicles during palpation. An adolescent boy may need to stand for the nurse

**FIGURE 32.35** Placing a digit over the inguinal canal during testicular palpation prevents retraction of the testis into the canal.

to fully palpate the scrotum. Document the presence of both testicles in the scrotal sac, if they are retractile, or if they are absent. Report undescended testicle or other abnormal findings.

## FEMALE

In most cases, the female genitalia examination is limited to assessment of the external genitalia. Internal examination is not routinely performed before maturity unless the adolescent anticipates becoming or is sexually active or requests birth control, or if pathology is suspected. If an internal examination is needed, refer the child or adolescent to the appropriate advanced practitioner or physician.

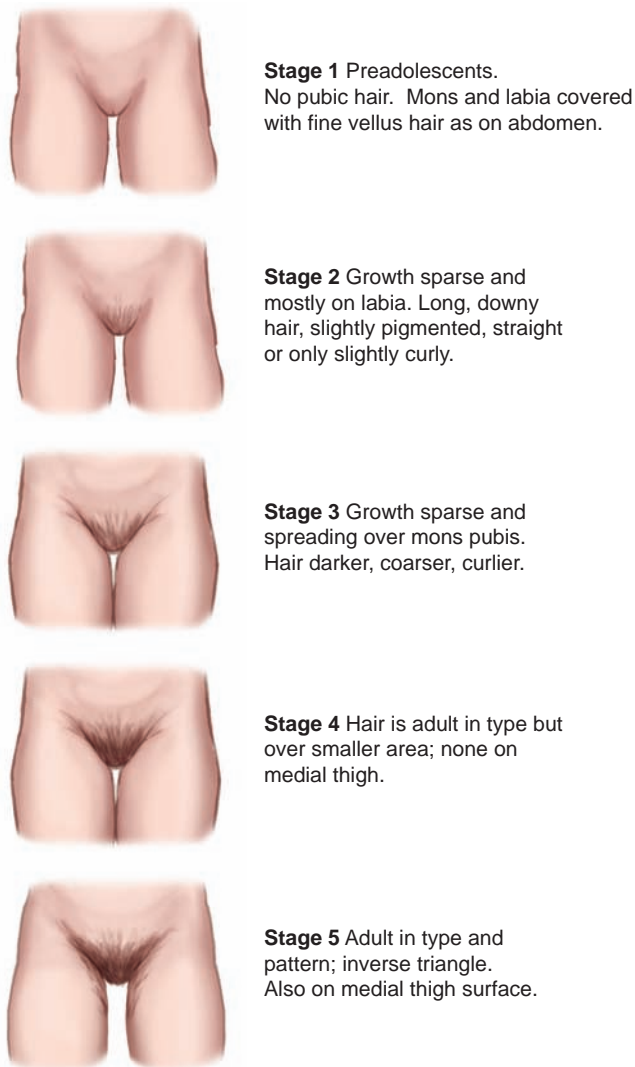

Position the infant in the parent's lap or on the examination table or crib. The toddler or preschooler should be examined in the parent's lap, in a frog-legged position. The school-age or adolescent girl should lie on the examination table or bed. Provide for privacy by keeping the genital area covered until it is time for the examination.

Perform the assessment of the external genitalia in a systematic fashion. First, determine the presence and distribution of pubic hair. Infants and young girls (particular those of dark-skinned races) may have a small amount of downy pubic hair. Otherwise, the appearance of pubic hair indicates the onset of pubertal changes, sometimes prior to breast changes. Pubic hair generally begins to appear by age 11 years, with age 13 being the latest. Figure 32.36 illustrates the development of pubic hair through puberty in girls.

Inspect the labia majora and minora for size, color, and skin integrity. The newborn's labia minora are swollen from the effects of maternal estrogen but will decrease in size and be hidden by the labia majora within the first weeks of life. Redness or swelling of the labia may occur with infection, sexual abuse, or masturbation. Lesions on the external genitalia may indicate sexually transmitted infection. Gently spread the labia to inspect the clitoris, urethral meatus, and vaginal opening. Some girls may prefer to spread the labia themselves. The urinary meatus and vaginal orifice should be visible and not occluded by the hymen. It is not uncommon to see a hymenal tag. Note clitoral size. Inspect the urinary meatus and vaginal opening for edema or redness, which should not be present. Observe for any vaginal discharge. A small amount of blood-tinged or mucoid discharge may be noted in the first few weeks of life as a result of maternal hormone exposure. A small amount of clear mucus-like discharge is normal in all females. If present, document labial adhesion or other abnormal findings.

## ANUS

Inspect the anal area for fissures, rash, hemorrhoids, prolapse, or skin tags. Examine the infant's anal area while examining the genitalia. The younger child may lie back

**FIGURE 32.36** Tanner female sexual maturity rating for pubic hair. (Adapted from Tanner, J. M. [1962]. *Growth at adolescence*. Oxford, England: Blackwell Scientific Publications.)

in the parent's lap and flex the knees to the chest. The older child or adolescent may be prone or in a side-lying position. If the adolescent boy is already standing for the scrotal assessment, have him bend forward so that you can assess the anal area. The anus should appear moist and hairless. Gently stroke the anal area to elicit the anal reflex (quick contraction). If indicated, inspect anal sphincter tone by inserting a gloved finger lubricated with water-soluble jelly just inside the anal sphincter.

### Musculoskeletal

Assessment of the musculoskeletal system includes examination of the clavicles and shoulders, spine, extremities, joints, and hips. Determining the child's ability to move all extremities through the full range of motion is also important.

### CLAVICLES AND SHOULDERS

Palpate the clavicles. In the newborn, tenderness or crepitus reveals a fracture sustained at birth. In the older infant or child, a bump indicates callus formation with clavicle fracture. Test shoulder strength and the function of cranial nerve XI in the older child by requesting that the child shrug the shoulders while you apply downward pressure.

### SPINE

Observe the child's resting posture and alignment of the trunk. The newborn's position will look like the position the baby preferred in utero and is one of general flexion. The older infant moves more and can sit unassisted in the second half of the first year. Toddlers stand with a wide-based gait, a slightly swayed back, and the abdomen slightly protruding. The posture straightens in the preschool and school-age years. Adolescents often demonstrate kyphosis as the skeleton and muscles are both growing rapidly (Fig. 32.37).

Inspect the child's spine. The newborn's spine has a single C-shaped curve and remains rounded for the first 3 months of life. The cervical curve begins to develop around 3 to 4 months of age as the baby gains head control. By 12 to 18 months of age, the lumbar curve develops, which corresponds to the onset of walking. The S-shaped spine in older children and adolescents is similar to that of the adult's. The spine should be flexible, with good muscle tone and no rigidity. Assess the back, and hip and shoulder heights for symmetry.

**FIGURE 32.37** The teen's posture often demonstrates kyphosis.

Examine the preadolescent and adolescent for the development of scoliosis. Refer to Chapter 45 for information about scoliosis screening. Scoliosis screening is generally performed during well-child examinations by the physician or nurse practitioner or by the middle or high school nurse on a particular day of the school year.

Note mobility of the vertebral column by having the child bend forward and side to side. Flex the neck and move it from side to side. No resistance or pain should occur. Inspect the back for discoloration, tufts of hair, or dimples. A normal pilonidal dimple is sometimes seen at the base of the spine, but there should be no tuft of hair or nevi along the spine. Document and report abnormal findings.

### EXTREMITIES

All children, even newborns, should be able to move all extremities spontaneously. Screen the infant younger than 6 months of age for developmental dysplasia of the hip by performing the Ortolani and Barlow maneuvers (refer to Chapter 45 for additional information). These maneuvers are usually best performed by a proficient examiner. Inspect and palpate the child's upper and lower extremities. Assess for symmetry in size, contour, movement, warmth, and color of the extremities. The infant's feet and legs appear bowed secondary to in utero positioning but can be straightened through passive range of motion. Observe the child in a standing position. Bowing of the lower legs (internal tibial torsion) lessens as the toddler begins to bear weight and usually resolves in the second or third year of life as the strength of the muscles and bones increases. When it persists past that time, it is termed genu varum (bow legs). Genu valgum (knock knee) is usually present until the child is 7 years old. Observe the child walking, noting any difficulty with leg position or balance. If the child is reluctant to walk, use play as a way to elicit the behavior. The school-age child should have gait and leg appearance similar to that of the adult.

Note the normal flat foot in the toddler and young child. The arch develops as the child grows and the muscles become less lax, though some children may continue with flexible flat feet; this is considered a normal variation.

Perform passive range of motion of the young infant's extremities. Inability to straighten the foot to midline may indicate clubfoot. Count the fingers and toes, noting abnormalities such as polydactyly (increased number of digits) or syndactyly (webbing of the digits). Palpate the joints for warmth or tenderness. Check the mobility of the joints of the upper and lower extremities by performing range of motion. Determine lower extremity muscle strength by having the child push against the examiner's hands with the soles of the forefoot. Assess upper extremity strength by having the child squeeze the examiner's crossed fingers and/or push up or down against the examiner's outstretched hands.

### Take Note!

Slight tremors may be noticed in the infant's extremities in the first month of life.

## Neurologic

The neurologic examination should include level of consciousness, balance and coordination, sensory function, reflexes, and a developmental screening. Motor function is assessed within the musculoskeletal section. Cranial nerve function is generally tested within other portions of the physical assessment as it applies to that section.

### LEVEL OF CONSCIOUSNESS

Note the state of alertness and attentiveness to parents and the environment in the newborn and infant. Older infants become interactive with other people, as do toddlers and preschoolers. Younger children demonstrate orientation by positive interaction with family members and by crying or fussing when they feel threatened. By school age, the child should be oriented to name and place and a few years later should be able to state the date as well (even if only the day of the week).

### BALANCE AND COORDINATION

The cerebellum controls balance and coordination. Observe the child's gait to assess balance and coordination. Observe toddlers and older children rising and walking from a seated and supine position. They should be able to stand and balance without straining or holding on to objects. Continue to test cerebellar function by having the younger child skip or hop and requesting that the older child or adolescent walk heel to toe. Further tests of cerebellar function responsible for balance and coordination are discussed in Box 32.3. Demonstrate each test and make sure the child understands your instructions.

### SENSORY TESTING

Portions of sensory testing related to most of the cranial nerves, vision, hearing, taste, and smell have already been incorporated into other sections as appropriate within the physical assessment. Test cranial nerve V (trigeminal) by lightly touching the child's cheek with a cotton ball. The young infant will root toward the side that is touched. With the child's eyes closed, ask the child to identify other locations where he or she is lightly touched (several different ones) to assess sensation. Ask the child to tell you when he or she is touched. Make a game of this activity to encourage cooperation in younger children. In the older child who knows the definition of sharp and dull, test for these sensations with the child's eyes closed. Use the rounded end of a tongue blade for dull and the broken edge of a tongue blade for the sharp sensation. The child should be able to discriminate the sensations of sharp and dull.

## BOX 32.3

## CEREBELLAR FUNCTION TESTING

- **Romberg:** Ask the school-age or older child to stand still with eyes closed and arms down by the sides. Observe the child for leaning (stand close in case this does occur). This is considered a positive Romberg test, indicating cerebellar dysfunction. For the following tests, the child should demonstrate accuracy and smoothness:
- **Heel-to-shin:** Have the child lie in a supine position, place one heel on the opposite knee, and run it down the shin.
- **Rapid alternating movements:** The child pats the thighs with the hands, lifts them, turns them over, pats the thighs with the back of the hands, and repeats the process multiple times. An alternate test is for the child to touch the thumb to each finger of the same hand starting at the index finger, then reverse the direction and repeat.
- **Finger-to-finger:** The child's eyes are open. The child touches the examiner's outstretched finger with the index finger, then touches his or her own nose. The examiner moves the finger to a different spot and the child repeats this process several times.
- **Finger-to-nose:** The child's eyes are closed. The child stretches the arm with the index finger extended, then touches his or her nose with that finger, keeping the eyes closed.

Adapted from Bickley, L., & Szilagyi, P. G. (2009). *Bates' guide to physical examination and history taking* (10th ed.). Philadelphia: Lippincott Williams & Wilkins; and Jarvis, C. (2012). *Physical examination and health assessment* (6th ed.). St. Louis: Saunders.

## REFLEXES

Assess the infant's primitive and protective reflexes. The primitive reflexes involve a whole-body response and are subcortical in nature. Selected primitive reflexes present at birth include Moro, root, suck, asymmetric tonic neck, plantar and palmar grasp, step, and Babinski. Most of the primitive reflexes diminish over the first few months of life, giving way to protective or postural reflexes. Protective reflexes are motor responses related to maintenance of equilibrium. They are necessary for appropriate motor development and remain throughout life once they are established. The protective reflexes include the righting and parachute reactions.

Place one finger in each of the infant's hands to elicit the palmar grasp reflex (usually disappears by age 3 to 4 months). Touch the thumb to the ball of the infant's foot to elicit the plantar grasp reflex. The infant's toes will curl down (this reflex disappears by 8 to 10 months). Refer to Table 25.2 for illustrations and additional explanation of the other reflexes. Appropriate presence and disappearance of primitive

reflexes, as well as development of protective reflexes, is indicative of a healthy neurologic system. Primitive reflexes that persist beyond the usual age of disappearance may indicate an abnormality of the neurologic system and should be further investigated (Bickley & Szilagyi, 2009).

Assess deep tendon reflexes in all infants and children. Appropriate responses indicate that the reflex arc is intact. Use the reflex hammer in all ages or the curved tips of the two first fingers to elicit the responses in infants. The limb must be relaxed and the muscle partly stretched. Use a snapping motion of the wrist to tap with the fingertips or the reflex hammer. Test the biceps, triceps, patellar, and Achilles reflexes as you would in the adult. It may help to place a finger under the infant's knee to encourage relaxation. Young children who tense up when their reflexes are being tested may relax the area if you have them focus on another area, so have the child clasp the hands while testing the Achilles and patellar reflexes. As the child focuses on the hands, the lower extremities relax (Jarvis, 2012). Distraction may also be helpful.

Grade the strength of the response using the standard scale from 0 to 4+:

- 0: no response
- 1+: diminished or sluggish
- 2+: average
- 3+: brisker than average
- 4+: very brisk, may involve clonus

The newborn's deep tendon reflexes are normally brisk (3+). They decrease to average (2+) usually by 4 months of age. Healthy children should have reflexes of 2+ if the reflex has been elicited properly. Absent, sluggish, or hyperreactive responses usually indicate disease (Bickley & Szilagyi, 2009).

## DEVELOPMENTAL SCREENING

An important component of the neurologic assessment and a comprehensive child health assessment is developmental screening. Developmental screening may be used to identify children whose developmental status may warrant additional evaluation. Become comfortable with the developmental screening tools used and what the results of the screening mean. Upon completion of the screening, discuss the child's abilities with the parent or caregiver. Developmental screening is often performed separately from the physical examination and is discussed in further detail in Chapter 31 (refer to page 1055).

*Refer back to Elliot, the 3-year-old from the beginning of the chapter. What are some important considerations when performing his physical examination?*

## KEY CONCEPTS

- The health history in children includes more than just the chief complaint, history of present illness, and past medical history; it is important to include the perinatal history and developmental milestones.
- Allow the chief complaint to determine which parts of the history require more in-depth investigation.
- The developmental history will warrant more attention in the younger child, while school performance and adjustment will be more important in the school-age child and adolescent.
- Though the parent will provide most of the health history for the infant and young child, allow the young verbal child to answer questions during the health history as appropriate.
- Direct health history questions to the school-age child and adolescent, seeking clarification from the parents as needed.
- Provide confidentiality and privacy for the adolescent during the health history.
- Weight and length or height should be assessed at each well-child visit to determine adequacy of growth.
- Measure head circumference until age 3 years to monitor brain growth.
- Perform hearing and vision screenings for children of all ages.
- BMI can be used to identify children who are overweight or at risk for being overweight.
- The normal range of vital signs varies based on the child's age.
- The sequence of the physical examination in children should be based on the child's developmental age, his or her level of cooperation, and the severity of the illness.
- Obtain heart rate and respiratory rate and auscultate the heart and lungs while the infant or young child is quiet.
- Perform intrusive procedures such as examination of the ears, mouth, and throat last in the infant or young child.
- Perform the health assessment in a head-to-toe fashion in the school-age child or adolescent, reserving the genitalia and anus examination for last.
- Plan the health assessment in such a way as to minimize trauma to the child or adolescent.
- Use age-appropriate measurement tools to assess pain in children.
- Allow the infant or young child to remain in the parent's lap for as much of the assessment as possible so that the child feels secure.
- Use age-appropriate games during the health assessment to gain cooperation in the younger child.
- Having the young boy sit cross-legged for a testicular examination may reduce the cremasteric reflex.
- The newborn may exhibit a wide variety of normal skin variations.
- The infant's fontanelles should be soft and flat; report a bulging fontanel immediately.
- Jaundice (outside of the newborn period), pallor, cyanosis, and poor skin turgor indicate illness and may need immediate intervention.
- Heart murmurs should be assessed for intensity, location, and duration. They may be innocent or may indicate a congenital heart defect.
- The infant's chest wall is relatively thin, allowing upper airway sounds to be transmitted throughout the lung fields.
- Substernal or xiphoid retractions indicate that the child is laboring to breathe, whereas a fixed, depressed sternum (pectus excavatum) is a structural abnormality.
- The Tanner stages of sexual maturity provide a basis for assessing pubertal development in boys and girls. Use the breast and pubic hair charts for girls and the pubic hair and penis and scrotum size chart for boys.

## MULTIPLE CHOICE QUESTIONS

1. A 5-year-old boy visits the physician's office with an upper respiratory infection. Which approach would give the nurse the most information about the child's developmental level?
  - a. Playing a game with the child
  - b. Talking with the child about the teddy bear next to him
  - c. Using a screening tool during a follow-up office visit
  - d. Asking the 10-year-old sibling about the child
2. Which statement indicates the best sequence for the nurse to conduct an assessment in a nonemergency situation?
  - a. Introduce yourself, ask about any problems, take a history, and do the physical examination.
  - b. Perform the physical examination and then ask the family if there are any problems in the child's life.
  - c. Do the physical examination while at the same time asking about the child's previous illnesses; then talk about the family's concerns.
  - d. Get a complete history of the family's health beliefs and practices, and then assess the child.
3. What approach by the nurse would most likely encourage a child to cooperate with an assessment of physical and developmental health?
  - a. Explain to the child what's going to happen when the child asks questions.
  - b. Explain what is going to happen in words the child can understand.
  - c. Force the child to cooperate by having a parent hold him or her down.
  - d. Give the child a sticker before beginning the examination.
4. A sleeping 5-month-old girl is being held by the mother when the nurse comes in to do a physical examination. What assessment should be done initially?
  - a. Listening to the bowel sounds
  - b. Counting the heart rate
  - c. Checking the temperature
  - d. Looking in the ears

5. Which assessment finding is considered normal in children?
  - a. Irregular respiratory rate and rhythm
  - b. Split S<sub>2</sub> and sinus arrhythmia
  - c. Decreased heart rate with crying
  - d. Genu varum past the age of 5 years

## CRITICAL THINKING EXERCISES

1. A soft and muffled heart murmur is heard in a 4-year-old patient. The mother states that she has never heard that the child has a murmur. What should the nurse do?
2. A nurse is helping a new mother breastfeed her 4-day-old baby. The mother notices that the baby has a bluish cast to the skin on his hands and that sometimes the infant has a tremor. She asks the nurse if the baby is cold, though the baby is swaddled and comfortably resting against the mother's skin. How might the nurse help teach this mother?
3. Devise a plan for encouraging cooperation of the toddler or preschooler during various parts of the physical examination.

## STUDY ACTIVITIES

1. In the clinical setting, obtain a health history on an infant, child, or adolescent.
2. In the clinical setting, compare the approach you use for the physical examination of a toddler versus a school-aged child or adolescent.
3. No matter how thoughtfully and appropriately you plan your assessment, odds are good that you will have difficulty assessing a 2-year-old. Discuss with your classmates the strategies that you have used for success and brainstorm with them about their ideas for assessing a crying or resistant young child.

## Caring for Children in Diverse Settings

### Learning Objectives

Upon completion of the chapter, you will be able to:

1. Define the key terms used in this chapter.
2. Identify the major stressors of illness and hospitalization for children.
3. Identify the reactions and responses of children and their families during illness and hospitalization.
4. Explain the factors that influence the reactions and responses of children and their families during illness and hospitalization.
5. Describe the nursing care that minimizes stressors for children who are ill or hospitalized.
6. Discuss the major components of admission for children to the hospital.
7. Discuss appropriate safety measures to use when caring for children of all ages.
8. Review nursing responsibilities related to client discharge from the hospital.
9. Discuss the variety of settings in which community-based care occurs.
10. Discuss the advantages and disadvantages of home health care.

*Jake Jorgenson, 8 years old, was brought to the clinic with a history of headaches, vomiting not related to feeding, and changes in his gait. Initial testing leads to a suspected brain tumor. Jake is to be admitted to the neurologic service at a pediatric hospital for further testing and treatment. Up until this point he has been a healthy child with no previous hospitalizations. He lives at home with his parents and two siblings, Jenny, age 11, and Joshua, age 5. As a nurse on this unit, how can you help prepare Jake and his family for this hospitalization?*

### Words of Wisdom

Nurses should leave their “comfort zone” of practice and reach out to children on their turf to make a difference.

**Nursing** care of the child occurs in a variety of settings, from acute care in a hospital to well and ill care in community settings such as physician offices, schools, churches, health departments, community centers, and even within the child's own home. Within each setting, the nurse incorporates basic nursing care with specific strategies to help promote positive outcomes for the child, family, and community as a whole.

## HOSPITALIZATION IN CHILDHOOD

In today's health care environment, children receive much of their care for illnesses in community health settings such as physician's offices, urgent care settings, or day surgery centers. As a result of this trend, fewer children may actually be admitted to a hospital unit, and those who are hospitalized are generally acutely ill. In addition, hospital stays are often shorter due to economic trends in the health care environment, such as the delivery system of managed care and other factors that attempt to control costs. Acute conditions, trauma, or chronic diseases or illnesses requiring surgical intervention lead to hospitalization for children.

According to Child Health USA 2011, diseases of the respiratory system account for the majority of hospitalizations in children under 5 years of age, while diseases of the respiratory system, mental health problems, injuries, and gastrointestinal disorders lead to more hospitalizations in older children. Adolescents between 15 and 19 years of age are often hospitalized because of problems related to pregnancy, childbearing, mental health, and injury (U.S. Department of Health and Human Services [USDHHS], Health Resources and Services Administration, Maternal and Child Health Bureau [MCHB], 2011).

Other health problems begin before birth or immediately following birth, such as congenital heart disease or gastrointestinal atresia. Just when they are getting used to the idea of having a new child, the family must also deal with illness and possibly extended hospitalizations. Specific genetic or environmental factors also predispose the child to disease and injury, such as the genetic disorder of hemophilia or the environmental situation of homelessness. Many of these factors or situations put the child and family at greater risk for chronic health conditions and long periods of illness, hospitalization, and even death.

Hospitalization is often confusing, complex, and overwhelming for children and their families. Reactions and responses to illness and hospitalization depend on a number of factors, including the child's developmental stage. Nursing strategies are needed to prepare children and their families for this experience while minimizing negative effects. These strategies include identifying the needs of children and families through astute assessment

of nonverbal and verbal behaviors, then validating the information with accurate interpretation and providing appropriate responses and interventions.

Although the nurse implements these strategies throughout the interaction with the child and family, a critical time to ensure the best outcome for the child and family is during the admission process. The nurse assesses the learning needs and abilities of the child and family. For the interventions to be successful, the nurse must communicate and teach in the most effective method for the individual child and family. The nurse also evaluates the child's and family's competence in performing specific activities prior to discharge.

## Children's Reactions to Hospitalization

In general, children are more vulnerable to the effects of illness and hospitalization because this is a change from their usual state of health and routine. They also have limited understanding and coping mechanisms to assist them in resolving the stressors that might occur during this time. Hospitalization creates a series of traumatic and stressful events in a climate of uncertainty for children and their families, whether it is an elective procedure that is planned in advance or an emergency situation resulting from trauma. The stressors that children experience in relation to hospitalization may result in various reactions. Children react to the stresses of hospitalization before admission, during hospitalization, and after discharge.

Besides the physiologic effects of the health problem, the psychological effects of illness and hospitalization on a child include anxiety and fear related to the overall process and the potential for bodily injury, physical harm, and pain. In addition, children are separated from their homes, families, friends, and what is familiar to them, which may result in **separation anxiety** (distress related to removal from family and familiar surroundings). There is a general loss of control over their lives and sometimes their emotions and behaviors. The result may be feelings of anger and guilt, **regression** (return to a previous stage of development), acting out, and other types of defense mechanisms to cope with these effects. Children's typical coping strategies are tested during this experience.

### Anxiety and Fear

For many children, entering the hospital is like entering a foreign world. The result is anxiety and fear. Anxiety often stems from the rapid onset of the illness or injury, particularly when the child has limited experiences with disease or injury. Normal fears of childhood include the fear of separation from parents and family or guardians, loss of control, and bodily injury, mutilation, or harm. Children's

fears are similar to adult fears of the unknown, including fear of unfamiliar environments and losing control.

Therefore, when the child is in the hospital, he or she becomes distressed about the unfamiliar environment, health care procedures, especially the use of needles or associated pain that may occur, and situations, such as the strange words being used, ominous-looking equipment, strangers in unusual attire (e.g., surgical caps, masks, gowns), unfamiliar and frightening noises and smells, or the sounds of other children crying. This exposure to people, situations, and procedures that may be new to them and cause them pain leads to increased anxiety and fear (Fig. 33.1). Overall, hospitalization is a difficult experience for children.

### Separation Anxiety

Separation anxiety is a major stressor for children of certain ages. It usually begins around 8 months and ends as the child nears 3 years of age (American Academy of Pediatrics [APA], 2011).

John Bowlby described three stages that the infant goes through during separation anxiety—namely, protest, despair, and detachment (Spender, Barnsley, Davies, & Murphy, 2011). The first phase, protest, occurs when the child is separated from the parents or primary caretaker. This phase may last from a few hours to several days. The child reacts aggressively to this separation and exhibits great distress by crying, expressing agitation, and rejecting others who attempt to offer comfort. The child may also display anger and inconsolable grief.

If the parents do not return within a short time, the child exhibits the second phase, despair. The child displays hopelessness by withdrawing from others, becoming quiet without crying, and exhibiting apathy, depression, lack of interest in play and food, and overall feelings of sadness.

**FIGURE 33.1** The presence of familiar objects and home routines normalizes the environment and helps the child cope with hospitalization. Reading a favorite bedtime story can be comforting.

Detachment (also known as denial) is the third and final phase of separation anxiety. During this phase the child forms coping mechanisms to protect against further emotional pain. This occurs more often in long-term separations. During this stage, the child shows interest in the environment, starts to play again, and forms superficial relationships with the nurses and other children. If the parents return, the child ignores them. A child in this phase of separation anxiety exhibits resignation, not contentment. It is more difficult to reverse this stage, and developmental delays may occur.

Today, health care providers primarily observe the first and second stages because of the shorter hospital stays and the more common use of a family-centered approach to care.

### Loss of Control

When hospitalized, children experience a significant loss of control. This loss of control increases the perception of threat and affects their coping skills. They lose control over routine self-care and their usual tasks and play as well as decisions related to the care of their own bodies. In the hospital, the child's usual routine is disrupted. He or she cannot choose what to do and at what time. The child can no longer accomplish simple tasks independently as he or she does at home or school. Confinement to the bed or crib worsens this loss of control. For example, if connected to tubes or intravenous lines, the child may not even be able to visit the bathroom alone.

Hospitalization also affects the child's control over decisions related to his or her own body. Many of the procedures and treatments that occur in the hospital are invasive or are at least disturbing to children, and much of the time they do not have the option to refuse to undergo them. Adults are presumed to be competent to make health care decisions, but generally children are not. Though the parents and nurses of hospitalized children have the children's best interest in mind, children often feel powerless when in the hospital, not having their feelings and wishes respected and having minimal control over events.

#### Take Note!

When advocating for a child, make sure to include the child's voice. Do not assume what his or her wishes may be; ask about them directly.

### Factors Affecting Children's Reaction to Hospitalization

Various factors have a great impact on the ability of children to handle illness and hospitalization. These factors may increase or diminish the fears of the child who is ill

## BOX 33.1

**FACTORS AFFECTING A CHILD'S RESPONSE TO ILLNESS AND HOSPITALIZATION**

- Amount of separation from parent/caregiver
- Age
- Developmental level
- Cognitive level
- Previous experience with illness and hospitalization
- Recent life stresses and changes
- Type and amount of preparation
- Temperament
- Innate and acquired coping skills
- Seriousness of the diagnosis/onset of illness or injury (e.g., acute or chronic)
- Support systems available, including the family and health care professionals
- Cultural background
- Parents' reaction to illness and hospitalization

and hospitalized. Each child responds differently and will perceive the hospital experience differently. Box 33.1 lists the various factors affecting a child's response to illness and hospitalization.

**Developmental Level**

The child's age, cognitive level, and developmental level will affect his or her perceptions of actual events, and this in turn will affect his or her reaction to illness and hospitalization. Children's responses to the stressors of fear, separation anxiety, and loss of control vary depending on their age and developmental level. Younger children, with their limited life experience and immature intellectual capacities, have a more difficult time comprehending what is happening to them. This can be particularly true for toddlers and preschoolers, who perceive the intactness of their bodies to be exposed during physical intrusions. In addition, they frequently interpret illness as punishment for wrongdoing or hospital procedures as hostile, mutilating acts. Although children are increasingly able to adapt as they grow older, lack of understanding about the need for hospitalization and threatened sense of control can make adaptation difficult.

**INFANTS**

Newborns and infants are adapting to life outside the womb with rapid growth and development and establishment of a healthy attachment to parents or primary caregivers. They are dependent on others for nurturance and protection. They gain a sense of trust in the world

through rhythmic and reciprocal patterns of contact and feeding, resulting in bonding to the primary caregiver. They need a secure pattern of restful sleep, satisfaction of oral and nutritional needs, relaxation of body systems, and spontaneous response to communication and gentle stimuli. The caregiver–infant attachment is critical for psychological health, especially during periods of illness and hospitalization.

Unfortunately, during illness and hospitalization, these critical patterns of feeding, contact, comfort, sleeping, elimination, and stimulation are disrupted, resulting in fear, separation anxiety, and loss of control. By 5 to 6 months of age, infants have developed an awareness of self as separate from mother. As a result, infants of this age are acutely aware of the absence of their primary caregiver and become fearful of unfamiliar persons. Infants may be separated from their parents when hospitalized if the parents cannot room-in because of hospital policy or if they must work or care for other children. This results in separation anxiety.

The infant's oral needs, the basic source of infant satisfaction, are often not met in the hospital due to the condition of the child or the procedures that must be performed. The infant is accustomed to having his or her basic needs met by the parent when he or she cries or gestures. The constraints of hospitalization result in loss of control over the environment, leading to additional anxiety in the infant.

**TODDLERS**

Toddlers are more aware of self and can communicate their desires. Because their autonomy is developing, toddlers need to master accomplishments to minimize the development of shame and doubt. Control becomes an issue for toddlers. Toddlers also need opportunities to explore, and they need consistent routines. In addition, toddlers are aware of the need for care and protection from others, so they need familiarity and closeness to the primary caregiver. When the toddler is hospitalized, disruption occurs in this development of autonomy.

Toddlers are often fearful of strangers and can recall traumatic events. Simply walking toward the treatment room where a traumatic procedure previously occurred may upset the toddler. Ordinarily a resurgence in separation anxiety occurs during the toddler years. When the toddler is separated from his or her parents or caregivers in an unfamiliar environment, separation anxiety is compounded. In response to this anxiety, toddlers may demonstrate behaviors such as pleading for the parents to stay, physically trying to go after the parents, throwing temper tantrums, and refusing to comply with usual routines. Restrictions related to mobility and new skill acquisition result in loss of control. Disruption in usual routines also contributes to loss of control, and the toddler feels insecure. As a result, regression in toilet training and refusal to eat are common reactions in toddlers.

## PRESCHOOLERS

The preschooler has better verbal and developmental skills to adapt to various situations, but illness and hospitalization can still be stressful. Preschoolers may understand that they are in the hospital because they are sick, but they may not understand the cause of their illness. Preschoolers fear mutilation and are afraid of intrusive procedures since they do not understand the body's integrity. They interpret words literally and have an active imagination. Therefore, when the nurse says, "I need to take some blood," preschoolers' fantasies may run wild. They may not understand the concept of blood and may think everything will come out of their body. They may think that blood is "taken" the same way a child picks up a toy to take it out of the room. Preschoolers' thinking is egocentric; they believe that some personal deed or thought caused their illness, which can lead to guilt and shame. These feelings may be internalized. Overall, preschoolers' concrete, egocentric, and **magical thinking** (type of thinking that allows for fantasies and creativity) limits their ability to understand, so communication and interventions must be on their level.

Separation anxiety may not be as much of an issue as it is for toddlers since preschoolers may already be spending time away from parents in preschool. They are, however, still acutely aware of the comfort and security that their family provides for them, so disruptions in these relationships lead to challenges. The preschooler may constantly ask for his or her parents or ask to call the parents. He or she may quietly cry, refuse to eat or take medication, or generally be uncooperative.

In addition, the hospitalized preschooler loses control over the environment. The preschooler is naturally curious about his or her surroundings and learns best by observing and working with objects. This might be limited during hospitalization. Because the preschooler cannot participate in typical activities and explore the environment as usual, the child's normal creative, curious nature may give rise to a variety of fantasies that may present challenges.

## SCHOOL-AGE CHILDREN

School-age children generally are hospitalized because of long-term illnesses or trauma. The general task of their development stage, to develop confidence through a sense of industry, can be disrupted during hospitalization. Even at this time, they generally want to continue to learn and maintain their skills and abilities. The stress of illness or anxiety related to diagnostic tests and therapeutic interventions may lead to inward or outward expressions of distress. If they have learned various coping skills, this distress may be minimized. After 11 years of age there is an increased awareness of physiologic, psychological, and behavioral causes of illness and injury. Typically, the school-age child has a more realistic understanding of the reasons for the illness and can better comprehend explanations. School-age children are

concerned about disability and death, and they fear injury and pain. They want to know why procedures and tests are being performed. They can understand cause and effect and how it relates to their illness. They are uncomfortable with any type of sexual examination.

Separation anxiety is not as much of an issue for school-age children. They are accustomed to periods of separation and may already be experiencing some separation anxiety related to being in school. At the same time, they may be missing school and friends as they try to adjust to the unfamiliar environment. They may feel that friends will forget them if they remain in the hospital for a long time. Some school-age children may regress and become needy, demanding their parents' attention or playing with special "comfort toys" they used at a younger age.

Since school-age children are accustomed to controlling self-care and typically are highly social, they like being involved. They are used to making choices about meals and activities. Hospitalization presents loss of control by limiting their activities, making them feel helpless and dependent. This may result in feelings of loneliness, boredom, isolation, and depression. The key is to give them opportunities to maintain independence, retain a sense of control, enhance self-esteem, and continue to work toward achieving a sense of industry.

## ADOLESCENTS

Adolescents fear injury and pain. Since appearance is important to them, they are concerned with how the illness or injury will affect their body image. Anything that changes their perceptions of themselves has a major impact on their response. Typically, adolescents do not like to be different; they like "being cool," which means being in control and not showing fear. They also may feel ambivalent about wanting their parents. Adolescents typically do not experience separation anxiety from being away from their parents; instead, their anxiety comes from being separated from friends.

Loss of control is a key factor affecting the behavior of adolescents who are hospitalized. Anger, withdrawal, or general lack of cooperation may occur due to the feelings of loss of control. In addition, their desire to appear confident may lead them to question everything that is being done or that they are asked to do. Their feelings of invincibility may cause them to take risks and be non-compliant with treatment. Overall, adolescents strive for independence, self-assertion, and liberation while developing their identity.

### *Previous Experiences*

In general, children's lack of understanding and experience of illness, hospitalization, and hospital procedures contributes to their anxiety level. However, previous experience with hospitalization and other health-related

experiences can either facilitate preparation or impair it if the experiences were perceived as negative. For example, the child who associates the hospital with the birth of a sibling may view this experience as positive. However, the child who associates the hospital with the serious illness or death of a relative or close friend will probably view the experience as negative.

The type of experience may contribute to increased anxiety and fear if the child must be admitted to the hospital. If children have had previous experiences, how the experience unfolded and their response to it will determine many of their reactions to hospitalization. Older children may cling to their parents, kick, or create a scene because of their previous experience.

### Recent Stresses and Changes and Individual Coping Skills

The effects of hospitalization on children are influenced by the nature and severity of the health problem, the condition of the child, and the degree to which activities and routines differ from those of everyday life. A lack of sensory stimulation in the hospital environment can lead to listlessness, indifference, unhappiness, and even appetite changes. When the child's motor activity is restricted, anger and hyperactivity may result. Play, recreation, and educational opportunities can provide an outlet to distract the child from the illness, provide pleasant experiences, and help the child understand his or her condition.

The child's ability to work through a situation will also affect his or her responses to illness and hospitalization. This ability depends on the age of the child, his or her perceptions of the event, previous encounters with health care personnel, and support from significant others. Box 33.2 lists various coping skills used by children and suggestions for promoting positive coping.

#### BOX 33.2

##### CHILDREN AND COPING

Behavior/Methods for Coping	Suggestions to Promote Coping
Ignore or negate the problem	Breathing techniques such as blowing bubbles, pinwheels, or party noise-makers
Stoicism, passive acceptance	Distraction with books or games
Acting out—yelling, kicking, screaming, crying	Imagery with tapes or scenarios
Anger, withdrawal, rejection	Music
Intellectualizing	Teaching before events or procedures

### Parents' Response to Child's Hospitalization

Children take in their parents' anxiety and concern. Even whispers can set off children's imaginations. For example, preschoolers may invent elaborate stories to explain what is happening to them. Parents who do not tell children the truth or do not answer their questions confuse and frighten them and may weaken the child's trust in the parents. It is important for children to believe that someone is in control and that the person can be trusted. Some parents, however, have their own fears and insecurities. Thus, a child's reaction often is related to the parents' reaction to the illness and hospitalization.

The relationship between the family and the hospital staff may either add to or ease the child's stress. This relationship can contribute significantly to the quality of the environment. Hospital personnel must assume responsibility for the care of hospitalized children by maintaining good partnerships with families.

*Remember Jake, the 8-year-old with a suspected brain tumor? What responses to hospitalization might you see in him and his family?*

### Family's Reactions to the Child's Hospitalization

Whether planned or unplanned, hospitalization increases the family's stress and anxiety level. The illness or serious injury of one family member affects all members of the family because the process disrupts the family's usual routines and may alter family roles. Parents and siblings have their own reactions to this experience.

#### Reactions of Parents

Watching a child in pain is difficult, especially when the parent is assisting with the procedure by holding the child. The parent may feel guilty for not seeking care sooner. Parents may also exhibit other feelings such as denial, anger, depression, and confusion. Parents may deny that the child is ill. They may express anger, especially directed at the nursing staff, another family member, or a higher power because of their loss of control in caring for the child. Depression may occur because of exhaustion and the psychological and physical requirements of spending long hours in a hospital caring for a child. Confusion may develop because of dealing with an unfamiliar environment or the loss of a parental role. Finally, the parents' marriage may be strained because of dual roles, long separation, and increased stress.

## Reactions of Siblings

Siblings of children who are hospitalized may experience jealousy, insecurity, resentment, confusion, and anxiety. They may have difficulty understanding why their sibling is ill or getting all the attention, leaving little for them. They may wonder if their sibling is going to die or ever return home. They may worry that their sibling's illness is going to happen to them. Certain age groups, such as preschoolers, may feel that they caused the illness. Little information or understanding about what is happening, combined with their magical and egocentric thinking, contributes to their fears that they may have caused the illness or injury by their thoughts, wishes, or behaviors. If the family roles or routines change significantly, the siblings may feel insecure or anxious. They may develop changes in behavior or in school performance.

### Take Note!

Research supports the need to provide support and information to the siblings to decrease their stress, anxiety, and confusion (Prchal, Graf, Bergstraesser, & Landolt, 2012)

## Factors Influencing Family Reactions

The parenting style and the family-child relationship can influence the hospital experience as well as the family members' coping skills. Cultural, ethnic, and religious variations, values, and practices related to illness, general response to stress, and attitudes about the care of a sick child have a significant influence on the family's response. For example, religious beliefs can raise problems or can be a source of strength to the family and child. Families already in crisis or without support systems have a more difficult time dealing with the added stress of hospitalization. Chapter 1 gives further explanations of some of these influences on children and their families.

*Jake's parents are very upset that he has to be hospitalized. His mother says to you, "I'm worried how Jake is going to react to all of this. What can we do to help him?" How would you address his mother's concerns?*

### EVIDENCE-BASED PRACTICE 33.1

#### WHAT ARE THE EFFECTS OF AN EARLY PSYCHOLOGICAL INTERVENTION ON SIBLINGS OF CHILDREN RECENTLY DIAGNOSED WITH CANCER?

*Studies have demonstrated that children who receive age-appropriate information handle the stress and anxiety associated with hospitalization better. Can the same hold true for siblings of an ill child?*

#### STUDY

In order to test the effectiveness of a 2-session psychological intervention on siblings of a child newly diagnosed with cancer a randomized controlled prospective design study was performed. Thirty siblings, age 6 to 17 years, were recruited from two children's hospital. The siblings were randomly assigned to an intervention group or an active control group that received standard psychological care. Siblings assigned to the intervention group received two 50 minute sessions within the first 2 months of diagnosis of the child. The intervention was performed on an individual basis and included medical information (such as understanding body functioning, the illness and location, and treatment), information on coping with stressful situations and information for parents on how to support siblings of a child diagnosed with cancer.

#### Findings

Siblings who received the 2 session interventions showed better psychological well-being, better medical knowledge and reported receiving more social support compared to siblings in the control group. No significant effects were shown on posttraumatic stress symptoms or anxiety although the results trended in the desired direction.

#### Nursing Considerations

Recognize siblings of a child newly diagnosed with cancer are at risk for emotional, behavioral and social problems. Provide education to the sibling regarding the medical condition of their sibling. Recognize that a 2 session early sibling intervention focusing on medical information and coping with stressful situations demonstrated a positive impact. Educate parents about the needs of the siblings of the sick child and ways they can help support them. Address the psychosocial and emotional needs of siblings of an ill child. Enlist child life specialists to assist with the siblings.

Adapted from Prchal, A., Graf, A., Bergstraesser, E. & Landolt, M.A. (2012). A two-session psychological intervention for siblings of pediatric cancer patients: a randomized controlled pilot trial. *Child and Adolescent Psychiatry and Mental Health*, 6(3): doi:10.1186/1753-2000-6-3

## The Nurse's Role in Caring for the Hospitalized Child

In most instances, the nurse is the primary person involved in the care of a hospitalized child. The nurse is probably the first one to see the child and family and will spend more time with them than other health care providers. Nurses are part of a medical community that makes decisions in the child's best interest, but the nurse needs to bear in mind the child's rights and must try to minimize the child's distress so that the hospital stay will be as pleasant an experience as possible. When establishing strategies to care for children in the hospital, nurses should examine the general effects of hospitalization on children in each developmental stage and should strive to understand both the reactions of the child and family to hospitalization and the factors affecting these reactions. The Nursing Care Plan Overview 33.1 summarizes the nursing care associated with a hospitalized child.

In a study of hospitalized children, Crole and Smith (2002) found the nursing care for a hospitalized child occurred in four phases: introduction, building a trusting relationship, decision-making phase, and providing comfort and reassurance. All of these phases are interconnected. For example, if trust is not established, it becomes difficult to move to the next phase.

The introduction phase involves the initial contact with children and their families and it establishes the foundation for a trusting relationship. Use favorite toys and common television shows to establish rapport. Allow the child to participate in the conversation without the pressure of having to comply with requests or undergo any procedures. Next, a trusting relationship can be built by using appropriate language, games, and play such as singing a song during a procedure, preparing the child adequately for procedures, and providing explanations and encouragement. Get down to the child's level and play on his or her terms.

In the decision-making phase, the nurse gives some control over to the child by allowing him or her to participate in making certain decisions. This phase is critical to maintaining the trust the child has developed. For example, it is imperative to decide how much control the child will have during treatment, how much information to share with the child about upcoming events, and whether parents should participate. Reinforce the child's use of coping strategies that lead to healthy outcomes by providing options whenever it is safe to do so. Finally, the comfort and reassurance phase uses techniques such as praising the child and providing opportunities to cuddle with a favorite toy.

### Preparing Children and Families for Hospitalization

When preparing children for hospitalization, be aware of the situations that may create distress in a child and try to minimize or eliminate them. Even the most

minor situations may be frightening to young children. Remember, new experiences, unfamiliar sights and sounds, disruption of sleep patterns, and pain associated with procedures and treatments are major causes of stress for the hospitalized child and family. Table 33.1 presents some hospital activities that may seem scary or stressful to a child and gives suggestions for preparing the child and family. Thoughtful preparation for these situations may help relieve stress. Educate children about what to expect so they can cope with their imagination and distinguish reality from fantasy. Describe the intervention and the sequence of steps that will occur, and include sensory information such as how the child will feel.

Good preparation can reduce the child's fears and increase his or her ability to cope with the hospital experience. Preparation should include exploring the child's perceptions, reviewing previous experiences, and identifying coping strategies. The goal should be to decrease fear and anxiety by allowing the child to better understand what is happening. Useful techniques include the following:

- Perform nursing care on stuffed animals or dolls and allow the child to do the same.
- Avoid the use of medical terms.
- Allow the child to handle some equipment.
- Teach the child the steps of the procedure or inform him or her exactly what will happen during the hospital stay.
- Show the child the room where he or she will be staying.
- Introduce the child to the health care personnel with whom he or she will come in contact.
- Explain the sounds the child may hear.
- Let the child sample the food that will be served.

All techniques used to prepare the child for hospitalization should emphasize the philosophy of atraumatic care. Adapt all information to the cognitive and developmental level of the child. Identify what role the child will play in the situation: It is always helpful for children to have something to do, since it shows them that they are included. A rehearsal of what will occur in the hospital allows the child to become comfortable with the situation. If time permits, provide pamphlets that describe the procedure and suggest preparation activities for the child at home before admission.

The child and family may be able to take a tour of the hospital unit or the surgical facility. Videotapes or DVDs, photographs, and books on hospitalization and surgery can serve as resources for the family and child. Many institutions offer programs to familiarize children and families with the hospital experience with a guided tour. During the tour, opportunities are provided for role playing, and during stops along the way the child can see, touch, and feel the equipment that may be used

## NURSING CARE PLAN 33.1

## Overview for the Hospitalized Child and Family

**NURSING DIAGNOSIS:** Anxiety related to hospital situation, fear of injury or bodily mutilation, separation from family or friends, changes in routine, painful procedures and treatments, and unfamiliar events and surroundings as evidenced by crying, fussing, withdrawal, or resistance

### Outcome Identification and Evaluation

Child and family will exhibit a decrease in anxiety level as evidenced by positive coping strategies, verbalization or playing out of feelings, appropriate behaviors, positive interactions with staff, child and parent cooperation and participation, and absence of signs and symptoms of increasing anxiety and fear.

### Interventions: *Minimizing Anxiety*

- Orient child and family to the unit and the child's room *to familiarize them with the facility.*
- Assess for signs and symptoms of anxiety and fear *to establish a baseline and assess effectiveness of interventions.*
- Place the child in a room with another child of a similar age, developmental level, and condition severity *to promote sharing.*
- Provide atraumatic care *to minimize exposure to distress, which would increase anxiety.*
- Explain all events, treatments, procedures, and activities to the parents and child (at a level the child can understand) in a calm, relaxed manner *to help the child prepare for what is to come and decrease fear of the unknown. A calm, relaxed manner helps to establish rapport and instill trust.*
- Enlist the aid of a child life specialist *to assist in age-appropriate preparation for all events, treatments, and procedures.*
- Encourage parents to room-in if possible *to provide the child with support; if parents cannot stay, encourage them to call to reduce child's fear of being alone.*
- Urge parents to inform the child when they will be leaving and when they are expected to return *to help child cope with their absence and promote trust.*
- Assess child's usual routine at home and attempt to incorporate aspects of usual routine into hospital routine *to ease the transition to the hospital and promote the child's participation in routine.*
- Offer comfort measures such as holding, stroking, and rocking *to relieve distress.*
- Encourage the child to play (unstructured and therapeutic play as necessary) *to allow for expression of feelings and fears and promote energy expenditure.*
- Suggest that parents bring in a special toy or object from home *to promote feelings of security.*
- Provide positive reinforcement for participation in care activities *to foster self-esteem.*
- Assess for regression behaviors and inform parents that such behaviors are common *to alleviate their concerns about this behavior.*
- Provide consistency with care measures *to facilitate trust and acceptance.*

**NURSING DIAGNOSIS:** Risk for powerlessness related to lack of control over procedures, treatments, and care, and changes in usual routine

### Outcome Identification and Evaluation

Child and family will demonstrate an increase in control over the situation as evidenced by participation in care activities, identification of needs and choices, and incorporation of appropriate aspects of child's usual routine with that of the hospital.

## NURSING CARE PLAN 33.1

**Overview for the Hospitalized Child and Family** (continued)**Interventions: Promoting Control**

- Encourage child and parents to identify areas of concern *to help determine priority needs.*
- Encourage parent and child to participate in care activities *to promote feelings of control.*
- Incorporate aspects of child's routine at home and use terms similar to those used at home *to foster a sense of normalcy.*
- Offer child choices as much as possible, such as options for foods, drinks, hygiene, activities, or clothing (if appropriate) *to promote feelings of individuality and control.*
- Allow child opportunities for being out of bed or room within limitations as appropriate *to foster independence.*
- Work with child, as age and development allow, and family to set up a schedule *to promote structure and routine.*

**NURSING DIAGNOSIS:** Deficient diversional activity related to confinement in bed or health care facility, lack of appropriate stimulation from toys or peers, limited mobility, activity restrictions, or equipment as evidenced by verbalization of boredom, lack of participation in play, reading, or schoolwork

**Outcome Identification and Evaluation**

Child will participate in diversional activities as evidenced by engagement in unstructured and therapeutic play that is developmentally appropriate and interaction with family, staff, and other children.

**Interventions: Promoting Adequate Diversional Activities**

- Question child and family about favorite types of activities *to establish a baseline for developing appropriate choices during hospitalization.*
- Assist with planning activities within the limits of the child's condition *to maintain muscle tone and strength without overexerting the child.*
- Spend time with the child *to provide stimulation and foster trust.*
- Enlist the aid of a child life specialist *to provide suggestions for appropriate activities.*
- Encourage interaction with other children *to promote sharing and avoid loneliness.*
- Provide developmentally appropriate opportunities for unstructured and therapeutic play *to facilitate expression of feelings.*
- Encourage short trips to the playroom or activity room *to provide a change of scenery and sensory stimulation.*
- Integrate play activities with nursing care *to achieve therapeutic effect.*

**NURSING DIAGNOSIS:** Interrupted family processes related to separation from child due to hospitalization, increased demands of caring for an ill child, changes in role function, and effect of hospitalization on other family members such as siblings, as evidenced by parental verbalization of issues, parental presence in hospital, or child's hospitalization requiring parent to miss work

**Outcome Identification and Evaluation**

Family will demonstrate positive coping strategies and mutual support for one another as evidenced by visiting frequently and staying with the child as necessary, sharing of family responsibilities, obtaining assistance for relief or respite, and visiting by other members of the child's family and friends.

(continued)

## NURSING CARE PLAN 33.1

## Overview for the Hospitalized Child and Family (continued)

**Interventions: Maximizing Family Functioning**

- Encourage parents and family members to verbalize concerns about child's illness, diagnosis, and prognosis *to promote family-centered care and identify areas where intervention may be needed.*
- Explain therapies, procedures, child's behaviors, and plan of care to parents *to promote understanding of the child's status and plan of care, which helps to decrease anxiety.*
- Encourage parental involvement in care *to promote feelings of the parents being needed and valued, providing them with a sense of control over their child's health.*
- Identify support system for family and child *to identify resources available for coping.*
- Educate family and child on additional resources available *to promote a wider base of support to deal with the situation.*
- Suggest ways that parents can divide time between child and other siblings *to prevent feelings of guilt.*
- Provide support and positive reinforcement *to promote family coping and foster family strength.*
- Encourage frequent visits by family members, including siblings as appropriate, *to promote ongoing family functioning.*
- Stress the need for adequate rest, sleep, exercise, and nutrition for family members *to promote family health and minimize stress of hospitalization on family.*
- Assist with referrals for resources and help from additional family members and friends as necessary *to allow for respite or relief of care responsibilities.*
- Encourage family to maintain usual routine as much as possible *to minimize the effects of hospitalization on family functioning.*

**NURSING DIAGNOSIS:** Self-care deficit related to immobility, activity restrictions, regression, or use of equipment, devices, or prescribed treatments as evidenced by inability to feed, bathe, or dress self or accomplish other activities of daily living

**Outcome Identification and Evaluation**

Child will participate in self-care within limitations of condition as evidenced by assisting with bathing and hygiene, feeding, toileting, and dressing and grooming.

**Interventions: Promoting Self-Care**

- Assess child's usual routine for self-care and self-care abilities *to provide a baseline for individualizing interventions.*
- Provide child-sized equipment and devices *to promote child's ability to complete the self-care task.*
- Encourage parents and child to do as much self-care as possible, within limitations of the child's condition and developmental level, *to promote feelings of independence and foster growth and development.*
- Offer praise and encouragement for activities performed *to foster self-esteem, confidence, and competence.*
- Ensure adequate rest periods *to minimize energy expenditure associated with self-care activities.*

**NURSING DIAGNOSIS:** Risk for delayed growth and development related to stressors associated with hospitalization, current condition or illness, separation from family, and sensory overload or sensory deprivation

**Outcome Identification and Evaluation**

Child will demonstrate developmentally appropriate milestones as evidenced by age-appropriate behaviors and activities.

## NURSING CARE PLAN 33.1

**Overview for the Hospitalized Child and Family** (continued)**Interventions: Promoting Growth and Development**

- Assess child's developmental stage *to establish a baseline and determine appropriate strategies.*
- Use unstructured and therapeutic play and adaptive toys *to promote developmental functioning.*
- Provide stimulating environment when possible *to maximize potential for growth and development.*
- Praise accomplishments and emphasize child's abilities *to foster self-esteem and encourage feelings of confidence and competence.*
- Include parents in techniques to foster growth and development *to promote feelings of control in their child's care.*

**NURSING DIAGNOSIS:** Deficient knowledge related to hospitalization, surgery, treatments, procedures, required care, and follow-up as evidenced by questioning and verbalization, lack of prior exposure

**Outcome Identification and Evaluation**

Child and family will demonstrate understanding of all aspects of child's current situation as evidenced by identification of child's and family's needs, verbal statements of understanding and/or need for additional information, return demonstration of procedures and treatments, and verbalization of instructions for follow-up and continued care.

**Interventions: Providing Child and Family Teaching**

- Assess child's and family's willingness to learn *to ensure effective teaching.*
- Provide family with time to adjust to diagnosis *to facilitate their ability to learn and participate in the child's care.*
- Repeat information *to promote multiple opportunities for child and family to learn.*
- Teach in short sessions *to prevent overloading the child and parents with information.*
- Gear teaching to appropriate level of understanding for the child and the family (depends on age of child, physical condition, memory) *to promote learning.*
- Provide reinforcement and rewards *to facilitate the teaching/learning process.*
- Use multiple modes of learning, such as written information, verbal instruction, demonstrations, and media, when possible *to facilitate learning and retention of information.*
- Provide the child and family with written step-by-step instructions for procedures or care *to provide a reference if needed at a later date.*
- Have child and family provide return demonstrations of care procedures *to ensure effectiveness of teaching.*
- Arrange for trial home care during hospitalization and after discharge as appropriate *to ensure understanding and provide opportunities for additional teaching and learning.*

(Fig. 33.2). If the tour guide notes a child or family member is really scared or concerned about something, the pediatric staff can be alerted and therefore address this issue further, leading to improved family-centered care.

The American Society of Anesthesiologists has prepared a coloring book entitled "My Trip to the Hospital"

(American Society of Anesthesiologists, 1998). This book is designed to alleviate some of the fears that younger children may have related to the hospital experience. It describes the process from admission (whether it be to the hospital or ambulatory surgery center) through discharge and includes information about preoperative

TABLE 33.1

## STRATEGIES TO REDUCE FEAR OF COMMON HOSPITALIZATION SITUATIONS

Situation	Strategies to Reduce Fear
Procedure involving intrusion into the body or use of equipment or technology	Describe the procedure and equipment in terms the child can understand. Review the steps of the procedure or steps involved with the use of the equipment. Explain what the child's role will be and what is or isn't allowed. If appropriate, have the child rehearse with the equipment or role play.
Darkness, such as with radiologic examinations or at night	Keep a light on in the examination area. Use a night light in the child's room. If possible, allow the child to hold the caregiver's or nurse's hand or a favorite toy.
Transport to other areas of the hospital	Allow caregiver to accompany child if possible. Inform the child of where he or she is going, about how long he or she will be there, and approximately when he or she will return. Introduce the child to the person who will be transporting the child.
Numerous personnel in and out of child's room	Identify all staff members working with the child (each shift and each day). Place a small board in the child's room with the name of the nurse caring for the child that shift or day. Inform the child how long the nurse will be caring for the child (adapt this information according to the child's cognitive level; for example, instead of saying that you'll be there for 8 hours, say, "I'll be your nurse until just before dinnertime" or "I'll be your nurse until you go for your test"). Say good-bye to the child when leaving for the day; tell the child about his or her new nurse; inform the child of when you will return.

**FIGURE 33.2** A child is being prepared for hospitalization by becoming familiar with some of the equipment that might be used.

testing, anesthesia, and recovery. The book also includes information for parents. A link to the book's website is listed on [thePoint](#).

Parents are instrumental in preparing children by reviewing the materials that are given, answering questions, and being truthful and supportive. Teaching Guidelines 33.1 provides suggestions for parents in preparing their child for hospitalization.

### Teaching Guidelines 33.1

#### PREPARING YOUR CHILD FOR HOSPITALIZATION

- Read stories about experiences with hospital or surgery.
- Talk about going to the hospital and what it will be like coming home.
- Be honest and encourage the child to ask questions.
- Visit the hospital and go through the preadmission tour if time permits.
- Provide support to the child via your presence, telephone calls, and special items brought from home.
- Encourage the child to draw pictures to express how he or she is feeling.
- Include siblings in the preparation.

#### Take Note!

Remember to enlist the assistance of the child life specialist, if possible, to assist with preparing children and families for hospitalization.

### Admitting the Child to the Facility

Admitting the child to the facility involves preparing him or her for admission and introducing the child to the

unit where he or she will be staying. Use the appropriate hospital forms. Chapters 2 and 30 give general information about communicating with and teaching children and families.

In today's health care environment, the admission process occurs quickly, with little time for extensive preparation; this is why preparation before admission is so important. Of course, the urgency of the child's medical condition also may limit the amount of preparation that can be done in advance.

### TYPES OF ADMISSIONS AND NURSING CARE

The hospital units to which a child may be admitted include:

- General inpatient unit
- Emergency and urgent care department
- Pediatric intensive care unit
- Outpatient or special procedures unit
- Rehabilitation unit or hospital

Regardless of the site of care, nursing care must begin by establishing a trusting, caring relationship with the child and family. Smile, introduce yourself, and give your title. Let the child and family know what will happen and what is expected of them. Ask the family and child what names they prefer to be called by. Maintain eye contact at the appropriate level. With a younger child, start with the family first so the child can see that the family trusts you. Communicate with children at age-appropriate levels.

The next step, as the child's medical condition allows, involves an orientation to the hospital unit. Briefly explain policies and routines and the personnel who will be involved in the care of the child.

During the nursing interview that follows, obtain information about the child's history, routines, and reason for admission. Obtain baseline vital signs, height and weight, and perform a physical assessment. Each health care setting has its own policies and procedures for this. Recognize the needs of the family and child during this process. If some of this information already exists, do not ask for it again, except to confirm vital information such as allergies, medications taken at home, and history of the illness. Typically, the information is collected immediately if the child's condition is urgent; otherwise, the information is collected within 8 hours, except for the information that is required for safe care.

**General Inpatient Unit Stays.** Today, general inpatient unit stays for children are shorter and involve more acute conditions, resulting in little time for admission preparation. Many times the admission procedure and treatment actually occur simultaneously. Sometimes the stay is in a special 23-hour observation unit so the child is in the setting for less than 24 hours. General hospital

stays may be in a pediatric hospital, a pediatric unit in a general hospital, or a general unit that occasionally admits children. General units often lack child-oriented services, such as play areas, child-size equipment, and staff familiar with caring for children.

### Take Note!

When a child is admitted to a general unit, take extra time to orient and explain the routines and procedures to the child and family. Emphasize that the parents can stay with the child (if institutional policy permits). If possible, place the child in a room close to the nurses' station and order food appropriate for the child's age and developmental level.

**Emergency and Urgent Care Departments.** A major cause for illness and hospitalization in children is injuries from accidents (USDHHS, 2011). Many times a family's first experience with the acute care setting is the urgent care or emergency department. Due to the situation, the child and family may experience increased anxiety, and it may become overwhelming as uncertainties develop and critical decisions must be made. The family may be frightened, insecure, and in a state of shock.

Procedures and tests are performed quickly, with minimal time for preparation. The family is often ill prepared for the visit, having little money or clothing with them. Siblings may be present if the parents did not have time to get a sitter.

Due to the fast pace of the emergency department, the family may be hesitant to ask questions, so keep the family and child well informed. Allow the family to stay with the child, provide support, and allow the family, and when appropriate the child, to participate in decisions.

Families may have a strong fear of the unknown and may be terrified that the child will die or be permanently disabled. Help the family to identify their concerns and their support systems. Prepare them for what they will experience. Provide comfort such as holding, touching, talking softly, and other appropriate interventions according to age and developmental level.

**Pediatric Intensive Care Units.** The pediatric intensive care unit (PICU) specializes in caring for children in crisis. The same principles and concepts of general care of children apply to this setting, but everything is intensified. Families will be faced with an unfamiliar, high-tech environment and a large number of staff.

Families must deal with the critical situation that brought them to the PICU. The child will likely experience pain, unusual noises, and increased stimulation and will probably undergo uncomfortable procedures. Parents may face the possibility of losing their child. Sometimes the child cannot talk, eat, or display other appropriate developmental behaviors. Sensory overload

(increased stimulation) or sensory deprivation (lack of stimulation) can affect both child and family.

Welcome families (if institutional policy permits) and encourage them to stay with the child and participate in care. Explain everything to the parents and, when appropriate, to the child. Frequently touch the child and encourage parents to provide comfort. Listen for clues about what the child and family need during the PICU stay.

**Isolation Rooms.** Isolation rooms are used for situations involving the risk for infection. When a child is admitted with an infectious disease, or to rule out an infectious disease, or if the child has impaired immune function, isolation will be instituted. Children in this setting may experience sensory deprivation due to the limited contact with others and the use of personal protective equipment such as gloves, masks, and gowns.

Encourage the family to visit often, and help them to understand the reason for the isolation and any special procedures that are required. Introduce yourself before entering the room and allow the child to view your face before applying a mask, if possible. Continue to have contact with the child and hold or touch the child often, especially if the parents are not present.

**Rehabilitation Units.** The rehabilitation unit provides care for children beyond the initial period of illness or injury. The care involves an interdisciplinary approach that assists the child to reach his or her potential and achieve developmental skills. For example, rehabilitation units help children regain abilities lost due to neurologic injuries or serious burns. The facilities often resemble a home environment, with special services to help children to relearn activities of daily living and to help them deal with the physical or mental challenges associated with the original illness or injury. Typically, families are encouraged to participate and are given support for their child's eventual return home. There is a balance of nurturing and firm discipline while the child reclaims independence.

### *Addressing the Effects of Hospitalization Developmentally*

When addressing the fears, separation anxiety, and loss of control that occur in hospitalized children, the nurse should consider the child's age and cognitive or developmental level. Interventions are then based on how the child experiences these stressors at that age or developmental level. The content, timing, setting, and method of preparation are also based on the child's age and cognitive or developmental level. General guidelines for addressing fear and anxiety, separation anxiety, and loss of control are provided in Box 33.3.

#### BOX 33.3

### **GUIDELINES TO ADDRESS THE GENERAL EFFECTS OF HOSPITALIZATION**

#### **Minimizing Fear And Anxiety**

- Prepare the child and family for hospitalization and procedures.
- Explain everything to the child and their families before it occurs (see Chapter 30).
- Use age-appropriate communication techniques. Include family members in this process so they can help the child cope with fears.
- Allow time for children to play out their fears and concerns.
- Talk to the child and parents using a soft, friendly, comforting tone of voice.
- Have a calm, empathetic approach when caring for the child.

#### **Addressing/Minimizing Separation Anxiety**

- Know the stages of separation anxiety and be able to recognize them.
- Remember that behaviors demonstrated during the first stage do not indicate that the child is "bad."
- Encourage the family to stay with the child and always use a family-centered approach to care.
- Help the child cope, and intervene before the behaviors of detachment occur.

#### **Addressing Loss Of Control**

- Minimize physical restrictions, altered routines and rituals, and dependency issues, because they produce loss of control.
- Allow as much independence as possible within the constraints of the diagnosis.
- Allow the child to participate in care and decisions regarding care whenever possible.

### **NEWBORNS AND INFANTS**

Assess the development or lack of development that is occurring in the infant, and assess the baby's attachment to the parents or primary caregivers. The infant's facial expression is the most consistent indicator of pain or bodily injury. To decrease fear and minimize separation anxiety, avoid separation from the primary caregiver if possible; this will also promote healthy attachment. If the parent or primary caregiver cannot stay with the infant, arrange for volunteers to provide consistent comfort to the baby. Maintaining the infant's home routine related to sleep and feeding helps decrease feelings of loss of control. Weigh the infant daily, at the same time, on the same scale. Monitor intake and output closely. Be alert to signs of discomfort other than crying, such as a furrowed brow or tense body posture. Additional nursing goals related to ensuring safety and promoting growth and development of the infant are presented in Table 33.2.

TABLE 33.2

### NURSING CONSIDERATIONS FOR PROVIDING SAFE, DEVELOPMENTALLY APPROPRIATE CARE

	Ensuring Safety	Promoting Healthy Growth and Development
<b>Infants</b>	<ul style="list-style-type: none"> <li>• Maintain close supervision of the infant.</li> <li>• Keep one hand on the infant when crib sides are down.</li> <li>• Keep crib rails up all the way when the infant is in the crib.</li> <li>• Avoid leaving small objects that are harmful or that can be swallowed in the crib.</li> <li>• Provide safe and appropriate toys for the infant.</li> <li>• Place infants in rooms close to the nurses' station.</li> <li>• Encourage a family member to stay with the infant at all times.</li> </ul>	<ul style="list-style-type: none"> <li>• Use the <i>en face</i> position when holding newborns.</li> <li>• Smile and talk to the infant during bathing, feeding, and other interactions.</li> <li>• Minimize the number of painful or uncomfortable procedures.</li> <li>• Provide comfort during and after procedures by holding or talking, using soothing tones and movements.</li> <li>• When handling the infant, use smooth, continuous movements.</li> <li>• Use gentle stroking and holding, which may reduce stress.</li> <li>• Serve as a role model for first-time parents.</li> <li>• Encourage the family to maintain home routines while in hospital, planning nursing care around the usual feeding and sleep times.</li> <li>• Use the pacifier between feedings to satisfy non-nutritive sucking needs.</li> </ul>
<b>Toddlers</b>	<ul style="list-style-type: none"> <li>• Keep crib side rails up with overhead crib protection intact when the toddler is in the crib.</li> <li>• Never leave a toddler alone in the room unless secured in the crib.</li> <li>• Use a bed only for the older toddler who has an adult present in the room at all times.</li> <li>• Avoid leaving small objects that can be swallowed or are harmful in the crib or bed.</li> <li>• Place crib out of reach of cords, equipment, and electrical outlets.</li> <li>• Provide safe and appropriate toys for the toddler.</li> <li>• Place toddlers in rooms close to the nurses' station.</li> <li>• Always have someone with the toddler when ambulating.</li> </ul>	<ul style="list-style-type: none"> <li>• Encourage the parent to stay with the toddler to decrease separation anxiety.</li> <li>• To promote autonomy, allow the toddler to make appropriate choices, such as which juice to take the medicine with.</li> <li>• Encourage active play in the playroom or with push/pull toys in the hallway (accompanied by an adult).</li> <li>• Expect and plan for regression in areas of toilet training, eating, and other behaviors.</li> <li>• Expect increased temper tantrums in general and intense reactions to intrusive procedures.</li> <li>• Maintain home routine while in hospital, planning nursing care around the usual feeding and sleep times.</li> <li>• Give simple directions with choices appropriate to the hospital situation.</li> <li>• Provide close supervision while encouraging independence.</li> </ul>
<b>Preschoolers</b>	<ul style="list-style-type: none"> <li>• Keep bed in low position with the side rails up when the preschooler is in the bed.</li> <li>• Instruct the child to call the nurse or caregiver for help getting out of bed.</li> <li>• Keep harmful objects out of reach of the child.</li> </ul>	<ul style="list-style-type: none"> <li>• Encourage parents to stay with the preschooler in the room as well as other areas of the hospital.</li> <li>• Encourage the preschooler to be involved in care by providing choices and opportunities for the child to help.</li> <li>• Use play as an opportunity to work through the preschooler's fears.</li> <li>• Explain activities in simple, concrete terms, being cautious with the words you use because of the preschooler's fantasies and magical thinking.</li> <li>• Expect reactions to pain and bodily injury to be verbally aggressive and specific.</li> <li>• Try to maintain home routines while the child is in the hospital, working them into the plan of care when possible.</li> </ul>

(continued)

TABLE 33.2

**NURSING CONSIDERATIONS FOR PROVIDING SAFE, DEVELOPMENTALLY APPROPRIATE CARE** (continued)

	Ensuring Safety	Promoting Healthy Growth and Development
<b>School-age children</b>	<ul style="list-style-type: none"> <li>Keep the bed in the low position with the side rails up while the child is in the bed, explaining that this is a hospital rule, not a punishment.</li> </ul>	<ul style="list-style-type: none"> <li>Provide opportunities for the child to be involved in care.</li> <li>Allow children to select their meals, assist with treatments, and keep their rooms neat.</li> <li>Allow visits with other children if condition allows.</li> <li>Encourage parents to tell the child when they will return.</li> <li>Plan care around the child's usual home routines (meals, sleep).</li> <li>Encourage the child to do schoolwork.</li> </ul>
<b>Adolescents</b>	<ul style="list-style-type: none"> <li>Be aware of the adolescent's whereabouts. The teen may not wish to stay in the room but may become confused about where the room or unit is located in the hospital.</li> </ul>	<ul style="list-style-type: none"> <li>Allow teens to interact with others.</li> <li>Alter hospital routines as possible to allow the teen to sleep in or stay up later at night.</li> <li>Provide others close to their age as roommates.</li> <li>Encourage visits from friends.</li> <li>Provide emotional support for feelings of being alone or away from friends; be alert for regression, which may result in the teen becoming emotional.</li> <li>Answer questions honestly and with appropriate information.</li> <li>Give the teen a sense of control by allowing choices.</li> <li>Be sensitive to concerns about being "different."</li> </ul>

### TODDLERS

Key nursing concerns when caring for toddlers are separation anxiety, growth and development, and autonomy. Establishing a trusting relationship with the toddler through nonthreatening play may decrease the amount of fear the toddler feels. Be alert to subtle, nonverbal indicators of grief or discontent.

Encourage the parent or primary caregiver to stay with the toddler in the hospital to decrease separation anxiety. Maintaining the home routine related to meals and sleep or a nap provides structure and may help decrease the toddler's feelings of loss of control. If indicated, weigh the toddler daily. Closely monitor intake and output. Refer to Table 33.2 for additional nursing considerations related to ensuring safety and promoting growth and development in the hospitalized toddler.

### PRESCHOOLERS

Nursing care for hospitalized preschoolers focuses on their special needs, fears, and fantasies. When working with preschoolers, remember that they use magical

thinking and fantasy. Be honest and specific, providing information just prior to the intervention to allay the child's fears. As with toddlers, encouraging parental involvement may decrease the amount of separation anxiety the preschooler experiences while in the hospital. Allowing the preschooler to make simple decisions such as which color bandage to use or whether to take medicine from a cup or syringe helps the child to feel some sense of control. Table 33.2 gives specific nursing considerations related to ensuring safety and promoting growth and development for the preschooler in the hospital.

### SCHOOL-AGE CHILDREN

Provide honest information using concrete, meaningful words to the school-age child to minimize fear of the unknown. School-age children are still very attached to their parents, so encouraging parental involvement or rooming-in decreases separation anxiety. Involve the child in making simple decisions and planning the schedule as appropriate to give him or her a sense of control. Nursing considerations when caring for hospitalized school-age

children include ensuring safety and promoting growth and development (see Table 33.2).

### ADOLESCENTS

The adolescent may or may not express fears. Educate the teen honestly; younger teens require more concrete explanations, while older teens can process more abstract concepts. Respect the teen's need for privacy. Encourage visits from the adolescent's friends to minimize anxiety related to separation. Prepare a mutually agreeable schedule with the teen, as appropriate, that includes the teen's preferences while incorporating the required nursing care. Collaborating with the adolescent will provide the teen with increased control. Refer to Table 33.2 for additional nursing considerations related to care of the adolescent in the hospital.

*Think back to Jake, the 8-year-old from the beginning of the chapter. Discuss nursing care you could provide that will help minimize stressors.*

### Preparing the Child and Family for Surgery

If the child is to undergo a surgical procedure, whether in the hospital or an outpatient setting, special interventions are necessary. The parents should be allowed to stay with the child until surgery begins. Parents should also be allowed to be with the child when he or she wakes up in the post-anesthesia recovery area. Good

preparation provides reassurance and comfort to the child and allows him or her to know what will happen and what is expected of him or her.

Preoperative care for the child who is to undergo surgery is similar to that for an adult. The major difference is that the preparation and teaching must be geared to the child's age and developmental level. Table 33.3 discusses strategies for preoperative teaching. Many facilities offer special programs to help prepare children and families for the surgical experience. Presurgical preparation programs allow children and their families to experience a "trial run" in a supportive environment to reduce anxiety, increase knowledge, and enhance coping skills (Durani, 2011). Books, including the one cited earlier by the American Society of Anesthesiologists, are helpful in preparing the child and family.

Child and family teaching is essential. Like any intervention, adapt the teaching to the child's developmental level. For example, when teaching a toddler or preschooler about breathing exercises, have the child blow a pinwheel or cotton balls across the table through a straw. The child will enjoy the activity while also reaping the respiratory benefits of the activity.

In preparation for surgery, use items such as stuffed animals or dolls to help children understand what is going to happen to them (Fig. 33.3). Allow the child to role-play various experiences with dolls. Dolls designed to simulate surgical experiences have been developed. For example, Shadow Buddies are custom-made dolls that have the same illness or surgery as the child; the doll may have an ostomy, scar, or catheter (Shadow Buddies Foundation, n.d.). The dolls were developed to

**TABLE 33.3** STRATEGIES FOR PREOPERATIVE TEACHING

Developmental Level	Implications for Teaching
Infants and toddlers	<ul style="list-style-type: none"> <li>Encourage parents to use a soft tone of voice and stroking and secure, comfortable holding positions to promote calm.</li> <li>Remind parents to use positive facial expressions.</li> <li>Encourage the parent or caregiver to stay with the child as much as possible.</li> <li>Use terms that the child and parents can understand.</li> <li>For toddlers, provide information as close to the day of surgery as possible to prevent undue anxiety.</li> </ul>
Preschoolers and school-age children	<ul style="list-style-type: none"> <li>Provide factual explanations using terms the child and parents can understand.</li> <li>Incorporate pictures and other visual aids in explanation.</li> <li>Tailor the timing of education to meet the child's learning needs, allowing enough time for the child to ask questions. For preschoolers, provide information 1 to 2 days before surgery. For school-age, provide information 3 to 5 days before surgery.</li> </ul>
Adolescents	<ul style="list-style-type: none"> <li>Provide detailed explanations of the procedure at least 7 to 10 days beforehand.</li> <li>Answer questions honestly, ensuring privacy at all times.</li> <li>Remain available for questions or concerns arising before or after surgery.</li> </ul>

**FIGURE 33.3** Using a stuffed animal to explain a surgical procedure to the child.

help children cope with their illness or disease and send the message that it is okay to be different. These dolls also provide the child with a companion to talk to. Visit [thePoint](#) for a link to the Shadow Buddies website.

### Maintaining Safety During Hospitalization

Safety is a critical aspect of care of the child in the hospital. Due to their age and developmental level, children are vulnerable to harm. Ensure the child has an identification band in place at all times. Sometimes in implementing interventions an armband is removed, so make sure it is attached to another extremity. Monitor children closely to avoid accidents such as a child pushing the wrong knob, picking up a piece of equipment or supplies left in the bed or room, or climbing out of bed (Fig. 33.4). See Table 33.2, which highlights nursing goals for ensuring safe, developmentally appropriate care for the hospitalized child.

**FIGURE 33.4** Safety is an essential aspect of pediatric nursing. A clear plastic cover over the crib prevents the older infant or toddler from climbing out and falling.

### USE OF RESTRAINTS

When caring for children, some type of restriction may be necessary. The restriction, often referred to as a restraint, may be needed to ensure the child's safety, allow a therapeutic or diagnostic procedure to be done, immobilize a body part or limit movement, or prevent disruption of prescribed therapy. However, restraints can be overused and can cause harm (Joint Commission Resources, 2008). As a result, each facility will have specific procedures and policies in place related to the use of restraints based on standards developed from the Joint Commission regulations developed by the Centers for Medicare and Medicaid Services (CMS), state law, and facility requirements (Joint Commission Resources, 2008). These procedures and policies are designed to safeguard children's physical safety and psychological well-being.

According to these standards, hospitals are required to have a policy in place that specifies the following (Disability Rights California, 2008; Joint Commission Resources, 2008; Department of Health & Human Services, Centers for Medicare & Medicaid Services [DHHS-CMS], 2008):

- Reason for the restraint
- Client assessment parameters identifying the need for the restraint
- Use of at least one alternative method for restriction before using a restraint
- Use of the least restrictive type of restraint for the purpose after the decision is made that a restraint is necessary
- Need for a written order by a licensed independent practitioner (LIP) within 1 hour of application of the restraint
- Need for face-to-face evaluation by LIP within 1 hour of application of the restraint

In addition, the JCAHO standards and CMS regulations also identify the need for specific staff training and frequent assessment and appropriate discontinuation of use.

#### Take Note!

Always refer to your institution's policy regarding restraint use.

Restraints can promote physical distress in a child and be stressful for the parents as well. Children also may view restraints as punishment. Before a restraint is used, other measures need to be tried (Joint Commission Resources, 2008).

#### Take Note!

When deciding whether it is necessary to restrain a child, consider the child's age, developmental level, mental status, and threat to others and self.

Explain why the child should not touch the intravenous site or should maintain a certain position so that

he or she has a basic understanding of what is necessary. This may be all that is necessary for an older child. One-to-one supervision and behavior modification techniques may be other alternatives to the use of restraints.

Therapeutic hugging should be used for procedures and treatments, such as IV insertion, where the child needs to remain still. Refer to Chapter 30 for further information.

If it is determined that a restraint is needed, select the most appropriate, least restrictive type of restraint (Disability Rights California, 2008). For example, if the child has an intravenous catheter in the antecubital space that stops flowing when the child bends the arm, an elbow restraint or arm board, rather than a soft wrist restraint or four-point extremity restraint, would be appropriate. Table 33.4 lists the types of restraints and the major issues associated with the use of restraints in children.

**Take Note!**

When selecting a restraint, the nurse must choose the least restrictive type and apply it for the shortest time necessary (DHHS-CMS, 2008).

Before applying a restraint, explain the reason for the restraint to the child and the parents. Emphasize that

the rationale is to maintain the child's safety; the restraint is not punishment. Having the child and parents state the reason for the restraint demonstrates their understanding.

A written order for the restraint and an evaluation of the child by a LIP must occur within 1 hour of applying the restraint (DHHS-CMS, 2008). In addition, the nurse must do the following:

- Ensure that the restraint fits properly.
- Secure the restraints with ties to the bed or crib frame, not the side rails.
- Use a clove-hitch type of knot to secure the restraints with ties (this allows for quick, easy access and release of the restraint).
- Check restraints 15 minutes following initial placement and then every hour for proper placement.
- Assess the temperature of the affected extremities, pulses, and capillary refill, initially after 15 minutes and then every hour after placement.
- Remove the restraint every 2 hours to allow for range of motion and repositioning, with documentation of this process and any findings.
- Encourage parent participation, providing continuous explanations about the reasons for the restraints and tentative time frame for use.

**TABLE 33.4** TYPES OF RESTRAINTS AND ASSOCIATED SAFETY CONCERNS

Type of Restraint	Purpose	Safety Concerns
<p>Soft limb restraint</p> 	<p>Wrist or ankle restraint to prevent range of motion of extremities</p>	<p>Check wrist or ankle for any sign of circulatory, integumentary, or neurologic compromise.</p>
<p>Elbow restraint</p> 	<p>Prevents child from flexing and reaching face, head, IV and other tubes</p>	<p>Position the restraint so it does not rub against axilla. Check pulse, temperature, and capillary refill of the extremity.</p>

(continued)

TABLE 33.4

TYPES OF RESTRAINTS AND ASSOCIATED SAFETY CONCERNS (continued)

Type of Restraint	Purpose	Safety Concerns
<p>Mummy restraint</p> 	<p>Body restraint using a sheet folded in a square appropriate to size of infant or young child to secure the whole body of the child or every extremity except for one</p> 	<p>Ensure that all extremities are secured within the sheet.</p>
<p>Jacket (vest) restraint</p> 	<p>Jacket worn by child with ties attached to the child's back and to side of bed. Used to keep children flat in bed, such as after surgery, or safe in chair.</p>	<p>Ensure the child can turn head to side and that the head of the bed is elevated, if possible. Place ties in back so child cannot manipulate them.</p>
<p>Crib top bubble restraint</p> 	<p>Clear plastic cover over the bed to prevent older infant or young child from falling and climbing out of bed</p>	<p>Ensure that there are no tears or loose plastic.</p>

- Offer positive reinforcement to the child and parents.
- Review the criteria for removing the restraints; document removal and continued assessment.

It is important the nurse is familiar with federal standards and regulations and should always follow facility policy and procedures.

### TRANSPORT OF THE CHILD

Children may need to be transported to other units for diagnostic tests or surgery, to different areas in the same unit, such as the playroom or treatment room, or for discharge. When the child is transported to other areas, specific guidelines need to address safety issues, the age and developmental level of the child, the child's physical condition, and the destination. These factors need to be considered before transport so that the appropriate method can be used with the least amount of risk for the child. Various methods to transport children include carrying the infant and using strollers, wagons, or rolling beds (Fig. 33.5). If possible, the parents should accompany the child to offer support and comfort.

When carrying an infant, good support of the back and head is vital. Rails should be up on all beds and wagons. Use safety belts with strollers and wheelchairs.

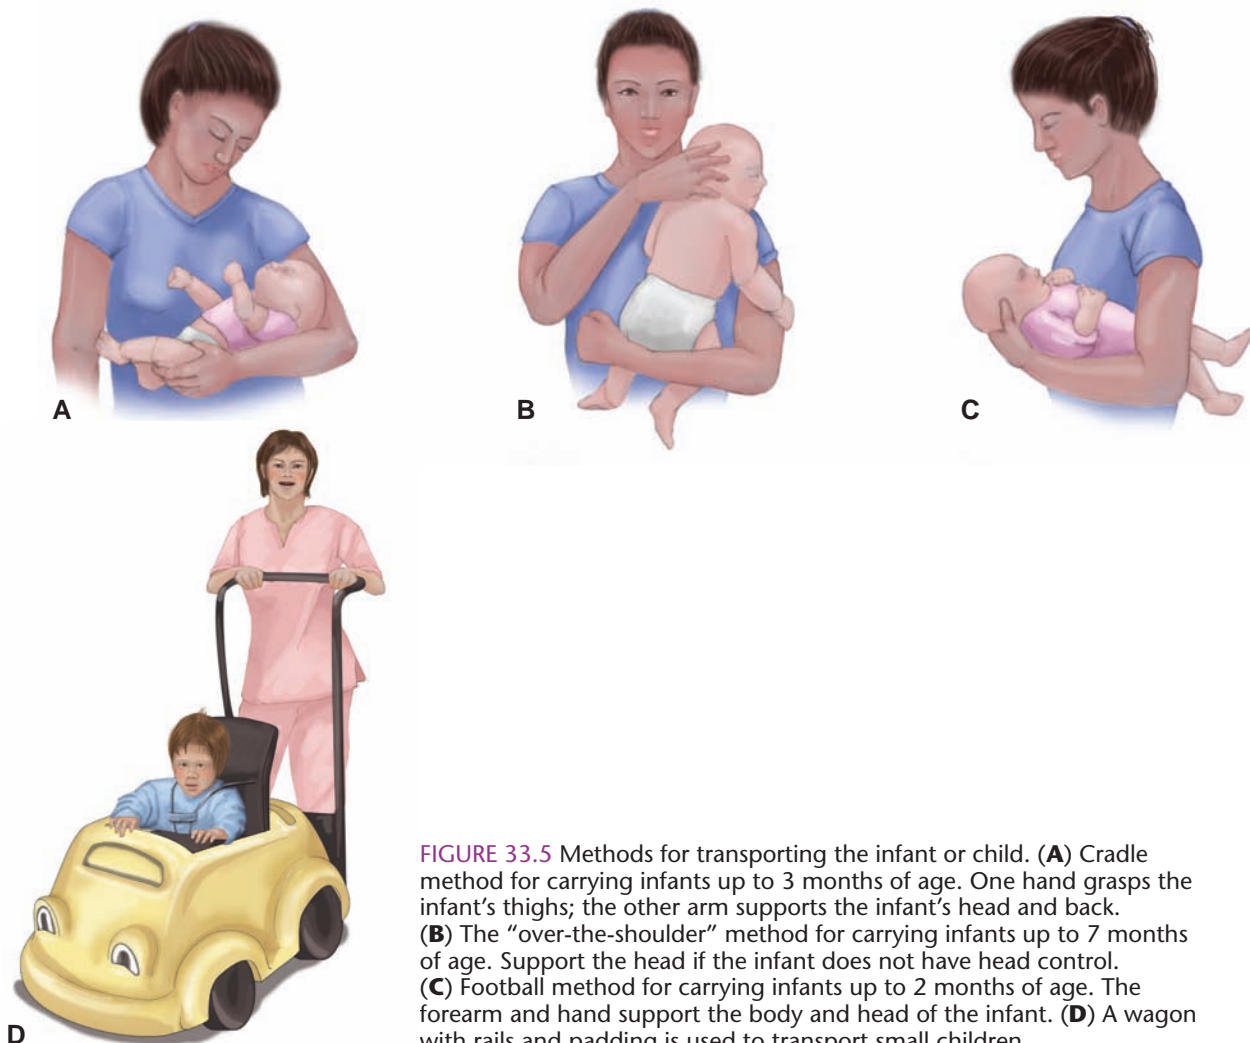

#### Take Note!

Never leave a child unattended during transport. Keep the child visible at all times during the transport.

### Providing Basic Care for the Hospitalized Child

Basic care involves general hygiene measures, including bathing, hair care, oral care, and nutritional care. Young children are dependent on an adult for most, if not all, of their self-care needs. If parents are present, allow them to provide care for the child to decrease the child's stress. Make sure to provide assistance and support as needed. Older children may perform hygiene measures themselves but may need some assistance from the nurse.

**FIGURE 33.5** Methods for transporting the infant or child. **(A)** Cradle method for carrying infants up to 3 months of age. One hand grasps the infant's thighs; the other arm supports the infant's head and back. **(B)** The "over-the-shoulder" method for carrying infants up to 7 months of age. Support the head if the infant does not have head control. **(C)** Football method for carrying infants up to 2 months of age. The forearm and hand support the body and head of the infant. **(D)** A wagon with rails and padding is used to transport small children.

## GENERAL HYGIENE MEASURES

General hygiene measures help to maintain healthy skin, hair, and teeth. Skin is a complex structure; its primary function is to protect the tissues that it encloses and to protect itself. Injury to the child's skin may occur when inserting and maintaining an intravenous line, removing a dressing, positioning a child in bed, changing a diaper, using and removing electrode patches, and maintaining restraints. Risk factors for problems include impaired mobility, protein malnutrition, edema, incontinence, sensory loss, anemia, and infection. A good time to assess the skin is during bath time.

**Bathing.** Bathing infants and children is a common daily hygiene measure in the health care environment. Although the parents or primary caregiver often does this in today's family-centered environment, the nurse is still responsible for ensuring that bathing is done safely and hygienically. Adhere to safety principles to prevent falls, burns, and aspiration of water. Never leave a child alone in a bathtub. Use a gentle, pH-balanced soap with moisturizer if there is a need to rehydrate the skin. Note any condition that might require special considerations or further assessment, such as paralysis, loss of sensation, surgical incisions, skin traction/cast, external lines (intravenous lines, urinary catheters, or feeding tubes), or other alterations in skin integrity. Pay close attention to the ears, between skinfolds, the neck, the back, and the genital area for alterations in skin integrity. Table 33.5 highlights specific developmental considerations for bathing.

Before bathing and performing other hygiene measures, assess the family's preferences and home practices for the child, such as time of day, rituals, special

equipment, and allergies to products. This is a good time to assess the amount of assistance that might be required by the parents and to address learning needs related to hygiene. Follow general guidelines in bathing any client with regard to equipment, room temperature, privacy, and use of products such as deodorant and lotion.

**Hair Care.** Lying in bed can make the hair matted and tangled. Avoid pulling on the child's hair when combing or brushing it. If necessary, use commercial detangling solutions to ease combing.

If the hair requires washing, this is often done during the daily bath for infants. Typically, shampooing once or twice a week is sufficient for younger children. Adolescents may need more frequent shampooing due to the increase in sebaceous gland secretion. The frequency of shampooing also varies based on the child's condition; for example, if the child has experienced diaphoresis, more frequent shampooing may be indicated.

Shampooing may be done at the bedside with specially adapted equipment, at a readily accessible sink while the child is sitting in a chair or lying on a stretcher, or in a tub or shower. Commercial no-rinse shampoos may be available for use. With these products, the shampoo is applied to the hair and then brushed or combed out.

If the child uses a tub or shower for hair care, monitor the child's safety throughout to ensure that the child does not slip and fall due to the slippery surface or is burned because of improper water temperature.

The child's ethnicity may require special measures for hair care. For example, a child of African American descent may use a broad-toothed comb for hair care. Ask the child's parents to bring one from home if one is not available. Also ask the child and parents about any products used on the hair to make it easier to handle; the parents can bring some from home. Encourage the parents to help with braiding or plaiting of the hair if desired.

TABLE 33.5

### DEVELOPMENTAL CONSIDERATIONS FOR BATHING

Age of Child	Special Considerations
Infants	Use a sponge bath or tub bath to bathe young infants who cannot sit unaided. Support the infant's body at all times. Ensure appropriate water temperature. Avoid use of talcum powder.
Toddlers	Bathe older infants and toddlers at the bedside or in a regular bathtub, depending on their health condition.
School-age children and adolescents	Older children may prefer a shower if available and acceptable for their health condition. Assess whether a shower would be safe. Provide privacy.

#### Take Note!

The hair of African Americans typically is easier to comb when wet, so if possible comb the child's hair soon after shampooing (Connecticut Department of Children and Families, 2008).

**Oral Hygiene.** Oral hygiene is an important part of basic care. Wipe the infant's gums with a wet cloth after each feeding. Assist children in brushing and flossing their teeth after each feeding or meal and before bedtime. The child who is immunosuppressed needs special attention to oral hygiene, such as using soft toothbrushes and moistened gauze sponges to prevent bleeding and careful inspection of the oral cavity for areas of breakdown.

## NUTRITIONAL CARE

Adequate nutrition is necessary for growth and development and tissue repair, so it is an essential component of care for the ill or hospitalized child.

Frequently, the ill or hospitalized child experiences a loss of appetite, which can affect the child's nutritional status. This may be compounded by other problems such as nausea and vomiting and NPO restrictions for testing or surgery. The hospitalized child may adopt feeding habits that do not fit their age or stage of development, such as use of a bottle in an older infant/child or a child capable of self-feeding may want to be fed. Readaptation of these feeding habits should be accommodated when possible.

### Take Note!

Relieve pain and nausea before meals are served.

If possible, schedule procedures or treatments away from mealtimes. In younger children, refusing to eat may be related to the child's feeling of separation; in others, refusing to eat may reflect the child's attempt to control the situation. Encourage parents to use gentle persuasion instead of force to assist with intake. The use of force can lead to an aversion for food that carries beyond the hospital stay into the home environment. They should give the child choices about what to eat; this reinforces the child's sense of control. Remind parents that the child's appetite will probably improve as his or her condition improves. Teaching Guidelines 33.2 provides tips for promoting nutrition in the hospitalized child. Although geared to parents, nurses also can incorporate these guidelines into the child's plan of care.

### Teaching Guidelines 33.2

#### PROMOTING NUTRITION FOR YOUR HOSPITALIZED CHILD

- Check with the nurse about any restrictions related to your child's diet. Find out if intake and output are being monitored.
- Encourage your child to eat his or her favorite foods.
- Assist your child with eating or drinking as necessary; be present at mealtimes to promote socialization.
- Frequently offer small cups of fluid and finger foods; avoid giving large quantities at one time.
- Try offering fluids at different temperatures at different times for variety.
- Remember that children can ingest greater amounts of thin liquids (e.g., gelatin or carbonated drinks) than thicker liquids (e.g., cream soups or milkshakes).
- Include ice chips as fluid intake. Ice is approximately equivalent to half the same amount of water (e.g., 1 cup of ice equals 1/2 cup of water).
- Use straws (unless not allowed) and brightly colored utensils, cups, or dishes to provide contrast and stimulation.
- Offer the child choices; allow the child to choose what he or she wants from the menu.
- Avoid spicy or highly seasoned foods.

- Talk with the dietitian to see if any special preferences can be addressed.
- Offer praise to your child for what he or she eats or drinks.
- Never punish the child for not eating or drinking.
- Encourage the older child to help keep track of what he or she eats and drinks.

### Providing Play, Activities, and Recreation for the Hospitalized Child

Play is an important component in the child's plan of care. Today many health care settings providing care for children have playrooms with age-appropriate toys, equipment, and other creative activities (Fig. 33.6). If the facility is large enough, there may even be a separate area for teens where they can listen to music, play video games, and visit with peers.

### Take Note!

Avoid using the term "playroom" when caring for older school-age children and adolescents. Instead, call it the "activity room" or "social room." Doing so promotes a greater feeling of maturity and makes it more likely that they will use the area.

**FIGURE 33.6** Children occupied in a hospital playroom. It is important to provide age-appropriate activities for younger and older children alike.

Obviously, some children will not be able to use these facilities if their activity level is restricted or if isolation is necessary. Children may also play in their rooms. Ensure that opportunities for unstructured play are provided to all children who can engage in play. Therapeutic play may be used to teach children about their health status or to allow them to work through issues in their lives.

### Take Note!

Keep the bed or crib and playroom as “safe” places. Perform invasive procedures such as venipunctures in the treatment room if possible. Never perform any nursing interventions in the playroom, no matter how nonthreatening they may appear to the nurse (Leahy et al., 2008).

The nurse’s greatest ally in the hospital in relation to atraumatic care is the child life specialist (CLS). This person not only prepares the child for procedures, but also provides activities and events to encourage play and normal growth and development.

### UNSTRUCTURED PLAY

Unstructured play allows children to control events, ideas, and relationships. Encourage parents to bring small toys and favorite stuffed animals from home to make the child feel more comfortable in the strange environment of the hospital. Children also enjoy receiving small new toys as surprises when they are hospitalized. Many children enjoy diversional activities such as playing board games or electronic games, reading books, and watching TV, videos, or DVDs. Quiet activities appropriate to the child’s developmental level provide the opportunity for play and encourage the use and development of fine motor skills even if the child is confined to bed. Infants and toddlers enjoy manipulating blocks and playing with stacking toys. The preschooler may enjoy coloring, dollhouses, or playing with plastic building blocks such as Legos. School-age children and adolescents may enjoy playing video games or building a model geared toward their developmental level.

### PLAY AS PART OF NURSING CARE

Play is also an important part of nursing care. Use play as appropriate while providing routine nursing care to the child. An example of the use of play in nursing care involves the school-age child’s love of competition and games. To increase range of motion in a school-age child who is hospitalized for traction due to a fracture, have the child throw a soft sponge ball or beanbag ball into a hoop, and compete against the child. To increase deep breathing, encourage the child to blow bubbles or blow a whistle. To increase intake of fluids, help the child create a graph to chart the number of glasses of fluids he or she drinks over a period of time. Award the child a sticker, baseball card, special pencil, or other small item if he or she reaches a certain level.

When using play as part of nursing care, it is important to evaluate the outcome of play. Play used in the manner described above should enhance the child’s outcome. For example, for the child blowing bubbles, determine whether this activity enhanced coughing and deep breathing.

### THERAPEUTIC PLAY

Another important aspect of play is therapeutic play. **Therapeutic play** is nondirected and focuses on helping the child cope with feelings and fears. Health care professionals use therapeutic play to help the child deal with the physical and psychological challenges of illness and hospitalization. Supervised play with medical equipment in the hospital environment can help children work through their feelings about what has happened to them (Fig. 33.7). In a large hospital or a children’s hospital, the CLS typically coordinates these activities. Goals include maintaining normal living patterns, minimizing psychological trauma, and promoting optimal development of the child. If a CLS is not available, the nurse provides this type of activity. There is a greater emphasis on the developmental and psychosocial implications of illness and hospitalization and validation of the child’s voice.

In emotional outlet play or traumatic play, the child acts out or dramatizes real-life stressors. For example, using a wooden hammer and pegs, a soft sponge ball, or boxing gloves can allow the child to express anger over separation from family and friends. Commercial toys such as anatomically correct dolls and puppets have removable parts so children can see various organs of the body. Sometimes younger children “talk” to puppets and dolls, allowing them to express their feelings to a nonthreatening “person” about a specific situation or what they want from the health care provider. For example, the Shadow Buddies dolls mentioned earlier in the chapter provide a way of coping with a specific

**FIGURE 33.7** The nurse supervises play with medical equipment to help the child work through her feelings about being hospitalized.

condition. The company creates an ostomy buddy who has a stoma, a cancer buddy with thinning hair and a chest catheter for chemotherapy treatments, and a heart buddy who has a chest incision and a repaired heart (Shadow Buddies Foundation, n.d.).

Other types of therapeutic play include drawing and supervised “needle play.” Drawing is a way for the child to express his or her thoughts and feelings. Supervised “needle play” assists children who must undergo frequent blood work, injections, or intravenous procedures. A doll can receive an injection as the child works out his or her anger and anxiety. Keep in mind safety and the child’s growth and developmental level before planning this type of directed play; an adult must always be present.

### **Promoting Schoolwork and Education During Hospitalization**

Promote schoolwork while the child is in the hospital. Determine the amount of schoolwork that can be done by assessing the child’s condition, the availability of teachers, and the family situation. Many children’s hospitals have teachers at the hospitals; there may be classrooms too. These teachers work closely with the child’s school to continue schoolwork as the child’s condition permits. Hospitals without an educational staff will rely on parents to coordinate with the child’s school. Parents may bring in schoolbooks and the child’s homework for completion while in the hospital. This connection to the child’s school helps maintain normalcy for the child and minimizes the disruption of everyday life.

### **Addressing the Needs of Family Members**

Assess the factors that may influence the family’s reaction to the child’s hospitalization and plan the care of the child to accommodate some of these issues. Encourage families to have support systems in place before, during, and after hospitalization. The practice of family-centered care, including good communication and ensuring nursing actions address the child’s and family’s needs and preferences, increase their overall satisfaction with the health care setting (American Academy of Pediatrics, Committee on Hospital Care, Institute for Family-Centered Care, 2012).

#### **PARENTS AND CAREGIVERS**

As stated previously, the anxiety level of caregivers greatly affects the anxiety level of the child. Thus, it is important to help the family members work through their feelings. Parents experience many emotions when a child is hospitalized, including disbelief, anger, guilt, fear, anxiety, frustration, and depression. Visiting restrictions, unexpected changes in the child’s health status, lack of information or understanding of their child’s health condition, changes in their routine and roles, financial stress,

and feelings of being undervalued in the care of their child all contribute to their feelings.

The importance of family involvement to the well-being of the child is reflected in the philosophies, policies, procedures, and physical environments where care is delivered. The philosophy of family-centered care places the family at the core of care. The family is the primary and continuing provider of care for the child. Encourage parents to room-in with the child throughout the hospital stay, if possible. Facilities can be designed to welcome family participation. For example, having computer ports and fax machines available and providing extra meals and beds for the parents can encourage parents to participate in care. View the parents as vital members of the health care team and partners in the care of the ill child.

#### **SIBLINGS**

Family-centered care recognizes the need to treat the child in context of the family, including siblings. Important questions that will affect how siblings deal with the hospitalization of their brother or sister include:

- Was the admission an emergency?
- Were there previous admissions, and how did the siblings perceive those hospitalizations?
- How serious is the illness or trauma?
- Is the prognosis known?

Address the sibling’s possible feelings of guilt. Use educational materials, allow time for visits, send photographs back and forth between siblings, and allow siblings to talk on the phone.

### **Providing Child and Family Teaching**

Not all experiences with hospitalization are negative; in fact, the experience may enhance the child’s and family’s coping skills, bolster self-esteem, and provide new socialization experiences. It may allow the child to master self-care skills and provide an opportunity for the child and family to learn new information. Parents may learn more about their child’s growth and development skills as well as additional parenting or caregiving skills, resulting in improved parenting abilities. In addition, the child’s overall health may be improved because of the hospital stay if the child receives current immunizations and the parents learn more about health care practices.

The overall goals of child and family teaching are to minimize the child’s and family’s stress, educate them about treatment and nursing care in the hospital, and ensure the family can provide appropriate care at home upon discharge. Providing support before, during, and after hospitalization may minimize stress. Preadmission programs can introduce the child and family to the setting. During the hospital stay, forming partnerships with the child and family, using strategies to promote coping,

and providing appropriate preparation for procedures, tests, and surgery serve to decrease stress.

Assess the child's and family's knowledge of the illness and hospital experience. This provides a baseline for teaching. Include hospital rules in child and family teaching. Behavioral changes in hospitalized children often disturb parents or caregivers. Determine the child's usual patterns of behavior and explain to the parents about the child's reaction to hospitalization. Encourage the family to maintain consistent discipline even while in the hospital to provide structure for the child as well as to prevent discipline issues after discharge. Also discuss how siblings may react to the hospitalization, and provide appropriate teaching to the siblings. Every interaction the nurse has with the child or family provides an opportunity for teaching. Explain the purpose of even simple procedures such as vital signs assessment to the child and family. Provide ongoing information about the child's illness or trauma, treatment plan, and expected outcomes. Chapter 2 provides general principles related to teaching children and their families; Chapter 30 provides specific teaching tips for children of all ages.

### Preparing the Child and Family for Discharge

Discharge planning actually begins upon admission. The nurse assesses the family's resources and knowledge level to determine what education and referrals they may need. Upon discharge, children and their parents or caregivers receive written instructions about home care, and a copy is retained in the medical record. These instructions are individualized for the child. Generally, discharge instructions should include:

- Follow-up appointment information
- Guidelines about when to contact the physician or nurse practitioner (e.g., new or worsening symptoms or indications that the child is not improving)
- Diet
- Activity level allowed
- Medications, including dose, times to be given, route, adverse effects, and special instructions; any prescriptions should be included
- Information on additional treatments the child requires at home
- Specific dates for when the child may return to school or daycare
- Names and phone numbers of agencies the family has been referred to, such as durable medical equipment providers

Provide and review educational booklets that give basic health information or general care for a child with a particular disease (Fig. 33.8). Videotapes, DVDs, or CD-ROMs may also be used if available. The ability to watch a procedure over and over is helpful to some families.

**FIGURE 33.8** The nurse uses charts with pictures to perform client teaching before the child goes home.

Explain, demonstrate, and request a return demonstration of any treatments or procedures to be done at home. Provide a written schedule if the child is to receive multiple medications, tube feedings, or other medical treatments. For complicated cases, a written teaching plan may be used to provide continuity of child/family education between various nurses. As the family attempts to perform each task, document whether the caregiver continues to require assistance or prompting with the task or whether he or she can perform the task independently.

Parents of children with multiple medical needs may benefit from a trial period of home care. This occurs while the child is still in the hospital, but the parents or caregivers provide all of the care that the child requires. Support the family and praise their accomplishments during this trial period.

## COMMUNITY CARE IN CHILDHOOD

*Remember Jake Jorgenson, the boy with the suspected brain tumor from the beginning of the chapter. After a long hospital stay and complications resulting from his brain tumor, Jake requires intermittent gastrostomy feedings and has frequent respiratory infections. He has been receiving nursing care at home along with therapies but is now ready to make the transition to the local elementary school.*

Children receive most of their health care, well and ill care, in the community setting. Nurses play an important role in the health and wellness of a community. They not only meet the health care needs of individuals but go beyond to create interventions that affect the community as a whole. *Community health nursing* refers to

nursing care that strives to improve the health of a specific community as a whole. For example, community health nurses working in the Department of Health and Human Services would strive to make sure that all children in their particular community were up-to-date on immunizations. *Community-based nursing* focuses more on providing care to the individual or family (which, of course, impacts the community) in settings outside of acute care. For example, a community-based nurse would work in the local public school to care for students' health needs. Nurses practicing in the community promote the health of individuals, families, groups, communities, and populations and promote an environment that supports health. See Chapter 2 for more information on Community Health and Community-Based Nursing. The following section focuses on community-based settings where nurses commonly care for children.

## Community-Based Nursing Settings

Community-based pediatric nursing takes place in a variety of settings, including outpatient and ambulatory care settings, physician's offices, clinics, health departments, urgent care centers, schools, camps, churches, shelters, and clients' homes. Community-based nurses provide well care, episodic ill care, and chronic care. They work to promote, preserve, and improve the health of children and families in these settings.

### Outpatient and Ambulatory Care

Outpatient and ambulatory care is health care provided to individuals who do not require care in an acute setting. Due to advances in medical technology, more medical procedures, such as diagnostic tests, treatments, and surgeries, can be administered on an outpatient basis and do not require clients to be hospitalized. Outpatient and ambulatory care delivers convenient and cost-effective health care to children and their families, many times right within their own community. These settings allow for increased independence and permit children to return to their normal routine as quickly as possible. More and more outpatient and ambulatory care centers are opening, sponsored by health maintenance organizations (HMOs), physician's offices, community agencies and public health departments, and hospitals.

Outpatient units are used to keep hospital stays short and decrease the cost of hospitalization. Outpatient units may be a part of the hospital or a freestanding facility. The child and family arrive in the morning; the child undergoes the procedure, test, or surgery and then goes home in the evening. Examples of surgeries and procedures performed in outpatient settings include tympanostomy tube placement, hernia repair, tonsillectomy, cystoscopy, bronchoscopy, blood transfusions, dialysis,

and chemotherapy. The advantages of this environment include minimal separation of the child from the family, minimal disruption of the family pattern, decreased risk of infection, and decreased cost. Disadvantages include that the unit does not have the equipment for overnight stays, so if there are complications the child will need to be transported to the hospital.

Many centers offer preoperative health assessment and teaching sessions. These allow the parent and child to ask questions and resolve them before the procedure. On the day of the procedure, parents should be allowed to be with their child until the procedure begins. Parents should also be allowed to be with their child in the post-anesthesia recovery unit as quickly as possible. This provides reassurance and comfort to the child while meeting his or her physical and emotional needs.

The role of the nurse in the outpatient or ambulatory setting includes admission and assessment, preoperative teaching and preparation, client assessment and support, postoperative monitoring, case management, discharge planning, and teaching. Before the procedure the nurse reviews with the family the routine to be followed and any special instructions (such as NPO orders), and familiarizes the child with the setting to help alleviate fears. This may occur during the preoperative health assessment.

#### Take Note!

Encourage the parent to bring one of the child's favorite toys, blankets, or games to make the child feel more comfortable.

The nurse performs any surgical preparation and discusses intraoperative procedures as necessary. The nurse provides postoperative care and assessment of the child. Once the child's condition is stable and he or she meets the discharge criteria of the facility, the nurse reviews with the parent postoperative instructions, including pain management, care of the incision if appropriate, diet, activity, including return to school, necessary follow-up, and when to call the physician or nurse practitioner.

### The Physician's Office or Clinic, Health Departments, and Urgent Care Centers

Physician's offices, clinics, health departments, and urgent care centers are used by children and their families for well care, episodic ill care, acute care, and care of chronic conditions. For well care and illness or injury, children are often seen by their primary care physician. They may visit a physician's office or clinic or the health department. In more acute situations or for after-hours issues that cannot wait until clinic operating hours, a child may be seen in an urgent care center or may be

referred to the emergency department. The American Academy of Pediatrics discourages clients from using urgent care centers or the emergency department for routine care, since it is difficult to provide coordinated, comprehensive family-centered care consistent with a “medical home” concept (see Chapter 31 on medical homes) (American Academy of Pediatrics, Committee on Pediatric Emergency Medicine, 2009).

The nurse’s role in these settings includes preparing clients, collecting pertinent health information, performing assessments, assisting the physician with diagnostic testing and procedures, administering injections and medications, changing wound dressings, assisting with minor surgery, helping to maintain records, and educating the child and family about home care and when to call the physician or nurse practitioner or return to be seen.

An essential component of primary care practice is telephone triage. Pediatric office nurses often fill this role. When parents feel comfortable with the providers in their child’s medical home office, they often call for advice in order to treat their child at home. A telephone triage nurse needs excellent assessment and critical thinking skills along with solid training and education. The triage nurse needs to assess the client’s entire situation, including current signs and symptoms, history, and home treatment.

Protocols, standardized policies and procedures, and professional judgment guide the triage nurse in the decision-making process. Pediatric telephone protocols are available for purchase through the American Academy of Pediatrics (<http://www.aap.org/>). The triage nurse needs to determine whether the child requires emergency care, an office visit, or home management. Good listening and the ability to maintain a calm voice when talking to parents are skills necessary for successful telephone triage. The triage nurse should not discourage parents from bringing the child into the office to be seen; triage is not meant to keep children out of the office, and if a parent is very concerned, that is reason enough to be seen.

### Take Note!

Parents often can pick up on subtle problems in their children. They may not be able to accurately describe signs and symptoms, but they know that their child “isn’t acting right.” Nurses must listen to parents and act on their concerns.

## Medically Fragile Daycare Centers

The **medically fragile child** is a child whose condition is considered medically complex. This child requires the use of medical technology and skilled nursing interventions (Rupert & Host, 2009). The number of medically fragile children is growing. Reasons include improvements in the treatment and care of complex medical conditions, increased sophistication of medical technology,

and the increase in premature deliveries. For many years these children lived in hospitals their entire lives. Due to concerns about the high cost of long-term hospitalization and the diminished quality of life for these children, alternative care settings in the community, such as medically fragile daycare centers, are being developed.

Medically fragile daycare centers are specifically designed to meet the needs of these children. Most centers accept children who have complicated medical needs or are dependent on technology. Examples include children with multiple congenital anomalies, children who are ventilator dependent, children with respiratory conditions, children with cardiac conditions, and children with cancer. Some centers accept children with less complicated needs, such as cardiorespiratory monitoring or asthma, and some enroll children without health care needs to promote peer relationships and acceptance. Just as at a regular daycare center, the parents or caregivers can drop the child off in the morning and pick the child up in the afternoon. Some centers offer after-school, weekend, or respite services. The centers usually provide needed therapies and have indoor and outdoor play areas, educational activities, and arts and crafts.

Health professionals are present at these centers to provide for the children’s medical, emotional, and developmental needs. Nurses trained in pediatric and neonatal care, physical therapists, occupational therapists, speech therapists, child life specialists, and social workers staff the centers; some centers have respiratory therapists on site. Children are able to receive all of their prescribed therapies while at the center. Nursing care includes direct care such as medication administration and dressing changes, assessment and evaluation of the child’s overall condition, identifying potential medical emergencies, determining the need for changes in care or treatment and monitoring, and providing frequent treatments or interventions to maintain life and health.

Most centers are located in the community to help ease transportation issues. Some centers provide transportation to and from home or school. Centers are licensed by the state daycare licensing authorities or in some states Physician Prescribed Extended Care (PPEC) agencies. Families may be able to obtain financial assistance from their private insurance or Medicaid. Advantages of community-based services over hospitalization or home care include decreased cost, social isolation, family stress, and rehospitalization rate (Rupert & Host, 2009).

## Schools

School nursing is a specialized practice of professional nursing and focuses on improving students’ health and safety to improve their achievement and success. School nurses work to remove or minimize health barriers to learning to provide students with the best opportunity to achieve academic success. The National Association

of School Nurses defines school nursing as “a specialized practice of professional nursing that advances the well-being, academic success, and life-long achievement of students. To that end, school nurses facilitate positive student responses to normal development; promote health and safety; intervene with actual and potential health problems; provide case management services; and actively collaborate with others to build student and family capacity for adaptation, self management, self-advocacy, and learning” (Council on School Health, 2008, p. 1052). See Healthy People 2020.

At the heart of school nursing is the belief that all children have the ability to learn and the right to health care and an education, and that all of society is best

### HEALTHY PEOPLE 2020

#### Objective

Increase the proportion of elementary, middle, and senior high schools that provide comprehensive school health education to prevent health problems in the following areas: unintentional injury; violence; suicide; tobacco use and addiction; alcohol or other drug use; unintended pregnancy, HIV/AIDS, and STD infection; unhealthy dietary patterns; and inadequate physical activity.

Increase the proportion of elementary, middle, and senior high schools that provide school health education to promote personal health and wellness in the following areas: hand washing or hand hygiene; oral health; growth and development; sun safety and skin cancer prevention; benefits of rest and sleep; ways to prevent vision and hearing loss; and the importance of health screenings and checkups.

Increase the proportion of elementary, middle, and senior high schools that have a full-time registered school nurse-to-student ratio of at least 1:750

#### Significance

- Provide education and training to school staff in health problem areas.
- Work with schools to develop appropriate health education with focus on health problem areas.
- Provide adequate health care services and health education to students.

served if all children are educated and healthy (School Nurse Organization of Minnesota, Centennial Celebration Committee, 2009). School nurses provide direct health care to students along with screening and referrals for health conditions. They provide leadership for health services, such as identifying health and safety concerns in the school environment and planning and training for emergencies and disasters. School nurses promote a healthy school environment by supporting healthy food services and promoting proper physical education and sports policies and practices. They promote health education through health counseling and education of students and staff. School nurses coordinate school health programs and link health service programs within the school and community. School nurses carry out a variety of roles in providing health care to children (Fig. 33.9). Box 33.4 lists some of the activities of the school nurse.

The population of students has changed over the years. Access to public schools for children with disabilities is mandated. Due to improvements in technology, children with chronic conditions or special needs live longer and enter school. There has been an increase in the number of children with psychiatric conditions such as depression, attention-deficit/hyperactivity disorder, and more serious conditions such as bipolar disorder. All have contributed to an increase in the number of children with diverse and sometimes complex health needs in the school system. The essential role of the school nurse has not changed, but the responsibilities and expectations have. School nurses are challenged to meet the growing needs of the changing school population.

**FIGURE 33.9** The school nurse provides nursing assessment as well as health education to students in the school setting.

## BOX 33.4

**EXAMPLES OF ACTIVITIES OF THE SCHOOL NURSE**

- Conduct health screenings (such as vision, hearing, and scoliosis)
- Assess growth and development
- Provide emergency first aid
- Train and educate staff on CPR, first aid, and health issues
- Assess, monitor, and refer students with communicable diseases
- Educate on health promotion and disease prevention (such as immunizations, bike and car safety, decreasing high-risk behaviors such as smoking, drinking, drug use, and sexual activity)
- Serve as a resource for health issues and education
- Act as a liaison between home, school, and community
- Act as a liaison between health care provider and school
- Reinforce client and family health education (such as discharge instructions, self-care measures)
- Monitor long-term illness in students
- Network with community agencies and make necessary referrals

*Recall Jake, the 8-year-old boy with history of a brain tumor and resulting complex medical needs. In recent years there have been many more children with special needs attending school than ever before. This brings many challenges for the teachers, staff, and school nurses employed by the school district. The principal of Jake's elementary school tells the school nurse that many of the teachers and staff have expressed concerns that they do not know anything about the health care needs of these children, including Jake. What kinds of interventions might the nurse plan?*

Just as nurses in the acute care setting develop nursing care plans, nurses in the school setting develop **individualized health plans (IHPs)**. An IHP formalizes the plan of support for a student with complex health care needs. It is a written agreement developed as part of an interdisciplinary collaboration of school staff along with the student, the student's family, and the student's health care provider. The plan describes the student's needs and how the school plans to meet these needs. The nurse plays a critical role in developing these plans. The nurse will use the nursing process and then, based

on the nursing assessment and diagnosis, will develop goals and interventions to ensure that the child's needs are being met. Examples of students who may need an IHP are those with asthma, serious allergies, chronic conditions such as type I diabetes, physical disabilities, attention-deficit/hyperactivity disorder, autism spectrum disorders and medication needs. Figure 33.10 gives an example of an IHP for a child with asthma.

**Take Note!**

The IHP needs to include directions for care while the child is at school and also must take into account circumstances that may affect the student's health care needs, such as variations in school routine, absence of staff, special outings such as field trips and extracurricular activities, and a plan in case of emergency.

**Other Community Settings**

Nurses work in a variety of different settings within the community. Their primary focus continues to be on promoting health, preventing disease and injury, and ensuring a safe environment. Nurses play important roles in child care centers, camps, health department clinics, and shelters. In child care centers, nurses help address infection control issues and assess for a safe environment. They provide education and training to staff members. A camp nurse ensures a safe environment for all campers and provides first-aid and acute illness care as needed. Camps for children with special needs exist, staffed by specially trained nurses. These camps cater to children with complex health care needs, such as diabetes, head injuries, and physical disabilities and allow the children the opportunity to experience camp life while providing a safe environment and necessary medical care. Health department and shelter nurses focus on health supervision services and connecting clients to needed community resources.

**Take Note!**

Nurses have a unique opportunity to give back to their community by volunteering their services in various settings, such as shelters and clinics in medically underserved areas.

**Home Health Care**

Home care provides short- or long-term services for children and their families in the home. It also is used for medically needy and technology-dependent children, such as ventilator-dependent children. Among those who often benefit from home care are children with acute illness, such as a child with osteomyelitis requiring intravenous antibiotics, or chronic health care issues, such as a child with bronchopulmonary dysplasia, that may have required traditional in-hospital care.

**FIGURE 33.10** Example of an individualized health plan. (Adapted from Arnold, M. J. & Silkworth, C. K. [1999]. *The school nurse's source book of individualized healthcare plans: Issues applications in school nursing practice, Vol. II; and Zentner-Schoessler, S. [1997]. Computerized version and manual, Vol. I. North Branch, MN: Sunrise River Press.*)

Home care is geared toward the needs of the child and family. Private-duty nursing care is used when more extensive care is needed; it may be delivered hourly (several hours per day) or on a full-time, live-in basis. Periodic visiting nurse care is used when the child needs intermittent interventions such as intravenous antibiotic administration, follow-up with client teaching, and periodic monitoring, such as bilirubin monitoring. The goals of nursing care in the home setting include promoting, restoring, and maintaining the health of the child. Home care focuses on minimizing the effects of the illness or disability, along with providing the child or family with the means to care for the illness or disability at home. Nurses in the home care setting are direct providers of care, child and family educators, child and family advocates, and case managers.

There are some disadvantages to home care. The presence of health care professionals in the home can be an intrusion on family privacy. Also, caring for children with complex medical needs can be overwhelming for some families. Financial issues can become a large burden, as families may have higher out-of-pocket costs if their insurance does not reimburse for home care. Having one parent at home full time and not earning an income can contribute to increased financial strain, not to mention social isolation of that parent. All of these can lead to increased stress on family members. The advantages of home care usually outweigh the disadvantages, but nurses need to be aware of these potential disadvantages and provide support and resources as necessary.

### FAMILY-CENTERED HOME CARE

**Family-centered care** is a challenging pediatric nursing philosophy and is driven by evidence that a nurturing environment improves the chances of positive outcomes for the child. It places the family in a central position relative to the child and to the child's plan of care. Refer to Chapters 2 and 30 for further information regarding family-centered care.

Family-centered home care focuses on increasing support for the emotional and developmental needs of the child. It encourages families to care for their children at home while health care professionals provide the necessary support, empowerment, education, and expertise that each family needs. In family-centered home care, the family and health care professionals build a partnership of trust to meet the needs of the child. The nurse must value the role of the family and regard family members as the ultimate experts in caring for their child. In home care the family is extensively involved in the child's care, and the home care nurse is there to facilitate this.

Any illness, especially a chronic illness, affects the entire family and can disrupt family structure. There is a change in the role of parents when they have to care for an ill child. These role changes can result in stress for the family members and can affect their participation in the child's care. It is important for home care nurses to seek

a partnership role with the family regarding care of the child. This can be difficult for both parties. Many times nurses set limits on parental involvement and do not consider the parents' perspective. Many nurses are concerned that the parents may not be able to care for the child safely. It is important for nurses to use self-awareness and reflective practice to help them understand and empower families as well as to develop a partnership for care. A communication framework, called the LEARN framework developed by Berlin and Fowkes (1983), can assist nurses in the home care setting to help create cross-cultural collaboration and communication between nurses and families (Box 33.5).

### THE NURSE'S ROLE IN HOME CARE

Early discharge planning, teaching, and case management are keys to promoting a successful transition from the hospital setting to home. The environment differs greatly between the acute setting and the home setting. In the acute setting, the nurse is in control of the environment; in the home setting, the nurse is a guest in the home. It is important for the nurse to establish a trusting relationship with both the child and family (Fig. 33.11). A trusting therapeutic relationship will make all aspects of care more effective. Box 33.6 gives hints on building this relationship.

Nursing in the home care setting can be challenging. The focus is on meeting the child's physical and psychological needs while involving the family. In meeting the child's needs while involving the family, the nurse uses the nursing process. Assessment in the home is similar to that in the acute care setting but involves obtaining firsthand data about the family and the way it functions. The nurse needs to assess the child's growth and development and thoroughly assess the home environment (refer to Chapters 25 through 29 and Chapter 32 for additional information). The nurse needs to ensure that the home offers a safe and nurturing environment for the child. The National Center for Healthy Housing has developed a Pediatric Environmental Home Assessment (PEHA) survey and nursing care plan to assist in

#### BOX 33.5

#### LEARN FRAMEWORK

- L: Listen empathetically and with understanding to the family's perception of the situation.
- E: Explain your perception of the situation.
- A: Acknowledge and discuss the similarities as well as differences between the two perceptions.
- R: Recommend interventions.
- N: Negotiate and agree on the interventions.

Used with permission from Berlin, E. A., & Fowkes, W. C. (1983). A teaching framework for cross-cultural health care. *Application to Practice, The Western Journal of Medicine*, 139(6), 934–938.

**FIGURE 33.11** Listening to the child helps to develop a trusting relationship between the home care nurse and the child and her family.

identifying and addressing hazards or potential threats that exist in the child's home (National Center for Healthy Housing, n.d.). These forms can be accessed from a link on [thePoint](#). Always individualize to meet the needs and requirements of each child and family.

The nurse also needs to assess availability of resources. This includes necessary equipment such as a hospital bed and oxygen, suitable physical and emotional surroundings (e.g., Are the family members able to deal with the stress of the situation?), ability to contact emergency services, power backup if needed, and ease of evacuation of the child in case of a fire. The nurse needs to assess whether electricity, sanitary conditions, heat, air conditioning, and telephone access are present. If there is no phone in the home, the family needs to have plans for accessing a phone in case of emergency (perhaps a neighbor's phone or a pay phone near the home). The nurse should identify areas of priority and provide appropriate referrals to resources.

During the assessment phase the nurse identifies the person who is the primary caregiver; this may be

#### BOX 33.6

#### HINTS TO ESTABLISHING A TRUSTING RELATIONSHIP IN HOME CARE

- Include the child in the conversation and make him or her feel a part of the interaction.
- Address caregivers formally unless otherwise instructed.
- Be friendly. Use a soft, calm voice.
- Be interested in the child's activities.
- Have the primary caregiver present at the initial visit.
- Listen to and show respect to the child and the family.

the mother, father, grandparent, or older sibling. It is essential to include this person when developing the plan of care, as he or she is the expert on the child and family. The primary caregiver can provide insight into direct care and which strategies will be most effective with this child, taking into account the physical layout of the home, the financial ability of the family, and the way the family functions. The home care nurse must also assess the family's teaching and learning needs.

After the assessment is complete, the nurse develops appropriate nursing diagnoses, outcomes, and goals and implements the plan of care. This will include the frequency and duration of the home visits. The nurse will use agency policies, certification standards, and private insurance and/or Medicaid regulations to assist in the development of the plan. The nurse may be the provider of direct care to the child, or the care may be indirect, in which case the nurse plans and supervises the care that is given by others, such as unlicensed personnel and parents.

Nursing care in the home requires excellent critical thinking skills. The nurse has a great deal of independence since there are no other nurses, supervisors, or physicians on site. When complex care is provided in the home, the nurse may need to adjust procedures to fit the setting. For example, feeding schedules may be adjusted to fit a child's school schedule or equipment may be adjusted to allow a child to receive feedings continuously while at school (Fig. 33.12).

An important role of the home care nurse is empowering children and their families through education (refer to Chapters 2 and 30 for further information related to teaching). The nurse assesses the learning needs and provides education that is appropriate to the educational and developmental levels of the child and family. The nurse must encourage the family to participate in the child's care. The education goals of home care vary. In

**FIGURE 33.12** The home care nurse may have to adjust procedures and equipment use to fit the home setting. Placing a feeding pump in a backpack allows this child to receive feedings continuously while at school.

many situations parents or caregivers must learn care immediately so the child can be cared for at home, such as a child who needs dressing changes four times a day or a child who is ventilator dependent. A child newly diagnosed with diabetes will have some immediate teaching needs, but as the child grows and his or her condition changes, additional care will need to be taught.

As with any nursing care, the effectiveness of nursing interventions along with changes in the child or family's status needs to be continuously evaluated and the plan of care altered as needed.

*As the home care nurse, what can you do to help with Jake's transition to school? On your last visit, Jake's parents express concerns about this transition and the added stress it is causing the family. They appear tired from the round-the-clock care that Jake requires. What suggestions can you make to help ease their stress and fatigue?*

## KEY CONCEPTS

- Stressors associated with hospitalization include separation from family and routines; fear of an unknown environment; potential for pain, bodily injury, or mutilation; and loss of control.
- Responses of children to the general stressors of hospitalization include anxiety, fear, anger, guilt, and regression.
- Parents may experience anger or guilt related to the hospitalization of their child.
- The responses of children and families to hospitalization can be influenced by the age and developmental level of the child, their perceptions of the situation, previous experiences, separation from family and peers, coping skills, and the preparation and support provided by the family, facility, and health care providers.
- Play, including therapeutic play, is an important strategy to prepare children for hospitalization and to help them adapt to the effects of illness and hospitalization. It provides an emotional outlet, opportunities for teaching and learning, and the ability to become familiar with a situation and improve physiologic abilities. A child life specialist is a specially trained individual who is a member of the child's multidisciplinary team. He or she works in conjunction with the child's health care providers and parents to foster an atmosphere that promotes the child's well-being.
- Family-centered care and atraumatic care are philosophies that pay special attention to the concerns of the family and child during hospitalization.
- Providing support to hospitalized children and their families is critical for minimizing stress.
- Whatever the reason for admission, preparation for admission is vital.
- Upon admission to the hospital or outpatient unit, orient the child and family to the unit, discuss unit policies and routines and the personnel who will be involved in the care of the child and begin client/family teaching.
- Establish a trusting, caring relationship with the child and family. Let the child and family know what will happen and what is expected of them. Obtain information about the child's history, routines, and reason for admission. Obtain baseline vital signs, height and weight, and perform a physical assessment. Each health care setting has its own policies and procedures for this.
- Due to their age and developmental level children may be vulnerable to harm, the nurse must use appropriate safety measures in caring for children (e.g., identification of children, use of restraints and transportation, basic hygiene measures). These measures need to address developmental risks (e.g., infants, toddlers, and preschoolers require close supervision, and the nurse must avoid leaving small objects within reach).
- Discharge planning begins upon admission. Each interaction with the family is an opportunity for client teaching.
- Provide and review discharge instructions with the child and primary caregiver. Use educational booklets, videotapes, DVDs, or CD-ROMs that give basic health information or general care for a child with a particular disease.
- Explain, demonstrate, and request a return demonstration of any treatments or procedures to be done at home. Provide a written schedule if the child is to receive multiple medications, tube feedings, or other medical treatments.
- Community-based nursing takes place in a variety of settings, including a physician's office, clinics, health departments, urgent care centers, the client's home, schools, camps, churches, and shelters (such as shelters for abused women, homeless shelter, and disaster shelters). Nurses provide well care, episodic ill care, and chronic care to children and their families in these various settings.
- Nursing in the home care setting can be challenging. The focus is on meeting the child's physical and psychological needs while involving the family. Health care professionals provide the support, empowerment, education, and expertise in caring for the child that families need.

- Goals of the nurse in the home care setting include promoting, restoring, and maintaining the health of the child. Home care focuses on minimizing the effects of the illness or disability and providing the child or family with the means to care for the illness or disability at home. Nurses in the home care setting are direct providers of care, child and family educators, child and family advocates, and case managers.
- Advantages of home care include shorter hospital stays and decreased health care costs, but the major advantage of home care is the comfort and family support it provides, promoting an improved quality of life for these children. Caring for children at home not only improves their physical health but also allows for adequate growth and development while keeping them within their family.
- Disadvantages to home care include intrusion on family privacy. Caring for children with complex medical needs can be overwhelming for some families, and financial issues related to home care can become a large burden to families.

## MULTIPLE-CHOICE QUESTIONS

- The nurse is preparing a 5-year-old boy for surgery on his lower leg. His mother is helping him into the hospital gown and the boy fights removal of his underwear. What is the most appropriate nursing action?
  - Allow the mother to remove the underwear.
  - Tell the boy he is acting childishly.
  - Notify the OR that the underwear is on.
  - Allow the boy to keep his underwear on.
- A 6-month-old infant requires restraint to prevent removal of his nasogastric tube. What is the priority nursing intervention?
  - Tie the restraint loosely to prevent skin breakdown.
  - Leave the baby unrestrained when directly observed.
  - Position the restrained infant prone to prevent aspiration.
  - Place the infant in a room near the nurses' station.
- A 10-year-old child on a regular diet refuses to eat the food on her meal tray. She requests chicken nuggets, French fries, and ice cream. What is the best nursing action?
  - Ask that the child's desired foods be sent up from the kitchen.
  - Negotiate with the child to eat at least part of the food on the tray.
  - Remove a privilege.
  - Offer the child cereal and milk from stock on the nursing unit.
- A child is to undergo a tympanostomy tube placement in a freestanding outpatient surgery center. What is the major disadvantage associated with this location?
  - Increased risk for infection
  - Increased health care costs
  - Need to be transferred if overnight stay is required
  - Increased disruption of family functioning

## CRITICAL THINKING EXERCISES

- Becky, an 8-year-old, is admitted to the pediatric unit for an emergency surgery. She is in third grade and very active in after-school programs. Her mother is with her during the admission process but will have to return to work shortly after Becky returns from surgery to the pediatric unit. Would the nurse expect Becky to show separation anxiety? What are the three top nursing diagnoses for Becky?
- A 6-year-old is admitted to the general pediatric unit after spending several hours in the emergency

department with an acute asthma attack. Her mother and two younger siblings are present, but the mother plans to leave shortly to take the siblings home. The father will visit in about 2 hours, after work. What is the overall goal for this child's care? What could the nurse say to promote coping in this child? What would be the best answer if the mother asks if she should stay?

- A child with cerebral palsy is discharged from the hospital, where he has been receiving treatment for pneumonia. Home health care nurses, through a local agency, are to help the family administer intravenous antibiotic therapy and to monitor the child's health status.
  - As the home health nurse assigned to this child, what should your nursing assessment include?
  - In this situation, what are some nursing interventions that will help ensure family-centered care?
  - When this child is stable and can go back to school, what will be the role of the school nurse in caring for this child?

## STUDY ACTIVITIES

- Follow a child and family during the admission process, from preadmission to initial time on the unit, to identify the procedures and tasks involved. Examine the response of the child and family and how the nursing staff responds to their needs.
- Develop a teaching plan to orient a toddler or preschooler and his or her family to a nursing unit. Include the resources, personnel, and techniques to include in the teaching plan.
- Shadow a nurse working in a community setting, such as a camp, school, shelter, or health department. Identify the role the nurse plays in the health of the children and families in the setting and the community.
- Spend a day in a medically fragile daycare setting. Identify the needs of one child and his or her family, how they may differ from those of a child in a traditional daycare setting, and the role of the nurse in meeting those needs.
- Develop an IHP for a child with diabetes. (Use the IHP in Fig. 33.10 as a reference.)
- Shadow a nurse working in a home health care setting. Identify ways he or she helps the family to promote the child's growth and development and to ensure that the child has as normal a childhood as possible. Identify interventions that embody the key concepts of family-centered care.

respite care  
terminal illness

## Caring for the Special Needs Child

### Learning Objectives

*Upon completion of the chapter, you will be able to:*

1. Define the key terms used in this chapter.
2. Analyze the impact that being a child with special needs has on the child and family.
3. Identify anticipated times when the child and family will require additional support.
4. Describe ways that nurses assist children with special needs and their families to obtain optimal functioning.
5. Discuss early intervention and public school education for the special needs child.
6. Plan for transition of the special needs child from the inpatient facility to the home, and from pediatric to adult medical care.
7. Discuss key elements related to pediatric end-of-life care.
8. Differentiate developmental responses to death and appropriate interventions.

*Preet Singh, a 2-year-old boy who was born at 27 weeks' gestation, is seen in your clinic for the first time. He has a history of hydrocephalus and developmental delay. During the examination, his mother states, "I'm concerned about finding a good, affordable preschool for Preet. His older brother attends public school, but I can't imagine Preet going there." After further discussion with Preet's mother, you realize he has not been involved in an early intervention program.*

### Words of Wisdom

The touch of a mother's hand and the sound of her voice bring comfort to her special child, and when you bring comfort, you strengthen both of them.

**The** Maternal Child Health Bureau defines children with special health care needs as those who have or are at risk for a chronic physical, developmental, behavioral, or emotional condition beyond needs generally required by children (U.S. Department of Health and Human Services (USDHHS), Health Resources and Services Administration (HRSA), Maternal and Child Health Bureau, 2008). Children who have a terminal illness, or are otherwise dying, also require additional care. Nurses are in a unique position, both in the inpatient and outpatient setting, to have a significant and positive influence on the lives of these children and their families. For children with special needs, in addition to providing direct care, the nurse fills the critical role of child and family advocate and case manager. When a child is dying, nurses not only provide physical care to the child but also strive to meet the emotional needs of the child and family.

## THE MEDICALLY FRAGILE CHILD

The numbers of children with **chronic illness** (a long-lasting or recurrent illness) are increasing. Children with special health care needs make up a little over one eighth of the population of children in the United States and, of those children, 24% report being affected a great deal by their condition (USDHHS, HRSA, Maternal and Child Health Bureau, 2008). Increasing numbers of children are being diagnosed with physical and mental disorders and larger numbers of children are living with the assistance of high-tech treatments and equipment.

### Impact of the Problem

Children with special needs may use or need prescription medication, medical care, mental health services, or education services more than other children their same age. They may be limited in abilities and may need physical, occupational, or speech therapy. Alternatively, they may require ongoing treatment for emotional, developmental, or behavioral problems (USDHHS, HRSA, Maternal and Child Health Bureau, 2008). These children and their families are often insured inadequately, have financial needs and/or unmet family support needs, or have difficulty obtaining the specialty care that the child requires (USDHHS, HRSA, Maternal and Child Health Bureau, 2008). It can be challenging for the family of a child with special needs to navigate the system and obtain all of the services their child requires.

When an infant is born very prematurely, when a child is injured and requires long-term rehabilitation and special care, or when a child is diagnosed with a complex chronic health condition, the parents are often devastated initially. The parents of medically fragile children may feel they must adapt to the risk and protect their child. They are interested in preserv-

ing their family while compensating for the past, and they cautiously look to the future and become hopeful again. While the infant or child is still in the hospital, nurses can help parents build on their strengths, empowering them to care for their medically fragile infant or special needs child. Education is paramount and should begin as early in the hospitalization as possible. In many situations, particular discharge needs are known early in the course of the infant's or child's hospitalization. Nurses should provide anticipatory guidance about the course of treatment and the expected outcome (Allen et al., 2010).

Most children with chronic illness, or those who are dependent on technology, progress through stages of growth and development just as typical children do, though possibly at a slower pace. The exception is the child with significant psychomotor retardation, though some developmental progression may occur. Children with special health care needs desire to be treated as normal, and they want to experience the same events that other children do.

Of particular concern is a growing subset of children with emotional, behavioral, and developmental problems. Children with these needs have even greater difficulty receiving the care and services they require (USDHHS, HRSA, Maternal and Child Health Bureau, 2008). Many children with emotional, behavioral, or developmental problems also have health problems. Often, these children's problems are not diagnosed early and treatment is difficult (Horowitz & Marchetti, 2010). Ongoing counseling and therapy is very difficult for some families to obtain. Ultimately, this has a negative impact on the child's physical and mental health and may result in decreased achievement and productivity as the child matures. See Healthy People 2020.

## HEALTHY PEOPLE 2020

### Objective

Reduce the proportion of people with disabilities who report serious psychological distress.

### Nursing Significance

- Screen children with special health care needs for depression or sadness.
- Refer children and their families to mental health providers as needed.

*Healthy People* Objectives based on data from <http://www.healthypeople.gov>.

## Effects of Special Needs on the Child

When a child is medically fragile or has special needs, the child's coping ability is affected. In addition, the

child's ability to cope is significantly affected by the family's response to stressors, which are often numerous in this population. Children with special health care needs experience differing effects of the chronic illness or disability based on their developmental level, which naturally changes over time for most children.

Infants may fail to develop a sense of trust or attach appropriately with the parents because of frequent hospitalizations, often with multiple caregivers involved; lack of consistency in nurturing; or parental detachment or grieving over the child's condition. The infant's ability to learn through sensorimotor exploration may be impaired due to lack of appropriate stimulation, confinement to a crib, or increased contact with painful experiences (Vessey & Sullivan, 2010).

The toddler may experience difficulty developing autonomy because of increased dependency on the parent or overinvolvement by the parent. Motor and language skill development may be delayed if the toddler is not given adequate opportunities to test his or her limits and abilities (Vessey & Sullivan, 2010).

Limited opportunity also reduces the preschooler's development of a sense of initiative. The preschooler may experience limited opportunities for socialization, causing him or her to withdraw or to feel criticized. Body image development may be hindered due to painful exposures and anxiety. In preschoolers, magical thinking may lead to feelings of guilt for having caused their own disease or condition (Vessey & Sullivan, 2010).

The school-age child may have limited opportunities to achieve a sense of industry because of school absence and inability to participate in activities or competitive events. Lack of socialization limits the school-age child's ability to form peer relationships. The ability to learn via concrete operations is affected by the child's physical limitations or possibly the treatments required (Vessey & Sullivan, 2010).

Adolescents may feel as though they are different from their peers because of their lack of skills/abilities or their appearance. This may hinder the teen's ability to form a sense of personal identity. Since the teen with special health care needs often requires significant amounts of support from the parents, it may be difficult for the adolescent to achieve independence. If the earlier stages of cognitive development have been delayed, then reaching the level of abstract thinking may be blocked (Vessey & Sullivan, 2010).

The child with special health care needs may be able to focus on the positive experiences in his or her life as a method of coping, leading to as much independence as possible. Other children may always feel different from their peers (in a negative sense) and withdraw. Irritability and acting out may also occur. Some children may be compliant and/or seek support for themselves. The child's coping pattern may change over time or with certain situations, such as relapse or worsening of the condition.

Children with overprotective parents may display marked dependence and may be very fearful. Children whose parents have been overly indulgent may be more independent and defiant. The nurse must assess the child's individual response to the current health care status and intervene as appropriate (Vessey & Sullivan, 2010).

## Effects on the Family

Each member of the family experiences effects related to the child's special needs. Family members' experiences and their responses to the child's illness influence each other directly.

### Effects on Parents

Raising a child with special needs is generally not the life parents expected to have. Some parents may adapt over time and ultimately accept the child's illness or disability. Others may adapt but do not accept the child's condition and experience the continual fading and reemergence of chronic sorrow. Denial of their child's problem may prevent parents from progressing through grief, but it also allows them to have hope (Knafl & Santacroce, 2010).

Caring for the special needs child at home (rather than having the child in a facility) may decrease the parents' feelings of anxiety and helplessness (Fig. 34.1). As with typically developing children, parents enjoy witnessing the emotional and social growth of the child. Parents of special needs children experience a multitude of emotions and changes in their lives. They worry about their child's and family's well-being, and as experts in

**FIGURE 34.1** The special needs child often requires a significant amount of care at home.

their child's care often feel burdened with continual care. They often feel helpless and overwhelmed when their child is discharged from the hospital. Though willing to carry the burden, they may experience fear, anger, sadness, guilt, frustration, or resentment. Many parents experience grief as a result of losing the perfect child of which they dreamed (Knafl & Santacroce, 2010).

### STRESSORS OF DAILY LIVING

Families with a child who has special health care needs experience life differently from other families. They may have to change their housing situation to accommodate the child's needs. Their sleep is affected. Constant supervision of the technology-dependent child makes it difficult to carry out other basic household activities. In addition to basic child care and running of the household, medical and technical care must be incorporated into daily life. The family's identity and the parents' employment may be altered radically. Holidays and vacations are affected, as it is difficult to plan activities. Nursing and other health care professional visits are disruptive to family life.

Mothers appear to carry the larger burden of care, though fathers are not unaffected. Somehow, parents eventually take charge, and though they fear failure, they display vigilance, can negotiate and seek information, and become advocates for their child and experts on his or her care. Though parents may feel trapped and isolated and experience a loss of freedom, their need to survive as a family continues to motivate them. Parents may feel a need to be with their child at all times and experience stress related to coping with the heavy load of caregiving.

The extended burden of caregiving can also have adverse health effects on caregivers: only a small percentage of parents of children with special health care needs report that they routinely participate in health-promoting activities for themselves. Additionally, parents of children with special health care needs are at increased risk for the development of depression (Knafl & Santacroce, 2010). In addition to the caregiving burden, parents experience role conflicts, financial burdens, and the struggle between independence in providing care and the isolation associated with it. It is very difficult to enjoy spontaneous events outside the home because so much planning is necessary.

The possibility of independence revolves around mobility issues, education, and assistive technology. Though education for all children is federally mandated, parents have anxiety about educational decisions and also find it difficult to obtain the support and educational services the child needs.

Additional stress is associated with transition times in the care of a special needs child. These transition times include:

- Initial diagnosis or change in prognosis
- Increased symptoms

- When the child moves to a new setting (hospital, school)
- During a parent's absence
- During periods of developmental change (Knafl & Santacroce, 2010; Looman, O'Conner-Von, & Lindeke, 2008)

### VULNERABLE CHILD SYNDROME

"Vulnerable child syndrome" is a clinical state in which the parents' reactions to a serious illness or event in the child's past continue to have long-term psychologically harmful effects on the child and parents for many years (Duncan & Caughy, 2009). The parents view the child as being at higher risk for medical, developmental, or behavioral problems. Parents exhibit excessive unwarranted concerns and seek health care for their child very frequently. Risk factors for the development of vulnerable child syndrome include preterm birth, a congenital anomaly, newborn jaundice, a handicapping condition, an accident or illness that the child is not expected to recover from, or crying or feeding problems in the first 5 years of life. The parent has difficulty separating from the child, and the child senses that anxiety and then develops symptoms that reinforce the parent's fears. Alternatively (or additionally), the parents may try to retain control, particularly at times of increasing independence, and fear disciplining the child as they do not want to "upset" the child.

### *Effects on Siblings*

The siblings of children with special health care needs are also affected dramatically. Their relationship with their parents is different from what it would have been if they had a typical brother or sister. Parents often need to spend more time with the child with special needs and have less time with their healthy children. Children exhibit emotional and psychological responses to their sibling's long-term needs (Looman et al., 2008). The sibling's knowledge about the illness, the sibling's attitude toward and adjustment to it, the sibling's own self-esteem, how socially supported the sibling is, and the parents' awareness of the sibling's feelings are all related to how well the sibling adjusts.

## **Nursing Management of the Medically Fragile Child and Family**

Family-centered care provides the optimal framework for caring for medically fragile children and their families. Family-centered care minimizes the impact of chronic illness and maximizes the child's developmental potential. To provide the best nursing care for these children and their families, the nurse must first develop a trusting relationship with the family.

To ensure optimal functioning, children with special health care needs require comprehensive and coordinated services from multiple professionals. These professionals should work collaboratively to address the child's health, educational, psychological, and social service needs. In addition to case management and advocacy, nursing management focuses on screening and ongoing assessment of the child, provision of home care, care of the technology-dependent child, education and support of the child and family, and referral for resources.

### Developing a Therapeutic Relationship

Raising children is always challenging, but for the parent of a special needs child it is often overwhelming and exhausting. The parents' needs change continuously, so it is best if the family has a permanent relationship with a physician or nurse practitioner. This promotes trust and a more efficient two-way flow of information.

Respect the parents' range of emotions and work with them as a team to manage the child's care. Parents need to be recognized for complying with the treatment plan or for other small gains that are made. Empowering the family strengthens them and gives them self-confidence. Feeling supported and invigorated gives parents strength, energy, and hope. Box 34.1 lists principles related to family involvement.

### Screening and Ongoing Assessment

Nurses should perform screening to identify children with unmet health care needs. A screening tool developed by the Child and Adolescent Health Measurement Initiative (Fig. 34.2) may help to identify children with special health care needs. Web links for additional information related to the screening tool can be found on

thePoint\*

#### BOX 34.1

#### PRINCIPLES RELATED TO FAMILY INVOLVEMENT

##### Families

- Are the constant in a child's life
- Define who they are and their culture
- Need to have access to information and training
- Deserve to receive culturally competent care
- Know their strengths, limitations, and fears
- Merit mutual respect and responsibility for outcomes

Adapted from Goode, T. D., Haywood, S. H., Wells, N., & Rhee, K. (2009). Family-centered, culturally, and linguistically competent care: Essential components of the medical home. *Pediatric Annals*, 38(9), 505–512.

Children with special health care needs may attain developmental milestones more slowly than typically developing children. If the Denver II is used for ongoing developmental surveillance of the young child, then the results should be compared from visit to visit to determine progress rather than using it as a screening tool. Assess special needs children and their families for vulnerable child syndrome.

### Promoting Home Care

Home is the most developmentally appropriate environment for all children, even those who are technologically dependent (Looman et al., 2008). The child's home provides an emotionally nurturing and socially stimulating environment. Children desire to be cared for at home, and those who are cared for at home display an improved physical, emotional, psychological, and social status.

Technology-dependent children may require supplemental oxygen, assisted ventilation, tracheostomy care, assisted enteral or parenteral feeding, or parenteral medication administration. Traditionally hospitalization would have been required for these children—in fact, intensive care would have been necessary for children who need assisted ventilation—but with advances in technology, today even children with extensive medical and developmental needs may be cared for at home (Looman et al., 2008). Early discharge planning is important, and parents will need detailed instructions and support in caring for the technology-dependent child at home (Allen et al., 2010).

#### EARLY DISCHARGE PLANNING

Early discharge planning and ongoing inclusion and education of the family facilitates continuity of care. Box 34.2 provides information about preparing the medically fragile child for discharge.

#### CARING FOR THE TECHNOLOGY-DEPENDENT CHILD AT HOME

Home care nurses are often involved in the care of technology-dependent children. Caring for a technology-dependent child at home is a complex process, yet children thrive in the home care setting with appropriate intervention and care. Many parents feel that rearing a technology-dependent child is different only because of the presence of the equipment. Nurses may tend to think that parents treat the technology-dependent child differently from the other children, while parents value normalization and want to raise and provide discipline to all of their children in the same manner. Parents should tell nurses about their childrearing expectations, and nurses need to respect the parents' wishes.

Improved collaboration between parents and home care nurses may decrease the parents' stress and maximize opportunities for appropriate growth and development in

**FIGURE 34.2** The CSHCN screener. (Used with permission from the Child and Adolescent Health Measurement Initiative (CAHMI) at Oregon Health & Science University.)

**Scoring the Children with Special Health Care Needs (CSHCN©) Screening Tool**

**Conceptual background**

The CSHCN Screener uses consequences-based criteria to screen for children with chronic or special health needs. To qualify as having chronic or special health needs, the following set of conditions must be met:

- a) The child currently experiences a specific consequence.
- b) The consequence is due to a medical or other health condition.
- c) The duration or expected duration of the condition is 12 months or longer.

The first part of each screener question asks whether a child experiences one of five different health consequences:

- 1) Use or need of prescription medication
- 2) Above-average use or need of medical, mental health or educational services
- 3) Functional limitations compared with others of same age
- 4) Use or need of specialized therapies (OT, PT, speech, etc.)
- 5) Treatment or counseling for emotional or developmental problems

The second and third parts\* of each screener question ask those responding “yes” to the first part of the question whether the consequence is due to any kind of health condition and if so, whether that condition has lasted or is expected to last for at least 12 months.

*\*NOTE: CSHCN screener question 5 is a two-part question. Both parts must be answered “yes” to qualify.*

All three parts of at least one screener question (or in the case of question 5, the two parts) must be answered “yes” in order for a child to meet CSHCN Screener criteria for having a chronic condition or special health care need.

The CSHCH Screener has three “definitional domains.” These are:

- 1) Dependency on prescription medications
- 2) Service use above that considered usual or routine
- 3) Functional limitations

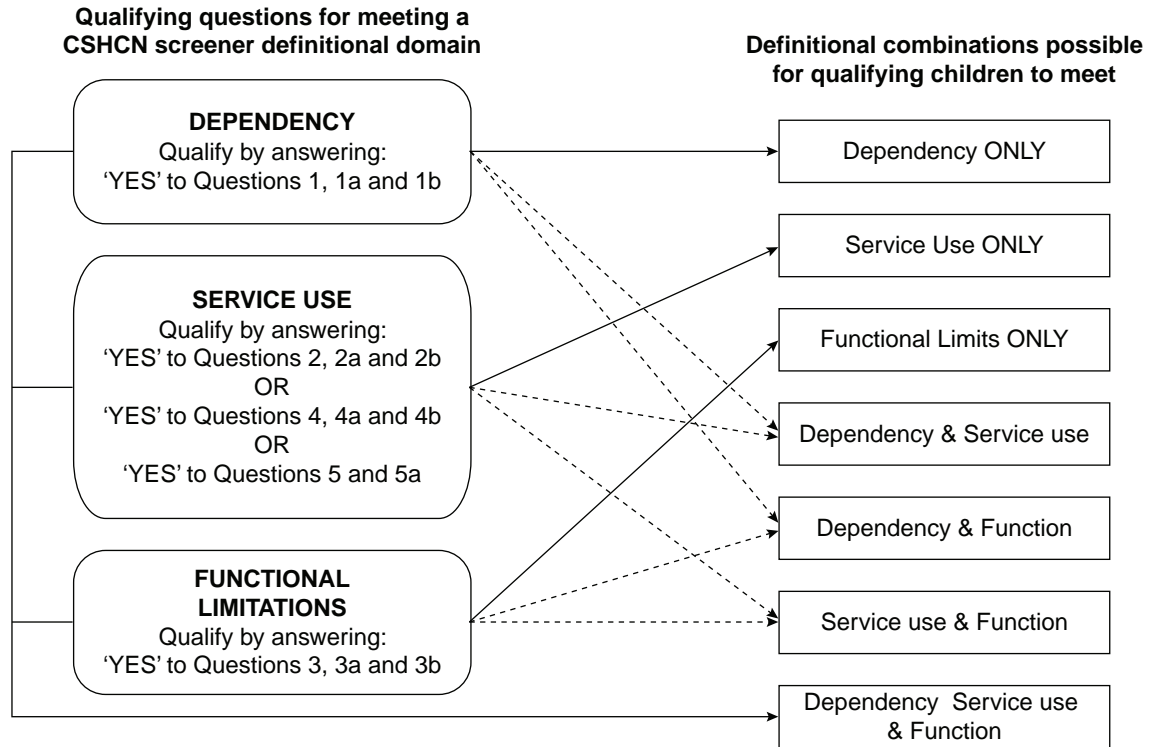

FIGURE 34.2 (Continued)

## BOX 34.2

**PREPARING FOR HOME CARE BEFORE DISCHARGE**

- Promote liaison with community resources. Develop communication between various services. Plan appointments. Set up home nursing care (either private duty or visits).
- Teach skills, encouraging active caregiving in the hospital setting to increase the parents' self-confidence.
- Discuss psychological and emotional issues with parents.
- Obtain/organize equipment and supplies (running out of supplies may cause significant stress on families).
- Refer the family for necessary financial resources.
- Ensure the family's home environment is adequate (enough room for equipment, electricity on, air conditioner for warm weather, heater for cold weather, and refrigeration for food).
- For the baby being discharged from the neonatal intensive care unit (NICU):
- Teach the parents about the infant's cues and behaviors and the preemie's different sleep-wake patterns.
- Encourage kangaroo care and infant massage while in the NICU (as the infant's condition allows).
- Educate the parents about possible effects on short- and long-term neurodevelopment.
- Refer to local early intervention program.
- Assist the family with finding a primary care provider who is experienced in the ongoing follow-up of high-risk infants.

Adapted from American Academy of Pediatrics, Committee on Fetus and Newborn. (2008). Hospital discharge of the high-risk neonate. *Pediatrics*, 122(5), 1119–1126.

the technology-dependent child. Thus, a strong relationship, good communication, and good negotiation skills are assets to the family and child.

Help the family to incorporate the medical regimen into daily life to minimize the child's self-perception of being different from other children. Teach families about the technical issues, such as home and travel oxygen therapy, use of the ventilator, suctioning, chest percussion and postural drainage, tube feedings and care of the feeding tube, and medications. Assist parents with the planning and management of routine care, respiratory treatments, nutritional support, and developmental interventions. Reinforce exercises and techniques as prescribed by developmental therapists. Refer to Chapter 33 for additional information about home care nursing.

**Providing Care Coordination**

Once a child with special health care needs has been identified and has been discharged to the home setting,

## BOX 34.3

**NURSING INTERVENTIONS FOR FAMILIES OF CHILDREN WITH SPECIAL HEALTH CARE NEEDS**

- Develop written health plans.
- Provide care coordination and collaboration with specialists in other disciplines, early intervention, schools, and public agencies.
- Address needs for prior authorization for treatments, medications, or specialist referrals; retain copies in the child's chart of authorization forms and approvals.
- Modify office routines to promote family and child comfort.
- Assist parents with child care decisions.
- Know community resources available to children with special health care needs.
- When the child is hospitalized, encourage high levels of parental participation.
- Provide care coordination across multiple health settings.
- Educate child care providers on child health needs.
- Help parents get involved with parent support networks.

Adapted from Looman, W. S., O'Conner-Von, S., & Lindeke, L. L. (2008). Caring for children with special health care needs and their families: What advanced practice nurses need to know. *Journal for Nurse Practitioners*, 4(7), 512–518; and McAllister, J. W., Presler, E., Turchi, R., & Antonelli, R. C. (2009). Achieving effective care coordination in the medical home. *Pediatric Annals*, 38(9), 491–497.

the nurse plays a vital role in care coordination. Any child with special health care needs benefits from a medical home. The nurse in the medical home is a critical team member, providing ongoing care coordination and follow-up. If such services are available in the local area, refer the child and family with special needs to an integrated health program that provides interdisciplinary, collaborative care for children requiring complex, coordinated care. Box 34.3 lists nursing interventions for families of children with special health care needs.

**Providing Ongoing Follow-Up of the Former Premature Infant**

Many former premature infants experience myriad medical and developmental problems throughout infancy, early childhood, and beyond. Upon or following discharge, many former premature infants display one or many of the following medical or developmental problems:

- Chronic lung disease (bronchopulmonary dysplasia)
- Cardiac changes such as right ventricular hypertrophy and pulmonary artery hypertension

- Growth retardation, poor feeding, anemia of prematurity, other nutrient deficiencies
- Apnea of prematurity, gastroesophageal reflux disease, bradycardia
- Sudden infant death syndrome (SIDS)
- Rickets (osteopenia) of prematurity
- Hydrocephalus, ventriculomegaly, abnormal head magnetic resonance imaging results, ventriculoperitoneal shunt
- Inguinal or umbilical hernias
- Retinopathy of prematurity, strabismus, decreased visual acuity
- Hearing deficits
- Delayed dentition
- Gross motor, fine motor, and language delay; sensory integration issues (Gargus et al., 2009; Kelly, 2010)

Over the long term, former premature infants are at higher risk than typical infants of developing cognitive delay, cerebral palsy, attention deficit disorder, learning disabilities, difficulties with socialization, and vulnerable child syndrome (Duncan & Caughy, 2009; Gargus et al., 2009). Additionally, many former premature infants display alterations in muscle tone at or shortly after discharge from the neonatal intensive care unit (NICU) that require physical therapy intervention.

For these reasons, high-risk infants require special attention and thorough, appropriate assessment to discern subtle changes that may affect their long-term physical, cognitive, emotional, and social outcome. The pediatric nurse should have an understanding of the special concerns that former premature infants and children as well as their families may face.

From the beginning, encourage families to keep a binder that includes all of the infant's pertinent check-up, insurance, and medical and developmental information; this will serve as a resource for the parents, and they will be able to supply complete information when visiting various providers.

### PROVIDING ROUTINE WELL-CHILD CARE OF THE FORMER PREMATURE INFANT

Former premature infants require similar well-child care as typical infants do, with additional visits for management of multiple complex medical issues and developmental screening/intervention. Teach families routine newborn care, including bathing, dressing, and avoidance of passive cigarette smoke. All visits for primary care follow-up will be scheduled based on the infant's chronological age.

Prior to discharge from the NICU, the infant will be tested for oxygen desaturation while seated in the car seat (Kelly, 2010). Clearance will be obtained prior to the infant's discharge. Former preemies require car seat use just as other infants do. Help the parents to find methods of padding the car seat or adding an additional semifirm

cushion inside the seat for the infant to ride in the car safely. Some infants may need to continue cardiac/apnea monitoring while in the car seat.

Since the former premature infant is at increased risk for SIDS compared to the general population, it is critical to teach parents to put the infant on his or her back to sleep (although this is contraindicated with gastroesophageal disease) (Kelly, 2010).

Give immunizations according to the current Centers for Disease Control and Prevention (CDC)-recommended immunization schedule, based on the infant's chronological age. All former preemies should receive the flu vaccine as recommended after 6 months chronological age. Respiratory syncytial virus (RSV) prophylaxis is critical for certain groups of premature infants (Kelly, 2010). Therefore, administer palivizumab (Synagis) vaccine according to the recommended schedule (refer to Chapter 40 for additional information about RSV prophylaxis).

### ASSESSING GROWTH AND DEVELOPMENT OF THE FORMER PREMATURE INFANT

When assessing growth and development of the infant or child who was born prematurely, determine the child's adjusted or corrected age so that you can perform an accurate assessment. The corrected or adjusted age should be used for evaluating progression in growth as well as development. For example, if a 6-month-old infant was born at 28 weeks' gestation (12 weeks or 3 months early), his growth and development expectations are those of a 3-month-old (corrected age). Continue to correct age for growth and development until the child is 3 years old.

Many former premature infants require special diets to foster catch-up growth (Kelly, 2010). Extra calories are needed for increased growth needs. Additional calcium and phosphorus are required for bone mineralization. For these reasons, former preemies should be fed breast milk fortified with additional nutrients or a commercially prepared formula specific for premature infants. When former preemies demonstrate consistent adequate growth (usually by 6 months corrected age), they may be switched to a "term infant formula" such as Similac or Enfamil, concentrated to a higher caloric density if needed. Assess the infant's ability to suck efficiently and refer him or her to occupational or speech therapy if the infant is a slow feeder or has difficulty feeding.

All anticipatory guidance related to nutrition is based on the child's corrected age. In other words, begin solids at 6 months corrected age, not chronological age, and delay the addition of whole milk until 12 months corrected age, rather than 1 year chronological age (Kelly, 2010). Signs that the former premature infant may be ready to attempt spoon feeding include interest in feeding, decrease in tongue thrust, and adequate head control.

Early screening and intervention for issues related to development are critical to the attainment of optimal

development in the former preemie. The comorbidities that ex-preemies exhibit in the form of prior and current medical problems place these infants at high risk for **developmental delay** (lag in meeting developmental milestones). Even mild developmental delays warrant evaluation and intervention. The Denver II may be used as a screening tool for developmental concerns in the ex-preemie, though it does not always identify children at risk. Parent-report questionnaires demonstrate fairly accurate estimations of developmental problems, and their use is recommended by the American Academy of Pediatrics (2008). Most importantly, assess the child's development based on corrected age until the child is 3 years old. Refer infants and children early if developmental concerns are suspected.

### Identifying and Managing Failure to Thrive and Feeding Disorders in Children With Special Needs

Failure to thrive (FTT) is a term used to describe inadequate growth in infants and children. The child fails to demonstrate appropriate weight gain over a prolonged period of time. Length or height velocity and head circumference growth may also be affected. Typical children may experience FTT, but it is much more common in the child with special needs. Adequate nutrition is critical for appropriate brain growth in the first 2 years of life and obviously for growth in general throughout childhood and adolescence (Burns, Dunn, Brady, Starr, & Blosser, 2009). **Developmental disability** (mental or physical or combination impairment resulting in lifelong disability) may contribute to FTT, as the child's ability to consume adequate nutrition is impaired because of sensory or motor delays, such as with cerebral palsy. Other organic causes of failure to thrive include inability to suck and/or swallow correctly, malabsorption, diarrhea, vomiting, or alterations in metabolism and caloric/nutrient needs associated with a variety of chronic illnesses. Infants and children with cardiac or metabolic disease, chronic lung disease (bronchopulmonary dysplasia), cleft palate, or gastroesophageal reflux disease are at particular risk. Feeding disorders or food refusal may occur in infants or children who have required prolonged mechanical ventilation, long-term enteral tube feedings, or an unpleasant event such as a choking episode. Inorganic causes of FTT include neglect, abuse, behavioral problems, lack of appropriate maternal interaction, poor feeding techniques, lack of parental knowledge, or parental mental illness. Additionally, children who live in poverty are at risk due to the inability to provide adequate nutrition (Dowshen, 2011; Sirotiak & Chisea, 2011).

The two categories of causes are not mutually exclusive. Organic causes of FTT may lead to behavioral

problems that potentiate problems with adequate growth; hence, FTT is thought of as a multifactorial problem (Bryant-Waugh, 2011).

Screen all children for FTT to identify them early. In addition to poor growth, the infant or child with FTT may present with a history of developmental delay or loss of acquired milestones. Infants or children with feeding problems may display nipple, spoon, or food refusal; difficulty sucking; disinterest in feeding; or difficulty progressing from liquid to puréed to textured food. Perform a detailed dietary history and instruct the parents to complete a 3-day food diary to identify what the child actually eats and drinks. Assess the parent-child interaction, with particular attention to the parent's ability to read and respond to the infant's or child's cues. Observe feeding, noting the child's oral interest or aversion, oral-motor coordination, and swallowing ability, as well as parent-child interactions before, during, and after the feeding. Further aversion to eating may occur as the parent's anxiety over the thought of the child not eating or losing weight leads to attempts to force-feed the child (Bryant-Waugh, 2011).

Significant FTT may require hospitalization for evaluation and management. Sometimes enteral tube feedings are necessary in order for children with FTT or feeding disorders to demonstrate adequate growth. Box 34.4 lists nursing interventions for the hospitalized child with FTT.

#### Take Note!

Infants with FTT related to maternal neglect may avoid eye contact and be less interactive than other infants (Burns et al., 2009).

#### BOX 34.4

#### NURSING INTERVENTIONS DURING THE CHILD'S HOSPITALIZATION FOR FAILURE TO THRIVE

- Observe parent-child interactions, especially during feedings.
- Develop an appropriate feeding schedule.
- Provide feedings as prescribed (usually 120 kcal/kg/day is needed to demonstrate proper weight gain).
- Weigh the child daily and maintain strict records of intake and output.
- Educate parents about proper feeding techniques and volumes.
- Provide extensive support to alleviate parental anxiety related to the child's inability to gain weight.

Adapted from Sirotiak, A. P. & Chisea, A. (2011). *Failure to thrive*. Retrieved June 10, 2012, from <http://emedicine.medscape.com/article/915575-overview>

## Promoting Growth and Development

When caring for the infant with special health care needs in the hospital, provide consistent caregivers to encourage the infant to develop a sense of trust. Allow and encourage the parent to stay with the infant, providing a comfortable place for the parent to sleep. To promote attachment, emphasize the baby's positive qualities. Encourage developmentally appropriate skills and allow the infant to have pleasurable experiences through all of the senses (Vessey & Sullivan, 2010).

For the toddler, begin developmentally appropriate limit setting and discipline. Encourage independence as the toddler is able. Modify gross motor and sensory activities to accommodate the toddler's limitations. To encourage a sense of control, offer the toddler simple choices. As the preschooler develops, encourage mastery of self-help skills as the child is able. Encourage socialization with same-age peers to develop a sense of friendship. Reinforce to the child that the illness or disability is not a punishment for wrongdoing or the child's fault in any way (Vessey & Sullivan, 2010).

Encourage the school-age child to attend school and make up work that must be missed for medical treatments or appointments. Provide education to the school staff and other students about the child's special needs. Promote involvement in appropriate sports activities; music, drama, or art activities; and clubs such as Boy Scouts or

Girl Scouts. Educate the child about the illness or disability and the course of treatment (Vessey & Sullivan, 2010).

Inform parents of teens that those with chronic illness often participate in the same activities as typical teens, such as risk taking, rebelling, and trying out different identities. Assist the teen with coping and interpersonal skills. Promote involvement in activities with other teens with special needs as well as typical adolescents. Ensure that the teen participates in rites of passage as able, such as attending the prom or obtaining a driver's license. Discuss future plans with the teen, such as college or vocation, as well as transition to a nonpediatric physician (Vessey & Sullivan, 2010). See Evidence-Based Practice 34.1.

## Providing Resources to the Child and Family

Nurses should be familiar with community resources available to children with special health care needs. Educational opportunities for children with special health care needs include early intervention programs and programs offered through the public school system. Financial resources, respite care, and complementary therapies are other areas the nurse should become familiar with.

### EDUCATIONAL OPPORTUNITIES FOR THE SPECIAL NEEDS CHILD

The foundation for health and development in children is laid during the first years of life. Children with special health care needs often require multiple developmental

#### EVIDENCE-BASED PRACTICE 34.1

#### LIFE SKILLS INTERVENTION FOR CHILDREN WITH CYSTIC FIBROSIS AND EFFECTS OF INTERVENTION ON PSYCHOSOCIAL ADJUSTMENT, FUNCTIONAL HEALTH STATUS, AND PHYSIOLOGIC STATUS OVER TIME

##### STUDY

As cystic fibrosis treatment methods have improved over the past couple of decades, enhanced survival and a healthier life course have resulted. With these improvements it has become necessary to further address the psychosocial and developmental needs of affected children. The authors performed a blinded, randomized controlled trial at four university cystic fibrosis (CF) centers. One hundred and sixteen children were participants in the study over a 9-month period of time. The intervention performed consisted of a home visit to assess each child's knowledge and management of CF. Information was provided using an educational problem-solving approach. Subsequent focus groups were held and the children discussed how to deal with peer issues.

##### Findings

Children who participated in the intervention group had greater improvements in loneliness, global self-worth,

and perceived illness experience. The intervention did not demonstrate an impact upon physical or functional health status but did improve psychosocial status.

##### Nursing Implications

In addition to CF, many chronic and debilitating conditions affect children's quality of life. Any school-age or older child with a chronic condition that impairs physical functioning would benefit from interventions similar to those performed in this study. In particular, nurses who work in settings that allow them to have long-term relationships with these children have the potential to positively influence their lives. Nurses should help children learn communication and problem-solving skills that could lessen the impact of their chronic condition.

Adapted from Christian, B. J., & D'Auria, J. P. (2006). Building life skills for children with cystic fibrosis: Effectiveness of an intervention. *Nursing Research*, 55, 300–307.

interventions and special education in the early years in order to reach their developmental potential later in childhood. Children learn best when they are at the stage of maximal readiness, and the early years must not be missed as an opportunity for development. See Healthy People 2020.

### HEALTHY PEOPLE 2020

#### Objective

Increase the proportion of children and youth with disabilities who spend at least 80% of their time in regular education programs.

#### Nursing Significance

- Ensure that children younger than age 3 years who may qualify are referred to the local early intervention program.
- Encourage families to advocate for their child's needs on the individualized education plan.

*Healthy People* Objectives based on data from <http://www.healthypeople.gov>.

Early intervention programs are intended to enhance the development of infants and toddlers with, or at risk for, disabilities, thereby minimizing educational costs and special education. Early intervention is also directed toward enhancing the capacity of families to meet their child's needs as well as to maximize the likelihood of independent living (Zero to Three, 2012).

The Individuals with Disabilities Education Improvement Act of 2004 (formerly called Public Law 99-457) mandates government-funded care coordination and special education for children up to 3 years of age. This early intervention program is administered through each state. Federal law allows each state to define “developmental disability” differently, but in general qualified personnel perform an evaluation of the child's physical, language, emotional, and social capabilities to determine eligibility (108th Congress, 2004). The law guarantees that eligible children will obtain access to services that will enhance their development. Children who qualify for services receive care coordination, and an individualized family service plan is developed by the service coordinator in conjunction with the family. The service coordinator manages the developmental services and special education that the child requires.

The intent of the program is that the child receives services in a “natural environment,” so most services occur in the home or day care center. Home visits by the service coordinator and maintenance of regular contact with the family ensure the success of the program.

Refer children suspected of developmental delay to the local early intervention program. For children receiving these services, collaborate with the service

coordinator on an ongoing basis, with particular involvement at hospital discharge and when transition of services occurs at age 3 years.

*Think back to Preet, the 2-year-old boy with a history of hydrocephalus and developmental delay, from the beginning of the chapter. Discuss with his mother the educational opportunities that are available for Preet. Explain what early intervention is and why it is important for Preet.*

Schools may have a profound impact on the child's overall health and development. Some children with special needs do not require additional services to succeed in school. For these children, the nurse's role is to assess for school success or failure and determine the effect of the school environment on the child's health. The Individuals with Disabilities Education Act, reauthorized in 2004, provides for the education of children with special needs through the public school system, from age 3 to 21 years. These services are provided within the public school system.

According to the law, each special needs student is entitled to an individualized education program (IEP), which is a written plan designed to meet the preschool, primary, or secondary school student's individual needs. A committee consisting of the child's parent, a regular teacher, a special education teacher, and various other specialists develops the IEP. Nurses may be called to serve upon this committee. The IEP must include measurable short- and long-term goals. Parents are informed of the student's progress routinely and the IEP is reviewed at least annually (108th Congress, 2004).

Preschool special education through the local public school system is provided from age 3 to 5 years; access to the curriculum is ensured for all children. A child is eligible for special needs preschool when a significant delay is present in the cognitive, language, adaptive, social-emotional, or motor development domains to the extent that it adversely affects the child's learning ability. The child receives (in the school setting) developmental therapy as needed to augment his or her ability to participate in the education process. The least restrictive environment is preferred, with special needs children participating in classes containing age-appropriate typical peers whenever possible (108th Congress, 2004). Special needs preschool services are often offered in the elementary school setting.

### FINANCIAL AND INSURANCE RESOURCES

Many special needs children whose families demonstrate financial need may be eligible for Supplemental Security Income (SSI). This program was created in 1972 through Public Law 92-603. SSI is a cash assistance program, and

monthly benefits vary per individual. SSI qualification also qualifies the child for state-administered Medicaid. Medicaid benefits vary slightly from state to state but generally cover medical visits, medication, hospitalization, and limited adjuvant therapies. The State Children's Health Insurance Program (SCHIP) provides low-cost health insurance to eligible children. Eligibility and the extent of benefits provided by SCHIP vary by state (Vessey & Brown, 2010).

Public Law 94-566 provides for state-administered Title V programs under the Maternal and Child Health Bureau Block Grant program. State Title V programs provide community-based, comprehensive service coordination for children with special needs (USA.gov, 2011).

Online directories providing a wealth of links to resources for special needs children include Children's Disabilities Information and Special Child. Web links to these sites can be found on [thePoint](#).

### RESPIRE CARE

Primary caregivers of children with special health care needs must be dedicated, skillful, vigilant, and knowledgeable. Constant care is a stress on the primary caregiver, who needs temporary relief from the daily caregiving demands. **Respite care** provides an opportunity for families to take a break from the daily intensive caregiving responsibilities. Respite care should meet the child's health care needs and offer the child developmental opportunities. Finding and using respite care that the family is comfortable with and trusts may decrease the family's stress and lead to an enhanced quality of life for special needs children and their families. Nurses can facilitate access to respite care, educate respite providers, and ensure quality respite care practices through involvement in community agencies.

### COMPLEMENTARY THERAPIES

Families of children with special health care needs often use adjuvant therapies. These may include, among others, homeopathic and herbal medicine, pet therapy, hippotherapy, music, and massage. Many families desire to blend natural or Eastern medicine with traditional allopathic medicine for their special needs child in search of palliation or a cure. When obtaining the health history, ask specifically about homeopathy or herbal medications the child may be taking. Pet therapy may be used to decrease stress or as a component of psychotherapy.

Hippotherapy is also referred to as horseback riding for the handicapped, therapeutic horseback riding, or equine-facilitated psychotherapy. Individuals with almost any cognitive, physical, or emotional disability may benefit from therapeutic riding or other supervised interaction with horses. The unique movement of the horse under the child helps the child with physical disabilities to achieve increased flexibility, balance, and muscle strength. Children with mental or emotional disabilities may experience increased self-esteem, confidence, and

#### BOX 34.5

### CONDITIONS BENEFITING FROM HIPPO THERAPY

- Muscular dystrophy
- Cerebral palsy
- Visual impairment
- Down syndrome
- Intellectual disability
- Autism
- Multiple sclerosis
- Emotional disabilities
- Brain injury
- Myelomeningocele
- Spinal cord injury
- Amputation
- Attention deficit disorder
- Learning disabilities
- Deafness
- Cerebrovascular accident (stroke)

patience as a result of the unique relationship with the horse. A physical therapist or psychotherapist (depending on the situation) generally works very closely with specially trained equine staff (Gasalberti, 2006). Box 34.5 lists chronic medical conditions for which hippotherapy may be beneficial. Additional information may be obtained through the North American Riding for the Handicapped Association or the American Hippotherapy Association. Links to these sites can be found on [thePoint](#).

Music may be used to induce positive behavioral changes or various other positive effects. Massage therapy may be beneficial to a wide variety of children. It may be used to reduce pain, promote relaxation, or demonstrate a specific positive effect related to the child's particular medical condition (Gasalberti, 2006).

#### Take Note!

Become familiar with the risks and benefits of homeopathic and herbal medications, as many families use these treatments in an effort to improve their child's quality of life or outcome.

### Providing Support and Education

At the time of initial diagnosis, allow and encourage the family to express their feelings. Parents of children with special health care needs require emotional, practical,

economic, and social support. Encourage parents to obtain help with daily routines. Encourage stress reduction for the parents through exercise and allowing time for themselves. Be a supportive and encouraging listener, making sure to nurture the whole child, not just his or her special condition.

Parents value peer support groups, sometimes feeling that only other parents of disabled or chronically ill children could understand the heartache, fear, and other emotions they often experience. Pediatric nurses should be proactive in helping families find support systems.

Fathers have the same concerns about their children as mothers do, but they may show these concerns differently. It is important for nurses to involve them in the child's care. Teach skills to both parents, and actively involve fathers by asking about their observations and opinions.

Parents become the experts on their child's needs and care, and they should be recognized as such. Parents want to be taken seriously and do not like being ignored. They should be viewed as having reliable and valuable information about their children. By being an active and reflective listener, the nurse can demonstrate to the parents that their opinion is valued, in addition to finding out what the child really needs. Some parents may hesitate to volunteer information, unsure about which information the nurse needs. Show respect for the parents' knowledge of their child's needs by seeking advice on the child's daily care, medical/physical needs, and current developmental level, no matter what the site of care is.

Families may need additional support from the nurse at times of transition. As the equipment or treatment needs change, adjust the teaching plan. Educate the child and family about the use of adaptive equipment. Ensure that families understand how specific activities must be modified to accommodate the child's needs. Provide anticipatory guidance related to expected developmental changes, including resources and laws related to education. Act as a liaison between the family and the day care center or school. As the child grows and matures, encourage parents to relinquish caregiving tasks to the child as appropriate to encourage independence and promote self-esteem.

### ***Assisting the Adolescent With Special Health Needs Making the Transition to Adulthood***

Adolescence is a time of physical changes, psychosocial challenges, and initiation of independence from parents. The adolescent with a chronic illness or one who is technology dependent may experience this period differently from other teens. Puberty is often affected by chronic illness (either delayed or earlier). Chronic illness may lead

to isolation from peers at a time when peer interaction is the core of psychosocial development. Teens may struggle to fit in with their peers by hiding their illness or health care needs (ignoring them), complying poorly with treatment regimens, or participating in risky behaviors. At a time when the child should be developing independence from the parents, he or she may be experiencing significant dependence related to the special health condition. For these reasons, the adolescent with special health care needs may require increased amounts of support from the nurse.

Making the transition to adult care for a child with special health care needs can be difficult, and advance planning leads to a smoother transition. Transition planning involves multidisciplinary care coordination; acknowledgement of the changing roles among the youth, family, and health care professionals; and fostering of the youth's self-determination skills. A written plan for transition to adult care should be initiated in mid-adolescence. Have ongoing conversations with the teen about this transition. Issues to be resolved prior to the transition include financial resources for medical care, college or vocational school attendance, living arrangements, and caretaking arrangements (White & Hackette, 2009).

The Adolescent Health Transition Project (AHTP) recommends the following schedule:

- By age 14, ensure that a transition plan is initiated and that the IEP reflects post-high school plans.
- By age 17, explore health care financing for young adults. If needed, notify the local division of vocational rehabilitation by the autumn before the teen is to graduate from high school of the impending transition. Initiate guardianship procedures if appropriate.
- Notify the teen that all rights transfer to him or her at the age of majority. Check the teen's eligibility for SSI the month the child turns 18. Determine if the child is eligible for SSI work incentives.
- If the youth is attending college, contact the college's campus student disability service program.
- By age 21, ensure that the young adult has registered with the Division of Developmental Disabilities for adult services if applicable (AHTP, 2012).

Prior to moving to adult care (with an adult medical provider), ensure that the adolescent understands the treatment rationale, symptoms of worsening condition, and especially danger signs. Teach the adolescent about when to seek help from a health professional. Introduce the teen to the medical insurance process. At transition, coordinate a seamless transfer by providing a detailed written plan to the care coordinator or advanced practice nurse (after verbal collaboration).

After the transition, serve as a consultant to the adult office in relation to the teen's needs. Consult with a transition services coordinator or other service agency

as available in the local community (AHTP, 2012). See Healthy People 2020.

### HEALTHY PEOPLE 2020

#### Objective

(Developmental) Increase the proportion of children with special health care needs whose physician has discussed transition planning from pediatric to adult health care.

#### Nursing Significance

- In the primary care setting, assist families with planning for transition beginning in early adolescence.
- If available, refer families to multidisciplinary programs for medically complex children.

*Healthy People Objectives based on data from <http://www.healthypeople.gov>.*

## THE DYING CHILD

The idea that a child may die is simply unimaginable to most people, yet children die daily. Each year, about 50,000 children die in the United States; of those, about 28,500 are infants (Heron et al., 2009). A child's chronic illness may progress to the point of becoming a **terminal illness** (illness deemed to be noncurable, ultimately leading to death). For example, despite the increased survival rates for children with cancer as a result of improved treatment options and protocols, cancer remains the leading cause of death from disease in all children older than the age of 1 year (Heron et al., 2009). Less frequently, other diseases also lead to terminal illness in children, with congenital defects and traumatic injuries being the more common causes. Pediatric nurses will inevitably encounter situations in which a child dies. These situations are extremely difficult for all persons involved, and the nurse plays a key role in caring for the dying child and his or her family. Caring for the dying child is a family-centered, multidisciplinary process. Nurses must respond to the child's and family's physiologic, emotional, and spiritual needs during this difficult time. Children display differing responses to the dying process and impending death depending on their developmental level. Children and their families need significant amounts of support throughout the process of dying.

## End-of-Life Decision Making

Parents are obligated not only to protect their children from harm but also to do as much good for them as possible, both from an ethical and a legal standpoint. When the time comes for end-of-life decision making,

parents are often torn about the “right” course of action. Parents may be asked to make decisions about stopping treatment, withdrawing treatment, providing palliative care, or consenting to “do not resuscitate” (DNR) orders. Children, parents, and physicians are generally in agreement that continued suffering is not desired for any child with a terminal illness. When all possible curative attempts have been made, then survival is no longer possible (Carter et al., 2011).

Nurses involved in this process must examine their own values related to dying and consider the American Nurses Association's code of ethics for nurses as well (2001). The family's feelings must also be acknowledged. During the process of end-of-life decision making, health care providers must assure families that the focus of care is changing and that the child is not being abandoned. Emphasize to parents that no matter what their decision is, the health care team is dedicated to the comfort and expert care of their child (Carter et al., 2011).

Ensure that communication is family centered. Quality of life must be taken into consideration when making decisions to continue or withhold treatment. Provide parents facing end-of-life decisions with honest information and education from the time of the diagnosis/prognosis forward. Anticipate that parents may vacillate in the decision-making process. Clarify information for them and allow them private time to discuss the options. Do not make judgments about or question the parents' decision. Be sensitive to any ethnic, spiritual, or cultural preferences during the terminal stage of the illness. Encourage parents to interact with other parents who have a child with a terminal illness (Carter et al., 2011).

### Allowing Natural Death

The decision to institute a DNR order is one of the most difficult decisions a family may ever have to make. DNR refers to withholding cardiopulmonary resuscitation should the child's heart stop beating. Parents may initially feel like this means they are giving up on their child. Nurses must educate families that resuscitation may be inappropriate and lead to more suffering than if death were allowed to occur naturally. The parents need to understand that when a palliative care route is chosen, rather than continuing a curative or treatment route, the focus of the child's care is changing but the child and family are not being abandoned. Families may wish to specify a certain extent of resuscitation that they feel more comfortable with (e.g., allowing supplemental oxygen but not providing chest compressions). Some institutions are now replacing the DNR terminology with “allow natural death” (AND), which may be more acceptable to families facing the decision to withhold resuscitation (Sokol, 2009).

## Involving the Dying Child in the Decision-Making Process

End-of-life decision making often involves ethical dilemmas for the child, family, and health care team. This is particularly true when the parents' wishes conflict with the child's or adolescent's desires. Children should be involved in decision making to the extent that they are able. Discuss intervention within the context of the child's condition and wishes. Children older than the age of 7 may "assent" to the continuation or withdrawal of treatment (Unguru et al., 2008). Be available to the older child or adolescent to provide support and information if he or she desires. Talk with the child or adolescent with the parents present, as well as in private. Maintain the child's comfort and dignity. Encourage the child to spend time with other children with a terminal illness. Assure the child that everything will be done to make him or her comfortable. Consult parents about the timing and depth of end-of-life discussions. Just as parents do, the terminally ill child may vacillate in the decision-making process. Remain sensitive, and respect the child's decisions.

## Organ or Tissue Donation

With large numbers of organ transplant candidates on waiting lists and the shortage of viable organs, pediatric organ and tissue donation is a priority (Hittle, 2012). For many families, knowing that a child's organs or tissues may save another child's life provides a way to help others despite their own loss. A healthy child who dies unexpectedly is an excellent candidate for organ donation. Many chronic illnesses in children preclude the option of organ or tissue donation, though individual determinations of eligibility should be made.

The discussion of organ donation should be separated from the discussion of impending death or brain death notification. Written consent is necessary for organ donation, so the family must be appropriately informed and educated. Many families who never thought about it before may consider the option of donation if adequately educated about the process. All expenses for organ procurement are borne by the recipient's family, not the donor's. Ask whether the dying child ever expressed a wish to donate organs and whether the parents have considered it.

Families need to know that procurement of the organs does not mar the child's appearance, so that an open casket at the child's funeral is still possible if the family desires. The donating child will not suffer further because of organ donation. The organs or tissues will be harvested in a timely fashion after the declaration of death, so the family need not worry about delay of the wake or funeral. The family's cultural and religious beliefs must be considered, and the team discussing

organ donation with the family must do so in a sensitive and ethical manner (Hittle, 2012).

## Palliative Care of the Dying Child

Appropriate **palliative care** is essential for any child with a life-threatening or progressive incurable condition. Whether palliative care is provided in the home, hospital, or hospice setting, the goal is to provide the best quality of life possible at the end of life while alleviating physical, psychological, emotional, and spiritual suffering. The Last Acts Palliative Care Task Force has established principles on which palliative care of children should be based. These include:

- Respecting children's goals, preferences, and choices
- Comprehensive caring
- Using the strengths of interdisciplinary resources
- Acknowledging and addressing caregivers' concerns
- Building systems and mechanisms of support (Association of Pediatric Oncology Nurses [APON], 2003)

## Hospice Care

Hospice allows for family-centered care in the child's home or a hospice facility. As with adult hospice care, the comfort of the entire family is important. The goals of pediatric hospice care are enhancement of quality of life for the child and family through an individualized plan of care. The recommended standards for pediatric hospice care do not preclude involvement in ongoing treatment (this is in contrast to adult hospice), but certain eligibility criteria must be met (Children's Hospice International, 2011). Parents are educated on ways to comfort and interact with their dying child, such as massage, movement, or singing. Spiritual support is available through a chaplain, a social worker, or the family's minister. The nurse not only educates the family about the dying process but also assists them with providing basic care and pain management. The decision to withhold nutrition or hydration may be made in certain instances. Pain management is of the utmost importance for the terminally ill child (APON, 2003). Ongoing bereavement care is also provided to the family by the hospice after the child's death.

## Nursing Management of the Dying Child

Though interdisciplinary care is essential for quality care at the end of life, it is the nurse who plays the key role of child/family advocate and who is usually the constant presence throughout the dying process. Nursing management of the dying child focuses on managing pain and discomfort, providing nutrition, providing emotional support to the dying child and family, and assisting the family through the grief process. Throughout the process, it is important to focus on the family as the unit of care.

## Managing Pain and Discomfort

Pain management is an essential component of care for the child with a terminal illness. Providing for comfort enhances the child's quality of life and minimizes suffering (Baker et al., 2008). Assess pain using a developmentally appropriate tool (see Chapter 36 for further information). Provide pain medication around the clock rather than on an "as needed" basis to prevent recurrence or escalation of pain. Determine the child's preferred comfort measures and use them to provide additional relief. Change the child's position frequently but gently to minimize discomfort. Limit nursing care to comfort measures that ease the child's discomfort. Maintain a calm environment, minimizing noise and light.

## Providing Nutrition

Since the body naturally requires less nutrition as the child is dying, do not excessively coax the child to eat or drink. Offer frequent small meals or snacks of the child's choosing. Soups and shakes require less energy to eat and so may be desirable. If the child desires a different food, provide that one. Keep strong odors away from the child to decrease nausea. Administer antiemetics as needed. Provide mouth care and keep the lips lubricated to keep the mouth feeling clean and prevent the discomfort associated with chapped lips. Make sure the environment is a pleasant one for eating.

## Providing Emotional Support to the Dying Child and Family

Be attuned to the entire family's needs and emotions in order to foster a holistic connection with the child and family. Nurses provide physical care through specific tasks and interventions for the dying child, but they also need to be fully present emotionally with the child and family. In general, people are uncomfortable with the concept of a dying child. Nurses should work through their own feelings about the situation to be able to be "in the moment" with the child and family. Ask yourself: Can I be fully present with this family? If not, then what can I change to be so? (Carter et al., 2011).

Families and dying children benefit from the presence of the nurse, not just the interventions he or she performs. Families report that the simple act of being present with the family is very healing (Carter et al., 2011). Listen to the child and family; be still and silent for a time to accomplish this. Foster respect for the whole child by attending to him or her as such.

Respect the parents of the dying child by helping them honor the commitments they have made to their child. Acknowledge that parents have diverse needs for information and participation in decision making. Allow and encourage family customs or rituals in relation

to death and dying. Families may desire the pastor or priest to be present when the child's death is imminent. Certain rituals may be desired, depending on the family's religious or spiritual background. Ensure that these important events occur, and alter nursing care routines as needed to accommodate them. Respect the family's need to participate in these rituals and customs (Ethier, 2010).

Work collaboratively with the family and health care team to provide for the needs of the child and family. Resources for families of a dying child are listed in Box 34.6. The Make-a-Wish Foundation works to grant the wishes of terminally ill children, giving the child and family an experience of hope, strength, and love. A link to the Make-a-Wish Foundation is included on [thePoint](#).

#### EASING ANXIETY OR FEARS

Parents may be afraid of their child dying alone or not know what to expect in the death process. This fear may contribute to increased anxiety, which the child may sense. Younger children may fear separation from their parents and older children may not want to die alone or experience pain or discomfort associated with dying. Each child and family is individual; discuss their particular fears and anxieties in order to determine the child's and family's needs for education and support (Baker et al., 2008).

Involve the parents and other family members in all phases of the child's care. Explain all aspects of care to the child to minimize anxiety related to nursing interventions. Answer the child's questions honestly. Involve the child in decision making whenever possible. Limit interventions to those related to palliation, rather than treatment, advocating for the child as needed. Remain with the child when a parent or family member is not in the room so the child will not fear dying alone.

### MEETING THE DYING CHILD'S NEEDS ACCORDING TO DEVELOPMENTAL STAGE

It is important to provide the type of support and education that the dying child needs according to his or her developmental stage. For the infant, unconditional love and trust are of utmost importance. Ensure that the infant's family is available to the child. The toddler, 1 to 3 years old, thrives on familiarity and routine. Maximize the toddler's time with parents, be consistent, provide favorite toys, and ensure physical comfort. Spirituality in the preschool years focuses on the concept of right versus wrong. The 3- to 5-year-old may see death as punishment for wrongdoing; correct this misunderstanding. Use honest and precise language. Help the parents to teach the child that though the family will miss the child, it will continue to function without him or her (Ethier, 2010).

The school-age child has a concrete understanding of death. Children who are 5 to 10 years old need specific, honest details (as desired). Encourage the child to help make decisions, and help the child to establish a sense of control (Ethier, 2010).

The young adolescent (10 to 14 years old) will benefit from reinforcement of self-esteem, self-respect, and a sense of worth. Respect the child's need for privacy and time alone as well as time requested with peers. Support the need for independence and encourage the child to participate in decision making. The older teen (14 to 18 years of age) has a more adult-like understanding of death and will need further support through honest, detailed explanations and will want to feel truly involved and listened to (Ethier, 2010).

### *Assisting the Family Through the Grief Process*

The family may experience anticipatory grief when the diagnosis of terminal illness is made. Families may deny the prognosis, become angry at the health care system or a higher power, or experience depression. Acute grief is an intense process that occurs around the time of the actual death. Family members may feel short of breath or as though the throat is tight. They may verbalize that the situation is unreal to them or search for

reasons why the death was not prevented. Families may also display hostility or restlessness. Each individual will express grief in his or her own manner. Mourning the death of a loved one takes a long time, and families should be supported throughout the process (Ethier, 2010). Local and national resources are available for grieving parents. Several resources for grieving parents are listed on [thePoint](#). Refer parents to bereavement resources as appropriate.

### KEY CONCEPTS

- Children with special health care needs are those who have, or are at risk for, a chronic physical, developmental, behavioral, or emotional condition that generally requires more intensive and diverse health services, as well as coordination of those services, than do typical children.
- Most children with chronic illnesses or who are dependent on technology progress through stages of growth and development just as typical children do, though possibly at a slower pace.
- Parents of special needs children experience a multitude of emotions and changes in their lives, often carrying a heavy caregiving burden. They become the experts on their child's care and should be empowered and supported in their efforts.
- The child and family with special needs may require additional support during times of transition, such as at initial diagnosis or change in prognosis, when symptoms increase, when the child moves to a new setting (hospital, school), during periods of developmental change, or during a parent's absence.
- Children with special health care needs are at increased risk for the development of vulnerable child syndrome, which may have psychologically harmful effects on the child and parents for many years.
- Home is the most developmentally appropriate environment for children with special health care needs and those who are technology dependent. Children display an improved physical, emotional, psychological, and social status when they are cared for at home.
- Family-centered care provides the optimal framework for caring for children and families with special needs. Empowering the family strengthens them. A medical home or permanent relationship with the physician or nurse practitioner benefits the family, as care coordination and advocacy are provided.

- Use adjusted (or corrected) age when assessing growth and development of the infant or child who was born prematurely. Provide early screening and intervention for issues related to development to maximize the former preemie's potential for growth and development.
- Become familiar with the risks and benefits of adjuvant therapies used by some families of children with special health care needs.
- Screen children with special health care needs for failure to thrive or a feeding disorder.
- Screening helps to identify children with unmet health needs so that intervention may begin.
- Early intervention provides care coordination (developmental services and special education), as well as an individualized family service plan for qualifying children and their families.
- Each special needs student is entitled to an IEP, which is a written plan that is designed to meet the preschool, primary, or secondary school student's needs.
- Early discharge planning and ongoing inclusion and education of the family facilitate continuity of care. During midadolescence, initiate a written plan to help the special needs child make the transition to adult care.
- Support the dying child and the family throughout the end-of-life decision-making process, providing facts as desired about palliative care, hospice, and organ donation.
- Younger children who are dying generally need for their families to be close and to trust their needs will be provided for. Older children require honest explanations given at a level appropriate for the child's age or developmental stage.

## MULTIPLE CHOICE QUESTIONS

1. A 5-year-old boy visits the physician's office with an upper respiratory infection. Which approach would give the nurse the most information about the child's developmental level?
  - a. Playing a game with the child
  - b. Talking with the child about the teddy bear next to him
  - c. Using a screening tool during a follow-up office visit
  - d. Asking the 10-year-old sibling about the child
2. Which statement indicates the best sequence for the nurse to conduct an assessment in a nonemergency situation?
  - a. Introduce yourself, ask about any problems, take a history, and do the physical examination.
  - b. Perform the physical examination and then ask the family if there are any problems in the child's life.
  - c. Do the physical examination while at the same time asking about the child's previous illnesses; then talk about the family's concerns.
  - d. Get a complete history of the family's health beliefs and practices, and then assess the child.
3. What approach by the nurse would most likely encourage a child to cooperate with an assessment of physical and developmental health?
  - a. Explain to the child what's going to happen when the child asks questions.
  - b. Explain what is going to happen in words the child can understand.
  - c. Force the child to cooperate by having a parent hold him or her down.
  - d. Give the child a sticker before beginning the examination.
4. A sleeping 5-month-old girl is being held by the mother when the nurse comes in to do a physical examination. What assessment should be done initially?
  - a. Listening to the bowel sounds
  - b. Counting the heart rate
  - c. Checking the temperature
  - d. Looking in the ears
5. Which assessment finding is considered normal in children?
  - a. Irregular respiratory rate and rhythm
  - b. Split S<sub>2</sub> and sinus arrhythmia
  - c. Decreased heart rate with crying
  - d. Genu varum past the age of 5 years

## CRITICAL THINKING EXERCISES

1. A soft and muffled heart murmur is heard in a 4-year-old patient. The mother states that she has never heard that the child has a murmur. What should the nurse do?
2. A nurse is helping a new mother breastfeed her 4-day-old baby. The mother notices that the baby has a bluish cast to the skin on his hands and that sometimes the infant has a tremor. She asks the nurse if the baby is cold, though the baby is swaddled and comfortably resting against the mother's skin. How might the nurse help teach this mother?
3. Devise a plan for encouraging cooperation of the toddler or preschooler during various parts of the physical examination.

## STUDY ACTIVITIES

1. In the clinical setting, obtain a health history on an infant, child, or adolescent.
2. In the clinical setting, compare the approach you use for the physical examination of a toddler versus a school-aged child or adolescent.
3. No matter how thoughtfully and appropriately you plan your assessment, odds are good that you will have difficulty assessing a 2-year-old. Discuss with your classmates the strategies that you have used for success and brainstorm with them about their ideas for assessing a crying or resistant young child.

#### KEY TERMS

biotransformation  
bolus feeding  
enteral nutrition  
gastrostomy  
gavage feedings  
infiltration  
parenteral nutrition  
pharmacodynamics  
pharmacokinetics  
residual  
total parenteral  
nutrition

## Key Pediatric Nursing Interventions

### Learning Objectives

*Upon completion of this chapter, you will be able to:*

1. Define the key terms used in this chapter.
2. Describe the “eight rights” of pediatric medication administration.
3. Explain the physiologic differences in children affecting a medication’s pharmacodynamic and pharmacokinetic properties.
4. Accurately determine recommended pediatric medication doses.
5. Demonstrate the proper technique for administering medication to children via the oral, rectal, ophthalmic, otic, intravenous, intramuscular, and subcutaneous routes.
6. Integrate the concepts of atraumatic care in medication administration for children.
7. Identify the preferred sites for peripheral and central intravenous medication administration.
8. Describe nursing management related to maintenance of intravenous infusions in children, as well as prevention of complications.
9. Explain nursing care related to enteral tube feedings.
10. Describe nursing management of the child receiving total parenteral nutrition.

*Lily Kline, a 9-month-old, is admitted to your unit for failure to thrive. The physician has ordered insertion of a nasogastric tube to begin gavage feedings. The parents are very nervous and upset about this. They ask, “What will this tube do for Lily? It sounds very uncomfortable. What do you have to do to insert it? Will it have to stay in all the time? Won’t it move?” How would you address their concerns?*

#### Words of Wisdom

Quality technical skills delivered by a caring hand are a vital part of good nursing care.

**The** ill child often requires medications, intravenous (IV) therapy, or enteral nutrition to restore health. These interventions occur most often in the inpatient setting, but with today's advanced technology many children may receive treatment in the home, day care center, school, physician's office, or other community setting.

This chapter will discuss the key elements of, and guidelines for, care related to medication administration, IV therapy, and nutritional support in children. Child and parent education is emphasized. The chapter will focus on adapting and modifying medication administration and nursing procedures based on the child's growth and development and providing these treatments using a family-centered, atraumatic approach. Refer back to Chapter 30 for an overview of the important aspects of caring for a child who is to undergo a procedure.

## CONCEPTS IN ACTION MEDICATION ADMINISTRATION

At one time or another, every child will need to receive medication. As with adults, pediatric medication administration is a critical component of safe and effective nursing care. The pediatric nurse must adapt administration principles and techniques to meet the child's needs. Medication administration, regardless of the route, requires a solid knowledge base about the drug and its action. As with medication administration to any child, the nurse must adhere to the "rights" of medication administration (Box 35.1).

## Differences in Pharmacodynamics and Pharmacokinetics

Although a drug's mechanism of action is the same in any individual, the physiologic immaturity of some body systems in a child can affect a drug's **pharmacodynamics** (behavior of the medication at the cellular level). As a result, the body may not respond to the drug as intended. The intended effect may be enhanced or diminished, necessitating a change in the dosage to ensure optimal effectiveness without increasing the child's risk for toxicity.

The child's age, weight, body surface area, and body composition also can affect the drug's **pharmacokinetics** (movement of drugs throughout the body via absorption, distribution, metabolism, and excretion). Drugs are administered to children via many of the same routes that are used for adults. However, this similarity ends once the drug is administered. During the absorption process, drugs move from the administration site into the bloodstream. In infants and young children, the absorption of orally administered medications is affected by slower gastric emptying, increased intestinal motility, a proportionately larger small intestine surface area, higher gastric pH, and decreased lipase and amylase secretion compared with adults. Intramuscular absorption in infants and young children is affected by the amount of

### BOX 35.1

## EIGHT RIGHTS OF PEDIATRIC MEDICATION ADMINISTRATION

### Right Medication

- Check order and expiration dates.
- Know action of medication and potential side effects (use pharmacy, drug formulary).
- Ensure that the medication provided is the medication that is ordered.

### Right Patient

- Confirm child identity since children may deny their identity in attempt to avoid an unpleasant situation, play in another child's bed, or remove ID bracelet.
- Confirm identity each time medication is given.
- Verify child's name with caregiver to provide additional verification.

### Right Time

- Give within 20 to 30 minutes of the ordered time.
- For a medication given on an as-needed (PRN) basis, know when it was last given and how much was given during the past 24 hours.

### Right Route of Administration

- Check ordered route and ensure this is the most effective and safest route for this child; clarify any order that is confusing or unclear.
- Give the medication by the route ordered. If there is a need to change route, always check with prescriber (e.g., if a child is vomiting and has an order for an oral medication, the medication may need to be given via the IV or rectal route).

### Right Dose

- Calculate the recommended dose according to child's weight and double-check your calculations.
- Always question the pharmacist and/or prescriber if the ordered dose falls outside the recommended dose range.
- Unusually large or small volumes or dosages should always be verified.

### Right Documentation

- Record administration of the medication on the appropriate paper or computerized form according to agency policy.
- Ensure that all medications administered and refused are documented.

### Right to Be Educated

- Provide simple explanations to the child based on his or her level of understanding.
- Explain to the parents or caregiver about the medication to be given and what to expect from it.
- Use a positive, firm approach with the child.

### Right to Refuse

- Provide explanations to the child and parents to clarify any misconceptions or relieve fears.
- Reinforce the rationale for medication use.
- Respect the child's or parents' option to refuse.

muscle mass, muscle tone and perfusion, and vasomotor instability. Similarly, decreased perfusion alters subcutaneous absorption. Absorption by these routes is erratic and may be decreased. In contrast, topical absorption of medications is increased in infants and young children, which can result in adverse effects not seen in adults. Infants and young children have a greater body surface area, leading to increased absorption of topical medications. Absorption in infants is also increased due to greater permeability of the infant's skin.

The distribution (movement of a drug from the blood to interstitial spaces and then into cells) of medications is also altered in infants and young children. Medication distribution in children is affected by:

- Higher percentage of body water than adults
- More rapid extracellular fluid exchange
- Decreased body fat
- Liver immaturity, altering first-pass elimination
- Decreased amounts of plasma proteins available for drug binding
- Immature blood–brain barrier, especially in neonates, allowing permeation by certain medications

Metabolism of medications in children is altered because of differences in hepatic enzyme production and the child's increased metabolic rate. **Biotransformation** (the alteration of chemical structures from their original form, which allows for the eventual excretion of the substance) is affected by the same variations affecting distribution in children. In addition, the immaturity of the kidneys until the age of 1 to 2 years affects renal blood flow, glomerular filtration, and active tubular secretion. This results in a longer half-life and increases the potential for toxicity of drugs primarily excreted by the kidneys.

## Developmental Issues and Concerns

Children are constantly growing and developing. The specific psychosocial, cognitive, physical, and motor developmental levels of children are important. Nurses need a solid understanding of growth and development to ensure safe administration of medications to children. Table 35.1 details some growth and development issues related to administering medications to children. Always give developmentally appropriate, truthful explanations before administering medications to children, including:

- Why the drug is needed
- What the child will experience
- What is expected of the child
- How the parents can participate and support their child

Refer to Chapters 25 through 29 for further information about growth and developmental issues.

The child's past experiences with taking medications and the approaches that may have been used will often affect how the child reacts. Always approach children positively; let your manner convey the belief that they

can accomplish this needed behavior. Never label the child as “bad” if he or she did not fully cooperate in taking medication. When medications must be administered with a needle (intramuscularly or subcutaneously), assure the child that this method is not a consequence of the child's behavior. Help parents to work through the feelings of frustration that may result from the child's refusal to cooperate with medication administration. Provide parents with facts about growth and developmental issues and children's fears and anxiety related to medication administration. Model alternative ways for the parents to deal with undesirable behavior.

### Take Note!

Always administer medications promptly, assist the child in holding still using a comforting position for the child, and reward positive behavior.

## Determination of Correct Dose

Administering the correct dose is a key component of medication administration. Incorrect dosing or quantity is the most commonly reported medication error in the pediatric population (The Joint Commission, 2008). Many drug references list recommended pediatric dosages, and nurses are responsible for checking doses to ensure that they are appropriate for the child. Two common methods for determining pediatric doses are based on the unit of drug per kilogram of body weight or body surface area (BSA).

### Dose Determination by Body Weight

The most common method for calculating pediatric medication doses is based on body weight. The recommended dosage is usually expressed as the amount of drug to be given over a 24-hour period (mg/kg/day) or as a single dose (mg/kg/dose). Differentiate between the 24-hour dosage and the single dose. Use these guidelines to determine the correct dose by body weight:

1. Weigh the child.
2. If the child's weight is in pounds, convert it to kilograms (divide the child's weight in pounds by 2.2).
3. Check a drug reference for the safe dose range (for example, 10 to 20 mg/kg of body weight).
4. Calculate the low safe dose (Box 35.2).
5. Calculate the high safe dose (Box 35.2).
6. Determine if the dose ordered is within this range.

The pediatric dosage should not exceed the minimum recommended adult dosage. Generally, once a child or adolescent weighs 50 kg or greater, the adult dose is frequently prescribed (Bowden & Greenberg, 2008). However, it remains important to always verify that the dose does not exceed the recommended adult dose.

TABLE 35.1

## GROWTH AND DEVELOPMENT ISSUES RELATED TO PEDIATRIC MEDICATION ADMINISTRATION

Stage of Development	Issue/Concern	Nursing Interventions
Infant	Development of trust, which is fostered by consistent care; development of stranger anxiety later in infancy	Involve parents in medication administration to reduce stress for infant. Ensure that parents hold and comfort infant during intervention.
Toddler	Development of autonomy with displays of negativism; rituals, routines, and choices necessary to maintain some sense of control	Follow routines and rituals from home in giving medications if these are safe and positive approaches. Involve parents in medication administration. Offer simple choices (e.g., “Do you want Mom or me to give you your medicine?”). Allow child to touch or handle equipment as appropriate.
Preschooler	Development of initiative, which is fostered when they sense they are helping	Provide an opportunity to play with the equipment and respond positively to explanations and comforting. Provide choices that are possible and keep them simple (e.g., “Do you want juice or water with your medication?” or “Which medication do you want to take first?”). Do not ask, “Will you take your medicine now?” Involve parents in medication administration. Be aware that giving suppositories is particularly upsetting to this age group because of their fears of bodily intrusion and mutilation.
School-aged child	Development of industry, benefiting from being a part of their care; generally very cooperative	Explain to child in simple terms the purpose of the medication. Seek their assistance, such as putting pills in cup or opening the packet, and allow a broader range of choices. Establish a reward system to enhance their cooperation if necessary.
Adolescent	Development of identity, benefiting from much more control over their care	Approach in same manner as adults, with respect and sensitivity to their needs. Maintain the adolescent’s privacy as much as possible.

### Dose Determination by Body Surface Area

Calculating the dosage based on BSA takes into account the child’s metabolic rate and growth. It is commonly used for chemotherapeutic agents. Some recommended medication doses may read “mg/BSA/dose.” To determine the dose using BSA, you will need to know the child’s height and weight, which will be plotted on a nomogram (Fig. 35.1). A nomogram is a graph divided into three columns: height (left column), surface area (middle column), and weight (right column).

Use these guidelines to determine BSA:

1. Measure the child’s height.
2. Determine the child’s weight.
3. Using the nomogram, draw a line to connect the height measurement in the left column and the weight measurement in the right column.
4. Determine the point where this line intersects the line in the surface area column. This is the BSA, expressed in meters squared ( $m^2$ ).

Once you have determined the BSA, use the recommended dosage range to calculate the safe dosage.

### Oral Administration

Medications to be given via the oral route are supplied in many forms, including liquids (elixirs, syrups, or suspensions), powders, tablets, and capsules. Generally, children younger than the age of 5 to 6 are at risk for aspiration because they have difficulty swallowing tablets or capsules. Therefore, if a tablet or capsule is the only oral form available, it needs to be crushed or opened and mixed with a pleasant-tasting liquid or a small amount

**BOX 35.2**

**DOSAGE CALCULATION USING BODY WEIGHT**

After converting the child's weight in pounds to kilograms and checking the safe dose range:

- Calculate the low safe dose range (e.g., 10 to 20 mg/kg and the child weighs 30 kg):
  - Set up a proportion using the low safe dose range  
 $10 \text{ mg}/1 \text{ kg} = x \text{ mg}/30 \text{ kg}$
  - Solve for  $x$  by cross-multiplying:  
 $1 \times x = 10 \times 30$   
 $x = 300 \text{ mg}$
- Calculate the high safe dose range:
  - Set up a proportion using the high safe dose range  
 $20 \text{ mg}/1 \text{ kg} = x \text{ mg}/30 \text{ kg}$
  - Solve for  $x$  by cross-multiplying:  
 $1 \times x = 20 \times 30$   
 $x = 600$
- Compare the safe dose range (for this example, 300 to 600 mg) with the ordered dose. If the dose falls within the range, the dose is safe. If the dose falls outside the range, notify the prescriber.

(generally no more than a tablespoon) of a nonessential food such as applesauce. However, never crush or open an enteric-coated or time-release tablet or capsule. The crushed tablet or inside of a capsule may taste bitter, so never mix it with formula or other essential foods. Otherwise, the child may associate the bitter taste with the food and later refuse to eat it.

**Take Note!**

Certain drug formulations should not be crushed. Before crushing a pill or opening a capsule, always check that this will not alter the intended effects of the drug.

Liquid medications, primarily suspensions, may be less concentrated at the top of the bottle than at the bottom of the bottle. Always shake the liquid to ensure even drug distribution. The key to administering liquid forms of oral medications is to use calibrated equipment such as a medicine cup, spoon, plastic oral syringe, or dropper (Fig. 35.2).

**Take Note!**

Use the medicine cup or syringe with proper calibration instead of household cups or measuring spoons, since they are not calibrated and may deliver an incorrect dose of medication.

If a dropper is packaged with a certain medication, never use it to administer another medication, since the drop size may vary from one dropper to another. If using a syringe for oral administration, only use the type intended for oral medications, not one designed for parenteral administration. When using a dropper or oral syringe (without a needle) for infants or young children, direct the liquid toward the posterior side of the mouth. Give the drug slowly in small amounts (0.2 to 0.5 mL)

**FIGURE 35.1** A nomogram to determine body surface area.

**FIGURE 35.2** Devices used to administer oral medications to children.

**FIGURE 35.3** Position the infant or young child for safe medication administration.

and allow the child to swallow before more medication is placed in the mouth (Fig. 35.3). A nipple without the bottle attached is sometimes used to administer medication to infants. Place the medication directly in the nipple and keep the nipple filled with medication as the infant sucks so no air is taken in while the infant takes the medication. Always place the infant or young child upright (at least a 45-degree angle) to avoid aspiration. The toddler or young preschooler may enjoy using the oral syringe to squirt the medicine into his or her mouth. Older children can take oral medication from a medicine cup or measured medicine spoon.

#### Take Note!

Never force an oral medication into a child's mouth or pinch the child's nose. Doing so increases the risk for aspiration and interferes with the development of a trusting relationship.

As children adapt to swallowing tablets or capsules, administration is similar to that of adults. When helping the younger child learn how to swallow medication, the tablet or capsule can be placed at the back of the tongue

#### BOX 35.3

#### GUIDELINES FOR ADMINISTERING MEDICATIONS VIA GASTROSTOMY OR JEJUNOSTOMY TUBES

- Verify correct placement (refer to Box 35.4).
- Give liquid medications directly into the tube. Draw appropriate amount into syringe and clear air.
- Mix powdered medications well with warm water first.
- If medication is in pill form, verify it is OK to crush. Then, crush tablets and mix with warm water to prevent tube occlusion.
- Open up capsules and mix the contents with warm water to dissolve the contents and prevent tube occlusion.
  - Label each syringe appropriately.
- Flush the tube with water after administering medications to ensure that the entire amount of medication has been given and to prevent tube occlusion.

Adapted from Bowden, V. R., & Greenberg, C. S. (2008). *Pediatric nursing procedures*. Philadelphia: Lippincott Williams & Wilkins; and Cincinnati Children's Hospital Medical Center. (2012). Gastrostomy tube (G-Tube) Homecare. Retrieved July 7, 2012, from <http://www.cincinnatichildrens.org/health/info/abdomen/home/g-tube-care.htm>

or in a small amount of food such as ice cream or applesauce. Always tell children if there is medicine in the food; otherwise, they may not trust you.

When the child has a nasogastric, orogastric, nasojejun, nasoduodenal, **gastrostomy** (opening into the stomach), or jejunostomy tube, oral medications may be given via these devices. The tube allows for the medication to be placed directly into the stomach or small intestine area. Be aware that not all medications can be placed directly into the duodenum or jejunum. Medication for administration via a tube must be supplied in a liquid form, or a crushed tablet or opened capsule can be mixed with a liquid (Box 35.3). Always check tube placement prior to administering the medication. After administration, flush the tube to maintain patency.

## Rectal Administration

Rectal medications are typically supplied in the form of suppositories. The rectal route is not a preferred route for medication administration in children because the drug's absorption may be erratic and unpredictable and the method is invasive. The rectal route can be extremely upsetting to the toddler and preschooler because of age-related fears, and may be embarrassing to the school-age child or adolescent. However, the rectal route may be used when the child is vomiting or receiving nothing by mouth (NPO). Use age-appropriate explanations and reassurance. Helping the child to maintain the correct

**FIGURE 35.4** Administering eye medication: gently press the lower lid down and have the child look up as the medication is instilled into the lower conjunctival sac.

position may be necessary to ensure proper insertion and safety of rectal suppositories.

Lubricate the suppository well with a water-soluble lubricant. With the child in the side-lying position, insert the suppository into the rectum quickly but gently. Wear gloves or use a finger cot to insert the suppository. Insert the suppository above the anal sphincter. For an infant or child younger than the age of 3, use the fifth finger for insertion. For an older child, use the index finger. To prevent expulsion of the suppository, hold the buttocks together for several minutes or until the child loses the urge to defecate. If the child has a bowel movement within 10 to 30 minutes after administration of the medication, examine the stool for the presence of the suppository. If it is observed, notify the physician or nurse practitioner to determine if the drug needs to be administered again.

## Ophthalmic Administration

Ophthalmic medications are typically supplied in the form of drops or ointment. Many children have a fear of having anything placed in their eyes. Therefore, provide an age-appropriate explanation to gain their cooperation. Also, have the child keep his or her eyes closed until you are ready to administer the medication. Ensure that the medication is at room temperature, as chilled medication may be uncomfortable to the child. Proper positioning of the child is necessary to control the child's head, keep the child's hands from interfering, and prevent injury to the eye. Attempt to administer the medication when the child is not crying to ensure that the medication reaches its intended target area.

Wash hands thoroughly and don gloves. Place the child in the supine position, slightly hyperextending the neck with the head lower than the body so the medication will be dispersed over the cornea. Rest the heel of your hand on the child's forehead to stabilize it. Retract the lower eyelid and place the medication in the conjunctival

sac; maintain sterile technique by being careful not to touch the tip of the tube or dropper to the sac. For eye drops, place the prescribed number of drops into the lower conjunctival sac (Fig. 35.4). For ointment, apply the medication in a thin ribbon from the inner canthus outward without touching the eye or eyelashes. If the child is old enough to cooperate, instruct the child to gently close the eyes to allow the medication to be dispersed.

If a child is uncooperative, he or she may need to be immobilized in order to administer the eye drops. Alternatively, one or two drops on the inner canthus of the closed eye can be administered while the child is lying supine. Then instruct the child to open his or her eyes and the drops will enter the eye. Wipe any excess medication from the skin. Placing a finger on the tear duct and gently applying pressure after application is also important to slow systemic absorption and ensure the medicine stays in the eye.

Children often require ophthalmic medications at home. Parents or caregivers need instruction about how to administer this type of medication. Teaching Guidelines 35.1 provides information on administering eye drops and eye ointments.

### Teaching Guidelines 35.1

#### APPLYING EYE MEDICATIONS

- Wash your hands with soap and water. Dry them thoroughly using paper towels or a clean cloth.
- Allow the eye drops or ointment to come to room temperature (if the medication was stored in the refrigerator). If necessary, warm the eye drops or ointment tube in the palm of your hand. Keep the cap on to avoid any spillage. Make sure medication is well mixed if needed.
- Remove the cap, placing it on a dry, clean surface.
- For young children (3 years or younger), obtain assistance to keep their arms and fingers away during the

procedure. If doing this procedure alone, wrap the child in a towel or blanket, keeping the arms inside.

- If you are applying eye drops, it may be easiest if you are standing or sitting behind the child, looking over the back of the child's head as he or she reclines. If you are applying an eye ointment, it may be easiest to face the child directly.
- Using one hand, hold the child's forehead in place while raising the eyelid with your thumb.
- With your other hand, hold the eye drop bottle or ointment tube above the eye, using an extended finger against the child's cheek, forehead, or nose to steady your hand.
- Gently squeeze the eye drop bottle, dispensing the proper number of drops, or gently squeeze the ointment tube, dispensing a small trail (about 2 cm) of ointment into the gap between the lower portion of the eye and bottom eyelid.
- Make sure the tip of the bottle or tube does not make contact with the eye or any other surface.
- For eye drops, gently press your finger against the inside corner where the eye meets the nose for about 1 minute, blocking the tears and medication from exiting through the tear duct. This will help the eye retain more of the medication. If the child is old enough, he or she may be able to do this unassisted.
- For ointment, have the child close his or her eye and not rub the area.
- Ask the child not to blink or squeeze the eye shut more than normal, as this may wash away the medication prematurely.
- Gently dab away any tears or medication on the face with a clean tissue.
- If necessary, clean the tip of the bottle or tube with a clean tissue and recap.
- Wash your hands again and dry them thoroughly.

## Otic Administration

Medications for otic administration are typically in the form of ear drops. This route of administration can be upsetting to the child because he or she cannot see what is happening. The child often receives otic drugs for an earache, and he or she may fear that the ear drops will increase the pain. Explain the procedure to the younger child in terms that he or she can understand to help allay these fears. Gain the older child's cooperation by explaining the purpose of the medication and the procedure for administration.

Reinforce the need for the child to keep the head still. Younger children may require assistance to do so. Be sure that the ear drops are at room temperature. If

necessary, roll the container between the palms of your hands to help warm the drops. Using cold ear drops can cause pain and possibly vertigo when they reach the eardrum (Bowden & Greenberg, 2008).

Place the child in a supine or side-lying position with the affected ear exposed (Fig. 35.5). Pull the pinna downward and back in children younger than age 3 and upward and back in older children. Instill the medication using a dropper. Then have the child remain in the same position for several minutes to ensure that the medication stays in the ear canal. Massage the area anterior to the affected ear to promote passage of the medication into the ear canal. If necessary, place a piece of cotton or a cotton ball loosely in the ear canal to prevent the medication from leaking.

## Nasal Administration

Nasally administered medications are typically drops and sprays. Administering nose drops to infants and young children may be difficult, and additional help may be needed to help maintain the child's position. For nose drops, position the child supine with the head hyperextended to ensure that the drops will flow back into the nares. A pillow or folded towel can be used to facilitate

**FIGURE 35.5** Administering ear drops. **(A)** For the child younger than 3 years of age, the nurse pulls the pinna of the ear down and back. **(B)** For a child older than age 3 years, the nurse pulls the pinna of the affected ear up and back.

**FIGURE 35.6** Administering nose drops. Tilt the head down and back to instill nose drops.

this hyperextension. Place the tip of the dropper just at or inside the nasal opening, taking care not to touch the nares with the dropper (Fig. 35.6). Doing so might stimulate the child to sneeze. Although the nasal membranes are not sterile, the drop solution is, and sneezing would contaminate the dropper, leading to contamination of the drop solution when the dropper is returned to the bottle. Once the drops are instilled, maintain the child's head in hyperextension for at least 1 minute to ensure that the drops have come in contact with the nasal membranes.

For nasal sprays, position the child upright and place the tip of the spray bottle just inside the nasal opening and tilted toward the back. Squeeze the container, providing just enough force for the spray to be expelled from the container. Using too great a force can push the spray solution and secretions into the sinuses or eustachian tube.

**Take Note!**

In young infants, instill the medication in one naris at a time, since they are obligate nose breathers.

## Intramuscular Administration

Intramuscular (IM) administration delivers medication to the muscle. In children, this method of medication administration is used infrequently because it is painful and children often lack adequate muscle mass for medication absorption. However, IM administration is used to administer certain medications, such as many immunizations.

Muscle development and the amount of fluid to be injected determine IM injection sites in children. Needle size (gauge and length) is determined by the size of the muscle and the viscosity of the medication. For example, more viscous medications often require a larger-gauge needle. In addition, the needle must be long enough to ensure that the medication reaches the muscle.

The preferred injection site for infants is the vastus lateralis muscle (Immunization Action Coalition, 2010). The dorsogluteal site, often used in adults, is not recommended in children younger than 5 years of age (Bowden & Greenberg, 2008). The muscle has not fully developed and the sciatic nerve occupies a larger portion of this area in the young child.

**Take Note!**

Some experts no longer recommend use of the dorsogluteal site at any age due to the risk of damaging the sciatic nerve (Aschenbrenner & Venable, 2008).

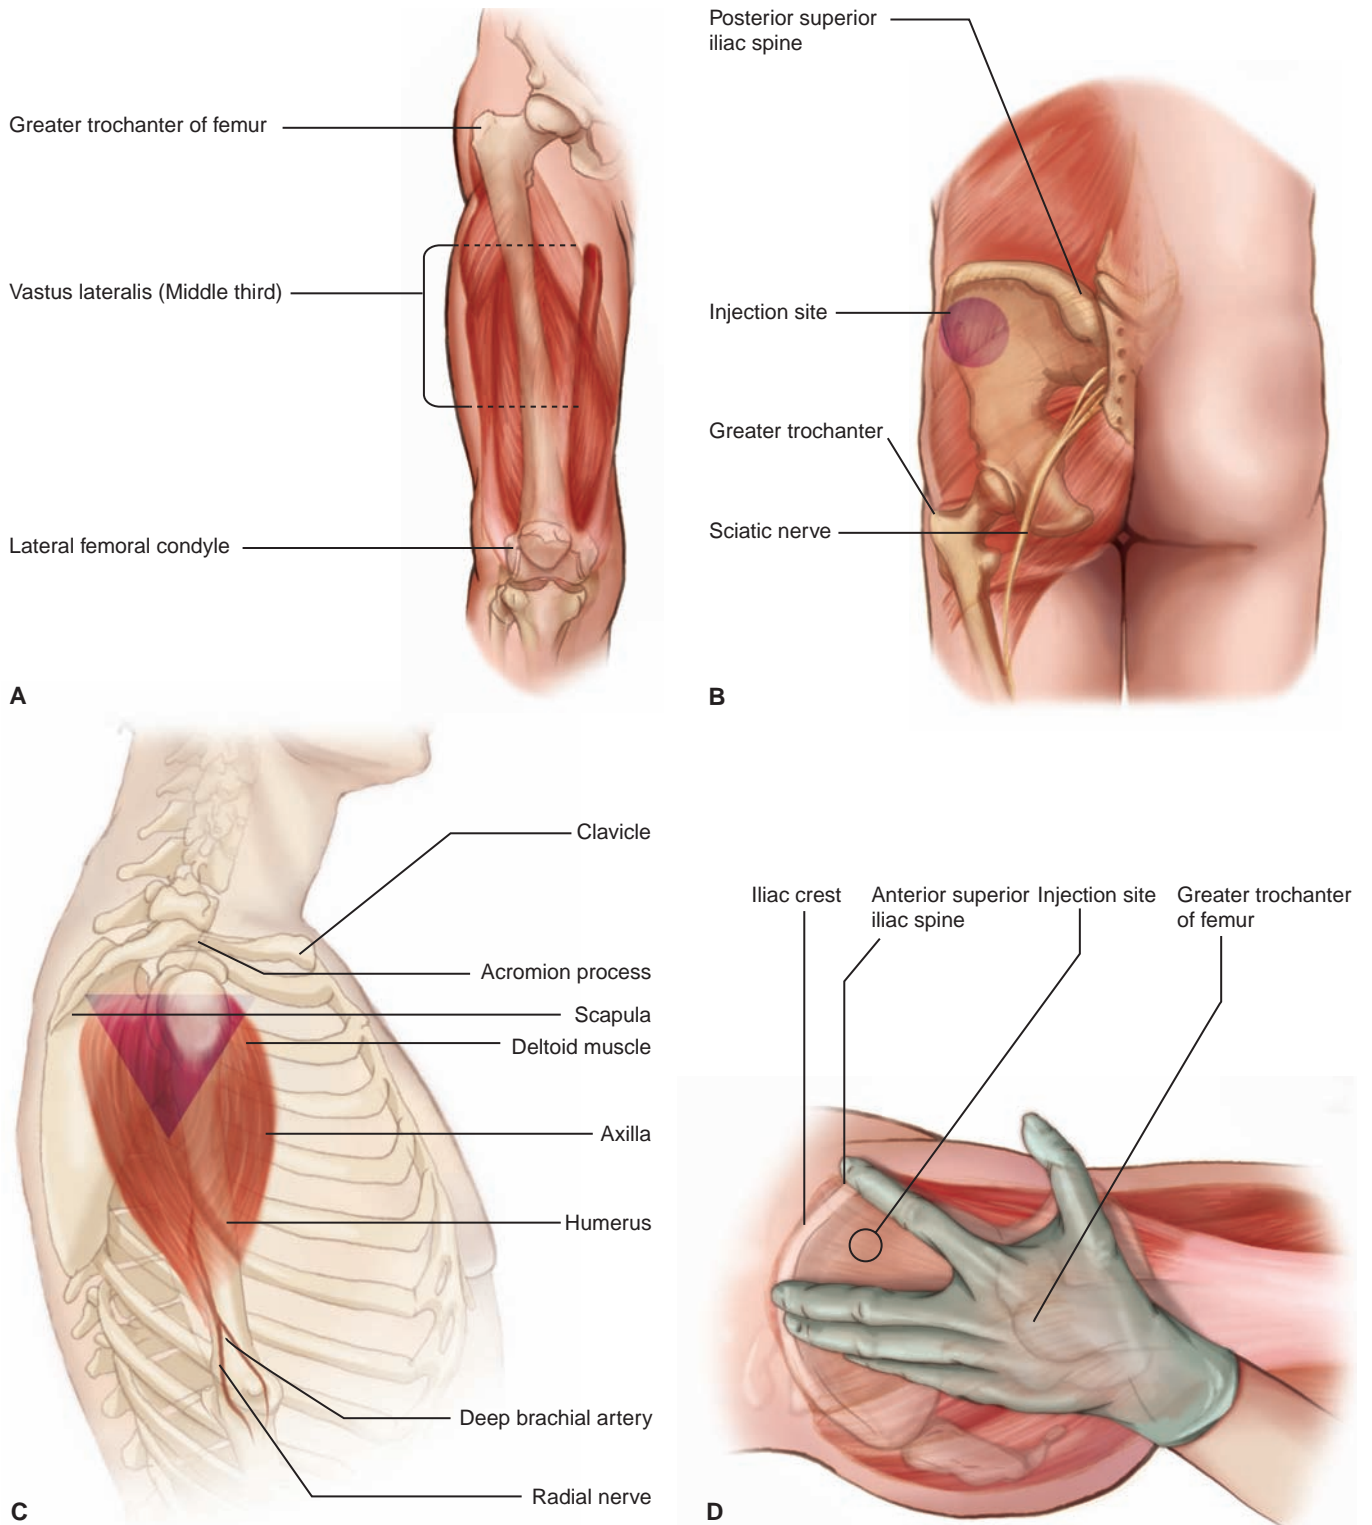

The deltoid muscle is used as an IM injection site in children older than 3 years of age and may be used in toddlers if the muscle mass is sufficient (Immunization Action Coalition, 2010). Figure 35.7 illustrates IM injection sites.

Select the needle size and gauge based on the size of the child's muscle. The goal is to use the smallest length and gauge that will deposit the medication in the muscle. Table 35.2 provides general guidelines for solution amount, needle size, and needle gauge when administering IM medications.

Insert the needle into the skin at a 90-degree angle. Aspirating and, if no blood was present, injecting the medication was the traditional procedure. However, recent research has shown decreased discomfort and no associated complications with rapid injection of intramuscular immunizations without aspiration (Centers for Disease Control and Prevention, 2010). In addition, there are no large blood vessels present in the currently recommended injection sites, the vastus lateralis and deltoid muscles (Kroger, Sumaya, Pickering, & Atkinson, 2011). Therefore, the Centers for Disease Control and Prevention (CDC) and the Advisory Committee on Immunization Practices (ACIP) no longer recommend aspiration before injection (Centers for Disease Control and Prevention, 2010; Kroger et al., 2011).

## Subcutaneous and Intradermal Administration

Subcutaneous (SQ) administration distributes medication into the fatty layers of the body. It is used primarily for insulin administration, heparin, and certain immunizations, such as the MMR. The amount of subcutaneous tissue differs among individuals. Therefore, when selecting a site and needle size, choose the most appropriate based on adequacy and condition of the subcutaneous tissue and the frequency and duration of the therapy.

**FIGURE 35.7** Locating intramuscular injection sites. **(A)** Vastus lateralis: identify the greater trochanter and the lateral femoral condyle; inject in middle third and anterior lateral aspect. **(B)** Dorsogluteal: place hand on iliac crest and locate the posterosuperior iliac spine; inject in the outer quadrant formed when an imaginary line is drawn between the trochanter and the iliac spine. **(C)** Deltoid: locate the lateral side of the humerus, one to two finger widths below the acromion process. Inject into upper third of muscle. **(D)** Ventrogluteal: place palm of left hand on right greater trochanter so index finger points toward anterosuperior iliac spine, spread middle finger to form a V, and inject in the middle of the V.

TABLE 35.2

**GUIDELINES FOR SOLUTION AMOUNT, NEEDLE LENGTH, AND NEEDLE GAUGE FOR IM INJECTIONS<sup>a</sup>**

	Solution Amount				Length	Gauge
	Vastus Lateralis	Deltoid	Ventrogluteal	Dorsogluteal		
Infant	0.5 mL	Not recommended	Not recommended until 7 months; then 0.5 mL	Not recommended	$\frac{5}{8}$ to 1 inch	22–25
Toddler	0.5–1 mL	0.5 mL	1 mL	Not recommended	$\frac{5}{8}$ to 1 inch	22–25
Preschooler	1 mL	0.5 mL	1.5 mL	Not recommended	$\frac{5}{8}$ to 1 inch	22–25
School age	1.5–2 mL	0.5–1 mL	1.5–2 mL	1.5–2 mL	$\frac{5}{8}$ to 1.5 inch	22–25

<sup>a</sup>Needle size and site need to be individualized based on the size of the muscle, amount of adipose tissue, and amount of solution to be administered.

Adapted from Centers for Disease Control and Prevention. (2010). *Vaccine administration guidelines*. Retrieved May 23, 2011, from [http://www.cdc.gov/vaccines/pubs/pinkbook/downloads/appendices/D/vacc\\_admin.pdf](http://www.cdc.gov/vaccines/pubs/pinkbook/downloads/appendices/D/vacc_admin.pdf); Bowden, V. R., & Greenberg, C. S. (2008). *Pediatric nursing procedures*. Philadelphia: Lippincott Williams & Wilkins; and Immunization Action Coalition. (2010). *How to administer intramuscular (IM) and how to administer subcutaneous (SC) injections*. Retrieved May 22, 2011, from <http://www.immunize.org/catg.d/p2020.pdf>

The preferred sites for SQ administration include the anterior thigh, lateral upper arms, and abdomen (Bowden & Greenberg, 2008; Immunization Action Coalition, 2010). Use a 3/8- or 5/8-inch, 23- to 25-gauge needle. Pinch up the skin with the nondominant hand to isolate the tissue from the muscle. Insert the needle at a 45- to 90-degree angle, release the skin if pinched, and inject the medication slowly.

Intradermal (ID) administration deposits medication just under the epidermis. The forearm is the usual site for administration. ID administration is used primarily for tuberculosis screening and allergy testing. A 1-mL syringe with a 5/8-inch, 25- or 27-gauge needle is commonly used to administer the medication. Insert the needle, with the bevel up, beneath the skin at a 5- to 15-degree angle. Keep the fingers and thumb resting on the sides of the syringe to ensure the proper angle.

## Intravenous Administration

Intravenous (IV) medication administration is commonly used with children, especially when a rapid response to a drug is desired or when absorption via other routes is difficult due to the child's illness or condition. In some cases, the IV route is the only effective method for administering a medication. Use of the IV route requires that the child have an IV device inserted, peripherally or centrally. Although insertion of this device is invasive and traumatic for the child, IV medication administration is considered to be less traumatic when compared to the trauma associated with multiple injections. Unfortunately, the veins of a child are small and easily irritated.

Most medications given by the IV route must be given at a specified rate and diluted properly to prevent overdose or toxicity due to the rapid onset of action that occurs with this route. Therefore, when administering medications via the IV route, knowledge of the drug, the amount of drug to be administered, the minimum dilution of the drug, the type of solution for dilution or infusion, the compatibility or various solutions and medications, the length of time for infusion, and the rate of infusion is required. Careful maintenance of the IV site is required to prevent complications.

The primary method for IV medication administration is a syringe pump. This method provides a highly precise rate of infusion. Nursing Procedure 35.1 gives the steps for administering medication via a syringe pump.

If a pump is unavailable, the medication may be administered via a volume control device. The medication is added to the device with a specified amount of compatible fluid and then infused at the ordered rate.

Direct IV push medication typically is reserved for emergency situations and when therapeutic blood levels must be reached quickly to achieve the desired effect. Direct IV push administration requires that the drug be diluted appropriately and given at a specified rate, such as over 2 to 3 minutes. Care must be taken to prevent fluid overload, which may occur due to flushing needed to maintain IV patency and prevent drug incompatibilities, and from the administration of multiple drug therapies.

## Providing Atraumatic Care

When administering any medication, including oral medications, use the principles of atraumatic care (see Chapter 30 for more information). Children can experience stress

## NURSING PROCEDURE 35.1

## Administering Medication via a Syringe Pump

**Purpose: To provide accurate and safe administration of IV medication**

1. Verify the medication order.
2. Gather the medication and necessary equipment and supplies.
3. Wash hands and put on gloves.
4. Attach the syringe pump tubing to the medication syringe and purge air from the tubing by gently filling the tubing with medication from the syringe.
5. Insert the syringe into the pump according to the manufacturer's directions.
6. Clean the appropriate port on the child's IV access device or tubing, flush the device or tubing if appropriate (e.g., an intermittent infusion device [saline lock or heparin lock]), and attach the syringe tubing to the IV tubing or device.
7. Set the infusion rate on the pump as ordered.
8. When the medication infusion is completed, flush the syringe pump tubing to deliver any medication remaining in the tubing, according to institution protocol.

9. Document the procedure and the child's response to it.

Adapted from Bowden, V. R., & Greenberg, C. S. (2008). *Pediatric nursing procedures*. Philadelphia: Lippincott Williams & Wilkins.

and fear or upset when they must take medications. The child may become upset or stressed when he or she must be secured snugly or positioned to minimize movement. The child may experience further discomfort if the medication has an unpleasant taste or results in pain, such as with an injection.

### Atraumatic Care

*Encourage the child to participate in care and provide the child with developmentally appropriate options, such as which fluid to drink with the medication or which flavor of ice pop to suck on before or after the administration (see Table 35.1).*

To decrease discomfort and pain for the child who is to receive an injection, apply a topical anesthetic such as EMLA (eutectic mixture of local anesthetic) cream or vapocoolant spray to the site before injection (Kroger et al., 2011) (see Chapter 36 for additional information).

Ensuring that the child doesn't move is essential to prevent injury when administering an injection. When administering an injection to a young child, at least two

adults should hold him or her; this may also be necessary to help an older child to remain still.

### Atraumatic Care

*Use positions that are comforting to the child, such as therapeutic hugging, during injections. Have the child sit on the caregiver's lap with the caregiver holding the child's arms and legs to his or her body. Refer to Chapter 30, Figure 30.1. After administration, encourage the parents or caregivers to hold and cuddle the child and offer praise.*

### Educating the Child and Parents

Teaching the child and parents or caregivers about medication administration is key. Many medications are given in the home, making the parents or caregivers the persons responsible for administration. They need to know what medications they are giving and why, how to give them, and what to expect from the drug, including adverse effects. Caregivers and parents often incorrectly dose

**EVIDENCE-BASED PRACTICE 35.1****DOES A PICTOGRAM-BASED HEALTH LITERACY INTERVENTION DECREASE LIQUID MEDICATION ADMINISTRATION ERRORS BY CAREGIVERS OF YOUNG CHILDREN?**

Research suggests that caregivers of young children make frequent mistakes when administering medication at home, including improper dosing and not following medication regimens correctly. Need for liquid medications, availability of varying concentrations of pediatric medications, and variation in dosing instruments all can contribute to medication errors at home. Good communication from health care providers is essential in ensuring proper medication administration at home. Complex medication regimens; the use of different units of measure such as milliliters, teaspoons, and tablespoons; and communication issues can contribute to confusion of the caregiver and lead to errors in medication administration at home. Parents or caregivers with language barriers, low literacy levels, and low socioeconomic status appear to be at higher risk.

**STUDY**

A randomized controlled trial was performed at an urban public hospital pediatric emergency department. A randomized sample of parents and caregivers of children aged 30 days to 8 years, who were prescribed liquid medications, was divided into a group to receive the pictogram-based intervention and a group to receive standard care (the control group). The pictogram intervention consisted of education that used plain language, pictogram-based medication, and patient-specific instruction sheets in both English and Spanish. The instruction sheets included the medication name, indication, dose, dose frequency, length of treatment, preparation, and storage. A medication log was also included for the caregivers. Research staff also demonstrated dosing with a standardized instrument and parents then demonstrated back to the research staff how

they would give the medication (referred to as “teach-back”). The pictogram instruction sheet and a standard dosing instrument were given to each caregiver in the intervention group to take home. The intervention took 1.5 to 3 minutes to complete. More information about the specific intervention can be obtained at <http://helpix.med.nyu.edu/> (NYU Langone Medical Center, 2009). The parents or caregivers were assessed before the intervention and then by phone or in person, 1 day after for daily dose medication and 3 to 5 days after for as-needed medications, after the emergency room visit.

**Findings**

The pictogram intervention significantly improved caregiver dosing accuracy and adherence to medication. Increased knowledge of dosing frequency was higher in the intervention group regarding daily dose medication. Correct medication preparation, such as to shake or not, was also higher in the intervention group. The intervention group was significantly more likely to use a standardized dosing instrument compared to the control group.

**Nursing Implications**

Nurses should consider the use of pictogram instruction sheets when discharging a child with home medications, especially if medication instructions are complex or the caregiver has a language barrier or low literacy levels. Nurses should demonstrate how to give home medications and utilize the method of teachback in order to improve caregiver dosing accuracy at home. Nurses should ensure caregivers are given a standardized dosing instrument to use at home to administer medications.

Adapted from Yin, H. S., Dreyer, B. P., van Schaick, L., Foltin, G. L., Dinglas, C., & Mendelsohn, A. L. (2008). Randomized controlled trial of a pictogram-based intervention to reduce liquid medication dosing errors and improve adherence among caregivers of young children. *Archives of Pediatrics and Adolescent Medicine*, 162(9), 814–822.

over-the-counter medications and prescription medications or fail to complete prescribed orders (Broselow, Lutten, & Schuman, 2008a). Therefore, ensure thorough instruction, including frequency of administration, when the next dose is due, and length of time the medication is to be given. Emphasize the importance of completing the prescribed dose. Demonstrate use with an actual syringe if possible, encourage return demonstration of medication administration, advise against the use of home measuring devices (such as a spoon), and emphasize the importance of always using the calibrated dispensing device that was given with the medication. If the medication is to be given via injection, parents and caregivers need to learn how to administer the injection properly. Encourage questions or concerns from parents or caregivers. See Evidence-Based Practice 35.1.

Parents and caregivers commonly need suggestions about the best ways to administer the medication to their child. Provide them with tips for administration, such as

mixing unpleasant-tasting medications with applesauce or yogurt or offering a favorite liquid as a chaser. Also teach the parents how to properly measure the amount of drug to be given. Teaching Guidelines 35.2 gives pointers about oral medication administration. Refer to Chapter 30 for further information on teaching children and families about medication administration.

**Teaching Guidelines 35.2****ADMINISTERING ORAL MEDICATIONS**

- Be firm when telling your child that it is time for his or her medication. State, “It’s time for your medicine” instead of asking, “Will you take your medicine?” or “Can you take your medicine for me?”
- Allow your child to choose an appropriate liquid to help swallow the medication or drink after taking it. Limit the choices to two or three.

- Never bribe or threaten your child to take his or her medication.
- Never refer to the medication as “candy.”
- Be honest about the taste of the medication. If necessary, mix it with another food such as applesauce, yogurt, or syrup to help mask the taste.
- Do not mix the medication with formula or baby food.
- Always check with your physician or nurse practitioner and pharmacy about opening capsules or crushing tablets and mixing them with food. Some medications should not be opened or crushed.
- If you are giving a liquid using an oral syringe or dropper, place the medication slowly along the inside of the cheek. Never squirt the medication forcibly to the back of the child’s throat. It may cause the child to gag and spit out the medication or aspirate it into his or her lungs.
- Always praise the child after taking the medication and provide comfort and cuddling.

## Preventing Medication Errors

The incidence of potentially harmful medication errors may be three times as high in pediatrics compared to adults (The Joint Commission, 2008). This can be related to weight-based dosing calculations, fractional dosing, and the need for the use of decimal points. Children are also more susceptible because many drugs used in pediatrics are formulated and packaged for adults and lack U.S. Food and Drug Administration (FDA) approval and dosing guidelines for children. Children, especially the very young, are less able to physiologically tolerate medication errors and are often unable to communicate if an adverse reaction is occurring (The Joint Commission, 2008).

The need for safety takes on even greater importance due to the physiologic, psychological, and cognitive differences inherent in children. Confirming the child’s identity and double-checking the dosage before administration of any medication are two critical safeguards that play a major role in preventing medication errors. Other ways to prevent medication errors include the following:

- Confirm the children’s weight is accurate.
- Always weigh children in kilograms.
- Double-check medication calculations; utilize another health care provider when possible, especially for high-risk medications.
- If a dose seems unusually small or large, verify the order.
- Utilize medication ordering and dispensing systems if available.
- Always report medication errors or near-miss errors to help prevent future mistakes.
- Utilize the Joint Commission’s official “Do Not Use” list (link to this list is provided on [http://www.jointcommission.org/assets/1/18/Do\\_Not\\_Use\\_List.pdf](http://www.jointcommission.org/assets/1/18/Do_Not_Use_List.pdf)).

### Take Note!

If a parent, caregiver, or child questions whether a medication should be given, listen attentively, answer their questions, and double-check the order.

## INTRAVENOUS THERAPY

IV access provides a route for the administration of medications and fluids. It is commonly used for children because it is the quickest, and often the most effective, method of administration. As with adults, numerous sites and various devices and equipment may be used to provide IV therapy over a short or long period of time. When administering IV therapy, safety is crucial. The nurse must have a solid knowledge base about the fluids or medications to be given as well as a thorough understanding of the child’s physical and emotional development. Venipuncture can be a terrifying and painful experience for children and their families. Nurses play a crucial role in providing support and education to the child and family before, during, and after the procedure (refer to Chapter 30 for additional information related to provision of atraumatic care with procedures).

### Sites

IV therapy may be administered via a peripheral vein or a central vein. Peripheral IV therapy sites commonly include the hands, feet, and forearms (Fig. 35.8). In neonates and

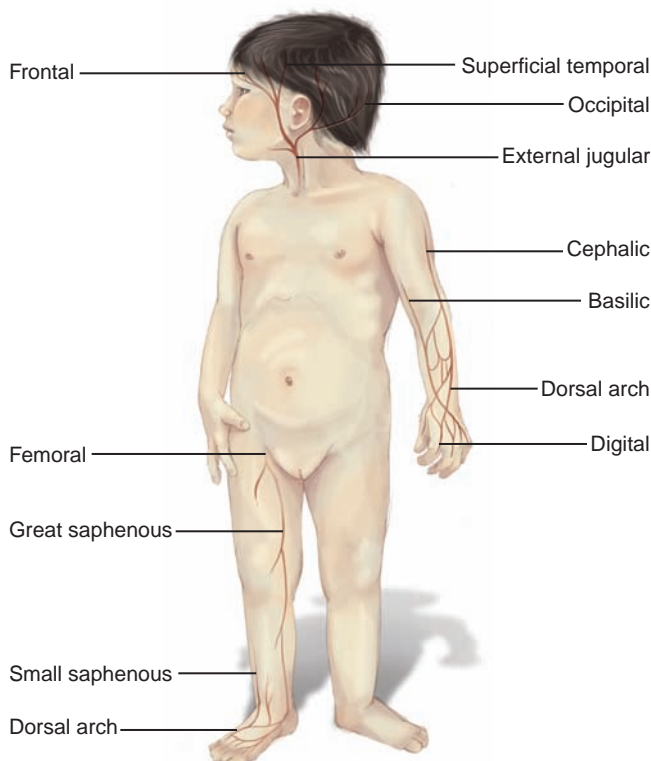

FIGURE 35.8 Preferred peripheral sites for intravenous insertion.

young infants, the scalp veins may be used (O'Grady et al., 2011). The scalp veins are easily visualized, being covered only by a thin layer of subcutaneous tissue. These veins do not have valves, so the device may be inserted in either direction, although the preference would be in the direction of blood flow. However, use of a scalp vein requires that that area of the infant's head be cleared of hair to enhance visualization. In addition, use of the scalp veins can be frightening to parents, who may think the fluid is infusing into the infant's brain. Thus, scalp veins are usually used only if attempts at other sites have been unsuccessful (Bergvall & Sawyer, 2009). When used, ensure appropriate education of the parents prior to insertion and, if shaving the child's hair is needed, inquire if parents would like to keep the child's hair.

### Take Note!

When selecting an IV site in an extremity, always choose the most distal site. Doing so prevents injury to the veins superior to the site and allows additional access sites should complications develop in the most distal site.

Central IV therapy usually is administered through a large vein, such as the subclavian, femoral, or jugular vein or the vena cava. The tip of the device lies in the superior vena cava just at the entrance to the right atrium. The device is inserted surgically or percutaneously and exits the body typically in the chest area, just below the clavicle. A device can be inserted via a peripheral vein, such as the median, cephalic, or basilic vein, and then threaded into the superior vena cava.

## Equipment

The choice of equipment is determined by the solution or medication to be administered, the duration of the therapy, the age and developmental level of the child, the child's status, and the condition of his or her veins. Various types of IV devices are commercially available. In addition, different types of tubing and infusion control devices may be necessary.

### Peripheral Access Devices

Devices used for peripheral venous access in a child include over-the-needle catheters or winged-infusion sets, commonly referred to as “butterflies” or scalp vein needles. These devices are inserted into the vein and then connected to the IV solution via tubing to provide a continuous infusion of fluid. These devices can also be inserted for intermittent use if the child does not require a continuous fluid infusion. Typically, the hub of the device is capped or plugged to allow intermittent access, such as for administering medications or obtaining blood specimens. When used in this manner, these devices are termed peripheral intermittent infusion devices or saline or heparin locks.

Needle size on the device also varies. Typically, the needle ranges from 21 to 25 gauge, depending on the child's size. The rule of thumb is to use the smallest-gauge catheter with the shortest length possible to prevent traumatizing the child's fragile veins. Typically, peripheral IV devices are used for short-term therapy, usually averaging 3 to 5 days (O'Grady et al., 2011). Midline catheters are also available, and the CDC recommends the use of midline catheters if therapy is to exceed 6 days (O'Grady et al., 2011). These catheters are longer than peripheral catheters and can stay in for 2 to 4 weeks (Rosenthal, 2008). They are seated deep in the cephalic or basilic veins, but the tip does not extend past the axilla.

### Central Access Devices

Numerous devices for central venous access are available. The type chosen depends on several factors, including the duration of the therapy, the child's diagnosis, the risks to the child from insertion, and the ability of the child and family to care for the device. The device may have one or multiple lumens. Although central venous access devices can be used short term, the majority are used for moderate- to long-term therapy.

Central venous access devices are indicated when the child lacks suitable peripheral access, requires IV fluid or medication for more than 3 to 5 days, or is to receive specific treatments, such as the administration of highly concentrated solutions or irritating drugs that require rapid dilution (Putigna, 2011). Central venous access is advantageous because it provides vascular access without the need for multiple IV starts, thus decreasing discomfort and fear. However, central venous access devices are associated with complications such as infection at the site, sepsis due to the direct access to the central circulation, and thrombosis due to partial occlusion of the vessel. Typically, a chest radiograph is performed after a central venous access device is inserted to verify proper placement. No fluids are administered until correct placement is confirmed. Table 35.3 describes the major types of central venous access devices.

### Infusion Control Devices

Infants and young children are at increased risk for fluid volume overload compared with adults. Also, malfunction at the IV insertion site, such as infiltration, may result in much greater injury than a similar incident would cause in an adult. Therefore, IV fluids must be carefully administered and monitored. To ensure accurate fluid administration, infusion control devices such as infusion pumps, syringe pumps, and volume control sets may be used.

Infusion pumps used for children are similar to those used for adults. Typically, the IV solution bag is attached to a calibrated volume control set that has been filled with a specified amount of IV solution

**TABLE 35.3** TYPES OF CENTRAL VENOUS ACCESS DEVICES

Device	Description
Nontunneled central venous catheter (CVC)	Usually used short term One or more lumens Surgical or percutaneous insertion most commonly via the subclavian, internal jugular, or femoral vein with the tip of the catheter at the top of the superior vena cava just above the right atrium Useful for emergency situations Catheter sutured in place at the exit site
Peripherally inserted central catheter (PICC)	Short- to moderate-term therapy Insertion via a peripheral vein such as antecubital, basilic, cephalic, or medial antecubital vein Catheter typically threaded into superior vena cava; distal tip terminates in the superior vena cava, inferior vena cava, or proximal right atrium. Insertion via saphenous vein with tip terminating in inferior vena cava above the diaphragm for infants Single or multiple lumens PICC insertion requires additional training and advanced skill.
Tunneled central venous catheter (e.g., Groshong, Hickman/Broviac)	Usually for long-term use Catheter inserted by a physician via small incision in jugular or subclavian vein and tunneled in the subcutaneous tissue under the skin Initially sutured in place to stabilize position; sutures removed after approximately 1 to 2 weeks when cuff on catheter attaches to subcutaneous tissue Single or multiple lumens Some have valves that prevent backflow of blood and air entrance.
Implanted ports (e.g., Port-a-Cath, Infus-a-Port, Mediport)	Surgically inserted by a physician Stainless steel port with a polyurethane or silicone catheter attached Catheter tip lying in subclavian or jugular vein; port implanted under skin in a subcutaneous pocket, usually on the upper chest wall Port covered completely by skin and visible only as a slight bulging on the chest; possibly more appealing to the older child and adolescent because there are no visible parts or dressings Access to port via a specially angled, noncoring needle (Huber needle) Site preparation and pain relief measures necessary before accessing the port

Adapted from Cook, L. S. (2007). Choosing the right intravascular catheter. *Home Healthcare Nurse*, 25(8), 523–531, and Bowden, V. R., & Greenberg, C. S. (2008). *Pediatric nursing procedures*. Philadelphia: Lippincott Williams & Wilkins.

(Fig. 35.9). The fluid chamber holds a maximum of 100 to 150 mL of fluid that can be infused over a specified period of time as ordered. Usually, a maximum of a 2-hour infusion amount in the chamber avoids accidental fluid overload in the pediatric population. This chamber can be filled every 1 to 2 hours so only small amounts of ordered quantities of fluid can infuse and the child is protected from receiving too much fluid volume. In addition, syringe pumps may be used to deliver fluid and medications to children. These pumps can be programmed to deliver minute amounts of fluid over controlled periods of time (see discussion on p. 388 for additional information about syringe pumps).

## Inserting Peripheral IV Access Devices

Peripheral IV devices are used for most IV therapies. Prior to insertion, review the child's diagnosis and medical

history for information that may affect therapy, such as site selection or insertion. For example, a child who has a history of chronic illness may have heightened fears and anxieties related to insertion due to his or her previous experiences or difficulty in accessing IV sites. Typically, the nondominant extremity should be used for insertion, but this may not be possible in certain situations, such as if a right-handed child has a cast on his left arm.

Check the orders for the prescribed therapy. Determine the purpose and length of the IV therapy and the type of fluid or medication that is to be administered. This information aids in selecting the best device and insertion site. For example, the device needs to be of an adequate gauge to allow the solution or medication to infuse into the vein while at the same time allowing enough blood flow around the device to promote dilution of the infusion.

Establish rapport with the child and parents. Inform them about IV therapy and what to expect. Be honest

FIGURE 35.9 Volume control infusion device.

with the child. Explain that the venipuncture will hurt but only for a short time. Provide the child with a time frame that he or she can understand, such as the time it takes to brush his or her teeth or eat a snack.

### Atraumatic Care

*Use therapeutic play to assist the child in preparation and coping for the procedure (see Chapter 33 for more information).*

Insertion of an IV therapy device is traumatic. Follow the principles of atraumatic care, including the following:

- Gather all equipment needed before approaching the child.
- If possible, select a site using hand veins rather than wrist or upper arm veins to reduce the risk of phlebitis. Avoid using lower extremity veins and areas of joint flexion if possible because these are associated with an increased risk of thrombophlebitis and other complications (Alexander, Corrigan, Gorski, Hankins, & Perucca 2010).
- Ensure adequate pain relief using pharmacologic and nonpharmacologic methods prior to insertion of the device (see Chapter 36 for more information about management of pain related to procedures).
- Allow the antiseptic used to prepare the site to dry completely before attempting insertion.
- Use a barrier such as gauze or a washcloth or the sleeve of the child's gown under the tourniquet to avoid pinching or damaging the skin.
- If the child's veins are difficult to locate, use a device to transilluminate the vein (utilizes a bright light, which illuminates the vein's size and direction of travel).
- Make only two attempts to gain access; if you are unsuccessful after two attempts, allow another individual two attempts to access a site. If still unsuccessful, evaluate the need for insertion of another device.

#### Take Note!

Some facilities have policies in place allowing only one stick per nurse with a maximum of two sticks; then the doctor needs to be notified unless the situation is an emergency.

- Encourage parental participation as appropriate in helping to position the child or to provide comfort positioning, such as therapeutic hugging.
- Coordinate care with other departments such as the laboratory for blood specimen collection to minimize the number of venipunctures for the child.
- Secure the IV line using a minimal amount of tape or transparent dressing.
- Protect the site from bumping by using a security device such as the IV house dressing (see Fig. 35.10).

## IV Fluid Administration

Administering IV fluids to an infant or child requires close attention to the child's fluid status. Typically, the amount of fluid to be administered in a day (24 hours) is determined by the child's weight (in kilograms) using the following formula:

100 mL per kg of body weight for the first 10 kg  
 50 mL per kg of body weight for the next 10 kg  
 20 mL per kg of body weight for the remainder of body weight in kilograms

**TABLE 35.4** INTRAVENOUS MAINTENANCE FLUID CALCULATIONS BY BODY WEIGHT

<10 kg in weight	100 mL per kg of weight = # mL for 24 hours Example: A child weighs 7.4 kg. $7.4 \times 100 = 740$ mL (daily requirement) $740/24 = 30.8$ or 31 mL/hour
11–20 kg in weight	100 mL per kg of weight for the first 10 kg + 50 mL/kg for the next 10 kg = # mL for 24 hours Example: A child weighs 16 kg. $(10 \times 100 = 1,000)$ plus $(6 \times 50 = 300)$ Total = 1,300 mL (daily requirement) $1,300/24 = 54$ mL/hour
>20 kg in weight	100 mL/kg for the first 10 kg + 50 mL/kg for the next 10 kg + 20 mL/kg for each kg > 20 kg = # mL for 24 hours Example: A child weighs 30 kg. $(10 \times 100 = 1,000)$ plus $(10 \times 50 = 500)$ plus $(10 \times 20 = 200)$ Total = 1,700 mL (daily requirement) $1,700/24 = 70.8$ or 71 mL/hr

Table 35.4 gives examples of calculating a child's fluid requirements using body weight. Once the 24-hour total fluid requirement is determined, this amount is divided by 24 hours to arrive at the correct hourly rate of infusion.

### Maintaining IV Fluid Therapy

Throughout the course of therapy, monitor the fluid infusion rate and volume closely, as often as every hour. If a volume control set is used to administer the IV infusion, fill the device with the allotted amount of fluid that the child is to receive in 1 hour. Doing so prevents inadvertent administration of too much fluid. Never assume that just because an infusion pump is in use, the infusion is being administered without problems. Pumps can malfunction. The tubing can become blocked, or the IV device can move out of the vein lumen. Not enough fluid, fluid overload, or infiltration of the solution into the tissues can occur.

In addition to monitoring the fluid infusion, closely monitor the child's output. Expected urine output for children and adolescents is 1.0 to 2.0 mL/kg/hour.

#### Take Note!

When measuring the output of an infant or child who is not toilet trained or who is incontinent, weigh the diaper to determine the output. Remember that 1 gram of weight is equal to 1 mL of fluid.

Flushing the IV line when the device is used intermittently may be necessary to maintain patency, such as before and/or after medication is administered and after obtaining blood specimens. However, there is much debate as to how often flushing should be done and the best flush solution to use, heparin or saline (Hepzibha, 2010; Pryce, 2009; Tripathi, Kaushik, & Singh, 2008). Saline has been found to be more compatible with the

numerous solutions and medications administered intravenously, and is less expensive and less irritating to the vein. In addition, using saline lessens the incidence of pain and phlebitis. Heparin is expensive and incompatible with numerous medications and solutions, and it can affect clotting time, depending on the concentration of the flush solution used. Evidence appears to support the use of normal saline flush with catheters larger than 22 gauge, but more studies are needed to determine the effectiveness of normal saline flushes with catheters smaller than 22 gauge (Alexander et al., 2010). Additional research is also needed to determine the volume and concentration of the flush solution and interval for flushing. Always follow your agency's policy for flushing IV lines.

If the child is receiving IV therapy via a central venous access device, provide site care using sterile technique and flush the device according to agency policy. Note the exit site for the device and inspect it frequently for signs of infection. If the device has multiple lumens, label each lumen with its use (i.e., blood specimen, medication, or fluid). Always check the compatibilities of solutions and medications being given simultaneously.

#### Take Note!

When flushing or administering medications through a peripherally inserted central catheter (PICC) line, follow the manufacturer's recommended syringe size, because PICC lines are fragile. Using a larger-volume syringe (i.e., 5 mL or larger) exerts less pressure on the PICC, thereby reducing the risk of complications (Bowden & Greenberg, 2008).

## Preventing Complications

IV therapy is an invasive procedure that is associated with numerous complications. Strict aseptic technique is necessary when inserting the device and caring for the site. Adherence to standard precautions is key. Inspect the

insertion site every 1 to 2 hours for inflammation or **infiltration** (inadvertent infusion of a nonirritant solution or medication into the surrounding tissue). Note signs of inflammation such as warmth, redness, induration, or tender skin. Check closely for signs of infiltration such as cool, blanched, or puffy skin. Use of a transparent dressing or IV house dressing provides easy access for assessing the IV insertion site. These types of dressings also help to prevent movement of the catheter hub, thus minimizing the risk of mechanical irritation, dislodgement, and complications such as phlebitis or infection (see Fig. 35.10).

Typically in adults, an IV site is changed every 72 to 96 hours and at any time when the integrity of the system has been compromised or contamination is suspected (O'Grady et al., 2011). However, with children, the 72- to 96-hour time frame may need to be adjusted to minimize the child's exposure to the repeated trauma of insertion. Current recommendations include replacement in children only when clinically indicated (O'Grady et al., 2011). Follow the agency's policies and procedures related to site changes. Consider an alternative route for fluid and medication administration or the insertion of an alternative IV device, such as a PICC line. Catheter-related bloodstream

infections often can occur with the use of central venous lines. These infections result in increased morbidity and health care costs (O'Grady et al., 2011). Prevention is paramount. Nurses need to practice proper hand hygiene, use maximal barrier protection during insertion, assess the site frequently, provide proper site care using strict sterile technique, and ensure the child's central venous catheter is removed as soon as it is no longer needed. In children it is important also to prevent the child from touching and playing with the central venous line site or dressing. Replace administration sets per agency policy.

Administration sets or IV tubing should be changed at least every 96 hours (other than those used for blood, blood products, and lipids) (National Guideline Clearinghouse, 2008). Ensure proper disinfecting of all catheter hubs, needleless connectors, and injection ports prior to accessing them to minimize contamination.

### Take Note!

Chlorhexidine-impregnated sponge (Biopatch) dressings may be used to help prevent infection in children older than 2 months of age (O'Grady et al., 2011). Always follow agency or institution policy and procedures regarding site care.

**FIGURE 35.10** (A) Intravenous (IV) house over the IV site on a child's hand. (B) IV house over the site on an infant's foot.

## Atraumatic Care

*If appropriate, allow the child to assist in removing the tape or dressing. This gives the child a sense of control over the situation and also encourages his or her cooperation.*

## Discontinuing the IV Device

Prepare the child for removal of the IV device in much the same manner as for insertion. Many children may fear the removal of the device to the same extent that they feared its insertion. Explain what is to occur and enlist the child's help in the removal.

In addition, practice atraumatic care by doing the following:

- Use water or adhesive remover to help loosen the tape.
- If a transparent dressing is in place, gently lift off the dressing by pulling up opposite corners using a motion parallel to the skin surface.
- Avoid using scissors to cut the tape, but if cutting the tape is necessary, be sure that the child's fingers are clear of the tape and scissors.
- Turn off the infusion solution and pump.
- Once all tape and dressings are removed, gently slide the IV device out using a motion opposite to that used for the insertion.
- Apply pressure to the site with a dry gauze dressing and then cover with a small adhesive bandage. If possible, allow the child to choose the bandage.

## PROVIDING NUTRITIONAL SUPPORT

Adequate nutrition is important for all individuals but especially for children. During the growing years the quality of a child's nutrition affects his or her overall health and development. The presence of a chronic illness, disease, or trauma can increase the child's nutritional demands; if the child cannot meet these even with oral supplementation, other measures may be necessary to provide nutritional support. Such measures may include **enteral nutrition** (delivery of nutrition into the gastrointestinal tract via a tube) and **parenteral nutrition** (IV delivery of nutritional substances). The nutritional plan is determined by the child's age, developmental level, and health status.

### Enteral Nutrition

Enteral nutrition, commonly called tube feedings, involves the insertion of a tube so that feedings can be delivered directly into the child's gastrointestinal tract. The tube may be inserted via the nose or mouth or through an opening in the abdominal area, with the tube ending in the stomach or small intestine. Nasogastric or orogastric feedings, a tube from the nose to the stomach or from the mouth to the stomach, respectively, are commonly referred to as **gavage feedings**. Nasoduodenal or nasojejunal feedings involve a tube that is inserted through the nose and ends in either the duodenum or jejunum. Gastrostomy feedings involve the insertion of a gastrostomy tube through an opening in the abdominal wall and into the stomach. Jejunostomy feedings are similar to gastrostomy feedings except that the tube lies in the jejunum.

Enteral nutrition is indicated for children who have a functioning gastrointestinal tract but cannot ingest enough nutrients orally. The child may be unconscious or have a severely debilitating condition that interferes with his or her ability to consume adequate food and fluids. Other conditions that may warrant the use of enteral nutrition include:

- Failure to thrive
- Inability to suck or tiring easily during sucking
- Abnormalities of the throat or esophagus
- Swallowing difficulties or risk for aspiration
- Respiratory distress
- Metabolic conditions
- Severe gastroesophageal reflux disease (GERD)
- Surgery
- Severe trauma

Enteral feedings may be given via nasogastric, orogastric, nasojejunal, nasoduodenal, gastrostomy, or jejunostomy tubes (Fig. 35.11). Table 35.5 provides additional information about these types of feeding tubes. Enteral feedings costs less, are associated with fewer complications, and are considered safer than

**FIGURE 35.11 (A)** Gastrostomy tube. **(B)** Low-profile (button) gastrostomy tube. The filled balloon keeps the tube in place inside the stomach.

parenteral feedings. However, tube misplacement is a serious complication.

#### Take Note!

Small-diameter feeding tubes, though more comfortable, may easily become dislodged if the child coughs vigorously or vomits (Bowden & Greenberg, 2008; Florida State Hospital, 2009).

### Inserting a Nasogastric or Orogastric Feeding Tube

Tubes for gavage feeding can be inserted via the nose or mouth. For infants, who are obligate nose breathers, insertion via the mouth may be appropriate. Oral insertion also promotes sucking in the infant. For the older child, nasal insertion is usually the preferred method. If the tube is to remain in place, the nose also is considered to be more comfortable. Nursing Procedure 35.2 gives the steps for inserting a gavage feeding tube.

#### DETERMINING TUBING LENGTH FOR INSERTION

Traditionally, morphologic methods, measuring from the nose to ear to midxiphoid to umbilicus or just nose to ear to midxiphoid, have been used to determine tube length for insertion. Recent research has shown that this way of measurement frequently underestimates the tube length (Cincinnati Children's Hospital Medical Center, 2011a). Improving the accuracy of predicting tube length will lead to an increase in successful nasogastric tube placements, and therefore improved outcomes and decreased health care costs.

**TABLE 35.5** TYPES OF ENTERAL FEEDING TUBES

Type of Tube	Indication	Nursing Implications
Nasogastric (inserted via the nose into the stomach) Orogastric (inserted via the mouth into the stomach)	Short-term enteral feeding Orogastric usually limited to young infants only	<ul style="list-style-type: none"> <li>• Long-term use or repeated insertion causes irritation and discomfort.</li> <li>• Silicone and polyurethane tubes are very flexible and more comfortable; they require a stylet or guidewire for insertion.</li> <li>• Length of long-term use varies according to the type of tube used and the institution protocol. Periodically a nasogastric tube is removed and reinserted via the opposite nostril to prevent pressure on the nasal mucosa.</li> <li>• Maintaining orogastric placement between feedings can be difficult due to oral secretions.</li> </ul>
Nasoduodenal (inserted via the nose to the duodenum) or nasojejunal (inserted via the nose to the jejunum)	Short-term enteral feeding. Indicated if child has trouble digesting food, cannot use his or her gastrointestinal tract secondary to congenital anomalies or surgery, or is at risk for or has a history of severe reflux or aspiration	<ul style="list-style-type: none"> <li>• Silicone and polyurethane tubes with weighted tip allow tube to pass from pylorus into small intestines.</li> <li>• Agency may require special training in order to place at bedside; may also be performed in radiology</li> <li>• Length of use same as nasogastric or orogastric tubes</li> </ul>
Gastrostomy (surgically inserted through the abdominal wall into the stomach) Jejunostomy (surgically inserted through the abdominal wall into the jejunum)	Long-term enteral feeding or when esophageal atresia or stricture is present Jejunostomy tubes are indicated when gastric feeding is not tolerated.	<ul style="list-style-type: none"> <li>• The inner section of the tube is below the skin surface with the tip located in the stomach or jejunum (may be balloon, winged, or mushroom shaped). The outer section appears above the skin surface at the insertion site and has an opening or feeding port to which the feeding solution is attached.</li> <li>• Low-profile gastrostomy device (gastrostomy button) is flush with the abdominal surface. The flip-top opening is anchored by a dome that fits against the stomach wall. Less conspicuous, it allows the child to be more active and mobile.</li> <li>• After initial insertion, the tube length is measured from the insertion site to the far end of the tube and recorded. This measurement is checked at least daily to ensure that the tube has not moved.</li> <li>• There are many different devices available. For any gastrostomy or jejunostomy tube, the type and size of tube inserted as well as the amount required to fill the balloon if present should be known.</li> </ul>

According to the Agency for Healthcare Research and Quality's National Guideline Clearinghouse (2011), determining tubing length for insertion of a nasogastric tube using age-related height-based methods versus the traditional morphologic, nose–ear–midxiphoid–umbilicus method is more accurate for children > 2 weeks of age:

- In children between ages 2 weeks and 28 months tube insertion length is determined by  $17.6 + 0.197(\text{height in centimeters})$ .
- In children between ages 28 months and 8 years 4 months tube insertion length is determined by  $21.1 + 0.197(\text{height in centimeters})$ .
- In children between the ages of 8 years 4 months and 10 years tube insertion length is determined by  $18.7 + 0.218(\text{height in centimeters})$ .
- In children greater than 10 years tube insertion length is determined by  $21.2 + 0.218(\text{height in centimeters})$  (National Guideline Clearinghouse, 2011; Cincinnati Children's Hospital Medical Center, 2011a [thePoint](#)®).

Continue to use traditional morphologic methods in neonates less than 2 weeks, children with short stature, or if unable to obtain an accurate height (National Guideline Clearinghouse, 2011 [thePoint](#)®).

## NURSING PROCEDURE 35.2

## Inserting a Gavage Feeding Tube

**Purpose: To provide a means for delivering nutrition to the child's functioning gastrointestinal tract**

1. Verify the order for gavage feeding.
2. Explain the procedure to the child and parents using appropriate language geared to the child's development level.
3. Gather the necessary equipment; remove formula for feeding from refrigerator if appropriate and allow it to come to room temperature.
4. Wash hands and put on gloves.
5. Inspect the child's nose and mouth for deformities that may interfere with passage of the tube.
6. Position the infant supine with the head slightly elevated and with the neck slightly hyperextended so that the nose is pointed upward. If necessary, place a rolled towel or blanket under the neck to help in maintaining this position. Assist the older child to a sitting position if appropriate. Alternatively, have the parent or another person hold the child to promote comfort and reassurance. Enlist the aid of additional persons, such as a parent or other health care team member, to assist in maintaining the child's position.
7. Determine the tubing length for insertion: Use age related height based methods or traditional morphologic methods. Refer to previous section DETERMINING TUBING LENGTH FOR INSERTION on p. 000 Mark this measurement on the tube with an indelible pen or with a piece of tape.
8. Lubricate the tube with a generous amount of sterile water (many small-bore feeding tubes have a water-activated lubricant) or water-soluble lubricant to promote passage of the tube and minimize trauma to the child's mucosa.
9. Insert the tube into one of the nares or the mouth. Direct a nasally inserted tube straight back toward the occiput; direct an orally inserted tube toward the back of the throat.
10. Advance the tube slowly to the designated length; encourage the child (if capable) to swallow frequently to assist with advancing the tube.
11. Watch for signs of distress, such as gasping, coughing, or cyanosis, indicating that the tube is in the airway. If these signs develop, withdraw the tube and allow the child to rest before attempting reinsertion.
12. Temporarily secure tube, remove stylet if applicable, and check for proper placement of the tube. Refer to Box 35.4.
13. Document the type of tube inserted; length of tubing inserted; measurement of external tubing length, from nares to end of tube, after insertion; and confirmation of placement.

## CHECKING TUBE PLACEMENT

Once the gavage feeding tube is inserted, checking for placement is essential. Tube placement must be confirmed each time the tube is inserted and before each use. Radiologic confirmation of tube placement is considered the most accurate method, but the risks associated with repeated radiation exposure, high costs, and the impractical nature of obtaining a radiograph before feeding tube use make it unrealistic. Several methods have been proposed as reliable for checking tube placement, but no single method has been shown to be consistently accurate for continually assessing tube placement.

### Take Note!

Instilling air into the tube and then auscultating for the sound is no longer considered a viable method for checking tube placement. (National Guideline Clearinghouse, 2011).

Research has suggested using measurements of bilirubin, trypsin, and pepsin levels and CO<sub>2</sub> monitoring to enhance assessment of tube placement, but no methods are available for bedside testing of these levels.

Refer to Box 35.4 for methods to verify feeding tube placement. However, keep in mind that even with these methods, tube malpositioning can occur. Therefore, nurses need to be vigilant in checking for tube placement using the recommended methods and be cautious and proactive if there is any suspicion that the tube may be misplaced.

### Take Note!

If bedside methods are conflicting or the child is high risk, such as children with swallowing problems, children with altered levels of consciousness, or children in the intensive care unit, radiologic verification is recommended (National Guideline Clearinghouse, 2011).

If the gavage feeding tube is to remain in place, secure it to the child's cheek. Do not tape the tube to the child's forehead, because this could lead to irritation and pressure on, and possible breakdown of, the nasal mucosa. Also measure the length of the tube extending from the nose or mouth to the end and record this information. Double-check this measurement before administering each intermittent tube feeding to verify that the feeding tube is in the proper position. Once the position of the gavage feeding tube is confirmed, the feeding solution or medication can be administered.

## Administering Enteral Feedings

Enteral feedings can be given continuously or intermittently, regardless of the type of tube used. Intermittent

*Remember Lily, the 9-month-old infant diagnosed with failure to thrive who is to receive gavage feedings with a nasogastric tube? What equipment will be needed, and what steps will you take to complete the procedure?*

feedings are commonly called **bolus feedings**. With a bolus feeding, a specified amount of feeding solution is given at specific intervals, usually over a short period of time such as 15 to 30 minutes. Given via a syringe, feeding bag, or infusion pump, bolus feedings most closely resemble regular meals. Continuous feedings are given at a slower rate over a longer period of time. In some cases, the feeding may be given during the night so that the child can be free to move about and participate in activities during the day. For continuous feedings, an enteral feeding pump is used to administer the solution at a prescribed rate.

Checking for tube placement is a priority before administering any intermittent tube feeding and periodically during continuous tube feedings, regardless of the type of tube being used. (Refer to Box 35.4.) For gastrostomy and jejunostomy tubes, ensure that the calibration, if present, has not changed. Measure the length of the tube daily from the exit site on the stomach to the end of the tube. Assess the abdomen for distension and bowel sounds (Bowden & Greenberg, 2008). Also, measure the gastric **residual** (the amount remaining in the stomach; indicates gastric emptying time) by aspirating the gastric contents with a syringe, measuring it, and then replacing the contents. Check the residuals periodically, according to the facility's policy, such as every 4 to 6 hours, and before each intermittent feeding. If the residual volume exceeds the amount specified by the physician's order, hold the feeding and notify the physician or nurse practitioner.

Begin the feeding by placing the child in a supine position with the head and shoulders elevated approximately 30 degrees so that the feeding will remain in the stomach area (Bowden & Greenberg, 2008). Flush the tube with a small amount of water to clear it and prevent occlusion. This is not necessary for a gavage feeding if the tube is being inserted each time a feeding is given. Ensure that the feeding solution is at room temperature. Administer the feeding per the facility's policy.

Feeding solutions may be placed into the barrel of a syringe or into a feeding bag attached to the feeding tube and allowed to flow by gravity. The rate of flow for gravity-assisted feedings can be increased or decreased by raising or lowering the feeding solution container, respectively. Typically, intermittent feedings last from 15 to 30 minutes. A feeding bag also may be attached to a pump to control the rate of flow. Monitor the child's tolerance to the feeding.

## BOX 35.4

**METHODS FOR VERIFICATION OF FEEDING TUBE PLACEMENT**

- Obtain radiographic confirmation of proper tube placement after initial placement.
- After initial confirmation, document pH of aspirate; document insertion distance and external length of tube in the chart. Mark and document the tube's exit site from the nose or mouth.
- Use bedside techniques at regular intervals to determine proper tube positioning.
  - Measuring pH
    - Gastric secretions have a pH less than 5. Small intestine secretions will usually have a pH greater than 6, but this does not reliably predict proper tube placement. A pH greater than 6 can occur with respiratory or esophageal placement, with proper tube placement (gastric or intestinal) when feedings are given continuously, or if the child is receiving acid-inhibiting medications. Therefore, if the pH is greater than 5, additional assessment is warranted.
  - Observing appearance of fluid aspirated from tube (not reliable as sole verification)
    - Gastric secretions are usually grassy green or clear and colorless and can have off-white or tan mucous shreds. It may also be brown tinged if blood is present.
    - Intestinal secretions are often bile stained, light golden yellow to brownish green. They tend to be thicker and more translucent than gastric secretions.
    - Respiratory secretions can be white, yellow, straw colored, or clear.
  - Instill air into the tube and then auscultate for the sound (gastric auscultation). (not reliable as sole verification)
  - Check external markings on tube and external tube length (tube remaining from nares to end of tube) to determine if the tube seems to have migrated or been misplaced.
- Continually assess for signs indicative of feeding tube misplacement, such as unexplained gagging, vomiting, or coughing; signs and symptoms of respiratory distress; and decreased oxygen saturations.
- If bedside techniques reveal conflicting results or the child is high risk, radiologic confirmation is recommended.
- Review routine chest and abdominal radiographs (if obtained) to double-check correct tube position.

Always follow agencies' policy and procedures.

Adapted from Cincinnati Children's Hospital Medical Center. (2011a). Best Evidence Statement (BEST). Confirmation of nasogastric tube (NGT/OGT) placement. Retrieved July 7, 2012, from <http://www.cincinnatichildrens.org/assets/0/78/1067/2709/2777/2793/9198/ad67ab29-2a71-42a4-b78e-3d0e9710adac.pdf>

Once the feeding is complete, but before the formula completely empties from the container, flush the tube with water. As the water leaves the syringe or tubing, clamp the tube to prevent air from entering the stomach. Then disconnect the syringe or tube-feeding bag from the tube.

**Take Note!**

If the child vomits during the feeding, stop the feeding immediately and turn the child onto his or her side or sit him or her up.

If the child has a gastrostomy button, open the cap and connect an adaptor or insert extension tubing through the one-way valve. This allows access to the gastric conduit. The feeding solution container is connected to the extension tubing or adaptor and the feeding is given as described previously. After the feeding is completed, the extension tubing or adaptor is flushed with water and the flip-top opening is closed.

Burp the infant during and after any type of tube feeding in the same manner as for an infant who is bottle- or breast-fed. Also, position the child on his or her right side with the head slightly elevated, approximately 30 degrees, for about 1 hour after the feeding to facilitate gastric emptying and reduce the risk of aspiration and regurgitation. Some children have a difficult time with gas and burping on their own after tube placement. Venting, which helps relieve gas, may be ordered by the physician or nurse practitioner. It removes excess air and can be helpful if the child is bloated or the abdomen is distended. Use a catheter-tip syringe with the plunger removed and attach to the end of the tube. Hold the syringe above the child's stomach for a few minutes. Once the air or gas is removed, allow any stomach contents or formula to flow back into the stomach.

Weigh the child daily throughout enteral nutrition therapy to determine the effectiveness of the therapy.

**Providing Skin and Insertion Site Care**

Skin around the gastrostomy or jejunostomy insertion site may become irritated from movement of the tube, moisture, leakage of stomach or intestinal contents, or the adhesive device holding the tube in place. Keeping the skin clean and dry is important and will help prevent most of these problems.

The skin around a gastrostomy or jejunostomy tube requires cleaning at least once a day. Routine site care includes gentle cleansing with sterile water or saline for newly placed tubes, or for established tubes, soap and water followed by rinsing or cleaning with water alone. To clean under an external disc or bumper, a

cotton-tipped applicator may be used. Diluted hydrogen peroxide may be necessary to clean crusted drainage off the skin, tube, or disc (Cincinnati Children's Hospital Medical Center, 2011b). During insertion site care, rotate the gastrostomy tube or button a quarter-turn to prevent skin adherence and irritation. Always follow agency or institution policies and procedures.

### Take Note!

Do not rotate a jejunal tube because it can cause kinking (Bowden & Greenberg, 2008).

Assess the insertion site and condition of the surrounding skin for signs and symptoms of infection, such as erythema, induration, foul drainage, or pain. A small amount of clear or tan drainage is normal. If any drainage is present, a dressing can be placed. Use a presplit 2 × 2 gauze and place it loosely around the site. Change this dressing when it is soiled. If no drainage is present, do not place a dressing as it can cause undue pressure and trap moisture, leading to skin irritation.

Preventing movement of the tube also helps reduce skin irritation. Check the volume of the balloon with a balloon-tipped device about once or twice a week and reinflate the balloon to the initial volume if needed. The tube should be able to move slightly in and out of the child's stomach. The plastic disc should be snug against the skin but not tight enough to cause pressure. Tube stabilization methods help prevent the tube from moving around and sliding further into the stomach or jejunum. Stabilize the tube by pulling gently on the tubing and sliding the stabilizer bar or disc snugly against the abdomen.

### Take Note!

Rotate sites where the tube is secured to the abdomen to prevent tension on the stoma or skin breakdown.

Measure and record the length of the tube from the exit site of the abdominal wall to the end of the tube. All future measurements should be the same unless the tube length is changed. For tubes without a stabilizer bar or disc or for additional stabilization needs, several other methods may be used, including cut baby bottle nipples, taping methods, and commercially available stabilizers (see Fig. 35.12). It is always important to follow agency policy.

### Take Note!

When using the nipple method, make sure to cut several holes in the base of the nipple to allow air circulation and site assessment.

## Promoting Growth and Development

Some children receive all of their nutritional needs through tube feedings, whereas other children use tube

feedings as a supplement to eating by mouth. Feeding time is a special time for infants and children. Occasionally, babies who are fed solely through an enteral feeding tube may forget or lose the desire to eat by mouth. Use a pacifier to help avoid this, allowing the infant to associate the nipple in his or her mouth with a feeding (Sexton & Natale, 2009). The sucking motion will also exercise the jaw and promote the flow of the feedings. The saliva produced during sucking aids in digestion. Combined with holding the infant and cuddling, rocking, and talking to him or her, this promotes a more normal feeding time.

Talking with children, playing music, or reading a story promotes an active feeding time. At home, encourage parents to include the feeding as a part of regular family mealtime together to provide socialization for the child. Allow the child to participate in the feedings by gathering supplies and administering the actual feeding so that the child may experience independence and adaptation. If the child also eats food by mouth, feed him or her by mouth first and then administer the tube feeding. During tube feedings in bed, make sure the head of the bed is elevated at least 30 degrees to help prevent vomiting and aspiration (Bowden & Greenberg, 2008).

Children with feeding tubes should be allowed as normal a routine as possible. For example, they can crawl, walk, and jump just like children of the same age and developmental level. However, in some cases, contact sports such as football, hockey, and wrestling should be avoided because of the higher risk of injury. Securing the tubing under the child's clothing will prevent it from becoming accidentally dislodged and prevent the child from pulling and playing with it. Using one-piece outfits, an Ace wrap, or stretchy gauze to cover the tube can help protect it.

## Educating the Child and Family

Educate children receiving enteral feedings and their parents thoroughly about this method of nutritional support. Reinforce the reason for the therapy and provide the child and parents with opportunities to verbalize their concerns and ask questions. Ensure that the parents understand the risks and benefits of the therapy and the expected duration.

Provide the child, if developmentally appropriate, and parents with opportunities to participate in the feeding sessions. This helps allay some of their fears and anxieties and promotes a sense of control over the situation. They will also gain valuable practice in learning the skill should the feedings be required at home. Teaching Guidelines 35.3 identifies important topics to include in the teaching plan for a child receiving enteral nutrition at home. Troubleshooting problems at home is an important topic to cover. Refer to Teaching Guidelines 35.4. Education also involves helping the family develop appropriate coping strategies to adapt, solve problems, and access the support and services they will need after discharge.

**FIGURE 35.12** Methods to stabilize a gastrostomy tube include (A) the nipple method, (B) taping methods, (C) the tension loop method, and (D) commercially available stabilizing devices (GripLok® pictured here).

### Teaching Guidelines 35.3

#### TOPICS TO BE COVERED FOR HOME ENTERAL NUTRITION

- Type and size of tube
- Type of nutritional support
- Rationale for therapy
- Expected results from therapy
- Duration of therapy
- Frequency of feedings
- Feeding solution and equipment
- Tube insertion technique (if appropriate)
- Methods to check for correct placement
- Steps for administering the feeding (and medication if ordered)
- Procedure for flushing tube
- Procedure for venting the tube, if appropriate
- Frequency of weighing the child
- Signs and symptoms of complications and when to notify physician or nurse practitioner
- Troubleshooting problems, such as clogging of the tube or dislodgement (see Teaching Guidelines 35.4)
- Daily tube care (e.g., cleaning the site, rotating tube)
- Site assessment
- Technique for reinsertion/replacement of tube as appropriate
- Equipment suppliers
- Resources for support
- Follow-up visits and referrals

### Teaching Guidelines 35.4

#### TROUBLESHOOTING COMPLICATIONS AT HOME

- If a tube becomes clogged, instruct caregivers to slowly push warm water into the tube. Amount and size of syringe will vary based on child's size and facility policy. Repeat if necessary. Instruct caregivers to never use an object or put anything into the tube. They should call the doctor or nurse if they are unable to unclog the tube. Declogging medications may be prescribed.
- If a tube is inadvertently removed, instruct the caregiver to cover the site with a small clean dressing and tape, then to call the physician or nurse immediately; the tube needs to be replaced as soon as possible or the tract will close. Some institutions may instruct the family on how to replace the tube once the tube is more than 6 weeks old and has formed an established G-tube tract.
- If the site is red or irritated, instruct caregivers to continue with routine cleaning and call the physician. An antibiotic or skin barrier cream may be ordered. Assess for leakage and try to minimize if possible. Ensure tube is stabilized and secure and not dangling.
- If the tube is leaking, the caregiver needs to keep the dressing clean and dry. More frequent venting may help and the physician should be notified.

Always teach following the instructions per agency policy and procedure regarding home care.

Gastrostomy tube (G-Tube) Homecare. Retrieved July 7, 2012, from <http://www.cincinnatichildrens.org/health/info/abdomen/home/g-tube-care.htm>

*Remember Lily from the beginning of the chapter? She is to be discharged home after having a gastrostomy tube inserted to continue feedings at home. What teaching is needed for her family prior to discharge?*

## Parenteral Nutrition

Nutritional support can be administered IV through a peripheral or central venous catheter. The concentration and components of the solution determine the type of parenteral nutrition. Parenteral nutrition given via a central venous access device is termed **total parenteral nutrition (TPN)**. Comparison Chart 35.1 gives information about peripheral and central parenteral nutrition.

### Administering TPN

Typically, the physician or nurse practitioner determines the concentration and components of the TPN solution based on a thorough assessment of the child’s status, including the results of laboratory testing. This information is used as a baseline for evaluating the effectiveness of therapy.

The solution is prepared under sterile conditions in the pharmacy. For TPN, a central venous access device is inserted and secured, if one is not already in place. Use

specialized tubing with an in-line filter (to prevent small microparticles from entering the circulation).

TPN solutions may be refrigerated until they are to be used. Once started, a single solution of TPN should hang for no longer than 24 hours (Springhouse, 2007). The infusion of the solution is initiated at a slow rate that is gradually increased as ordered based on how the child tolerates the therapy. TPN solutions are highly concentrated glucose solutions that can cause hyperglycemia if given too rapidly. Use of an infusion pump is essential to control the rate of infusion. Fat emulsions are administered periodically to meet the child’s need for essential fatty acids. These solutions are given as a piggyback solution into the TPN line, but below the in-line filter.

Throughout TPN therapy, be vigilant in monitoring the infusion rate, and report any changes in the infusion rate to the physician or nurse practitioner immediately. Adjustments may be made to the rate, but only as ordered by the physician or nurse practitioner. The infusion rate should never be adjusted more than 10% higher or lower than the current rate (Weinstein, 2007).

Initially, check blood glucose levels frequently, such as every 4 to 6 hours, to evaluate for hyperglycemia. These levels can be obtained with a bedside glucose meter. Minimize the trauma and discomfort associated with frequent invasive procedures by using the principles of atraumatic care. If blood glucose levels are elevated, subcutaneous administration of insulin may be needed. Once the child’s glucose levels stabilize, the frequency

COMPARISON CHART 35.1

### PERIPHERAL PARENTERAL NUTRITION VERSUS TOTAL PARENTERAL NUTRITION

	Peripheral Parenteral Nutrition	Total Parenteral Nutrition
<i>Indications/use</i>	Primarily supplemental Short-term use to supply additional calories and nutrients	Provides all nutrients to meet child’s needs Enough calories supplied to maintain a positive nitrogen balance <sup>a</sup>
<i>Route</i>	Peripheral vein	Central venous access to allow rapid dilution of hypertonic solution
<i>Child’s status</i>	Nutritional status usually within acceptable parameters Oral intake decreased or absent	Child with a nonfunctioning gastrointestinal (GI) tract, such as a congenital or acquired GI disorder Severe failure to thrive Multisystem trauma or organ involvement Preterm newborns
<i>Components</i>	Fluid, electrolytes, and carbohydrates (dextrose); usually no protein or fats Carbohydrate concentration usually limited to 10% <sup>a</sup>	Highly concentrated solution of carbohydrates, electrolytes, vitamins, and minerals Lipid emulsion to supply need for essential fatty acids Total nutrient admixture (TNA) with components of TPN plus lipids and other additives in one container

<sup>a</sup>Weinstein, S. M. (2007). *Plumer’s principles and practice of intravenous therapy* (8th ed.). Philadelphia: Lippincott Williams & Wilkins.

of blood glucose level determinations decreases, such as every 8 to 12 hours, based on the facility's policy.

### Take Note!

If for any reason the TPN infusion is interrupted or stops, be prepared to begin an infusion of a 5% to 10% dextrose solution at the same infusion rate as the TPN (Bowden & Greenberg, 2008). This helps to prevent rebound hypoglycemia that may occur due to the increased insulin secretion by the child's body in response to the use of the highly concentrated TPN solution.

Perform catheter site care, tubing and filter changes, and dressing changes according to the facility's policy. Inspect the insertion site closely for signs of infection. Also monitor the child's vital signs, daily weights, and intake and output closely for changes. In addition, review laboratory test results, which can aid in early detection of problems, such as infection or electrolyte excesses or deficits.

TPN can be administered continuously over a 24-hour period, or after initiation it may be given on a cyclic basis, such as over a 12-hour period during the night. When administering cycled TPN, the solution is infused at half the prescribed rate for the first and last hour to prevent hyper- and hypoglycemia.

## Preventing Complications

Nurses play a key role in minimizing the risk for complications related to use of central venous access devices and TPN. Box 35.5 describes these complications. Key measures to reduce the risk of complications include the following:

- Monitor the child's vital signs closely for changes.
- Adhere to strict aseptic technique when caring for the catheter and administering TPN.
- Ensure that the system remains a closed system at all times. Secure all connections and clamp the catheter or have the child perform the Valsalva maneuver during tubing and cap changes.
- Use occlusive dressings. Chlorhexidine-impregnated sponge (Biopatch) dressings may be used to help prevent infection. Always follow agency or institution policy and procedures.
- Adhere to agency policy for flushing of the catheter and maintaining catheter patency.
- Assess intake and output frequently.
- Monitor blood glucose levels and obtain laboratory tests as ordered to evaluate for changes in fluid and electrolytes.

### Take Note!

Never administer any medication, blood, or other solution through the TPN lumen. Doing so increases the risk for contamination of the system and subsequent infection (Bowden & Greenberg, 2008; Springhouse, 2007).

## BOX 35.5

### COMPLICATIONS THAT CAN OCCUR WITH CENTRAL VENOUS ACCESS DEVICES AND TOTAL PARENTERAL NUTRITION (TPN)

- Air embolism from inadvertent entry of air into the system during tubing or cap changes or accidental disconnection
- Cardiac tamponade due to catheter advancement with movement of the arm, neck, or shoulder
- Catheter occlusion from the development of a fibrin sheath or thrombus at the catheter tip, malpositioning or kinking, or the deposition of precipitates or a blood clot
- Venous thrombosis from injury to the vessel wall during insertion or movement of the catheter after insertion or from chemical irritation due to administration of concentrated solutions, vesicants, and other medications through the catheter
- Hyperglycemia, typically with too rapid an infusion of TPN
- Hypoglycemia, which may occur with rapid cessation
- Dehydration as the child's body attempts to rid itself of excess glucose through renal excretion
- Electrolyte imbalance (particularly potassium, sodium, calcium, magnesium, and phosphorus)
- Infection at the skin insertion site, along the catheter pathway, or in the bloodstream. Organisms can arise from the skin, hands of caregivers, or other areas such as wound drainage, droplets from the lungs, or urine. For example, connection sites can be contaminated during tubing or dressing changes.

## Promoting Growth and Development

Meals are a time for meeting nutritional needs as well as a time for love, comfort, support, and socialization. TPN meets the child's nutritional needs, but the child's need for love and support also must be met. Implement measures similar to those for children receiving enteral nutrition (see discussion earlier in this chapter). Also provide opportunities for holding and cuddling the child. Allow the older child to participate in activities that can help to occupy the time associated with meals. Encourage the child and parents to participate in the care to promote a sense of independence as well as a sense of control over the situation.

## Educating the Child and Family

Children who require long-term TPN therapy may receive TPN in the home. Administering TPN at home requires thorough education of the child and parents. This teaching can occur in the health care agency or in the child's home. The amount of information to be taught can be overwhelming, so ensure that ample time is available. Allow time for questions and concerns. Offer emotional support and guidance whenever necessary.

Provide written and verbal instructions about the care involved. Have the child (if appropriate) and parents demonstrate the care needed, including care of the central venous access device. Review with them the measures for obtaining, storing, and handling the solutions and supplies. Develop plans for troubleshooting problems with devices and equipment, and give instructions on how to recognize and treat complications. Also teach them about danger signs and symptoms that require immediate notification. Be sure they have the name and number of a contact person in case of emergency situations.

Initiate the appropriate referrals for support. Specialized home care infusion services are available for follow-up in the home. In addition, social services can be helpful in providing assistance with finances, health insurance reimbursement, scheduling, transportation, emotional support, and community resources.

### KEY CONCEPTS

- The “eight rights” of pediatric medication administration are the right drug, right dose, right route, right time, right patient, right documentation, right to be educated, and right to refuse.
- The physiologic immaturity of some body systems in children can affect a drug’s pharmacodynamics, leading to differences in the body’s response to the drug and thus enhancing or diminishing the drug’s effects. The child’s age, weight, body surface area, and body composition can affect the drug’s pharmacokinetics.
- The two most common methods for determining pediatric drug doses involve the use of the child’s body weight and body surface area.
- Children younger than the age of 5 to 6 are at risk for aspiration when receiving tablets or capsules because they have difficulty swallowing them; liquids may be more appropriate. When administering oral medications to children, always tell them whether a medication is being mixed with food.
- Medication administration via the rectal route is not preferred because the drug’s absorption may be erratic and unpredictable and children find this route extremely upsetting or embarrassing.
- When administering otic medications, pull the pinna downward and back if the child is younger than age 3, and up and back for older children.
- Intramuscular administration is used infrequently in children because it is painful and children often lack the adequate muscle mass. When used with infants, the preferred site is the vastus lateralis muscle.
- Administration of medication via the IV route is common with children, especially when a rapid response to the drug is desired or when absorption via other routes is difficult or impossible. The primary method for IV medication administration is via a syringe pump.
- Preferred sites for peripheral IV therapy include the veins of the hands, feet, and forearms. The scalp vein may be used in infants but only if attempts at other sites have been unsuccessful. The rule of thumb for insertion of any peripheral devices is to use the smallest-gauge catheter for the shortest length of time possible to prevent trauma to the child’s fragile veins.
- Central venous therapy usually is administered through a large vein, such as the subclavian, femoral, or jugular vein or vena cava. The tip of the device lies in the superior vena cava just at the entrance to the right atrium. Devices include single- or multiple-lumen short- and long-term catheters, peripherally inserted central catheters, tunneled catheters, and vascular access ports.
- Monitoring intake and output is important when a child is receiving IV therapy. Site inspection, proper care of the site, and proper dressing changes are key to preventing complications.
- Nutritional support can be administered enterally via a nasogastric or orogastric tube (gavage feeding) or via a gastrostomy or jejunostomy device or administered parenterally through a peripheral or central venous access device.
- Enteral nutrition is indicated for children who have a functioning gastrointestinal tract but cannot consume adequate amounts of nutrients orally.
- Prior to any enteral feeding, placement of the feeding tube must be confirmed. The gold standard for confirming placement is with a radiograph. At the bedside, checking the pH of the aspirate is used to confirm placement.
- Children receiving TPN require close monitoring of the infusion rate and volume, intake and output, vital signs, and blood glucose levels. Strict aseptic technique is necessary when caring for the central venous access site and TPN infusion.

## MULTIPLE CHOICE QUESTIONS

1. A nurse is preparing to administer an intramuscular injection to an infant. What is the most appropriate site for this injection?
  - a. Deltoid muscle
  - b. Vastus lateralis
  - c. Dorsogluteal
  - d. Rectus femoris
2. A 3-year-old child is to receive a medication that is supplied as an enteric-coated tablet. What is the best nursing action?
  - a. Crush the tablet and mix it with applesauce.
  - b. Dissolve the medication in the child's milk.
  - c. Place a pill in the posterior part of the pharynx and tell the child to swallow.
  - d. Check with the prescriber to see if an alternative form can be used.
3. The nurse is caring for an infant who weighs 8.2 kg and is NPO and receiving IV fluid therapy. What rate does the nurse calculate as meeting the child's daily fluid requirements?
  - a. 82 mL per hour
  - b. 41 mL per hour
  - c. 34 mL per hour
  - d. 22 mL per hour
4. When administering ear drops to a 2-year-old, which action would be most appropriate?
  - a. Tell the child that the drops are to treat his infection.
  - b. Pull the pinna of the child's ear down and back.
  - c. Have the child turn his head to the opposite side after giving the drops.
  - d. Massage the child's forehead to facilitate absorption of the medication.

## CRITICAL THINKING EXERCISES

1. When reviewing the medical record of a child, the nurse notes that the ordered dose of medication is different from the recommended dose. How should the nurse proceed?
2. While caring for a 5-year-old child who is receiving IV fluid therapy at a rate of 100 mL per hour, the nurse notes that the infusion is running slowly. The insertion site appears slightly reddened and swollen. What should the nurse do next?

3. A school-aged child is to be discharged, continuing TPN therapy at home. The child lives with his parents and two younger siblings. How would the nurse prepare this child and family for discharge? How could the nurse promote growth and development for this child during TPN therapy?

## STUDY ACTIVITIES

1. Review the medical records of several children who are on a pediatric unit in your agency. Note the type of medication, route ordered, and what specific interventions are needed for each child related to the medication administration and developmental age of the child, include atraumatic care interventions. Compile a list of the most commonly used routes.
2. Interview several parents about their experiences in giving medications to their children. From these interviews, develop a teaching sheet that provides tips to facilitate oral medication administration to children.
3. Create a chart that compares and contrasts the subcutaneous, intramuscular, and intravenous methods of medication administration. Include examples of medications given via these routes, onset of action, appropriate sites, and necessary safety measures for each.
4. An infant is to receive intermittent gavage feedings via a nasogastric tube every 6 hours. The feeding tube was inserted with a previous feeding and remains in place. The nurse is preparing to administer the next scheduled feeding. Place the events in the proper sequence.
  - \_\_\_\_\_ a. Check the placement of the feeding tube.
  - \_\_\_\_\_ b. Position the infant on his right side with the head of the bed slightly elevated.
  - \_\_\_\_\_ c. Allow the feeding to come to room temperature.
  - \_\_\_\_\_ d. Flush the tube with water.
  - \_\_\_\_\_ e. Clamp the tube to prevent air from entering the stomach.
  - \_\_\_\_\_ f. Pour the solution into the barrel of the syringe.

#### KEY TERMS

acute pain  
 chronic pain  
 drug tolerance  
 epidural analgesia  
 moderate sedation  
 neuromodulators  
 neuropathic pain  
 nociceptive pain  
 nociceptors  
 pain  
 pain threshold  
 patient-controlled  
 analgesia (PCA)  
 physical  
 dependence  
 somatic pain  
 transduction  
 visceral pain

## Pain Management in Children

### Learning Objectives

Upon completion of the chapter, you will be able to:

1. Define the key terms used in this chapter.
2. Identify the major physiologic events associated with the perception of pain.
3. Discuss the factors that influence the pain response.
4. Identify the developmental considerations of the effects and management of pain in the infant, toddler, preschooler, school-age child, and adolescent.
5. Explain the principles of pain assessment as they relate to children.
6. Understand the use of the various pain rating scales and physiologic monitoring for children.
7. Establish a nursing care plan for children related to management of pain, including pharmacologic and nonpharmacologic techniques and strategies.

*Aiden Russell is a 6-year-old on the pediatric unit admitted for a wound infection. He requires BID dressing changes. In report you are told that Aiden cries and fights during the dressing change but otherwise seems to be playing and not experiencing much pain. The nurse reporting off duty states, "Aiden's mother keeps requesting pain medication for Aiden. She states he's complaining of pain most of the time. I'm not sure if I believe her: when I see Aiden, he's playing Nintendo games or watching television and seems to be fine. I've tried to hold off on his pain medication as long as I can."*

### Words of Wisdom

All of our children in pain deserve as much comfort as we can give.

**Pain** is a highly individualized, subjective experience that can affect any person of any age. It is a complex phenomenon that involves multiple components and is influenced by myriad factors. **Pain** is defined by the International Association for the Study of Pain as “an unpleasant sensory and emotional experience that is associated with actual or potential tissue damage” (International Association for the Study of Pain, 2012). Another definition of pain that is commonly used defines pain as whatever the person says it is, existing whenever the person says it does—that is, pain is present when the person says that it is (Ferrell, 2005; McCaffery, 1968; McCaffery & Pasero, 2011). The person experiencing the pain is the only one who can identify pain and know what the pain is like.

Pain is a universal experience. Pain affects adults and children of all ages, even preterm infants. Pain can result from numerous causes, including disease processes, injuries, procedures, and surgical interventions. In 1995 the American Pain Society (1995) labeled it “the fifth vital sign.” The American Pain Society’s goal was to encourage health care professionals to assess pain every time that temperature, pulse, respirations, and blood pressure are assessed and to institute measures to manage the pain.

Unlike adults, however, children may lack the verbal capacity to describe their pain accurately. In addition, many caregivers and health care providers have misconceptions about pain in children, it is difficult to assess the complex nature of the pain experience, and limited resources and research are available related to pain relief strategies for children. Therefore, pain is a major source of distress for children and their families as well as for health care providers.

If left unmanaged, pain in children can lead to serious physical and emotional consequences, such as increased oxygen consumption and alterations in blood glucose metabolism. In addition, the experience of untreated pain early in life may lead to long-term physiologic and psychological consequences for the child (Bowden & Greenberg, 2008). For example, inadequately controlled pain can have long-lasting negative outcomes such as increased distress during later procedures, nonadherence to treatment regimens, inactivity, prolonged bed rest, and the development of chronic pain. Detrimental effects on the course of the disease itself may also be seen with untreated pain. Preterm infants, due to long hospitalizations and numerous painful and invasive procedures, are often at greater risk for experiencing memories of pain (American Academy of Pediatrics, 2010).

All these factors make pain management a critical element in the plan of care for children. Treating pain reduces anxiety during procedures and decreases the need for physical restraints, reduces anxiety regarding subsequent procedures, and prevents short- and long-term consequences of inadequately treated pain, particularly in newborns (Cohen & Baxter, 2008; Kennedy, Luhmann, & Zempsky,

2008). Pain management in children has improved, but underestimation and inadequate management still remain a problem (Bowden & Greenberg, 2008). Various national health associations have issued position papers and guidelines related to the need to treat pain and suffering in children. Effective pain management involves initial pain assessment, therapeutic interventions, and reassessment for all children in any health care setting.

This chapter describes the pain experience in children, including the types of pain, factors influencing pain, and common fallacies and myths associated with pain in children. The nursing process is applied to provide an overview of the care for a child in pain. Various pain management strategies are described, including nonpharmacologic and pharmacologic interventions and measures to address procedure-related and chronic pain.

## PHYSIOLOGY OF PAIN

The sensation of pain is a complex phenomenon that involves a sequence of physiologic events in the nervous system. These events are transduction, transmission, perception, and modulation.

### Transduction

Peripheral nerve fibers extend from the spinal cord to various locations in and throughout the body’s tissues, such as skin, joints, bones, and membranes covering the internal organs. At the end of these fibers are specialized receptors, called **nociceptors**, which become activated when they are exposed to noxious stimuli. The noxious stimuli can be mechanical, chemical, or thermal. Mechanical stimuli may include intense pressure to an area, a strong muscular contraction, or extensive pressure due to muscular overstretching. Chemical stimulation may involve the release of mediators, such as histamine, prostaglandins, leukotrienes, or bradykinin, as a response to tissue trauma, ischemia, or inflammation. Thermal stimuli typically involve extremes of heat and cold. This process of nociceptor activation is called **transduction**.

### Transmission

When nociceptors are activated by noxious stimuli, the stimuli are converted to electrical impulses that are relayed along the peripheral nerves to the spinal cord and brain. Specialized afferent nerve fibers are responsible for moving the electrical impulse along. Myelinated A-delta fibers are large fibers that conduct the impulse at very rapid rates. The pain transmitted by these fibers is often referred to as fast pain, most commonly associated with mechanical or thermal stimuli (Porth & Matfin, 2009). Pain also is transmitted by unmyelinated small C fibers. These fibers transmit the impulse slowly and

are often activated by chemical stimuli or continued mechanical or thermal stimuli (Porth & Matfin, 2009). These fibers carry the impulse to the spinal cord via the dorsal horn. Neurotransmitters are released to facilitate the transmission process to the brain.

Several theories have been proposed in an attempt to explain the process of pain transmission. The best known of these is the gate-control theory. According to this theory, the dorsal horn of the spinal cord contains interneuronal or interconnecting fibers. Large-diameter faster fibers carry nonnociceptive, tactile information, while small nerve fibers carry nociceptive or pain signals. Large fibers, when stimulated, close the gate or pathway to the brain, thereby inhibiting or blocking the transmission of the pain impulse. Subsequently, the impulse does not reach the brain, where it would be interpreted as pain. This theory helps explain why some nonpharmacologic therapies, such as massage and pressure, are effective in reducing pain (Porth & Matfin, 2009).

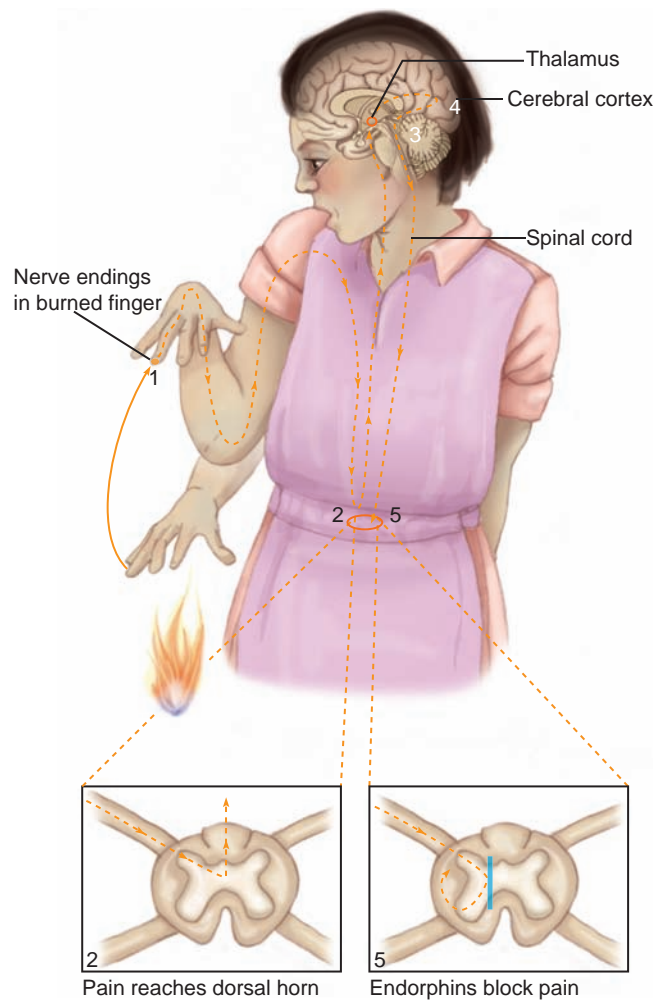

## Perception

Once in the dorsal horn of the spinal cord, the nerve fibers divide and then cross to the opposite side and rise upward to the thalamus. The thalamus responds quickly and sends a message to the somatosensory cortex of the brain, where the impulse is interpreted as the physical sensation of pain. The impulses carried by the fast A-delta fibers lead to the perception of sharp, stabbing localized pain that also commonly involves a reflex response to withdraw from the stimulus. The impulses carried by the slow C fibers lead to the perception of diffuse, dull, burning or aching pain. The point at which the person first feels the lowest intensity of the painful stimulus is termed the **pain threshold**. In addition to sending a message to the cerebral cortex, the thalamus also sends a message to the limbic system, where the sensation is interpreted emotionally, and to the brain stem centers, where autonomic nervous system responses begin.

## Modulation

Research has identified substances called **neuromodulators** that appear to modify the pain sensation. These substances have been found to change a person's perception of pain. Examples of these neuromodulators include serotonin, endorphins, enkephalins, and dynorphins.

Pain perception can be modified peripherally or centrally. In the peripheral nerve fibers, chemical substances are released that either stimulate the nerve fibers or sensitize them. Peripheral sensitization allows the nerve fibers to react to a stimulus that is of lower intensity than would be needed to cause pain. As a result, the person perceives more pain. Actions that block or inhibit

**FIGURE 36.1** Physiology of pain. (1) Exposure to thermal noxious stimuli results in activation of nociception (transduction). (2) Impulses are relayed along the peripheral nerves to the spinal cord through the dorsal horn (transmission). (3, 4) This results in the individual feeling the sensation of pain (perception). (5) Neurons in the brain stem send signals back down to the dorsal horn, and these fibers release substances such as endorphins, which can inhibit painful impulses in the dorsal horn (modulation). These neurotransmitters are taken back by the body, therefore limiting the analgesic value.

the release of these substances can lead to a decrease in pain perception.

Modification of pain perception can occur centrally in the spinal cord at the dorsal horn. Substances released by the excited interneurons can potentiate the pain sensation. Other neurochemicals, through their binding to specific receptors, can inhibit the perception of pain. Figure 36.1 illustrates the physiology of pain.

## TYPES OF PAIN

Many different systems can be used to classify pain. Most commonly, pain is classified based on its duration, etiology, or source or location.

## Classification by Duration

Pain is classified by duration as acute or chronic.

### Acute Pain

**Acute pain** is defined as pain that is associated with a rapid onset of varying intensity. It usually indicates tissue damage and resolves with healing of the injury. Acute pain reflects stimulation of nociceptors and serves a protective function (i.e., alerting the person to a problem). Examples of causes of acute pain include trauma, invasive procedures, acute illnesses such as sore throat or appendicitis, and surgery. This type of pain generally lasts a few days.

#### Take Note!

Children often experience pain associated with various procedures done in health care settings. This type of pain is usually short in duration. Preparation of the child and family will help to decrease fears or anxiety. Depending on the type of procedure and the child's age, cognitive level, and temperament, various techniques and methods can be used. Advocating for atraumatic care and adhering to its guidelines will help to minimize procedure-related pain.

### Chronic Pain

**Chronic pain** is defined as pain that continues past the expected point of healing for injured tissue. It provides no protective function. It may be continuous or intermittent, with and without periods of exacerbation or remission. It often interferes with sleep and performance of activities of daily living. It can result in loss of appetite and depression. Thus, chronic pain impairs a person's ability to function. In contrast to acute pain, environmental and psychological factors influence behaviors associated with chronic pain. In children, chronic, recurrent pain is most commonly associated with abdominal pain, nonspecific headache, limb pain, or chest pain. Some conditions, such as sickle cell disease and migraines, have characteristics of both acute and chronic pain (Porth & Matfin, 2009). Children with chronic pain may not exhibit the same physical or emotional responses as seen with acute pain. As pain becomes prolonged and continuous, the autonomic nervous system response tends to diminish.

## Classification by Etiology

Pain can be classified by etiology as nociceptive or neuropathic.

### Nociceptive Pain

**Nociceptive pain** reflects pain due to noxious stimuli that damages normal tissues or has the potential to do so if the pain is prolonged. The pain perceived often correlates

closely with the degree or intensity of the stimulus and the extent of real or possible tissue damage. With nociceptive pain, nervous system functioning is intact. Reports of nociceptive pain vary depending on the location of the nociceptors being stimulated. Nociceptive pain ranges from sharp or burning, to dull, aching, or cramping, and to deep aching or sharp stabbing. Examples of conditions that result in nociceptive pain include chemical burns, sunburn, cuts, appendicitis, and bladder distention.

### Neuropathic Pain

**Neuropathic pain** is pain due to malfunctioning of the peripheral or central nervous system. It may be continuous or intermittent and is commonly described as burning, tingling, shooting, squeezing, or spasm-like pain. Examples of neuropathic pain include posttraumatic and postsurgical peripheral nerve injuries, pain after spinal cord injury, metabolic neuropathies, phantom limb pain after amputation, and poststroke pain.

## Classification by Source or Location

Pain also may be classified by the source or location of the area involved. It can be somatic pain (superficial and deep) or visceral pain. These classifications typically indicate nociceptive pain.

### Somatic Pain

**Somatic pain** refers to pain that develops in the tissues. It can be further divided into two groups—superficial and deep. Superficial somatic pain, often called cutaneous pain, involves stimulation of nociceptors in the skin, subcutaneous tissue, or mucous membranes. Typically the pain is well localized and described as a sharp, pricking, or burning sensation. Superficial somatic pain may be due to external mechanical, chemical, or thermal injury or skin disorders. Tenderness commonly is present.

Deep somatic pain typically involves the muscles, tendons, joints, fasciae, and bones. It can be localized or diffuse and is usually described as dull, aching, or cramping. Deep somatic pain may be due to strain from overuse or direct injury, ischemia, and inflammation. Tenderness and reflex spasm may be present. Additionally, the person may exhibit sympathetic nervous system activation such as tachycardia, hypertension, tachypnea, diaphoresis, pallor, and pupillary dilation.

### Visceral Pain

**Visceral pain** is pain that develops within organs such as the heart, lungs, gastrointestinal tract, pancreas, liver, gallbladder, kidneys, or bladder. It is often produced by

disease. It usually is diffuse and poorly localized and is described as a deep ache or sharp stabbing sensation that may be referred to other areas. Visceral pain may be due to distention of the organ, organ muscular spasm, contraction, pulling, ischemia, or inflammation. Tenderness, nausea, vomiting, and diaphoresis may be present.

## FACTORS INFLUENCING PAIN

Children, like adults, experience neurologic events that result in the perception of pain. However, research has found that environmental and psychological factors may exert a greater influence on the child's perception of pain (McGrath & Hillier, 2003). Certain factors such as age, gender, cognitive level, temperament, previous pain experiences, and family and cultural background cannot be changed. However, situational factors involving behavioral, cognitive, and emotional aspects can be modified. These situation-specific factors that affect the child's pain experience include "what the child and parents understand, what they and the health care staff do and how the child and parents feel. Certain situational factors can intensify pain and distress, whereas others can eventually trigger pain episodes, prolong pain-related disability or maintain the repeated pain episodes in recurrent pain syndrome" (McGrath, 2005, p. 437).

### Age and Gender

Research has demonstrated that the nervous system structures needed for pain impulse transmission and perception are present by mid to late gestation (Oakes, 2011). Therefore, children of any age, including preterm newborns, are capable of experiencing pain (Oakes, 2011). Early on, children can interpret pain as an unpleasant sensation, but this interpretation is based on their comparison with other sensations. As they get older, they learn to use words to describe their pain more fully.

Gender and sex also may play a role in a child's perception of pain, but research has failed to yield concrete evidence supporting it (Hurley & Adams, 2008). It has been suggested that boys and girls differ in how they perceive and cope with pain and respond to analgesics. This may be influenced by various factors including genetics, hormones, family, and culture. Further research is warranted in this area to allow for more focused care in pain management.

### Cognitive Level

Cognitive level is a key factor affecting a child's pain perception and response and usually goes hand in hand with the child's age. Cognitive level typically increases with age, thereby influencing the child's understanding

of the pain and its impact and his or her choices for coping strategies. In addition, as the child's cognitive level increases, his or her ability to communicate information about pain increases. However, this increased understanding and ability to communicate with advancing age may not apply to the child experiencing developmental delays. For example, a developmentally delayed school-aged child or adolescent may have the cognitive level of a toddler or preschooler. Health care providers need to be cognizant of this difference when caring for the child in pain. Numerous research studies have revealed that young children often describe pain in concrete terms, whereas older children use more abstract terms that involve both physical and psychological components (McGrath, 2005).

### Temperament

Literature suggests that temperament plays a role in predicting distress and pain levels in a child during painful events (Ranger & Campbell, 2008). For example, a child with a "difficult temperament" is more likely to have an increased distress response to pain. Nurses can personalize interventions in the clinical environment and during the pain experience to better fit the child's temperament and other personality traits of the child and family.

### Previous Pain Experiences

A child identifies pain based on his or her experiences with pain in the past. The number of episodes of pain, the type of pain, the severity or intensity of the previous pain experience, the effectiveness of treatment of pain, and how the child responded all affect how the child will perceive and respond to the current experience. Research suggests that severe pain experiences in the neonate or young infant can lead to sensory disturbances and altered pain responses lasting into adulthood (Hatfield, Chang, Bittle, Deluca, & Polomano, 2011). Previous pain experiences with inadequate pain control may lead to increased distress during future painful procedures. For example, research studies have demonstrated that neonates who had undergone painful procedures such as circumcision and heel lancing showed a stronger negative response to routine immunizations and venipuncture weeks to months later (Kennedy et al., 2008).

### Family and Culture

The child's cultural and family background will influence how he or she will express and manage pain. Some cultures transmit the standard of accepting pain stoically; others allow outward expression. The parents have a strong influence on the child's ability to cope. For example, if a parent reacts to the child's pain in a

positive manner and offers comfort measures, the child may have an easier time coping. If the parent shows anger or disapproval, the pain experience may be intensified for the child.

## Situational Factors

Situational factors involve factors or elements that interact with the child and his or her current situation involving the experience of pain. These factors are highly variable and dependent on the specific situation. Situational factors result from the context in which the child is experiencing pain and include cognitive, which is what the child understands and believes about the pain experience; behavioral, which is how the child and family react and what they do about the pain experience; and emotional, which is how the child and family feels about the pain experience (Crowell, 2009). Due to children's limited experience with pain, situational factors may affect them more than adults (McGrath, 2005). A thorough pain assessment must include assessment for situational factors that may exacerbate pain. Examples of situational factors include:

- Child's lack of understanding of the source of pain
- Child's lack of ability to use coping mechanisms or pain-relieving strategies to decrease pain
- Stress and anxiety in anticipation of pain
- Child's lack of control of cause of pain
- Child's lack of ability to understand what to expect from potentially painful experiences
- Increased anxiety exhibited by the family
- Overly protective behaviors exhibited by the family
- Presence of emotions such as fear, anxiety, frustration, distress, underlying anxiety, and depression (Crowell, 2009; McGrath, 2005; McGrath & Hillier, 2003)

## DEVELOPMENTAL CONSIDERATIONS

Since children of various developmental ages respond differently to pain and perceive pain in different ways, it is important to review developmental considerations. Refer to Chapters 25 through 29 for a more complete understanding of childhood development. Nurses must understand how children of various ages respond to painful stimuli and what behaviors may be expected based on their developmental level. By understanding these developmental considerations, the nurse can appropriately assess the child's pain and provide effective interventions.

### Infants

Research has demonstrated that infants, including preterm infants, experience pain and can distinguish pain from other tactile experiences (Weissman, Aranovitch, Blazer, &

Zimmer, 2009). Much of this research focuses on pain related to invasive procedures, such as heel sticks and intravenous catheter insertion. Research suggests that neonates, especially preterm infants, actually experience pain at a greater intensity than older-age children and adults (American Medical Association, 2010; Codipietro, Ceccarelli, & Ponzone, 2008). The belief is related to the immaturity of the inhibitory mechanisms that develop higher in the central nervous system at a later time during fetal development. These mechanisms are more complex and do not become functional until later in gestation.

In preterm and term newborns, behavioral and physiologic indicators are used for determining pain. Behavioral indicators include facial expression, such as brow contracting and chin quivering; body movements; and crying (American Academy of Pediatrics, 2010; Henry, Haubold, & Dobrzykowski, 2004). Physiologic signs include changes in heart rate, respiratory rate, blood pressure, oxygen saturation levels, intracranial pressure, and vagal tone, palmar sweating, and an increase in plasma cortisol or catecholamine levels (American Academy of Pediatrics, 2010; Henry et al., 2004).

In the younger infant, facial expression is the most common response to pain (Fig. 36.2). The brows may be lowered and drawn together, with the eyes tightly closed. The mouth is open, often forming a square. The body may be stiff, and thrashing may be seen. When the area is stimulated, the infant may demonstrate a generalized reflex withdrawal. The infant may exhibit a high-pitched, shrill cry.

**FIGURE 36.2** In the younger infant, facial expression is the most common response to pain.

The older infant often displays similar behavioral manifestations of pain. The older infant may display an angry facial expression, but the eyes are open. He or she often demonstrates a definite withdrawal response when the area is stimulated. The older infant cries loudly and tries to push away the stimulus that is causing the pain. Other manifestations include irritability, restless sleeping, and poor feeding.

### Take Note!

Although an infant usually exhibits typical behaviors indicating pain, absence of these manifestations does not indicate a lack of a pain; the response to pain is highly variable (Ranger, Johnston, & Anand, 2007; Weissman, Aranovitch, Blazer, & Zimmer, 2009).

Infants also demonstrate physiologic responses to pain. These may include:

- Increased heart rate, possibly bradycardia in preterm newborns
- Decreased vagal tone
- Decreased oxygen saturation
- Palmar or plantar sweating (as measured by skin conductivity testing); not reliable in infants before 37 weeks' gestation

## Toddlers

Toddlers can react to painless procedures as intensely as painful ones, with intense emotional upset and physical resistance or aggression. They may bite, hit, scream, or kick. Other behaviors may include being very quiet, pointing to where it hurt, or saying such words as “owww.” Facial grimacing and teeth clenching may be noted. They may also react with fear and try to hide or leave the room. They often have limited vocabularies, so it may be difficult for them to express pain. It is important to ask about and encourage the child to verbalize his or her pain. Ensure the use of words the toddler understands, such as “owie” or “boo-boo.” Toddlers may demonstrate regressive behaviors, such as clinging to the parent or crying loudly.

### Take Note!

Children do not use the word “pain” until around the age of 6. By 2.5 years they spontaneously will use the word “hurt” (von Baeyer, 2006).

## Preschoolers

Preschoolers may become quiet or try to withdraw and hide in response to actual or perceived pain. For example, the child may say he or she needs to go to the bathroom or needs to get something from another room. Because of their magical type of thinking, preschoolers

may believe pain is a punishment for misbehaving or having bad thoughts. Preschoolers may not verbally report their pain, thinking that pain is something to be expected or that the adults are aware of their pain. They can tell someone where it hurts and can use various tools to describe the severity of pain. However, because they may have limited experience with pain, they may have difficulty distinguishing between types of pain (sharp or dull), describing the intensity of the pain, and determining whether the pain is worse or better.

## School-Age Children

School-age children can usually communicate the type, location, and severity of pain. Children older than the age of 8 years can use specific words, such as “sharp as a knife,” “burning,” or “pulling” to describe their pain. However, they may deny pain in an attempt to appear brave or to avoid further pain related to a procedure or intervention. They may be more concerned with their fear about the illness and its effects rather than the pain. They also may fear being embarrassed by acting-out behaviors in response to pain, such as screaming or thrashing. Thus, a typical response might be to withdraw by staring at the television. Other behaviors that may indicate pain in a school-age child include muscular rigidity, such as clenching the fists, stiffening the body, closing the eyes, wrinkling the forehead, or gritting the teeth.

## Adolescents

Adolescents may be concerned primarily about body image and fear losing control over their behavior. This may result in denial or refusal of medications. Their mood and what they think is expected of them will also affect their response to pain. Adolescents often ask numerous questions and pay close attention to how others respond to them. Fearing that their behavior may be viewed as juvenile, they may attempt to remain stoic and not exhibit any emotion. Subtle changes such as increased muscle tension with clenched fists and teeth, rapid breathing, and guarding the affected body part may occur. They may also show lack of interest in everyday activities or a decreased ability to concentrate.

## COMMON FALLACIES AND MYTHS ABOUT PAIN IN CHILDREN

In general, children respond to pain based on the type of pain, the extent of pain, and their age and developmental level. Table 36.1 highlights some common myths and misconceptions related to pain in children. Because of these myths, children have been medicated less than adults with a similar diagnosis, leading to inadequate pain management.

TABLE 36.1

## MYTHS AND MISCONCEPTIONS ABOUT CHILDREN AND PAIN

Myth or Misconception	Fact
Newborns do not feel pain.	Newborns, including preterm newborns, do feel pain. The neurologic and hormonal systems needed for the transmission of painful stimuli are sufficiently developed.
Exposure to pain at an early age has little to no effect on the child.	Prolonged or severe pain can lead to increased newborn morbidity. Infants who have experienced pain during the neonatal period respond differently to subsequent painful events. <sup>a</sup>
Infants and small children have little memory of pain.	Repeated exposure to painful procedures and events can have long-term consequences. Memories of pain may be stored in the child's nervous system, influencing later reactions to painful stimuli. <sup>b</sup>
The intensity of a child's behavioral reaction indicates the intensity of the child's pain.	Numerous factors affect a child's response to pain. Each child is an individual, with his or her own set of responses.
A child who is sleeping or playing is not in pain.	Sleep or play may be a coping strategy for the child in pain. Sleep may reflect exhaustion of the child who is coping with pain.
Children are truthful when they are asked if they are experiencing pain.	Often children deny pain to avoid a painful situation or procedure, embarrassment, or loss of control. Children may assume that others know how they are feeling and thus will not verbalize their complaints.
Children learn to adapt to pain and painful procedures.	Repeated exposure to pain or painful procedures can result in an increase in behavioral manifestations.
Children experience more adverse effects of narcotic analgesics than adults do.	The risk of adverse effects of narcotic analgesics is the same for children as for adults.
Children are more prone to addiction to narcotic analgesics.	Addiction to narcotics when used to treat children's pain is very rare. <sup>c</sup>

## NURSING PROCESS OVERVIEW FOR THE CHILD IN PAIN

Nursing care of the child with pain includes nursing assessment, nursing diagnosis, planning, interventions, and evaluation. Each step of this process must be individualized for each child. A general understanding of the physiology of pain, factors that influence pain, and effective pain management techniques can help to individualize the child's plan of care.

## Assessment

Assessment of pain in children consists of both subjective and objective data collection. The acronym **QUESTT** is an excellent way to remember the key principles of pain assessment (Baker & Wong, 1987):

- **Question** the child.
- **Use** a reliable and valid pain scale.
- **Evaluate** the child's behavior and physiologic changes to establish a baseline and determine the

effectiveness of the intervention. The child's behavior and motor activity may include irritability and protection as well as withdrawal of the affected painful area.

- **Secure** the parent's involvement.
- **Take** the cause of pain into account when intervening.
- **Take** action.

### Take Note!

Children do experience pain! Pain management techniques work just as well with children as they do with adults.

## Health History

When assessing pain in children, tailor the assessment to the child's developmental level and ask questions geared to the child's cognitive ability. During the health history, determine the child's previous exposure to pain, if any, and how the child responded. This information will provide clues about how the child copes and his or her current response. Attempt to determine what word the child uses to denote pain. Some children may not understand the term "pain" but do understand terms such as "ouchie" or "boo-boo."

The health history also includes questioning the parents about their cultural beliefs related to pain and their child's usual responses. This information aids in planning developmentally and culturally appropriate family-centered care.

## QUESTIONING THE CHILD

When questioning the child, phrase the questions in a manner that the child will be able to understand based on his or her developmental level. Some input from the child's family may be helpful in determining where best to focus the questions.

Ask the child what pain means to him or her. Use words that the child may comprehend more easily, such as "hurt," "boo-boo," or "ouch," as appropriate. Inquire about similar experiences in the past and how he or she responded. Determine whether the child let others know that he or she was hurting and how this message was conveyed (e.g., crying, acting out, or pointing to the hurting area).

Review the history of the pain and various influences such as cultural aspects, caregiver attitudes or expectations, previous experiences, and any education or teaching related to pain management. Continue to formulate questions to ascertain the following:

- Location, quality, severity, and onset of the pain, as well as the circumstances in which the child experiences the pain. Have the child point to the area

where it hurts or identify the location on a diagram or doll.

- Conditions, if any, that preceded the onset of pain and the conditions that followed the onset of pain
- Any associated symptoms, such as weight loss, fever, vomiting, or diarrhea, which may indicate a current illness
- Any recent trauma, including any interventions that were used in an attempt to relieve the pain

Continue the health history by inquiring about what the child wants others, including the nurse, to do when the child hurts. Conversely, ask the child what he or she doesn't want others to do. Finally, question the child about measures that seem to be most effective in relieving the pain. Ask if there is anything special the child wants to tell the nurse, such as a special pain relief technique or a specific comfort object.

If the child is experiencing chronic or recurrent pain, suggest the child and family record information in a symptom diary. Explain that this will be helpful in identifying the best ways to manage the pain.

## QUESTIONING THE PARENTS

Parents play a key role in assessing pain in children. Often it is the parents who provide information about the child's current and past experiences with pain. In addition, parents can provide information about how the child exhibits and responds to pain. Parents may be aware of subtle changes in the child's behavior that may precede the pain, occur with the pain, or indicate relief of pain. Including the parents in this process helps create a positive experience for all involved and promotes feelings of control over the situation.

The questions posed to the parents are similar in focus to those posed to the child. However, more detailed information may be obtained from the parents because they are usually able to describe events more fully or in greater detail due to their higher cognitive level. Parents typically know their child best.

### Take Note!

Parents may assume that nurses have greater expertise when it comes to assessing their child's pain and taking appropriate action. Thus, they may not always report when they notice changes suggesting that their child is uncomfortable. Emphasize the important role that parents play in reporting any changes in their child so that pain relief measures can be instituted as soon as possible.

When questioning the parents, use the following examples as a guide for assessing the child's pain:

- Has your child ever been in pain before? If so, what was the cause of the pain? How long did he or she have the pain? Where was the pain located?

- How did your child react to the pain? What did you do to lessen the pain?
- Did your child let you know that he or she was in pain? Did he or she tell you or did you notice something?
- Are there any special signs that let you know that your child is hurting? If so, what are they?
- Is there anything that your child does or that you do when he or she is hurting that helps relieve the pain?
- Does one thing work better than another when your child is hurting?
- Is there any special information that you want to tell me about your child?

**USING PAIN RATING SCALES**

Various pain assessment, or pain rating, scales are available. These scales allow the child to report his or her pain, and the pain level is quantified. These standardized rating scales provide a greater alignment between the child’s pain and the nurse’s assessment of the severity of the pain. Self-report measures should be used in conjunction with observation and discussion with the child and family, especially in children younger than age 5 or in children with cognitive impairments (American Academy of Pediatrics and the American Pain Society, 2001; Tomlinson, von Baeyer, Stinson, & Sung, 2010). Some studies have found validity in self-report tools used in children as young as 3 years of age, while others have found inconsistent findings when they are used in children younger than 5 years of age (Besenski, Forsyth, & von Baeyer, 2007; Tomlinson, von Baeyer, Stinson, & Sung, 2010). Therefore, it is important to assess young children’s ability to perform self-report tasks rather than rely solely on their chronological age (Besenski et al., 2007).

Many health care facilities have specific policies and procedures related to pain assessment, including the frequency of assessment, the rating tool to use, and nursing interventions to be instituted based on the rating. For example, many facilities require assessment of the child using a specific tool with documentation at least once a shift and 30 minutes to 1 hour after a non-pharmacologic or pharmacologic pain relief intervention. This process provides a more objective method to determine whether the pain is increasing or decreasing and whether pain relief methods are effective.

**Take Note!**

Typically, different pain rating scales are appropriate for different developmental levels. However, children may regress when in pain, so a simpler tool may be needed to make sure that the child understands what is being asked. Regardless of the tool used, nurses need to be consistent in using the same tool so that appropriate comparisons

can be made and effective interventions can be planned and implemented. Using the most appropriate tool consistently allows the most accurate assessment of the child’s pain.

**FACES Pain Rating Scale.** The FACES pain rating scale (Fig. 36.3) is a self-report tool that can be used by children as young as 3 or 4 years of age (Oakes, 2011). The scale consists of six illustrations of faces arranged horizontally with expressions ranging from smiling (indicating no hurt) to crying with frowning (indicating hurts worst). Under each face is a short description such as “hurts little bit” and a number. The number scale can be 0, 1, 2, 3, 4, and 5 or 0, 2, 4, 6, 8, and 10. The nurse explains the words associated with each face to the child. Then the nurse asks the child to select the facial expression that best describes the level of pain he or she is feeling. The nurse then documents the number corresponding to the word description and face (Hockenberry & Wilson, 2009).

**Oucher Pain Rating Scale.** The Oucher pain rating scale is similar to the FACES scale in that it uses facial expressions to indicate increasing degrees of hurt. However, instead of illustrations, six photographs are used: “no hurt” is placed at the bottom of the arrangement and “most hurt” at the top. Alongside the photos is a scale ranging from 0 to 10 that corresponds to the facial expressions in the photographs (Fig. 36.4). After explaining the photos and numeric scale, the child is asked to point to the number that best describes his or her level of pain (Beyer, Denyes, & Villarruel, 1992).

This scale is useful for self-reporting of pain in children between 3 and 13 years of age (Oakes, 2011).

**Wong-Baker FACES Pain Rating Scale**

**Instructions:** Explain to the person that each face is for a person who feels happy because he has no pain (hurt) or sad because he has some or a lot of pain. **Face 0** is very happy because he doesn’t hurt at all. **Face 1** hurts just a little bit. **Face 2** hurts a little more. **Face 3** hurts even more. **Face 4** hurts a whole lot. **Face 5** hurts as much as you can imagine, although you don’t have to be crying to feel this bad. Ask the person to choose the face that best describes how he is feeling.

**FIGURE 36.3** FACES pain rating scale. (From Hockenberry, M. J., & Wilson, D. [2009]. *Wong’s essentials of pediatric nursing* [8th ed., p. 162]. St. Louis, MO. Used with permission. Copyright, Mosby.)

**FIGURE 36.4** Oucher pain rating scale. (Used with permission from Beyer, J. E., Denyes, M. J., & Villarruel, A. M. [1992]. The creation, validation, and continuing development of the Oucher: A measure of pain intensity in children. *Journal of Pediatric Nursing*, 7[5], 335–346.)

Three different scales have been developed for use with Caucasian, Hispanic, and African American children (Cohen et al., 2008).

**Poker Chip Tool.** The poker chip tool, also known as the pieces of hurt tool, is a self-reporting pain assessment tool that uses four red poker chips to quantify the child's level of pain (von Baeyer, 2006). The chips are arranged in a horizontal line on a surface in front of the child. Starting with the chip closest to the child's left side, the nurse points to the chip and explains that the first chip means a little hurt, the next chip means more hurt, the third chip means more hurt, and the fourth chip means the worst hurt ever. Then the nurse asks the child how many "pieces of hurt" he or she is having (Fig. 36.5). If the child is not experiencing any pain, typically the child will state that he or she isn't having any. When the child identifies the number of "pieces of hurt," the nurse follows up by asking the child to tell the nurse more about his or her hurt (Hester, 1979).

The poker chip tool is useful for assessing pain in children who are 3 to 4 years of age or older (Cohen et al., 2008; Stinson, Kavanagh, Yamada, Gill, & Stevens, 2006). Children may view this assessment tool as a game since it involves poker chips. However, the nurse needs to ensure that the child has the cognitive ability to distinguish the numbers.

**FIGURE 36.5** The poker chip tool. Here the nurse asks the child to identify the number of chips that indicate her degree of "hurt."

**Word-Graphic Rating Scale.** The word-graphic rating scale is a self-reporting scale that consists of a line with descriptors underneath: no pain, little pain, medium pain, large pain, and worst possible pain (Fig. 36.6). The nurse explains the line and descriptors to the child. Then the child is asked to make a vertical mark on the horizontal line at the point that best describes the child's level of pain. The nurse uses a ruler to measure the distance from the "no pain" starting point to the area marked by the child. This measurement is recorded as the pain score. The word-graphic rating scale is useful for children between 4 and 17 years old.

#### Take Note!

Toddlers and preschoolers may not be used to being asked questions by strangers, and may not understand quantitative ratings or estimation. Preschoolers will often construct an answer even if they do not understand the question. They also will often use extremes

**FIGURE 36.6** Word-graphic rating scale.

FIGURE 36.7 (A) Visual analog scale. (B) Numeric scale.

of scales, such as no pain or the worst pain (von Baeyer, 2006).

**Visual Analog and Numeric Scales.** Visual analog and numeric scales involve a horizontal or vertical line with marked endpoints. With a visual analog scale, the endpoints are identified as no pain and worst pain. A numeric scale typically has endpoints of 0 and 10, reflecting no pain and worst pain, respectively (Fig. 36.7). The nurse explains the scale to the child. With the visual analog scale, the child makes a line that best describes the level of pain. The nurse then measures the distance from the “no pain” endpoint to the child’s mark and records this as the pain score. With the numeric scale, the nurse asks the child to pick the number that best describes his or her level of pain.

The visual analog scale can be used in children 7 years or older (Oakes, 2011). The numeric scale can be used with children 8 years or older (von Baeyer, 2006). Even though a younger child may be able to count and give numbers on the scale, they have not yet developed an understanding of the quantitative significance of the numbers.

**Adolescent Pediatric Pain Tool.** The Adolescent Pediatric Pain Tool is a self-report type of tool useful for older children, usually between 8 and 17 years of age (Bowden & Greenberg, 2008). The tool involves three aspects of assessment. In the first assessment the child identifies the location of the pain on two illustrations of the body—front and back views (Fig. 36.8).

The child is instructed to color the areas where he or she is hurting. The child is also instructed to color the area as big or as small as how much he or she is hurting. For example, if the hurt is mild or moderate, the child would color a moderate area of the

location; if the pain is severe, he or she would color a much larger area. The second portion of the tool involves a scale that ranges from “no pain” to “worst possible pain.” The nurse instructs the child to identify the severity of his or her pain. The third assessment is a list of words that may be used to describe pain, such as throbbing, pounding, stabbing, or sharp. The nurse asks the child to point to or circle the words that describe the current pain. Children with limited reading skills or vocabulary may have difficulty with some of the words listed to describe pain. Work with the child and encourage the parents to help the child understand the various descriptive words. Parental participation fosters control over the situation and gives the parents some insight into what their child is experiencing (Crandall & Savedra, 2005).

### Thinking About Development

Kaylee Cooper is a 4-year-old female with a fractured femur. She has been in traction since arriving in the emergency room last night. When you enter her room at the beginning of your shift you note she is quiet and withdrawn. How will Kaylee’s developmental stage affect the use of self-report? What special considerations must the nurse think about when using self-report of pain with Kaylee? What is the most appropriate pain rating scale to be used for Kaylee?

### Physical Examination

Physical examination of the child for pain primarily involves the skills of observation and inspection. These skills are used to assess for physiologic and behavioral changes that indicate pain. Auscultation also may be used to assess for changes in vital signs, specifically heart rate and blood pressure.

### OBSERVE FOR MANIFESTATIONS OF PAIN

Observe for physical signs and symptoms of pain, keeping in mind the child’s developmental level. Look for facial expressions of discomfort, grimacing, or crying. Be alert for movements that may suggest pain. For example, an infant or toddler may pull on the ear when experiencing ear pain. The child may move the head from side to side, suggesting head pain. Typically, children with abdominal pain will lie on one side and draw their knees up to the abdomen. Inspect the child’s gait: a limp or avoidance of weight bearing may suggest leg pain. Immobility, guarding of a particular body area,

**Sensory**

Aching ("pain all over")  
 Hurting ("pain all over")  
 Sore ("like a cut")  
 Beating (procedural pain "spots")  
 Pounding ("gets on your nerves")  
 Cutting ("hurts more than a cut")  
 Like a sharp knife ("stabbing and sharp")  
 Sharp (no meaning)  
 Stabbing (no meaning)  
 Cramping ("everywhere like a plane crash")  
 Crushing (no meaning)  
 Pressure ("pushing all over")  
 Itching ("all over")  
 Scratching ("helps sometimes")  
 Shocking (pain "surprises" her)  
 Splitting ("splitting in half" her body)  
 Numb ("knows pain is there"/ procedural pain)  
 Stiff ("cannot move")  
 Swollen ("meds do not help")  
 Tight ("cannot move")

**Affective**

Awful ("cannot do anything")  
 Crying ("hurts so bad")  
 Frightening ("scared it won't stop")  
 Screaming (afraid of "going to the hospital")  
 Terrifying ("cannot sleep," "really tired," "not going to live")  
 Dizzy ("don't know where I am")

**Evaluative**

Annoying ("cannot sleep")  
 Bad ("cannot stop the hurting")  
 Miserable ("cannot sleep or do stuff")  
 Terrible ("don't like it")  
 Uncomfortable ("can't stay in one spot")  
 Uncontrollable ("cannot stop it")

**Temporal**

Always ("pain always there")  
 Comes and goes ("always pain")  
 Comes on all of a sudden ("no warning")  
 Constant ("never goes away")  
 Continuous ("pain not going away")  
 Forever ("never will go away")  
 Once in a while ("in a month sometimes pain; sometimes not")  
 Sneaks up ("don't know when the pain will happen")  
 Sometimes ("goes away sometimes; sometimes not")

**FIGURE 36.8** Adolescent Pediatric Assessment Tool. (Top) Adolescent Pediatric Pain Tool (APPT): body outline. (Bottom) Pain Quality: Words chosen and meaning of words. (Used with permission from Crandall, M., & Savedra, M. [2005]. Multidimensional assessment using the adolescent pediatric pain tool: A case report. *Journal for Specialists in Pediatric Nursing*, 10(3), 115–123.)

or refusal to move an area may be observed. Inspect the skin for flushing or diaphoresis, possible indicators of pain. Also monitor vital signs for changes. Pulse or heart rate, respiratory rate, and blood pressure may increase. Other physiologic parameters that suggest pain may include elevated intracranial pressure and pulmonary vascular resistance and decreased oxygen saturation levels.

### Take Note!

The body responds to acute pain via the sympathetic nervous system, leading to stimulation and a subsequent increase in vital signs. However, if the child has persistent or chronic pain, the body adapts and these changes may be less noticeable (Bowden & Greenberg, 2008; Oakes, 2011).

The child also may exhibit behavioral changes indicating pain. Be alert for irritability and restlessness. Watch for clenching of teeth or fists, body stiffening, or increased muscle tension. Note any changes in the child's behavior. For example, a child who previously was talkative and playful may become quiet and almost withdrawn in response to pain. Remember, a child in pain may sleep or play in order to cope with the pain. In addition, pay close attention to the child's cultural background and how these beliefs may be affecting the behavioral response to pain.

Each child is an individual with unique responses to pain, so the nurse must ensure that observations

of behavior do indeed reflect the child's pain level. To help ensure the accuracy of observations, several physiologic and behavioral assessment tools have been developed to help quantify the observations.

### USING PHYSIOLOGIC AND BEHAVIORAL PAIN ASSESSMENT TOOLS

Use of physiologic and behavioral pain assessment tools allows measurement of specific parameters and changes that would indicate that the child is experiencing pain. These measurements aid in determining the intensity of the pain experience. Along with the self-report pain rating scales, measurement of these changes allows the nurse to objectively assess pain and the effectiveness of pain management measures.

**Neonatal Infant Pain Scale.** The Neonatal Infant Pain Scale (NIPS) is a behavioral assessment tool that is useful for measuring pain in preterm and full-term neonates (Lawrence et al., 1993). Six parameters are measured: facial expression, cry, breathing patterns, arms, legs, and state of arousal (Table 36.2). Each parameter except for cry is scored as a 0 or 1; cry is scored as 0, 1, or 2. The scores are then totaled and the maximum score that can be achieved is 7. A higher score indicates increased pain. This scale does not include any physiologic parameters; therefore, it may not detect early pain in neonates who are too ill to respond, who are receiving paralyzing agents, or who are premature (Hand, Noble, Geiss, Wozniak, &

**TABLE 36.2** THE NEONATAL INFANT PAIN SCALE (NIPS)

Parameter	Finding	Score
Facial expression	Relaxed (restful face; neutral expression)	0
	Grimace (tight facial muscles; furrowed brow, chin, or jaw; negative facial expression)	1
Cry	No cry (quiet; not crying)	0
	Whimper (mild intermittent moaning)	1
	Vigorous crying (loud screaming, shrill, continuous)	2
Breathing patterns	Relaxed	0
	Change in breathing (irregular; faster than usual; gagging; breath holding)	1
Arms	Relaxed (no muscular rigidity; occasional random movements of arm)	0
	Flexed/extended (tense, straight, rigid, or rapid flexion or extension)	1
Legs	Relaxed (no muscular rigidity; occasional random movements of leg)	0
	Flexed/extended (tense, straight, rigid, or rapid flexion or extension)	1
State of arousal	Sleeping/awake (quiet, peaceful; settled)	0
	Fussy (alert, restless, thrashing)	1

Reproduced from Lawrence, J., Alcock, D., MacGrath, P., Kay, J., MacMurray, S. B., & Dulberg, C. (1993). The development of a tool to assess neonatal pain. *Neonatal Network*, 12(6), 59–66. Copyright © 1993 Springer Publishing Company, LLC. With Permission.

Hall, 2010). In these cases, a falsely low score may be produced.

**Riley Infant Pain Scale.** The Riley Infant Pain Scale (RIPS) is a behavioral assessment tool useful for infants who lack verbal ability (Schade, Joyce, Gerkenmeyer, & Keck, 1996). Like NIPS, RIPS measures six parameters: facial expression, body movement, sleep, verbal or vocal ability, consolability, and response to movements and touch (Table 36.3). Each parameter is scored as 0, 1, 2, or 3. The score is then totaled and the maximum

**TABLE 36.3 THE RILEY INFANT PAIN SCALE**

Parameter	Score
Facial expression	
• Neutral/smiling	0
• Frowning/grimacing	1
• Clenched teeth	2
• Full cry expression	3
Body movement	
• Calm, relaxed	0
• Restless, fidgeting	1
• Moderate agitation or mobility; thrashing, flailing, incessant agitation or strong voluntary mobility	2
• Voluntary immobility	3
Sleep	
• Sleeping quietly with easy respirations	0
• Restless while asleep	1
• Sleeping intermittently (sleep/awake)	2
• Sleeping for prolonged periods of time interrupted by jerky movements or inability to sleep	3
Verbal/vocal	
• No cry	0
• Whimpering, complaining	1
• Pain crying	2
• Screaming, high-pitched cry	3
Consolability	
• Neutral	0
• Easy to console	1
• Not easy to console	2
• Inconsolable	3
Response to movement/touch	
• Moves easily	0
• Winces when touched or moved	1
• Cries out when moved or touched	2
• High-pitched cry or scream when touched or moved	3

**TABLE 36.4 THE PAIN OBSERVATION SCALE FOR YOUNG CHILDREN (POCIS)**

Parameter	Finding	Score
Facial expression	Neutral	0
	Grimace (negative)	1
Cry	No cry	0
	Moan, scream	1
Breathing	Relaxed and regular	0
	Irregular and indrawn	1
Torso	At rest, inactive	0
	Tense, shivering	1
Arms and fingers	At rest, inactive	0
	Tense, restless	1
Legs and toes	At rest, inactive	0
	Tense, restless	1
State of arousal	Calm, sleepy	0
	Fussy	1

Used with permission from Boelen-van der Loo, W. J. C., Scheffer, E., de Haan, R. J., & de Groot, C. J. (1999). Clinimetric evaluation of the pain observation scale for young children in children aged between 1 and 4 years after ear, nose, and throat surgery. *Developmental and Behavioral Pediatrics*, 20(4), 222–227.

score that can be achieved is 18. The higher the total score, the more intense the pain.

**Pain Observation Scale for Young Children.** The Pain Observation Scale for Young Children (POCIS) is a behavioral assessment tool designed for use in children between 1 and 4 years of age (Boelen-van der Loo, Scheffer, de Haan, & de Groot, 1999). This tool measures seven parameters: facial expression, cry, breathing, torso, arms and fingers, legs and toes, and state of arousal (Table 36.4). Each parameter is scored as 0 or 1; the maximum score achievable is 7. The higher the score, the greater the pain being experienced by the child.

**CRIS Scale for Neonatal Postoperative Pain Assessment.** The CRIS scale is a behavioral assessment tool that also includes measures of physiologic parameters (Krechel & Bildner, 1995). It was developed to quantify postoperative pain in the newborn. The tool also may be used to monitor the infant's progress over time during recovery or after interventions. The tool assesses five parameters: cry, oxygen required for saturation levels less than 95%, increased vital signs, facial expression, and sleeplessness (Table 36.5). Each parameter is scored as 0, 1, or 2 and then totaled. As

**TABLE 36.5 THE CRIES SCALE FOR NEONATAL POSTOPERATIVE PAIN ASSESSMENT**

Assessment	0	1	2
Crying	No	High-pitched, but consolable	High-pitched, inconsolable
Oxygen required for saturation above 95%	No	<30%	>30%
Increased vital signs	Heart rate and blood pressure within 10% of preoperative values	Heart rate or blood pressure 11% to 20% higher than preoperative values	Heart rate or blood pressure 21% or more above preoperative values
Expression	No grimace	Grimace	Grimace with grunt
Sleepless	No	Waking at frequent intervals	Constantly awake
<b>Total infant score</b>			
Used with permission from Krechel, S. W., & Bildner, J. (1995). CRIES: A new neonatal postoperative pain measurement score. Initial testing of validity and reliability. <i>Paediatric Anaesthesia</i> , 5, 53–61.			

with other assessment tools, the higher the score, the greater the infant’s pain.

**FLACC Behavioral Scale for Postoperative Pain in Young Children.** The FLACC behavioral scale is a behavioral assessment tool that is useful in assessing a child’s pain when the child cannot report accurately his or her level of pain (Merkel, Voepel-Lewis, Shayevitz, &

Malviya, 1997). It has been demonstrated to be a reliable tool for children from age 2 months to 7 years of age (Oakes, 2011). This tool measures five parameters: facial expression, legs, activity, cry, and consolability (Table 36.6). Observe the child with the legs and body uncovered. If the child is awake, observe him or her for 2 to 5 minutes; if sleeping, observe the child for 5 minutes or longer. Each parameter is scored as 0, 1, or 2.

**TABLE 36.6 FLACC BEHAVIORAL SCALE**

Category	Scoring		
	0	1	2
Face	No particular expression or smile	Occasional grimace or frown, withdrawn, disinterested	Frequent to constant frown, clenched jaw, quivering chin
Legs	Normal position or relaxed	Uneasy, restless, tense	Kicking, or legs drawn up
Activity	Lying quietly, normal position, moves easily	Squirming, shifting back and forth, tense	Arched, rigid, or jerking
Cry	No cry (awake or asleep)	Moans or whimpers, occasional complaint	Crying steadily, screams or sobs, frequent complaints
Consolability	Content, relaxed	Reassured by occasional touching, hugging, or being talked to, distractible	Difficult to console or comfort
Each of the five categories is scored from 0 to 2, which results in a total score between 0 and 10. © 2002, The Regents of the University of Michigan. All rights reserved.			

The scores are totaled, with a maximum achievable score of 10. As with other assessment tools, the higher the score, the greater the pain.

## Nursing Diagnoses, Goals, Interventions, and Evaluation

After assessing the child, the nurse identifies appropriate nursing diagnoses. The most commonly identified nursing diagnosis would be acute or chronic pain. However, the related factors and defining characteristics can vary widely. Nursing diagnoses will focus on the effects of pain on the child, for example, the stress incurred as a result of the pain or the fear or anxiety associated with the pain or events causing the pain. Moreover, pain can affect physiologic functions, such as sleep, nutrition, mobility, and elimination. Examples of common nursing diagnoses may include:

- Acute pain related to repeated need for invasive procedures, surgical experience, recent trauma, or infection
- Chronic pain related to prolonged illness or injury, effects of cancer on surrounding tissues, or treatment-related effects
- Fear related to the unknown, separation from family, anticipation of invasive procedures, or effects of treatment
- Anxiety related to the stress and uncertainty of the situation
- Deficient knowledge related to current condition and appropriate methods for managing pain
- Sleep deprivation related to inability to manage pain effectively
- Impaired mobility related to increased episodes of pain
- Risk for constipation related to potential adverse effects of narcotic analgesic agents

When caring for a child experiencing pain, the ultimate goal is that the child will be free of pain as evidenced by participation in age-appropriate activities of daily living and vital signs within age-appropriate parameters. However, at times, this may be unrealistic, especially if the child is experiencing chronic pain. Therefore, a more appropriate goal would be that the child reports that his or her pain has decreased to a tolerable level. Pain assessment tools can be used to quantify the amount by which the child's pain has decreased. For example, if the child has rated the pain as 7 out of 10, a realistic goal might be that the child reports a pain rating of no more than 4 out of 10. Additional goals would reflect improvement or resolution of the identified problem. For example, a short-term goal for a child experiencing disturbed sleep due to the pain might be that the child sleeps for a minimum of 4 consecutive hours through the night. A long-term goal

might be that the child sleeps for 7 to 8 hours undisturbed through the night.

Various interventions can be used for pain management. These interventions include nonpharmacologic and pharmacologic measures. A guiding principle when caring for the child experiencing pain is the provision of atraumatic care (see Chapter 30 for more information). For example, cognitive and behavioral approaches are appropriate for pain management, including pain management related to procedures. In addition to nonpharmacologic measures, pharmacologic measures are appropriate for pain management. For example, apply a topical anesthetic cream to a site early enough before a venipuncture that it becomes effective. Another idea is to use an intermittent infusion device to obtain multiple blood specimen samples rather than performing repeated venipunctures. In addition, it is a good idea to consider the use of sedation for more painful procedures.

Throughout the child's care, be sure to discuss specific goals and interventions with the child and family as appropriate. Include the family in developing appropriate interventions so they can continue to support the child. Education of the child and family about interventions, including various therapies, is key. Ongoing assessment is needed to determine the effectiveness of the pain relief measures in achieving the desired goals.

### Atraumatic Care

**Play therapy may be helpful in allowing the child to express his or her feelings and adapt to the stressors of the current situation.**

Nursing Care Plan 36.1 can be used as a guide in planning nursing care for the child experiencing pain. The nursing care plan should be individualized based on the child's symptoms and needs. Specific information related to pain management and the nurse's role will be discussed later in the chapter.

**When you enter Aiden's room, he is crying and says his leg hurts. What will be your initial action? What will be your plan of care to manage Aiden's pain (refer to QUESTT assessment)? How would you address the statements made by the nurse in report? What approaches can you use to change staff behavior about pain management?**

## NURSING CARE PLAN 36.1

## Overview for the Child in Pain

**NURSING DIAGNOSIS:** Acute pain related to need for invasive procedures, surgery, recent trauma, or infection as evidenced by pain rating scale, facial grimacing, crying, irritability, withdrawal activity, or changes in vital signs

### Outcome Identification and Evaluation

Child will achieve adequate comfort level as evidenced by a decrease in rating number on a pain rating scale, quietness, calm resting behaviors, decrease in crying and irritability, and vital signs within acceptable parameters.

### Interventions: *Promoting Pain Relief*

- Assess pain level using a developmentally appropriate pain rating tool *to establish a baseline.*
- Assess for verbal and nonverbal indicators of pain *to help determine child's pain level*; question parents about child's typical behaviors and previous experiences with pain *to determine factors that may be influencing child's response to pain.*
- Institute nonpharmacologic methods for pain control based on the child's age and cognitive level *to help decrease pain*; encourage parental participation in use of methods *to provide additional support and pain relief for the child.*
- Administer pharmacologic agents as ordered using the least traumatic route possible *to alter pain impulse transmission and minimize distress while promoting effective pain relief.*
- Explain the action of the drug and what the child should expect from the medication at a level that the child can understand *to promote trust and reduce fear while providing effective pain relief.*
- Give analgesics around the clock if pain is continuous and can be predicted *to maintain steady blood levels of the drug, thereby maximizing the drug's effect.*
- Perform atraumatic care at all times *to minimize the child's exposure to physical and psychological distress and pain.*
- Anticipate timing of procedures or situations that may lead to pain and provide appropriate analgesic therapy as ordered *to ensure that therapy is most effective at the time of the procedure.*
- Ensure that the child's environment is quiet and conducive to rest, dim the lights, and close the door or curtain *to reduce sensory overload that would increase the child's pain sensation.*
- Encourage the parents to stroke, touch, caress, and hold the child *to reduce discomfort and promote feelings of security.*
- Reassess the child's pain level after use of nonpharmacologic and pharmacologic methods *to determine effectiveness*; anticipate the need to modify or adapt nonpharmacologic methods or adjust analgesic dosage, route, or frequency *to promote maximum pain relief.*
- Perform nursing care activities after administering analgesic *to prevent exacerbating the child's pain.*
- Use diversional activities, distraction, and play appropriate to the child's age and cognitive level *to promote additional pain relief.*

**NURSING DIAGNOSIS:** Anxiety related to stress and uncertainty of the situation, unknown cause of pain, lack of familiarity with procedures, testing, and health care facility, and painful procedures, as evidenced by crying, irritability, withdrawal, stoic or aggressive behaviors

### Outcome Identification and Evaluation

Child and family will demonstrate a decrease in anxiety level as evidenced by age-appropriate positive coping behaviors, verbalization of feelings, playing out of feelings, child and family cooperation with plan of care, and absence of signs and symptoms associated with escalating anxiety.

**Overview for the Child in Pain** (continued)**Interventions: *Minimizing Anxiety***

- Assess child's and parents' understanding of the situation, including their understanding of what may be causing the pain and the reasons for the procedures and testing, *to provide baseline information about the child's and parents' knowledge and possible clues to anxiety.*
- Spend time with the child and parents discussing what they think might be happening, encouraging the child and parents to talk openly about their feelings, *to facilitate continued expressions and communication.* Allow time for questions and answer questions honestly *to establish rapport and build trust.*
- Approach the child and family in a calm, relaxed manner *to foster trust and communication and decrease anxiety.*
- Allow the child options related to interventions as much as possible, such as fluid to drink or snack to eat, extremity to use for venipuncture (right or left), color of bandage, or holding tape or dressing, *to foster feelings of control.*
- Provide atraumatic care *to reduce exposure to distress, which would exacerbate the child's anxiety level.*
- Explain any procedures, tests, or activities at a level the child can understand *to reduce fear of the unknown.*
- Incorporate aspects of the child's routine at home as much as possible *to reduce feelings of separation and promote feelings of normalcy.*
- Ensure consistency in care *to facilitate trust and acceptance.*
- Encourage parents in the use of comfort measures such as stroking, cuddling, holding, and rocking *to promote feelings of security and minimize stress.*
- Provide positive reinforcement for choices, participation in activities, and use of appropriate coping methods *to foster self-esteem.*
- Encourage the child's participation in play (unstructured and therapeutic play as needed) *to promote expression of feelings and fears.*

**NURSING DIAGNOSIS:** Deficient knowledge related to current condition and appropriate methods for managing pain as evidenced by crying, irritability, pushing away, questions and verbalizations about pain and relief methods

**Outcome Identification and Evaluation**

Child and parents will demonstrate adequate knowledge about the child's current condition and use of pain relief methods as evidenced by statements about the cause of the child's pain, demonstration of chosen nonpharmacologic relief methods, use of pharmacologic agents, and statements related to signs and symptoms of increased and decreased pain.

**Intervention: *Providing Child and Family Teaching***

- Assess the child's and parents' knowledge and understanding of the child's current condition and current pain level *to establish a baseline for teaching.*
- Provide time for the child and parents to ask questions; answer questions honestly and in terms they can understand *to promote learning.*
- Explain in simplified terms how the child's condition is associated with pain or the rationale for procedures needed that may contribute *to pain to promote understanding and foster trust.*
- Teach in short sessions *to prevent overloading the child and parents with information.*
- Provide reinforcement and rewards *to help facilitate the teaching/learning process.*
- Use multiple modes of learning, such as written information, verbal instruction, demonstrations, and media when possible, *to facilitate learning and retention of information.*
- Instruct the parents and child as appropriate in nonpharmacologic methods for pain relief; encourage practice and participation by parents in methods chosen *to foster independence and use of method when necessary.*
- Teach the child as appropriate and parents about pharmacologic methods for pain relief; review specific information about the drug to be used, including action, duration, administration, possible adverse effects, and care necessary when the drug is used, *to promote learning;* have the child and parents report back information or demonstrate administration *to evaluate effectiveness of teaching.*
- Provide parents with written information about pain relief methods for use at home if indicated *to allow for reference at a later date.*

(continued)

## NURSING CARE PLAN 36.1

## Overview for the Child in Pain (continued)

**NURSING DIAGNOSIS:** Sleep deprivation related to inability to manage pain effectively as evidenced by frequent waking by child during night, signs and symptoms of pain including irritability and restlessness, statements about being tired, pain rating scale

**Outcome Identification and Evaluation**

Child will exhibit increased ability to sleep during the night as evidenced by increasing periods of calm and restfulness (initially starting at 2 hours and gradually increasing to 7 to 8 hours), decreased pain level on pain rating scale, and statements of decreased fatigue.

**Intervention: Promoting Sleep and Rest**

- Assist the child in using nonpharmacologic methods of pain relief, such as imagery, distraction, and muscle relaxation, *to promote relaxation.*
- Administer pharmacologic pain relief as ordered *to minimize pain interfering with sleep*; anticipate a change in drug therapy if pain relief is inadequate.
- Cluster nursing care activities *to minimize energy expenditure and disruptions in the child's ability to rest.*
- Help the child with a nighttime routine similar to one he or she uses at home *to promote feelings of security.*
- Offer the child a back rub, warm bath, or warm liquids; reading a story; or listening to music *to facilitate relaxation*; provide stroking, hugging, cuddling, rocking, and light touch *to promote a sense of security and calm.*
- Dim the lights and close the curtain or door to the room *to provide a quiet, restful environment.*
- Ensure round-the-clock pain relief for the child through the night *to minimize the risk of pain.*

**NURSING DIAGNOSIS:** Risk for injury related to possible adverse effects of analgesics

**Outcome Identification and Evaluation**

Child will remain free of any injury related to signs and symptoms of adverse effects of analgesic therapy as evidenced by respiratory rate appropriate for age and no complaints of gastrointestinal (GI) upset, dizziness, or sedation or episodes of constipation, nausea, vomiting, or pruritus.

**Intervention: Promoting Safety**

- Ensure that the child's call light is within reach *to allow for notification of health care personnel should problems arise.*
- Administer analgesic exactly as prescribed *to reduce the risk of error and development of adverse effects.*
- Assess the child's respiratory status closely for changes *to allow for early detection of respiratory depression.*
- If an opioid analgesic is being given, have naloxone readily available *to reverse the action of the narcotic if respiratory depression occurs.*
- Monitor appetite and assess bowel sounds for changes; note any abdominal distention or decreased bowel sounds, *which would suggest decreased peristalsis.*
- Ensure adequate fluid and fiber intake *to reduce risk of constipation.*
- Offer small frequent meals and give medication with food *to minimize risk of GI upset.*
- Assess for nausea and vomiting; if necessary, withhold food and fluids *to rest the GI tract* and administer antiemetics until nausea and vomiting resolve.
- Instruct the child to remain in bed after receiving analgesic, raise crib or side rails as appropriate, and instruct the child and parents to have someone accompany the child to the bathroom if allowed *to reduce the risk of falls from sedation.*
- Assess for complaints of itching and observe for rash or reddened areas; if pruritus occurs, urge the child not to scratch and expect to administer antihistamine as ordered *to reduce pruritus.*
- Provide the child with distraction to assist in helping *to reduce effects of pruritus.*

## MANAGEMENT OF PAIN

Management of pain begins with assessment of the child's comfort level. If pain or the potential for pain, such as during an invasive procedure, is identified, steps must be taken to minimize or treat the pain. Three general principles guide pain management in children:

1. Individualize interventions based on the amount of pain experienced and the child's characteristics, such as developmental level, temperament, previous pain experience, and coping strategies.
2. Use nonpharmacologic and pharmacologic approaches to ease or eliminate the pain.
3. Teach the child and family about pain relief interventions and techniques and discuss with the child and family expectations of pain management.

Specific strategies for pain management include nonpharmacologic interventions such as relaxation, distraction, and guided imagery and pharmacologic interventions such as analgesics, patient-controlled analgesia, local analgesia, epidural analgesia, and moderate sedation.

### Nonpharmacologic Management

Various techniques may be available to assist in managing mild pain in children or to augment the effectiveness of medications for moderate or severe pain. Many of these nonpharmacologic techniques assist children in coping with pain and give them an opportunity to feel a sense of mastery or control over the situation. Two types of techniques are behavioral-cognitive strategies and biophysical strategies. It is important to involve the parents in the process when using these techniques.

#### *Behavioral-Cognitive Strategies*

Behavioral-cognitive strategies for pain management involve measures that require the child to focus on a specific area rather than the pain. These strategies help to change the interpretation of the painful stimuli, reducing pain perception or making pain more tolerable. In addition, these strategies help to decrease negative attitudes, thoughts, and anxieties, thereby improving the child's coping mechanisms. Typically, these interventions work well with older children, but younger children also benefit from these techniques if they are adapted to the child's age and developmental level. Common behavioral-cognitive strategies include relaxation, distraction, imagery, biofeedback, thought stopping, and positive self-talk.

#### RELAXATION

Relaxation aids in reducing muscle tension and anxiety. A wide variety of techniques can be used. Relaxation can be as simple as holding an infant or young child closely

while stroking the child or speaking in a soft soothing manner, or having the child inhale and exhale slowly using rhythmically controlled deep breathing. It also can involve more sophisticated techniques such as progressive relaxation. With this technique the child is asked to focus on one area of the body and let that body part go limp. Then in an organized fashion, usually working from the toes to the head or vice versa, the child is asked to focus on another body part, making it go limp. Eventually the exercises work through all body areas, leading to relaxation of the entire body.

#### DISTRACTION

Distraction involves having the child focus on another stimulus, thereby attempting to shield him or her from pain. Research has shown distraction to be a statistically and clinically significant intervention in reducing pain. In addition, it is time and cost efficient to use (MacLaren & Cohen, 2007).

This technique does not eliminate the pain but does help to make it more tolerable. Various methods can be used for distraction, including:

- Counting
- Repeating specific phrases or words
- Listening to music or singing
- Playing games, including computer and video games
- Blowing bubbles or blowing pinwheels or party favors
- Listening to favorite stories (Fig. 36.9)
- Watching cartoons, television shows, or movies
- Visiting with friends
- Humor

Humor has been demonstrated to be an effective distracting technique for pain management. However, make sure that the technique is age appropriate and be sure to determine what or who will make the child laugh. If possible, allow the child and his or her family to choose the materials that they consider humorous.

The type of distraction used depends on the age of the child. For example, a younger child may enjoy blowing

FIGURE 36.9 A child using distraction for pain management.

**EVIDENCE-BASED PRACTICE 36.1****WHAT ARE THE EFFECTS OF COMPLEMENTARY AND ALTERNATIVE MEDICAL (CAM) INTERVENTIONS ON PROCEDURAL RELATED PAIN, ANXIETY, AND DISTRESS IN CHILDREN WITH CANCER?**

Children with cancer undergo multiple procedures, and many describe these procedures as one of the most distressing parts of their disease. Complementary and alternative therapies may be effective in decreasing procedural pain, distress, and anxiety resulting in a therapeutic benefit.

**STUDY**

These authors performed an integrative literature review and provided a narrative summary of research to assist in drawing overall conclusions of the effectiveness of CAM. Thirty two articles met study inclusion criteria and were used in the final sample.

**Findings**

The 3 most common CAM therapies studied were hypnosis, distraction and imagery. Many studies found hypnosis more effective than distraction, especially in higher pain

producing procedures. Self-hypnosis seemed to be helpful in reducing anxiety depending on the level of hypnotic susceptibility of the child. Imagery and distraction demonstrated potential in reducing fear, distress and pain in some children.

**Nursing Implications**

Nurses need to encourage use of mind body therapies such as hypnosis, distraction and imagery as they have been shown to positively enhance procedure outcomes in some studies. They may provide some symptom relief (decreased pain, anxiety and distress) and increased self-efficacy without adverse effects. The nurse needs to perform a thorough assessment to look at individual differences to determine the most appropriate and effective interventions for each individual child. The nurse needs to facilitate and encourage parent participation in the use of these strategies.

Adapted from Landier, W. & Tse, A.M. (2010). Use of Complementary and Alternative Medical Interventions for the Management of Procedure-Related Pain, Anxiety, and Distress in Pediatric Oncology: An Integrative Review. *Journal of Pediatric Nursing*, 2010(25), 566–79.

pinwheels and blowing bubbles. He or she also will enjoy listening to favorite stories or books. Older children may enjoy computer or video games, listening to favorite music, or visiting with friends. See Evidence-Based Practice 36.1.

**IMAGERY**

Imagery involves the use of the imagination to create a mental image. This mental image usually is a positive, pleasurable image, but it need not be real. The child is encouraged to include details and sensations that are associated with the image, such as specific descriptions of the image, colors, sounds, feelings, and smells. In some instances, the child may write down or record the image on a tape or compact disc. When pain occurs, the child is encouraged to create the mental image or read or listen to the description.

**BIOFEEDBACK**

Biofeedback involves having the child gain an awareness of his or her body functions and learn ways to modify them voluntarily. The child usually is taught specific skills about how to modify body functions using an apparatus that measures pain-related changes in muscle tone or physiologic data, such as blood pressure or pulse rate. This teaching usually is performed by a specialized health care provider and occurs over several sessions, in advance of the pain experience. With practice, the child learns to control the changes without the apparatus. This technique can be used by older children, such as adolescents, who can concentrate for longer periods of time.

**THOUGHT STOPPING**

Thought stopping involves substituting a pleasurable or positive thought for the painful experience. Examples of positive thoughts might be, “It’s only for a short time” or “It’s important so I get better.” The negative component of the pain is not ignored or suppressed; rather, it is transformed into something positive. Thought stopping also can involve the use of short, positive phrases. For example, the child may repeat “quick stick, feel better go home soon” when he or she anticipates pain or experiences pain.

Thought stopping is a useful method for reducing anxiety before and during events associated with pain. Children can be taught to use this technique any time they experience anxiety related to a painful experience. Doing so helps to promote the child’s sense of control over the situation.

**POSITIVE SELF-TALK**

Positive self-talk is similar to thought stopping in that it involves the use of positive statements. With positive self-talk the child is taught to say positive statements when he or she is experiencing pain. For example, the child may be taught to say, “I will feel better and be able to go home and play with my friends.”

**Take Note!**

Studies have shown hypnosis to be consistently effective in decreasing pain and anxiety in children during procedures involving acute pain (Evans, Tsao, & Zelter, 2008).

## Biophysical Interventions

Biophysical interventions focus on interfering with the transmission of pain impulses reaching the brain. The interventions involve some type of cutaneous stimulation near the site of the pain. This stimulation decreases the ability of the A-delta and C fibers to transmit pain impulses. Examples of biophysical interventions include application of heat and cold, massage and pressure, and transcutaneous electrical nerve stimulation (TENS).

### SUCKING AND SUCROSE

Sucking is a behavior from which infants derive satisfaction. Therefore, nonnutritive sucking (e.g., sucking a pacifier) can be used to reduce pain behaviors in neonates undergoing painful procedures. In addition, infants show reduced pain behaviors after ingestion of sucrose or other sweet-tasting solutions such as glucose during single-event procedures, such as heel lancing (Stevens, Yamada, & Ohlsson, 2010). Optimal dosing for sucrose needs further research and caution must be used in extremely low-birthweight infants and infants with unstable blood glucose levels.

### Atraumatic Care

*Breastfeeding is also a noninvasive, natural, and feasible way to use sucking to reduce pain in infants.*

### HEAT AND COLD APPLICATIONS

Heat and cold applications alter physiologic mechanisms associated with pain. Cold results in vasoconstriction and alters capillary permeability, leading to a decrease in edema at the site of the injury. Due to vasoconstriction, blood flow is reduced and the release of pain-producing substances such as histamine and serotonin also is decreased. Moreover, transmission of painful stimuli via peripheral nerve fibers is decreased.

Heat results in vasodilation and increases blood flow to the area. It also leads to a decrease in nociceptive stimulation and removal of chemical substances that can stimulate nociceptive fibers. The increase in blood flow alters capillary permeability, leading to a reduction in swelling and pressure on nociceptive nerve fibers. Heat may also trigger the release of endogenous opioids, which mediate the pain response.

### MASSAGE AND PRESSURE

Massage and pressure, like other biophysical interventions, are believed to inhibit stimulation of the A-delta and C fibers. These methods are helpful in relaxing muscles and reducing tension. In addition, these techniques can aid in distracting the child. Massage can be as simple as rubbing a body part or pressing on an area such as an injection site for about 10 seconds. It can

also be more involved, requiring the use of another person to perform the massage. Lotion or ointment can be used during the massage and may provide a comforting effect. Contralateral pressure or massage (i.e., of the opposite area) may be used, especially if the area of pain cannot be accessed or if the affected area is too painful to touch.

A more formal method of pressure application is acupressure. In acupressure the fingertip, the thumb, or a blunt instrument is used to apply gentle, firm pressure to specifically designated sites to control pain. The pressure may be applied in one motion followed by releasing, in a circular motion for several minutes and then releasing or with a vibrating motion using the fingertips. The motion of applying and then releasing pressure is thought to facilitate the release of endogenous endorphins and enkephalins. The techniques of pressure and massage are easy to learn and use and can be taught to children and parents.

## The Nurse's Role in Nonpharmacologic Pain Intervention

The nurse plays a major role in teaching the child and family about nonpharmacologic pain interventions. Help the child and family choose the most appropriate and most effective methods and ensure that the child and parents use the method before pain occurs as well as before the pain increases. Teaching Guidelines 36.1 lists some helpful instructions for the parents and child about nonpharmacologic pain management.

### Teaching Guidelines 36.1

#### TEACHING TO MANAGE PAIN WITHOUT DRUGS

- Review the methods available and choose the method(s) that your child and you find best for your situation.
- Learn to identify the ways in which your child shows pain or demonstrates he or she is anxious about the possibility of pain. For example, does he or she get restless, make a face, or get flushed in the face?
- Begin using the technique chosen before your child experiences pain or when your child first indicates he or she is anxious about, or beginning to experience, pain.
- Practice the technique with your child and encourage the child to use the technique when he or she feels anxious about pain or anticipates that a procedure or experience will be painful.
- Perform the technique with your child. For example, take the deep breath in and out or blow bubbles with him or her; listen to the music or play the computer game with your child.

- Avoid using terms such as “hurt” or “pain” that suggest or cause your child to expect pain.
- Use descriptive terms like “pushing,” “pulling,” “pinching,” or “heat.”
- Avoid overly descriptive or judgmental statements such as, “This will really hurt a lot” or “This will be terrible.”
- Stay with your child as much as possible; speak softly and gently stroke or cuddle your child.
- Offer praise, positive reinforcement, hugs, and support for using the technique even when it was not effective.

It is also important to assist the child and parents when using the technique in order to make sure that they are using the technique correctly. Offer suggestions for modifications or adaptations as necessary.

Parents are important components of the pain management program. Give them the option to stay with the child, or let them know that someone else will support the child if they opt not to stay. Offer simple, concrete ways to assist and help the child to manage pain. Many of the nonpharmacologic techniques can be done by parents, and children may respond better if their parents demonstrate the technique and encourage them to use it. Invite parents to participate in decisions as well as act as a coach to their child during procedures. Prepare the parents and explain the most appropriate pain management approaches and strategies. Discuss the type and amount of pain expected as well as the potential complications associated with pain management approaches. Ask how the parent predicts the child will react to a painful situation. Finally, offer techniques and strategies to the parents as they act as the coach during these situations.

### Take Note!

Although parents want to help their children and some are able to act as coaches, the response of the child to pain and stress and to their parents' distraction interventions is highly variable. Some children appear to be soothed by their parents' distraction actions; others appear to become distressed. Be alert to factors that may influence the child's response, including age, sex, diagnosis, ethnicity, previous experience, temperament, anxiety, and coping style. Also be aware of parental factors, including ethnicity, sex, previous experience, belief in the helpfulness of the intervention, parenting style, and parental anxiety (McCarthy & Kleiber, 2006).

## Pharmacologic Management

Pharmacologic interventions involve the administration of drugs for pain relief. Administration may occur using a wide variety of methods. The selection of the method is determined by the drug being administered; the child's status; the type, intensity, and location of the pain; and any factors that may be influencing the child's pain.

Research overwhelmingly supports the appropriate use of analgesics to reduce pain perception in children.

### Medications Used for Pain Management

Analgesics (medications for pain relief) typically fall into one of two categories—nonopioid analgesics and opioid analgesics. Anesthetics also may be used. Drugs such as sedatives and hypnotics may be used as adjuvant medications to help minimize anxiety or provide or assist with pain relief when typical analgesics are ineffective.

#### NONOPIOID ANALGESICS

Nonopioid analgesics include acetaminophen and nonsteroidal anti-inflammatory drugs (NSAIDs) such as ibuprofen, ketorolac, naproxen, indomethacin, diclofenac, and piroxicam (Drug Guide 36.1). These agents may be used to treat mild to moderate pain, often for conditions such as arthritis; joint, bone, and muscle pain; headache; dental pain; and menstrual pain. Acetaminophen, probably the most widely known nonopioid analgesic, and ibuprofen are also commonly used to treat fever in children.

### Take Note!

Aspirin should not be used in children for analgesic and antipyretic purposes because of the high risk of Reye syndrome.

According to the World Health Organization's (WHO's) pain ladder, acetaminophen and NSAIDs are first-line agents for the treatment of pain (WHO, 2010). Although this ladder was developed for the relief of cancer pain, it can be applied to any child experiencing pain of increasing intensity.

Nonopioid agents are typically administered orally or rectally. In some cases, such as with postoperative pain, they may be administered intravenously as a continuous infusion or as bolus doses. Administration via intramuscular injection is not recommended because the injection can cause significant pain and the onset of pain relief is not increased.

Adverse effects commonly associated with these agents include gastrointestinal irritation, blood clotting problems, and renal dysfunction. However, research has demonstrated that children experience only mild gastrointestinal upset and negligible effects on a healthy, well-functioning renal system. Blood clotting problems arise primarily when these agents are given perioperatively before primary hemostasis has occurred (Mau-nuksela & Olkkola, 2003). Nonopioids are relatively safe, have few incompatibilities with other medications, and do not depress the central nervous system. Unfortunately, they exhibit a ceiling effect for analgesia. That is, after a certain level, they do not provide increasing pain relief even when administered at increased doses.

## DRUG GUIDE 36.1 COMMON DRUGS FOR PAIN MANAGEMENT

Drug	Actions/Indications	Nursing Implications
Acetaminophen (Tylenol)	<p>Possible inhibition of cyclooxygenase in the central nervous system</p> <p>Direct action on hypothalamic heat-regulating center</p> <p>Mild to moderate pain, fever; arthritis, musculoskeletal pain, headache</p>	<ul style="list-style-type: none"> <li>• Administer orally or rectally. Do not exceed five doses of drug in 24 hours.</li> <li>• Caution parents to read labels of other over-the-counter (OTC) drugs carefully; some may contain acetaminophen and if given in conjunction may lead to overdose.</li> </ul>
Ibuprofen (Motrin, Advil)	<p>Inhibition of prostaglandin synthesis</p> <p>Mild to moderate pain, fever, treatment of inflammatory diseases</p>	<ul style="list-style-type: none"> <li>• Administer orally.</li> <li>• Give with food or after meals if GI upset occurs.</li> <li>• Assess for easy bruising, bleeding gums, or frank or occult blood in urine or stool.</li> <li>• Monitor for nausea, vomiting, GI upset, diarrhea or constipation, dizziness, or drowsiness.</li> <li>• Caution parents to read labels of OTC medications closely; some may contain ibuprofen or other NSAIDs and if given in conjunction may lead to overdose.</li> </ul>
Other NSAIDs: ketorolac (Toradol), diclofenac (Voltaren), indomethacin (Indocin), naproxen (Naprosyn, Aleve)	<p>Inhibition of prostaglandin synthesis</p> <p>Moderate to severe pain</p>	<ul style="list-style-type: none"> <li>• Administer oral form with food or after meals if GI upset occurs.</li> <li>• Monitor for headache, dizziness, nausea, vomiting, constipation, or diarrhea.</li> <li>• Assess for signs and symptoms of bleeding, such as bruising, epistaxis, gingival bleeding, or frank or occult blood in urine or stool.</li> <li>• Ketorolac: may also be given IV or IM. In children ages 2 to 16 years, recommended as single dose only</li> <li>• Naproxen: also available in combination products (caution parents to read OTC labels carefully)</li> <li>• Indomethacin: when administering IV, report oliguria or anuria.</li> <li>• Diclofenac: may also be given rectally</li> </ul>
Opioid agents: morphine, codeine, fentanyl (Sublimaze), hydromorphone (Dilaudid), oxycodone (OxyContin), Methadone	<p>Opioid agonist acting primarily at <math>\mu</math>-receptor sites (morphine, codeine, fentanyl, hydromorphone, oxycodone, methadone)</p> <p>Moderate to severe acute and chronic pain</p> <p>Morphine: intractable pain, preoperative sedation</p> <p>Codeine: also suppresses cough reflex</p> <p>Fentanyl: pain associated with short procedures such as bone marrow aspiration, fracture reductions, suturing</p>	<ul style="list-style-type: none"> <li>• Assess respiratory status frequently, noting any decrease in ventilatory rate or changes in breathing patterns; have naloxone readily available in case of respiratory depression (particularly morphine, fentanyl, hydromorphone).</li> <li>• Monitor for sedation, dizziness, lethargy, or confusion.</li> <li>• Educate parents and child that the drug may make the child sleepy, drowsy, or lightheaded.</li> <li>• Institute safety measures to prevent injury to the child.</li> <li>• Assess bowel sounds for decreased peristalsis; observe for abdominal distention.</li> <li>• Ensure adequate fiber intake and administer stool softeners as prescribed to minimize risk for constipation.</li> <li>• Monitor urine output for changes and report.</li> <li>• Morphine: may cause itching, particularly facial</li> </ul>

(continued)

**DRUG GUIDE 36.1 COMMON DRUGS FOR PAIN MANAGEMENT** (continued)

Drug	Actions/Indications	Nursing Implications
		<ul style="list-style-type: none"> <li>• Codeine: may cause nausea, vomiting, abdominal pain. IV administration results in apnea and severe hypotension. Most commonly administered orally in combination with acetaminophen</li> <li>• Fentanyl: observe for chest wall rigidity, which can occur with rapid IV infusion.</li> <li>• Oxycodone is the opioid component of Tylox and Percocet.</li> </ul>
Mixed opioid agonist–antagonist: pentazocine (Talwin), butorphanol (Stadol), nalbuphine (Nubain)	Pentazocine: antagonist at $\mu$ -receptor sites, agonist at $\kappa$ -receptor sites. Butorphanol: high affinity for $\kappa$ -receptor sites, minimal affinity for $\sigma$ -receptor sites. Nalbuphine: partial agonist at $\kappa$ -receptor sites, antagonist at $\mu$ -receptor sites  Moderate to severe pain  Relief of migraine headache (butorphanol)  Preoperative analgesia (nalbuphine)	<ul style="list-style-type: none"> <li>• Monitor the child for sedation. Educate child and parents that the drug may make the child sleepy, drowsy, or lightheaded.</li> <li>• Institute safety measures to prevent injury to the child.</li> <li>• Pentazocine, butorphanol: monitor for diaphoresis, dizziness. Assess for tachycardia and hypertension.</li> <li>• Butorphanol is given intranasally for migraine headaches.</li> </ul>

GI, gastrointestinal.

Adapted from Karch, A. (2010). *2010 Lippincott's nursing drug guide*. Philadelphia: Wolters Kluwer Health/Lippincott Williams & Wilkins; and Taketokmo, C. K., Hodding, J. H., & Kraus, D. M. (2010). *Lexi-comp's Drug Reference Handbook: Pediatric & Neonatal Dosage Handbook* (18th ed.). Hudson, OH: Lexi-comp, Inc.

As a result, they may be combined with opioids for more effective pain relief.

### OPIOID ANALGESICS

Opioid analgesics are typically used for moderate to severe pain. They are classified as either agonists (when they act as the neurotransmitter at the receptor site) or antagonists (when they block the action at the receptor site). Opioid agents that act as agonists include morphine, codeine, fentanyl, meperidine, hydromorphone, oxycodone, and hydrocodone. Opioids that act as mixed agonist–antagonists include pentazocine, butorphanol, and nalbuphine (see Drug Guide 36.1). Opioids can be administered orally, rectally, intramuscularly, or intravenously. In addition, some agents such as fentanyl can be administered transdermally or transmucosally. Morphine is considered the “gold standard” for all opioid agonists; it is the drug to which all other opioids are compared and is usually the drug of choice for severe pain (Oakes, 2011).

Opioid agonists, such as morphine, are associated with numerous adverse effects, resulting primarily from their depressant action on the central nervous system.

#### Take Note!

When administering parenteral or epidural opioids, always have naloxone (Narcan) readily available to reverse the opioid's effects should respiratory depression occur.

Opioids stimulate the chemoreceptor trigger zone (CTZ), leading to nausea and vomiting. Moreover, **drug tolerance** (increased dosage required for the same pain relief previously achieved with a lower dose) and **physical dependence** (need for continued administration of the drug to prevent withdrawal symptoms) are commonly noted when opioids are given repeatedly. Drug Guide 36.1 gives additional information related to the opioid analgesics.

#### Take Note!

Drug tolerance occurs when increasing doses are required to manage the pain. Physical dependence can occur after as few as 5 days of continuous use of the drug; symptoms of withdrawal begin if it is suddenly stopped (Oakes, 2011).

Mixed agonist–antagonists are associated with less respiratory depression than agonists. Unfortunately, like NSAIDs, this group also has a ceiling effect, leading to inadequate pain relief even with increased dosages. When this occurs, increasing the dosage of the mixed agonist–antagonist or combining it with an agonist provides no additional pain relief.

#### Take Note!

Meperidine (Demerol), an opioid agonist, is not recommended as a first-choice agent for pain relief in children. Meperidine's metabolite, normeperidine, is associated

with the development of restlessness, irritability, twitching, agitation, tremors, and, most importantly, seizures (American Medical Association, 2010). Normeperidine is a central nervous stimulant and its adverse effects cannot be reversed by an opioid antagonist such as naloxone (Kim, 2009).

### ADJUVANT DRUGS

Adjuvant drugs are drugs that are used to promote more effective pain relief, either alone or in combination with nonopioids or opioids. Their primary indication is for diagnoses other than pain. These agents are not classified as analgesics but may provide a coanalgesic effect or may treat side effects. Benzodiazepines, such as diazepam and midazolam, help to relieve anxiety. Midazolam also produces amnesia. Anticonvulsants, such as carbamazepine, and tricyclic antidepressants, such as amitriptyline and nortriptyline, are used to treat neuropathic pain.

### LOCAL ANESTHETICS

Local anesthetics are commonly used to provide analgesia for procedures. They are effective in providing successful pain relief with only minimal risk of systemic adverse effects. However, local anesthetics such as lidocaine historically were not used in children because these drugs need to be injected. The belief was that children feared needles and use of a local anesthetic subjected the child to two needlesticks instead of one. Advances in technology have led to the development of improved methods of delivery such as topical ointments and iontophoresis for administration of local anesthetics, thereby promoting atraumatic care. (For a more detailed discussion, see the next section on drug administration methods and later in the chapter on the nurse's role in managing procedure-related pain.)

## Drug Administration Methods

With any medication administered for pain management, the timing of administration is vital. Timing depends on the type of pain. For continuous pain, the current recommendation is to administer analgesia around the clock at scheduled intervals to achieve the necessary effect (Oakes, 2011). Scheduled dosing has been associated with decreased pain intensity ratings for children (Paice, Noskin, Vanagunas, & Shott, 2005; Sutters et al., 2010). As-needed or PRN dosing is not recommended for continuous pain. This method can lead to inadequate pain relief because of the delay before the drug reaches its peak effectiveness, and as a result the child continues to experience pain, possibly necessitating a higher dose of analgesic to achieve relief. This then places the child at risk for overmedication and toxic effects.

For pain that can be predicted or considered temporary, such as with a procedure, analgesia is administered so that the peak action of the drug matches the time of the painful event.

There are various methods for administering pain medications to children. The preferred methods are the oral, rectal, intravenous, topical, or local nerve block

routes. Epidural administration and moderate sedation also can be used.

### ORAL METHOD

The oral method is often preferred because it is simple, easy, and convenient. The medication may be in the form of a pill, capsule, tablet, syrup, or elixir. Oral administration provides relatively steady blood levels of the drug when administered as a scheduled dose. Effectiveness typically occurs 1 to 2 hours after administration. As soon as possible, switch the child to oral dosing from parenteral dosing. However, keep in mind that higher doses of the oral medication may be needed to achieve the same effect.

### RECTAL METHOD

The rectal method may be used when the child cannot take the medication orally, such as when he or she has difficulty swallowing or is experiencing nausea and vomiting. It is a viable alternative for drug administration. Some analgesics are available in suppository form. For others that are not, the drug can be compounded into a suppository form. The absorption rate varies with rectal administration, and children may find insertion of a suppository uncomfortable and embarrassing (Bowden & Greenberg, 2008).

### INTRAVENOUS METHOD

Intravenous analgesia administration is the method of choice in emergency situations and when pain is severe and quick relief is needed. With intravenous administration, the drug usually takes effect within 5 minutes. Intravenous administration can be accomplished with bolus injections or continuous infusions. Continuous infusions may be preferred over bolus doses because steady blood levels are more easily maintained, thereby enhancing the drug's effect in relieving pain. Typically, opioids such as morphine, hydromorphone, and fentanyl are used due to their short half-life and decreased risk for toxicity.

### PATIENT-CONTROLLED ANALGESIA

In **patient-controlled analgesia (PCA)**, a computerized pump is programmed to deliver an infusion of analgesics via a catheter inserted intravenously, epidurally, or subcutaneously. The analgesic may be given as a continuous infusion, as a continuous infusion supplemented by patient-delivered bolus doses, or as patient-delivered bolus doses only. Typically the child presses a button to administer a bolus dose. The pump has a lockout function that is preset with the dose and time interval. If the child presses the button before the preset time, he or she will not receive an overdose of medication. By delivering small, frequent doses of opioids, the child can experience pain relief without the effects of oversedation. The child also experiences a sense of control over the pain experience.

Both the Institute for Safe Medical Practices (ISMP) and the Joint Commission have identified infants and young children as not being good candidates for PCA

usage (D'Arcy, 2007). However, PCA has been used successfully in children 8 to 9 and some success in children as young as 4 to 6 years old (Franson, 2010; D'Arcy, 2007). It is essential to assess each child individually and consider his or her developmental level and psychosocial factors in determining appropriate PCA use. The child must have the necessary intellect, manual dexterity, and strength to operate the device.

PCA has been used to control postoperative pain and the pain associated with trauma, cancer, and sickle cell crisis. It can be used in acute care settings or in the home. Most commonly, morphine, hydromorphone, and fentanyl are the drugs used with PCA. The dosage is based on the child's response. Dosages for infusions depend on the child's age, the opioid used, and the type of pain. A commonly used range for morphine infusion to treat postoperative pain ranges from 0.01 to 0.04 mg/kg/hour. Higher dosage ranges have been used to treat the pain associated with sickle cell crisis and cancer.

Serious adverse events, such as oversedation, respiratory depression, and even death, can occur when family members, caregivers, or clinicians who are not authorized administer PCA doses "by proxy" (D'Arcy, 2007; The Joint Commission, 2004). The ISMP recommends developing specific criteria in any situation where authorized agent-activated PCA is being used (D'Arcy, 2007). Proper education and instruction are crucial in any situation where someone other than the child may be administering PCA doses. Thorough assessment is necessary to ensure the child's pain is neither undertreated nor overtreated. To ensure safety with PCA use, each institution must have policies and procedures in place, appropriate education of health care staff, quality control measures, and quality machines.

### LOCAL ANESTHETIC APPLICATION

A local anesthetic may sometimes be used to alleviate the pain associated with procedures such as venipuncture, injections, wound repair, lumbar puncture, or accessing of implanted ports. Local anesthesia is a type of regional analgesia that blocks or numbs specific nerves in a region of the body. Medications called local anesthetics include topical forms, such as creams, agents delivered by iontophoresis, vapocoolants, and skin refrigerants, and injectable forms.

**Topical Forms.** A common choice for effective, painless local anesthesia is EMLA (eutectic mixture of local anesthetics [lidocaine and prilocaine]). It achieves anesthesia to a depth of 2 to 4 mm, so it reduces pain of phlebotomy, venous cannulation, and intramuscular injections for up to 24 hours after the injection. However, it requires a 60- to 90-minute application time to intact skin using an occlusive dressing for superficial procedures and up to 2 to 3 hours for deeper, more invasive procedures (Box 36.1). EMLA is approved for use in infants 37 weeks' gestation or older. Maximum dosage and maximum area

#### BOX 36.1

### APPLYING EMLA

Follow these guidelines when applying EMLA:

- Explain the purpose of the medication to the child and parents, reinforcing that it will help the pain go away.
- Check the scheduled time for the procedure; plan to apply the cream 60 minutes before a superficial procedure such as a heel stick or venipuncture or 2 to 3 hours before a deeper procedure such as a lumbar puncture or bone marrow aspiration.
- Place a thick layer of the cream on the skin at the intended site of the procedure, making sure that the area where the cream is being applied is free of any breaks. Do not rub the cream in once it is applied to the skin.
- Cover the site with a transparent dressing such as Tegaderm or Op-site and secure it so that the dressing is occlusive. Alternatively, use plastic film wrap and tape the edges to secure the dressing.
- Instruct the child not to touch the dressing once it is secured. If necessary, cover the occlusive dressing with a protection device or a loosely applied gauze or elastic bandage.
- After the allotted time, remove the occlusive dressing and wipe the cream from the skin. Inspect the skin for a change in color (blanching or redness), which indicates that the medication has penetrated the skin adequately.
- Verify that sensation is absent by lightly tapping or scratching the area. Use this technique also to demonstrate to the child that the anesthetic is effective. If sensation is present, reapply the cream.
- Prepare the child for the procedure. Assess the child's pain after the procedure to evaluate for pain and to differentiate pain from fear and anxiety.

of application are based on the child's weight. Parents can be taught how to apply the EMLA at home in preparation for a procedure (Fig. 36.10). Sometimes EMLA is not used due to the expense and the time needed to allow the drug to act. New approaches to EMLA delivery have been developed. Examples include other drug formulations and a patch delivery with a heat-activated system (Synera) that enhances the delivery of lidocaine and prilocaine. Synera is labeled for children older than 3 years of age and needs to be applied only 20 to 30 minutes before the procedure.

#### Take Note!

EMLA is used with caution in children younger than 3 months and other susceptible persons because it may be associated with methemoglobinemia (Oakes, 2011; Zempsky, 2008). It is contraindicated in children who have congenital or idiopathic methemoglobinemia (OpenAnesthesia.org, 2011). It must be used cautiously in those younger than

**FIGURE 36.10** A parent applies EMLA cream to the child at home in preparation for a procedure.

age 12 months who are receiving methemoglobin-inducing agents, such as sulfonamides, phenytoin, phenobarbital, and acetaminophen. Use of these agents in combination with EMLA increases the child's risk for methemoglobinemia, a condition that could lead to cyanosis and hypoxemia (OpenAnesthesia.org, 2011).

TAC (tetracaine, epinephrine, cocaine) and LET (lidocaine, epinephrine, tetracaine) are other examples of topical anesthetics. These are commonly used for lacerations that require suturing. The agent is applied directly to the wound with a cotton ball or swab for 20 to 30 minutes until the area is numb. These methods are not used in children with known sensitivity to any of these medications.

Lidocaine can also be dispersed in liposomes to allow for transcutaneous delivery (liposomal lidocaine). Over-the-counter LMX4 (lidocaine 4%), formerly called ELA-Max, is massaged into the skin without the use of an occlusive dressing. Anesthesia to the area is reached in 15 to 30 minutes and lasts about 60 minutes. Recent studies suggest that the analgesic effect may be equal to that of EMLA with the advantage of a shorter onset (American Medical Association, 2010). Research has shown that liposomal lidocaine 4% cream was highly effective in reducing the pain associated with intravenous cannulation (Zempsky, 2008). The researchers cited a short onset of action (30 minutes) and minimal vascular effects as benefits. They found that the liposomal encapsulation protects the anesthetic from being metabolized too quickly (Zempsky, 2008).

Needle-free powder lidocaine (Zingo) is another topical analgesic. It is labeled for use in children 3 to 18 years of age. It is a single-use, prefilled disposable

system that provides analgesia in 1 to 3 minutes. Studies have shown it to be safe and well tolerated with a rapid onset and significant reduction in needlestick pain (Zempsky et al., 2008).

Another choice for local anesthesia is iontophoresis. Iontophoretic lidocaine (Numby Stuff) provides a deeper analgesia in a shorter duration (approximately 10 to 25 minutes) and is used over intact skin. A mild electrical current from a small battery-powered generator and two iontophoretic drug-delivery electrodes push drug molecules (lidocaine HCl 2% with epinephrine 1:100,000) into the skin. A mild tingling sensation may be felt during drug delivery, with an increase in tingling noted with higher currents. This type of local anesthesia is not recommended for use in children who have a history of allergy or sensitivity to these drugs, in children who have electrically sensitive equipment such as a pacemaker, or in children who have damaged skin or scar tissue.

Vapocoolant spray, another type of local analgesia, can be sprayed onto the skin or administered using a cotton ball soaked in liquid. The depth of anesthesia is not known, but it appears to provide immediate pain control. It is inexpensive and requires no waiting time. The effect lasts for approximately 1 to 2 minutes. Studies have found it to be an effective analgesic for short-duration procedures (American Medical Association, 2010).

**Injectable Forms.** Injectable forms of lidocaine or procaine can be administered subcutaneously or intradermally around the procedural area approximately 5 to 10 minutes before the procedure. Common problems with this form of anesthetic include the pain associated with the subcutaneous injection and some burning associated with lidocaine administration, as well as blanching of the skin.

#### Take Note!

The burning that lidocaine causes on injection may be diminished by buffering lidocaine with sodium bicarbonate, using 10 parts lidocaine and 1 part sodium bicarbonate (1 mL of 1% to 2% lidocaine and 0.1 mL of 8.4% sodium bicarbonate). Then inject 0.1 mL or less of the solution intradermally at the site of venipuncture. Anesthetic action is almost immediate. The solution is stable for only approximately 1 week if not refrigerated.

### EPIDURAL ANALGESIA

For **epidural analgesia**, a catheter is inserted in the epidural space at L1–L2, L3–L4, or L4–L5. The drug, usually fentanyl or morphine, diffuses into the cerebrospinal fluid and crosses the dura mater to the spinal cord. Then it binds with the opioid receptors located at the dorsal horn. The drugs can be administered as bolus injections (a one-time bolus or on an intermittent schedule),

a continuous infusion, or PCA. Usually an opioid, such as morphine, fentanyl, or hydromorphone, is given in conjunction with a long-acting local anesthetic such as bupivacaine.

Epidural analgesia is typically used postoperatively, providing analgesia to the lower body for approximately 12 to 14 hours. The small amount of medication used with this type of analgesia causes less sedation, thereby allowing the child to participate more actively in postoperative care activities. This type of analgesia also is effective for children undergoing upper or lower abdominal surgeries because it controls localized intense pain, somatic pain, and visceral pain.

When epidural analgesia is being administered, additional narcotic analgesics are not given in order to prevent complications such as respiratory depression, pruritus, nausea, vomiting, and urinary retention.

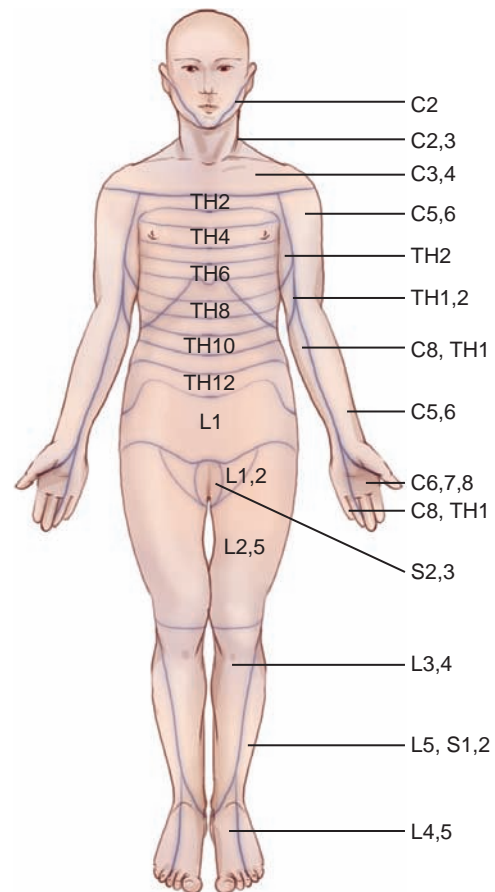

### Take Note!

Respiratory depression, although rare when epidural analgesia is used, is always a possibility. When it does occur, it usually occurs gradually over a period of several hours after the medication is initiated. This allows adequate time for early detection and prompt intervention.

Constant assessment is essential because insertion of an epidural catheter and epidural analgesia can lead to infection at the site of the insertion, epidural hematoma, arachnoiditis, neuritis, or spinal headache (rare) due to a cerebrospinal fluid leak and respiratory depression. Frequent assessment, typically every 1 to 2 hours, of heart rate, respiratory rate, and depth of sedation, and every 2 to 4 hours of blood pressure, pain level, and motor function, is imperative (Oakes, 2011). Assessing for adverse reactions such as nausea and vomiting and pruritus, checking the tubing and catheter site, and ensuring the occlusive dressing is intact are all important nursing interventions. The dermatome, which is the area of the body associated with supply by a particular nerve, that innervates the diaphragm can become suppressed during continuous epidural analgesia, resulting in respiratory depression. It is important to assess the child's sensory level frequently. Using cool water or an alcohol pad, bilaterally touch the child's body every 2 to 3 cm. The level where the child states he or she feels the temperature change is the level of anesthesia. (Refer to Figure 36.11 for dermatome levels.)

## MODERATE (CONSCIOUS) SEDATION

**Moderate sedation** used to be labeled conscious sedation, but the term "conscious" has been replaced since it can be misleading (Krauss & Green, 2006). It is a medically controlled state of depressed consciousness that allows protective reflexes to be maintained so

**FIGURE 36.11** The level of anesthesia should not go higher than T4, the nipple line, in children.

the child has the ability to maintain a patent airway and respond to physical or verbal stimulation. This procedure requires adherence to specific protocols, and many regulatory bodies, such as the Joint Commission, and societies, including the American Academy of Pediatrics, American Society of Anesthesiologists, and American College of Emergency Physicians, have published standards and guidelines to improve patient safety and outcomes (Krauss & Green, 2006). The depressed state is obtained by using various agents such as morphine, fentanyl, midazolam, chloral hydrate, or diazepam and other adjuvants such as pentobarbital. Midazolam and fentanyl often are the drugs of choice for moderate sedation because they act quickly, last only a short time, and are available in oral and intravenous formulations (Box 36.2). Midazolam provides only sedative effects and no analgesia; therefore, it is commonly administered with an opioid.

### Take Note!

The combination of meperidine (Demerol), promethazine (Phenergan), and chlorpromazine (Thorazine), commonly called DPT, is no longer recommended because it

## BOX 36.2

**ORAL FORMS OF MIDAZOLAM AND FENTANYL**

Two commonly used agents for moderate sedation are midazolam and fentanyl. Each of these is available in an oral form, which promotes atraumatic care.

**Oral Midazolam Syrup**

- Clear purplish-red cherry-flavored syrup
- Syrup containing 2 mg/mL
- Recommended dosage: 0.25 to 0.5 mg/kg to a maximum dose of 20 mg
- Action usually within 10 to 20 minutes
- Major adverse effects: respiratory depression and arrest

**Transmucosal Fentanyl**

- Candy-type lozenge on a plastic holder
- Available in 200, 300, and 400 mcg
- Recommended dose: 5 to 15 mcg/kg
- Onset of action in about 15 minutes of sucking lozenge; duration of action approximately 1 hour

has been shown to cause excessive depression of the central nervous system, extrapyramidal reactions, and prolonged recovery times (Buck, 2010; American Academy of Pediatrics, 1995). In addition, the combination must be administered intramuscularly, which causes the child to experience more pain.

Moderate sedation is used for procedures that are painful and stressful. For example, moderate sedation is suggested instead of restraints, especially for toddlers and preschool children who are undergoing frightening or invasive procedures and who are manifesting extreme anxiety and behavioral upset. Other indications include situations involving:

- Evidence that the child is experiencing a heightened stress reaction (e.g., attempting to flee, crying inconsolably, or flailing)
- Verbalization by the child that he or she is frightened and does not want to be touched
- Inability to remain immobilized, such as during laceration repair or computed tomography
- Any procedure that is painful and fear provoking

The route of administering the medications for sedation should follow the guidelines of atraumatic care. Oral, topical, or an existing intravenous route should be used. Personnel administering moderate sedation must be specially trained, and emergency equipment and medications must be readily available.

**The Nurse's Role in Pharmacologic Pain Management**

The nurse plays a major role in providing pharmacologic pain relief. As with any medication, the nurse is responsible for adhering to the rights of medication administration—right drug, right dose, right route, right time, and right patient. In addition, the nurse also adheres to three additional rights—the right of the child and parents to be educated, the right of the child to refuse the medication, and the right documentation. The nurse also must have a solid knowledge base about the medications used for pain relief. This knowledge includes information about the drug's pharmacokinetics (absorption, distribution, metabolism, and excretion) and pharmacodynamics (mechanism of action, including adverse effects). Refer to Chapter 35 for further information.

Assessment is crucial when pharmacologic pain interventions are used. An initial assessment of pain provides a baseline from which options for relief can be chosen. Factors that can affect the choice of analgesic, such as the child's age, pain intensity, physiologic status, or previous experiences with pain, also need to be considered. The nurse acts as an advocate for the child and the family to ensure that the most appropriate pharmacologic agent is chosen for the situation.

Assessment is ongoing once the agent is administered. Monitor physiologic parameters such as level of consciousness, vital signs, oxygen saturation levels, and urinary output for changes that might indicate an adverse reaction to the agent. More intensive monitoring is needed when agents are administered intravenously or epidurally or by moderate sedation. For example, if the child is receiving moderate sedation, interventions include:

- Ensuring that emergency equipment is readily available
- Maintaining a patent airway
- Monitoring the child's level of consciousness and responsiveness
- Assessing the child's vital signs (especially pulse rate, heart rate, blood pressure, and respiratory rate)
- Monitoring oxygen saturation levels

Typically, a specially trained health care provider is specifically designated to perform these activities during the administration of the sedation. Afterwards, the nurse is responsible for ongoing monitoring of the child's status.

Monitor the child closely for evidence of adverse effects. Table 36.7 describes the interventions useful for responding to these adverse effects. Be alert for signs and symptoms of respiratory depression secondary to opioid administration. Have an opioid antagonist such as naloxone (Narcan) and the benzodiazepine antagonist

TABLE 36.7

## INTERVENTIONS FOR COMMON OPIOID-INDUCED ADVERSE EFFECTS

Adverse Effect	Nursing Interventions
Constipation	Encourage fluid intake unless contraindicated. Ensure intake of high-fiber foods, including fruits, if allowed. Encourage activity, including ambulation if possible. Obtain order for stool softener. Administer laxative as ordered.
Pruritus	Apply cool compresses and lotions. Administer antihistamine as ordered.
Nausea and vomiting	Inform child and parents that these symptoms usually subside in 1 to 2 days. Encourage small frequent meals with bland foods. Administer antiemetic if ordered.

flumazenil (Romazicon) readily available should the child experience respiratory depression.

In addition to assessing physiologic parameters, assess the child's and parents' emotional status before and after the agent is administered. For example, increased anxiety and fear may necessitate a change in method of administration, such as topical application instead of an intradermal injection of a local anesthetic. Use nonpharmacologic methods to help lessen anxiety, thereby promoting more effective relief from the drug.

Nurses also are responsible for ensuring that the child and parents are adequately prepared for the use of the pharmacologic agent. Teach the child and parents about the drug, why it is being used, its intended effects, and possible adverse effects, tailoring the teaching to the child's cognitive level. Provide opportunities for the child and parents to ask questions, offering support and guidance throughout the experience. Provide a demonstration or use visual aids so that the child and parents know exactly what to expect. Encourage the use of play to help the child express fears and anxieties related to the administration.

## Management of Procedure-Related Pain

One of the most common causes of pain in children is procedure-related pain. The procedure may be minor, such as an intramuscular injection, heel stick, or venipuncture, or it may be more involved, such as lumbar puncture, bone marrow aspiration, or wound care.

Regardless, pain is real for children and painful procedures are often extremely distressing to them. Variables that affect pain include the intensity or length of the procedure and the skill of the health care provider performing the procedure.

### The Nurse's Role in Managing Procedure-Related Pain

Through the use of behavioral and pharmacologic approaches, nurses can significantly reduce the pain and distress of procedures. Use the guiding principles of atraumatic care, which include the following:

- Use topical EMLA, iontophoretic lidocaine, vapocoolant spray, or buffered lidocaine at the intended site of a skin or vessel puncture.
- Incorporate the use of nonpharmacologic strategies for pain relief in conjunction with pharmacologic methods.
- Prepare the child and parents ahead of time about the procedure and then keep all equipment out of site until it is ready to be used.
- Use therapeutic hugging (see Chapter 30) to secure the child.
- Use the smallest-gauge needle possible or an automated lancet device to puncture the skin.
- Use an intermittent infusion device or peripherally inserted central catheter (PICC) if multiple or repeated blood samples are necessary. Coordinate care so that several tests can be performed from one sample if possible.
- Opt for venipuncture in newborns instead of heel sticks if the amount of blood needed would require much squeezing.
- Use kangaroo care (skin-to-skin contact) for newborns before and after heel stick.
- Provide nonnutritive sucking, with sucrose solution, if appropriate; pacifier; or breastfeeding for newborns several minutes before the procedure.

#### Take Note!

Individualize interventions based on the painfulness of the procedure and the child's developmental age and personality. Use behavioral-cognitive approaches and pharmacologic interventions. For example, encouraging the school-age child to assist during painful procedures in age-appropriate ways may actually help ease some of the pain related to a heightened state of anxiety, or at least assist the child in coping with the situation. Always use appropriate pharmacologic treatment especially for the first procedure to provide as painless an experience as possible for the child.

Nursing care for the child with procedure-related pain includes the child as well as the parents. Be sure to prepare them for the procedure using an appropriate

developmental approach. Promote environmental comfort, too. Ensure that the child's privacy is maintained and that the lighting is adequate for the procedure but not so bright as to cause the child discomfort.

Painful procedures performed in the child's room can lead to an association of pain or fear with the room or bed. Many hospitals have a special treatment room where procedures can be performed. These rooms are usually equipped with many activities, toys, and decorations to help distract the child. The use of a treatment room may not be feasible or desirable in all situations or for all procedures. The ultimate goal is to do what is best for the child; therefore, the nurse needs to consider the needs of the child, the demands of the procedures, and the conditions that would facilitate the best outcome.

Unless contraindicated, encourage the parents to be present before, during, and after the procedure to provide comforting support to the child. Also encourage the child and parents to use nonpharmacologic methods to help maximize pain relief and reduce anxiety. For example, nonpharmacologic methods that are helpful for the toddler and preschooler may include positioning the child on the lap and hugging the child, distracting the child with toys or interactive books, and blowing bubbles.

Play therapy can be useful when preparing children for painful procedures. Encourage children to make decisions about their care related to pain management if their condition or procedure allows. It is also helpful to anticipate and recognize painful situations and provide pain medication before the actual procedure to ensure comfort. Many nonpharmacologic strategies can be enhanced and better implemented with the help of the child life specialist or play therapist, who have specialized training in these techniques.

*Recall Aiden from the beginning of the chapter. What are some interventions that may be helpful prior to, during, and after his dressing change?*

## Management of Chronic Pain

Typically, pain in children is acute pain, but chronic pain is a significant problem in the pediatric population. Chronic pain is pain that is persistent and recurrent beyond the expected healing time (American Pain Society, 2012). Currently, chronic pain is identified as the complex interplay of biological, psychological, and environmental factors (American Pain Society, 2012). According to the American Pain Society (2012), children with

chronic pain and their families experience significant emotional and social consequences from the pain and disability; also, the experience of chronic pain in childhood may predispose the individual to chronic pain in adulthood.

### *The Nurse's Role in Managing Chronic Pain*

The nurse's role in managing chronic pain in children is similar to that for the child experiencing acute pain or procedure-related pain. Assessment of the child's pain is key and should include a history of the present problem. Questions should focus on the onset of the pain; its intensity, duration, and location; and any factors that alleviate or exacerbate it. In addition, it is important to question the child and parents about the impact of the pain on the child's daily life, such as sleep, play, eating, school, and interactions with peers, other family members, and friends. Also address the impact of the child's chronic pain on the family's life.

Another key area of assessment is determining how the pain affects the child's and family's level of stress. Areas to address include the child's and parents' feelings of hopelessness, anxiety, and depression. Also question the child and parents about what they think has caused the pain and how they have coped with it. In addition, ascertain what methods the child and parents have used to alleviate the pain and the success of these methods. Inquire about any home remedies or alternative therapies that may have been used.

Review past physical examination findings for clues to the underlying problem. Observe the child's overall appearance, gait, and posture. Assess the child's cognitive level and emotional response, especially related to the experience of pain. Expect to complete a neurologic examination and observe for muscle spasms, trigger points, and increased sensitivity to light touch. Abnormal body postures assumed by the child due to chronic pain may result in the development of secondary pain in the muscles and fascia. When children tense their muscles due to fear of examination, somatic pain may occur.

Various nonpharmacologic and pharmacologic strategies are used to manage chronic pain. Often multiple strategies are combined to address pain relief as well as the pain's impact on other areas, such as sleep or school functioning. When pharmacologic agents are used, the oral form is the method of choice. As with any pain management strategy, education of the child and family is paramount. A referral to a pediatric pain specialist may be needed if the child's pain is not controlled effectively.

## KEY CONCEPTS

- Pain is a highly individualized subjective experience affecting persons of any age. It is a universal experience and is considered the fifth vital sign.
- Pain management is a critical element in a child's plan of care because children may lack the verbal capacity to describe their pain experience; caregivers and health care providers often have misconceptions about pain; assessment of the complex nature of the pain experience is difficult; if left unmanaged, pain in children can lead to serious physical and emotional consequences; and available resources and research related to pain relief strategies in children are limited.
- The sensation of pain involves a sequence of physiologic events: transduction, transmission, perception, and modulation.
- Pain can be classified by duration as acute or chronic, by etiology as nociceptive or neuropathic, or by source or location as somatic or visceral.
- Factors influencing a child's perception of pain include age and gender, cognitive level, temperament, previous pain experiences, and family and cultural background, all of which cannot be changed. Situational factors involve behavioral, cognitive, and emotional aspects and can be changed.
- Infants, including preterm infants, experience pain. Behavioral and physiologic indicators are used to assess pain. Toddlers commonly react with intense emotional upset and physical resistance or aggression. Preschoolers may feel that pain is a punishment for misbehaving or having bad thoughts. School-age children can communicate the type, location, and severity of pain but may deny having pain to appear brave or avoid further pain. Adolescents, with their focus on body image and fear of loss of control, often ask numerous questions and may attempt to remain stoic to avoid being viewed as childish.
- Assessment of pain in children includes both subjective and objective data. Nurses need to tailor the assessment to the child's developmental level and ask appropriate questions geared to the child's cognitive level. Parental questioning during the health history also is important.
- Self-report pain rating scales are valuable assessment tools that allow the child's level of pain to be quantified. Examples include the FACES pain rating scale, the Oucher pain rating scale, the poker chip tool, the word-graphic rating scale, visual analog and numeric scales, and the Adolescent Pediatric Pain Tool.
- Different pain rating scales are appropriate for different developmental levels. However, children may regress when in pain, so a simpler tool may be needed to make sure that the child understands what is being asked. Consistency in using the same tool is essential so that appropriate comparisons can be made and effective interventions can be planned and implemented.
- Physical examination of the child for pain primarily involves the skills of observation and inspection. These skills are used to assess for physiologic and behavioral changes that indicate pain. Auscultation also may be used to assess for changes in vital signs, specifically heart rate and blood pressure. Physiologic and behavioral pain assessment tools, such as the Neonatal Infant Pain Scale, Riley Infant Pain Scale, Pain Observation Scale for Young Children, CRIES Scale for Neonatal Postoperative Pain Assessment, and FLACC Behavioral Scale for Postoperative Pain in Young Children, measure specific parameters and changes that would indicate that the child is in pain.
- Nonpharmacologic pain management strategies aim to assist children in coping with pain and to give them a sense of mastery or control over the situation. These strategies may be categorized as behavioral-cognitive, in which the child focuses on a specific area or aspect rather than the pain (e.g., relaxation, distraction, imagery, biofeedback, thought stopping, and positive self-talk), or biophysical, in which the focus is on interfering with the transmission of pain impulses reaching the brain (e.g., heat and cold applications, massage and pressure).
- The nurse plays a major role in teaching the child and family about available nonpharmacologic pain interventions, helping them choose the most appropriate and most effective methods, and ensuring that the child and parents use the method before the pain occurs as well as before it increases.
- Pharmacologic interventions involve the administration of drugs for pain relief, most commonly nonopioids and opioid analgesics. The selection of the method is determined by the drug being administered; the child's status; the type, intensity, and location of the pain; and any factors that may be influencing the child's pain. The preferred methods for administering analgesics include the oral, rectal, intravenous, or local nerve block routes; epidural administration; and moderate sedation.
- Nonopioid analgesics used to treat mild to moderate pain include acetaminophen and NSAIDs such

as ibuprofen, ketorolac, naproxen, and, less commonly, indomethacin, diclofenac, and piroxicam.

- Morphine is considered the “gold standard” for all opioid agonists; it is the drug to which all other opioids are compared and is usually the drug of choice for severe pain (Oakes, 2011).
- Local anesthetics are commonly used to provide analgesia for procedures. They are effective in providing successful pain relief with only minimal risk of systemic adverse effects. The first choice for the most effective, painless local anesthesia is EMLA (eutectic mixture of local anesthetics [lidocaine and prilocaine]). It achieves anesthesia to a depth of 2 to 4 mm, so it reduces pain of phlebotomy, venous cannulation, and intramuscular injections up to 24 hours after injection.
- Epidural analgesia involves the insertion of a catheter into the epidural space through which drugs can be administered as bolus injections (a one-time bolus or on an intermittent schedule), as a continuous infusion, or as PCA. Usually an opioid, such as morphine, fentanyl, or hydromorphone, is given in conjunction with a long-acting local anesthetic, such as bupivacaine.
- Moderate sedation is a medically controlled state of depressed consciousness that allows protective reflexes to be maintained so the child has the ability to maintain a patent airway and respond to physical or verbal stimulation.
- When providing pharmacologic pain relief, the nurse must adhere to the five rights of medication administration and have a solid knowledge base about the medications used for pain relief and the drug’s pharmacokinetics (absorption, distribution, metabolism, and excretion) and pharmacodynamics (mechanism of action, including adverse effects). Initial and ongoing assessment is crucial.
- The principles of atraumatic care guide nursing interventions for providing pain relief, especially for procedure-related pain.
- Chronic pain in children can significantly affect the child’s daily life and activities as well as the family’s life.

## MULTIPLE CHOICE QUESTIONS

- The nurse is preparing to assess the pain of a 3-year-old child who had surgery the day before. Which pain assessment method would be most appropriate for the nurse to use?
  - FACES pain rating scale and poker chip tool
  - FACES pain rating scale, observation of the child, and parent report
  - Asking the parents to rate their child's pain using the word-graphic rating scale
  - Visual analog scale
- When developing the plan of care for a child in pain, the nurse identifies appropriate strategies aimed at modifying which factors influencing pain?
  - Gender
  - Cognitive level
  - Previous pain experiences
  - Anticipatory anxiety
- An adolescent who is a competitive swimmer comes to the emergency department complaining of localized aching pain in his shoulder. He states, "I've been practicing really hard and long to get myself ready for my meet this weekend." The area is tender to the touch. The nurse determines that the adolescent is most likely experiencing which type of pain?
  - Cutaneous pain
  - Deep somatic pain
  - Visceral pain
  - Neuropathic pain
- After teaching a child's parents about the different methods of distraction that can be used for pain management, which statement by the parents indicates a need for additional teaching?
  - "We'll have her focus on her hand and count each finger slowly."
  - "We'll read some of her favorite stories to her."
  - "We'll have her imagine that she's at the beach this summer."
  - "She likes to play video games, so we'll bring in some from home."
- A child is scheduled for a bone marrow aspiration at 4 p.m. The nurse would plan to apply EMLA cream to the intended site at which time?
  - 1:30 p.m.
  - 3:00 p.m.
  - 3:30 p.m.
  - 4:00 p.m.

## CRITICAL THINKING EXERCISES

- The nurse asks a 12-year-old girl if she is having pain. She denies pain, even though she is lying on her left side holding her abdomen with her knees flexed up to it. What might be some underlying factors leading the child to deny her pain? How would the nurse go about assessing this child's pain?
- The nurse comes into the room of a 6-year-old who is sleeping. His mother states, "He's asleep, so he's not in pain." How should the nurse respond?
- A child who is receiving ibuprofen is experiencing increased pain. The dosage of ibuprofen is increased but is no longer effective in providing adequate pain relief. What is occurring? What would be most likely to happen next?

## STUDY ACTIVITIES

- Interview nurses who work on a pediatric unit about their experiences with managing pain in children. Ask them how they assess pain in children and the major methods they use to assist the children in managing their pain.
- Interview families of children with chronic illnesses who deal with pain. Ask the parents how they assess their children's pain level and what methods they have used in assisting their children in managing pain.
- Compare and contrast the drugs fentanyl and midazolam when used for moderate sedation in terms of onset of action, duration, primary effects, and antidotes.
- A child is receiving epidural analgesia with morphine. The nurse would be alert for which of the following adverse effects? Select all that apply.
  - Respiratory depression
  - Pruritus
  - Constipation
  - Vomiting
  - Amnesia
  - Hematoma

# Nursing Care of the Child With an Infectious or Communicable Disorder

## Learning Objectives

*Upon completion of the chapter, you will be able to:*

1. Define the key terms used in this chapter.
2. Discuss anatomic and physiologic differences in children versus adults in relation to the infectious process.
3. Identify nursing interventions related to common laboratory and diagnostic tests used in the diagnosis and management of infectious conditions.
4. Identify appropriate nursing assessments and interventions related to medications and treatments for childhood infectious and communicable disorders.
5. Distinguish various infectious illnesses occurring in childhood.
6. Devise an individualized nursing care plan for the child with an infectious or communicable disorder.
7. Develop child/family teaching plans for the child with an infectious or communicable disorder.

*Mrs. Goldberg brings her son Samuel, 3 months old, to the clinic. He presents with a history of fever and nasal congestion. His mother tells you, "He's been very irritable and crying more than usual."*

### Words of Wisdom

Complete and lasting freedom from infectious disease remains a dream, but one worth fighting a hard battle for.

**Infectious** and communicable diseases are one of the leading causes of death worldwide. As the world has become increasingly connected, infectious diseases have presented new challenges. Children are particularly vulnerable to these types of illnesses. Their immune systems are still developing and their natural curiosity, especially in infants and toddlers, leads to wide-range handling of objects and surfaces coupled with a tendency to place their hands and objects in their mouths without washing first. Infectious diseases in children can range in severity from mild with few or no symptoms to serious illness, such as damage to organs, and even death. Infectious and communicable diseases include bacterial infections (e.g., sepsis), viral infections (e.g., viral exanthems and rabies), zoonotic infections, vector-borne infections, parasitic and helminthic infections (e.g., roundworm and pediculosis capitis [head lice]), and sexually transmitted infections (e.g., chlamydia and gonorrhea).

There has been a dramatic decrease in the incidence and severity of infectious and communicable diseases since the advent of vaccines, antibiotics, antiviral drugs, and antitoxins (Global Health Council, 2011). Some diseases have been effectively controlled, but the vast majority will not be eliminated. New diseases emerge and old diseases are reappearing, sometimes in a drug-resistant form. The Centers for Disease Control and Prevention (CDC) tracks certain infectious diseases. This list of nationally reportable diseases is revised periodically to add new pathogens or remove diseases as their incidence declines. Reporting by each state to the CDC is voluntary. Therefore, slight variations exist from state to state. Box 37.1 lists nationally reportable diseases.

### BOX 37.1

#### NATIONALLY NOTIFIABLE DISEASES

- Botulism
- *Chlamydia trachomatis*
- Diphtheria
- Ehrlichiosis
- Gonorrhea
- Hepatitis A, B, and C
- Influenza (pediatric mortality)
- Lyme disease
- Malaria
- Measles
- *Meningococcus*
- Mumps
- Pertussis
- Poliomyelitis, paralytic
- Q fever
- Rabies
- Rocky Mountain spotted fever (spotted fever rickettsiosis)
- Rubella
- Streptococcal disease, invasive group A
- Syphilis
- Tetanus
- Tuberculosis
- Varicella (morbidity)
- Varicella (deaths only)

For a complete list of nationally notifiable diseases in the United States, go to [http://www.cdc.gov/osels/ph\\_surveillance/nndss/phs/infdis2011.htm](http://www.cdc.gov/osels/ph_surveillance/nndss/phs/infdis2011.htm)

Nurses, particularly those working in schools, child care centers, and outpatient settings, are often the first to see the signs of infectious or communicable diseases in children. These signs are often vague at first (e.g., a sore throat or rash). Therefore, nurses must have accurate assessment skills and be familiar with the signs and symptoms of common childhood infectious diseases so that they can provide prompt recognition, treatment, guidance, and support to families. Identifying the infectious agent is of primary importance to prevent further spread.

Many infectious diseases can be prevented through simple and inexpensive methods such as hand washing, adequate immunization, proper handling and preparation of food, and judicious antibiotic use. Nurses play a key role in educating parents and the community on ways to prevent infectious and communicable diseases.

### HEALTHY PEOPLE 2020

#### Objective

Reduce, eliminate, or maintain elimination of cases of vaccine-preventable diseases.

Achieve and maintain effective vaccination coverage levels for universally recommended vaccines among young children.

#### Nursing Significance

- Educate children and their families on the importance of proper immunizations.
- Assess immunization status at every healthy encounter.
- Provide families with a written record of immunizations given.

*Healthy People Objectives based on data from <http://www.healthypeople.gov>.*

### INFECTIOUS PROCESS

Infection occurs when an organism enters the body and multiplies, causing damage to the tissues and cells. The body's response to this damage due to infection or injury is inflammation. The body delivers fluid, blood, and nutrients to the area of infection or injury and attempts to eliminate the pathogens and repair the tissues. The body does this through vascular and cellular reactions. The vascular response is an initial period of vasoconstriction followed by vasodilatation. This vasodilatation allows for the increase of fluids, blood, and nutrients to the area.

The cellular response involves the arrival of white blood cells (WBCs) to the area. WBCs are the body's defense against infection or injury. The types of WBCs are neutrophils, basophils, eosinophils, lymphocytes, and monocytes. Elevations in certain portions of the WBC

**TABLE 37.1** FUNCTION OF WHITE BLOOD CELLS BY LEUKOCYTE TYPE

Type of White Blood Cell	Function
Granulocytes <ul style="list-style-type: none"> <li>• Neutrophils (polymorphonuclear leukocytes or PMNs, segs)</li> <li>• Eosinophils</li> <li>• Basophils</li> </ul>	Phagocytic cells <ul style="list-style-type: none"> <li>• First line of defense upon invasion of bacteria, fungus, cell debris, and other foreign substances</li> <li>• Respond to allergic disorders and parasitic infections</li> <li>• Respond to allergic disorders and hypersensitivity reactions; used to study chronic inflammation</li> </ul>
Lymphocytes (B lymphocytes, T lymphocytes, and natural killer cells)	Main source of producing an immune response; respond to viral infections (measles, rubella, chickenpox, infectious mononucleosis); tumors
Monocytes	Second line of defense; respond to larger and more severe infections than neutrophils by phagocytosis; leukemias and lymphomas; chronic inflammation

Adapted from Fischbach, F. T., & Dunning III, M. B. (2009). *A manual of laboratory and diagnostic tests* (8th ed., pp. 74–85). Philadelphia: Lippincott Williams & Wilkins; and Gaspard, K. J. (2009). Blood cells and the hematopoietic system. In C. M. Porth & G. Matfin (Eds.), *Pathophysiology: Concepts of altered health states* (8th ed., pp. 254–261). Philadelphia: Wolters Kluwer Health/Lippincott Williams & Wilkins.

count reflect different processes occurring in the body, such as infection, allergic reaction, or leukemia. Table 37.1 explains the function of each type of WBC. Each type is generally present in a balanced state; the types are reported as a percentage of the total WBC count or as the number per certain volume of blood.

WBCs use **phagocytosis** to ingest and destroy the **pathogen**. If bacteria escape the action of phagocytosis, they enter the bloodstream and lymph system and the immune system is activated. With activation of the immune system, B lymphocytes (humoral immunity) and T lymphocytes (cell-mediated immunity) are matured and activated. B and T cells recognize and attack infectious pathogens. B cells, which mature in the bone marrow, produce specific antibodies to a specific offending **antigen** (a substance that the body recognizes as foreign). T cells, which mature in the thymus, attack the antigen directly. Once B and T cells have been exposed to an antigen, some cells will remember the antigen. Therefore, if the particular antigen invades again, the body will act more quickly. A third type of lymphocyte, natural killer cells are a part of the innate immune system and function to destroy foreign material present.

## Fever

Infection or inflammation caused by bacteria, viruses, or other pathogens stimulates the release of **endogenous pyrogens** (interleukins, tumor necrosis factor, and interferon). The pyrogens act on the hypothalamus, where

they trigger prostaglandin production and increase the body's temperature set point. This triggers the cold response, resulting in shivering, vasoconstriction, and a decrease in peripheral perfusion to help decrease heat loss and allow the body's temperature to rise to the new set point. Fever, defined as a temperature greater than 38°C (100.4°F), then occurs. Box 37.2 gives specific temperature parameters for fever based on what route is used for measurement.

Antipyretics are often used to lower fever and increase comfort. They decrease the temperature set point by inhibiting the production of prostaglandins. As a result, sweating and vasodilation occur and there is heat loss and a drop in temperature.

It is important to distinguish between fever and hyperthermia. Hyperthermia occurs when normal thermoregulation fails, resulting in an unregulated rise in core temperature. Hyperthermia may occur if the central nervous system of the child becomes impaired by disease, drugs, and abnormalities of heat production or

### BOX 37.2

#### DEFINITION OF FEVER BY MEASUREMENT ROUTE

- Oral: > 37.5°C (99.5°F)
- Rectal or Temporal Artery: >38°C (100.4°F)
- Axillary: >37.3°C (99.1°F)
- Tympanic: >38°C (100.4°F)

**TABLE 37.2** STAGES OF INFECTIOUS DISEASE

Stage	Explanation
Incubation	Time from entrance of pathogen into the body to appearance of first symptoms; during this time, pathogens grow and multiply
Prodrome	Time from onset of nonspecific symptoms such as fever, malaise, and fatigue to more specific symptoms
Illness	Time during which child demonstrates signs and symptoms specific to an infection type
Convalescence	Time when acute symptoms of illness disappear

thermal stressors, such as being left in a hot automobile or exertional heat stroke. In the absence of hyperthermia and in the normally neurologic child, the body does not allow fever to rise to lethal levels. The body actually produces a natural antipyretic, called cryogen. If there is no hyperthermic insult, it is rare to see a neurologically intact child's temperature rise above 41.7°C (107°F) (Nield & Kamat, 2011a).

## Stages of Infectious Disease

Infectious diseases follow a similar pattern. They progress through certain stages (Table 37.2) in which **communicability** (ability to spread to others) can be predicted. It is important for nurses to understand these stages to help control and manage infectious diseases.

## Chain of Infection

The **chain of infection** is the process by which an organism is spread. Behaviors of infants and young children, mainly pertaining to hygiene, increase their risk for infection by promoting the chain of infection. Poor hygiene habits, including lack of hand washing, placing toys and hands in the mouth, drooling, and leaking diapers, all can contribute to the spread of infection and communicable diseases. Table 37.3 reviews the chain of infection and nursing implications related to it.

## Preventing the Spread of Infection

Nurses play a key role in breaking the chain of infection and preventing the spread of diseases. It is important to follow infection control and prevention practices. It is also very important to educate parents and children on the measures they can take to prevent the spread of infection.

### Take Note!

Frequent hand washing is the most important way to prevent the spread of infection.

Isolation precautions help nurses break the chain of infection and provide strategies to prevent the spread of pathogens among hospitalized children. Guidelines can be found on the CDC website (<http://www.cdc.gov/hicpac/2007IP/2007isolationPrecautions.html>). Additional guidelines are available from various infection control societies and regulatory agencies such as the Occupational Safety and Health Administration (OSHA). The Joint Commission has also developed infection control standards. This leads to an array of complex guidelines that all health professionals need to be familiar with.

The Hospital Infection Control Practices Advisory Committee (HICPAC) has presented guidelines for hospitalized children that include two tiers (Siegel, Rhinehart, Jackson, Chiarello, and the Healthcare Infection Control Practices Advisory Committee, 2007). Tier 1 is standard precautions, which are designed for the care of all children in the hospital regardless of their diagnosis. Tier 2 is transmission-based precautions, designed for children who are known, or suspected, to be infected with epidemiologically important pathogens. These pathogens can be spread by air-borne, droplet, or contact transmission. Box 37.3 gives an overview of standard and transmission-based precautions.

### Take Note!

Hand hygiene includes both hand washing with soap and water and the use of alcohol-based products (gels, rinses, foams) that do not require water. If there is no visible soiling of the hands, approved alcohol-based products are preferred because of their superior microbicidal activity, reduced drying of the skin, and convenience (World Health Organization, 2009).

When caring for children, these guidelines may need to be modified. For instance, diaper changing is routine in the pediatric setting. Since it does not usually soil hands, it is not mandatory to wear gloves (except if gloves are required due to transmission-based precautions). According to the standard precaution guidelines, single rooms are required for those who are incontinent and cannot control bodily excretions. Since the majority

TABLE 37.3

## CHAIN OF INFECTION

Chain Link	Explanation	Nursing Implications
Infectious agent	Any agent capable of causing infection; examples: bacteria, viruses, rickettsiae, protozoa, and fungi	<ul style="list-style-type: none"> <li>Control or eliminate infectious agents through:               <ul style="list-style-type: none"> <li>Hand washing</li> <li>Wearing gloves</li> <li>Cleaning, disinfecting, or sterilizing equipment</li> </ul> </li> </ul>
Reservoir	A place where the pathogen can thrive and reproduce; examples: human body, animals, insects, food, water, inanimate objects (e.g., stethoscopes)	<ul style="list-style-type: none"> <li>Control or eliminate reservoirs.</li> <li>Control sources of body fluids, drainage, or solutions that may harbor pathogens.</li> <li>Follow institutional guidelines for disposing of infectious wastes.</li> <li>Provide proper wound care; change dressings or bandages when soiled.</li> <li>Assist children to carry out appropriate skin and oral care.</li> <li>Keep linens clean and dry.</li> </ul>
Portal of exit	A way for the pathogen to exit the reservoir; examples: skin and mucous membranes, respiratory tract, urinary tract, gastrointestinal tract, reproductive tract	<ul style="list-style-type: none"> <li>Control portals of exit and educate children and families.</li> <li>Cover mouth and nose when sneezing or coughing.</li> <li>Avoid talking, coughing, or sneezing over open wounds or sterile fields.</li> <li>Use personal protective equipment.</li> </ul>
Modes of transmission	Direct transmission: body-to-body contact Indirect transmission: transferred by <b>fomite</b> or vector; spread by droplet or air-borne transmission	<ul style="list-style-type: none"> <li>Wash hands before and after child contact, invasive procedures, or touching open wounds.</li> <li>Use personal protective equipment when necessary.</li> <li>Urge children and family to wash hands frequently, especially before eating or handling food, after eliminating, and after touching infectious material.</li> </ul>
Portal of entry	A way for the pathogen to enter the host; examples: skin and mucous membranes, respiratory tract, urinary tract, gastrointestinal tract, reproductive tract	<ul style="list-style-type: none"> <li>Use proper sterile technique during invasive procedures.</li> <li>Provide appropriate wound care.</li> <li>Dispose of needles and sharps in puncture-resistant containers.</li> <li>Provide all children with their own personal care items.</li> </ul>
Susceptible host	Any person who cannot resist the pathogen	<ul style="list-style-type: none"> <li>Protect susceptible host by promoting normal body defenses against infection.</li> <li>Maintain integrity of the child's skin and mucous membranes.</li> <li>Protect normal defenses by regular bathing and oral care, adequate fluid intake and nutrition, and proper immunization.</li> </ul>

of young children are incontinent, obviously this guideline is inappropriate in the pediatric setting. Pediatric units often have common rooms, such as playrooms and schoolrooms. Children placed on transmission-based isolation are not allowed to leave their rooms and therefore are not allowed to use these common rooms.

## VARIATIONS IN PEDIATRIC ANATOMY AND PHYSIOLOGY

Normal immune function is an amazing protective response by the body. It involves complex responses including phagocytosis, humoral immunity, cellular immunity, and

activation of the complement system. Blood and lymph are responsible for transporting the agents of the immune system. Due to the immature responses of the immune system, infants and young children are more susceptible to infection. The newborn displays a decreased inflammatory response to invading organisms, contributing to an increased risk for infection. Cellular immunity is generally functional at birth, and humoral immunity occurs when the body encounters and then develops immunity to new diseases. Since the infant has had limited exposure to disease and is losing the passive immunity acquired from maternal antibodies, the risk of infection is higher. Young children continue to have an increased risk for infection and communicable disorders because

## BOX 37.3

**STANDARD PRECAUTIONS AND ISOLATION PRECAUTIONS****Standard Precautions (Tier One)**

- Apply to all children
- Apply to all body fluids, secretions, and excretions except sweat, nonintact skin, and mucous membranes
- Designed to reduce the risk of transmission of microorganisms from recognized and unrecognized sources
- Techniques include:
  - Proper hand hygiene
  - Use of gloves (clean or sterile) when touching blood, body fluids, secretions or excretions, and contaminated items
  - Masks, eye protection, and face shields when patient care may include splashing or sprays of blood, body fluid secretions, or excretions, and during bronchoscopy, endotracheal intubation, and open suctioning of the respiratory tract
  - Fluid-resistant nonsterile gowns, to protect skin and clothing, when patient care may include splashing or sprays of blood, body fluid secretions, or excretions
  - Patient care equipment handled in a manner that prevents skin or mucous membrane exposure and contamination of clothing
  - All used linen is considered contaminated and needs to be handled and disposed of appropriately.
  - Mouthpieces, resuscitation bags with one-way valves, and other ventilation devices should be readily available.
  - Cleaning and disinfecting noncritical surfaces in patient care areas
  - Respiratory hygiene/cough etiquette: applies to any person with signs of illness including cough, congestion, rhinorrhea, or increased respiratory secretions that is entering a health care facility. It includes education regarding covering the mouth/nose with a tissue; prompt disposal of used tissues, along with surgical masks used by a person who is coughing when appropriate; hand hygiene after contact with respiratory secretions; and separation, ideally greater than 3 feet, of persons with respiratory infections in common waiting areas when possible.
  - Safe injection practices: use of sterile single-use disposable needle. When possible use of single-dose vials; precautions used to prevent injury when using, cleaning, or disposing of needles and sharps
  - Use of masks for insertion of catheters or injection into the spinal or epidural space via lumbar puncture procedures

**Transmission-Based Precautions (Tier Two)**

Designed for children with known or suspected infection with pathogens for which additional precautions are warranted to interrupt transmission

**Air-Borne**

- Designed to reduce the risk of infectious agents transmitted by air-borne droplet nuclei or dust particles that may contain the infectious agent
- Examples of such illnesses include measles, varicella, and tuberculosis.
- Techniques include standard precautions as well as:
  - Room with negative air pressure ventilation, with air externally exhausted or high-efficiency particulate air filtered if recirculated; if unavailable, mask the child and place in private room with the door closed.
  - Wear a mask or respirator depending on specific recommendations based on disease, such as if infectious pulmonary tuberculosis is suspected or proven, wear a respiratory protective device, such as an N95 respirator, while in the child's room.
  - Susceptible health care personnel should not enter the room of children with measles or varicella zoster infections. Those with proven immunity to these viruses need not wear a mask.

**Droplet**

- Intended to prevent transmission of pathogens spread through close respiratory or mucous membrane contact with respiratory secretions. Designed to reduce the risk of infectious agents transmitted by contact of the conjunctivae or the mucous membranes of the nose or mouth of a susceptible person with large-particle droplets containing pathogens generated from a person (generally through coughing, sneezing, talking, or procedures such as suctioning) who has a clinical disease or who is a carrier of the disease
- Examples of such illnesses include diphtheria, pertussis, streptococcal group A, influenza, mumps, rubella, and scarlet fever.
- Techniques include standard precautions as well as:
  - Private room (if unavailable, consider cohorting children with the same disease. If this is not possible, separation of at least 3 feet between other children and visitors should be maintained.)
  - Wear a mask if within 3 feet of the child.

**Contact**

- Most important and most common route of transmission of health care-associated infections
- Designed to reduce the risk of infectious agents transmitted by direct or indirect contact. Direct-contact transmission involves skin-to-skin contact and physical transfer of pathogens between a susceptible host and an infected or colonized person. Examples include patient care activities that involve physical contact such as turning and bathing. Direct-contact transmission also can occur between two children, where one serves as the source of infectious pathogen and the other as a susceptible host. Indirect-contact transmission involves contact of a susceptible host with a contaminated intermediate object, usually inanimate, in the child's environment.
- Examples of such illnesses include diphtheria,<sup>a</sup> pediculosis, scabies, and multidrug-resistant bacteria.

- Techniques include standard precautions as well as:
  - Private room (if unavailable, consultation with infection control personnel is recommended. Consider cohorting children with the same disease. If this is not possible, separation of at least 3 feet between other children and visitors should be maintained.)
  - Gloves (clean or sterile) should be used at all times.
- Proper hand hygiene after glove removal
- Use gloves and gowns for all interactions that involve contact with the child or potentially contaminated areas. Don before entering and remove before leaving the child's room.

Prevention standards are applied in all health care settings and are modified to meet each setting's unique needs. Health care workers must practice within the specific institution's guidelines.

\*Certain infections require more than one precaution.

Adapted from Siegel, J. D., Rhinehart, E., Jackson, M., Chiarello, L., and the Healthcare Infection Control Practices Advisory Committee. (2007). *Guideline for isolation precautions: Preventing transmission of infectious agents in healthcare settings*. Retrieved on July 7, 2012, from <http://www.cdc.gov/hicpac/pdf/isolation/Isolation2007.pdf>

disease protection from immunizations is not complete. (Refer to Chapter 31 for further details.)

## COMMON MEDICAL TREATMENTS

A variety of medications and other medical treatments are used to treat infectious disorders in children. Most of these treatments will require a physician's or nurse practitioner's order when the child is in the hospital. The most common treatments and medications are listed in Common Medical Treatments 37.1 and Drug Guide 37.1. The nurse caring for the child with an infectious disorder should be familiar with what the procedures are, how they work, and common nursing implications related to use of these modalities.

## NURSING PROCESS OVERVIEW FOR THE CHILD WITH AN INFECTIOUS OR COMMUNICABLE DISORDER

Care of the child with an infectious or communicable disorder includes assessment, nursing diagnosis, planning, interventions, and evaluation. There are a number of general concepts related to the nursing process that may be applied to the care of children with infectious disorders. From a general understanding of the care involved for a child with an infectious disorder, the nurse can then individualize the care based on the child's specifics.

### COMMON MEDICAL TREATMENTS 37.1

Treatment	Explanation	Indications	Nursing Implications
Hydration	Promoting proper fluid balance either orally or intravenously	Child who can't replace insensible loss due to fever, child who is vomiting or has diarrhea	<ul style="list-style-type: none"> <li>• Encourage oral fluids, if possible.</li> <li>• Offer child preferred fluid; try popsicles or games to promote fluid intake.</li> <li>• If administering IV fluids, ensure proper fluid and rate per order and assess IV site and fluid intake every hour.</li> <li>• Maintain strict record of intake and output.</li> </ul>
Fever reduction	Reducing temperature by use of antipyretics or nonpharmacologic interventions	Febrile child who is uncomfortable or who can't keep up with the increased metabolic demands associated with fever	<ul style="list-style-type: none"> <li>• Administer antipyretics, such as ibuprofen and acetaminophen.</li> <li>• Avoid aspirin use in children and adolescents.</li> <li>• Use nonpharmacologic interventions such as dressing lightly, removing blankets, use of a fan, tepid bath, and cooling blanket. Make sure that nonpharmacologic measures do not induce shivering or discomfort. If they do, they should be stopped immediately.</li> </ul>

IV, intravenous.

## DRUG GUIDE 37.1 COMMON DRUGS FOR COMMUNICABLE DISORDERS

Medication	Actions/Indications	Nursing Implications
Antibiotics	Kill and prevent the growth of bacteria Used for treatment of bacterial infections such as sepsis	<ul style="list-style-type: none"> <li>• Check for antibiotic allergies.</li> <li>• Give as prescribed for the length of time prescribed.</li> </ul>
Antivirals (e.g., acyclovir)	Kill and prevent the growth of viruses Used for treatment of viral infections such as herpes simplex 2	<ul style="list-style-type: none"> <li>• Observe infusion site for signs of tissue damage.</li> <li>• If administering topically, clean and dry area before application and wear gloves.</li> <li>• Give as prescribed for the length of time prescribed.</li> </ul>
Antipyretics (acetaminophen, ibuprofen)	Decrease the temperature set point (only in a child with a raised temperature) by inhibiting the production of prostaglandins, leading to heat loss (through vasodilation and sweating) and resulting in a reduction in fever  Used to decrease temperature in the febrile child who is uncomfortable or who can't keep up with the increased metabolic demands associated with fever	<ul style="list-style-type: none"> <li>• Ensure proper dosing, concentration, and dosing interval.</li> <li>• Avoid aspirin use in children and adolescents.</li> <li>• Avoid ibuprofen use in children with a bleeding disorder.</li> <li>• Assess fever and any related symptoms such as tachycardia, shivering, or diaphoresis.</li> <li>• Properly educate caregivers on appropriate dosing, concentration, dosing interval, and use of accurate measuring device.</li> </ul>
Antipruritics (usually antihistamines)	Given orally or topically to block the histamine reaction  Used to relieve discomfort associated with itching	<ul style="list-style-type: none"> <li>• When applying topically, wear gloves.</li> <li>• Do not apply to open wounds.</li> <li>• Oral antihistamines may cause drowsiness.</li> </ul>

(2010). *Lexi-comp's Drug Reference Handbook: Pediatric & Neonatal Dosage Handbook* (18th ed.). Hudson, OH: Lexi-comp, Inc.

**Remember Samuel, the 3-month-old with fever, congestion, and irritability? What additional health history and physical examination assessment information should you obtain?**

### Assessment

Assessment of the child with a communicable or infectious disorder includes health history, physical examination, and laboratory and diagnostic testing.

### Health History

The health history consists of the past medical history, including the mother's pregnancy history; family history; and history of present illness (when the symptoms started and how they have progressed), as well

as treatments used at home. The past medical history might be significant for lack of recommended immunizations, prematurity, maternal infection during pregnancy or labor, prolonged difficult delivery, or immunocompromise. Family history might be significant for lack of immunization or recent infectious or communicable disease. When eliciting the history of the present illness, inquire about the following:

- Any known exposure to infectious or communicable disease
- Immunization history
- History of having any common childhood communicable diseases
- Fever
- Sore throat
- Lethargy
- Malaise
- Poor feeding or decreased appetite
- Vomiting
- Diarrhea

- Cough
- Rash (in the older child ask for a description [i.e., Is it painful? Does it itch?])

### Take Note!

Many childhood infections and communicable diseases involve a rash. Rashes can be difficult to identify. Therefore, it is important to obtain a thorough description and history from the caregiver.

## Physical Examination

Physical examination of the child with an infectious disorder includes inspection, observation, and palpation.

### INSPECTION AND OBSERVATION

Begin the physical examination with inspection and observation. Assess the child's skin, mouth, throat, and hair for lesions or wounds. Note the color, shape, and distribution of any lesions or wounds. Assess whether there is any exudate from the lesions or wounds. A thorough and accurate description is important to assist in identifying the rash and causative organism. Observe for scratching, restlessness, avoidance of the use of a body part, or guarding of a body part. Observe the child's affect, energy level, and interaction with caregivers. Lethargy can indicate serious infection or sepsis. Observe if there is any discharge from the nose, cough, or respiratory difficulty.

Assess hydration status. Inspect the oral mucosa; dry and pale mucous membranes can indicate dehydration. Observe for other signs of dehydration, such as sunken eyes and no tears with crying.

Assessment of vital signs can provide more information about the child's condition. Elevated temperature can indicate infection. Often tachypnea and tachycardia accompany fever. Hypotension may also occur, but it is usually a late sign with sepsis.

### Take Note!

Neonates may not present with fever; some may be hypothermic (Anderson-Berry, Bellig, & Ohning, 2012).

### PALPATION

Palpate the skin to assess temperature, moisture, texture, and turgor. In a child with an infectious or communicable disease, the skin may be warm and moist due to fever. Turgor may be decreased secondary to dehydration. In infants, palpate the fontanels; if they are sunken, the infant may be dehydrated. Palpate the rash to determine if it is raised or flat. A thorough picture of the presenting rash can help identify the child's illness. Palpate the lymph nodes and note any that are swollen and tender.

## Laboratory and Diagnostic Testing

Common Laboratory and Diagnostic Tests 37.1 discusses the tests used most commonly when communicable disorders are suspected. The tests can assist the physician or nurse practitioner in diagnosing the disorder and/or be used as guidelines in determining ongoing treatment. Laboratory or nonnursing personnel obtain some of the tests, while the nurse might obtain others. In either instance the nurse should be familiar with how the tests are obtained, what they are used for, and normal versus abnormal results. This knowledge will also be necessary when providing child and family education related to the testing.

### OBTAINING BLOOD SPECIMENS

Giving a blood specimen may be very frightening to children because of the fear of needles, pain, and blood loss. Provide atraumatic care when performing venipunctures and other needlesticks in children (refer to Chapter 30 for further information). Whether the laboratory technician or the nurse is drawing the blood, the procedure should be performed in an area other than the child's bed, such as the treatment room; the child's bed should be kept as a "safe" area. Provide teaching about the procedure based on the child's developmental level and readiness to learn. In infants and younger children, additional assistance with positioning and restraint will be needed to perform the procedure safely and to ensure proper collection. Use a topical anesthetic cream or gel, refrigerant spray, or iontophoresis before venipuncture. In young infants, administer oral sucrose beginning 1 to 2 minutes before the procedure and throughout the course of the venipuncture (Hatfield, Chang, Bittle, Deluca, & Polomano, 2011). Refer to Chapter 36 for additional information about decreasing venipuncture-related pain in infants and children.

The usual sites for obtaining blood specimens via venipuncture are the superficial veins of the dorsal surface of the hand or the antecubital fossa, although other locations may also be used. In specific situations, the jugular or femoral vein may be used; in this case either the physician or nurse practitioner will perform the venipuncture.

Capillary puncture of the child's fingertip, the great toe, or the infant's heel may also be used to obtain blood specimens. Fingertip puncture is similar to that in the adult, directed to the sides of the fingertip. Great toe puncture is performed in the same way. Capillary heel puncture must be performed in the proper location to avoid striking the medial plantar artery or periosteum (see Nursing Procedure 37.1). Automatic lancet devices can be used to deliver a more precise puncture depth and may be less painful manual lancets (Bowden & Greener, 2008).

## COMMON LABORATORY AND DIAGNOSTIC TESTS 37.1

Test	Explanation	Indications	Nursing Implications
Complete blood count (CBC)	Evaluate white blood cell count (particularly the percentage of individual white cells)	Detect the presence of inflammation, infection	<ul style="list-style-type: none"> <li>• Normal values vary according to age and gender.</li> <li>• White blood cell count differential is helpful in differentiating source of infection.</li> <li>• May be affected by myelosuppressive drugs</li> </ul>
Erythrocyte sedimentation rate (ESR)	Nonspecific test used in conjunction with other tests to determine presence of infection or inflammation	Detect the presence of inflammation, infection	<ul style="list-style-type: none"> <li>• Send to laboratory immediately; specimens allowed to stand for longer than 3 hours may produce a falsely low result.</li> </ul>
C-reactive protein (CRP)	<p>Nonspecific test that measures a type of protein produced in the liver that is present during episodes of acute inflammation or infection</p> <p>Usually used to diagnose bacterial infections; does not consistently rise with viral infections</p>	To detect the presence of infection, CRP is a more sensitive and rapidly responding indicator than ESR.	<ul style="list-style-type: none"> <li>• Presence of an intrauterine device may cause positive test results because of tissue inflammation.</li> <li>• Exogenous hormones, such as oral contraceptives, may cause increased levels.</li> <li>• Nonsteroidal anti-inflammatories, salicylates, and steroids may cause decreased levels.</li> <li>• Fasting may be required.</li> </ul>
Blood culture and sensitivity	Deliberate growing of microorganism in a solid or liquid medium. Once it has grown, it is tested against various antibiotics to determine which antibiotics will kill it.	<p>Detect the presence of bacteria or yeast, which may have spread from a certain site in the body into the bloodstream</p> <p>Determine which antibiotics the bacteria or yeast is sensitive to</p>	<ul style="list-style-type: none"> <li>• Follow aseptic technique and hospital protocol to prevent contamination.</li> <li>• Two cultures obtained from two different sites are preferred.</li> <li>• Ideally obtain before administering antibiotics; if child is taking antibiotics, notify laboratory and draw specimen shortly before next dose.</li> <li>• Deliver specimen to laboratory immediately (within 30 minutes).</li> </ul>
Stool culture (including stool for ova and parasites [O&P])	To determine if bacteria or parasite has infected the intestines	Detect pathogens, including parasites or overgrowth of normal flora in the bowel. Indicated for children with diarrhea, fever, or abdominal pain	<ul style="list-style-type: none"> <li>• Stool must be free of urine, water, and toilet paper.</li> <li>• Do not retrieve out of toilet water.</li> <li>• Deliver to laboratory immediately.</li> <li>• Mineral oil, barium, and bismuth interfere with the detection of parasites; specimen collection should be delayed for 7 to 10 days.</li> <li>• Often a minimum of three specimens on 3 separate days are required for adequate examination, since many parasites and worm eggs are shed intermittently.</li> </ul>

**COMMON LABORATORY AND DIAGNOSTIC TESTS 37.1** (continued)

Test	Explanation	Indications	Nursing Implications
Urine culture	Collection of urine to detect the presence of bacteria in the urine	Detect the presence of bacteria in the urine. Indicated for children with fever of unknown origin, dysuria, frequency, or urgency, or if urinalysis suggests infection	<ul style="list-style-type: none"> <li>• Should be obtained by midstream clean-catch, catheterization, or suprapubic aspiration. Avoid contamination with stool, vaginal secretions, hands, or clothing.</li> <li>• Placing bags on the perineum is not acceptable due to high chance of contamination.</li> <li>• Obtain before antibiotics are administered.</li> <li>• Deliver to laboratory immediately or refrigerate.</li> </ul>
Wound culture	Allows for microbial growth and identification of specific organism	Identification of specific organism	<ul style="list-style-type: none"> <li>• Do not take from exudate or eschar.</li> <li>• Irrigate the wound with sterile saline if necessary.</li> <li>• Note sensitivities.</li> <li>• Specimens taken from wounds can harbor a variety of organisms. Pathogenicity depends of the quantity of organisms present.</li> </ul>

## Atraumatic Care

*The young infant will benefit from the use of oral sucrose via pacifier before and during the capillary puncture (Hatfield et al., 2011).*

Occasionally, blood samples may be obtained from an artery rather than a vein or capillary. Blood gases in particular are usually obtained by arterial puncture. Arterial puncture requires additional training and in many institutions is performed only by the respiratory therapist, physician, or nurse practitioner.

Children with indwelling venous access devices may be spared the trauma of puncture for blood specimens. Follow your institution's guidelines for withdrawing blood from peripherally inserted venous

catheters or central venous catheters. The initial blood will be discarded to prevent contamination with intravenous fluids or medications such as heparin. The amount discarded depends on the size of the catheter, the weight of the child, and the institution's guidelines. After aspirating the specimen, flush the venous access device with normal saline to prevent clogging. The device may then be reconnected to the intravenous fluid or flushed according to the institution's protocol.

## Nursing Diagnoses, Goals, Interventions, and Evaluations

After completing a thorough assessment, the nurse might identify several nursing diagnoses, including:

- Risk for imbalanced body temperature
- Impaired comfort
- Impaired skin integrity

## NURSING PROCEDURE 37.1

## Capillary Heel Puncture

1. Choose the collection site and apply a commercial heel warmer or warm pack for several minutes prior to specimen collection.
2. Assemble equipment:
  - Gloves
  - Automatic lancet
  - Antiseptic wipe
  - Cotton ball or dry gauze
  - Capillary blood collection tube
  - Band-aid
3. Perform hand hygiene and don gloves. Remove the warm pack.
4. Cleanse the site with antiseptic prep pad and allow to dry.
5. Hold the dorsum of the foot with the nondominant hand; with the dominant hand, pierce the heel with the lancet. Place the extremity in the dependent position.
6. Wipe away the first drop of blood with the cotton ball or dry gauze.
7. Collect the blood specimen with a capillary specimen collection tube. Avoid squeezing the foot during specimen collection if possible, as it may contribute to hemolysis of the specimen.
8. Hold dry gauze over the site until bleeding stops, elevate extremity above the level of the heart, and then apply a Band-aid.

- Risk for infection
- Deficient fluid volume
- Social isolation
- Deficient knowledge (specify)

**After completing an assessment of Samuel, you note the following: rectal temperature of 39°C, poor sucking, and lethargy. Based on these assessment findings, what would your top three nursing diagnoses be for Samuel?**

Nursing goals, interventions, and evaluation for the child with a communicable or infectious disorder are based on the nursing diagnoses. Nursing Care Plan 37.1 provides a general guide for planning care for a child with an infectious or communicable disorder. Additional information about nursing management will

be included later in the chapter as it relates to specific disorders.

### Managing Fever

Fever in their children is one of the most common reasons parents seek medical attention (Sullivan, Farrar, & the AAP's Section on Clinical Pharmacology and Therapeutics, and Committee on Drugs, 2011). Most infections or communicable diseases are accompanied by fever. Many parents have great concerns about fever. For example, they fear febrile seizures, neurologic complications, and a potential serious underlying disease. Many health care providers share these fears. This leads to the common recommendation to intervene and reduce fever. These fears and misconceptions about fever can lead to mismanagement of fever, such as inappropriate dosing of antipyretics, awakening the child during sleep to give antipyretics, or inappropriate use of nonpharmacologic treatments such as sponging

## NURSING CARE PLAN 37.1

## Overview for the Child With an Infectious or Communicable Disorder

**NURSING DIAGNOSIS:** Risk for imbalanced body temperature: fever related to infectious disease process as evidenced by rectal temperature greater than 38°C or 100.4°F

**Outcome Identification and Evaluation**

Child will maintain temperature within adaptive levels and be comfortable and remain hydrated. *Temperature will be 38°C or 100.4°F or less. Child will verbalize or exhibit signs of comfort during febrile episode; child will demonstrate adequate signs of hydration.*

**Interventions: Managing Fever**

- Assess temperature at least every 4 to 6 hours, 30 to 60 minutes after antipyretic is given and with any change in condition: *recognizing the pattern of fever may help identify source.*
- Use same site and device for temperature measurement to *reflect a more accurate trend in temperature, since different sites can result in significant differences in temperature reading.*
- Administer antipyretics per physician order when the child is experiencing discomfort or cannot keep up with the metabolic demands of the fever. *Fever is a protective response of the body to fight infection. Antipyretics provide symptomatic relief but do not change the course of the infection. The major benefits to decreasing fever are increasing comfort in the child and decreasing fluid requirements, helping to prevent dehydration.*
- Notify physician of temperature per institution or specific order guidelines: *increases in temperature may indicate worsening infection and relevant changes in condition.*
- Assess fluid intake and encourage oral intake or administer intravenous fluids per physician order: *increased metabolic rate and diaphoresis related to fever can cause fluid loss and lead to fluid volume deficit.*
- Keep linens and clothing clean and dry: *diaphoresis can leave clothing and linen soaked, increasing discomfort for the child.*
- Use of nonpharmacologic measures such as tepid bath and removal of clothing and blankets is controversial. If used, discontinue if shivering begins.

**NURSING DIAGNOSIS:** Impaired comfort related to infectious and/or inflammatory process as evidenced by hyperthermia, pruritus, rash or skin lesions, sore throat, or joint pain

**Outcome Identification and Evaluation**

Pain or discomfort will be reduced to level acceptable to child. *Child will verbalize absence or decrease of pain using a pain scale (FLACC, FACES, or linear pain scale), will verbalize decrease in uncomfortable sensations such as itching and aches; infants will exhibit decreased crying and ability to rest quietly.*

**Interventions: Improving Comfort**

- Assess pain and response to interventions frequently with use of pain scales or other pain measurement tools: *provides baseline of pain and allows for evaluation of effectiveness of interventions.*
- Administer analgesics and antipruritics as ordered to *relieve pain via interruption of central nervous system (CNS) pathways and to decrease discomfort related to itching.*
- Apply cool compresses to areas of pruritus or provide a cool bath to *decrease inflammation and soothe pruritus.*
- Keep child's fingernails short (use mitts, gloves, or socks over hands if necessary) to prevent injury to the skin, *which leads to increased pain.*
- Encourage child to press on rather than scratch the area of pruritus: *pressing on the area that itches can soothe the itching and prevent scratching, which can lead to skin injury.*
- Provide fluids frequently and offer warm fluids such as soup or cold foods such as popsicles to *ease the discomfort of a sore throat.*
- Provide cool mist humidification to *ease the discomfort of a sore throat.*
- Dress the child in light clothing: *restrictive clothing and diaphoresis can lead to increased pruritus.*
- Use diversional activities and distraction appropriate to developmental level: *distraction from pain can reduce the need for pharmacologic agents, and distraction from pruritus can minimize scratching.*

(continued)

## NURSING CARE PLAN 37.1

**Overview for the Child With an Infectious or Communicable Disorder** (continued)

**NURSING DIAGNOSIS:** Impaired skin integrity related to mechanical trauma secondary to infectious disease process as evidenced by rash, pruritus, and scratching

**Outcome Identification and Evaluation**

Child will maintain or regain skin integrity. *Child will not demonstrate increased skin breakdown. Child or parent will be able to describe or demonstrate measures to protect and heal skin and proper care for any lesions.*

**Interventions: Promoting Skin Integrity**

- Monitor skin for color changes, temperature, redness, swelling, warmth, pain, signs of infection, or changes in rash lesions, distribution, or size *to help identify problems early and allow for prevention of infection; can also provide information regarding the course of the illness.*
- Encourage fluid intake and proper nutrition *to promote wound healing.*
- Keep child's fingernails short (use mitts, gloves, or socks over hands if necessary) *to prevent injury to the skin, which leads to increased pain.*
- Encourage child to press on rather than scratch the area of pruritus; *pressing on the area that itches can soothe the itching and prevent scratching, which can lead to skin injury.*
- Use antipruritics and topical ointments or creams as ordered *to minimize scratching to prevent injury to skin; can aid in healing.*

**NURSING DIAGNOSIS:** Risk for infection related to insufficient knowledge regarding measures to avoid exposure to pathogens, increased environmental exposure to pathogens, transmission to others secondary to contagious organism or presence of infectious organisms

**Outcome Identification and Evaluation**

Child will exhibit no signs or symptoms of local or systemic infection. Child will not spread infection to others. *Symptoms of infection will decrease over time; others will remain free of infection. Child and family will demonstrate appropriate hygiene measures using proper technique, such as hand washing, to prevent the spread of infection.*

**Interventions: Preventing and Controlling Infection**

- Monitor vital signs: *elevation in temperature may indicate infection.*
- Monitor skin lesions for signs of local infection: *redness, warmth, drainage, swelling, and pain at lesions can indicate infection.*
- Maintain aseptic technique and practice good hand washing *to prevent introduction of further infectious agents and prevent transmission to others.*
- Administer antibiotics as prescribed *to prevent or treat bacterial infection.*
- Encourage nutritious diet and proper hydration according to child's preferences and ability to feed orally *to assist body's natural defenses against infection.*
- Isolate child as required based on transmission-based precautions *to prevent nosocomial spread of infection.*
- Teach child and family preventive measures such as good hand washing, covering mouth and nose with cough or sneeze, and proper disposal of used tissues *to prevent nosocomial or community spread of infection.*

## NURSING CARE PLAN 37.1

**Overview for the Child With an Infectious or Communicable Disorder** (continued)

**NURSING DIAGNOSIS:** Fluid volume deficit, risk for, related to increased metabolic demands and insensible loss due to fever, vomiting, poor feeding or intake

**Outcome Identification and Evaluation**

Fluid volume will be maintained and balanced. *Oral mucosa is moist and pink, skin turgor is elastic, urine output is at least 1 to 2 mL/kg/hour.*

**Interventions: Promoting Adequate Fluid Balance**

- Administer IV fluids if ordered *to maintain adequate hydration in children who are NPO (nothing by mouth), unable to tolerate oral intake, or unable to keep up with fluid losses.*
- When oral intake is allowed and tolerated, encourage oral fluids *to promote intake and maintain hydration.*
- Assess for signs of adequate hydration such as pink and moist oral mucosa, elastic skin turgor, and adequate urine output *to detect fluid imbalance.*
- Monitor intake and output *to identify fluid imbalance.*
- Assess urine specific gravity, urine and serum electrolytes, blood urea nitrogen, creatinine, and osmolality and daily weights *to monitor fluid status.*

**NURSING DIAGNOSIS:** Social isolation related to required isolation from peers secondary to transmission-based precautions, as evidenced by disruption in usual play secondary to inability to leave hospital room, activity intolerance, and fatigue

**Outcome Identification and Evaluation**

Child will participate in stimulating activities. *Child is able to verbalize reason for isolation and length of isolation (if developmentally appropriate); child verbalizes interest in activities.*

**Interventions: Preventing Social Isolation**

- Explain reasons for transmission-based precautions and length of time: *this helps increase understanding and decrease anxiety about isolation. Children sometimes mistake isolation as punishment. Explaining length of time gives child an endpoint he or she can work toward.*
- Visit child frequently, at least every hour, and try to spend some uninterrupted time to play and allow child time to verbalize feelings about separation from others: *helps establish a therapeutic relationship and demonstrates caring.*
- Let child see caregiver's face before applying mask if appropriate *to help child identify and relate to those caring for him or her and minimize anxiety about strangers and the unknown.*
- Consult child life specialist *to arrange for stimulating activities child enjoys: can help child to understand reasons for isolation.*
- Contact volunteers to spend time with child, if appropriate: *gives child attention and support, which will help child to cope and decrease stress.*

(continued)

## NURSING CARE PLAN 37.1

## Overview for the Child With an Infectious or Communicable Disorder (continued)

**NURSING DIAGNOSIS:** Knowledge deficit related to lack of information regarding medical condition, prognosis, and medical needs as evidenced by verbalization, questions, or actions demonstrating lack of understanding regarding child's condition or care

### Outcome Identification and Evaluation

Child and family will verbalize accurate information and understanding about condition, prognosis, and medical needs. *Child and family demonstrate knowledge of condition and prognosis and medical needs, including possible causes, contributing factors, and treatment measures.*

### Interventions: Providing Child and Family Teaching

- Assess child's and family's willingness to learn: *child and family must be willing to learn in order for teaching to be effective.*
- Provide family with time to adjust to diagnosis to *facilitate adjustment and ability to learn and participate in child's care.*
- Repeat information to *give family and child time to learn and understand.*
- Teach in short sessions: *many short sessions are more helpful than one long session.*
- Gear teaching to level of understanding of the child and family (depends on age of child, physical condition, memory) *to ensure understanding.*
- Provide reinforcement and rewards *to facilitate the teaching/learning process.*
- Use multiple modes of learning involving many senses (provide written, verbal, demonstration, and videos) when possible: *the child and family are more likely to retain information when it is presented in different ways using many senses.*

the child with alcohol or cold water (Sullivan et al., 2011).

It is important to educate parents that fever is a protective mechanism the body uses to fight infection. Evidence exists that an elevated body temperature actually enhances various components of the immune response (Sullivan et al., 2011). Studies have shown that the use of antipyretics may prolong illness (Sullivan et al., 2011). Another concern is that reducing fever may hide signs of serious bacterial illness (Sullivan et al., 2011).

#### Take Note!

Infants younger than 3 months of age with a rectal temperature greater than 38°C should be seen by a physician or nurse practitioner. They are considered at risk for sepsis until proven otherwise due to their immature immune system and inability to localize or handle infection very well (Nield & Kamat, 2011b).

In infants older than 3 months of age, fever less than 39°C usually does not require treatment (Nield & Kamat, 2011b). Antipyretics provide symptomatic relief but do not change the course of the infection. The major benefits of decreasing fever are increasing comfort in the child and decreasing fluid requirements, which helps to prevent dehydration. Children with certain underlying conditions, such as cardiovascular

disease or pulmonary disease, also benefit from treating fever because such treatment decreases demands on the body.

### HOME MANAGEMENT OF FEVER

Fever is typically managed at home, so it is important to give guidance and instruction at well-child visits and review this information at subsequent visits. Written and video materials about fever management may be effective in increasing caregivers' knowledge. Parents can refer to the written instructions when needed (see Teaching Guidelines 37.1).

### Teaching Guidelines 37.1 FEVER MANAGEMENT

- Fever is a sign of illness, not a disease; it is the body's weapon to fight infection.
- Diurnal variation may allow temperature changes as much as 1°C (1.8°F) over a 24-hour period, peaking in the evening.
- Antipyretics are used if the child demonstrates discomfort. Always check correct doses before administration. Never give aspirin or aspirin-containing products to a child younger than 19 years with a fever due to the risk of Reye syndrome.

- In some children fever can be associated with a seizure or dehydration, but this will not lead to brain damage or death. Discuss the facts about febrile seizures (see Chapter 38 for further information on febrile seizures).
- Watch for the signs and symptoms of dehydration; it is important to provide oral rehydration by increasing fluid intake.
- Dress the child lightly and avoid warm, binding clothing or blankets.
- The use of sponging with tepid water is controversial; if used, encourage the parent to give an antipyretic prior to sponging. Ensure the sponging does not produce shivering (which causes the body to produce heat and maintain the elevated set point), and reinforce the importance of using tepid water, not cold water or alcohol. Instruct the parent to stop if the child experiences discomfort.
- Call the provider for:
  - Any child younger than 3 months of age who has a rectal temperature above 38°C (100.4°F)
  - Any child who is lethargic or listless, regardless of temperature
  - Fever lasting more than 3 to 5 days
  - Fever greater than 40.6°C (105°F)
  - Any child who is immunocompromised by illness, such as cancer or HIV, will need further evaluation and treatment.

The use of acetaminophen or ibuprofen to reduce fever in children has been shown to be safe and effective when the appropriate dose is administered at the appropriate interval (American Academy of Pediatrics, 2012). However, some studies have shown that ibuprofen is superior in reducing fever faster and lasts longer than acetaminophen (Walling, 2009).

Box 37.4 gives dosing recommendations for both medications.

#### BOX 37.4

##### DOSE RECOMMENDATIONS FOR ACETAMINOPHEN AND IBUPROFEN

Acetaminophen, 10 to 15 mg/kg/dose

- No more than every 4 hours
  - No more than five doses in a 24-hour period
- Ibuprofen, 5 to 10 mg/kg/dose
- Only children older than 6 months of age
  - No more than every 6 to 8 hours
  - No more than four doses in a 24-hour period

Adapted from Taketomo, C. K., Hodding, J. H., & Kraus, D. M. (2010). Lexi-comp's Drug Reference Handbook: Pediatric & Neonatal Dosage Handbook (18th ed.). Hudson, OH: Lexi-comp, Inc.

#### Take Note!

Never give aspirin to children to reduce fever, due to the risk of Reye syndrome.

#### CAUTIONS ABOUT ACETAMINOPHEN USE

Acetaminophen is widely used and accepted, but toxic reactions can be seen in children (American Academy of Pediatrics, 2009). Causes of acetaminophen toxicity include overdosing or incorrect dosing due to failure to read and understand the label instructions, use of an incorrect measuring device or concentration, and coadministration with an over-the-counter fixed-dose combination medication (the parent may not recognize that it has acetaminophen in it).

Another factor that may cause acetaminophen toxicity is the controversial, but common, practice of alternating acetaminophen and ibuprofen to help reduce fever. Studies of the use of alternating acetaminophen with ibuprofen have had conflicting results (Walling, 2009). This practice can result in overdose or improper administration. It can be hard for parents to keep track of the time each medication is due. Parents may confuse which medication is given every 4 hours and which is given every 6 hours. They may exceed the recommended daily doses or may confuse the strength or dosage of the medicines. See Evidence-Based Practice 37.1.

#### Managing Skin Rashes

Skin rashes accompany many infectious or communicable diseases. These rashes can be very uncomfortable and irritating for the child. Management often occurs at home, so it is important to educate parents on ways to relieve the discomfort and protect and maintain skin integrity. The physician may prescribe antipruritics, including oral medications or topical creams or ointments (see Drug Guide 37.1). Instruct parents on the importance of maintaining skin integrity to prevent infection or scarring. Teach parents to keep their child's fingernails short and hands clean. Explain the importance of discouraging scratching, and discuss distraction techniques they can use with the child. Cool compresses or cool baths can relieve itching. Encourage the child to press on rather than scratch the itchy area; this can relieve discomfort while maintaining skin integrity. Refer to Chapter 46 for more information on managing skin rashes.

**Based on your top three nursing diagnoses for Samuel, describe appropriate nursing interventions.**

**EVIDENCE-BASED PRACTICE 37.1****IS ALTERNATING ACETAMINOPHEN WITH IBUPROFEN MORE EFFECTIVE THAN IBUPROFEN ALONE?**

Fever is one of the most common health concerns seen in pediatrics. Alternating acetaminophen and ibuprofen for fever reduction is a common practice, but there has been limited evidence on its safety or efficacy. It may be a harmful practice due to combined toxicity and potential parental confusion in timing and dosing.

**STUDY**

This study was a randomized, double-blinded, placebo-controlled trial. It evaluated the antipyretic efficacy of alternating acetaminophen with ibuprofen versus acetaminophen with a placebo. It also evaluated the safety of the two regimens along with caretaker perception of efficacy. Study participants were healthy children ages 6 months to 6 years presenting to a medical center with the chief complaint of fever.

**Findings**

A significant difference was seen in fever reduction in the alternating group versus the acetaminophen alone

Adapted from Kramer, L.C., Richards, P.A., Thompson, A.M., Harper, D.P., & Fairchok, M.P. (2008). Alternating antipyretics: Antipyretic efficacy of acetaminophen versus acetaminophen alternated with ibuprofen in children. *Clinical Pediatrics*, 47(9), 907–912.

group at hours 4 and 5, but this difference diminished by hour 6. Administration, including dosing and interval, were undercontrolled conditions during this study; however, safety concerns remain. Parents, even without the confusion of alternating two medications, often over- or underdose these medications. No association of perception of efficacy by caregivers was found based on regimen used.

**Nursing Implications**

Although this study suggests improved fever reduction with alternating of acetaminophen and ibuprofen, safety concerns remain. Further research with larger sample sizes and longer follow-up are warranted. To alleviate some of the concerns that parents have with fever, nurses should consistently educate parents about why fever occurs and fever facts and myths.

**SEPSIS**

Sepsis is a systemic overresponse to infection resulting from bacteria (most common), fungi, viruses, or parasites. It can lead to septic shock, which results in hypotension, low blood flow, and multisystem organ failure. Septic shock is a medical emergency and children are usually admitted to an intensive care unit (see Chapter 53). The cause of sepsis may not be known, but common causative organisms in neonates include *Escherichia coli*, *Listeria monocytogenes*, group B *Streptococcus*, enteroviruses, and herpes simplex virus, and in older children include *Neisseria meningitidis*, *Streptococcus pneumoniae*, *Salmonella*, and *Staphylococcus aureus* (Nield & Kamat, 2011b). Sepsis can affect any age group but is more common in neonates and young infants (Santhanam & Tolan Jr., 2011). Neonates and young infants have a higher susceptibility due to their immature immune system, inability to localize infections, and lack of immunoglobulin M (IgM), which is necessary to protect against bacterial infections.

The prognosis for sepsis is variable and depends on the child's age and the cause of the sepsis. The mortality rate ranges from 9% to 35% (Santhanam & Tolan Jr., 2011). Neonates are at highest risk for a poor outcome. Due to this high mortality rate, when an ill-appearing febrile neonate presents, a full workup is indicated (Nield & Kamat, 2011b). Usually, admission to the hospital to rule out sepsis is the standard of practice.

**Pathophysiology**

Sepsis results in the systemic inflammatory response syndrome (SIRS) due to infection. The pathophysiology of sepsis is complex. It results from the effects of circulating bacterial products or toxins, mediated by cytokine release, occurring as a result of sustained bacteremia. The pathogens cause an overproduction of proinflammatory cytokines, previously termed endotoxins. These cytokines are responsible for the clinically observable effects of the sepsis. Impaired pulmonary, hepatic, or renal function may result from excessive cytokine release during the septic process.

**Therapeutic Management**

Therapeutic management of sepsis in infants, especially neonates, is more aggressive than for older children. Neonates and infants with sepsis or even suspected sepsis are treated in the hospital. The infant is admitted for close monitoring along with antibiotic therapy. Intravenous antibiotics are started immediately after the blood, urine, and cerebrospinal fluid cultures have been obtained. The length of therapy and the specific antibiotic used will be determined based on the source of the positive culture and the results of the culture and sensitivity. If final culture reports are negative and symptoms have subsided, antibiotics may be discontinued (usually after 72 hours of treatment). If the child is not responding to therapy and

symptoms worsen, sepsis may be progressing to shock. Management of the child with septic shock is usually done in the intensive care unit.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1264. Assessment findings pertinent to sepsis are discussed below.

### Health History

Elicit a description of the present illness and chief complaint. Signs of sepsis can vary with each child. Some common signs and symptoms reported during the health history might include:

- Child just does not look or act right
- Crying more than usual, inconsolable
- Fever
- Hypothermia (in neonates and those with severe disease)
- Lethargic and less interactive or playful
- Increased irritability
- Poor feeding or poor suck
- Rash (e.g., petechiae, ecchymosis, diffuse erythema)
- Difficulty breathing
- Nasal congestion
- Diarrhea
- Vomiting
- Decreased urine output
- Hypotonia
- Changes in mental status (confused, anxious, excited)
- Seizures
- Older child may complain of heart racing

Explore the child's current and past medical history for risk factors such as:

- Prematurity
- Lack of immunizations
- Immunocompromise
- Exposure to communicable pathogens

In neonates and young infants, seek pregnancy and labor risk factors such as:

- Premature rupture of membranes or prolonged rupture
- Difficult delivery
- Maternal infection or fever, including sexually transmitted infections
- Resuscitation and other invasive procedures
- Positive maternal group  $\beta$ -streptococcal vaginosis

Sepsis may occur in the hospitalized child. Assess for risk factors such as:

- Intensive care unit stay
- Presence of central line or other invasive lines or tubes
- Immunosuppression

### Take Note!

Listen to the parents' descriptions of the neonate's or infant's behavior and appearance, as well as changes they have observed. Many times they are the first to notice when their child is not acting right, even before clinical signs of infection are seen.

## Physical Examination

Perform a thorough physical examination of the infant or child with proven or suspected sepsis. Specific findings related to inspection and observation are noted below.

### INSPECTION AND OBSERVATION

Observe the child's general appearance, color, level of arousal, and hydration status. The child with sepsis may appear lethargic and pale and show signs of dehydration. In neonates and infants, observe the quality of their cry and reaction to parental stimulation, noting weak cry, lack of smile or facial expression, or lack of responsiveness. Inspect the skin for petechiae or other skin lesions. Petechiae may indicate a serious bacterial infection (often *N. meningitidis*), and other skin lesion patterns may help identify the cause of the fever. Observe respiratory effort and rate. The infant or child with sepsis may demonstrate tachypnea and increased work of breathing, such as nasal flaring, grunting, and retractions.

Assess vital signs, noting abnormalities. Note elevation in temperature or hypothermia in the young infant. Note tachypnea or tachycardia in the child or apnea or bradycardia in the infant. Document blood pressure. Hypotension, especially when accompanied by signs of poor perfusion, can be a sign of worsening sepsis with progression to shock (refer to Chapter 53).

## Laboratory and Diagnostic Tests

Symptoms of sepsis can be vague in infants. Therefore, laboratory tests play a crucial role in confirming or ruling out sepsis. Common laboratory and diagnostic studies ordered for the assessment of sepsis include:

- Complete blood count: WBC levels will be elevated; in severe cases they may be decreased (this is an ominous sign)
- C-reactive protein: elevated
- Blood culture: positive in septicemia, indicating bacteria is present in the blood
- Urine culture: may be positive, indicating presence of bacteria in the urine
- Cerebrospinal fluid analysis: may reveal increased WBCs and protein and low glucose
- Stool culture: may be positive for bacteria or other infectious organisms
- Culture of tubes, catheters, or shunts suspected to be infected: the fluid inside these tubes may be tested for bacteria

- Chest radiograph: may reveal signs of pneumonia such as hyperinflation and patchy areas of atelectasis or infiltration

## Nursing Management

Monitor the infant or child closely for changes in condition, especially the development of shock. Administer antibiotics as ordered. Refer to Nursing Care Plan 37.1 for nursing diagnoses and related interventions. In addition to these interventions, it is important to prevent infection and provide education to the child and family.

### Preventing Infection

Sepsis is a potentially life-threatening illness, and prevention is important. Hand washing is the most effective intervention against nosocomial infection. Nurses play a key role in minimizing environmental sources by cleaning equipment, disposing of soiled linens and dressings properly, and adhering to proper aseptic technique with all invasive procedures. Follow your institution's policies and use evidence-based practice guidelines for interventions such as invasive line dressing changes and intravenous tubing changes to reduce the risk of infection. Encourage immunization as recommended. To reduce group B streptococcus infection in neonates, screen pregnant woman. If the results are positive, administer intrapartum antibiotics.

#### Take Note!

There has been a dramatic reduction in invasive *Haemophilus influenzae* type B diseases since the widespread use of the Hib vaccine (Centers for Disease Control and Prevention, 2008).

### Educating the Child and Family

Early recognition of the signs of sepsis is essential in preventing morbidity and mortality. Educate parents about the significance of fever, especially in neonates and infants younger than 3 months old. Instruct parents to contact their physician or nurse practitioner if their infant or neonate has a fever. A physician or nurse practitioner should see any child with a fever accompanied by lethargy, poor responsiveness, or lack of facial expressions. Signs and symptoms of sepsis can be vague and vary from child to child. Encourage parents to contact their physician or nurse practitioner if they feel their febrile child is “just not acting right.”

## BACTERIAL INFECTIONS

Bacteria are one-celled organisms that can live, grow, and reproduce. They exist everywhere. Most are completely harmless and some are very useful. Others can

lead to disease either because they are in the wrong place in the body or they are designed to invade and cause disease in humans and animals. Children are at a high risk of developing bacterial infections, which can result in life-threatening illness. Fortunately, many bacterial diseases, such as diphtheria, pertussis, and tetanus, can be prevented by immunization (see Chapter 31 for more information on immunizations).

### Community-Acquired Methicillin-Resistant *Staphylococcus Aureus*

Community-acquired methicillin-resistant *Staphylococcus aureus* (CAMRSA) is a staphylococcal infection that is resistant to certain antibiotics. Methicillin-resistant *S. aureus* (MRSA) in the community is increasing in occurrence throughout the United States (Centers for Disease Control and Prevention, 2011a). These infections range from minor skin rashes to abscesses to serious, complicated, life-threatening infections. Serious and invasive infections, such as sepsis, necrotizing pneumonia, and osteomyelitis, often are secondary to a skin or soft tissue infection. The CDC and World Health Organization (WHO) have recognized MRSA as a major health threat (Hinckley & Allen, 2008). Prior to the early 1990s, MRSA was mainly considered a hospital-acquired infection. However, health care professionals began to identify MRSA in the community setting in seemingly healthy individuals, including children (Rose & Senita, 2009).

Transmission occurs through direct person-to-person contact, respiratory droplets, blood, or sharing personal items, such as hair brushes, towels, and sports equipment, and touching surfaces or items contaminated with MRSA. Clusters of MRSA have been found in day care centers and among athletic teams. Staphylococci are resistant to heat and drying and can be found on environmental surfaces months after contamination. Intact skin and mucous membranes, along with proper hand hygiene, are the best barriers to MRSA.

## Nursing Assessment

In the child, skin and tissue infections are common infections caused by CAMRSA. Symptoms include a bump or skin area that is red, swollen, painful, and warm to touch. It may also include fever, fluctuance, and purulent drainage. The lesion may have appeared suddenly and be red and raised, resembling an insect bite. Necrotic areas may develop. Abscesses, especially abscessed hair follicles, and pimples are common presentations. Assessment needs to include a thorough past medical history to determine history of recurrent skin infections with or without complete resolution along with assessment for risk factors. Risk factors include playing contact sports; openings in the skin, such as abrasions and cuts; contact

with contaminated items and surfaces; poor hygiene; and crowded living conditions (Hinckley & Allen, 2008).

Diagnosis is determined through culture. Diagnostic tests include incision and drainage (I&D), aspiration of the abscess, and culturing the fluid or tissue. Antimicrobial susceptibility along with culture is critical.

## Nursing Management

Care of the child with CAMRSA will typically occur at home. Antibiotics with microbial susceptibility will often be prescribed. Comprehensive wound care, which may include I&D, may occur. Follow-up for reassessment is key. Child and family education is crucial. Include the following in the teaching plan:

- Educate the family on the importance of taking the antibiotics as directed and finishing all the medicine. Emphasize that this will help slow the creation of antimicrobial-resistant organisms.
- Teach the child and parents proper hand hygiene and hand washing.
- Discourage family members from sharing personal items.
- Explain the risk factors involved in transmission.
- Explain the importance of keeping cuts and scrapes cleaned and covered.
- Review the signs of MRSA and emphasize the importance of early recognition and treatment.

### Scarlet Fever

Scarlet fever is an infection resulting from group A streptococci. It usually occurs with a group A streptococci throat infection (i.e., strep throat). However, in the case of scarlet fever, the bacteria produce a toxin that causes a rash. Not all children with a group A streptococci infection will develop the rash of scarlet fever. Only children who are infected with streptococci that produce pyrogenic exotoxins and do not have antitoxin antibodies, making them sensitive to the bacterial toxin, will develop scarlet fever (Gerber, 2011). Scarlet fever is usually seen in children younger than 18 years of age, with the peak incidence between the ages of 4 and 8 years (Balentine & Lombardi, 2010). It is rare in children younger than 2 years old (Balentine & Lombardi, 2010). Transmission is through droplets and follows contact with respiratory tract secretions. Transmission is facilitated by the type of close contact that occurs in schools and child care centers. Food-borne outbreaks have occurred due to human contamination of food. After exposure, the incubation period is 2 to 5 days (Gerber, 2011). Communicability is highest during acute infection, and the child is no longer contagious 24 hours after the initiation of appropriate antimicrobial therapy (Gerber, 2011).

There has been a dramatic decrease in the mortality rate from scarlet fever due to antibiotic use, but complications such as rheumatic fever and glomerulonephritis can still occur (Balentine, & Lombardi, 2010; Gerber, 2011).

## Nursing Assessment

Symptoms of scarlet fever begin abruptly. The health history may reveal a fever greater than 101°F, chills, body aches, loss of appetite, nausea, and vomiting. Inspect the pharynx, which is usually very red and swollen. The tonsils may have yellow or white specks of pus, and cervical lymph nodes may be swollen. Inspect the skin for the most striking symptom of scarlet fever, which is an erythematous rash appearing on the face, trunk, and extremities. The rash is typically absent from the palms and soles of the feet. It looks like a sunburn but feels like sandpaper (Fig. 37.1A). The rash lasts approximately 5 days and is followed by desquamation, typically on the fingers and toes. Early in the illness the tongue develops a thick coat with a strawberry appearance. The tongue will later lose the coating and become bright red (see Fig. 37.1B).

Diagnosis is made by identification of group A streptococcus on throat culture. Several rapid tests for group A streptococcal pharyngitis are available. The accuracy of these tests depends on the quality of the specimen. It is important that the secretions obtained are pharyngeal or tonsillar (see Common Medical Treatments 37.1 for more information on throat cultures).

## Nursing Management

Children with scarlet fever are usually cared for at home. Penicillin V is the antibiotic of choice. In those sensitive to penicillin, erythromycin may be used. Educate the family on the importance of taking the antibiotic as directed and finishing all the medicine.

Encourage fluid intake to maintain adequate hydration due to fever. Teach parents ways to provide comfort for the child. A cool mist humidifier can soothe the child's sore throat. Soft foods, warm liquids like soup, or cold foods like Popsicles may also be helpful. If the child is hospitalized, droplet precautions, along with standard precautions, are necessary.

### Diphtheria

Diphtheria is caused by infection with *Corynebacterium diphtheriae* and may affect the nose, larynx, tonsils, or pharynx. Tonsillar and pharyngeal infections are the most common and will be the focus of this discussion. A pseudomembrane forms over the pharynx, uvula, tonsils, and soft palate (Fig. 37.2). The neck becomes edematous

FIGURE 37.1 (A) Rash of scarlet fever. (B) Strawberry tongue.

and lymphadenopathy develops. The pseudomembrane causes airway obstruction and suffocation. Diphtheria is very rare in the United States but continues to infect people worldwide due to lack of routine immunization (Mayo Clinic Staff, 2011). Risk factors include children and adults who are unimmunized or underimmunized, living in crowded or unsanitary living conditions, having a compromised immune system, and traveling to developing countries where diphtheria remains endemic (Mayo Clinic Staff, 2011). Routine infant immunization can prevent the disease. Therapeutic management

involves administration of antibiotics and antitoxin, as well as airway management.

### Nursing Assessment

Children at risk for diphtheria are those who are unimmunized. Note history of sore throat and fever, usually less than 38.9°C. As the pseudomembrane forms, swallowing becomes difficult and signs of airway obstruction become apparent. A specimen of the membrane may be cultured for *C. diphtheriae*.

### Nursing Management

Close observation of respiratory status is of utmost importance. Administration of antibiotics and the antitoxin is critical to encourage sloughing of the membrane. The child should remain on strict droplet precautions in addition to standard precautions and should maintain bed rest.

FIGURE 37.2 In diphtheria a pseudomembrane forms over the pharynx, uvula, tonsils, and soft palate.

### Pertussis

Pertussis is an acute respiratory disorder characterized by paroxysmal cough (whooping cough) and copious secretions. The highest incidence is seen in children younger than 1 year of age, and children younger than 6 months of age are at greatest risk for severe disease and death (Centers for Disease Control and Prevention, 2012c). The disease is caused by *Bordetella pertussis*. The incubation period is 6 to 21 days, usually 7 to 10 days. Pertussis usually starts with 7 to 10 days of cold symptoms. The paroxysmal coughing spells then begin

and can last 1 to 4 weeks. Convalescence occurs over the course of several weeks to months. Initially, immunization decreased the incidence of pertussis, but since the 1980s there has been a gradual increase (Centers for Disease Control and Prevention, 2011b). In recent years, there has been an increase in pertussis cases and reports of localized outbreaks, especially in adolescents and adults (Centers for Disease Control and Prevention, 2011b). Therefore, children older than 11 years of age and adults are now required to get one immunization booster of Tdap (tetanus, diphtheria, and pertussis) instead of Td (tetanus and diphtheria) (Centers for Disease Control and Prevention, 2011b, 2011c). Over the last several years an increased incidence of disease in children 7 to 10 years has been reported. The Advisory Committee on Immunization Practices (ACIP) revised their recommendations and currently recommends the use of Tdap in undervaccinated children aged 7 to 10 years (Centers for Disease Control and Prevention, 2011c). Infants and young children continue to be required to get five doses of DTaP (diphtheria, tetanus, and pertussis) at 2 months, 4 months, 6 months, 15 to 18 months, and 4 to 6 years. Complications of pertussis include hypoxia, apnea, pneumonia, seizures, encephalopathy, and death.

## Therapeutic Management

Therapeutic management of pertussis focuses on eradicating the bacterial infection and providing respiratory support. CDC guidelines recommend antimicrobial treatment (Centers for Disease Control and Prevention, 2011b). For infants older than 1 month of age, macrolide drugs, including erythromycin, clarithromycin, and azithromycin, are the drugs of choice (Long, 2011; Centers for Disease Control and Prevention, 2005). For younger infants, azithromycin should be used and erythromycin and clarithromycin avoided (Long, 2011; Centers for Disease Control and Prevention, 2005). An alternative to macrolides in children older than 2 months is trimethoprim-sulfamethoxazole (TMP-SMZ) (Long, 2011; Centers for Disease Control and Prevention, 2005). A course of macrolide antibiotics is also recommended to treat symptomatic close contacts within 3 weeks of exposure (Long, 2011; Centers for Disease Control and Prevention, 2005).

## Nursing Assessment

The most important risk factor for the development of pertussis is lack of immunization. The history may reveal cold and cough symptoms, progressing to paroxysmal coughing spells. During the paroxysms, the child might cough 10 to 30 times in a row, followed by a whooping sound. This might be accompanied by redness in the face, progressive cyanosis, and protrusion of the tongue. Saliva, mucus, and tears flow from the mouth, nose, and

eyes. Between the paroxysmal episodes, the child might rest well and appear relatively unaffected. Auscultate the lungs to assess air exchange. The diagnosis may be confirmed by a variety of laboratory tests accompanied by clinical history. Culture is considered the gold standard, but polymerase chain reaction (PCR) is used by some laboratories due to its increased sensitivity and faster results (Centers for Disease Control and Prevention, 2011b).

## Nursing Management

Nursing care will focus on providing a high-humidity environment and frequent suctioning to mobilize secretions. Administration of ordered antibiotics. Observe for signs of airway obstruction. Encourage fluids to keep secretions thin and maintain adequate hydration. Offer reassurance to the child and family; the coughing episodes can be very frightening. Droplet precautions along with standard precautions are necessary for the hospitalized child.

### Tetanus

Tetanus is an acute, often fatal neurologic disease caused by the toxins produced by *Clostridium tetani*. Tetanus is rare in the United States but continues to be significant worldwide due to lack of routine immunization (Arnon, 2011). It is characterized by increased muscle tone and spasm. *C. tetani* spores can live anywhere but are found most commonly in soil, dust, and feces from humans or animals, such as sheep, cattle, chickens, dogs, cats, and rats. The spores can enter the body through a wound that is contaminated, through a burn, or by injecting contaminated street drugs. Once it enters the body, an anaerobic environment allows it to multiply and a poisonous toxin is released.

There are four forms of tetanus. Neonatal tetanus is the most common worldwide, affecting newborns born to an unimmunized mother in the first week of life secondary to an infected umbilical stump or unsterile surgical technique during circumcision (Arnon, 2011). Most women in the United States have been immunized and will pass the immunity to their fetus. Along with proper hygiene during delivery and adequate cord care, this makes this type rare in the United States, but in underdeveloped countries it remains a significant problem (Centers for Disease Control and Prevention, 2011b). The second form is local tetanus. This rare form is characterized by local muscle spasms within the area of the wound. The third type is cephalic tetanus, which is associated with recurrent otitis media or head trauma. It is also rare and affects the cranial nerves, especially facial nerves. Generalized tetanus is the most common form and results in spasms that progress in a descending fashion beginning at the jaw. The most profoundly affected muscles are those of the neck and back.

In the United States the fatality rate associated with tetanus has declined and cases are rare, but 1 in 10 cases will result in death (Centers for Disease Control and Prevention, 2011i). The general incubation period is 3 to 21 days, with an average of 8 days. Recovery can be long and difficult, and children with tetanus may have to spend several weeks in the hospital in an intensive care setting. It has been suggested that the shorter the incubation period, the higher the risk of more severe illness and poorer prognosis. Complications associated with tetanus include breathing problems, fractures, elevated blood pressure, dysrhythmias, clotting in the blood vessels of the lung, pneumonia, and coma.

## Therapeutic Management

Therapeutic management is directed toward supporting respiratory and cardiovascular function. Tetanus immunoglobulin may be given as well as the tetanus vaccine. Removal of the offending organism, by débridement of the wound, may occur, and intravenous antibiotics such as metronidazole may be initiated. In severe cases, the child may require intensive nursing care with mechanical ventilation.

## Nursing Assessment

Note history of initial signs such as headache, spasms, crankiness, and cramping of the jaw (lockjaw), which are followed by difficulty swallowing and a stiff neck. Tetanus progresses in a descending fashion to other muscle groups, causing spasms of the neck, arms, legs, and stomach; seizures may result. Document the presence of fever along with an elevated blood pressure and tachycardia. Opisthotonos may be noted due to severe spasms of the neck and back. The spasms or muscle contractions in children may be strong enough to result in fractures. The diagnosis of tetanus is based on the clinical findings of the history and physical examination.

## Nursing Management

Nursing management focuses on observing for signs of respiratory distress. Provide a quiet environment with reduced external stimuli to decrease the incidence of spasms. Appropriately manage pain. Encourage adequate nutrition and hydration. Administer sedatives and muscle relaxants as ordered to reduce the pain associated with the muscle spasms and to prevent seizures. Encourage the parents to stay with their child. The child's mental status is unaffected by the disease, and therefore he or she is aware of what is happening. Efforts need to be made to reduce the child's anxiety and to provide reassuring, sympathetic care to the child and family. Tetanus is

not contagious from person to person; therefore, standard precautions are sufficient.

Tetanus is a preventable but potentially fatal disease. Education is essential regarding the importance of receiving this routine immunization (refer to Chapter 31 for immunization schedule) as well as a booster every 10 years. Instructing parents on proper wound care can also help prevent tetanus. All wounds should be cleaned thoroughly and a proper antiseptic used. If a wound is deep and contamination is suspected, the child should be seen by a physician or nurse practitioner. If it has been more than 5 years since the last tetanus dose, a booster may be needed. This can help to neutralize the poison and prevent it from entering the nervous system.

## VIRAL INFECTIONS

Viruses are very small particles that infect cells. They cannot multiply on their own and require a living host, such as humans, animals, or plants. They can reproduce only by invading and taking over the host cells. Young children are highly sensitive to viruses; their resistance is low and exposure is high. Viruses are hard to destroy without damaging or killing the living cells they infect. Therefore, drugs are not used to control them. However, many viral diseases can be prevented by immunization, such as measles, rubella, varicella, mumps, and poliomyelitis (see Chapter 31 for more information on immunizations).

### Viral Exanthems

Many viral infections of the skin in childhood are called viral exanthems. **Exanthem** means rash or skin eruption. Viral exanthems of childhood often present with a distinct rash pattern that assists in the diagnosis of the virus. Table 37.4 discusses common childhood exanthems. Immunizations have led to a decrease in the incidence of certain viral exanthems, such as measles, rubella, and varicella.

Typically, children with viral exanthems are cared for at home, but there are times when a child may be hospitalized or may develop the disease while being hospitalized. Appropriate transmission-based precautions must be taken. Therapeutic management of the viral exanthems focuses on fever management and relief of discomfort.

## Nursing Assessment

Obtain the history of the present illness, noting the onset of rash in relation to the onset of fever. Note accompanying symptoms such as respiratory complaints. Document known exposure to childhood diseases. Note immunization status. Inspect the skin for rash, noting the distribution, type, and extent of lesions. Table 37.4 describes the rash as well as accompanying symptoms for each of the viral exanthems.

Disease	Clinical Manifestations	Management/Complications	Nursing Implications
<p><b>Rubella (German measles)</b></p> <ul style="list-style-type: none"> <li>• Caused by rubella virus</li> <li>• Transmitted by direct or indirect contact with droplets, primarily by nasopharyngeal secretions, but also in blood, stool, and urine. Also transmitted from mother to fetus</li> <li>• Peak incidence during late winter and early spring</li> <li>• Incubation period: 14 to 21 days (usually 16 to 18)</li> <li>• Communicable 5 days before to 6 days after onset of rash</li> </ul>	<ul style="list-style-type: none"> <li>• Lymphadenopathy (retroauricular, posterior cervical, postoccipital) 24 hours before the onset of the rash; lasting up to 1 week</li> <li>• Rash begins on face and spreads quickly down the neck, trunk, and extremities; disappears in same order it spread, usually by third day. On the second day the rash may appear pinpoint. Desquamation is minimal.</li> <li>• Mild pruritus</li> <li>• Polyarthralgia and polyarthrits (rare in children but common in adolescents)</li> </ul>	<ul style="list-style-type: none"> <li>• Usually mild and self-limiting</li> <li>• Treatment is mainly supportive.</li> <li>• Complications: encephalitis and thrombocytopenia (rare)</li> <li>• Maternal rubella during pregnancy can result in miscarriage, fetal death, or congenital malformations.</li> </ul>	<ul style="list-style-type: none"> <li>• Comfort measures such as antipyretics, antipruritics, and analgesics for joint pain</li> <li>• Droplet precautions for the duration of the illness in the hospitalized child</li> <li>• Avoid exposure to pregnant women.</li> </ul>

## COMMON VIRAL EXANTHEMS OF CHILDHOOD (continued)

Disease	Clinical Manifestations	Management/Complications	Nursing Implications
<p><b>Varicella zoster (chickenpox)</b></p> <ul style="list-style-type: none"> <li>Caused by varicella zoster virus, human herpes virus 3</li> <li>Highly contagious. Transmitted by direct contact with infected persons' nasopharyngeal secretions or via air-borne spread, to a lesser degree by contact with unscabbed lesions. Also transmitted from mother to fetus</li> <li>Peak incidence late fall, winter, and spring</li> <li>Incubation period: 10 to 21 days, usually 14 to 16</li> <li>Communicable 1 to 2 days before onset of rash until all vesicles have crusted over (about 3 to 7 days after onset of rash)</li> </ul>	<ul style="list-style-type: none"> <li>Prodromal symptoms (fever, malaise, anorexia, headache, mild abdominal pain) may be present 24 to 48 hours before the onset of the rash. In children, rash is often the first sign of disease.</li> <li>Lesions often appear first on scalp, face, trunk, then extremities; initially intensely pruritic erythematous macules that evolve to papules and then form clear, fluid-filled vesicles</li> <li>Vesicles eventually erupt, and then lesions scab and crust. A variety of lesions are present at one time.</li> <li>More severe in adolescents and adults than in young children</li> </ul>	<ul style="list-style-type: none"> <li>Usually self-limiting; treatment is mainly supportive: fever reduction, antipruritics, and skin care to prevent infection of lesions.</li> <li>Antiviral therapy and varicella zoster immune globulin may be used in those considered to be at high risk (immunocompromised, pregnant women, and newborns exposed to maternal varicella). Routine antiviral therapy is not recommended for the treatment of uncomplicated varicella infection in otherwise healthy children.</li> <li>Complications: bacterial superinfection of skin lesions, thrombocytopenia, arthritis, hepatitis, cerebellar ataxia, encephalitis, meningitis, pneumonia, glomerulonephritis, congenital infection, and life-threatening perinatal infection</li> <li>Lifelong latent infection occurs; reactivation results in herpes zoster (shingles), uncommon in childhood</li> </ul>	<ul style="list-style-type: none"> <li>Comfort measures, such as antipyretics and antipruritics</li> <li>Air-borne and contact precautions in the hospitalized child for a minimum of 5 days after onset of rash and as long as vesicular lesions are present</li> <li>For those with exposure to susceptible persons, air-borne and contact precautions, from 8 to 21 days after exposure</li> <li>Children may return to school or child care once lesions have crusted.</li> </ul>
<p><b>Rubeola. (CDC. [1963]. Obtained at <a href="http://phil.cdc.gov/phil/details.asp">http://phil.cdc.gov/phil/details.asp</a>)</b></p>			

### **Exanthem subitum (roseola infantum or sixth disease)**

- Caused by human herpes virus 6 (HHV-6); less frequently human herpes virus 7 (HHV-7)
- Transmission mode: little is known but suspected to be from saliva of infected person and enters the host through the oral, nasal, or conjunctival mucosa
- Peak incidence age 6 to 9 months
- Incubation period: 5 to 15 days, average of 10 days
- Communicability is unknown, but most likely contagious during febrile stage

Varicella. (CDC/Dr. John Noble, Jr. [1968]. Obtained at <http://phil.cdc.gov/phil/details.asp>)

- Prodromal phase: usually asymptomatic but may include upper respiratory signs
- Clinical illness: high fever ranging from 37.9°C to 40°C (101°C to 106°F) for 3 to 5 days; resolves abruptly; rash appears 12 to 24 hours later, lasting about 1 to 3 days. Rash is pinkish red, flat or raised spots that blanch when touched

- Course is generally benign.
- In children who are uncomfortable or irritable or have a history of febrile seizures, antipyretics may be warranted.
- Complications: HSV-6 may be responsible for some febrile seizures, encephalitis, and meningoencephalitis (rare).

- Comfort measures, such as antipyretics, antipruritics
- Standard precautions are sufficient in the hospitalized child.

(continued)

TABLE 37.4

## COMMON VIRAL EXANTHEMS OF CHILDHOOD (continued)

Disease	Clinical Manifestations	Management/Complications	Nursing Implications
<p><b>Erythema infectiosum (fifth disease)</b></p> <ul style="list-style-type: none"> <li>Caused by human parvovirus B19</li> <li>Transmitted by large droplet spread from nasopharyngeal viral shedding or percutaneous exposure to blood and blood products. Also transmitted from mother to fetus</li> <li>Peak incidence late winter and early spring</li> <li>Incubation period: 4 to 28 days, average 16 to 17 days</li> <li>Communicability is uncertain, but most children are no longer infectious by the time the rash appears and diagnosis is made, so isolation or exclusion from school, once the child is diagnosed, is unnecessary (those with aplastic crisis may be communicable up to 1 week after onset of symptoms and those who are immunosuppressed with chronic infection and severe anemia may be communicable for months to years).</li> </ul>	<ul style="list-style-type: none"> <li>Prodromal phase: mild symptoms, low-grade fever, headache, mild upper respiratory infection</li> <li>Characteristic rash occurs in three stages:               <ul style="list-style-type: none"> <li>Begins with erythematous flushing often described as “slapped-cheek” appearance, often with circumoral pallor</li> <li>Spreads to trunk</li> <li>Moves peripherally, appearing as a maculopapular, lace-like appearance; often pruritic</li> <li>Palms and soles are usually spared. Rash fluctuates in intensity and will disappear and reappear with environmental changes such as exposure to sunlight.</li> </ul> </li> <li>Resolves spontaneously over 1 to 3 weeks</li> <li>Children with preexisting anemias may develop aplastic crisis (will have fever, malaise, myalgia, but usually no rash).</li> </ul>	<ul style="list-style-type: none"> <li>Usually benign and self-limited; supportive treatment is all that is needed.</li> <li>Blood transfusion may be necessary in children with aplastic crisis.</li> <li>Complications: arthritis and arthralgia</li> <li>May result in fetal loss, hydrops fetalis in pregnant woman</li> </ul>	<ul style="list-style-type: none"> <li>Comfort measures, such as antipyretics, antipruritics</li> <li>Droplet precautions are required in the hospitalized child.</li> <li>Inform pregnant women (including health care workers) of the potential risks to the fetus and preventive measures to decrease these risks (strict infection control practices, not caring for those likely to be contagious). The CDC does not recommend routine exclusion from a workplace where an outbreak is occurring.</li> </ul>

Exanthem subitum (roseola infantum).

**Hand, foot, and mouth disease, or herpangina** (if only mouth involvement)

- Caused by viruses belonging to enterovirus genus. Coxsackie A viruses (especially A16) is the most common. Transmitted by direct contact with infected fecal, oral secretions; spread mostly through saliva
- Peak incidence during spring and summer, particularly in children who wear diapers (1- to 4-year-olds)
- Incubation period: 3 to 6 days
- Communicable from time of infection until fever resolves; virus is shed for several weeks after the infection begins.
- High fever usually occurs first.
- Vesicles on tongue and oral mucosa erode to shallow ulcers; vesicles on hands and feet are football shaped, with erythematous rims.
- Extensive mouth lesions may lead to anorexia, dehydration, and drooling.
- Usually mild and self-limiting, resolving within 1 week
- Treatment is mainly supportive.
- Complications: dehydration, meningitis, encephalitis, and pulmonary edema
- Standard precautions and good hand hygiene are necessary.
- Encourage oral fluids of preference, popsicles.
- Provide analgesics as needed.

**Erythema infectiosum (fifth disease).**

## Nursing Management

Nursing management of viral exanthems focuses on fever reduction, relief of discomfort, and protection of skin integrity. Encourage hydration. Administer antipyretics and antipruritics as needed (refer to Drug Guide 37.1). Nonpharmacologic interventions to reduce fever, such as tepid sponging and cool compresses, may be used. Refer to Nursing Care Plan 37.1 for additional information; care should be individualized based on the child's and family's response to the illness.

### Take Note!

Trim the child's fingernails or cover hands with mitts, gloves, or socks (which work well with younger infants and children) if the rash itches to help prevent breaks in the skin, which can lead to discomfort and infection.

## Mumps

Mumps, a contagious disease caused by Paramyxovirus, is characterized by fever and parotitis (inflammation and swelling of the parotid gland). Mumps is spread via contact with infected droplets. Infected individuals are contagious for 1 to 7 days prior to onset of symptoms and for 7 to 9 days after parotid swelling begins. About 50% of all infected postpubertal boys also develop orchitis (inflammation of the testicle) (Centers for Disease Control and Prevention, 2011b). Orchitis in prepubertal males is rare (Mason, 2011c). This may lead to some degree of testicular atrophy, but rarely sterility. In about 5% of females oophoritis (ovarian inflammation) occurs with no relationship to infertility (Centers for Disease Control and Prevention, 2011b). Complications of mumps include meningitis with or without encephalitis with seizures, pancreatitis, and auditory neuritis, which can result in deafness. Therapeutic management is supportive.

Since the recommendation of the two-dose MMR (measles, mumps, rubella) vaccine, the incidence of mumps has declined and made mumps a rare disease seen in the United States (Centers for Disease Control and Prevention, 2011b). The American Academy of Pediatrics (AAP) and the ACIP recommends immunization against mumps for all children (Centers for Disease Control and Prevention, 2012d). Current recommendations include first mumps immunization between 12 and 15 months of age, followed by a second vaccine between 4 and 6 years of age (Centers for Disease Control and Prevention, 2010g). According to the CDC (2010), one dose of MMR prevents between 73% and 91% of cases and two doses prevent approximately 79% to 95% of cases (see Chapter 31 for information on mumps vaccination).

FIGURE 37.3 Parotitis associated with mumps.

## Nursing Assessment

Note history of exposure to infected individuals as well as immunization status. Determine history of low-grade fever and onset and progression of parotid swelling. History may also include malaise, anorexia, headache, and abdominal pain. The parotid swelling is easily observed as swelling of the neck either bilaterally or unilaterally (Fig. 37.3). In boys, note orchitis. The diagnosis is usually based on the history and clinical presentation, but serum may be tested for the presence of mumps IgG or IgM antibody.

## Nursing Management

Nursing management of mumps is primarily supportive. Acetaminophen or ibuprofen is used for fever management, and occasionally narcotic analgesics are required for pain management. Oral fluids are encouraged to prevent dehydration. If orchitis is present, ice packs to the testicles and gentle testicular support may be helpful. Hospitalized children should be confined to respiratory isolation to prevent spread of the disease. Infected children are considered no longer contagious 9 days following onset of parotid swelling (Centers for Disease Control and Prevention, 2011b).

### Take Note!

In recent years mumps outbreaks have occurred, mainly in settings where prolonged close contact with other people occurs, such as college campuses and camps. The mumps vaccine is not 100% effective, and mumps infection can occur in vaccinated individuals. During an outbreak it is essential to define the population at risk and transmission

setting, identify and isolate suspected cases, and identify and vaccinate susceptible individuals (Centers for Disease Control and Prevention, 2010).

## ZOOBOTIC INFECTIONS

Zoonotic infections are diseases caused by infectious agents that are transmitted directly or indirectly from animals to humans. Zoonotic infections are responsible for about 75% of emerging infectious diseases, with approximately 60% of all human pathogens originating from animals (Centers for Disease Prevention and Control, 2011j). Two infections are covered below. Refer to Table 37.5 for other zoonotic infections.

### Cat Scratch Disease

Cat scratch disease is a relatively common and occasionally serious disease caused by the bacteria *Bartonella henselae*. It occurs in both children and adults but is more common in children (Klein, 2009). Cats can carry the bacteria in their saliva. In 90% of cases the child has had a recent interaction with cats and often kittens (Klein, 2009). No evidence exists to support person-to-person transmission (Klein, 2009). *B. henselae* is transmitted between cats via the cat flea. The incubation period is 7 to 12 days, with lymphadenopathy appearing in 5 to 50 days. Therapeutic management is supportive and is aimed at management of symptoms. The disease itself is usually self-limited, resolving on its own in 2 to 4 months. If lymphadenopathy persists or if the child is immunocompromised, antibiotics may be needed. Painful, swollen nodes may be treated with needle aspiration to provide symptom relief.

### Nursing Assessment

Note history of headaches, fever, anorexia, and fatigue. The history may also include interaction or rough play with cats or kittens, resulting in a scratch. Document the temperature, noting fever. Palpate for enlarged lymph nodes, noting their location. A skin papule or pustule may be present or reported at this site of the bite or scratch. Diagnostic tests are available to detect serum antibodies to antigens of *Bartonella* species.

### Nursing Management

Administer antibiotics if ordered. No transmission-based isolation is required; standard precautions are sufficient. Educate the child and family about prevention and control measures. Teach children to avoid rough play with cats and kittens. Teach parents and children to immediately wash any bites or scratches with soap and running water. Explain that cats should never lick open wounds on the child. Control of fleas in cats is important to prevent the spread of *B. henselae*.

### Rabies

Rabies is a preventable viral infection of the central nervous system. It is transmitted to other animals and humans through close contact with the saliva of a rabid animal, usually by a bite. The number of cases of rabies has steadily declined in the United States (Immunization Action Coalition, 2010). It is rare in the United States and Western Europe due to routine vaccination of domestic animals, such as dogs, and the availability of effective postexposure prophylaxis. Now most cases of rabies in these areas are due to wild animals such as raccoons, skunks, bats, and foxes (Immunization Action Coalition, 2010). Rabies continues to be a major health problem in other parts of the world, especially in areas where dogs are not controlled.

Most cases of rabies occur in children younger than 15 years of age, and most human deaths occur in Asia and Africa (World Health Organization, 2010). Children have an increased susceptibility to rabies due to their fearlessness around animals, eagerness to play with animals, shorter stature, and inability to protect themselves. The incubation period for rabies is extremely variable. Typically it is several weeks to months but can range from days to years (Immunization Action Coalition, 2010). The incubation period tends to be shorter in children. Once symptoms of rabies have developed, the prognosis is poor. Death usually occurs within days of the onset of symptoms. Prevention is of paramount importance, and eliminating infection in animal vectors is essential. Successful animal vaccination and animal control campaigns in the United States have led to a very low rate of human rabies cases. Rabies among dogs in the United States has been virtually eliminated (Immunization Action Coalition, 2010). Recently, rabies transmitted from other animals, especially raccoons and bats, has become a cause for concern (Immunization Action Coalition, 2010).

It is important to contact the local health department whenever there is an exposure, or suspected exposure, to rabies. Several factors need to be considered when deciding to provide postexposure prophylaxis, such as local epidemiology, type of animal involved, availability of the responsible animal for testing or quarantine, and the circumstances of the exposure, such as a provoked versus an unprovoked attack. In a previously unvaccinated child, postexposure prophylaxis should begin with a thorough cleansing of all wounds with soap and water or a virucidal agent, such as povidone-iodine solution. In the United States, concurrent use of passive and active immunoprophylaxis is then recommended. It consists of a regimen of one dose of immune globulin and four doses of human rabies vaccine. Rabies immune globulin and the first dose of rabies vaccine should be given as soon as possible after exposure, ideally within 24 hours. Additional doses of rabies vaccine should be given on days 3, 7, and 14 after the first vaccination. Rabies immune globulin is infiltrated into and around

TABLE 37.5

## OTHER ZOOBOTIC AND VECTOR-BORNE ILLNESSES

Disease	Causative Organism	Geographic Distribution	Vector of Transmission	Manifestations
Rat bite fever	<i>Streptobacillus moniliformis</i> <i>Spirillum minus</i>	Throughout United States Asia and Africa	Bite or scratch from infected rat, after handling a rat, or ingestion of food or water contaminated with rat excreta Historically found mostly in wild or laboratory rats but pet rats have been a source especially affecting young children	Abrupt fever, chills, headache, and myalgias 2 to 10 days after infection 2 to 4 days after onset of fever, maculopapular rash develops, mainly on palms and soles, that may evolve into petechiae, purpura, and vesicles.
<i>Escherichia coli</i> O157:H7	<i>E. coli</i>	Worldwide	Ingestion of contaminated food or water or fecal–oral spread from an infected animal (children who touched animals at a farm, fair, or petting zoo)	Symptoms range from asymptomatic infection to mild diarrhea to hemorrhagic colitis Often visible blood is present in stool of children with diarrhea Complaints of abdominal pain and vomiting, fever is usually low grade or absent
West Nile virus	<i>Flavivirus</i>	Throughout United States with higher rates found in Great Plains and mountain regions; seasonal epidemic from summer to fall	Mosquito bites Rare cases spread through blood transfusions, transplants, and mother to baby during pregnancy and breastfeeding.	Symptoms include febrile illness, meningitis, encephalitis, or acute flaccid paralysis. Children more likely to be asymptomatic or have milder form of disease than adults but children manifest as meningitis more often than adults <sup>a</sup>
Rickettsial pox	<i>Rickettsia akari</i>	Northeastern cities in United States, Europe and Asia, mainly urban settings	Mouse mite bite	<ul style="list-style-type: none"> <li>• Bite becomes a papule, then pustule, then ulcerates and forms eschar at site.</li> <li>• Fever, local adenopathy, headache, myalgia, maculopapular rash that may become vesicular</li> </ul>

TABLE 37.5

## OTHER ZOONOTIC AND VECTOR-BORNE ILLNESSES (continued)

Disease	Causative Organism	Geographic Distribution	Vector of Transmission	Manifestations
Epidemic typhus	<i>Rickettsia prowazekii</i>	Africa, South America, Central America, Mexico, Asia; occasional cases seen in United States	Louse feces (typically from the body louse) that are rubbed into broken skin or mucous membranes Cases in United States associated with louse or flea of flying squirrel	<ul style="list-style-type: none"> <li>• Abrupt onset of high fever, chills, and myalgia with severe headache and malaise</li> <li>• Rash appears 4 to 7 days after onset of symptoms, beginning on the trunk and spreading to the extremities.</li> <li>• Maculopapular rash becomes petechial or hemorrhagic, then develops brown pigmented areas.</li> <li>• Changes in mental status may occur.</li> <li>• Flying squirrel–related disease typically presents as a milder illness.</li> </ul>
Endemic typhus (murine typhus)	<i>Rickettsia typhi</i> and <i>Rickettsia felis</i>	Worldwide, especially warm coastal ports. In United States, most prevalent in Texas, parts of California, and Hawaii	Rat flea or cat flea feces	<ul style="list-style-type: none"> <li>• Headache, myalgia, and chills that slowly worsen</li> <li>• Fever for 10 to 14 days</li> <li>• Rash appears after 3 to 8 days; it is macular or maculopapular with sparse lesions and no hemorrhage.</li> </ul>
Ehrlichiosis and anaplasmosis	Three pathogens: <i>Ehrlichia chaffeensis</i> , <i>Anaplasma phagocytophilum</i> , <i>Ehrlichia ewingii</i>	Mostly in southeastern and south-central United States	Tick	<ul style="list-style-type: none"> <li>• Fever with clinical signs similar to Rocky Mountain spotted fever. Rash is less commonly associated.</li> <li>• May also present with leukopenia, anemia, and hepatitis</li> </ul>
Q fever	<i>Coxiella burnetii</i>	Worldwide	Inhalation of infected aerosols, ingestion of contaminated dairy products	<ul style="list-style-type: none"> <li>• Most cases are initially asymptomatic. Occurs in two forms: <ul style="list-style-type: none"> <li>• Acute: follows initial exposure and presents with abrupt onset of fever, chills, weakness, headache, and loss of appetite</li> <li>• Chronic: occurs years after initial exposure and may present with endocarditis (in clients with underlying heart disease), hepatitis, or fever of unknown origin</li> </ul> </li> </ul>

(continued)

TABLE 37.5

## OTHER ZONOTIC AND VECTOR-BORNE ILLNESSES (continued)

Disease	Causative Organism	Geographic Distribution	Vector of Transmission	Manifestations
Malaria	<i>Plasmodium</i> (four species exist that infect humans: <i>P. falciparum</i> , <i>P. vivax</i> , <i>P. ovale</i> , <i>P. malariae</i> )	Endemic in tropical areas of the world Highest risk in sub-Saharan Africa, Papua New Guinea, the Solomon Islands, and Vanuatu Other areas of risk: Haiti and Indian subcontinent Cases in the United States are usually in travelers and immigrants returning from countries where malaria transmission occurs	Bite of <i>Anopheles</i> species of mosquito	<ul style="list-style-type: none"> <li>High fever with chills, rigors, sweats, and headache, which may be paroxysmal</li> <li>Nausea, vomiting, diarrhea, cough, arthralgia, and abdominal and back pain may also occur.</li> <li>Anemia and thrombocytopenia with pallor and jaundice may be seen.</li> <li>May occur in a cyclic pattern, and depending on the species fever may occur every other day or every third day.</li> </ul>

the wound, with any remaining volume administered intramuscularly at a site distant from the vaccine inoculation. Human rabies vaccine is administered intramuscularly into the anterolateral thigh or deltoid, depending on the age and size of the child. Administration into the gluteus muscle should be avoided, since this site has been associated with vaccine failure (Rupprecht et al., 2010; Willoughby, 2011).

## Nursing Assessment

Note the history of an animal bite, especially if it was unprovoked, and exposure to bats. Document history of early symptoms of rabies infection, which are nonspecific and flu-like, such as fever, headache, and general malaise. The child may complain of pain, pruritus, and paresthesia at the bite site. As the virus spreads to the central nervous system, encephalitis develops. The disease will have progressive neurologic manifestations, which may include insomnia, confusion, anxiety, changes in behavior, agi-

tation or excitation, hallucinations, hypersalivation, dysphagia, and hydrophobia, which results from aspiration when swallowing liquid or saliva. In some cases progressive paralysis may be present. The child may have periods of lucidity alternating with these neurologic changes.

Laboratory testing may include hair and saliva specimens from which the virus may be isolated. Serum and cerebrospinal fluid can be tested for antibodies to the rabies virus. Direct fluorescent antibody testing can be done to diagnose rabies in a suspected animal. The test can only be done postmortem and requires brain tissue from the potentially rabid animal.

## Nursing Management

Few people survive once symptomatic rabies infection develops. Intensive supportive care is required, but recovery is extremely rare. Therefore, it is vital to educate children and families about the importance of

seeking medical care after any animal bite to prevent death from rabies infection. Also, teach children to avoid wild animals, stray animals, and any animal with unusual behavior. Teach children not to provoke or attempt to capture wild or stray animals.

Regardless of whether immunoprophylaxis is initiated, appropriate wound management is necessary in all victims of a bite from a potentially rabid animal. This includes a thorough cleansing of all wounds with soap and water. Irrigation of wounds for at least 10 minutes with a virucidal agent, such as povidone-iodine solution, is recommended (Willoughby, 2011).

When caring for a child requiring postexposure prophylaxis, provide support and education to the child and family. Due to the seriousness and urgency surrounding this disease and treatment, the child and family are often very frightened. Consider comfort measures, such as EMLA (eutectic mixture of local anesthetics) cream and positioning, when giving immunization.

## VECTOR-BORNE INFECTIONS

Children are at a particular risk for contracting vector-borne diseases, which are diseases transmitted by ticks, mosquitoes, or other insect vectors (Table 37.5). Young children are unaware of the health risks around them and cannot take protective measures. Their immature immune system leads to a decreased capacity to resist vector-borne diseases. These diseases can be severe and even fatal, though most are treatable if identified early. Many times the child presents initially with nonspecific symptoms. Coupled with the fact that there are few definitive diagnostic tests available, this can lead to difficulty in promptly recognizing and treating these diseases.

Tick-borne diseases are common vector-borne illnesses in the United States. Two of the most common will be covered below.

### Lyme Disease

Lyme disease, the most common reported vector-borne disease in the United States, is caused by the spirochete *Borrelia burgdorferi* (Centers for Disease Control and Prevention, 2011e). It is transmitted to humans via the bite of an infected black-legged (deer) tick. Ninety-five percent of reported Lyme disease cases occurred in 12 states, mainly in the northeast (Pennsylvania, New Jersey, New York, Massachusetts, Connecticut, Maryland, New Hampshire, Delaware, Maine, and Virginia) and the upper Midwest (Minnesota and Wisconsin) (Centers for Disease Control and Prevention, 2011g).

Most cases are seen between June and August (Centers for Disease Control and Prevention, 2011e). Lyme disease can affect any age group, but the incidence is highest among children between 5 and 9 years of age (Eppes, 2011). The prognosis for recovery in children who are treated is excellent.

## Therapeutic Management

In most cases Lyme disease can be cured by antibiotics, especially if they are started early in the illness. Doxycycline is the drug of choice for children older than 8 years (Eppes, 2011). Because it can cause permanent discoloration of the teeth, children younger than 8 years should be treated with amoxicillin (Eppes, 2011). For children allergic to penicillin, cefuroxime or erythromycin can be used. Duration of treatment is usually 14 to 28 days, depending on the stage of disease.

## Nursing Assessment

The clinical signs of Lyme disease are divided into three stages—early localized, early disseminated, and late disease. Untreated children may progress through the three stages or may present with early disseminated or late disease without having any symptoms of the earlier stages. If children are treated in the early stage, it is uncommon to see them with late disease. Nursing assessment for Lyme disease includes an accurate health history as well as physical examination.

### Health History

Explore the health history for a tick bite. Document onset of rash. In early localized disease, the rash usually occurs 7 to 14 days after the tick bite (though it can appear 3 to 32 days after the bite). In early disseminated disease, the rash usually begins 3 to 5 weeks after the tick bite. Note complaints of fever, malaise, mild neck stiffness, headache, fatigue, myalgia, and arthralgia or pain in the joints. In late disease, note recurrent arthritis of the large joints, such as the knees, beginning weeks to months after the tick bite. The child with late disease may or may not have a history of earlier stages of the disease, including erythema migrans.

### Physical Examination

Observe for a rash. A ring-like rash at the site of the tick bite (erythema migrans) characterizes early local disease (Fig. 37.4). If untreated, the rash gradually expands and will remain for 1 to 2 weeks. Suspect early disseminated disease if multiple areas of erythema migrans are found. The multiple lesions are usually smaller than the primary lesions. Note cranial nerve palsies (especially cranial nerve VII), conjunctivitis, or signs of meningeal irritation, which occur in early disseminated disease.

### Laboratory and Diagnostic Testing

Immunoglobulin-specific antibody tests may not be positive in the early stage of the disease but may be useful in the later stages. The CDC recommends a two-step test—a sensitive enzyme immunoassay (EIA) or immunofluorescent assay (IFA), if positive, followed by a Western

**FIGURE 37.4** Erythema migrans, a ring-like rash at the site of the tick bite, occurs in Lyme disease. (CDC/James Gathany. [2007]. Obtained at <http://phil.cdc.gov/phil/details.asp?pid=9875>)

immunoblot (Centers for Disease Control and Prevention, 2011g). If these are negative, no further testing is indicated.

## Nursing Management

Administer antibiotics as ordered. In the hospitalized child, no transmission-based precautions are necessary. Educate the child and family on the importance of taking the antibiotic as directed and finishing all the medicine. Another important nursing function is educating the child, family, and community on prevention measures (Box 37.5). For infection to occur, typically the tick must be attached for 36 to 48 hours (Centers for Disease Control and Prevention, 2011e). Therefore, prompt removal of ticks is essential to the prevention of Lyme disease. Teaching Guidelines 37.2 gives information on tick removal.

### BOX 37.5

#### PREVENTION OF TICK-BORNE ILLNESSES

- Wear appropriate protective clothing when entering tick-infested areas. Clothing should fit tightly around wrists, waists, and ankles. Tuck pants into socks if possible.
- After leaving the area, check for ticks and remove them promptly.
- Insect repellent may provide temporary relief but may produce toxicity, especially in children, if used frequently or in large doses.

### Teaching Guidelines 37.2

#### TICK REMOVAL

- Use fine-tipped tweezers.
- Protect fingers with a tissue, paper towel, or latex gloves.
- Grasp tick as close to the skin as possible and pull upward with steady, even pressure.
- Do not twist or jerk the tick.
- Once the tick is removed, clean site with soap and water and wash your hands.
- Save the tick for identification in case the child becomes sick. Place in a sealable plastic bag and put it in your freezer. Write date of bite on the bag.

## Rocky Mountain Spotted Fever

Rocky Mountain spotted fever (RMSF) is the most severe and frequently reported rickettsial illness in the United States (Reller & Dumler, 2011a). RMSF is caused by the bacteria *Rickettsia rickettsii*. The American dog tick and Rocky Mountain wood tick are the primary vectors, although others have been implicated. RMSF can be fatal without prompt and appropriate treatment (Reller & Dumler, 2011a). Most cases occur between April and September (Reller & Dumler, 2011a).

RMSF occurs throughout the United States. Its name is derived from the fact that it was discovered in the Rocky Mountain region, though few cases are found there today. RMSF is more common in the coastal Atlantic states, but the highest incidence has been found in North Carolina and Oklahoma. It occurs in all age groups but most frequently in children, with the peak incidence in children greater than 5 years of age (Reller & Dumler, 2011a).

Complications of RMSF include noncardiogenic pulmonary edema, cerebral edema, and multiorgan damage. Long-term neurologic involvement, such as partial paralysis of the lower extremities, hearing loss, loss of bladder and bowel control, movement disorders, and language disorders, may be seen, especially in children with severe illness who require long hospital stays.

## Therapeutic Management

The fatality rate from RMSF has decreased with the widespread use of antimicrobial therapy (Reller & Dumler, 2011a). However, delays in diagnosis and therapy are significant factors associated with severity of disease and death. In most cases RMSF resolves rapidly with appropriate antibiotic therapy, especially if it is started early. Treatments of choice are tetracyclines, such as doxycycline. Doxycycline and other tetracyclines are not normally used in children younger than 8 years due to the risk of teeth staining. However, due to the life-threatening nature of RMSF and

the limited course of antibiotic therapy, the American Academy of Pediatrics Committee on Infectious Diseases revised its recommendations and has identified doxycycline as the drug of choice for treating presumed or confirmed RMSF in children of any age (Center for Disease Control and Prevention, 2010n). Length of treatment is 7 to 14 days (Center for Disease Control and Prevention, 2010n).

## Nursing Assessment

Note history of early signs of RMSF, such as sudden onset of fever, headache, malaise, nausea and vomiting, muscle pain, and anorexia. The incubation period varies from 2 to 14 days, with the average being around 7 days after the tick bite. Late signs include a rash, usually seen 2 to 5 days after the onset of the fever, abdominal pain, joint pain, and diarrhea. Inspect the skin for a rash, which starts as small, pink, macular, nonitchy, blanchable spots on the wrists, forearms, and ankles. The rash then spreads rapidly over the entire body, including the soles and palms. After several days the rash will appear red, spotted, and petechial or hemorrhagic (Fig. 37.5). Approximately 5% of children with RMSF do not have a rash (Reller & Dumler, 2011a). Laboratory findings may include a low leukocyte count, low or decreasing platelet count, and hyponatremia. Biopsy of the rash with immunofluorescent assay and serologic tests may also be used.

## Nursing Management

Nursing management is similar to that for Lyme disease. Educate the family about completing the antibiotic course, preventing tick bites, and appropriate tick removal (refer to Box 37.5 and Teaching Guidelines 37.2).

**FIGURE 37.5** Rash associated with Rocky Mountain spotted fever.

### Take Note!

Many folklore remedies exist for tick removal such as use of petroleum jelly or hot matches. These often do little to get the tick to detach and may actually irritate the tick and stimulate it to release more saliva or gut contents, therefore increasing the chance of disease. The goal of tick removal is to detach it as quickly as possible (Centers for Disease Control and Prevention, 2011h).

## PARASITIC AND HELMINTHIC INFECTIONS

Parasites are organisms larger than yeast or bacteria that can cause infection. They live in or on a host. Parasites receive nourishment from the host without benefiting or killing the host. Parasites frequently seen in children are scabies and head lice. A helminth is a parasitic intestinal worm. Helminthic infections seen in children include pinworms, roundworms, and hookworms. Children are at an increased risk for parasitic or helminthic infections due to poor hygiene practices. For example, children typically are more careless about hand washing and they tend to put things in their mouths and share toys and objects with other children.

## Nursing Assessment and Management

Parents are often embarrassed when they find out that their child has a parasitic or helminthic infection. Reassure them that these infections can occur in any child. Tables 37.6 and 37.7 give nursing assessment and management information related to specific common parasitic and helminthic infections in children.

### Take Note!

The head louse is becoming increasingly resistant to pediculicides (Diamantis, Morrell, & Burkhart, 2009). This may lead parents to resort to home remedies, such as covering the head with real mayonnaise or Vaseline. Inform parents that these remedies have not been proven to be effective (Durani, 2011).

### Consider This

As the nurse in a pediatric clinic, you receive a call from a frantic mother. She tells you, “The school sent my daughter home and told me she has lice! We are clean people! I don’t understand how this could happen!” How would you address her concerns? Discuss the plan of care for this child. What education and interventions will be necessary to prevent the spread of pediculosis capitis?

Infection/Causative Organism	Transmission	Clinical Manifestations	Diagnosis/Treatment	Isolation/Control Measures/Concerns
Pediculosis capitis (head lice) Caused by <i>Pediculus humanus capitis</i> (head louse)	Direct contact with hair of infested people, less commonly with personal belongings, such as combs and hats, of those infested Incubation period from laying of eggs to hatching of nymph is 6 to 10 days; adult lice will appear 2 to 3 weeks later.	Extreme pruritus is the most common symptom. Adult eggs (nits) or lice may be seen, especially behind the ears and at the nape of the neck.	Diagnosis by identification of eggs, nymph, and lice with the naked eye is possible; adult lice are rarely seen. Treatment: washing hair with a pediculicide such as permethrin, pyrethrins, lindane, malathion Careful instructions on proper use of any product should be given and strict adherence to application instructions encouraged. Retreatment is usually recommended depending on treatment used. Detection of living lice 24 hours after treatment suggests incorrect use, a very heavy infestation, reinfestation, or resistance to treatment.	Contact precautions After treatment check hair and comb nits and lice from hair shafts every 2 to 3 days to prevent reinfestation. Control measures: Household and other close contacts should be examined and if infested treated. Bedmates should be treated prophylactically. Head lice do not survive long once they have fallen off. Most children can be treated effectively without treating their clothing and bedding. But to help avoid reinfestation disinfection of clothing, headgear, pillowcases, towels, and other items used by the individual within the past 2 days by washing in hot water and drying on the hot cycle may be helpful. Dry-cleaning nonwashable items or simply sealing them in a plastic bag for 10 days is effective. Soaking combs and hairbrushes in pediculicide, shampoo, or hot water Lice infestation is not a sign of poor hygiene; all socioeconomic groups are affected.
Pediculosis pubis (pubic lice) Caused by <i>Phthirus pubis</i>	Transmission usually occurs through sexual contact; also can be through contaminated items such as towels.	Pruritus of anogenital area; other hairy areas of the body, including eyelashes, eyebrows, axilla, legs, and beard, can be affected.	Diagnosis by identification of eggs, nymph, and lice with the naked eye is possible; adult lice are rarely seen. Same as treatment with pediculicides to treat head lice Retreat 7 to 10 days later. To treat eyelashes and eyebrows: if only a few nits are present remove these with fingernails or a nit comb; if additional treatment is needed apply ophthalmic-grade petrolatum ointment (prescription).	Standard precautions Control measures similar to head lice All sexual contacts should be treated. Avoid sexual contact with partners until both they and their partners have been successfully treated and reevaluated. Evaluation for presence of other sexually transmitted infections If found on children, may be a sign of sexual exposure or abuse

Scabies  
Caused by *Sarcoptes  
scabiei*

Scabies.

Incubation period from laying of eggs to hatching of nymph is 3 to 4 days; adult lice will appear 2 to 4 weeks later. Transmission usually occurs through prolonged, close personal contact. Incubation period in those without previous exposure is 4 to 6 weeks. Usually no symptoms are present during this time but transmission to others can occur. People who were previously infested can develop symptoms in 1 to 4 days.

Intense pruritus (especially at night) with presence of erythematous, papular rash with excoriations. The lesions are generally distributed but often are concentrated on the hands and feet and in body folds. May be found on head and neck. In infants and young children and those who are immunocompromised, the rash may include vesicles, pustules, or nodules.

Diagnosis can be made by a history of itching (especially at night), classic rash, and reports of itching in household or sexual contacts. Mites can be seen on microscopic examination of skin scrapings to confirm diagnosis. Treatment: A scabicide, such as permethrin or lindane, should be applied to the entire body below the head. Treatment of infants and young children should include the head, neck, and body. The cream is left on for a specified time (usually 8 to 14 hours) depending on the type of scabicide. Careful instructions on proper use of any product should be given and strict adherence to application instructions should be urged. Itching may not subside for several weeks, even after successful treatment.

Contact precautions  
Prophylactic therapy for household members and sexual contacts  
Bedding and clothing used by infested person or household, sexual, or close contacts within 4 days before treatment should be laundered in hot water and dried on the hot cycle (mites do not survive more than 3 to 4 days without skin contact).  
Avoid direct skin-to-skin contact with person or items used by those infested.  
Room used by an infested person, especially if he or she had crusted scabies, should be thoroughly cleaned and vacuumed.

TABLE 37.7

## COMMON HELMINTHIC INFECTIONS IN CHILDREN

Infection/Causative Organism	Clinical Manifestations	Transmission	Diagnosis/Treatment	Isolation/Control Measures
Roundworm (ascariasis) Caused by <i>Ascaris lumbricoïdes</i> , common in temperate and tropical areas	<p>Most people are asymptomatic, may demonstrate slower growth and weight gain.</p> <p>In more severe infections, loss of appetite, nausea, vomiting, and abdominal pain may be seen. Cough and difficulty breathing may be present as immature worms migrate through the lungs.</p> <p>In significant infestation, partial or complete intestinal obstruction may occur. The more worms, the worse the symptoms.</p>	<p>Human feces are the major source of infected eggs. Hand to mouth is the usual route of transmission.</p> <p>The eggs are swallowed due to unclean hands or contaminated food.</p> <p>They pass into the intestine; larvae then hatch, penetrate the intestinal wall, enter the circulatory system, and migrate to any body tissue.</p>	<p>Diagnosis: once female worms are in the intestine, eggs can be visualized by microscopic evaluation of the stool.</p> <p>Occasionally a worm may be coughed up and visualized or seen in vomit or stool.</p> <p>Treatment is with mebendazole, albendazole, or pyrantel pamoate.</p>	<ul style="list-style-type: none"> <li>Standard precautions are sufficient.</li> <li>Sanitary disposal of feces</li> <li>Proper hand hygiene</li> </ul>
Hookworm Caused by <i>Ancylostoma duodenale</i> (roundworm) and <i>Necator americanus</i> (roundworm); common in rural areas (especially with unsanitary conditions)	<p>Most often people are asymptomatic until significant worms are established.</p> <p>May see pruritic erythematous papular rash at entry site (referred to as ground itch) or pulmonary symptoms as the larvae migrate</p> <p>One of the greatest concerns in chronic infection is anemia (microcytic hypochromic anemia) secondary to blood loss as the worms suck blood and juices from the intestines. This can lead to hypoproteinemia, edema, pica, and wasting.</p> <p>The infection may result in physical or intellectual disability in children.</p>	<p>Hookworms are found in soil and enter the host through pores, hair follicles, and even intact skin (hands and feet are major sites of entry). The maturing larvae travel through the circulatory system into the lungs and then up the bronchial tree and are swallowed with secretions. They then migrate into the intestinal tract and attach to the wall of the small intestines, where they feed and reproduce.</p> <p>Transmission via ingested soil has been seen with <i>Ancylostoma duodenale</i> only.</p>	<p>Diagnosis is made through microscopic examination of feces that reveals hookworm eggs.</p> <p>Treatment: albendazole, mebendazole, and pyrantel pamoate</p> <p>Iron supplementation and possible blood transfusion in severe cases</p>	<ul style="list-style-type: none"> <li>Standard precautions are sufficient.</li> <li>Proper sanitation and disposal of feces</li> <li>Treatment of all known infested people</li> <li>Screening of high-risk individuals</li> <li>Encourage the wearing of shoes and avoiding going barefoot.</li> </ul>

<p>Pinworm Caused by <i>Enterobius vermicularis</i> (roundworm); found in temperate climates</p>	<p>Some people are asymptomatic. May cause anal itching (pruritus ani), especially at night Other clinical findings may include restlessness and teeth grinding at night, weight loss, and enuresis.</p>	<p>Fecal–oral route directly, indirectly, or inadvertently by contaminated hands or shared toys, bedding, clothing, toilet seats Incubation period is 1 to 2 months or longer.</p>	<p>Diagnosis is made when adult worms are visualized in the perianal region; they are best viewed when the child is sleeping. Very few ova are present in stool, so examination of stool is not recommended. Transparent tape pressed to perianal area and then viewed under a microscope may reveal eggs. Three consecutive specimens should be obtained when the child first awakens in the morning. Treatment of choice is mebendazole, pyrantel pamoate, and albendazole, usually single doses and repeated in 2 weeks. All family members should be treated since transmission from person to person is very easy.</p>	<p>Standard precautions are sufficient. Reinfection occurs easily. Infected people should bathe, preferably in a shower, in the morning, which will remove a large portion of the eggs. Frequent changing of underclothes and bedding Personal hygiene measures such as keeping fingernails short, avoiding scratching of perianal area and nail biting Good hand hygiene is the most effective preventive measure, especially after using the bathroom and before eating.</p>

## SEXUALLY TRANSMITTED INFECTIONS

Sexually transmitted infections (STIs), commonly called sexually transmitted diseases, are infectious diseases transmitted through sexual contact, including oral, vaginal, or anal intercourse. Certain infections can be transmitted in utero to the fetus or during childbirth to the newborn leading to miscarriage, stillbirth, ectopic pregnancy, preterm delivery, birth defects, and illness of disease (March of Dimes, 2008).

STIs are a major health concern for adolescents. The rates of many STIs are highest in adolescents (Centers for Disease Control and Prevention, 2010b). It is estimated that one in four adolescent women in the United States has an STI (Holland-Hall, 2008). Adolescents are at a greater risk for developing STIs for a variety of reasons, including frequency of unprotected intercourse, being biologically more susceptible to infection, engaging in partnerships of limited duration, and possible difficulty accessing the health care system (Centers for Disease Control and Prevention, 2010b).

Detection of STIs in infants and children is an important warning sign of potential sexual abuse. Due to the serious implications that a diagnosis of an STI can have in children, only tests that have high specificities and that can isolate an organism should be used. Also, treatment for the child with a suspected STI may be delayed until a definitive diagnosis can be made. Refer to Chapter 5 for more information on common sexually transmitted infections in adolescents and Chapter 48 for information related to HIV.

### KEY CONCEPTS

- Infants and young children are more susceptible to infection due to their immature immune system. Young children continue to have an increased risk for infections and communicable disorders because disease protection from immunizations is not complete.
- Health care providers need to remember to educate parents that fever is a protective mechanism the body uses to fight infection.
- When obtaining blood cultures, follow aseptic technique and hospital protocol to prevent contamination. Obtain the specimen before administering antibiotics.
- When administering antipyretics, proper education must be given to caregivers on appropriate dosing, concentration, dosing interval, and use of proper measuring device.
- Promoting proper fluid balance and reducing temperature in a febrile child are important nursing

interventions when caring for a child with an infection or communicable illness.

- Many childhood infectious and communicable diseases involve a rash. Rashes can be difficult to identify, so a thorough description and history from the caregiver is important.
- Sepsis, a systemic overresponse to infection resulting from bacteria, fungi, viruses, or parasites, can lead to septic shock. Any infant younger than 3 months old with a fever or any child with a fever accompanied by extreme lethargy, unresponsiveness, or lack of facial expressions should be seen by a physician or nurse practitioner.
- Many bacterial and viral infections, such as diphtheria, tetanus, pertussis, mumps, measles, rubella, varicella, and poliomyelitis, can be prevented by vaccination.
- Viral exanthems of childhood often present with a distinct rash pattern that assists in the diagnosis of the virus. Common childhood exanthems include exanthem subitum (roseola infantum), rubella (German measles), rubeola (measles), varicella (chickenpox), and erythema infectiosum (fifth disease).
- Nurses play a key role in educating the public on the importance of immunizations.
- Zoonotic infections are diseases caused by infectious agents that are transmitted directly or indirectly from animals to humans. Cat scratch disease and rabies are types of zoonotic infections.
- Children are at a particular risk for contracting vector-borne diseases, which are diseases transmitted by ticks, mosquitoes, or other insect vectors. Two of the most commonly seen are Lyme disease and Rocky Mountain spotted fever.
- Parasites frequently seen in children are scabies and head lice. Helminthic infections seen in children include pinworms, roundworms, and hookworms.
- STIs are infectious diseases transmitted through sexual contact, including oral, vaginal, or anal intercourse. Certain infections can be transmitted in utero to the fetus or during childbirth to the newborn.
- STIs are a major health concern for adolescents. Adolescents are at a greater risk for developing STIs for a variety of reasons, including frequency of unprotected intercourse, being biologically more susceptible to infection, engaging in partnerships of limited duration, and possible difficulty accessing the health care system (Centers for Disease Control and Prevention, 2010b).

## MULTIPLE CHOICE QUESTIONS

- Compared with adults, why are infants and children at an increased risk for infection and communicable diseases?
  - The infant has had limited exposure to disease and is losing the passive immunity acquired from maternal antibodies.
  - The infant demonstrates an increased inflammatory response.
  - Cellular immunity is not functional at birth.
  - Infants have an increased risk for infection until they receive their first set of immunizations.
- A mother calls the clinic because her 2-year-old daughter has a rectal temperature of 37.8°C (100°F). She wonders how high a fever should be before she should give medications to reduce it. What is the best response by the nurse?
  - “All fevers should be treated to prevent seizures.”
  - “Antipyretics should be used with any rise in temperature. They can help change the course of the infection.”
  - “Give your child aspirin when her fever is above 38°C (100.4°F).”
  - “In a normal healthy child, if your child is not uncomfortable, fevers less than 39°C (102.2°F) do not require medication.”
- A neonate should be evaluated by a physician if which signs and symptoms are present?
  - Acting fussier than normal
  - Refusing the pacifier
  - Rectal temperature above 38°C
  - Mottling that is present during bathing
- The public health nurse has been asked to provide information to local child care centers on controlling the spread of infectious diseases. What is the best information the nurse can provide?
  - The etiology of common infectious diseases
  - Proper hand washing techniques
  - The physiology of the immune system
  - Why children are at a higher risk of infection than adults

## CRITICAL THINKING EXERCISES

- A 12-year-old boy presents with a very sore throat and fever. On assessment you find an erythematous rash on his face that feels like sandpaper. You obtain a throat culture, which is positive for group A streptococcus. What instructions would you give the parents regarding his care at home?
- A 1-month-old infant is admitted to the hospital to rule out sepsis. What would be your priority nursing interventions?
- A 4-year-old child presents with a fever and rash. What three of the following items should the nurse obtain during the health history?
  - Immunization history
  - Any exposure to communicable or infectious diseases
  - Whether the child takes a daily vitamin
  - Thorough description and history of the rash
  - Mother's immunization history

## STUDY ACTIVITIES

- The 4-year-old presented in question 3 above was diagnosed with varicella zoster virus. Write a nursing care plan for a child with varicella.
- You are asked to give a presentation to a group of adolescents on sexually transmitted infections, including transmission, symptoms, treatment, and prevention. What information would you include?
- A child is brought to the school nurse with intense itching. Upon assessment the nurse finds an erythematous, papular rash with excoriations on the child's hands and feet. As suspected, the diagnosis of scabies is confirmed. What teaching is necessary for the parents, family, and classmates of the child?

**KEY TERMS**

central nervous system (CNS)

 opisthotonic postictal  
 status epilepticus  
 teratogen

# Nursing Care of the Child With a Neurologic Disorder

## Learning Objectives

*Upon completion of the chapter, you will be able to:*

1. Define the key terms used in this chapter.
2. Compare how the anatomy and physiology of the neurologic system in children differs from adults.
3. Identify various factors associated with neurologic disease in infants and children.
4. Discuss common laboratory and other diagnostic tests useful in the diagnosis of neurologic conditions.
5. Discuss common medications and other treatments used for treatment and palliation of neurologic conditions.
6. Recognize risk factors associated with various neurologic disorders.
7. Distinguish among different neurologic illnesses based on the signs and symptoms associated with them.
8. Discuss nursing interventions commonly used for neurologic illnesses.
9. Devise an individualized nursing care plan for the child with a neurologic disorder.
10. Develop child and family teaching plans for the child with a neurologic disorder.
11. Describe the psychosocial impact of chronic neurologic disorders on children.

*Antonio Chapman, 3 months old, has had increased irritability, poor sucking and feeding, and a fever for the past 24 hours. Today he is lethargic with a weak cry and is vomiting his feeds.*

## Words of Wisdom

As long as nurses possess inner integrity, they will be able to handle the life challenges of the children for whom they care.

**Neurologic** disorders in children often have a devastating and lasting impact. Neurologic disorders can be divided into several categories, including structural disorders, seizure disorders, infectious disorders, trauma to the neurologic system, blood flow disruption disorders, and chronic disorders.

Nurses must be familiar with neurologic conditions affecting children in order to provide prevention, prompt treatment, guidance, and support to families. Neurologic disorders require acute interventions, but many times have long-lasting implications on the child's health and development. Due to the potentially devastating effects that neurologic disorders can have on children and their families, nurses need to be skilled in assessment and interventions in this area and must be able to provide support throughout the course of the illness and beyond.

## VARIATIONS IN PEDIATRIC ANATOMY AND PHYSIOLOGY

Neurologic disorders can result from congenital problems as well as from infections or traumas. Certain neurologic conditions occur in children more often than adults and these conditions will affect their growth and development. In addition, children are at an increased risk for different neurologic problems compared to adults due to anatomic and physiologic differences.

## Brain and Spinal Cord Development

The brain and spinal cord make up the **central nervous system (CNS)**. Development of these structures occurs in the first 3 to 4 weeks of gestation from the **neural tube**. Infection, trauma, **teratogens** (any environmental substance that can cause physical defects in the developing embryo and fetus), and malnutrition during this period can result in malformations in brain and spinal cord development and may affect normal CNS development.

At birth, the cranial bones are not well developed and are not fused. Therefore, there is an increased risk for fracture. The brain is highly vascular, leading to an increased risk for hemorrhage. Premature infants are at greater risk for brain damage; the more premature the infant, the greater the risk. The premature infant has more capillaries in the periventricular area, which is the brain tissue that lines the outside of the lateral ventricles. These capillaries are fragile and at greater risk for rupture, leading to intracranial bleeding. Also, because the cranium is very soft in the preterm infant, external pressure can change its shape and cause increased pressure in areas of the brain and possible hemorrhage.

The sutures and fontanels present in the newborn help make the skull more flexible and help to accommodate for brain growth that continues after birth. Closure

of the fontanels too early or too late can be indicative of problems with brain growth. The child's spine is very mobile, especially the cervical spine region, resulting in a high risk for cervical spine injury.

## Nervous System

The development of the nervous system is complete but immature at birth. The infant is born with all the nerve cells that he or she will have throughout life. However, **myelination**, the formation of myelin, which covers and protects the nerves, is incomplete. The speed and accuracy of nerve impulses increases as myelination increases. This process accounts for the acquisition of fine and gross motor movements and coordination in early childhood. Myelination proceeds in the cephalocaudal direction. For example, infants are able to control the head and neck before the trunk and extremities.

The immaturity of the CNS in preterm infants can result in delayed development of motor skills. Premature newborns may have difficulty coordinating sucking and swallowing, leading to feeding and growth issues. Also, episodes of apnea can be problematic in the preterm newborn due to the underdevelopment of the nervous system.

## Head Size

The head of the infant and young child is large in proportion to the body. The head of an infant accounts for a quarter of the body height; in adults it accounts for one eighth of the body height (Fig. 38.1). In addition, the infant's and child's neck muscles are not well developed. Both of these differences lead to an increased incidence of head injury from falls. The head is the fastest growing body part during infancy and continues to grow until the child is 5 years old.

## COMMON MEDICAL TREATMENTS

A variety of interventions, including medical treatments and medications, are used to treat neurologic illness in children. Most of these treatments will require a physician's or nurse practitioner's order when the child is hospitalized. The most common treatments and medications used for neurologic disorders are listed in Common Medical Treatments 38.1 and Drug Guide 38.1.

## NURSING PROCESS OVERVIEW FOR THE CHILD WITH A NEUROLOGIC DISORDER

Care of the child with a neurologic disorder includes assessment, nursing diagnosis, planning, intervention, and evaluation. There are a number of general concepts related to the nursing process that can be applied to the

**FIGURE 38.1** Proportion of head to body height in the newborn, child, and adult.

management of neurologic disorders. From a general understanding of the care involved for a child with neurologic dysfunction, the nurse can then individualize the care based on the particular child's specifics.

**Remember Antonio, the 3-month-old with lethargy, a weak cry, and vomiting? What additional health history and physical examination assessment information should the nurse obtain?**

## Assessment

Assessment of neurologic dysfunction in children includes health history, physical examination, and laboratory and diagnostic testing.

### Take Note!

Neurologic assessment should proceed from least invasive to most invasive. The use of toys and familiar objects, as well as incorporating play, will help promote cooperation from the child.

## Health History

The health history consists of past medical history, including the mother's pregnancy history, family history, and history of present illness (when the symptoms started and how they have progressed) as well as treatments used

at home. The past medical history might be significant for prematurity, difficult birth, infection during pregnancy, nausea, vomiting, headaches, changes in gait, falls, visual disturbances, or recent trauma. Family history might be significant for genetic disorders with neurologic manifestations, seizure disorders, or headaches. When eliciting the history of the present illness, inquire about the following:

- Nausea
- Vomiting
- Changes in gait
- Visual disturbances
- Complaints of headaches
- Recent trauma
- Changes in cognition
- Change in consciousness, including any loss of consciousness
- Poor feeding
- Lethargy
- Increased irritability
- Fever
- Neck pain
- Altered muscle tonicity
- Delays in growth and development
- Ingestion or inhalation of neurotoxic substances or chemicals

## Physical Examination

Physical examination of the nervous system consists of inspection and observation, palpation, and auscultation.

## COMMON MEDICAL TREATMENTS 38.1

Treatment	Explanation	Indications	Nursing Implications
Shunt placement	A catheter is placed in the ventricle to pass the CSF to the peritoneal cavity, atrium of the heart, or pleural spaces. (Ventriculoperitoneal shunts are commonly used.)	Hydrocephalus, increased ICP	Monitor: <ul style="list-style-type: none"> <li>• For signs and symptoms of increased ICP</li> <li>• Neurologic status closely</li> <li>• Level of consciousness and vital signs</li> <li>• For signs and symptoms of infection</li> </ul>
Ventilation	Hyperventilation to decrease PaCO <sub>2</sub> , which will result in vasoconstriction and therefore decrease ICP  Adequate oxygenation to prevent hypoxia and further damage to the brain	Increased ICP	Monitor: <ul style="list-style-type: none"> <li>• Arterial blood gases</li> <li>• For signs and symptoms of increased ICP</li> <li>• Pulse oximetry</li> </ul>
PT/OT/ST	Therapies are used to improve motor function and ability of children with neurologic disorders.	Head injury, intellectual disability	Ensure adequate communication exists within the interdisciplinary team.
External ventricular drainage (EVD)	A catheter is temporarily placed in the ventricle and CSF is drained in a closed system to an external reservoir	Most commonly used with shunt infections until CSF is sterile and shunt can be replaced; treats acute-onset hydrocephalus, meningitis, encephalitis, tumors that cause blockage of CSF, closed head injury, subarachnoid hemorrhage, increased ICP; also can be used to monitor ICP	Monitor: <ul style="list-style-type: none"> <li>• For signs and symptoms of increased ICP</li> <li>• Neurologic status closely</li> <li>• Level of consciousness and vital signs</li> <li>• For signs and symptoms of infection</li> <li>• Level of collection container when drain is unclamped</li> </ul>
Ventricular tap	To reduce accumulation of CSF and decrease ICP	Increased ICP	Monitor: <ul style="list-style-type: none"> <li>• Level of consciousness</li> <li>• Neurologic status</li> </ul>
Vagal nerve stimulator	A nerve stimulator is implanted and a lead wire running under the skin is wrapped around the vagus nerve. The stimulator is programmed to provide the appropriate dose of stimulation at preset intervals; additional stimulation can be administered.	Short- and long-term seizure management in children older than 12 years of age	Monitor: <ul style="list-style-type: none"> <li>• For signs and symptoms of infection</li> <li>• For seizure activity</li> </ul>
Ketogenic diet	Diet involving high intake of fats, adequate protein, and a very low intake of carbohydrates, resulting in a ketosis state. Child is kept in a mild state of dehydration.	Prevention, control, and reduction of seizures, in particular for children with difficult-to-control seizures	Monitor: <ul style="list-style-type: none"> <li>• Input and output closely</li> <li>• For seizure activity</li> <li>• Growth and nutritional status</li> </ul> <p>The diet is time consuming and many children find it unpalatable; therefore, all families and children do not accept it.</p>

OT, occupational therapy; PT, physical therapy; ST, speech therapy.

## DRUG GUIDE 38.1

Medication	Actions/Indications	Nursing Implications
Antibiotics (oral, parenteral, intrathecal)	Treatment of bacterial meningitis and shunt infections; kill and prevent the growth of bacteria	Check for antibiotic allergies. Monitor serum levels to ensure therapeutic dosing if indicated. Give as prescribed for the length of time prescribed.
Anticonvulsants (oral, parenteral)	Decrease hyperexcitability of nerves Treatment and prevention of seizures	Maintain seizure precautions. Monitor for drug interactions and long-term adverse effects. Monitor and document all seizure activity. Many are used in combination, but need to be aware of interactions and long-term adverse effects. Stopping drug abruptly may precipitate seizures or even status epilepticus.
Benzodiazepines Diazepam (oral, rectal, or parenteral) Lorazepam (parenteral or oral)	Minor sedative that prevents or stops seizures by slowing down the CNS, making abnormal electrical activity unlikely. Treatment for status epilepticus	Diazepam is available in rectal form to stop prolonged seizures in children. Useful for home management; nurses must educate family members on administration and when to call physician or nurse practitioner. Monitor sedation level and for cessation of seizure activity.
Analgesics (acetaminophen, ibuprofen, ketorolac, morphine)	Block pain impulse in response to inhibition of prostaglandin synthesis. Narcotic analgesics (i.e., morphine) act on receptors in the brain to alter perception of pain. Used to treat pain. Used to help avoid increase in ICP	Monitor for improvements in pain. Monitor sedation and respiratory status with narcotics. Monitor neurologic status closely. Used cautiously because loss of accurate neurologic evaluation can occur
Osmotic diuretics (i.e., mannitol)	Increase plasma osmolality, therefore inducing diffusion back into plasma and extravascular space; reduces ICP	Monitor electrolytes. Monitor I/O closely. Monitor vital signs. Monitor for signs and symptoms of increased ICP.
Corticosteroids (i.e., dexamethasone)	Suppress inflammation and normal immune response/reduce cerebral edema	Give oral doses with food. Dosage must be tapered before discontinuing.

I/O, intake/output.  
Adapted from Karch, A. (2010). *2010 Lippincott's nursing drug guide*. Philadelphia: Wolters Kluwer Health/Lippincott Williams & Wilkins; and Taketomo, C. K., Hodding, J. H., & Kraus, D. M. (2010). *Lexi-comp's Drug Reference Handbook: Pediatric & Neonatal Dosage Handbook* (18th ed.). Hudson, OH: Lexi-comp, Inc.

### INSPECTION AND OBSERVATION

Specific areas to inspect and observe include:

- Level of consciousness (LOC)
- Vital signs
- Head, face, and neck
- Cranial nerve function
- Motor function

- Reflexes
- Sensory function
- Increased **intracranial pressure (ICP)** (a rise in the normal pressure within the skull)

**Level of Consciousness.** Begin the physical examination with inspection and observation. Observe the

child's LOC, noting a decrease or significant changes. LOC is the earliest indicator of improvement or deterioration of neurologic status. Extreme irritability or lethargy is considered an abnormal finding. Consciousness consists of alertness, which is a wakeful state and includes the ability to respond to stimuli, and cognition, which includes the ability to process stimuli and demonstrate a verbal or motor response. Five different states constitute the levels of consciousness:

1. *Full consciousness* is defined as a state in which the child is awake and alert; is oriented to time, place, and person; and exhibits age-appropriate behaviors.
2. *Confusion* is defined as a state in which disorientation exists. The child may be alert but responds inappropriately to questions.
3. *Obtunded* is defined as a state in which the child has limited responses to the environment and falls asleep unless stimulation is provided.
4. *Stupor* exists when the child only responds to vigorous stimulation.
5. *Coma* defines a state in which the child cannot be aroused, even with painful stimuli.

**Take Note!**

Lack of response to painful stimuli is abnormal and can indicate a life-threatening condition. Report this finding immediately.

The Pediatric Glasgow Coma Scale is a popular scale used to standardize degree of consciousness. It consists of three parts: eye opening, verbal response, and motor response (Fig. 38.2). When assessing LOC in children, consider that the infant or child may not respond to unfamiliar voices in an unfamiliar environment. Therefore, it may be helpful to have a parent present to elicit the response.

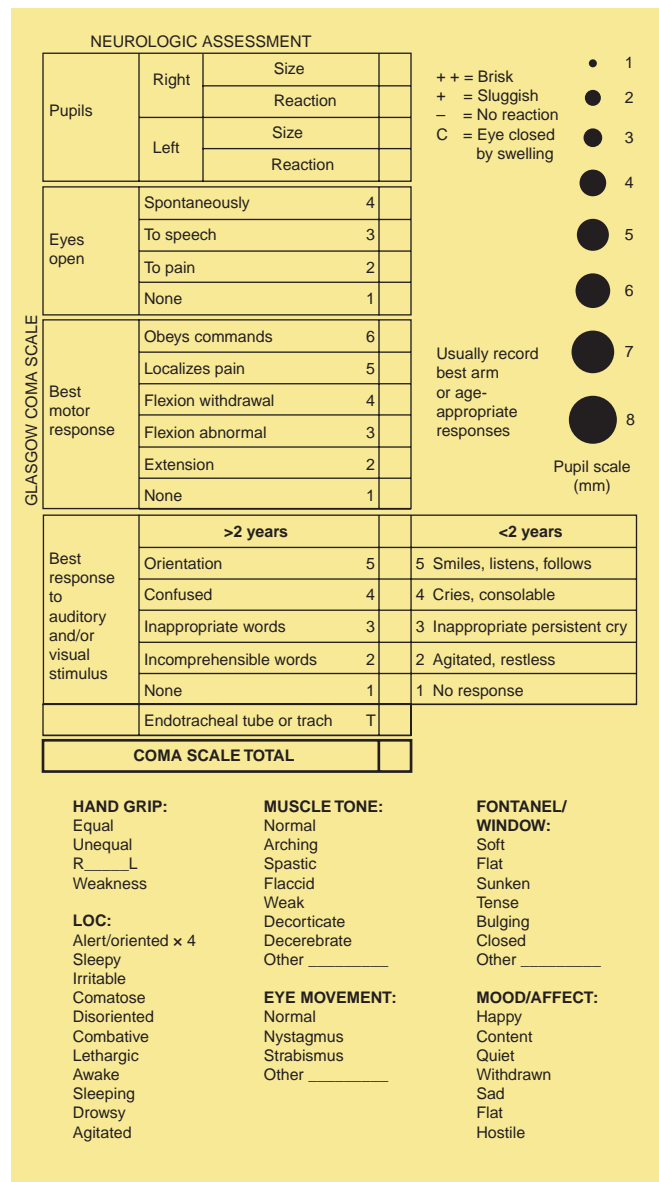

**Take Note!**

Parents will often be the first to notice changes in their child's LOC. Listen to parents and respond to their concerns.

**Vital Signs.** Assessment of vital signs can provide probable underlying causes for altered LOC as well as reveal the adequacy of oxygenation and circulation. Certain neurologic conditions like cerebral infections, increased ICP, coma, brain stem injury, or head injuries can cause alterations in the child's vital signs.

**Head, Face, and Neck.** Inspect and observe the head for size and shape. Abnormal skull shape can result from premature closure or widening of sutures. Inspect and observe the face for symmetry. Asymmetry may occur due to paralysis of certain cranial nerves, position in utero, or swelling caused by trauma. Assess range of

**FIGURE 38.2** Pediatric Glasgow Coma Scale (GCS). The Pediatric GCS provides for developmentally appropriate cues to assess level of consciousness (LOC) in infants and children. Numeric values are assigned to the levels of response and the sum provides an overall picture, as well as an objective measure, of the child's LOC. The lower the score, the less responsive the child.

motion of the neck. Alterations in range of motion can indicate CNS infections such as meningitis.

The most dramatic increase in brain volume occurs during the last 3 months of fetal development and the first 2 years of life. The relationship between head and brain growth explains why head circumference is a standard assessment made in children younger than 3 years of age. All children younger than 3 years old, and any child whose head size is questionable, should have their head circumference measured and plotted on a growth chart (see Appendix F for growth charts).

Assessment of the growth trend of the head is important in detecting potential neurologic conditions. Report and investigate any variation in head circumference percentiles over time because variations may indicate abnormal brain or skull growth. A smaller than normal **head circumference**, which measures around the child's head at the largest area, may indicate microcephaly, and a larger than normal head circumference may indicate hydrocephalus.

**Take Note!**

Do not attempt any assessment that involves movement of the head and neck in cases of trauma or suspected trauma until cervical injury is ruled out. Maintain complete immobilization of the cervical spine until that time.

**Cranial Nerve Function.** Techniques of assessment of cranial nerve function are similar to techniques for adult assessment. The method of obtaining responses may vary based on age and developmental level of the child. Certain elements of the adult assessment may be omitted. Alterations in cranial nerve function can be the

result of compression of a specific nerve, infection, or trauma leading to brain injury. Refer to Table 38.1 for an explanation of cranial nerve assessment in children.

Use the doll's eyes maneuver to evaluate cranial nerves III, IV, and VI. This maneuver can be helpful when assessing an infant, uncooperative child, or comatose child. It examines horizontal and vertical eye movements by turning the head in one direction and assessing if the eyes move symmetrically in the other direction. For example, if you suddenly turn the child's head to the right, the child's eyes should look to the left symmetrically. Assess vertical eye movements in a similar manner by flexing or extending the neck. Absence of expected eye movements may indicate increased ICP.

When assessing oculomotor function, be sure to note nystagmus or sunset appearance of the eyes. Observe for nystagmus by looking for involuntary, rapid, rhythmic eye movements that may be present at rest or with eye movement. Horizontal nystagmus may occur with lesions in the brain stem and can be the result of certain medications (phenytoin in particular). Vertical nystagmus indicates brain stem dysfunction.

**TABLE 38.1 ASSESSMENT OF CRANIAL NERVES IN INFANTS AND CHILDREN**

Cranial Nerve	Function	Assessment Procedure
I (olfactory)	Sense of smell	Not evaluated in infants and young children. In children, assess child's ability to recognize common smells (i.e., an orange) while eyes are closed.
II (optic), III (oculomotor), IV (trochlear), VI (abducens)	Vision, motor control and sensation of eye muscles, movement of major eye muscles	Assess oculomotor ability by having child follow object (toy or brightly colored object). Assess vision fields and visual acuity in older child. Assess pupil reaction same as adult. May need to talk to child or have parent in visual field while applying light stimulus.
V (trigeminal)	Mastication muscles and facial sensation	Note strength of infant's suck on pacifier, examiner's thumb, or bottle. In children, assess strength of bite and ability to discern light touch on face.
VII (facial)	Facial muscles, salivation, and taste	Note symmetry of facial expressions; in infant, monitor during spontaneous cries or smiles. In older child, test as in adults. Assess taste by asking to discern certain common tastes (salt, sugar).
VIII (acoustic)	Hearing	In infant, note response to voice. In children, use whisper test or Weber or Rinne test.
IX (glossopharyngeal), X (vagus)	Motor impulses to heart and other organs, swallowing, and gag reflex	Gag reflex and swallowing tested as in adults. Check time of last feeding, especially in the infant, to avoid vomiting when gag reflex is tested.
XI (accessory)	Impulses to muscles of shoulders and pharynx	In infants, note symmetry of head position when placed in the sitting position. In children, same as adults.
XII (hypoglossal)	Motor impulses to tongue and skeletal muscles	In infants, note spontaneous tongue movements. In children, same as adults.

**FIGURE 38.3** Sunsetting of the eyes is a sign of increased intracranial pressure.

*Sunsetting* is when the sclera of the eyes is showing over the top of the iris (Fig. 38.3). Sunset eyes may indicate increased ICP as seen in hydrocephalus. Pupillary response is often abnormal when a neurologic disorder is present. Refer to Figure 38.4 for illustrations of varied pupillary responses.

**Take Note!**

Immediately report the sudden presence of fixed and dilated pupils.

**Motor Function.** Observe muscle strength, size, and tone in the infant or child. Assess bilaterally and compare. Observe spontaneous activity, posture, and balance and

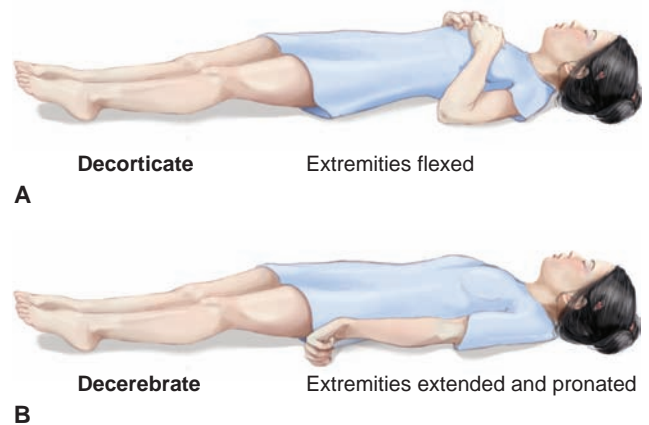

**FIGURE 38.4** Assessing pupil size and reaction: **(A)** Pinpoint is commonly observed in poisonings, brain stem dysfunction, and opiate use. **(B)** Dilated but reactive is seen after seizures. Fixed and dilated is associated with brain stem herniation secondary to increased intracranial pressure. **(C)** One dilated but reactive is associated with intracranial mass.

assess for asymmetric movements. In the infant, observe resting posture, which will normally be a slightly flexed posture. The infant should be able to extend extremities to a normal stretch. Alterations in motor function, like changes in gait, muscle tone, or strength, may indicate certain neurologic problems such as increased ICP, head injury, and cerebral infections. Because cortical control of motor function is lost in certain neurologic disorders, postural reflexes reemerge and are directly related to the area of the brain that is damaged. Therefore, it is important to assess for two distinct types of posturing that may occur. **Decorticate posturing** occurs with damage of the cerebral cortex (Fig. 38.5A). **Decerebrate posturing** occurs with damage at the level of the brain stem (Fig. 38.5B). Both types of posturing are characterized by extremely rigid muscle tone.

**Reflexes.** Testing of deep tendon reflexes is part of the neurologic assessment, just as it is in adults. Testing of primitive and protective reflexes in the infant is important because infants cannot perform tasks on command. The Moro, tonic neck, and withdrawal reflexes are important in assessing neurologic health in infants. Refer to Chapter 25 for a further explanation of primitive and protective reflexes in infants (see Chapter 25, Table 25.2). Absence of certain reflexes, persistence of primitive reflexes after age of normal disappearance, or increases in reflexes may be present in specific neurologic conditions.

**Sensory Function.** When assessing the child, use techniques similar to those used in the adult assessment. Make sure to explain what you are doing to the child, especially before the pinprick test, to gain continued cooperation. When assessing sensory function, the child should be able to distinguish between light touch, pain,

**FIGURE 38.5** **(A)** Decorticate posturing occurs with damage of the cerebral cortex and includes adduction of the arms, flexion at the elbows with arms held over chest, and flexion of the wrists with hands fisted. Lower extremities are adducted and extended. **(B)** Decerebrate posturing occurs with damage to the midbrain and includes extension and pronation of the arms and legs.

## COMPARISON CHART 38.1

## EARLY VS. LATE SIGNS OF INCREASED INTRACRANIAL PRESSURE

## Early Signs

- Headache
- Vomiting, possibly projectile
- Blurred vision, double vision (diplopia)
- Dizziness
- Decreased pulse and respirations
- Increased blood pressure or pulse pressure
- Pupil reaction time decreased and unequal
- Sunset eyes
- Changes in level of consciousness, irritability
- Seizure activity
- In infant will also see:
  - Bulging, tense fontanel
  - Wide sutures and increased head circumference
  - Dilated scalp veins
  - High-pitched cry

## Late Signs

- Lowered level of consciousness
- Decreased motor and sensory responses
- Bradycardia
- Irregular respirations
- Cheyne-Stokes respirations
- Decerebrate or decorticate posturing
- Fixed and dilated pupils

vibration, heat, and cold. When assessing an infant, limit the examination to responses to touch or pain. The normal response in a 4-month-old infant will be movement away from the stimulus. Alterations in sensory function can result from brain or spinal cord lesions.

**Increased Intracranial Pressure.** Observe for signs and symptoms associated with increased ICP while caring for a child with a potential or suspected neurologic disorder. Refer to Comparison Chart 38.1 for early versus late signs and symptoms of increased ICP. Increased ICP is a sign that may occur with many neurologic disorders. It may result from head trauma, birth trauma, hydrocephalus, infection, and brain tumors. As ICP increases, LOC decreases and the signs and symptoms will become more pronounced. It is essential to recognize early signs and symptoms of increased ICP and intervene immediately to prevent long-term damage and possible death.

**PALPATION**

Palpation of the newborn and infant skull and fontanels is an important function of the neurologic examination. Changes in size or fullness of the fontanels may exist in certain neurologic conditions and must be noted. A bulging fontanel can be a sign of increased ICP and is seen in such neurologic disorders as hydrocephalus and head traumas. It is normal for the fontanels to be

full or bulging during crying; take this into consideration during assessment.

Note any premature closure of fontanels, which can indicate skull deformities such as craniosynostosis. The posterior fontanel normally closes by 2 months of age and the anterior fontanel normally closes by 12 to 18 months of age. In children with hydrocephalus, widening of the fontanels may be noted, along with a tense appearance and a resulting increase in head circumference.

**AUSCULTATION**

Physicians or nurse practitioners may perform auscultation of the skull. Soft, symmetric bruits may be found in children younger than 4 years of age or in children with acute febrile illness. A finding of a loud or localized bruit is usually significant and requires immediate further investigation. Increased ICP, resulting from conditions such as hydrocephalus, tumor, or meningitis, frequently produces intracranial bruits. Arterial venous malformations may also produce large bruits.

**Laboratory and Diagnostic Testing**

Common Laboratory and Diagnostic Tests 38.1 offers an explanation of the most commonly used laboratory and diagnostic tests utilized when considering neurologic disorders. The tests can assist the physician or nurse practitioner in diagnosing the disorder and/or serve as

## COMMON LABORATORY AND DIAGNOSTIC TESTS 38.1

Test	Explanation	Indications	Nursing Implications
Lumbar puncture (LP)	Withdrawal of cerebrospinal fluid (CSF) from the subarachnoid space for analysis	To diagnose hemorrhage, infection, or obstruction Can obtain measurement of spinal fluid pressure	Assist with proper positioning (see Fig. 38.6). Help child maintain position and remain still. Maintain strict asepsis. Assist with collection and transport of specimen. Encourage fluids after procedure if not contraindicated. Keep child flat for 1 hour if ordered. Apply EMLA cream to puncture site 30–60 minutes before procedure to reduce pain, if ordered.
Head and neck X-ray	Radiographic image of the head and neck will show skull and spine structures	Detects skull and spinal fractures; shows location and course of ventricular catheters; reveals information about increased intracranial pressure (ICP) and skull defects	Children may be afraid. Allow a parent or family member to accompany the child. If the child is unable or unwilling to stay still for the x-ray, restraint may be necessary. The time of restraint should be limited to the amount of time needed for the x-ray.
Fluoroscopy	Radiographic examination that uses continuous x-rays to show live up-to-date images	Can assess cervical spine for instability during movement	Same as head and neck x-rays. Child will need to cooperate with flexion and extension of neck.
Cerebral angiography	X-ray study of cerebral blood vessels. Involves injection of a contrast medium and use of fluoroscopy	Can assess for vessel defects or space-occupying lesions	Same as head and neck x-rays. Assess for allergy to contrast medium. Push fluids following procedure, if not contraindicated, to help flush out contrast medium.
Ultrasound	Use of sound waves to locate the depth and structure within soft tissues and fluid	Used to assess intracranial hemorrhage in newborns, and ventricular size	Better tolerated by nonsedated children than CT or MRI Can be performed portably at bedside
Computed tomography (CT)	Noninvasive x-ray study that looks at tissue density and structures. Images a “slice” of child’s tissue	To diagnose congenital abnormalities, such as neural tube defects, hemorrhage, tumors, fractures	Machine is large and can be frightening to children. Procedure can be lengthy and child must remain still. If unable to do so, sedation may be necessary. Can be performed with or without use of contrast medium; if used, assess for allergy. Encourage fluids postprocedure if not contraindicated.

(continued)

**COMMON LABORATORY AND DIAGNOSTIC TESTS 38.1** (continued)

Test	Explanation	Indications	Nursing Implications
Electroencephalogram (EEG)	Measures electrical activity of the brain	To diagnose seizures and brain death	<p>Must remain still. If unable to do so, sedation may be necessary but should be avoided if possible because sedatives can alter the EEG reading.</p> <p>Inform technician of what anticonvulsants the child is taking. Morning anticonvulsants may need to be held.</p>
Magnetic resonance imaging (MRI)	Use of magnetic field to show different tissue compositions	Used to assess tumors and inflammation; used to diagnose congenital abnormalities, such as neural tube defects; shows normal versus abnormal brain tissue	<p>Child may not have any metal devices, internal or external, while undergoing MRI (ensure hospital gown does not have metal snaps). Procedure can be lengthy and child must remain still. Child is placed in long narrow tube and the machine makes a booming noise when it is turned on and off during the procedure; therefore, can be difficult to gain cooperation. If the child is unable to remain still, sedation may be necessary.</p> <p>Can be performed with or without use of a contrast medium. If contrast medium is used, assess for allergy. Encourage fluids postprocedure if not contraindicated.</p>
Positron emission tomography (PET)	Similar to CT or MRI but radioisotope is added. Measures physiologic function	Provides information on brain functional development. Can assist in identifying seizure foci. Can assess tumors and brain metabolism	<p>Procedure can be lengthy and child must remain still. If unable to do so, sedation may be necessary.</p> <p>Intravenous access will be needed for the procedure.</p> <p>Encourage fluids postprocedure if not contraindicated, to help body eliminate radioisotopes.</p>
Intracranial pressure (ICP) monitoring (intraventricular catheter, subarachnoid screw or bolt, epidural sensor, anterior fontanel pressure monitor)	A sensing device is placed in the head that monitors the pressure intracranially.	Used to monitor ICP resulting from hydrocephalus, acute head trauma, and brain tumors. Ventricular catheter also allows for draining of CSF to help reduce ICP.	<p>Usually monitored in critical care setting</p> <p>Monitor for signs and symptoms of increased ICP.</p> <p>Monitor for infection.</p> <p>Keep head of bed elevated 15–30 degrees.</p> <p>Alarms for monitoring device should remain on at all times.</p> <p>Reduce stimulation and avoid interventions that may cause pain or stress and result in an increased ICP.</p>

**COMMON LABORATORY AND DIAGNOSTIC TESTS 38.1** (continued)

Test	Explanation	Indications	Nursing Implications
Video EEG	Measures electrical activity of the brain continuously along with recorded video of actions and behaviors	Can help determine precise localization of seizure area before surgery. Assists in diagnosis and management of seizures by correlating behaviors with abnormal EEG activity	<p>Ensure that seizure precautions are in place.</p> <p>Parent or caregiver must be with child at all times.</p> <p>The child's movements are limited and usually confined to the room. When the child changes position, ensure that he or she is still seen by video camera. Boredom can be a problem. Must notify nurse if seizure activity occurs; push the alert button to highlight attack on EEG recording.</p> <p>Nurse must immediately go to the room, expose as much of the child as possible (remove covers; if at night, turn on light), and avoid blocking the camera. Ask questions (i.e., what is your name, can you raise your left arm, remember the word banana) to help assess responsiveness more accurately. Stay with the child until a full recovery has occurred. Ask the child what word you asked him or her to remember, and document all findings and time of the event.</p>

Adapted from Fischbach, F. T., & Dunning III, M. B. (2009). *A manual of laboratory and diagnostic tests (8th ed.)*. Philadelphia: Lippincott Williams & Wilkins.

guidelines in determining ongoing treatment. Laboratory or nonnursing personnel obtain some of the tests, while the nurse might obtain others. In either instance, it is important to be familiar with how the tests are obtained, what they are used for, and normal versus abnormal results. This knowledge will also be necessary when providing child and family education related to the testing. Many of these tests, such as lumbar puncture (LP; see Fig. 38.6), can be frightening to parents and the child. Prepare the family and the child and provide support and reassurance during and after the test or procedure.

**After completing an assessment of Antonio, the nurse noted the following: a full anterior fontanel; when being held, Antonio was inconsolable; when lying still, he was calmer and in the opisthotonic position.**

## Nursing Diagnoses and Related Interventions

Upon completion of a thorough assessment, the nurse might identify several nursing diagnoses, including:

- Decreased intracranial adaptive capacity
- Risk for ineffective tissue perfusion: cerebral
- Risk for injury
- Disturbed sensory perception
- Risk for infection
- Pain
- Self-care deficit (specify)
- Impaired physical mobility
- Risk for delayed development
- Imbalanced nutrition: less than body requirements
- Risk for deficient fluid volume
- Deficient knowledge (specify)
- Interrupted family processes

**FIGURE 38.6** Proper positioning for a lumbar puncture. **(A)** The newborn is positioned upright with head flexed forward. **(B)** Child or older infant is positioned on the side with head flexed forward and knees flexed to abdomen.

Nursing goals, interventions, and evaluation for the child with a neurologic disorder are based on the nursing diagnoses.

**Based on the assessment findings, what would be your top three prioritized nursing diagnoses for Antonio?**

Nursing Care Plan 38.1 may be used as a guide in planning nursing care for the child with a neurologic disorder. It should be individualized based on the child's symptoms and needs. Additional information will be included later in this chapter related to specific disorders.

**Based on your top three nursing diagnoses for Antonio, describe appropriate nursing interventions.**

## SEIZURE DISORDERS

Seizures occur in about 4-10% of children (Mikati, 2011). Most seizures are caused by disorders that originate outside of the brain such as a high fever, infection, head trauma, hypoxia, toxins, or cardiac arrhythmias. Less than one third of seizures in children are caused by epilepsy (Mikati, 2011). Seizure disorders discussed below include epilepsy, febrile seizures, and neonatal seizures.

### Epilepsy

Epilepsy is a condition in which seizures are triggered recurrently from within the brain. Epilepsy is a common neurologic disorder discovered in childhood, although

brain injury or infection can cause epilepsy at any age. Two or more unprovoked seizures, which occur more than 24 hours apart, is indicative of epilepsy (Cavazos & Spitz, 2011; Mikati, 2011; Zak & Chan, 2010). The prognosis for most children with seizures associated with epilepsy is good. Many children will outgrow epilepsy, but some children will have persistent seizures that are difficult to manage and may be unresponsive to pharmacologic interventions. Living with a seizure disorder may have a devastating impact on the quality of life of the child and family.

## Pathophysiology

Epilepsy is a complex disorder of the CNS in which brain function is affected. Recurrent or unprovoked seizures are the clinical manifestation of epilepsy and result from a disruption of electrical communication among the neurons of the brain. This disruption results from an imbalance between the excitatory and inhibitory mechanisms in the brain, causing the neurons to either fire when they are not supposed to or not fire when they should. Epilepsy has numerous causes. It may be acquired and related to brain injury or it may be a familial tendency, but in many cases the cause is unknown (CDC, 2011).

There are two major categories of seizures—partial and generalized seizures. In partial seizures only one area of the brain is involved, while general seizures involve the entire brain. Partial seizures account for a large portion of childhood seizures and are classified as *simple* or *complex* (Mikati, 2011). Generalized seizures include infantile spasms, absence seizures, tonic-clonic seizures, myoclonic seizures, and atonic seizures. There are many different types of seizures, and the classification of the type of seizure is crucial in assisting with the management and control of seizures. Not all cases are easily classified. The most common seizure types are discussed in Table 38.2.

## NURSING CARE PLAN 38.1

## Overview for the Child with a Neurologic Disorder

**NURSING DIAGNOSIS:** Decreased intracranial adaptive capacity related to compression of brain tissue due to increased cerebrospinal fluid (CSF) or cerebral edema secondary to increased intracranial pressure (ICP) resulting from brain injury, congenital structural defects, brain tumor, decreased reabsorption of CSF, or shunt malfunction as evidenced by vomiting, headache, complaints of visual disturbances, decreased pulse and respirations, elevated blood pressure or pulse pressure, changes in level of consciousness, increased head circumference, or bulging fontanel

**Outcome Identification and Evaluation**

Child will remain free of signs and symptoms of increased intracranial pressure as evidenced by *remaining free of headache, vomiting, vision disturbances, vital signs within parameters for age, no signs of altered levels of consciousness, able to maintain effective breathing pattern, free of excessive irritability or lethargy, head circumference within parameters for age.*

**Interventions: Promoting Adequate Intracranial Adaptive Capacity**

- Assess neurologic status closely, and monitor for signs and symptoms of increased ICP: *changes in level of consciousness, signs of irritability or lethargy, and changes in pupillary reaction can indicate changes in ICP.*
- Monitor vital signs: *decreased pulse and respiratory rate and increased blood pressure or pulse pressure can indicate increased ICP.*
- Measure head circumference in children younger than 3 years of age: *increases in head circumference outside parameters for age can indicate increased ICP.*
- Elevate head of bed 15–30 degrees *to facilitate venous return and help to reduce ICP.*
- Minimize environmental stimuli and noise, and avoid pain-producing procedures if possible: *all can increase ICP.*
- Have emergency equipment ready and available: *increased ICP can result in respiratory or cardiac failure.*
- Notify physician or nurse practitioner immediately if changes in assessment are noted: *early intervention is critical to prevent neurologic damage and death.*

**NURSING DIAGNOSIS:** Risk for ineffective (cerebral) tissue perfusion related to increased ICP, alteration in blood flow secondary to hemorrhage, vessel malformation, cerebral edema

**Outcome Identification and Evaluation**

Child will exhibit adequate cerebral tissue perfusion through course of illness and childhood: *child will remain alert and oriented with no signs of altered level of consciousness; vital signs will be within parameters for age; motor, sensory, and cognitive function will be within parameters for age; head circumference will remain within parameters for age.*

**Interventions: Promoting Adequate Tissue Perfusion**

- Assess neurologic status closely, and monitor for signs and symptoms of increased ICP: *changes in level of consciousness, signs of irritability or lethargy, and changes in pupillary reaction can indicate decreased cerebral tissue perfusion.*
- Monitor vital signs: *decreased pulse and respiratory rate and increased blood pressure or pulse pressure can indicate increased ICP, which can lead to decreased cerebral perfusion.*
- Have emergency equipment ready and available: *decreased cerebral perfusion can result in respiratory or cardiac failure.*
- Notify physician or nurse practitioner immediately if changes in assessment are noted: *early intervention is critical to prevent neurologic damage and death.*

(continued)

## NURSING CARE PLAN 38.1

## Overview for the Child with a Neurologic Disorder (continued)

**NURSING DIAGNOSIS:** Risk for injury related to altered level of consciousness, weakness, dizziness, ataxia, loss of muscle coordination secondary to seizure activity

**Outcome Identification and Evaluation**

Child will remain free of injury as evidenced by *no signs of aspiration or traumatic injury*.

**Interventions: Preventing Injury**

- Ensure child has patent airway and adequate oxygenation (have suction, oxygen available at bedside) and place child in side-lying position if possible: *a child with altered level of consciousness may not be able to manage his or her secretions and is at risk for aspiration and ineffective airway clearance; providing suction and oxygenation can help ensure an open airway and the side-lying position can help secretions drain and prevent obstruction of airway or aspiration.*
- Protect child from hurting self during seizures or changes in level of consciousness by removing environmental obstacles, easing child to lying position, and padding side rails: *helps to keep environment safe.*
- Institute seizure precautions for any child at risk for seizure activity (see Box 38.2) *to help prevent injury that can result from acute seizure activity.*
- With seizure activity do not insert a tongue blade or restrain child: *can lead to injury to caregiver and child.*
- Administer anticonvulsant medications as ordered: *will help to promote cessation and prevention of seizure activity.*
- Assist child with ambulation *to help prevent injury in child with weakness, dizziness, or ataxia.*
- Allow for periods of rest *to prevent fatigue and decrease risk of injury.*

**NURSING DIAGNOSIS:** Disturbed sensory perception related to presence of neurologic lesion or pressure on sensory or motor nerves secondary to increased ICP, presence of tumor, swelling post-operatively as evidenced by visual disturbances (i.e., reports of double vision), pupillary changes, nystagmus, ataxia, balance disturbances, or loss of response to stimuli

**Outcome Identification and Evaluation**

Child will be free of changes in sensory perception or will remain at baseline as evidenced by *no complaints of double vision, PERRLA, no disturbances of gait or balance noted, and no increase in loss of responses to stimuli.*

**Interventions: Managing Disturbed Sensory Perception**

- Assess for changes in sensory perception: *provides baseline data and allows nurse to recognize change in sensory perception early.*
- Monitor child for risk of injury secondary to changes in sensory perception: *visual changes and disturbances of gait or balance increase child's risk for injury.*
- Notify physician or nurse practitioner of changes in sensory perception: *can indicate increased ICP and medical emergency.*
- Assist child to learn to use adaptive methods to live with permanent changes in sensory perception (i.e., use of eyeglasses) and maximize the use of intact senses: *adaptive devices can enhance sensory input and intact senses can often compensate for impaired senses.*
- Provide familiar sounds (voices, music): *can help relieve anxiety related to changes in sensory perception, especially visual changes.*

## NURSING CARE PLAN 38.1

**Overview for the Child with a Neurologic Disorder** (continued)

**NURSING DIAGNOSIS:** Risk for infection related to surgical interventions, presence of foreign body (i.e., shunt), trauma to skull, nutritional deficiencies, stasis of pulmonary secretions and urine, presence of infectious organisms as evidenced by fever, poor feeding, decreased responsiveness, and presence of virus or bacteria on laboratory screening

**Outcome Identification and Evaluation**

Child will exhibit no signs or symptoms of local or systemic infection and will not spread infection to others: *symptoms of infection will decrease over time; others will remain free of infection.*

**Interventions: Preventing Infection**

- Monitor vital signs: *elevation in temperature can indicate presence of infection.*
- Monitor incision sites for signs of local infection: *redness, warmth, drainage, swelling, and pain at incision site can indicate presence of infection.*
- Maintain aseptic technique—practice good hand washing and use proper technique when managing postoperative incisions and external shunts *to prevent introduction of further infectious agents.*
- Administer antibiotics as prescribed *to prevent or treat bacterial infection.*
- Encourage nutritious diet and proper hydration according to child's preferences and ability to feed orally *to assist body's natural defenses against infection.*
- Isolate the child as required *to prevent nosocomial spread of infection.*
- Teach child and family preventive measures such as good hand washing, covering mouth and nose upon cough or sneeze, and adequate disposal of used tissues *to prevent nosocomial or community spread of infection.*

**NURSING DIAGNOSIS:** Self-care deficit (specify) related to neuromuscular impairments; cognitive deficits as evidenced by an inability to perform hygiene care and transfer self independently

**Outcome Identification and Evaluation**

Child will demonstrate ability to care for self within age parameters and limits of disease: *child is able to feed, dress, and manage elimination within limits of disease and age.*

**Interventions: Maximizing Self-Care**

- Introduce child and family to self-help methods as soon as possible: *promotes independence from the beginning.*
- Encourage family and staff to allow child to do as much as possible: *allows child to gain confidence and independence.*
- Teach specific measures for bowel and urinary elimination as needed: *promotes independence and increases self-care abilities and self-esteem.*
- Collaborate with physical therapy, occupational therapy, and speech therapy departments to provide child and family with appropriate tools to modify environment and methods to promote transferring and self-care: *allows for maximum functioning.*
- Praise accomplishments and emphasize child's abilities: *helps improve self-esteem and encourages feeling of confidence and competence.*
- Balance activity with periods to rest *to reduce fatigue and increase energy for self-care.*

(continued)

## NURSING CARE PLAN 38.1

## Overview for the Child with a Neurologic Disorder (continued)

**NURSING DIAGNOSIS:** Impaired physical mobility related to muscle weakness, hypertonicity, impaired coordination, loss of muscle function or control as evidenced by an inability to move extremities, to ambulate without assistance, to move without limitations

**Outcome Identification and Evaluation**

Child will be able to engage in activities within age parameters and limits of disease: *child is able to move extremities, move about environment, and participate in exercise programs within limits of age and disease.*

**Interventions: Maximizing Physical Mobility**

- Encourage gross and fine motor activities: *facilitates motor development.*
- Collaborate with physical therapy, occupational therapy, and speech therapy departments to strengthen muscles and promote optimal mobility: *facilitates motor development.*
- Utilize passive and active range of motion (ROM) and teach child and family how to perform: *prevents contractures and facilitates joint mobility and muscle development (active ROM) to help increase mobility.*
- Praise accomplishments and emphasize child's abilities: *helps improve self-esteem and encourages feeling of confidence and competence.*

**NURSING DIAGNOSIS:** Risk for delayed development related to physical disability, cognitive deficits, activity restrictions

**Outcome Identification and Evaluation**

Child will demonstrate developmental milestones within age parameters and limits of disease: *child expresses interest in the environment and people around him or her, and interacts with environment age appropriately.*

**Interventions: Maximizing Development**

- Use therapeutic play and adaptive toys: *helps facilitate developmental functioning.*
- Provide stimulating environment when possible to maximize potential for growth and development.
- Praise accomplishments and emphasize child's abilities: *helps improve self-esteem and encourages feeling of confidence and competence.*

**NURSING DIAGNOSIS:** Nutrition, imbalanced: less than body requirements related to vomiting and difficulty feeding secondary to increased ICP; difficulty sucking, swallowing, or chewing; surgical incision pain or difficulty assuming normal feeding position; inability to feed self as evidenced by decreased oral intake, impaired swallowing, weight loss

**Outcome Identification and Evaluation**

Child will exhibit signs of adequate nutrition: *weight will remain within parameters for age, skin turgor will be good, intake/output (I/O) will be within normal limits, adequate calories will be ingested, and vomiting will cease or decrease.*

## NURSING CARE PLAN 38.1

**Overview for the Child with a Neurologic Disorder** (continued)**Interventions: Promoting Adequate Nutrition**

- Monitor height and weight: *insufficient intake will lead to impaired growth and weight gain.*
- Monitor hydration status (moist mucous membranes, elastic skin turgor, adequate urine output): *insufficient intake can lead to dehydration.*
- Use techniques to promote caloric and nutritional intake and teach family (i.e., positioning, modified utensils, soft or blended foods, allow extra time): *these techniques can facilitate intake.*
- Assess respiratory system frequently *to assess for aspiration.*
- Monitor for nausea and vomiting and medicate if ordered *to help reduce vomiting and increase intake.*
- Monitor for pain and medicate if ordered *to help reduce pain related to surgical incisions and trauma, and increase intake.*
- Assist family to assume as normal a feeding position as possible *to help increase oral intake.*

**NURSING DIAGNOSIS:** Risk for deficient fluid volume related to vomiting, altered level of consciousness, poor feeding or intake, insensible loss due to fever, failure of regulatory mechanisms (as in diabetes insipidus) as evidenced by dry oral mucosa, decreased skin turgor, sudden weight loss, hypotension, and tachycardia

**Outcome Identification and Evaluation**

Fluid volume will be maintained and balanced: *oral mucosa moist and pink, skin turgor elastic, urine output at least 1–2 mL/kg/hour.*

**Interventions: Promoting Adequate Fluid Balance**

- Administer intravenous (IV) fluids if ordered *to maintain adequate hydration in children who are NPO (nothing by mouth) or unable to tolerate oral intake.*
- When oral intake is allowed and tolerated, encourage oral (PO) fluids *to promote intake and maintain hydration.*
- Strict intake and output monitoring: *can help identify fluid imbalance and also detect signs of abnormal pituitary secretions resulting in conditions like syndrome of inappropriate antidiuretic hormone secretion (SIADH) and diabetes insipidus (DI) (see Chapter 49 for further information).*
- Maintain minimum hydration and avoid overhydration in children where cerebral edema is a concern: *fluid overload can contribute to cerebral edema.*
- Urine specific gravity, urine and serum electrolytes (especially serum sodium), blood urea nitrogen, creatinine and osmolality, and daily weights: *are reliable indicators of fluid status and can also detect signs of abnormal pituitary secretions resulting in conditions like SIADH and DI.*

(continued)

## NURSING CARE PLAN 38.1

**Overview for the Child with a Neurologic Disorder** (continued)

**NURSING DIAGNOSIS:** Knowledge deficit (specify) related to lack of information regarding complex medical condition, prognosis, and medical needs as evidenced by verbalization, questions, or actions demonstrating lack of understanding regarding child's condition or care

**Outcome Identification and Evaluation**

Child and family will verbalize accurate information and understanding about condition, prognosis, and medical needs: *child and family demonstrate knowledge of condition and prognosis and medical needs including possible causes, contributing factors, and treatment measures.*

**Interventions: Providing Child and Family Teaching**

- Assess child's and family's willingness to learn: *child and family must be willing to learn for teaching to be effective.*
- Provide family with time to adjust to diagnosis: *will help facilitate adjustment and ability to learn and participate in child's care.*
- Repeat information: *allows family and child time to learn and understand.*
- Teach in short sessions: *many short sessions are found to be more helpful than one long session.*
- Gear teaching to a level of understanding of the child and also the family (depends on age of child, physical condition, memory) *to ensure understanding.*
- Provide reinforcement and rewards: *helps facilitate the teaching–learning process.*
- Use multiple modes of learning involving many senses (provide written, verbal, demonstration, and videos) when possible: *child and family more likely to retain information when presented in different ways using many senses.*

**NURSING DIAGNOSIS:** Family processes, interrupted related to child's illness, hospitalization, diagnosis of chronic illness in child, and potential long-term effects of illness as evidenced by family's presence in hospital, missed work, demonstration of inadequate coping

**Outcome Identification and Evaluation**

Family will maintain functional system of support and demonstrate adequate coping, adaptation of roles and functions, and decreased anxiety: *parents are involved in child's care, ask appropriate questions, express fears and concerns, and are able to discuss child's care and condition calmly.*

**Interventions: Promoting Adequate Family Processes**

- Encourage parents and family members to verbalize concerns related to child's illness, diagnosis, and prognosis: *allows the nurse to identify concerns and areas where further education may be needed; demonstrates family-centered care.*
- Explain therapies, procedures, child's behaviors, and plan of care to parents: *understanding the child's current status and plan of care helps decrease anxiety.*
- Encourage parental involvement in care: *allows parents to feel needed and valued with a sense of control over their child's health.*
- Identify support system for family and child: *helps nurse identify needs and resources available for coping.*
- Educate family and child on additional resources available *to help them develop a wide base of support.*

TABLE 38.2 COMMON TYPES OF SEIZURES

Type	Description	Characteristics
Infantile spasms	<p>Uncommon type of generalized seizure seen in an epilepsy syndrome of infancy and childhood</p> <p>Usually seen between 3 and 12 months of age, peak incidence 4 to 8 months and usually stops by 2 years of age</p>	<p>Presents as a sudden jerk followed by stiffening</p> <p>May see:</p> <ul style="list-style-type: none"> <li>• Head flexed, arms extended, and legs drawn up</li> <li>• Arms flung out, knees are pulled up, and the body bends forward (referred to as “jackknife seizures”)</li> <li>• Cry may precede or follow</li> </ul> <p>Majority of infants have some brain disorder before seizures begin. The infant seems to stop developing and may lose skills that he or she has already attained after the onset of infantile spasms. Steroid therapy and anticonvulsants are common forms of treatment.</p>
Absence (formerly <i>petit mal</i> )	<p>Type of generalized seizure; occurs more frequently in girls than boys</p> <p>Uncommon before age 5</p>	<p>Sudden cessation of motor activity or speech with a blank facial expression or rhythmic twitching of the mouth or blinking of the eyelids</p> <p>Complex absence seizure consists of myoclonic movements of the face, fingers, or extremities and possible loss of body tone.</p> <p>Lasts less than 30 seconds</p> <p>Child may experience countless seizures in a day.</p> <p>Not associated with a postictal (after seizure) state</p> <p>May go unrecognized or mistaken for inattentiveness because of subtle change in child’s behavior</p>
Tonic-clonic (formerly <i>grand mal</i> )	<p>Extremely common generalized seizures. Most dramatic seizure type</p>	<p>Associated with an aura</p> <p>Loss of consciousness occurs and may be preceded by a piercing cry.</p> <p>Presents with entire body experiencing tonic contractions followed by rhythmic clonic contractions alternating with relaxation of all muscle groups</p> <p>Cyanosis may be noted due to apnea.</p> <p>Saliva may collect in the mouth due to inability to swallow.</p> <p>Child may bite tongue.</p> <p>Loss of sphincter control, especially the bladder, is common.</p> <p>Postictal phase: child will be semicomatose or in a deep sleep for approximately 30 minutes to 2 hours; usually responds only to painful stimuli</p> <p>Child will have no memory of the seizure; may complain of headache and feeling fatigue</p> <p>Safety of the child is a primary concern.</p> <p>See Teaching Guidelines 38.1.</p>
Myoclonic	<p>Type of generalized seizure that involves the motor cortex of the brain. May occur along with other seizure forms</p>	<p>Sudden, brief, massive muscle jerks that may involve the whole body or one body part</p> <p>Child may or may not lose consciousness.</p>
Atonic	<p>Type of generalized seizure often referred to as “drop attacks.”</p> <p>Seen in children with Lennox-Gastaut syndrome</p>	<p>Sudden loss of muscle tone. In children, may only be a sudden drop of the head. Child will regain consciousness within a few seconds to a minute.</p> <p>Can result in injury related to violent fall</p>
Simple partial	<p>Type of partial seizure that occurs in part of the brain. The symptoms seen will depend on which area of the brain is affected.</p>	<p>Motor activity characterized by clonic or tonic movements involving the face, neck, and extremities</p> <p>Can include sensory signs such as numbness, tingling, paresthesia, or pain</p> <p>Usually persists for 10–20 seconds</p> <p>Child remains conscious and may verbalize during the seizure.</p> <p>No postictal state</p>

(continued)

TABLE 38.2

COMMON TYPES OF SEIZURES (continued)

Type	Description	Characteristics
Complex partial	Common type of partial seizure May begin with a simple partial seizure then progress	May or may not have a preceding aura Consciousness will be impaired. Automatisms and complex purposeful movements are common features in infants and children. Infants will present with behaviors such as lip smacking, chewing, swallowing, and excessive salivation; can be difficult to distinguish from normal infant behavior In older children, will see picking or pulling at bed sheets or clothing, rubbing objects, or running or walking in a nondirective and repetitive fashion These seizures can be difficult to control.
Status epilepticus	Common neurologic emergency in children. Can occur with any seizure activity. Febrile seizures are the most common type. In children with epilepsy, it commonly occurs early in the course of epilepsy. Can be life threatening	Prolonged or clustered seizures where consciousness does not return between seizures The age of the child, cause of the seizures, and duration of status epilepticus influence prognosis. Prompt medical intervention is essential to reduce morbidity and mortality. Treatment: <ul style="list-style-type: none"> <li>• Basic life support—ABCs (airway, breathing, circulation)</li> <li>• Administration of anticonvulsants to cease seizures is crucial. Common medications include benzodiazepines such as lorazepam and diazepam, and fosphenytoin. (See Drug Guide 38.1 and Table 38.3.)</li> <li>• Blood glucose levels and electrolytes along with evaluation of the underlying cause should be initiated.</li> </ul>

## Therapeutic Management

Management of epilepsy focuses on controlling seizures or reducing their frequency. Another focus of epilepsy management involves helping the child who has recurrent seizures and his or her family to learn to live with the seizures. The primary mode of treatment is the use of anticonvulsants. The goal for every child should be the use of the fewest drugs with the fewest possible side effects for the control of seizures. There have been significant advances in the treatment of epilepsy due to the many new anticonvulsant medications that have become available in recent years (Table 38.3). Most anticonvulsants are taken orally and are often used in combination. Different medications control different types of seizures, which may be due to individual variation. It can take time to find the right combination to best control an individual's seizures.

If seizures remain uncontrolled, another option for managing them is surgery. Depending on the area of the brain that is affected, it may be possible to remove

the area that is responsible for the seizure activity or to interrupt the impulses from spreading and therefore stop or reduce the seizures. The adverse effects of surgery range from mild to severe, depending on the area of the brain that is affected. Other nonpharmacologic treatments that may be considered in children with intractable seizures include a ketogenic diet or placement of a vagal nerve stimulator. Refer to Common Medical Treatments 38.1.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1304. Assessment findings pertinent to epilepsy are discussed below.

### Health History

Elicit a description of the present illness and chief complaint, which will usually involve a seizure episode. Gain

**TABLE 38.3** COMMON ANTICONVULSANT MEDICATIONS

Medication	Nursing Implications
Phenytoin (IV and PO; IM administration is contraindicated)	Monitor serum levels to ensure therapeutic dosing. Be aware that gingival hyperplasia appears most commonly in children and adolescents. If on prolonged therapy, ensure adequate intake of vitamin D-containing foods. Monitor serum calcium and magnesium levels. IV form given in normal saline to prevent precipitation.
Fosphenytoin (IM or IV only)	Adverse effects are said to be less common than with phenytoin. It does not cause local irritation, but it is a more expensive drug than phenytoin. It is water soluble, therefore allowing faster and easier administration than phenytoin. All dosing is in phenytoin sodium equivalents. It does not precipitate in commonly used IV diluents.
Phenobarbital	Assess for excessive sedation. Monitor serum levels to ensure therapeutic dosing. Monitor for drug interactions. Increase vitamin D–fortified foods or administer supplement if prescribed. Withdrawal symptoms will occur if drug is stopped abruptly. Valproic acid interferes with this drug, causing increased phenobarbital levels.
Felbamate	Monitor for drug interactions, especially if child is taking phenytoin or carbamazepine.
Valproic acid (divalproex sodium, sodium valproate)	Monitor serum levels to ensure therapeutic dosing. Depakote sprinkles are available and useful for children who are unable to tolerate valproate suspension, tablets, or capsules. The contents can be sprinkled on food that does not require chewing.
Carbamazepine	Monitor serum levels to ensure therapeutic dosing; toxicity can occur even with levels slightly above therapeutic range. Plasma concentration decreased by phenytoin, phenobarbital, and valproic acid
Gabapentin	Do not administer within 2 hours of antacids. Rapidly absorbed in the gastrointestinal tract
Topiramate	Dilantin, Tegretol, and valproic acid decrease concentration of topiramate.
Oxcarbazepine	Monitor phenytoin levels if administering concurrently. Monitor serum sodium.
Zonisamide	Presence of food will delay absorption. Phenytoin, phenobarbital, and carbamazepine all increase the metabolism of this drug.
Lamotrigine	Valproate inhibits metabolism; therefore, monitor serum blood values and decrease the dose if necessary.
Levetiracetam	Monitor phenytoin levels if administering concurrently. Monitor for difficulty with gait or coordination. B-complex vitamin supplementation can help manage side effects.
Ethosuximide	Give with food if GI upset occurs. Monitor closely during periods of dosage adjustment or addition of new medications.

GI, gastrointestinal; IM, intramuscular; IV, intravenous; PO, by mouth.

Adapted from Mikati, M. A. (2011). Seizures in childhood. In R. M. Kliegman, B. F. Stanton, St. Geme, J. W., Schor, N. F., & Behrman, R. E. (Eds.), *Nelson's textbook of pediatrics* (19th ed., pp. 2013-2039). Philadelphia: Saunders; and Karch, A. (2010). *2010 Lippincott's nursing drug guide*. Philadelphia: Wolters Kluwer Health/Lippincott Williams & Wilkins.

information to help characterize the episode as a seizure or as a nonepileptic event (see Box 38.1 for a list of nonepileptic events). It is rare to actually observe the child having a seizure; therefore, a complete, accurate, and detailed history from a reliable source is essential. Questions should include:

- Where did the event occur—while sleeping, eating, playing, or just after waking?
- Description of child's behavior during the event—what types of movements, progression, length, respiratory status, apnea?
- How did the child act after the event?

## BOX 38.1

**NONEPILEPTIC EVENTS**

- Syncope
- Breath holding
- Jitteriness
- Apnea
- Gastroesophageal reflux
- Cardiac conduction abnormalities
- Migraines
- Tics
- Night terrors
- Benign sleep movements

- Have the episodes been recurrent? If so, how frequent?
- Any precipitating factors such as a fever, fall, activity, anxiety, infection, or exposure to strong stimuli such as flashing lights or loud noises?

Explore the child's current and past medical history for risk factors such as:

- Family history of seizures or epilepsy
- Any complications during the prenatal, perinatal, or postnatal periods
- Changes in developmental status or delays in developmental milestones
- Any recent illness, fever, trauma, or toxin exposure

Children known to have epilepsy are often admitted to the hospital for other health-related issues or complications and treatment of their seizure disorder. The health history should include questions related to:

- Age of onset of seizures
- Seizure control—what medications is the child taking and has he or she been able to take them; when was his or her last seizure?
- Description and classification of seizures—does the child lose consciousness; does the child become apneic?
- Precipitating factors that may contribute to onset of seizures
- Adverse effects related to anticonvulsant medications
- Compliance with medication regimen

**Physical Examination**

Perform a complete neurologic examination. Careful assessment of the child's mental status, language, learning, behavior, and motor abilities can help provide information about any neurologic deficits. If you observe seizure activity directly, provide a thorough and accurate description of the event. This description needs to include:

- Time of onset and length of seizure activity
- Alterations in behavior such as a cry or changes in facial expression, motor abilities, or sensory alterations before the seizure that may indicate an aura

- Precipitating factors such as fever, anxiety, just waking, or eating
- Description of movements and any progression
- Description of respiratory effort and any apnea noted
- Changes in color (pallor or cyanosis) noted
- Position of mouth, any injury to mouth or tongue, inability to swallow, or excessive salivation
- Loss of bladder or bowel control
- State of consciousness during seizure and **postictal** (after seizure) state—during the seizure the nurse may ask the child to remember a word; after the seizure, assess if child is able to recall it, to help accurately establish current mental state
- Assess orientation to person, place, and time; motor abilities; speech; behavior; alterations in sensation postictally
- Duration of postictal state

**Laboratory and Diagnostic Tests**

Laboratory and diagnostic tests are used to evaluate the cause of, and also aid in identifying the type of, seizure activity (refer to Common Laboratory and Diagnostic Tests 38.1). Common laboratory and diagnostic studies ordered for the diagnosis and assessment of epilepsy include:

- Serum glucose, electrolytes, and calcium—to rule out metabolic causes such as hypoglycemia and hypocalcemia
- Lumbar puncture—to analyze cerebrospinal fluid (CSF) to rule out meningitis or encephalitis
- Skull x-ray examinations—to evaluate for the presence of fracture or trauma
- Computed tomography (CT) and magnetic resonance imaging (MRI) studies—to identify abnormalities and intracranial bleeds and rule out tumors
- Electroencephalographs (EEGs)—EEG findings may be noted with certain seizure types, but a normal EEG does not rule out epilepsy because seizure activity rarely occurs during the actual testing time. EEGs are useful in evaluating seizure type and assisting in medication selection. They can be useful in differentiating seizures from nonepileptic activity.
- Video EEGs—provide the opportunity to see the child's actual behavior on video, accompanied with EEG changes; can improve the chance of catching a seizure because the monitoring is done over a period of time

**Nursing Management**

Nursing management focuses on preventing injury during seizures, administering appropriate medication and treatments to prevent or reduce seizures, and providing education and support to the child and family to help them cope with the challenges of living with a chronic seizure disorder. See Box 38.2 for a list of basic seizure precautions. In addition to the nursing diagnoses and

## BOX 38.2

**SEIZURE PRECAUTIONS**

- Padding of side rails and other hard objects
- Side rails raised on bed at all times when child is in bed
- Oxygen and suction at bedside
- Supervision, especially during bathing, ambulation, or other potentially hazardous activities
- Use of a protective helmet during activity may be appropriate.
- Child should wear a medical alert bracelet.

related interventions discussed in Nursing Care Plan 38.1, interventions common to epilepsy follow.

**Relieving Anxiety**

Seizures produce fear and anxiety due to their unpredictable nature along with their uncontrolled, forceful, and, at times, violent appearance. Instruct parents and family members, along with those in the community who may care for the child, on how to respond in case of a seizure (see Teaching Guidelines 38.1). This will help to empower the parents, family, and other caregivers, and in turn alleviate some of the anxiety that they may feel.

**Teaching Guidelines 38.1****HOW TO RESPOND WHEN YOUR CHILD HAS A SEIZURE**

Instruct parents and caregivers:

- Remain calm.
- Time seizure episode.
- If child is standing or sitting, ease child to the ground if possible.
- Tight clothing and jewelry around the neck should be loosened if possible.
- Place child on one side and open airway if possible.
- Do not restrain the child.
- Remove hazards in the area.
- Do not forcibly open jaw with a tongue blade or fingers.
- Document length of seizure and movements noted, also cyanosis or loss of bladder or bowel control and any other characteristics.
- Remain with child until fully conscious.
- Call emergency medical services (EMS) if:
  - The child stops breathing
  - Any injury has occurred
  - Seizure lasts for more than 5 minutes
  - This is the child's first seizure
  - Child is unresponsive to painful stimuli after seizure

**Managing Treatment**

Provide child and family teaching and instruction regarding the administration of anticonvulsant therapy and its importance. Included in this discussion should be common adverse effects, the need to continue the medication unless instructed otherwise by the physician or nurse practitioner, and the need to call the physician or nurse practitioner if the child is ill and vomiting and unable to take his or her medication. Encourage parents to discuss unwanted adverse effects with the physician or nurse practitioner so that they can be addressed and noncompliance with the medication regimen can be reduced. A common cause of breakthrough seizures is medication noncompliance.

**Providing Family Support and Education**

Having a child with a chronic seizure disorder can place stress and anxiety on the family. This stress and anxiety is often due to fears and misconceptions they may have. An important nursing function is to educate not only the child and family but also the community, including the child's teachers and caregivers, on the reality and facts of the disorder. Encourage parents to be involved in the management of their child's seizures, but to allow the child to learn about the disorder and its management as soon as he or she is old enough. Encourage parents to treat the child with epilepsy just as they would a child without this disorder. Children who are brought up no differently than children without epilepsy will be more likely to develop a positive self-image and have increased self-esteem. Any activity restrictions, such as limiting swimming or participation in sports, will be based on the type, frequency, and severity of the seizures the child has. Educate parents and children on any restrictions and encourage parents to place only the necessary restrictions on the child.

The needs of the child and family will change as the child grows and develops. The nurse needs to recognize these changes and provide appropriate education and support. Referral to support groups is appropriate. Links to helpful information about epilepsy including foundation information can be found on [thePoint](#).

**Febrile Seizures**

Febrile seizures are the most common type of seizure seen during childhood (American Academy of Pediatrics, 2008 [AAP]; Mikati, 2011). They usually affect children who are younger than 5 years of age, with the peak incidence occurring in children between 14 and 18 months old. It is rare to see febrile seizures in children younger than 6 months and older than 5 years of age. Febrile seizures are more commonly seen in boys and there is an increased risk for children who have a family history

of febrile seizures. Febrile seizures are associated with a fever, usually related to a viral illness. These seizures are usually benign but can be very frightening for both the child and family. In most cases the prognosis is excellent. However, febrile seizures may be a sign of a dangerous underlying infection, such as meningitis or sepsis. Though rare, complications associated with febrile seizures include status epilepticus, motor coordination deficits, intellectual disability, and behavioral problems.

## Therapeutic Management

Therapeutic management includes determination and treatment of the cause of the fever and interventions to control the fever. The American Academy of Pediatrics does not recommend long-term or intermittent anticonvulsant therapy for the child who has suffered one or more simple febrile seizures (AAP, 2008). Rectal diazepam has been shown to be safe and effective in terminating febrile seizures and may be used in children at high risk for febrile seizures or in children whose parents are extremely anxious.

## Nursing Assessment

A febrile seizure is usually associated with a rapid rise in core temperature to 39°C (102.2°F) or higher. A simple febrile seizure is defined as a generalized seizure lasting less than 15 minutes (usually a few seconds to 10 minutes) that occurs once in a 24-hour period and is accompanied by a fever without any central nervous system infection present (AAP, 2008; Mikati, 2011). A brief postictal period is often seen where the child appears drowsy. The seizure is likely to have stopped by the time a child receives medical attention. Diagnosis is made based on a thorough history and physical examination, accompanied by a determination of the source of the fever. In some cases an LP may be performed to rule out meningitis or encephalitis. This will be based on the age and the clinical presentation of the child.

Risk factors for recurrence of a febrile seizure include young age at first febrile seizure and family history of febrile seizures and high fever. Children who experience one or more simple febrile seizures have a slightly greater risk of developing epilepsy than the general population (AAP, 2008; Mikati, 2011). No evidence exists that febrile seizures cause structural damage or cognitive declines (AAP, 2008; Mikati, 2011).

## Nursing Management

Provide parental support and education regarding febrile seizures. Reassure parents of the benign nature of febrile seizures. Counsel parents on controlling fever, discuss how to keep a child safe during a seizure, and provide

instruction and demonstration in the administration of rectal diazepam at the onset of a seizure (if applicable). Instruct parents when to call their physician or nurse practitioner and when to take their child to the emergency room. Reinforce that any recurrent seizure activity will require prompt medical attention.

## Neonatal Seizures

There is a high incidence of seizures during the neonatal period. The immature brain is more prone to seizure activity and metabolic, infectious, structural, and toxic diseases are more likely to be seen in this age group (Mikati, 2011). Neonatal seizures are seizures that occur within the first 4 weeks of life and are most commonly seen within the first 10 days. They are different from those in the child or adult because generalized tonic-clonic seizures tend not to occur during the first month of life (Mikati, 2011). Seizures in newborns are associated with underlying conditions such as hypoxic ischemic encephalopathy, metabolic disorders (hypoglycemia and hypocalcemia), neonatal infection (meningitis and encephalitis), and intracranial hemorrhage. The prognosis depends mainly on the underlying cause of the seizures and the severity of the insult. There is increasing evidence that neonatal seizures have an adverse effect on neurodevelopment and may predispose the infant to cognitive, behavioral, or epileptic complications later in life.

## Therapeutic Management

Acute neonatal seizures should be treated aggressively because repeated seizure activity may result in injury to the brain. Treatment focuses on ensuring adequate ventilation; correcting any underlying metabolic disturbance that may exist, such as hypoglycemia; and possibly administering anticonvulsant therapy. Phenobarbital is often used in the initial management of neonatal seizures but efficacy remains uncertain. The dosage of anticonvulsants may be higher in the neonate because neonates metabolize drugs more rapidly than older infants.

## Nursing Assessment

Neonatal seizures may be hard to recognize clinically and may be accompanied by a normal EEG (Mikati, 2011). Certain clinical features are often seen in neonates experiencing seizures, such as tachycardia and hypertension. These symptoms can help distinguish seizures from nonepileptic movements in neonates. Nonepileptic movements, such as tremors or jitters, are often caused by sensory stimulation such as loud noises and can be diminished or stopped by holding the limb to limit movement; in true seizures this is not the case (Mikati, 2011). Ocular deviation may be seen with seizure activity but will not be present with

**TABLE 38.4** TYPES OF SEIZURES SEEN IN NEWBORN INFANTS

Type	Age Affected	Characteristics
Subtle	Preterm and full term	Chewing motions, excessive salivation, alterations in respiratory rate, apnea, blinking, and pedaling movements
Tonic	Preterm	Rigid posturing of the extremities and trunk May be associated with fixed deviation of the eyes
Focal clonic	Full term	Rhythmic twitching of local muscle groups such as the extremities or face
Multifocal clonic	Full term	Similar to focal clonic, except many muscle groups are involved, frequently simultaneously
Myoclonic	Rare in neonatal period	Brief focal jerks, involving one extremity; or multifocal jerks, involving several body parts

Adapted from Mikati, M. A. (2011). Seizures in childhood. In R. M. Kliegman, B. F. Stanton, St. Geme, J. W., Schor, N. F., & Behrman, R. E. (Eds.), *Nelson's textbook of pediatrics* (19th ed., pp. 2013-2039). Philadelphia: Saunders.

nonepileptic activity. The characteristics of seizures seen in the neonatal period differ from those seen in older children. Five major seizure types have been recognized in the neonatal period. See Table 38.4 for information on types of seizures seen in newborn infants.

Laboratory and diagnostic tests including serum testing (e.g., serum glucose, electrolytes, calcium), LP (to analyze CSF), cranial ultrasound, CT, and MRI may be performed to help determine the cause of the seizures. EEGs and video EEGs may assist in the characterization of neonatal seizures and their medical management.

## Nursing Management

Nursing management will focus on carrying out interventions to cease seizure activity, monitoring neurologic status closely, recognizing the seizures, preventing injury during seizure activity, and providing support and education to the parents and family.

## STRUCTURAL DEFECTS

Due to the sensitivity of the development of the neurologic system in the first weeks of embryonic life, there exists a potential for defects to occur. These structural defects include neural tube defects, microcephaly, Arnold-Chiari malformation, hydrocephalus, intracranial arteriovenous malformation, and craniosynostosis.

### Neural Tube Defects

Neural tube defects (NTDs) account for the majority of congenital anomalies of the CNS (Kinsman & Johnston, 2011). They are one of the most common birth defects

contributing to infant mortality and disability. NTDs affect 1 per 1,000 live births in the United States, with approximately 4,000 pregnancies affected annually (Jallo, 2011). They are serious birth defects of the spine and the brain and include disorders such as spina bifida occulta, myelomeningocele, meningocele, anencephaly, and encephalocele. The neural tube closes between the third and fourth week in utero. The cause of neural tube defects is not known, but many factors such as drugs, malnutrition, chemicals, and genetics can adversely affect normal CNS development. Strong evidence exists that maternal pre-conception supplementation of folic acid can decrease the incidence of neural tube defects in pregnancies at risk by 50% (Kinsman & Johnston, 2011). In 1992, the U.S. Public Health Service recommended that all women of childbearing age who are capable of becoming pregnant take 0.4 mg (400 mcg) of folic acid daily. Pregnant women with a history of pregnancies affected by NTDs are recommended to take a higher dosage. Prenatal screening of maternal serum for  $\alpha$ -fetoprotein (AFP) and ultrasound examination at 16 to 18 weeks' gestation can help identify fetuses at risk. Anencephaly and encephalocele are discussed below. Refer to Chapter 44 for information on spina bifida occulta, meningocele, and myelomeningocele.

### Anencephaly

Anencephaly is a defect in brain development resulting in small or missing brain hemispheres, skull, and scalp. It occurs when the cephalic or upper end of the neural tube fails to close during the third to fourth week of gestation. These infants are born without both a forebrain and a cerebrum and the remaining brain tissue may be exposed. The condition is incompatible with life. The

FIGURE 38.7 Anencephalic infant.

incidence of anencephaly is 1 in 1,000 live births (Kinsman & Johnston, 2011).

### Nursing Assessment

Anencephalic infants have a distinctive appearance, with a large defect noted in the vault of the skull (Fig. 38.7). The mother may have had a difficult labor due to the malformation of the head not allowing it to engage in the cervix. The majority of infants will be stillborn. If not, most anencephalic infants die within hours to several days of birth (Kinsman & Johnston, 2011). There have been a few cases in which the infant has lived for several months. The infant is usually blind, deaf, unconscious, and unable to feel pain. Some infants born with anencephaly may be born with a brain stem, but due to the lack of a cerebrum there is no possibility of gaining consciousness. Reflex actions such as respirations, reactions to sound and touch, and ability to suck may be present.

### Nursing Management

The prognosis is extremely poor. Nursing management is supportive in nature and focuses on comfort measures for the dying infant. Some parents may have been aware of the diagnosis prenatally due to screening tests such as AFP and ultrasounds. Parents and family will need support and understanding from all health care professionals during this difficult time. Fear of what the child will look like may be overwhelming. Use of an infant

cap can be helpful and allow parents to feel more comfortable holding and comforting their infant. Assisting with anticipatory grieving and decision making related to end-of-life care will also be key nursing interventions.

### Encephalocele

Encephalocele is a protrusion of the brain and meninges through a skull defect. It results from failure of the anterior portion of the neural tube to close. The prognosis, including the extent of complications and cognitive deficits, will depend on the size and location of the encephalocele and involvement of other brain structures. Encephaloceles are often accompanied by craniofacial and other abnormalities such as hydrocephalus, microcephaly, spastic quadriplegia, ataxia, visual problems, developmental delay, mental and growth retardation, and seizures. Some children who are affected may display normal intelligence.

Therapeutic management consists of surgical repair, including placement of tissues back into the skull and removal of the sac; possible shunt placement to correct associated hydrocephalus; and corrective repair of any craniofacial abnormalities.

### Nursing Assessment

Initial assessment after delivery will reveal a visible external sac protruding from the skull area. It occurs most commonly in the occipital region but can occur elsewhere, such as frontally or nasofrontally. Generally the lesion is covered by skin, but it may also be open. Therefore, assessment to ensure that the sac covering is intact remains important. Assess neurologic status carefully. Before surgical correction, the infant will be examined thoroughly to determine brain tissue involvement or associated anomalies. Diagnostic procedures such as CT, MRI, and ultrasound may be performed.

### Nursing Management

Nursing management will consist of preoperative and postoperative care, along with symptomatic and supportive care. Preoperative and postoperative care will be similar to that for the child with myelomeningocele, with a focus on preventing rupture of the sac, preventing infection, and providing adequate nutrition and hydration. Infants with an encephalocele are at an increased risk for developing hydrocephalus. Therefore, monitor for signs and symptoms of increased ICP and head circumference.

### Microcephaly

Microcephaly is defined as a head circumference that is more than three standard deviations below the mean for the age and sex of the infant (Kinsman & Johnston, 2011). It may be congenital or it may be acquired and develop

in the first few years of life. It generally results in intellectual disability due to the lack of functioning brain tissue. There are many causes. Microcephaly can be caused by abnormal development during gestation or follow intrauterine infections such as rubella, toxoplasmosis, and cytomegalovirus. It can also be caused by chromosomal abnormalities or be associated with other syndromes. Acquired microcephaly may occur due to severe malnutrition, perinatal infections, or anoxia in early infancy.

## Nursing Assessment

Microcephalic infants will present at birth with a normal or reduced head size. As the child ages, head growth will fail while the face will continue to grow at a normal rate. This results in a small head, a large face, and a loose, often wrinkled, scalp. As the child grows older, this smallness of the skull becomes more pronounced. Development of motor functions and speech may be delayed. The degree of intellectual disability varies, but it is a common occurrence. Convulsions may be present, and motor deficit ranges from clumsiness to spastic quadriplegia.

## Nursing Management

There is no treatment. Nursing care will be supportive and focus on determining the extent of neurologic and cognitive deficits, as well as teaching parents how to care for a child with such impairments.

### Arnold-Chiari Malformation

Arnold-Chiari malformation consists of two major subgroups—type I and type II. In type I, symptoms are typically seen in adolescence and adulthood. This type is usually not associated with hydrocephalus and is the more benign form. The deformity is a result of the cerebellar tonsils displacing into the upper cervical canal. The client will usually complain of neck pain, recurrent headaches, lower extremity spasticity, and urinary frequency. Type II is the most common and is usually associated with hydrocephalus and myelomeningocele. The deformity results from the cerebellum, the medulla oblongata, and the fourth ventricle displacing into the cervical canal, resulting in an obstruction of the CSF and causing hydrocephalus. The prognosis depends on the extent of the defect. Therapeutic management of type II Chiari malformation includes surgical decompression.

## Nursing Assessment

Approximately 10% of type II Arnold-Chiari malformations result in symptoms in infancy, such as a weak cry, stridor, and apnea (Kinsman & Johnston, 2011). These

symptoms require prompt medical treatment to reduce mortality. Gastrointestinal disturbances along with a history of chronic aspiration, choking, gagging, prolonged feeding times, and weight loss may also be present. Physical signs include coarse upper airway sounds heard on auscultation and diminished or absent gag reflex. In the older child, signs and symptoms seen are subtler and less frequently life threatening. Upper extremity weakness, spasticity, ataxia, and headaches are frequent signs found. Assessment of shunt function is extremely important in the infant and older child presenting with type II Chiari malformation and associated hydrocephalus (refer to Hydrocephalus section). An MRI may be performed to help evaluate and diagnose Chiari malformations.

## Nursing Management

Nursing management will focus on preoperative and postoperative care, prevention of infection, monitoring of blood loss, improvement of preoperative symptoms in the postoperative period, identification of any signs and symptoms of increased ICP, and identification of any resultant CNS injury.

## Hydrocephalus

Hydrocephalus is not a specific illness, but results from underlying brain disorders. It is a frequently seen disorder of the nervous system occurring in 0.5 to 4 per 1,000 live births (Zak & Chan, 2010). It results from an imbalance in the production and absorption of CSF. In hydrocephalus, CSF accumulates within the ventricular system and causes the ventricles to enlarge and increases in ICP to occur.

Hydrocephalus may be congenital or acquired. Congenital hydrocephalus is present at birth and is often due to a genetic disposition or environmental influences during fetal development. Causes of congenital hydrocephalus include abnormal intrauterine development, as is the case with myelomeningocele or other NTDs or intrauterine infections. Acquired hydrocephalus develops at the time of birth or at some point after. It can occur at any age and can result from injury or disease. Acquired hydrocephalus can result from intentional or nonintentional trauma, intraventricular hemorrhage in premature infants, neoplasms (e.g., posterior fossa brain tumor), infections (e.g., meningitis), or malformations (e.g., Chiari malformations).

Hydrocephalus is also classified as obstructive or noncommunicating versus nonobstructive or communicating. Obstructive or noncommunicating hydrocephalus occurs when the flow of CSF is blocked within the ventricular system. NTDs, neonatal meningitis, trauma, tumors, or Chiari malformations usually result in this type of hydrocephalus. One of the most common causes of obstructive or noncommunicating hydrocephalus in children is aqueductal stenosis, which results from the narrowing of the aqueduct of Sylvius (a passageway between the third and

fourth ventricles in the middle brain) (Kinsman & Johnston, 2011). Nonobstructive or communicating hydrocephalus occurs when the flow of CSF is blocked after it exits from the ventricles. This form of hydrocephalus, in which the CSF can still flow between the ventricles, is most often caused by defective absorption of CSF. Examples include hydrocephalus that results from subarachnoid hemorrhage and intrauterine infections.

Prognosis for the child with hydrocephalus depends mainly on the cause and whether or not brain damage has occurred prior to recognition and treatment. Children with hydrocephalus are at increased risk for developmental disabilities, visual problems, abnormalities in memory, and reduced intelligence. Long-term follow-up and multidisciplinary care are necessary.

## Pathophysiology

CSF is formed primarily in the ventricular system by the choroid plexus. It flows as a result of the pressure gradient that exists between the ventricular system and the venous channels. CSF is absorbed primarily by the arachnoid villi. Hydrocephalus results when there is an obstruction in the ventricular system or obliteration or malfunction of the arachnoid villi. This results in impaired absorption or circulation of the CSF. In rare cases, hydrocephalus can be caused by an overproduction of CSF by the choroid plexus (Porth & Matfin, 2009).

## Therapeutic Management

Hydrocephalus must be identified early. Treatment needs to be initiated in order to prevent brain tissue damage that can result from the increased ICP that hydrocephalus creates. Specific treatment will depend on the underlying etiology. The goals of treatment include relieving hydrocephalus and managing complications associated with the disorder, such as growth and developmental delay. Most cases of hydrocephalus are treated with the surgical placement of an extracranial shunt. Most often a ventriculoperitoneal shunt (VP shunt) is placed. See Figure 38.8 for an illustration of a shunt. The shunt will need to be replaced as the child grows. Therefore, the child will undergo shunt revision surgery at various times during his or her life. It is important for health care professionals and parents to be able to recognize when a shunt needs replacing or when complications are occurring, to decrease the possibility of death or disability that may occur due to increased ICP.

Though shunts have been the mainstay of treatment for hydrocephalus, they are not without complications such as infection, obstruction, and need for revision as the child grows. Endoscopic third ventriculostomy is an alternative to shunt placement to treat obstructive hydrocephalus in select children. A small perforation is made in the thinned floor of the third ventricle, which allows

**FIGURE 38.8** To treat hydrocephalus, a ventriculoperitoneal (VP) shunt catheter is placed in an enlarged ventricle. The shunt diverts the flow of cerebrospinal fluid (CSF) within the central nervous system to the peritoneum, where CSF is now absorbed across the peritoneal membrane into the body's circulation.

for egress of CSF from the ventricle to the subarachnoid space. No permanently implanted hardware is needed. Clinical trials are under way evaluating the use of endoscopic third ventriculostomy versus ventriculoperitoneal shunt placement (ClinicalTrials.gov, 2010).

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1304. Assessment findings pertinent to hydrocephalus are discussed below.

### Health History

Explore the pregnancy history and past medical history for:

- Intrauterine infections
- Prematurity with intracranial hemorrhage
- Meningitis
- Mumps
- Encephalitis

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history of the undiagnosed child might include:

- Irritability
- Lethargy
- Poor feeding
- Vomiting
- Complaints of headache in older children
- Altered, diminished, or changes in LOC

Children known to have hydrocephalus are often admitted to the hospital for shunt malfunctions or other complications of the disease. The health history should include questions related to:

- Neurologic status—have there been changes or decreases in LOC, changes in personality, or deterioration in school performance?
- Complaints of headache
- Vomiting
- Visual disturbances
- Any other changes in physical or cognitive state

### Physical Examination

Physical examination of the infant or child with hydrocephalus will include inspection and observation; palpation; and percussion.

#### INSPECTION AND OBSERVATION

Observe general appearance and affect. Pay particular attention to the size of the skull and note any asymmetry. Note LOC and motor function. Changes or decreases in LOC may be noted along with brisk reflexes and spasticity of the lower extremities. Symptoms seen vary by age, primarily due to the fact that the infant's skull is able to accommodate the buildup of CSF because the sutures have not closed. In the infant, the most obvious indication is often a rapid increase in head circumference (Fig. 38.9). In the older child, loss of development and changes in personality may be seen. Signs and symptoms associated

with increased ICP may be seen (refer to Comparison Chart 38.1).

#### PALPATION

In the infant, palpation of the fontanels may reveal wide-open, bulging fontanels. They will be nonpulsatile and feel tense and very full.

#### PERCUSSION

Upon percussion of the skull, by physicians or nurse practitioners, a positive Macewen sign may be noted. This is when a “cracked pot” sound is heard during percussion and can indicate separation of the sutures.

### Laboratory and Diagnostic Tests

Common laboratory and diagnostic tests ordered for the diagnosis and assessment of hydrocephalus include:

- Skull x-ray studies (may reveal separation of sutures)
- CT
- MRI

CT and MRI are used to evaluate for the presence of hydrocephalus and can also aid in identifying the cause

#### Consider This

Sandra and Michael Graham have brought their 6-month-old son, Thomas, to the pediatric unit for observation. Thomas's head circumference has increased from the 25th percentile at the 4-month check-up to the 75th percentile at the 6-month check-up. Upon assessment, the nurse notes a bulging anterior fontanel and persistent primitive reflexes.

What do you think is going on?

Identify early signs.

Identify late signs.

Describe nursing care for Thomas.

What teaching will the nurse do with Sandra and Michael?

**FIGURE 38.9** (A) Infant without hydrocephalus. (B) Infant with hydrocephalus. Note broadening of the forehead and large head size.

of hydrocephalus. Refer to Common Laboratory and Diagnostic Tests 38.1.

## Nursing Management

Nursing management of the child with hydrocephalus will focus on maintaining cerebral perfusion, minimizing neurologic complications, maintaining adequate nutrition, promoting growth and development, and supporting and educating the child and family. In addition to the nursing diagnoses and related interventions discussed in Nursing Care Plan 38.1, interventions common to hydrocephalus are discussed below.

### Preventing and Recognizing Shunt Infection and Malfunction

The major complications associated with shunts are infection and malfunction. Due to the serious nature and potentially devastating effects of shunt infection or malfunction, parents and health professionals need to be aware of the signs and symptoms to provide early recognition and prompt treatment. Signs and symptoms of a shunt infection include elevated vital signs, poor feeding, vomiting, decreased responsiveness, seizure activity, and signs of local inflammation along the shunt tract. Signs and symptoms of shunt malfunction include vomiting, drowsiness, and headache. Signs and symptoms of increased ICP, as listed in Comparison Chart 38.1, can also be indicative of shunt complications.

Infection can occur at any time but is more common 1 to 2 months after placement. Infection is treated with intravenous antibiotics and, if the infection is persistent, the shunt will be removed and an external ventricular drainage (EVD) system will be put into place until the CSF is sterile (refer to Common Medical Treatments 38.1 and Box 38.3).

#### Take Note!

Rapid drainage of CSF, which may occur if the child sits up without the EVD system being clamped, will decrease ICP and can lead to extreme headache, collapse of the ventricles, formation of subdural hematomas, and neurologic deterioration.

A new shunt will be placed after the infection has cleared. Intrathecal administration of antibiotics may be performed by the physician or nurse practitioner. Keeping the peritoneal surgical incision free of feces and urine can help prevent infection. Additionally, inspect surgical incisions after shunt placement for signs and symptoms of infection and any signs of leaking CSF.

Malfunction of the shunt can occur due to kinking, clogging, or separation of the tubing. Blockage is the most common reported complication. A shunt that has

#### BOX 38.3

### NURSING MANAGEMENT OF EXTERNAL VENTRICULAR DRAINAGE (EVD) DEVICE

- Ensure all connections are secure and label line as EVD.
- Regularly check that drip chamber of manometer is set at the height prescribed in relation to the child (i.e., zero at clavicle).
- Clamp the drain in the event of child movement or movement anticipated with care. Rezero and open clamps when done.
- Accurately document volume and color of cerebrospinal fluid (CSF) every hour (CSF is normally clear and colorless; cloudiness indicates infection). Notify physician, nurse practitioner, or charge nurse of any significant increase in amount of drainage (if exceeds 10 mL more than previous volumes).
- If minimal or no drainage, check tubing for kinks, blockage, or closed clamps. Check to see if CSF is oscillating in tubing. If blockage is suspected, notify neurosurgery department immediately.
- Dress the entry site into the skull with a sterile occlusive dressing; change the dressing if it is soiled or nonocclusive.
- Routine CSF samples may be sent for culture and analysis.
- Child may be taking prophylactic antibiotics due to increased risk of infection from the drain.

been placed within the past year is at higher risk of malfunction. Early recognition and operative intervention are essential to prevent neurologic deficits or possible death from occurring.

### Supporting and Educating the Child and Family

Hydrocephalus is a serious and chronic illness. It will require lifelong follow-up and regular evaluations. It requires early recognition of complications to prevent neurologic damage. Children will require future surgeries and hospitalizations, which can place a strain on the family and its finances. Potential growth and developmental disabilities are an additional strain. The support of the family in establishing realistic goals and helping the child to achieve his or her developmental and educational potential is important.

The family should be involved in the child's care from the time of diagnosis. Initially parents may be frightened because shunt placement involves entering the brain. Provide parents with accurate information regarding the procedure, and be available to listen to parents' concerns and to answer questions that arise. Ongoing education about the illness and its treatment are important, including signs and symptoms of shunt

complications. As the family becomes more comfortable with the diagnosis, treatment, and signs and symptoms of complications, they will become experts on the child's care and will often recognize subtle changes in him or her that may be indicative of shunt complications. Referral to support groups can be helpful for both the family and the child. Links for helpful information about hydrocephalus are provided on [thePoint](#).

### Intracranial Arteriovenous Malformation

Intracranial arteriovenous malformation (AVM) is a rare congenital disorder. It is caused by an abnormal development of blood vessels and can occur in the brain, brain stem, or spinal cord. AVMs that hemorrhage can lead to serious neurologic deficits and even death. However, some cases of AVMs never cause problems.

### Therapeutic Management

More aggressive treatment strategies are used in children. Treatment options used include surgical excision; endovascular embolization, which involves closing off the vessels of the AVM by injecting glue into them; and radiosurgery, which involves focusing radiation on the AVM. The therapeutic management approach will be based on the age of the child and size and location of the malformation in the brain. The child will usually require at least 24 hours of intensive care monitoring following surgery.

### Nursing Assessment

The most common symptoms seen include intracranial hemorrhage (children are more likely to present with hemorrhage than adults), seizures, headaches, and progressive neurologic deficits such as vision problems, loss of speech, problems with memory, and paralysis. In children younger than 2 years of age, presentation may include cardiac failure due to arteriovenous shunting in neonates and infants; a large head secondary to hydrocephalus; and seizure activity. Diagnosis is made using diagnostic imaging procedures such as MRI, CT, and arteriography.

### Nursing Management

Nursing management for these children is aimed at supportive care. Monitor for changes in neurologic status, noting any seizure activity, signs or symptoms of increased ICP, or signs and symptoms of intracranial hemorrhage. Hydrocephalus may occur as a result of intracranial hemorrhage secondary to the AVM. An EVD and eventual shunt placement may be necessary (refer to Hydrocephalus section).

FIGURE 38.10 Skull sutures in the infant.

### Craniosynostosis

Craniosynostosis is premature closure of the cranial sutures (Fig. 38.10). Complete closure of all sutures does not normally occur until late in childhood. Premature closure can inhibit brain growth and a distorted skull appearance will be evident. In cases where only one suture is fused, neurologic impairments are rarely seen. When two or more sutures are fused, neurologic complications such as hydrocephalus with increased ICP are more likely to occur. The incidence of craniosynostosis is approximately 1 in 2,000 births (Kinsman & Johnston, 2011). The cause is unknown, but in 10% to 20% of cases a genetic disorder such as Carpenter syndrome or Apert, Crouzon, or Pfeiffer disease is present (Kinsman & Johnston, 2011). There are numerous different types of craniosynostosis; they are listed and illustrated in Table 38.5. The prognosis is good for the majority of infants presenting with craniosynostosis, and normal brain development will occur. Exceptions to this are the infant or child who has associated genetic disorders that involve brain function and development.

Surgical correction may be done and allows for normal expansion of the brain and acceptable appearance of the head and skull. If one suture is fused, the surgical intervention is done mainly for cosmetic reasons. If more than one suture is fused, operative intervention is essential to prevent neurologic complications.

### Nursing Assessment

Most cases of craniosynostosis are present at birth. Skull deformity is evident as well as a prominent bony ridge

TABLE 38.5  
TYPES OF CRANIOSYNOSTOSIS

Types	Description
Sagittal synostosis (scaphocephaly)	<p>Sagittal suture is closed. Head grows long and narrow in anterior–posterior direction. Broad forehead and a prominent occiput are present. Most common form</p> 
Metopic synostosis (trigonocephaly)	<p>Metopic suture is closed. Usually a ridge down the forehead can be seen or felt. Triangular-shaped forehead Eyebrows may appear “pinched” on either side. Eyes may also appear close together.</p> 
Unilateral coronal synostosis (anterior plagiocephaly)	<p>Early closure of one side of the coronal suture Forehead and orbital rim (eyebrow) have a flattened appearance on that side. Eye on affected side has a different shape</p> 
Bicoronal synostosis (brachycephaly)	<p>Very flat, tall, recessed forehead Skull is shortened in the anterior–posterior direction. Wide-shaped head Commonly seen in Apert and Crouzon disease</p> 
Lambdoid (posterior plagiocephaly)	<p>Early closure of one lambdoid suture Flattening of back of head. Similar to shape found in positional molding or positional plagiocephaly</p> 

that can be palpated. X-ray studies can confirm fusion of the sutures. It is important that craniosynostosis be detected early if it is not evident at birth because premature closure of the suture lines will inhibit brain development. Therefore, measure head circumference in all children younger than 3 years old and compare findings with normal head circumference parameters as well as past measurements of the infant or child.

## Nursing Management

Nursing management focuses on postoperative care. This includes observing hemoglobin and hematocrit levels due to large volumes of blood loss that can occur, and observing for pain, hemorrhage, fever, infection, and swelling. Due to the location of the surgery and incision line, large amounts of facial swelling may be present. This can result in an inability of the child to open his or her eyes for a few days postoperatively. Make sure that parents are aware of this. Encourage the parents to talk to, hold, and comfort their child during this time. Provide support and education to the parents before, during, and after the procedure.

### Positional Plagiocephaly

Since the inception of the “back to sleep” program, which recommends placing all infants supine to sleep to decrease the risk of sudden infant death syndrome (SIDS), there has been a dramatic increase in the incidence of positional plagiocephaly (Piatt, 2011). Positional plagiocephaly refers to asymmetry in head shape without fused sutures. It results from gravitational force exertion on the developing cranium. Torticollis, which is when the neck muscles are too tight, have inadequate tone, or are shorter on one side, can contribute to plagiocephaly. Each condition, plagiocephaly and torticollis, exacerbates the other. Refer to Chapter 45 for further information on torticollis.

Therapeutic management for positional plagiocephaly is generally conservative, such as changing the infant’s position, encouraging “tummy time,” and avoiding excessive use of the car seat for infant seating outside of the automobile. Some infants may benefit from the use of a molding helmet (Fig. 38.11).

## Nursing Assessment

View the infant’s head from the top, noting asymmetry ranging from flattening on one side posteriorly to posterior flattening associated with anterior bulging (Fig. 38.12). Assess neck range of motion to determine if torticollis is also present. Palpate the cranial sutures, which will not feel overlapped as they do when they are fused.

**FIGURE 38.11** Molding helmet for positional plagiocephaly.

Skull x-ray examination or head CT scan will rule out craniosynostosis by demonstrating evidence of open sutures.

## Nursing Management

Nursing management is directed toward repositioning the infant to decrease time spent with the flattened area in the dependent position. Position the infant so that turning away from the affected side is necessary for him or her to view objects of interest. Place the infant on the abdomen when awake and supervised.

**FIGURE 38.12** Note flattening of the right posterior parietal and occipital regions of the skull in this infant with positional plagiocephaly.

Discourage use of the car seat outside of the automobile. Place a rolled washcloth along the affected side of the head to discourage turning the head in that direction. Following these recommendations may prevent positional plagiocephaly in the infant without congenital torticollis.

## INFECTIOUS DISORDERS

Infectious disorders of the neurologic system include bacterial meningitis, aseptic meningitis, encephalitis, and Reye syndrome.

### Bacterial Meningitis

Bacterial meningitis is an infection of the meninges, the lining that surrounds the brain and spinal cord. It is a serious illness in children and can lead to brain damage, nerve damage, deafness, stroke, and even death. It requires rapid assessment and treatment. The leading cause of bacterial meningitis in newborns is group B streptococcus, gram-negative enteric bacilli such as *Escherichia coli*, and *Listeria monocytogenes* (CDC, 2012a). In children, the leading causative agents are *Neisseria meningitidis* and *Streptococcus pneumoniae* (CDC, 2012a). See Table 38.6 for types of meningitis seen in different age groups. In developed countries, disease resulting from *Haemophilus influenzae* type B, once the most common cause of meningitis in children, has decreased dramatically since the introduction of the Hib vaccine. In less developed countries, infection with *H. influenzae* type B still remains a concern.

### Pathophysiology

Bacterial meningitis causes inflammation, swelling, purulent exudates, and tissue damage to the brain. It can occur as a secondary infection to upper respiratory infec-

tions, sinus infections, or ear infections, and can also be the result of direct introduction through LP; skull fracture or severe head injury; neurosurgical intervention; congenital structural abnormalities, such as spina bifida; or the presence of foreign bodies, such as a ventricular shunt or cochlear implants.

### Therapeutic Management

Bacterial meningitis is a medical emergency and requires prompt hospitalization and treatment. Deterioration may be rapid and occur in less than 24 hours, leading to long-term neurologic damage and even death. Intravenous antibiotics will be started immediately after the LP and blood cultures have been obtained if bacterial meningitis is suspected. The length of therapy and specific antibiotic will be determined based on the analysis and the culture and sensitivity of the CSF. Corticosteroids may be ordered to help reduce the inflammatory process. Specific medical treatment varies based on the suspected causative organism and will be determined by the physician or nurse practitioner.

### Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1304. Assessment findings pertinent to bacterial meningitis are discussed below.

#### Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Sudden onset of symptoms
- Preceding respiratory illness or sore throat
- Presence of fever, chills
- Headache

**TABLE 38.6** COMMON CAUSES OF MENINGITIS IN DIFFERENT AGE GROUPS

Causative Organism	Age Affected
<i>Escherichia coli</i>	Newborns and infants
Streptococcus group B	Infants younger than 1 month old
<i>Haemophilus influenzae</i> type B	3 months–6 years, typically 6–9 months old
<i>Streptococcus pneumoniae</i>	Children older than 3 months of age and adults
<i>Neisseria meningitidis</i>	Children older than 3 months of age and adults

Adapted from Zak, M., & Chan, V. W. (2010). Pediatric neurologic disorders. In S. M. Nettina (Ed.), *Lippincott manual of nursing practice* (9th ed., pp. 1543–1573). Philadelphia: Lippincott Williams & Wilkins.

- Vomiting
- Photophobia
- Stiff neck
- Rash
- Irritability
- Drowsiness
- Lethargy
- Muscle rigidity
- Seizures

Symptoms in infants can be more subtle and atypical, but the history may reveal:

- Poor sucking and feeding
- Weak cry
- Lethargy
- Vomiting

Explore the child's current and past medical history for risk factors such as:

- Young age: 1 month to 5 years, with most cases in children younger than 1 year of age and young adults 15 to 24 years of age
- Any fever or illness during pregnancy or around delivery (for infants younger than 3 months of age)
- Exposure to ill persons
- Exposure to tuberculosis
- Travel history
- History of maternal illness
- Recent neurosurgical procedure or head trauma
- Presence of a foreign body, such as a shunt or a cochlear implant
- Immunocompromised status
- Close-contact living spaces such as dormitories or military bases
- Day care attendance

### Physical Examination

Observe the general appearance of the child. The infant with bacterial meningitis may rest in the **opisthotonic** position (Fig. 38.13), and the older child may complain of neck pain. In the infant a bulging fontanel may be present, which is often a late sign, and the infant may

**FIGURE 38.13** Infant in opisthotonic position: head and neck are hyperextended to relieve discomfort.

be consolable when lying still as opposed to being held. Presence of positive Kernig and Brudzinski signs can indicate irritation of the meninges (Fig. 38.14). Inspect the child for presence of a rash; a petechial, vesicular, or macular rash may be seen.

#### Take Note!

Abrupt eruption of a petechial or purplish rash can be indicative of meningococemia (infection with *N. meningitidis*). Immediate medical attention is warranted.

### Laboratory and Diagnostic Tests

Common laboratory and diagnostic studies ordered for the assessment of bacterial meningitis include:

- LP—Fluid pressure will be measured and a sample is obtained for analysis and culture. CSF will reveal increased white blood cells (WBCs) and protein and low glucose (the bacteria present feed on the glucose).
- Complete blood count (CBC)—WBCs will be elevated.
- Blood culture—Performed to rule out sepsis. Blood culture will be positive in cases of septicemia.

### Nursing Management

Quickly initiate supportive measures to ensure proper ventilation, reduce the inflammatory response, and help prevent injury to the brain. Interventions are aimed at reducing ICP and maintaining cerebral perfusion along with treating fluid volume deficit, controlling seizures, and preventing injury that may result from altered LOC or seizure activity. Initiate appropriate isolation precautions. In addition to standard precautions, infants and children diagnosed with bacterial meningitis will be placed on droplet isolation until 24 hours of antibiotics have been received to help prevent transmission to others. Refer to Nursing Care Plan 38.1 for nursing diagnoses and related interventions. In addition to those diagnoses and interventions, measures taken to reduce fever and prevent bacterial meningitis are important to consider.

### Reducing Fever

Hyperthermia related to infectious process, increased metabolic rate, and dehydration as evidenced by increased body temperature; warm, flushed skin; and tachycardia may be present. Reducing fever is important to help maintain optimal cerebral perfusion by reducing the metabolic needs of the brain. Administer antipyretics such as acetaminophen and nonsteroidal anti-inflammatory drugs (NSAIDs) such as ibuprofen, per order. Institute nonpharmacologic measures if needed. Reduce environmental temperature and use cooling blankets, fans, cold compresses, and tepid baths to help reduce fever. Avoid measures that cause shivering because it increases heat production and is

**FIGURE 38.14** (A) Kernig sign is tested by flexing legs at the hip and knee (A1), then extending the knee (A2). A positive report of pain along the vertebral column is a positive sign and indicates irritation of meninges. (B) Brudzinski sign is tested by the child lying supine with the neck flexed (B1). A positive sign occurs if resistance or pain is met. The child may also passively flex hip and knees in reaction, indicating meningeal irritation (B2).

therefore counterproductive as well as uncomfortable for the child.

### Preventing Bacterial Meningitis

Bacterial meningitis is a serious illness and prevention is important. It is transmitted by direct close contact with respiratory droplets from the nose or throat. Most at risk are those living with the child or anyone with whom the child played or was in close contact. Postexposure prophylaxis and postexposure immunization may be effective. Control measures should be initiated in environments where risk exists. Disinfect toys and other shared objects to decrease transmission of the microorganisms to others.

To reduce group B streptococcus infection in neonates, screen pregnant women. If the screening results are positive, administer intrapartum antibiotics. Vaccines are available for some specific causative organisms, but complete vaccination prevention is not possible at this time. The Hib vaccine is routine starting at 2 months of age and all children should be immunized to continue the

reduction of bacterial meningitis caused by *H. influenzae* type B. The pneumococcal vaccine is also routine for all children starting at 2 months of age and should be considered for preschoolers who are at risk. Children at risk include those with immune deficiency; sickle cell disease; asplenia; chronic pulmonary, cardiac, or renal disease; diabetes mellitus; cochlear implants; cerebrospinal leaks; and organ transplants.

During the 1990s, a dramatic increase in the incidence of meningococcal meningitis (and the often fatal blood infection meningococcemia) among adolescents and young adults occurred and *N. meningitidis* became one of the leading causes of bacterial meningitis (MMWR, 2000). Living in close quarters, sleeping less than usual, and sharing personal items such as drinking glasses and lip balm contribute to the increase in disease. For these reasons, the American Academy of Pediatrics recommendations advise meningococcal vaccination for all children 11 to 12 years of age; adolescents at high school entry or age 15 (whichever comes first) who have not been previously vaccinated; all college freshmen living

in dormitories; and children who are at high risk, such as children with chronic conditions or immune suppression or those who travel to high-risk areas or live in crowded conditions (AAP, 2012). Further information and a resource for families are provided on [thePoint](#). (See Healthy People 2020.)

### HEALTHY PEOPLE 2020

#### Objective

Reduce meningococcal disease.

#### Nursing Significance

- Encourage appropriate immunization as recommended.
- Educate families to complete prescribed courses of antibiotics (to avoid progression of minor bacterial infections to meningitis).

*Healthy People Objectives based on data from <http://www.healthypeople.gov>.*

### Aseptic Meningitis

Aseptic meningitis is the most common type of meningitis, and the majority of children affected are younger than 1 year of age (Hom & Felter, 2012). If the causative organism can be identified, it is usually a virus. Enteroviruses, such as echovirus and coxsackievirus, account for many cases of aseptic meningitis. Less common causes include mumps, herpesvirus, HIV, measles, varicella, and polio.

### Therapeutic Management

Prompt diagnosis and treatment are essential to improve outcomes. The child is treated aggressively as if he or she has bacterial meningitis until the diagnosis is confirmed. Antibiotics are administered and continued until the causative organism is recognized. If the cause is viral, antibiotics may be discontinued and antiviral agents may be started at this time. After diagnosis is confirmed, treatment is mainly supportive in nature and the illness is usually self-limiting, lasting 3 to 10 days.

### Nursing Assessment

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Fever
- General malaise

- Headache
- Photophobia
- Poor feeding
- Nausea
- Vomiting
- Irritability
- Lethargy
- Neck pain
- Positive Kernig and Brudzinski signs

The onset of symptoms may be abrupt or gradual. Assessment is similar to that of the child with bacterial meningitis. Signs and symptoms are similar to those seen in bacterial meningitis, but the child is usually less ill.

### Nursing Management

Nursing management is similar to the nursing care of the child with bacterial meningitis and will focus on comfort measures to reduce pain and fever. Aseptic meningitis can be managed successfully at home if the child's neurologic status is stable and he or she is tolerating oral intake.

### Encephalitis

Encephalitis is an inflammation of the brain that may also include an inflammation of the meninges. It is a rare complication and can be caused by protozoan, bacterial, fungal, or viral invasion. In children it is most often associated with a viral illness. Most cases of viral encephalitis in children are of unknown cause. In the United States, common causative organisms include the herpes simplex virus; enteroviruses, such as poliovirus and coxsackievirus; and arthropod-borne viruses. Arthropod-borne viruses (e.g., West Nile and St. Louis encephalitis) are spread by the bites of insects, especially mosquitoes and ticks. Enteroviral infections are usually seen in the late summer and early fall, and arthropod-borne viruses are seen in the summer months (Abzug, 2011; Halstead, 2011). Recovery from encephalitis can occur in a few days or may be complicated and involve severe neurologic damage with residual effects. Prognosis depends on the age of the child and the causative organism. Prompt diagnosis and treatment are essential. The child suspected of having encephalitis should be hospitalized. Therapeutic management is mainly supportive in nature and focuses on maintaining optimal cerebral perfusion; hydration and nutrition; and injury prevention.

### Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1304. Assessment findings pertinent to encephalitis are discussed below.

## Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Fever
- Flu-like symptoms
- Altered LOC
- Headache
- Lethargy
- Drowsiness
- Generalized weakness
- Seizure activity

Explore the child's current history for risk factors such as:

- Recent travel
- Recreational activities, such as hiking and camping
- Animal contacts

## Physical Examination

Perform a neurologic examination to distinguish between encephalitis and viral meningitis. In encephalitis, a neurologic examination will reveal changes in sensorium and focal neurologic changes. Neurologic findings vary and reflect the areas of the brain that are involved.

## Laboratory and Diagnostic Tests

An LP may be done and the CSF may show an elevated leukocyte count and elevated protein and glucose levels. However, in some cases, levels may be normal. MRI, CT, and EEG procedures may be performed to help identify early changes and provide useful clues in developing a diagnosis.

## Nursing Management

Nursing management is similar to nursing care for the child with meningitis. Teach children and their families how to prevent encephalitis. Encephalitis can result from complications of childhood illnesses such as measles, mumps, or chickenpox. Explain the importance of keeping children up to date in their immunizations. Effective vaccines are available for a few viral pathogens that cause encephalitis (such as rabies virus and Japanese encephalitis virus), but these vaccines are not routine; they are recommended for those at high risk. For example, postexposure rabies vaccines can be administered to a child who was bitten by a suspected rabid animal. Also, those traveling to areas where Japanese encephalitis is endemic, such as India and China, and planning a prolonged stay or extreme outdoor activity should receive the appropriate vaccine.

Vector control and avoiding mosquito and tick bites are the best prevention of arthropod-borne infection. Preventative measures include:

- Using insect repellent (repellents containing DEET should be used cautiously in children younger than 12 years of age and not at all in children younger than 1 year of age)
- Wearing clothing that covers the arms and legs
- Controlling mosquito populations by eliminating areas of standing water where mosquitoes can breed
- Using insect traps and public measures such as sprayed insecticides to reduce the mosquito population

Specific antiviral therapy may be used for diseases caused by the herpes simplex virus.

## Reye Syndrome

Reye syndrome is a disease that primarily affects children younger than 15 years of age who are recovering from a viral illness. The exact cause of Reye syndrome is unknown. It has been found that Reye syndrome is a reaction that is triggered by the use of salicylates or salicylate-containing products to treat a viral infection. This reaction causes brain swelling, liver failure, and death in hours if treatment is not initiated. In the 1980s, the adverse effects of salicylates used to treat viral illnesses began to be publicized and the U.S. Food and Drug Administration (FDA) required warning labels to be placed on all salicylate-containing products, such as aspirin. Since then there has been a dramatic decrease in the occurrence of Reye syndrome.

## Nursing Assessment

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Severe and continual vomiting
- Changes in mental status
- Lethargy
- Irritability
- Confusion
- Hyperreflexia

Explore the child's current and past medical history for risk factors such as:

- A prodromal viral illness, like chickenpox, croup, flu, or an upper respiratory infection
- Ingestion of salicylate-containing products within 3 weeks of the start of the viral illness

Elevated liver function tests and elevated serum ammonia levels can confirm diagnosis.

## Nursing Management

Early recognition and treatment are the most important aspects of managing this illness. Nursing management is aimed at maintaining cerebral perfusion, managing and preventing increased ICP, providing safety measures due to changes in LOC and risk for seizures, and monitoring fluid status to prevent dehydration and overhydration.

Education is an important aspect of preventing this disease. Salicylates are found in many products, including many over-the-counter products such as Alka-Seltzer and Pepto-Bismol. A complete list can be found on [thePoint](#). Recovery from Reye syndrome is dependent on the severity of swelling of the brain. Some children will make a full recovery, while others may suffer long-term neurologic damage.

## TRAUMA

Trauma or injury is a leading cause of childhood morbidity and mortality in the United States, with the highest rates among minority populations (Centers for Disease Control and Prevention (CDC), 2009b; CDC, 2012c). The child faces significant risk of trauma to his or her developing neurologic system, often leading to neurologic disorders with life-threatening and lasting effects. Neurologic trauma may include head trauma, nonaccidental head trauma, and near drowning. Birth trauma may also occur and is covered in Chapter 24.

### Head Trauma

In the United States, injury causes more death in children than disease (CDC, 2009a). Of these injuries, head injury is a frequent cause of death and disability in childhood. Common causes of head trauma in children include falls, motor vehicle accidents, pedestrian and bicycle accidents, and child abuse (see next section, Nonaccidental Head Trauma). Many factors make children more susceptible to head trauma than adults. Larger head size in relation to the body, coupled with a higher center of gravity, causes the child to hit his or her head more readily when involved in motor vehicle accidents, bicycle accidents, and falls. Children are also at risk for injury related to psychosocial factors such as their high activity level, curiosity, incomplete motor development, and lack of knowledge and judgment skills.

*Head trauma* is a broad term that can include specific patterns of injury. See Table 38.7 for descriptions of common head injuries seen in children. Head trauma in children is serious because it can cause an immediate threat to the child's life as well as a number of complications that can lead to lifelong impairment of an individual's physical, cognitive, and psychosocial functioning.

Prognosis for the child who has suffered a head trauma depends on the extent and severity of the injury as well as any complications (see Healthy People 2020).

### HEALTHY PEOPLE 2020

#### Objective

Reduce fatal and nonfatal traumatic brain injuries.

#### Nursing Significance

- Educate children and families about safety such as helmet use when inline skating, skateboarding, bicycling, and playing football or other sports that may result in head injury.
- Encourage appropriate child car seat and seat belt use.
- Use every encounter with a child and family as an opportunity to provide education related to injury prevention.

*Healthy People Objectives based on data from <http://www.healthypeople.gov>.*

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1304. Assessment findings pertinent to head trauma are discussed below.

### Health History

Take a detailed history, including past medical history along with details of the events surrounding the injury such as mental status at the time of the injury, any loss of consciousness, irritability, lethargy, abnormal behavior, vomiting (if so, how many times), any seizure activity, and any complaints of headache, visual changes, or neck pain.

### Physical Examination

Perform a thorough physical examination. Initial physical assessment will focus on the ABCs (airway, breathing, and circulation) (refer to Chapter 53 for further information on emergency management). All children who experience head trauma need an assessment of their neurologic function as soon as they are seen. This includes LOC, pupillary response, and any seizure activity. Fixed and dilated pupils, fixed and constricted pupils, or sluggish pupillary reaction to light will warrant prompt intervention.

#### Take Note!

A child's spine must remain stabilized after a head injury until spinal cord injury is ruled out.

**TABLE 38.7** COMMON HEAD INJURIES SEEN IN CHILDREN

Types	Description	Characteristics
Skull fractures	A break in the bone surrounding the brain	In infants and children younger than 2 years old, a great deal of force is needed to produce a skull fracture. Due to the flexibility of the immature skull, it is able to withstand a great degree of deformation before a fracture will occur. Can result in little or no brain damage, but may have serious consequences if the underlying brain tissue is injured
Linear skull fracture	A simple break in the skull that follows a relatively straight line	Most common skull fracture. Can result from minor head injuries such as being struck by a rock, stick, or other object; falls; or motor vehicle accidents. Not usually serious unless there is additional injury to the brain
Depressed skull fractures	The bone is locally broken and pushed inward, causing pressure on the brain.	Can result from forceful impact from a blunt object, such as a hammer or another heavy but fairly small object. Surgery is often required to elevate the bony pieces and inspect the brain for evidence of injury.
Diastatic skull fracture	A fracture through the skull sutures	Most commonly occurs in the lamboid sutures (refer to Fig. 38.10 for location of sutures). Usually treatment is not required but observation will be necessary.
Compound skull fracture	A laceration of the skin and splintering of the bone	The fracture can be linear or depressed. Generally is the result of blunt force. Usually requires medical intervention and surgery may be necessary
Basilar skull fracture	A fracture of the bones that form the base of the skull	Can result from severe blunt head trauma with significant force. Due to the proximity to the brain stem, this is a serious head injury. Findings include CSF rhinorrhea and otorrhea, bleeding from the ear, and orbital or postauricular ecchymosis (bruising behind ear is referred to as Battle sign), and these children are at increased risk for infection because the fracture may allow a portal of entry into the central nervous system.
Concussion	A mild brain injury that is caused by jarring or shaking and results in disruption or malfunction of the electrical activities of the brain	Most common head injury. Results from a blow or jolt to the head caused by sports injuries, motor vehicle accidents, and falls. Confusion and amnesia after the head injury are seen. Loss of consciousness may or may not occur. Noted symptoms may include increased distractibility and difficulty with concentration. Treatment includes rest and monitoring for neurologic changes that could indicate a more severe injury, such as increased sleepiness, worsening headache, increased vomiting, worsening confusion, difficulty walking or talking, changes in LOC, and seizures.
Contusion	Bruising of cerebral tissue	Results from a blow to the head from incidents such as a motor vehicle accident, falls, or abuse such as shaken baby syndrome. May cause focal disturbances in vision, strength, and sensation. The signs and symptoms will vary based on the extent of vascular injury and can range from mild weakness to prolonged unconsciousness and paralysis. Treatment includes close monitoring for neurologic changes. Surgery is usually not necessary.

TABLE 38.7

COMMON HEAD INJURIES SEEN IN CHILDREN (continued)

Types	Description	Characteristics
Subdural hematoma	Collection of blood between the dura and cerebrum	Low incidence of fracture. Most common in children younger than 2 years old, especially infants. Results from birth trauma, falls, bicycle injuries, and abuse such as shaken baby syndrome. Usually consists of venous bleeding. Symptoms may occur within 3 days of trauma or as late as 20 days. Symptoms include vomiting, failure to thrive, changes in LOC, seizures, and retinal hemorrhage. Treatment depends on clinical symptoms, size of clot, and area of the brain involved. In some cases, the bleed may be closely monitored for resolution. In other cases, treatment may include subdural taps in infants and surgical evacuation in older children. Close monitoring of neurologic status and for signs of increased ICP is indicated.
Epidural hematoma	Collection of blood located outside the dura but within the skull	Relatively uncommon. Often results from skull fracture. Seen when head trauma is severe. Usually arterial bleeding, therefore brain compression occurs rapidly and can result in impairment of the brain stem and respiratory or cardiovascular function. Symptoms include vomiting, headache, and lethargy. Treatment depends on clinical symptoms, the size of the clot, and the area of the brain involved. Treatment includes prompt surgical evacuation and cauterization of the artery. The earlier the bleed is recognized and treated, the more favorable the outcome. Close monitoring of neurologic status is indicated.

### Laboratory and Diagnostic Tests

Diagnostic tests that may be utilized include x-ray examinations of the head and neck and CT and MRI scans. These procedures can assist in providing a more definitive diagnosis of the severity and type of trauma.

#### Take Note!

If clear liquid fluid is noted draining from the ears or nose, notify the physician or nurse practitioner. If the fluid tests positive for glucose, this is indicative of leaking CSF.

### Nursing Management

Nursing management of the child with head trauma depends on the seriousness of the injury. For all head trauma, however, the nurse provides support and education to the family and provides teaching on ways to prevent future head injuries.

### Caring for the Child With Mild to Moderate Head Injury

Mild to moderate closed head injury is defined as brain injury without any penetrating injury to the brain, no loss of consciousness, no other injury to the head or

body, normal behavior after the injury, and healthy status before the injury. Most children with this type of injury can be cared for and observed at home. Provide parents and caregivers with clear instructions regarding the care of their child at home. Explain that they must seek medical attention if the child's condition worsens at any time during the first several days after injury. See Teaching Guidelines 38.2.

### Teaching Guidelines 38.2

#### MONITORING THE CHILD WITH CLOSED HEAD INJURY AT HOME

Instruct parents and caregivers:

- Stay with the child for the first 24 hours and be ready to take the child to the hospital if necessary.
- Wake the child every 2 hours to ensure that he or she moves normally, wakes enough to recognize the caregiver, and responds to the caregiver appropriately.
- Closely observe the child for a few days.
- Call the medical provider or bring child to the emergency room if the child exhibits any of the following:
  - Constant headache that gets worse
  - Slurred speech

- Dizziness that does not go away or happens repeatedly
- Extreme irritability or other abnormal behavior
- Vomiting more than two times
- Clumsiness or difficulty walking
- Oozing blood or watery fluid from ears or nose
- Difficulty waking up
- Unequal-sized pupils
- Unusual paleness that lasts longer than 1 hour
- Seizures
- Review signs and symptoms of increased intracranial pressure and provide parents with a number they can call if they have questions or concerns.

Children with mild closed head injury may exhibit some cognitive and behavioral symptoms, such as difficulty paying attention, problems making sense of what has been seen or heard, and forgetting things, in the early days after the injury. The majority make a full recovery. However, some may experience ongoing cognitive and behavioral difficulties, including slow information processing and attention difficulties.

### Caring for the Child With Severe Head Injury

Severe head injuries can range from a temporary unconsciousness that resolves quickly to children who may remain in a comatose state for a prolonged time. Nursing management of the comatose child is similar to nursing care of the comatose adult.

Children with more severe head injury may require intensive care initially until stabilized. Focus will be on maintaining the child’s airway; monitoring breathing, circulation, and neurologic status closely; preventing and ceasing any seizure activity; and treating any other injuries that may have occurred as a result of the trauma. Nursing management will continue to focus on evaluation of neurologic status and assessing for changes in LOC and signs and symptoms of increased ICP. Initiate seizure precautions as ordered.

Individualize care to the specific needs of the child. Maintain a quiet environment to help reduce restlessness and irritability. Manage pain and administer sedation as ordered. Observe the level of sedation closely to ensure that LOC will not become altered, which would hinder the ability to assess adequately for neurologic changes. Monitor for the development of complications, which include hemorrhage, infection, cerebral edema, and herniation.

#### Take Note!

Parents are extremely helpful resources in evaluating a child’s behavior for changes or abnormalities. They can provide insight into whether a behavior seen is normal or

abnormal for this child. Examples include the ease at which a child is normally aroused, how much the child normally sleeps during the day, and what is the child’s normal visual and hearing acuity.

### Providing Support and Education

Provide support and education for the family of a child who has suffered a head trauma. Encourage involvement in the child’s care. The extent of residual neurologic damage and recovery may be unclear for the child with a head injury. This can be frustrating and stressful for parents and family. Encourage verbalization of their feelings and concerns. Rehabilitation of the child with permanent brain damage is an essential component of his or her care. It should begin as soon as possible in the hospital setting and may continue for months to years. This can place a strain on the family and its finances. Families need to be involved in the rehabilitation process. The nurse will be a key member in ensuring the parents and family are involved with the interdisciplinary team.

### Preventing Head Injuries

Prevention of head injuries provides the greatest benefit to children and the community. Nurses play a key role in educating the public on topics such as helmet use with certain sports; bicycle and motorcycle safety; seat belt use; and providing adequate supervision of children to help prevent injuries and accidents—and resultant head trauma—from occurring (see Healthy People 2020).

#### HEALTHY PEOPLE 2020

##### Objective

Increase the number of states and the District of Columbia with laws requiring bicycle helmets for bicycle riders.

##### Nursing Significance

- Support legislation locally that calls for bicycle helmet laws.
- Participate in local “safe kids” activities to demonstrate support for helmet use

*Healthy People Objectives based on data from <http://www.healthypeople.gov>.*

### Nonaccidental Head Trauma

In the United States, inflicted or nonaccidental head trauma is the leading cause of traumatic death and morbidity during infancy (Hymel, Markoroff, Laskey, Conaway, & Blackman, 2007; Sum & Raghupathi, 2011). Children’s dependence on others to care for them places them at a high risk for injuries caused by child abuse.

The infant's large head size and weak neck muscles place him or her at an increased risk for head trauma due to violent shaking or cranial impacts compared to adults. In addition, children younger than 3 years of age have a very mobile spine, especially in the cervical region, along with immature neck muscles. This places them at a higher risk for injury from acceleration/deceleration injuries, which occur when the head receives a blow or is shaken. The sudden acceleration causes deformation of the skull and movement of the brain, allowing brain contents to strike parts of the skull. Bruising of the brain can occur at the point of impact or at that point distant from the impact where the brain collides with the skull. Another result of brain movement is hemorrhages in the brain, which are caused by the shearing forces that may tear small arteries. The child's thin skull places him or her at increased risk for skull fractures and penetrating injuries resulting from head trauma.

Causes of nonaccidental head trauma include violent shaking, referred to as shaken baby syndrome (SBS); blows to the head; and intentional cranial impacts against the wall, furniture, or the floor. The average victim is younger than 9 months of age. SBS is a form of child abuse and a significant number of head traumas result from it. However, it differs from many other forms of child abuse in that frequently there was no intent to harm the child. Shaking happens when the parent or caregiver becomes frustrated or angry because he or she cannot get the baby to stop crying.

The full appearance of neurologic deficits resulting from nonaccidental head trauma may take several years to be identified and recovery can be very slow. Long-term outcomes are not known, but many of these infants and children have poor outcomes and may suffer neurologic defects such as profound intellectual disability, spastic quadriplegia, severe motor dysfunction, and blindness. The majority of children with inflicted head injuries have some impairment of motor and cognitive abilities, language, vision, and behavior. These injuries may also contribute to later problems with education and social attainment.

## Nursing Assessment

The infant who has been a victim of nonaccidental trauma can present in many ways. Symptoms and physical findings may be similar to those seen in children with accidental head trauma or increased ICP related to infection. Therefore, many nonaccidental traumas remain unidentified. Nurses are mandatory reporters of abuse (for further information on this, see Chapter 52). Early recognition of suspected child abuse is essential to prevent death and disability from repetitive inflicted head trauma.

### Health History

It is important to review the child's history closely and pay particular attention to the caregivers' explanation of

the child's injury. Be alert to any discrepancies between the physical injuries and the history of injury given by the parent, especially if the stories are conflicting, or if the caregivers are unable to give an explanation for the injury. Also, note any previous intracranial or skeletal injuries that cannot be explained.

In less severe cases, common signs and symptoms may include:

- Poor feeding or sucking
- Vomiting
- Lethargy or irritability
- Failure to thrive
- Increased sleeping
- Difficulty arousing

In more severe cases, the symptoms will be more acute and may consist of:

- Seizure activity
- Apnea
- Bradycardia
- Decreased LOC
- Bulging fontanel

### Physical Examination

External bruising of the head and face may be evident in some inflicted head traumas. However, no evidence of external trauma, but the presence of intracranial or intraocular hemorrhages, is the classic presentation of SBS. Retinal hemorrhages are seen in the majority of cases, which is a rare finding in accidental or nontraumatic events.

### Laboratory and Diagnostic Tests

Diagnostic tests including CT, MRI, ophthalmologic examination to rule out retinal hemorrhages, and skeletal survey radiographs to rule out or confirm other injuries may be performed to help determine the extent and type of injury.

## Nursing Management

Treatment and nursing management will be similar to that for the child with accidental head trauma (see earlier section, Head Trauma). Prevention of nonaccidental head trauma, including SBS, is a major concern for all health care professionals. Be aware of risk factors related to the potential for SBS to occur. Recognizing these risk factors will allow appropriate intervention and protection of the child to take place. See Box 38.4 for risk factors related to SBS.

Educating parents and caregivers on appropriate ways to handle stress and ways to cope with a crying infant can help to prevent nonaccidental head trauma (see Teaching Guidelines 38.3 and Evidence-Based Practice 38.1). Many parents and caregivers may perceive shaking

**EVIDENCE-BASED PRACTICE 38.1****DO EDUCATIONAL MATERIALS CHANGE KNOWLEDGE AND BEHAVIOR ABOUT CRYING AND SHAKEN BABY SYNDROME?**

Shaken baby syndrome is caused by violent shaking often in response to infant crying and can result in significant head trauma and neurologic deficits. It is inflicted by a caregiver of the infant and may be attributed to lack of knowledge regarding the effects of shaking and therefore may be preventable. Crying, especially inconsolable and cluster crying, in the newborn infant is often the stimulus for shaking due to anger and frustration that the caregiver feels. Anticipatory guidance about crying may also be helpful in preventing shaken baby syndrome.

**STUDY**

A randomized controlled trial was performed with 1,279 mothers who had an uneventful pregnancy, a healthy singleton birth, and access to a DVD player and who were fluent in English. The participants either received the Period of PURPLE Crying materials, an 11-page booklet and DVD developed by the National Center on Shaken Baby Syndrome, or the control injury prevention material, two brochures and a DVD about infant safety, during a routine public health nurse visit within 2 weeks after discharge. Participants completed a Baby's Day Diary and a 20-minute questionnaire over the phone.

Adapted from Barr, R. G., Barr, M., Fujiwara, T., Conway, J., Catherine, N., & Brant, R. (2009). Do educational materials change knowledge and behaviour about crying and shaken baby syndrome? A randomized controlled trial. *Canadian Medical Association Journal*, 180(7), 727–734.

**Findings**

Mothers who received the PURPLE materials scored higher on the scales that measured knowledge about crying and more often shared descriptions of crying, advice about walking away if frustrated, and warnings about the danger of shaking to other caregivers. Walk-away behavior when faced with inconsolable crying was more frequent among mothers who received the PURPLE materials.

**Nursing Implications**

Nurses need to recognize the importance of providing education regarding the frustration of caring for a crying child, the dangers of shaking, and the recommended responses to a crying baby (refer to Teaching Guideline 38.3) shortly before or after birth. It is also important to emphasize that sharing this information with all caregivers of the child is imperative. Increases in knowledge and changes in behavior may lead to a reduction in the incidence of shaken baby syndrome. Further research is warranted in this area to determine if the incidence of inflicted trauma to infants is decreased when education programs are implemented in clinical practice.

a child as a less violent way to react than other means of enforcing discipline. They need to be aware that shaking a baby, even for only a few seconds, can cause serious brain damage and death. Decreasing mortality and morbidity associated with SBS and nonaccidental injury through early preventive education is an essential nursing concern. Information about the dangers of shaking a baby should be a part of prenatal care and standard discharge teaching on postpartum units. In addition, this information should be provided to the community and in health education classes to reach young potential child care providers.

**BOX 38.4****RISK FACTORS ASSOCIATED WITH SHAKEN BABY SYNDROME**

- Single parent
- Young parent
- Substance abuse by a parent
- Any external factors present such as financial, social, or physical burdens that place stress on the parent
- Premature or sick infant
- Infant with colic

**Teaching Guidelines 38.3****TIPS TO CALM A CRYING BABY**

Instruct parents and caregivers:

- Try to figure out what is upsetting the baby.
  - Is the baby hungry?
  - Is the baby's diaper dry?
  - Is the baby cold or hot?
  - Is the baby overtired or overstimulated?
  - Is the baby in pain?
  - Is the baby sick or running a fever?
- Try to help the baby relax.
  - Turn down the lights.
  - Swaddle the baby.
  - Walk the baby.
  - Rock the baby.
  - Give the baby a breast, bottle, or pacifier.
  - Shhh, talk to, or sing to the baby.
  - Talk the baby for a stroller or car ride.
- Sometimes the baby may continue to cry after all your efforts. If you feel overwhelmed, frustrated, or angry, focus on keeping the baby safe.
  - Stop what you are doing, take a deep breath, and count to 10.
  - Place the baby in a safe place, such as the crib or playpen.

## Near Drowning

Drowning is the second leading cause of unintentional injury-related death in children between the ages of 1 and 14 years (CDC, 2011). Drowning is a preventable problem that is far too common, especially in children. Those at greatest risk of drowning are toddlers and adolescent males (AAP, 2010).

*Near drowning* is described as an incident in which a child has suffered a submersion injury and has survived for at least 24 hours. Near-drowning events result in a significant number of injured children and can result in long-term neurologic deficits. Children younger than 1 year old most often drown in bathtubs, buckets, or toilets. Children between the ages of 1 and 4 years are more likely to drown or have a near-drowning incident in residential swimming pools (CDC, 2011). In children older than 15 years of age, most drownings occur in natural water settings, such as oceans or lakes (CDC, 2011). Most incidents are accidental and result from inadequately supervising children who are in or near water, lack of use of personal flotation devices while on recreational water apparatus such as boats, and diving accidents.

## Nursing Assessment

Hypoxia is the primary problem resulting from near drowning. Nursing assessment needs to begin with resuscitative measures. The child may be comatose, be hypothermic, lack spontaneous respirations, and present with hypoxia and hypercapnia. Gain information about the site of submersion (was it fresh or salt water?), the water temperature, the time of submersion, and how long it was until the child received interventions such as cardiopulmonary resuscitation (CPR) and emergency medical services (EMS).

## Nursing Management

Resuscitative measures should be started as soon as the child is pulled from the water, and the child should be transported to a hospital immediately. Management will be based on the degree of cerebral insult that has occurred. The child who has been successfully resuscitated will usually require intensive nursing care and monitoring. Promotion of oxygenation and monitoring for infection related to aspiration of water are primary nursing concerns. Chronic neurologic damage occurs in many near drownings secondary to hypoxia. The child may need rehabilitation and long-term follow-up. Provide parents with support and education relating to their child's condition. Educating children, families, and the community is an important nursing intervention to help prevent drowning (see Teaching Guidelines 38.4).

## Teaching Guidelines 38.4

### TEACHING TO PREVENT DROWNING

Instruct parents and caregivers:

- Install proper pool fencing.
- Start water safety training at a young age.
- Never leave an infant or young child without adult supervision in or near water (this includes bathtubs).
- Empty water from all containers, such as 5-gallon buckets, immediately after use.
- Use proper-fitting, Coast Guard–approved personal flotation devices at all times when near water.
- Never allow children to walk, skate, or ride on thinning or thawing ice.
- Learn cardiopulmonary resuscitation (CPR) and keep emergency numbers handy (make sure babysitters are CPR qualified).
- Know the depth of water before permitting a child to jump or dive.

## BLOOD FLOW DISRUPTION

Pediatric cerebral vascular disorders occur less often than in adults, but they are still an important cause of mortality and chronic morbidity in children (Roach, deVeber, Riela, & Wiznitzer, 2011). Many children will develop lifelong cognitive and motor impairments. Improvements in imaging techniques have led to an increase in the reported incidence and prevalence of cerebral vascular disorders in children in recent years (Roach et al., 2011). Childhood cerebral vascular disorders (stroke) are usually seen after the first month of life. Intraventricular hemorrhage is seen in preterm infants and in infants up to 1 month of age and is discussed in Chapter 24.

## Cerebral Vascular Disorders (Stroke)

A cerebral vascular disorder is a sudden disruption of the blood supply to the brain. It affects neurologic functioning, such as movement and speech. Two major types of adult cerebral vascular disorders are seen in children— ischemic stroke and hemorrhagic stroke. Ischemic stroke is more common than hemorrhagic stroke in children. In children, there is a wide array of risk factors and causes as compared to adults (see Comparison Chart 38.2), but in many cases the cause remains unidentified. The outcomes reported for cerebral vascular disorders in children vary, but many children will develop some neurologic or cognitive deficit.

Historically, children have been excluded from adult stroke studies. Therefore, many treatments used in

## COMPARISON CHART 38.2

## RISK FACTORS AND CAUSES OF STROKE IN CHILDREN AND ADULTS

	Risk Factors and Causes in Children	Risk Factors and Causes in Adults
<i>Ischemic stroke</i>	<ul style="list-style-type: none"> <li>Cardiac disorders and intracardiac defects (congenital such as ventricular septal defect, atrial septal defect, and aortic stenosis, or acquired such as rheumatic heart disease)</li> <li>Coagulation abnormalities that lead to thrombosis</li> <li>Sickle cell disease</li> <li>Infection, such as meningitis</li> <li>Arterial dissection</li> <li>Genetic disorders</li> </ul>	<ul style="list-style-type: none"> <li>Cardiac disease, including atherosclerosis</li> <li>Diabetes mellitus</li> <li>Hyperlipidemia</li> <li>Hypercoagulability states</li> <li>Polycythemia</li> <li>Sickle cell disease</li> <li>Smoking</li> <li>Increased age</li> <li>Male gender</li> <li>Obesity</li> <li>Excessive alcohol consumption</li> </ul>
<i>Hemorrhagic stroke</i>	<ul style="list-style-type: none"> <li>Vascular malformations such as intracranial arteriovenous malformation (AVM)</li> <li>Aneurysms</li> <li>Warfarin therapy</li> <li>Cavernous malformations</li> <li>Malignancy</li> <li>Trauma</li> <li>Coagulation disorders such as hemophilia</li> <li>Thrombocytopenia</li> <li>Liver failure</li> <li>Leukemia</li> <li>Intracranial tumors such as medulloblastomas</li> </ul>	<ul style="list-style-type: none"> <li>Hypertension</li> <li>Aneurysms</li> <li>Use of anticoagulant medications</li> <li>Smoking</li> <li>Increased age</li> <li>Male gender</li> <li>Obesity</li> <li>Excessive alcohol consumption</li> </ul>

children have had to be adapted from adult studies. Acute treatment is supportive and requires intensive care. The exact treatment will depend on the underlying cause.

## Nursing Assessment

The clinical presentation will vary according to age, the underlying cause, and the location of the stroke. Signs and symptoms of acute stroke are similar to those seen in the adult and depend on the area of the brain that has been affected. Common signs include:

- Weakness on one side or hemiplegia
- Facial droop
- Slurred speech
- Speech deficits

Strokes in children are diagnosed in the same manner as strokes in adults. However, further tests may need to be run in the child, such as metabolic studies, coagulation tests, echocardiogram, and LP to help identify the cause of the stroke.

## Nursing Management

Nursing management will be similar to that for the adult patient who has suffered a stroke. Care will focus on

assessing neurologic status, increasing mobility, providing adequate nutrition and hydration, and encouraging self-care. Rehabilitative care may be initiated, depending on the long-term deficits, to help the child attain optimal function. Parental support and education will be essential in helping them care for a child who has new disabilities.

## CHRONIC DISORDERS

Chronic disorders in children necessitate multidisciplinary care. Parents and children are in need of a large amount of education and support from the health care team. Chronic neurologic disorders commonly seen in children include headaches and breath holding.

### Headaches

Acute and chronic headaches, including migraines, are common reasons why children miss school, visit their physician or nurse practitioner, and receive subsequent referrals to neurologists. Children with reports or symptoms of headaches need to be examined thoroughly. Headaches may result from sinusitis

or eyestrain or can be indicative of more serious conditions such as brain tumors, acute meningitis, or increased ICP. Migraines are a specific type of headache. They are benign, recurrent, throbbing headaches often accompanied by nausea, vomiting, and photophobia. Acute migraines can occur in children as young as 3 to 4 years old. The cause of migraine headaches is not well understood.

After other acute or chronic conditions are ruled out, management will focus on treating the child's pain. Pharmacologic measures may be utilized in the treatment of chronic headaches and migraines. Medications used in children to treat and prevent headaches are similar to the medications used to treat adults. Recent attention has been paid to headaches caused by medication overuse. The child may have a primary headache disorder that is exacerbated by the frequent use of medications. Although medication overuse headaches are common in children, they are frequently underrecognized and underdiagnosed.

## Nursing Assessment

Elicit a description of the present illness and chief complaint. Important health history information to obtain is onset of the pain, aggravating and alleviating factors, frequency and duration of the pain, time of day the pain usually occurs, location of the pain, and quality and intensity of the pain.

In young children, symptoms of headache may be hard to recognize. However, common signs and symptoms may include:

- Irritability
- Lethargy
- Head holding
- Head banging
- Sensitivity to sound or light

Assessment also includes a thorough physical examination to rule out any life-threatening illness, such as a brain tumor or increased ICP. A detailed neurologic examination is warranted. Neuroimaging may be performed based on the child's history and physical examination, if needed, to rule out a brain tumor or mass as the cause of the headaches.

## Nursing Management

Nursing measures will focus on support and education. After serious illness has been ruled out, reassure the child and family that no serious medical or neurologic disease is present. Because headaches are recurring and the cause may be unknown, pain management can be difficult. Provide education to help the child and parents gain control over the headaches. Teach the child and family to keep a very accurate record of headaches and

### BOX 38.5

#### POTENTIAL HEADACHE TRIGGERS

- Foods, such as chocolate, caffeine, or monosodium glutamate (MSG)-containing foods
- Changes in hormone levels, around menses and ovulation
- Changes in:
  - Weather
  - Season
  - Sleep patterns
  - Meal schedule
- Stress
- Intense activity
- Bright or flickering lights
- Odors, such as strong perfumes

activities surrounding the headaches to help establish a pattern of occurrence and identify triggering factors. Encourage parents and the child to recognize the triggering factors and to avoid them (Box 38.5). Teach the child and family about pain medications and how to use them. Teach other management techniques, which may include exercise, sleep regulation, proper diet with regularly spaced meals, avoiding caffeine, avoiding inadequate hydration, regular attendance at school, use of biofeedback, stress reduction techniques, and possible psychiatric assessment.

## Breath Holding

Breath holding is a benign behavior of childhood, although it is extremely frightening for parents. It is normally seen in children 1 to 3 years old and typically is outgrown by 5 years of age. It is usually triggered by the child becoming angry or stressed after not getting his or her way. It can also occur as a reflexive response to fear, pain, or being startled. The child stops inhaling and exhaling or hyperventilates, the brain becomes anoxic, and the child becomes cyanotic and may pass out. In some cases a change in muscle tone, seizure-like activity, or hypoxic convulsions may be observed. This does not mean the child has a seizure disorder, but it must be ruled out. The spell usually resolves spontaneously. With the loss of consciousness the child will begin breathing on his or her own and will often begin crying, screaming, and trying to catch his or her breath. The spells usually only last 30 to 60 seconds and, as long as the child does not sustain an injury while falling, have no consequences.

If no underlying condition is found, the child needs no therapy. The condition is self-limiting and the

child will outgrow it. Iron deficiency may play a role; therefore, iron supplementation may be prescribed (Allsman, 2008).

## Nursing Assessment

The first time a spell occurs, a primary care provider should evaluate the child because the event could indicate a seizure. Breath holding also has been shown to be aggravated by iron-deficiency anemia and, in rare cases, it could indicate a more serious neurologic condition and therefore warrant a full evaluation. Elicit a full description of the episode and events leading up to it. Also, collect a thorough past medical history and perform a complete physical examination.

## Nursing Management

Nursing management should focus on educating and supporting the parents. Breath holding is a scary event and parents will want information on the effects of the behavior and how to prevent the behavior from recurring. Reinforce that the spells are involuntary and that they should not intervene to stop them. Encourage parents to maintain a safe environment when an episode is occurring, such as holding the child or placing him or her in the side-lying position. Reassure parents that the child will suffer no ill effects from breath holding and that they should not reinforce the breath-holding behavior or give in to the child. Children with breath-holding spells may benefit from structure and consistency to avoid unnecessary frustration and overtiredness.

### KEY CONCEPTS

- Development of the brain and spinal cord occurs early in gestation, in the first 3 to 4 weeks. Infection, trauma, teratogens, and malnutrition during this period can result in malformations and may affect normal CNS development.
- The brain of the newborn is highly vascular, leading to an increased risk for hemorrhage.
- The head of the infant and young child is large in proportion to the body and the neck muscles are not well developed, which places the infant at an increased risk of head injury from falls and accidents.
- Neurologic disorders in children can result from congenital problems as well as infections or trauma.
- LP and CSF analysis can be useful in the diagnosis of hemorrhage, infection, or obstruction.
- CT and MRI studies can be useful in diagnosing congenital abnormalities such as neural tube defects, hemorrhage, tumors, fractures, demyelination, or inflammation.
- EEGs measure the electrical activity of the brain and can be used in diagnosing seizures or brain death.
- Antibiotics are utilized in the treatment of bacterial meningitis and shunt infections.
- Anticonvulsants are used in the treatment and prevention of seizures and are often used in combination.
- Corticosteroids are used to reduce cerebral edema and must be tapered before discontinuing.
- Risk factors associated with neurologic disorders include prematurity, difficult birth, infection during pregnancy, family history of genetic disorders with a neurologic manifestation, seizure disorders, and headaches.
- Alterations in motor function, such as changes in gait or muscle tone or strength, may indicate certain neurologic problems such as increased ICP, head injury, and cerebral infections.
- Increased ICP is a sign that may occur with many neurologic disorders. It may result from head trauma, birth trauma, hydrocephalus, infection, and brain tumors. It is essential that the nurse observes for signs and symptoms associated with increased ICP while caring for a child with a potential or suspected neurologic disorder.
- Sunset eyes may indicate increased ICP as seen in hydrocephalus.
- A bulging fontanel can be a sign of increased ICP and is seen in such neurologic disorders as hydrocephalus and head traumas.
- Cortical control of motor function is lost in certain neurologic disorders; postural reflexes reemerge and are directly related to the area of the brain that is damaged. Decorticate posturing occurs with damage of the cerebral cortex. Decerebrate posturing occurs with damage at the level of the brain stem.
- Hydrocephalus results from an imbalance in the production and absorption of CSF. Key assessment findings include a rapid increase in head circumference seen in the infant, or loss of development and changes in personality in the older child. Signs and symptoms associated with increased ICP may be seen.
- Bacterial meningitis requires rapid assessment and treatment. On assessment, the nurse may find the infant with bacterial meningitis resting in the opisthotonic position, and the older child may complain of neck pain.

- Nursing management of seizures focuses on preventing injury during seizures, instituting seizure precautions, maintaining a patent airway, administering appropriate medication and treatments to prevent or reduce seizures, and providing education and support to the child and family to help them cope with the challenges of living with a chronic seizure disorder.
- Nursing management of the child with hydrocephalus will focus on maintaining cerebral perfusion, minimizing neurologic complications, recognizing and preventing shunt infection and malfunction, maintaining adequate nutrition, promoting growth and development, and supporting and educating the child and family.
- Nursing management of the child with bacterial meningitis will include administration of intravenous antibiotics, reducing ICP, and maintaining cerebral perfusion along with treating fluid volume deficit, controlling seizures, and preventing injury that may result from altered LOC or seizure activity.
- Nurses play a key role in educating the public on topics such as helmet use with certain sports, bicycle and motorcycle safety, seat belt use, and providing adequate supervision of children to help prevent injuries and accidents and resultant head trauma from occurring.
- Many neurologic disorders affect multiple body systems with lifelong deficits that require long-term rehabilitation. Adjusting to the demands this condition places on the child and family is difficult. Parents may need time to accept their child's condition but as soon as possible they should be involved in the child's care.
- Children with neurologic disorders and their families often need large amounts of education and support throughout the child's lifetime. As the child grows, the needs of the family and child will change. The nurse needs to provide ongoing education and support.
- Some neurologic disorders require complete intensive daily care. Adjusting to these demands can be difficult for the family. Encourage respite care and provide meaningful education programs that emphasize independence for the child in the least restrictive educational environment. Refer caregivers to local resources, including education services and support groups.

## MULTIPLE CHOICE QUESTIONS

- When compared with adults, why are infants and children at an increased risk of head trauma?
  - The head of the infant and young child is large in proportion to the body and the neck muscles are not well developed.
  - The development of the nervous system is complete at birth but remains immature.
  - The spine is very immobile in infants and young children.
  - The skull is more flexible due to the presence of sutures and fontanels.
- At a well-child visit, hydrocephalus may be suspected in an infant if upon assessment the nurse finds:
  - Narrow sutures
  - Sunken fontanels
  - A rapid increase in head circumference
  - Increase in weight since last visit
- A 10-year-old child is admitted to the hospital due to history of seizure activity. As his nurse, you are called into the room by his mother, who states he is having a seizure. What would be the priority nursing intervention?
  - Prevention of injury by removing the child from his bed
  - Prevention of injury by placing a tongue blade in the child's mouth
  - Prevention of injury by restraining the child
  - Prevention of injury by placing the child on his side and opening his airway
- A 6-month-old infant is admitted to the hospital with suspected bacterial meningitis. She is crying, irritable, and lying in the opisthotonic position. The priority nursing intervention would be:
  - Educate the family on ways to prevent bacterial meningitis.
  - Initiate appropriate isolation precautions and begin intravenous antibiotics.
  - Assess the infant's fontanels.
  - Encourage the mother to hold the infant and feed her.

## CRITICAL THINKING EXERCISES

- A child is seen in the doctor's office after hitting his head while skateboarding. The child suffered no loss of consciousness, and has no external injuries and no significant past medical history. He is acting appropriately at this time. His only complaint is a dull headache. What instructions would you give the parents regarding his care at home? Include when they should seek further medical care.
- A 10-year-old child is admitted to the pediatric unit after experiencing a seizure. A complete, accurate, and detailed history from a reliable source is essential. What information would you ask for while obtaining the history?
- A 6-year-old child is admitted to the hospital because of a possible seizure. The child's mother calls the nurse to the room because the child is "jerking all over" and won't respond when she calls the child's name. List appropriate nursing interventions for this child. Prioritize the list of interventions.
- Describe the impact of a cerebral vascular accident in the child as compared with the adult. How does it affect the child's future? How will the nurse provide care differently for the child stroke victim as compared with the adult?

## STUDY ACTIVITIES

- A 4-month-old child with a history of hydrocephalus has undergone surgery for placement of a VP shunt. What information would you include in the teaching plan?
- Develop an example of a "headache log" that could be used by the family for chronicling the child's headaches, including triggers, relieving factors, and precipitating events. Ensure that the log is developed at a 6th-grade reading level to make it practical for low-literacy parents.
- In the clinical setting, interview the parent of a child who has suffered significant brain trauma or injury (such as head trauma or stroke). Talk with the family about the types of care the child requires. Reflect upon this interview in your clinical journal, and compare how the ongoing care for this child compares with that for a typical child.

#### KEY TERMS

acuity  
 amblyopia  
 blindness  
 conductive  
   hearing loss  
 deafness  
 decibel  
 hearing impairment  
 nystagmus

 (PE) tubes  
 ptosis  
 sensorineural  
   hearing loss  
 strabismus  
 tympanometry  
 tympanostomy  
 vision impairment

## Nursing Care of the Child With a Disorder of the Eyes or Ears

### Learning Objectives

*Upon completion of the chapter, you will be able to:*

1. Define the key terms used in this chapter.
2. Differentiate between the anatomic and physiologic differences of the eyes and ears in children as compared with adults.
3. Identify various factors associated with disorders of the eyes and ears in infants and children.
4. Discuss common laboratory and other diagnostic tests useful in the diagnosis of disorders of the eyes and ears.
5. Discuss common medications and other treatments used for treatment and palliation of conditions affecting the eyes and ears.
6. Recognize risk factors associated with various disorders of the eyes and ears.
7. Distinguish between different disorders of the eyes and ears based on the signs and symptoms associated with them.
8. Discuss nursing interventions commonly used in regard to disorders of the eyes and ears.
9. Devise an individualized nursing care plan for the child with a sensory impairment or other disorder of the eyes or ears.
10. Develop child/family teaching plans for the child with a disorder of the eyes or ears.
11. Describe the psychosocial impact of sensory impairments on children.

*Enrique Baxter, a 9-month-old, is brought to the clinic by his mother. His mother tells you, “Enrique has been fussy and not eating or sleeping well for the past 2 days.”*

### Words of Wisdom

With the help of a nurse's care and healing, the child's senses provide him or her with an antenna to the universe.

**Children** commonly suffer from disorders related to the eyes and ears. Conjunctivitis and otitis media are two very common infectious and inflammatory disorders that affect the child's eyes or ears. Various alterations such as refractive error, strabismus, and amblyopia affect the development of visual **acuity** in children. Any alteration in the ear that contributes to hearing loss may have a significant impact on the child's language acquisition. It is important for the nurse to understand the impact of eye and ear disorders on the child's development. Some children may be born with anomalies of the eyes or ears that will have a significant impact on vision and hearing, as well as psychomotor development. On the other hand, disorders affecting the eyes or ears, particularly if chronic or recurrent, can have a significant impact on the development of visual acuity or may cause **hearing impairment**.

In addition, the nurse may be caring for a child with another problem who is also either visually or hearing impaired. The nurse must take these developmental differences into account when planning care for these children.

## VARIATIONS IN PEDIATRIC ANATOMY AND PHYSIOLOGY

The anatomy of children's eyes and ears differs somewhat from that of adults. Additionally, visual acuity develops from birth throughout early childhood. Hearing is intact at birth, but recurrent ear disorders may adversely affect the child's hearing.

### Eyes

Light-skinned children are often born with blue eyes. The iris becomes pigmented over time and eye color is determined by 6 to 12 months of age. The newborn's sclera may be slightly bluish tinged but becomes white within weeks. The eyeball of the infant and young child occupies a relatively larger space within the orbit than the adult's does, making it more susceptible to injury (Fig. 39.1).

The spherical shape of the newborn's lens does not allow for distance accommodation, so the newborn sees best at a distance of about 8 to 10 inches (Olitsky, et al., 2011d). The optic nerve is not completely myelinated, so color discrimination is incomplete. Visual acuity develops over the first few years of the child's life. At birth, acuity ranges from 20/100 to 20/400. Visual acuity improves over the first few years of the child's life, with 20/20 achieved by age 6 to 7 years (Weber & Kelley, 2010). The rectus muscles are uncoordinated at birth and mature over time so that binocular vision (the ability to focus with both eyes simultaneously) may be achieved by 4 months of age (Weber & Kelley, 2010). In the very preterm infant, retinal vascularization is incomplete, so visual acuity may be affected (American Academy of Pediatrics [AAP], 2006).

### Ears

Congenital deformities of the ear are often associated with other body system anomalies and genetic syndromes. The presence of ear anomalies may lead to the search for, and subsequent diagnosis of, the other anomalies or syndromes. The infant's relatively short, wide, and horizontally placed Eustachian tubes allow bacteria and viruses to gain access to the middle ear easily, resulting in increased numbers of ear infections as compared to the adult (Yoon, Kelley, & Friedman, 2011). As the child matures, the tubes assume a more slanted position. Therefore, older children and adults generally have fewer cases of middle ear effusion and infection (Fig. 39.2). Sometimes enlargement of the adenoids contributes to obstruction of the Eustachian tubes, leading to infection.

## COMMON MEDICAL TREATMENTS

A variety of interventions are used to treat disorders of the eyes and ears in children. The treatments listed in Common Medical Treatments 39.1 and Drug Guide 39.1 usually require a physician's order when a child is hospitalized.

**FIGURE 39.1** The relatively larger space that the infant's and young child's eyeball occupies within the orbit makes it more susceptible to injury as compared with the adult's eye.

**FIGURE 39.2** Note the child's relatively shorter, wider Eustachian tubes and their horizontal positioning (B) as compared with the adult's (A).

## NURSING PROCESS OVERVIEW FOR THE CHILD WITH A DISORDER OF THE EYES OR EARS

Care of the child with a disorder of the eyes and ears includes assessment, nursing diagnosis, planning, interventions, and evaluation. There are a number of general concepts related to the nursing process that can be applied to disorders of the eyes and ears. From a general understanding of the care involved for a child with alterations in the eyes or ears, the nurse can then individualize the care based on child specifics.

### Assessment

Assessment of disorders of the eyes and ears in children includes health history, physical assessment, and laboratory or diagnostic testing.

**Remember Enrique, the 9-month-old with fussiness and poor feeding who was not sleeping well? What additional health history and physical examination assessment information should you obtain?**

### Health History

The health history consists of past medical history, family history, history of present illness, and treatments used at home. The past medical history may be significant for prematurity, genetic defect, eye or ear deformities, visual acuity deficit or blindness, hearing impairment or **deafness**, recurrent ear infections, or ear surgeries. Family history might be significant for eye or ear deformities or vision or hearing impairment or may reveal contacts for infectious exposure.

When eliciting the history of the present illness, inquire about its onset and progression and the presence of fever, nasal congestion, eye or ear pain, eye rubbing, ear pulling, headache, lethargy, or behavioral changes. Document if the child has corrective lenses or hearing aids prescribed and to what extent these devices are actually used.

### Physical Examination

When assessing the eyes and ears, begin with inspection and observation. Additionally, testing of visual activity and hearing may be performed.

### INSPECTION AND OBSERVATION

Begin the physical examination with inspection and observation. Note whether the child uses eyeglasses, corrective lenses, or a hearing aid. Observe the eyes: note their positioning and symmetry and the presence of strabismus, nystagmus, and squinting. The eyelids should open equally (failure to open fully is termed **ptosis**). Note variations in eye slant and the presence of epicanthal folds. Assess the eyes for the presence of eyelid edema, sclera color, discharge, tearing, and pupillary equality, as well as the size and shape of the pupils.

#### Take Note!

Though the sclerae are bluish in newborns, they become white in the first few weeks of life. Blue sclerae that persist beyond a few weeks of life may be an indicator of osteogenesis imperfecta type I, an inherited connective tissue disorder (Weber & Kelley, 2010).

Evert the eyelid to inspect the palpebral conjunctivae for redness. Test for extraocular movements and pupillary light response and accommodation. Note the symmetry of the corneal light reflex. Note the presence

## COMMON MEDICAL TREATMENTS 39.1

Treatment	Explanation	Indications	Nursing Implications
Warm compress	Warm, moist washcloth	Conjunctivitis	<ul style="list-style-type: none"> <li>Use very warm water from the tap (to avoid risk of burning, do not microwave).</li> </ul>
Corrective lenses	In eyeglass form or as contact lenses	Correction of astigmatism, refractive error, strabismus	<ul style="list-style-type: none"> <li>Use a safety strap to help young children wear their eyeglasses.</li> </ul>
Patching	An adhesive patch is applied to the healthier eye for several hours each day.	Strabismus, amblyopia, any other eye condition that results in one eye being weaker than the other	<ul style="list-style-type: none"> <li>Inform parents that though difficult to obtain, compliance with patching is critical.</li> <li>A “pirate patch” may coax preschoolers into compliance.</li> </ul>
Eye muscle surgery	Surgical alignment of the eyes	Strabismus	<ul style="list-style-type: none"> <li>Protect the operative site with patching.</li> <li>Use elbow restraints if necessary.</li> </ul>
Pressure-equalizing (PE) tubes (tympanostomy tubes)	Tiny plastic tubes inserted in the tympanic membrane	Chronic otitis media with effusion	<ul style="list-style-type: none"> <li>Teach parents “dry ears” precautions if prescribed or preferred by the surgeon.</li> </ul>
Hearing aids	Amplification device worn in the ear	Hearing impairment	<ul style="list-style-type: none"> <li>Ensure appropriate fit and adequate amplification.</li> <li>Direct families to outfitters that provide loaner aids of various brands and styles to determine best fit and amplification for the child.</li> </ul>
Cochlear implants	Surgically inserted electronic prosthetic device	Sensorineural hearing loss	<ul style="list-style-type: none"> <li>Inform families that the usual minimum age for this procedure is 12 months.</li> </ul>

Adapted from Megerian, C. A., Roland, P. S., & Murray, G. S. (2011). *Cochlear implant surgery*. Retrieved July 4, 2012, from <http://emedicine.medscape.com/article/857242-overview>; and Yoon, P. J., Kelley, P. E., & Friedman, N. R. (2011). Ear, nose, & throat. In W. W. Hay, M. J. Levin, J. M. Sondheimer, & R. R. Deterding (Eds.), *Current pediatric diagnosis and treatment* (20th ed.). New York: McGraw-Hill.

## DRUG GUIDE 39.1 COMMON DRUGS FOR EAR AND EYE DISORDERS

Medication	Actions	Indications	Nursing Implications
Antibiotics (oral, otic, ophthalmic)	Treatment of bacterial infections of the eyes and ears	Acute otitis media, otitis externa, conjunctivitis	<p>Teach families to complete the entire course as prescribed.</p> <p>Check for drug allergies prior to administration.</p>
Antihistamines	Block histamine reaction	Allergic conjunctivitis	<p>Topical drops used.</p> <p>Oral agents usually prescribed if allergic rhinitis accompanies the conjunctivitis.</p>
Analgesics	Pain relief	Otitis media, otitis externa, after eye or ear surgery	Narcotic analgesics may be necessary in some instances.

Adapted from Taketokmo, C. K., Hodding, J. H., & Kraus, D. M. (2011). *Pediatric and neonatal dosage handbook* (18th ed.). Hudson, OH: Lexi-comp.

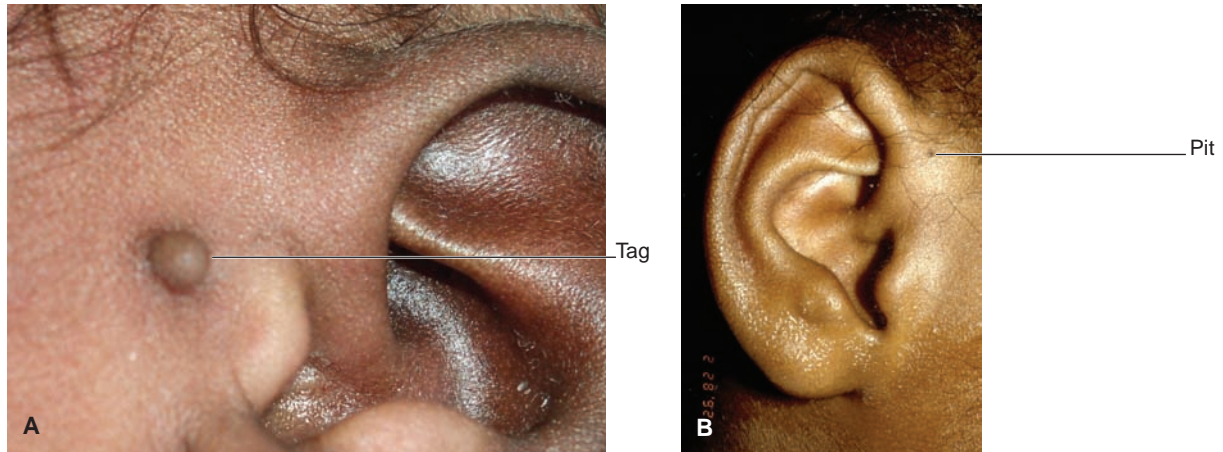

FIGURE 39.3 Note the skin tag (A) and preauricular pit (B) (in front of the ear).

of the red reflex with an ophthalmoscope. Perform an age-appropriate visual acuity test. Refer to Chapter 32 for more detailed information related to visual acuity testing.

#### Take Note!

Attempts to inspect the palpebral conjunctivae may be frightening to children. Ask the older, cooperative child to evert the eyelid himself or herself while the nurse inspects the conjunctivae.

Inspect the ears: note their size and shape, position, and the presence of skin tags, dimples, or other anomalies (Fig. 39.3). Upon otoscopic examination, note the presence of cerumen, discharge, inflammation, or a foreign body in the ear canal. Visualize the tympanic membrane and observe its color, landmarks, and light reflex, as well as the presence of perforation, scars, bulging, or retraction. Tympanic membrane mobility may be tested with pneumatic otoscopy. Auditory acuity is tested via the whisper test, audiometry, or other age-appropriate test (refer to Chapter 32 for a more detailed explanation of hearing testing).

#### PALPATION

Usually, the eyes are not palpated. In the case of injury the upper eyelid may be everted for examination purposes. Palpate the ear for tenderness over the tragus or pinna. Note the presence of tenderness over the mastoid area (tenderness may be present when otitis media progresses to mastoiditis). Palpate for enlarged cervical lymph nodes (this occurs when the eyes or ears are infected).

#### Laboratory and Diagnostic Testing

Common Laboratory and Diagnostic Tests 39.1 offers an explanation of the laboratory and diagnostic tests most commonly used for disorders of the eyes and ears.

These tests can assist the physician or nurse practitioner in diagnosing the disorder and/or can be used as guidelines in determining ongoing treatment. Laboratory or nonnursing personnel obtain some of the tests, while the nurse may obtain others. In either instance be familiar with how the tests are obtained, what they are used for, and normal versus abnormal results. This knowledge will also be necessary when providing child and family education related to the testing.

### Nursing Diagnoses and Related Interventions

Upon completion of a thorough assessment, the nurse might identify several nursing diagnoses, including:

- Disturbed sensory perception
- Risk for infection
- Pain
- Delayed growth and development
- Impaired verbal communication
- Deficient knowledge
- Interrupted family processes
- Risk for injury

**After completing an assessment of Enrique, the nurse noted the following: fever, tugging at his ears, and increased crying when lying down. Based on the assessment findings, what would your top three nursing diagnoses be for Enrique?**

Nursing goals, interventions, and evaluation for the child with an eye or ear disorder are based on the nursing diagnoses. Nursing Care Plan 39.1 may be used as a guide in planning nursing care for the child with an eye or ear disorder, but it should be individualized based

## COMMON LABORATORY AND DIAGNOSTIC TESTS 39.1

Test	Explanation	Indications	Nursing Implications
Culture of eye or ear discharge	Fluid draining from the eye or ear is cultured	To determine specific bacteria present and appropriate antibiotic coverage	Easy to collect, relatively pain-free. If drainage must be removed from within the ear canal, more likely to be painful
Tympanic fluid culture	Culture of fluid aspirated from the middle ear	To determine specific bacteria present and appropriate antibiotic coverage	Painful; usually performed only by specially trained physicians
Tympanometry	Probe in ear canal measures movement of the eardrum	Determines extent of effusion of the middle ear	Quick and easy to perform (seconds). Requires accurate-sized probe for adequate seal of the ear canal

Adapted from Yoon, P. J., Kelley, P. E., & Friedman, N. R. (2011). Ear, nose, & throat. In W. W. Hay, M. J. Levin, J. M. Sondheimer, & R. R. Deterding (Eds.), *Current pediatric diagnosis and treatment* (20th ed.). New York, NY: McGraw-Hill.

on the child's symptoms and needs. Refer to Chapter 36 for the nursing care plan for pain management. Additional information will be included later in the chapter as it relates to specific disorders.

**Based on your top three nursing diagnoses for Enrique, describe appropriate nursing interventions.**

## INFECTIOUS AND INFLAMMATORY DISORDERS OF THE EYES

Infectious and inflammatory disorders of the eyes include conjunctivitis, nasolacrimal duct obstruction, eyelid lesions, and periorbital cellulitis.

### Conjunctivitis

Inflammation of the bulbar or palpebral conjunctiva is referred to as conjunctivitis. It can be infectious, allergic, or chemical in nature. Viruses or bacteria may cause infectious conjunctivitis. Adenoviruses and influenza account for the bulk of cases of viral conjunctivitis. The most common bacterial cause is *Staphylococcus aureus*, but many cases are also caused by *Streptococcus pneumoniae*, *Haemophilus influenzae*, and other bacteria (Yoon et al., 2011). In the newborn, *Chlamydia trachomatis* and *Neisseria gonorrhoeae* are more common causes. Infectious conjunctivitis is very contagious, so epidemics are common, particularly in young

children. Risk factors for acute infectious conjunctivitis include age younger than 2 weeks; day care, preschool, or school attendance; concomitant viral upper respiratory infection; pharyngitis; or otitis media. Concurrent acute otitis media may occur depending on the bacterial cause. Complications from simple infectious conjunctivitis are uncommon. Neonates with chlamydial conjunctivitis may be at risk for the development of chlamydial pneumonia.

Allergic conjunctivitis results from exposure to particular allergens. Allergic conjunctivitis may be a seasonal or year-round complaint. A genetic predisposition to allergic conjunctivitis exists, just as it does for asthma, allergic rhinitis, and atopic dermatitis. Allergic conjunctivitis occurs more frequently in school-age children and adolescents than it does in infants and young children because of repeat exposure to allergens over time. In the case of seasonal allergic conjunctivitis, the severity of symptoms and the number of children affected are directly related to the pollen count in the area.

### Pathophysiology

When bacteria or viruses come in contact with the bulbar or palpebral conjunctiva, they are recognized as foreign antigens and an antigen–antibody immune reaction occurs, resulting in inflammation. Allergic conjunctivitis occurs through a different mechanism. Contact with the allergen results in an allergic response (overreaction of the immune response). The mast cell and histamine mediators are then activated, resulting in inflammation.

## NURSING CARE PLAN 39.1

**Overview for the Child With a Disorder of Eyes or Ears**

**NURSING DIAGNOSIS:** Sensory perception, disturbed (visual) related to visual impairment or blindness as evidenced by lack of reaction to visual stimuli, squinting, holding items close

**Outcome Identification and Evaluation**

Child will reach maximal vision potential: *child uses corrective lenses appropriately and is able to participate in play and schoolwork.*

**Intervention: Improving Vision**

- Encourage corrective lens use *for enhancement of vision.*
- For the severely impaired or blind child, identify yourself via voice and name items in environment for the child *so that the child is aware of his or her surroundings.*
- Support the family's efforts at vision therapy and other habilitation programs *to promote vision enhancement.*
- Engage the parents in bedside caregiving *because the parents' voice and presence are reassuring to the child.*

**NURSING DIAGNOSIS:** Sensory perception, disturbed (auditory) related to hearing loss as evidenced by lack of reaction to verbal stimuli, delayed attainment of language milestones

**Outcome Identification and Evaluation**

Child will reach maximal hearing and speech potential: *child uses aids appropriately and communicates effectively.*

**Intervention: Improving Hearing**

- Assess hearing ability frequently *because early detection of hearing loss allows for earlier intervention and correction.*
- Assess language development at each visit *to allow for early detection of hearing loss (earlier intervention and correction).*
- Encourage hearing aid use *for amplification of sound.*
- Teach about hearing aid battery safety *to avoid aspiration of battery.*
- Assist child with focusing on sounds in the environment *to encourage listening skills.*
- Refer for and encourage attendance at communication habilitation program *to maximize communication potential.*

**NURSING DIAGNOSIS:** Risk for infection related to presence of infectious organisms as evidenced by fever, presence of virus or bacteria on laboratory screening.

**Outcome Identification and Evaluation**

Child will exhibit no signs of secondary infection and will not spread infection to others: *symptoms of infection decrease over time, and others remain free from infection.*

## NURSING CARE PLAN 39.1

**Overview for the Child With a Disorder of Eyes or Ears** (continued)**Intervention: Reducing Infection Risk**

- Maintain aseptic technique and practice good hand washing *to prevent introduction of further infectious agents.*
- Limit number of visitors, and screen for recent illness, *to prevent further infection.*
- Administer antibiotics if prescribed *to prevent or treat bacterial infection.*
- Encourage nutritious diet according to child's preferences *to assist body's natural infection-fighting mechanisms.*
- Isolate the child as required *to prevent nosocomial spread of infection.*
- Teach child and family preventive measures such as good hand washing, covering mouth and nose when coughing or sneezing, and adequate disposal of used tissues *to prevent nosocomial or community spread of infection.*

**NURSING DIAGNOSIS:** Growth and development delay, related to sensory impairment as evidenced by delay in attainment of developmental milestones

**Outcome Identification and Evaluation**

Child will achieve optimum independence for age: *child participates in age-appropriate developmental activities.*

**Intervention: Encouraging Growth and Development**

- Encourage attainment of developmental milestones with use of assistive devices as needed *for timely developmental achievements.*
- Foster independence in activities of daily living (ADLs) *to promote sense of accomplishment.*
- Encourage participation in play with another child or within a group *to promote socialization.*
- Assist family to set limits and apply discipline *because structure and routine provide a secure environment in which the developing child can grow.*
- Encourage friendships with other children with a sensory impairment *to promote socialization and let the child know that he or she is not the only one with these challenges.*

**NURSING DIAGNOSIS:** Impaired verbal communication related to hearing loss as evidenced by lack of or inarticulate speech, lack of alternate communication channel

**Outcome Identification and Evaluation**

*The child will communicate effectively with the method chosen by the family (this may be sign language, oral/deaf speech, cued speech, or augmentative alternative communication device).*

**Intervention: Improving Communication**

- Encourage choice of and attendance at communication habilitation program *to promote continued learning.*
- Provide consistency between home and hospital in regard to communication style/devices *to promote continued learning.*
- Support the child's efforts at correct speech *to promote speech development through reinforcement and praise.*
- Encourage family to use spoken language and read books at home *to continue to promote appropriate language development.*

(continued)

## NURSING CARE PLAN 39.1

**Overview for the Child With a Disorder of Eyes or Ears** (continued)

**NURSING DIAGNOSIS:** Deficient knowledge related to sensory impairment (vision or hearing) as evidenced by new diagnosis and parents' questions

**Outcome Identification and Evaluation**

Parents express understanding of diagnosis and care of child: *parents verbalize understanding, demonstrate use of assistive devices, or independently perform medical treatments.*

**Intervention: Educating the Family**

- Review diagnosis and plan of care with the parents to *promote understanding of the disease process.*
- Refer family to resources available for sensory-impaired children to *provide further education and support to the parents.*
- Demonstrate medical treatments prescribed or use of assistive devices, requiring a return demonstration, *which shows the parents' ability to provide the prescribed care for the child.*
- Encourage exploration of different communication and learning modes available for the sensory-impaired child to *allow the child and family to find the right educational and communication style fit.*

**NURSING DIAGNOSIS:** Family processes, interrupted, related to child's sensory impairment as evidenced by parent verbalization, nonverbal communication, altered coping

**Outcome Identification and Evaluation**

Parents demonstrate adequate coping and decreased anxiety: *parents are involved in child's care, ask appropriate questions, and are able to discuss child's care and condition calmly.*

**Intervention: Encouraging Appropriate Family Interactions**

- Encourage parents' verbalization of grief if child is hearing or vision impaired. *Parents must deal with their own feelings of loss to successfully care for the child with an impairment.*
- Encourage parents' verbalization of concerns related to child's illness: *allows for identification of concerns and demonstrates to the family that the nurse also cares about them, not just the child.*
- Explain therapy, procedures, and child's behavior to parents: *developing an understanding of the child's current status helps decrease anxiety.*
- Encourage parental involvement in care so *that parents may continue to feel needed and valued.*

## NURSING CARE PLAN 39.1

## Overview for the Child With a Disorder of Eyes or Ears (continued)

**NURSING DIAGNOSIS:** Risk for injury related to vision loss as evidenced by difficulty navigating surroundings

**Outcome Identification and Evaluation**

*The infant or child will remain free from injury.*

**Intervention: Preventing Injury**

- Orient the child to hospital surroundings *because awareness is the first step to preventing injury.*
- Encourage parent to be at bedside *so that the child feels more comfortable.*
- Encourage use of assistive device *to promote safety.*

## Therapeutic Management

Therapeutic management of conjunctivitis is prescribed depending on the cause. Bacterial conjunctivitis is generally treated with an ophthalmic antibiotic preparation (drops or ointment). Viral conjunctivitis is a self-limiting disease and does not require topical medication. Eye drops with an antihistamine or mast cell stabilization effect may be helpful in alleviating symptoms of allergic conjunctivitis. If other allergy signs and symptoms are also present, an oral antihistamine may also be prescribed. Table 39.1 compares bacterial, viral, and allergic conjunctivitis.

## Nursing Assessment

Nursing assessment of the child with conjunctivitis, regardless of the cause, is similar. It includes health history, physical examination, and, in rare instances, laboratory testing.

## Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Redness
- Edema
- Tearing
- Discharge
- Eye pain
- Itching of the eyes (usually with allergic conjunctivitis)

Determine the onset of symptoms and their progression as well as response to treatments used at home. Assess for risk factors for infectious conjunctivitis, such as day care or school attendance. Note any history of an upper respiratory infection, sore throat, or earache. Question parents about possible infectious exposure. Review the health history for risk factors for allergic

**TABLE 39.1** TYPES OF CONJUNCTIVITIS

Type of Conjunctivitis	Conjunctivae	Discharge	Additional Findings	Eyelid Edema	Treatment
Bacterial	Inflamed	Purulent, mucoid	Mild pain	Occasional	Antibiotic drops or ointment
Viral	Inflamed	Watery, mucoid	Lymphadenopathy, photophobia, tearing	Usually present	Symptom relief; antiherpetic agent if cause is herpes
Allergic	Inflamed	Watery or stringy	Itching	Usually present	Antihistamine and/or mast cell stabilizer drops

Adapted from Braverman, R. S. (2011). Eye. In W. W. Hay, M. J. Levin, J. M. Sondheimer, & R. R. Deterding (Eds.), *Current pediatric diagnosis and treatment* (20th ed.). New York, NY: McGraw-Hill.

FIGURE 39.4 Note redness of conjunctiva.

conjunctivitis, such as a family history and a history of asthma, allergic rhinitis, or atopic dermatitis. Determine seasonality related to the symptoms and whether the symptoms occur after exposure to particular allergens, such as pollen, hay, or animals.

### Physical Examination

Observe for eyelid swelling or redness. Inspect the conjunctivae for redness (Fig. 39.4). Note quantity, color, and consistency of discharge. Bacterial infections generally result in a thick, colored discharge, whereas a clear or white discharge is generally seen with viral conjunctivitis. Allergic conjunctivitis often results in a watery discharge, sometimes profuse, which is usually present bilaterally. Contact with an allergen rubbed into one of the eyes may result in unilateral symptoms. Observe the child for other signs of allergic or atopic disease, and document the presence of a runny nose or cough as well.

### Laboratory and Diagnostic Tests

Cases of bacterial, viral, and allergic conjunctivitis are generally diagnosed based on history and clinical presentation. Cases of viral and allergic conjunctivitis do not warrant laboratory testing. If bacterial conjunctivitis is suspected, then a bacterial culture of the eye drainage may be performed to determine the exact causative organism, thus allowing the most appropriate antibiotic to be prescribed.

### Nursing Management

Nursing management of the various types of conjunctivitis focuses on alleviating symptoms and, for infectious causes, preventing spread.

### Alleviating Symptoms

Teach parents how to apply eye drops or ointment (antibiotic for bacterial causes and antihistamine or mast cell stabilizer for allergic). Warm compresses may be used to help loosen the crust that accumulates on the eyelids overnight when drainage is copious, particularly with bacterial conjunctivitis.

The child with allergic conjunctivitis may experience perennial or seasonal allergies (or both). Encourage the child to avoid perennial allergens once the offending allergen is determined (refer to Chapter 40 for additional information related to education about perennial allergen avoidance). Seasonal allergies may include tree pollen in the winter or spring, grass pollen in the summer, and ragweed or flower pollen in the fall.

It is impossible to completely eliminate seasonal allergic responses, partly because it is important for children to participate in physical activity outdoors. Teach families to minimize seasonal allergens on the child's skin and hair. Educate families to:

- Encourage the child not to rub or touch the eyes.
- Rinse the child's eyelids periodically with a clean washcloth and cool water.
- When the child comes in from outdoors, wash the child's face and hands.
- Ensure that the child showers and shampoos before bedtime.

#### Take Note!

The itching of allergic conjunctivitis may be relieved with cool compresses. An easy way to accomplish this is to have the child hold a tube of yogurt over the affected eye.

### Preventing Infectious Spread

Because infectious conjunctivitis is extremely contagious, the parent must wash hands diligently after caring for the child. Teach parents and children about appropriate hand washing and discourage them from sharing towels and washcloths. Children with viral conjunctivitis may return to school or day care when symptoms lessen. When mucopurulent drainage is no longer present (usually after 24 to 48 hours of treatment with a topical antibiotic), the child with bacterial conjunctivitis may safely return to day care or school (Durani, 2012).

#### Take Note!

Avoid the use of vasoconstricting eye drops such as Visine to rid the eyes of redness. Rebound vasodilation may occur, and with it the redness returns. This leads to repeated frequent use of the drops to keep the eyes from being red but does not treat the actual cause of the redness (Taketokmo, Hodding, & Kraus, 2010).

### Consider This

**B**ryn Carle, a 6-year-old, is brought to the clinic by her mother. She presents with redness of the left eye, edema, and drainage. What other assessment information would be helpful? Based on the history and clinical presentation, Bryn is diagnosed with conjunctivitis. What education will be necessary for the family to assist in alleviating symptoms and preventing infectious spread?

## Nasolacrimal Duct Obstruction

Stenosis or simple obstruction of the nasolacrimal duct is a common disorder of infancy, occurring in about 6% of the newborn infants (Olitsky et al., 2011c). It may occur in one or both eyes. Chronic tearing occurs and build-up in the lacrimal sac causes a mucoid or mucopurulent drainage. Over 90% of all cases resolve spontaneously by 1 year of age (American Association for Pediatric Ophthalmology and Strabismus [AAPOS], 2012). No apparent risk factors exist for the development of nasolacrimal duct obstruction or stenosis. Therapeutic management involves a “wait and see” approach. Massage may be prescribed, and if secondary bacterial infection is suspected or confirmed, antibiotic ointment or drops may be ordered. If the obstruction does not resolve by 12 months of age, then the pediatric ophthalmologist may probe the duct to relieve the obstruction (a brief outpatient procedure) (Olitsky et al., 2011c).

## Nursing Assessment

Tearing or discharge from one or both eyes is often first noted at the 2-week checkup. Obtain a thorough history about the eye drainage to distinguish it from neonatal conjunctivitis. Determine the onset and progression of symptoms, as well as the newborn’s response to any interventions attempted so far. Upon physical examination, note redness of the lower lid of the affected eye. If drainage is present, note its consistency, color, and quantity. Nasolacrimal duct obstruction is usually a diagnosis based on clinical presentation, but culture of the eye drainage may be used to rule out conjunctivitis or secondary bacterial infection (Fig. 39.5).

## Nursing Management

As previously stated, the majority of cases of nasolacrimal duct stenosis resolve spontaneously by 12 months of age (AAPOS, 2011). Nevertheless, the continual tearing and discharge is quite upsetting to the parents. Teach parents to clean the eye area frequently with a moist

**FIGURE 39.5** Mild eyelid redness and crusting are present in the infant with nasolacrimal duct stenosis.

cloth. In addition, teach parents to massage the nasolacrimal duct, which may change the pressure and cause it to open, allowing drainage to occur. Refer to Teaching Guidelines 39.1 for appropriate nasolacrimal duct massage technique. Ensure that parents are educated about when and how to administer antibiotic eye drops if ordered.

## Eyelid Disorders

Disorders of the eyelid include hordeolum (stye), chalazion, and blepharitis. Hordeolum is a localized infection of the sebaceous gland of the eyelid follicle, usually caused by bacterial invasion. Chalazion is a chronic painless infection of the meibomian gland. Blepharitis refers to chronic scaling and discharge along the eyelid margin. Chalazion may resolve spontaneously. Therapeutic management of hordeolum and blepharitis usually involves the use of antibiotic ointment.

## Nursing Assessment

Determine the child’s health history, noting onset of symptoms, extent and character of eye discharge, and presence of pain (hordeolum is usually painful). Inspect the eyelids, noting redness along the eyelid margin and presence of eyelid edema (hordeolum, blepharitis). Hordeolum may also be quite visible as an enlarged lesion along the lid margin, with purulent drainage present (Fig. 39.6). Chalazion may be visible as a small nodule on the lid margin. The conjunctivae remain clear with all three of these disorders.

## Teaching Guidelines 39.1

**NASOLACRIMAL DUCT MASSAGE**

- Using the forefinger or little finger, push on top of the bone (the puncta must be blocked).

- Gently push in and up.

- Then gently push downward along the side of the nose.

FIGURE 39.6 Hordeolum.

## Nursing Management

For hordeolum and blepharitis, instruct parents how to administer antibiotic ointment. Encourage the use of hot, moist compresses. Inform parents that the stye may require several weeks to resolve completely. Also inform parents that chalazion will usually resolve spontaneously; if it does not, it may require minor surgical drainage.

## Periorbital Cellulitis

Periorbital cellulitis is a bacterial infection of the eyelids and tissue surrounding the eye. The bacteria may gain entry to the skin via an abrasion, laceration, insect bite, foreign body, or impetiginous lesion. Periorbital cellulitis may also result from a nearby bacterial infection, such as sinusitis. *Staphylococcus aureus*, *Streptococcus pyogenes*, and *Streptococcus pneumoniae* are the most commonly implicated bacteria. The bacteria produce either an enzyme or endotoxins that initiate the inflammatory response. Redness, swelling, and infiltration of the skin by the inflammatory mediators occur.

Therapeutic management of periorbital cellulitis focuses on intravenous antibiotic administration during the acute phase followed by completion of the course with oral antibiotics. Complications of periorbital cellulitis include bacteremia and progression to orbital cellulitis, which is a more extensive infection involving the orbit of the eye.

## Nursing Assessment

Note the onset and duration of symptoms, as well as any treatment used so far. Document any history of fever. The child may complain of pain around the eye as well as restricted movement of the eye area. Inspect the eye, noting marked eyelid edema as well as a purplish or red color of the eyelid (Fig. 39.7). Usually the conjunctivae are clear and no discharge is present. If the extent of the edema allows the child to open the eye, assess visual acuity, which should be normal.

FIGURE 39.7 Periorbital cellulitis.

#### Take Note!

Notify the physician or nurse practitioner immediately if any of these signs of progression to orbital cellulitis occur: conjunctival redness, change in vision, pain with eye movement, eye muscle weakness or paralysis, or proptosis.

## Nursing Management

Apply warm soaks to the eye area for 20 minutes every 2 to 4 hours. Administer intravenous antibiotics as prescribed. Teach families the importance of completing the entire course of oral antibiotic treatment at home. Instruct parents to call the physician or nurse practitioner or have the child evaluated again if:

- The child is not improving.
- The child reports inability to move the eye.
- Visual acuity changes.
- Proptosis occurs.

## EYE INJURIES

As mentioned earlier, infants and young children are more susceptible to eye injuries than adults since the eyeball is relatively larger in relation to the space within the orbit. Developmental maturity may also play a part in eye injuries. For example, as infants and toddlers learn to walk and run, they do not have the awareness and maturity to avert disaster. Older children involved in sports and school science experiments are also at risk for eye injuries. A few of the more common eye injuries are eyelid injuries, contusion, scleral hemorrhage, corneal abrasion, a foreign body in the eye, and chemical injury (Braverman, 2011).

Therapeutic management depends on the type of injury. Eyelid lacerations may require suturing. Deep lacerations may result in ptosis at a later date, so these

children should be referred to an ophthalmologist. Simple contusions (black eye) usually need only observation, ice, and analgesics. Scleral hemorrhages resolve gradually without intervention over a few weeks. Corneal abrasions may be allowed to self-heal, or antibiotic ointment may be prescribed. Foreign bodies in the eye require removal to prevent further irritation or abrasion. Chemical injuries require irrigation and vision evaluation.

## Nursing Assessment

When a child presents with an eye injury, it is very important to obtain an accurate history related to the injury. Follow the history by performing a focused physical examination, which consists mostly of inspection and observation. It is important to determine whether an eye injury is nonemergent or emergent in order to provide rapid and appropriate treatment in the case of an emergency so that vision may be preserved.

## Health History

Obtain an accurate history. Determine the mechanism of injury and obtain as much detail about the injury as possible. Questions to ask during the health history include:

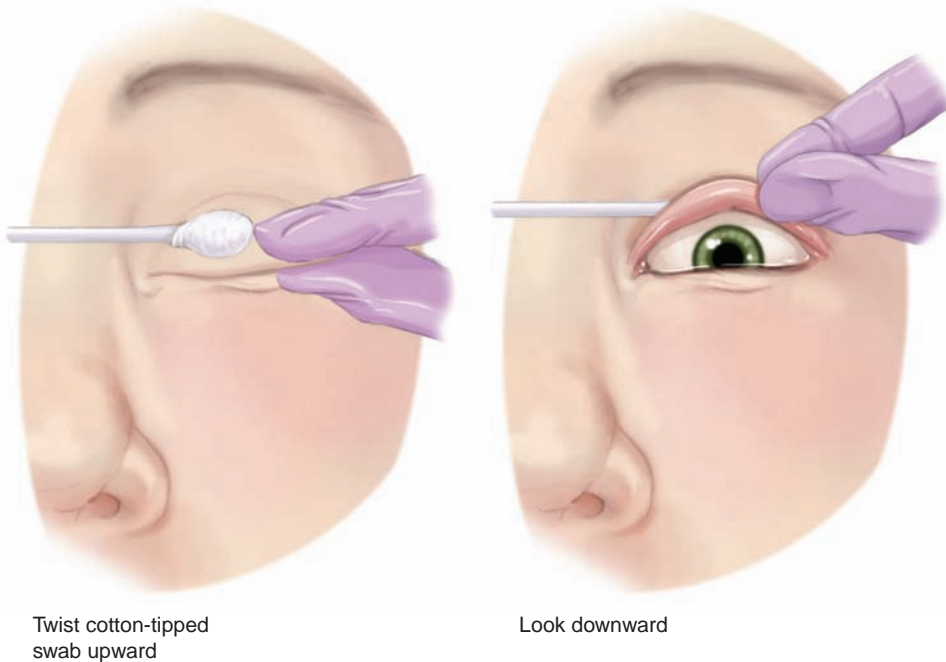

- When did the injury occur?
- What exactly happened?
- Was an object involved? If so, what type of object, and how fast was it going?
- Was it a splash injury?
- Was the child wearing eye protective gear or eyeglasses when the injury occurred?

Determine the extent of pain if present. Document photosensitivity, sensation of a foreign body in the eye, and blurry or lost vision. Inquire about past medical history, including previous eye injury or surgery or vision problems. Determine the child's immunization status.

## Physical Examination

Regardless of the type of eye injury, the examination of the child's eye can be quite difficult. The nurse plays an important role in assisting the child and family to cope with the examination. Children with an eye injury often are in acute pain. The area surrounding the eye swells quickly after blunt trauma. Edema and tearing make the eye examination more difficult. Children are very frightened because of the pain and difficulty seeing. Approach the child in a calm and gentle manner. Soothe and coax the child as the eye is examined. Younger children may need to be restrained briefly in order for the examination to proceed safely.

Note the eyelid placement and look for signs of trauma such as bleeding, edema, and eyelid malformation. Evaluate the child's ability to open the eyes. Use a penlight to evaluate the pupils' response to light and

**FIGURE 39.8** Eversion of the eyelid for examination. Place a cotton-tipped applicator over the eyelid. Pull the eyelid outward and up over the applicator.

accommodation (in the case of nonemergent eye trauma, the pupils should remain equally round and reactive to light and accommodation [PERRLA]). Note redness or irritation of the sclerae and/or conjunctivae. Observe for excessive tearing. Figure 39.8 shows the appropriate technique for eversion and examination of the interior of the eyelid.

In a nonemergent situation, evaluate visual acuity via the use of an age-appropriate vision-screening tool (refer to Chapter 32 for additional information related to visual acuity screening). Generally, radiologic testing is used only in emergency situations (Augsburger & Corrêa, 2011). Table 39.2 provides assessment information specific to eyelid laceration, simple contusion, scleral hemorrhage, corneal abrasion, and foreign body in the eye.

#### Take Note!

If pupillary reaction is abnormal, vision is affected (decreased acuity from the child's norm, diplopia, or blurriness), or extraocular movements are affected, the child should be immediately referred to an ophthalmologist for further evaluation (Braverman, 2011).

## Nursing Management

Children with urgent or emergent conditions must be referred to an ophthalmologist immediately to preserve vision. Urgent and emergent conditions include:

- Traumatic hyphema
- Blowout fracture
- Ruptured globe
- Thermal/chemical injury

- Extensive animal bite
- Lid laceration with underlying structural involvement
- Corneal abrasion in which corneal penetration is suspected
- Foreign body embedded in the globe (Augsburger & Corrêa, 2011; Braverman, 2011)

## Managing Nonemergent Eye Injuries

Nonemergent eye injuries usually need only simple management. Assist the physician or nurse practitioner with positioning and distraction of the child for eyelid laceration suturing. The child may require sedation or pain medication for this procedure.

To decrease edema in the child with a black eye (simple contusion), instruct the parent to apply an ice pack to the area for 20 minutes, then remove it for 20 minutes, and continue to repeat the cycle as often as possible during the first 24 hours. Tell the parents and child that bruising of the surrounding eye area may take up to 3 weeks to resolve.

The appearance of a scleral hemorrhage may be frightening. Instruct the parents and child about the benign nature of the hemorrhage and its natural history of resolution without intervention over a period of a few weeks.

If the child with a corneal abrasion has pain, analgesics may be helpful. Tell parents that most corneal abrasions heal on their own. If an antibiotic ointment is prescribed, instruct the parents how to administer the ointment appropriately.

**TABLE 39.2** ASSESSMENT OF EYE INJURIES

Description of Injury	Nursing Assessment
<b>Eyelid Injuries:</b> May occur as laceration to the eyelid	<ul style="list-style-type: none"> <li>Laceration is noted at any point along the lid</li> <li>Vision is unaffected</li> </ul>
<b>Simple Contusion (Black Eye):</b> Occurs as a result of blunt trauma to the eye area	<ul style="list-style-type: none"> <li>Bruising and edema of lids or area surrounding eye</li> <li>PERRLA</li> <li>Extraocular movements intact</li> <li>Visual acuity intact</li> <li>No diplopia or blurred vision</li> <li>Pain surrounding eye but not within the eye</li> </ul>
<b>Scleral Hemorrhage:</b> Caused by blunt trauma or increased pressure such as with coughing	<ul style="list-style-type: none"> <li>Painless</li> <li>Appears as erythema in the sclera; can be quite large initially</li> <li>Vision unaffected</li> </ul>
<b>Corneal Abrasion:</b> Results from foreign body such as sand, grit, or other small object scratching the cornea	<ul style="list-style-type: none"> <li>May have tearing</li> <li>Eye pain</li> <li>PERRLA</li> <li>Vision may be blurry</li> <li>Photophobia may be present</li> </ul>
<b>Foreign Body:</b> May be dirt, glass, or other small particle	<ul style="list-style-type: none"> <li>Tearing</li> <li>Complaint of “something in the eye”</li> <li>PERRLA</li> <li>Vision may be blurry</li> </ul>

Adapted from Augsburger, J., & Corrêa, Z. M. (2011). Ocular and orbital trauma. In P. Riordan-Eva & E. T. Cunningham (Eds.), *Vaughan & Asbury's general ophthalmology* (18th ed.). New York, NY: McGraw-Hill; and Braverman, R. S. (2011). Eye. In W. W. Hay, M. J. Levin, J. M. Sondheimer, & R. R. Deterding (Eds.), *Current pediatric diagnosis and treatment* (20th ed.). New York, NY: McGraw-Hill.

**Take Note!**

Patching of the eye with a corneal abrasion is no longer recommended, as children are often able to open the eye under the patch, which causes drying of the eye and further irritation, possibly contributing to prolonged recovery from the abrasion (Turner & Rabiou, 2007).

Foreign bodies may be removed from the eye by gently everting the eyelid and wiping the foreign body away with a sterile cotton-tipped applicator. Irrigation with normal saline may also wash the foreign body away.

For chemical injury, irrigate the eye with copious amounts of water. Consult ophthalmology for further evaluation and management.

**Take Note!**

Refer the child with a large foreign body in the eye or one that is embedded in the globe of the eye to the ophthalmologist for appropriate, safe removal.

Eye injuries can be prevented, and nurses play a vital role in educating the public about prevention of eye injuries and use of appropriate safety equipment. See Healthy People 2020 and Evidence-Based Practice 39.1.

**HEALTHY PEOPLE 2020****Objective**

Increase the use of personal protective eyewear in recreational activities and hazardous situations around the home among children and adolescents aged 6 to 17 years. Increase the proportion of public and private schools that require students to wear appropriate protective gear when engaged in school-sponsored physical activities.

*Healthy People* Objectives based on data from <http://www.healthypeople.gov>.

**Nursing Significance**

- Educate the family about appropriate use of eye protective equipment during sports, lawn care, chemical use, and other potentially hazardous activities.
- Encourage families to provide appropriate supervision of children (particularly young children) to reduce the risk of injury.
- Educate families to teach their children safe practices in and around the home (not running with scissors, etc.).

## EVIDENCE-BASED PRACTICE 39.1

## THE EFFECT OF PATCHING FOR CORNEAL ABRASION ON HEALING AND DECREASED PAIN

## STUDY

Acute otitis media occurs frequently in young children. Preventing recurrence of AOM would lessen suffering among children, decrease physician visits as well as missed work and school days, allow for less frequent antibiotic prescription and decrease the impact the contribution of AOM on hearing loss. The authors included quality randomized controlled trials in their review. A total of 1826 healthy children under 12 years of age attending day care and 1277 with respiratory infection were evaluated.

## Findings

Upon review, the authors noted that supplementation with Xylitol-containing gum was effective in preventing

Adapted from Azarpazhooh, A., Limeback, H., Lawrence, H. P., & Shah, P. S. (2011). Xylitol for preventing acute otitis media in children up to 12 years of age (review). *The Cochrane Library*. Retrieved July 4, 2012, from <http://onlinelibrary.wiley.com/doi/10.1002/14651858.CD007095.pub2/pdf/abstract>

acute otitis media in healthy children. The same finding was not demonstrated in children who already had an upper respiratory infection. The study was limited to one research group, so should be replicated elsewhere.

## Nursing Implications

AOM contributes significantly to childhood illness and U.S. healthcare costs. Xylitol containing gums may be recommended to parents as providing protection against acute otitis media. They have not been shown to have harmful side effects and have the added benefit of preventing dental caries.

## VISUAL DISORDERS

Adequate visual development requires appropriate sensory stimulation to both eyes over the first few years of life (Olitsky et al., 2011d). When one or both eyes are deprived of this stimulation, visual development does not progress appropriately, and visual impairment or **blindness** may result. This may occur when the eyes are not aligned properly, visual acuity between the eyes is disparate, or other problems with the eyes exist (Olitsky et al., 2011d). If vision disorders are diagnosed at an early age and treatment is begun, then vision may progress normally. However, when these disorders go untreated, the young child's developing vision may be reduced significantly. Therefore, it is important to appropriately screen children for these disorders.

Common visual disorders in childhood include refractive errors, astigmatism, strabismus, amblyopia, nystagmus, glaucoma, and cataracts.

## Refractive Errors

The most common cause of visual difficulties in children is refractive errors. When the light that enters the lens does not bend appropriately to allow it to fall directly on the retina, then a refractive error occurs. Young children naturally have hyperopia (farsightedness) because the depth of the eye globe is not fully developed until about 5 years of age (Braverman, 2011). These children may have blurriness at close range, but by school age this blurriness usually resolves.

When the light entering the eye focuses in front of the retina, it results in myopia (nearsightedness).

Children who are nearsighted may see well at close range but have difficulty focusing on the blackboard or other objects at a distance.

Therapeutic management for both hyperopia and myopia is prescription eyeglasses or contact lenses. Generally, a child 12 years of age can demonstrate the responsibility necessary to wear and care for contact lenses. Contact lenses may be used in younger children but are lost or damaged more readily. Because of the continuing refractive development in the child's vision through adolescence, laser surgery for vision correction is not recommended by the American Academy of Ophthalmology [AAO] until 21 years of age, though it may be done experimentally in some children (AAO, 2012).

## Nursing Assessment

Elicit the health history, noting blurred vision, complaints of eye fatigue with reading, or complaints of eye strain (headache, pulling sensation, or eye burning). Note complaints of difficulty concentrating on or maintaining a clear focus on objects up close, avoidance of up-close work, or poor work performance (hyperopia). Note the risk factor of family history of myopia. Observe for squinting when the child looks at objects at a distance. Observe the hyperopic child for the presence of esotropia. Readily observable physical findings are not noted in the myopic child. Test visual acuity using an age-appropriate screening tool (for more information related to visual acuity screening, refer to Chapter 32). Hyperopia is usually not identified with visual acuity screening alone; it usually requires a retinal examination by an ophthalmologist.

## Nursing Management

Nursing management of the child with a refractive error focuses on providing education about corrective lens use and monitoring for the need for new eyeglasses or contact lenses.

### Educating About Eyeglass Use

Children may or may not be compliant with wearing eyeglasses. Glasses may carry a stigma, and the child may be teased or bullied. However, many children enjoy the improved vision they achieve when wearing their eyeglasses and this can help them overcome the teasing they might suffer. Encourage the child with newly prescribed eyeglasses to wear them by having the parent spend “special time” with the child doing an activity that requires the glasses (such as reading or drawing). Teach the parent and child to remove eyeglasses with both hands and to lay them on their side (not directly on the lens on any surface). Instruct the child and family about cleaning the glasses daily with mild soap and water or a commercial cleansing agent provided by the optometrist. Use a soft cloth to clean the glasses, not paper towels, tissues, or toilet paper.

### Educating About Contact Lens Use

Teach the older child or adolescent how to care for the contact lenses properly, including lens hygiene and lens insertion and removal. Inform the child and parents that protective eyewear should be worn when the child is participating in contact sports. If the eye becomes inflamed, remove the contact lens and wear eyeglasses until the eye is improved. Consult with the child’s eye care provider to determine if medications prescribed for an eye problem can be used while the contact lens is in.

### Monitoring for Fit and Visual Correction

Encourage the family to complete visual assessments as scheduled. Since the child’s vision is continuing to develop and refraction is not stable, the corrective lens prescription may change more frequently than it does in an adult (AAO, 2011). As the young child in particular is continuing to grow at a rapid rate, the head size is also changing. Eyeglass frames may hurt or pinch the child as the child’s head becomes larger. Teach families to check the fit of the glasses monthly. Monitor for signs of ill fit, such as constant removal of the glasses in an older child or rubbing at the glasses or eyes in the very young child. Monitor for squinting, eye fatigue or strain, and complaints of headache or dizziness, which may indicate the need for a change in the lens prescription. See Healthy People 2020.

## HEALTHY PEOPLE 2020

### Objective

Increase the proportion of preschool children aged 5 years and under who receive vision screening.  
Increase the proportion of preschool children aged 5 years and younger who receive vision screening. Reduce uncorrected visual impairment due to uncorrected refractive errors. Reduce blindness and visual impairment in children and adolescents aged 17 years and younger.

### Nursing Significance

- Ensure that visual acuity testing begins with an age-appropriate screening tool by 3 years of age and continues yearly throughout childhood and adolescence.
- Refer for an eye evaluation any children with complaints of difficulty seeing the front of the classroom or complaints of eye strain or difficulty with close work.
- Screen infants and children for asymmetric corneal light reflex for early detection of amblyopia.

*Healthy People Objectives based on data from <http://www.healthypeople.gov>.*

## Astigmatism

In astigmatism the cornea’s curvature is uneven, which results in an irregular quality of vision because the light rays are refracted unevenly. Sometimes the lens is irregularly shaped, having the same result.

## Nursing Assessment

Explore the health history for symptoms of astigmatism. Children with astigmatism often have blurry vision and difficulty seeing letters as a whole, so their ability to read is affected. They may have headaches or dizziness. Older children may complain of eye fatigue or strain. Children with astigmatism often learn to tilt their heads slightly so that they can focus more effectively. This may lead to “normal” vision screenings, but the headache and dizziness still warrant further examination by an eye specialist (Braverman, 2011). The diagnosis of astigmatism requires not only a visual acuity test but also a refractive error evaluation by an optometrist or ophthalmologist.

## Nursing Management

Corrective lenses can help to, in effect, smooth out the curvature of the cornea, making the light ray refraction occur smoothly. As with refractive errors, encourage the

child who requires corrective lenses for astigmatism to wear the eyeglasses or contact lenses regularly.

## Strabismus

**Strabismus** refers to misalignment of the eyes. It is common and occurs in 4% of children up to 6 years old. (Olitsky et al., 2011a). The most common types of strabismus are exotropia and esotropia. In exotropia the eyes turn outward; in esotropia they turn inward. Because of this unequal alignment, visual development in each eye may proceed at different rates. Diplopia (double vision) may result, so vision in one eye may be “turned off” by the brain to avoid diplopia. Many infants have strabismus intermittently, but this usually resolves by 3 to 6 months of age. Intermittent strabismus that persists past 6 months of age or constant strabismus at any age warrants referral to an ophthalmologist for further evaluation (Burns, Dunn, Brady, Starr, & Blosser, 2009).

Therapeutic management of strabismus may include patching of the stronger eye or eye muscle surgery. Corrective lenses are also used for strabismus. Complications of strabismus include amblyopia and visual deficits.

## Nursing Assessment

Parents may be the first persons to notice that the child’s eyes do not face in the same direction. Question parents about the onset of the problem and whether it is continuous or intermittent. If intermittent, does it occur more often when the child is tired? Elicit the health history, noting complaints of blurred vision, tired eyes, squinting or closing one eye in bright sunlight, tilting the head to focus on an object, or a history of bumping into objects (depth perception may be limited).

Observe the child’s eyes for obvious exotropia or esotropia. In the absence of an obvious finding, assessment of the symmetry of the corneal light reflex is extremely helpful (Fig. 39.9). The “cover test” is also a useful tool for the identification of strabismus.

**FIGURE 39.9** Esotropia. Test for strabismus by observing symmetry of the corneal light reflex. The reflex falls to the left of one pupil and to the right of the other.

True strabismus should not be confused with pseudostrabismus. In pseudostrabismus, the eyes may appear slightly crossed (as in the child with a wide nasal bridge and epicanthal folds), but the corneal light reflex remains symmetric (Weber & Kelley, 2010).

## Nursing Management

It is extremely important to treat strabismus appropriately in the developing years so that equal visual acuity may be achieved in both eyes. When patching is prescribed, encourage the family to comply with this modality. Encourage eyeglass wearing if prescribed. Provide appropriate postoperative care by protecting the operative site with eye patching.

## Amblyopia

**Amblyopia** refers to poor visual development in the otherwise structurally normal eye. It develops within the first decade of life and, if left untreated, is the most common cause of vision loss in children and young adults (Yen, 2012). Amblyopia occurs in about 1% to 5.3% of children (Yen, 2012). The vision in one eye is reduced because the eye and the brain are not working together properly. While the eyes are fighting to focus differently because of their differences in visual acuity, one eye is stronger than the other. This is why amblyopia is often referred to as “lazy eye.”

Amblyopia may be caused by any disorder that affects normal visual development, including strabismus and differences in visual acuity or astigmatism between the two eyes. It may also result from eye trauma, ptosis, or cataract. If untreated, children with amblyopia will have worsening acuity of the poorer eye and strain in the better eye, which may also lead to worsening of acuity in that eye. Eventually blindness will result in one or both eyes.

Therapeutic management of amblyopia focuses on strengthening the weaker eye. This may be achieved through patching for several hours per day, using atropine drops in the better eye (once daily), vision therapy, or eye muscle surgery if the cause is strabismus.

## Nursing Assessment

One of the most important functions of the nurse is to identify on screening the preschool child with amblyopia. Begin visual acuity testing using an age-appropriate tool by 3 years of age. Observe for asymmetry of the corneal light reflex in the child of any age. This may be the only sign in the preverbal child.

## Nursing Management

It is very important for children with amblyopia to receive appropriate treatment during the early years of

visual development. Patching the better eye for several hours each day encourages the eye with poorer vision to be used appropriately and promotes visual development in that eye. The once-daily use of atropine drops in the better eye results in blurring in that eye, similarly encouraging use and development of the weaker eye (Olitsky, et al., 2011c). Support and encourage children and parents to comply with the patching protocol or atropine drop use.

Promoting eye safety is extremely important for the child with amblyopia; if the better eye suffers a serious injury, both eyes may become blind.

## Nystagmus

**Nystagmus** refers to a very rapid, irregular eye movement. It is described by some as “bouncing” of the eyes. It may occur in children with congenital cataracts, but the most common cause is a neurologic problem. It is difficult for the brain and eyes to communicate when the eyes are in continuous motion; thus, visual development may be affected. Children with nystagmus must receive further evaluation by an ophthalmologist and possibly a neurologist.

## Infantile Glaucoma

Infantile glaucoma is an autosomal recessive disorder that is more common in interrelated marriages or relationships. It is often associated with other genetic disorders. It occurs in about 1 of 10,000 live births (Lighthouse International, 2011). Infantile glaucoma is characterized by obstruction of aqueous humor flow and increased intraocular pressure that results in large, prominent eyes. Vision loss may occur as a result of corneal scarring, optic nerve damage, or, most commonly, amblyopia.

Unlike adult glaucoma, in which medical management is the first step, therapeutic management of infantile glaucoma is focused on surgical intervention. Infantile glaucoma is treated surgically via goniotomy (removal of obstruction of the aqueous humor). Laser surgery is being used as well. Sometimes several surgeries may be necessary to correct the problem. Ongoing medication therapy may also be required.

## Nursing Assessment

Note any family history of infantile glaucoma or other genetic disorders. Elicit the health history, noting history of the infant keeping the eyes closed most of the time or rubbing the eyes. Observe the eye for corneal enlargement and clouding; the eye may appear enlarged. Photophobia may occur, so bright light may bother the infant. Tearing or conjunctivitis and eyelid squeezing or spasm

may also occur. The pediatric ophthalmologist may use a tonometer to measure the intraocular pressure during the diagnostic phase.

## Nursing Management

The main goal of nursing care for the infant with glaucoma is postoperative care. Family education will also be important.

### *Providing Postoperative Care*

Postoperatively the eye will be patched and the child should be maintained on bed rest. Nursing care focuses on protection of the surgical site. Infants and toddlers may require elbow restraints to prevent them from rubbing the affected eye. These children may be quite anxious with one or both eyes patched, since their ability to see will be affected. Use a calm and soothing approach with these children, as well as distraction and developmentally appropriate play activities.

### *Educating the Family*

Instruct parents and children to avoid roughhousing for 1 week after surgery. Also avoid submersion of eyes underwater for 7–10 days (Pediatric Eye Specialists, 2012). Before the first surgery occurs, prepare parents for the possibility that three or four operations may be necessary. Teach families how to administer postoperative medications. Encourage parents to comply with ongoing recommended visual assessments.

## Congenital Cataract

A congenital cataract is an opacity of the lens of the eye that is present at birth. Sensory amblyopia will result if the infant goes untreated. Complications include visual developmental delay related to amblyopia. In children younger than 5 years of age, congenital cataract causes 16% of the cases of legal blindness (Lighthouse International, 2011). Bilateral cataracts may be associated with metabolic or genetic syndromes. Surgery to remove the opaque lens can be done as early as 2 weeks of age. The infant is then fitted with a contact lens. Intraocular lens implants are also being used (Lin & Buckley, 2010). The best visual outcomes occur when cataracts are removed prior to 3 months of age. Glaucoma may occur as a complication after cataract surgery.

## Nursing Assessment

Note history of lack of visual awareness. Observe the eyes for apparent cloudiness of the cornea (not always visible). Upon ophthalmoscopic examination, the red reflex will not be observed in the affected eye.

## Nursing Management

Postoperative care focuses on protecting the operative site and providing developmentally appropriate activities. Ensure that the protective eye patch is secure. Elbow restraints may be necessary in the older infant to prevent accidental injury to the operative site. Teach families how to administer antibiotic or corticosteroid ophthalmic drops if prescribed for postoperative use. Once the surgical site is healed, the “good” eye may be patched for several hours a day to promote visual development in the eye with the contact or intraocular lens. Regular visual assessments are critical for determining the adequacy of visual development after cataract removal. Instruct parents about the importance of using sunglasses that block ultraviolet rays in the child who has had a lens removed. See Healthy People 2020.

### HEALTHY PEOPLE 2020

Objective	Nursing Significance
Reduce visual impairment due to glaucoma.	<ul style="list-style-type: none"> <li>• Appropriately screen infants and children for glaucoma or cataract.</li> </ul>
Reduce visual impairment due to cataract.	<ul style="list-style-type: none"> <li>• Refer suspected cases to a pediatric ophthalmologist for further evaluation.</li> </ul>

*Healthy People* Objectives based on data from <http://www.healthypeople.gov>.

## Retinopathy of Prematurity

Retinopathy of prematurity (ROP) is a disorder characterized by rapid growth of retinal blood vessels in the premature infant. In the fetus, retinal vascularization begins at 4 months and progresses until completion at 9 months or shortly after birth. The premature infant is born with incomplete retinal vascularization, yet new vessels continue to grow between the vascularized and nonvascularized retina. Risk factors include low birthweight, early gestational age, sepsis, high light intensity, and hypothermia. Changes in oxygen tension resulting from hypoxia, oxyhemoglobin dissociation curve changes that occur when adult blood is transfused to the premature infant, and the duration/concentration of supplemental oxygen are thought to play an important role in the development of ROP.

Premature infants should have serial examinations by an ophthalmologist until the ROP has regressed and normal vascularization is seen. If ROP continues to progress, laser surgery may be necessary to prevent blindness. Complications of ROP include myopia, glaucoma, and blindness. Strabismus may occur even in

cases of regressed (resolved) ROP. Refractive errors and amblyopia may occur as early as 3 months corrected age. In the first year of life, ophthalmologic examinations should occur frequently so that if corrective lenses are needed, they may be prescribed at the earliest possible time. After 1 year corrected age, former premature infants should continue to have yearly ophthalmologic examinations to detect and treat visual deficits early (AAP, 2006).

## Nursing Assessment

Ensure that all former premature infants are routinely screened for visual deficits. Discuss developmental progress with the parents. Observe for the development of strabismus, manifested by an asymmetric corneal light reflex.

## Nursing Management

Nursing management of infants with ROP mainly focuses on ensuring that the family is compliant with the ophthalmologist’s follow-up recommendations. Recurrent illness or rehospitalization of premature infants may interfere with scheduled eye follow-up appointments. Ensure that these appointments are rescheduled and that the family understands the importance of them. Many children who have regressed ROP or who require cryotherapy have refractive errors, so even when the ROP is considered resolved, these children should still maintain appropriate ophthalmology follow-up.

## Visual Impairment

**Vision impairment** in children refers to acuity between 20/60 and 20/200 in the better eye on examination. “Legal blindness” is a term used to refer to vision of less than 20/200 or peripheral vision less than 20 degrees. In most cases, vision may be augmented with corrective lenses. Some blind children can differentiate light versus dark, while others live in total darkness.

Visual impairment in children may result from a number of different causes. In the United States, visual impairment and blindness are most often caused by refractive error, astigmatism, strabismus, amblyopia, nystagmus, infantile glaucoma, congenital cataract, retinopathy of prematurity, and retinoblastoma (Lighthouse International, 2011). Factors that increase the risk for developing visual impairment include prematurity, developmental delay, genetic syndrome, family history of eye disease, African American heritage, previous serious eye injury, diabetes, HIV, and chronic corticosteroid use. Trauma is also an important cause of blindness in children. Visual impairments are associated with many other syndromes.

For example, many children with genetic syndromes have visual impairments, and albinism is associated with blindness (Lighthouse International, 2011).

Children with visual impairments often exhibit motor and cognitive delays as well (Carter, 2012). With one less sense with which to experience their environment, these children may lag behind in developmental milestones.

### Take Note!

Laser pointers pose a risk of retinal damage in infants and young children. Damage occurs if the child stares at the red light for longer than 10 seconds. They should not be used as toys (U.S. Food and Drug Administration, 2010).

## Nursing Assessment

Nursing assessment for visual impairment includes a careful health history, physical examination, and visual acuity testing.

### Health History

Parents and nurses alike should be alert to signs of potential visual impairment. One of the most important functions of the nurse is to recognize signs of visual impairment as early as possible. These signs may include:

- At any age:
  - Dull, vacant stare
- Infants:
  - Do not “fix and follow”
  - Do not make eye contact
  - Unaffected by bright light
  - Do not imitate facial expression
- Toddlers and older children:
  - Rub, shut, and cover eyes
  - Squinting
  - Frequent blinking
  - Hold objects close or sit close to television
  - Bumping into objects
  - Head tilt or forward thrust

### Physical Examination

Assess for symmetry or asymmetry of the corneal light reflex. Perform the “cover test.” Use an age-appropriate visual acuity screening tool (refer to Chapter 32 for additional information on visual acuity screening).

## Nursing Management

Important nursing functions in relation to visual impairment and blindness are supporting the child and family and promoting socialization, development, and education.

### BOX 39.1

#### TIPS FOR INTERACTING WITH THE VISUALLY IMPAIRED CHILD

- Use the child’s name to gain attention.
- Identify yourself and let the child know you are there before you touch the child.
- Encourage the child to be independent while maintaining safety.
- Name and describe people/objects to make the child more aware of what is happening.
- Discuss upcoming activities with the child.
- Explain what other children or individuals are doing.
- Make directions simple and specific.
- Allow the child additional time to think about the response to a question or statement.
- Use touch and tone of voice appropriate to the situation.
- Use parts of the child’s body as reference points for the location of items.
- Encourage exploration of objects through touch.
- Describe unfamiliar environments and provide reference points.
- Use the sighted-guide technique when walking with a visually impaired child.

Adapted from Delta Gamma Center for Children with Visual Impairments. (2011). *Interacting with visually impaired*. Retrieved July 4, 2011, from <http://dgckids.org/resources/interacting-with-visually-impaired/>

In addition, when the child with a visual impairment is hospitalized for any reason, the nurse must plan appropriate care for that child, taking into consideration the child’s level of disability. Box 39.1 provides tips on working with the visually impaired child. It is important to teach these tips to families.

### Supporting the Child and Family

Provide emotional support to the family with a visually impaired child. Ensure that the child’s environment provides familiarity and security. Encourage activities that stimulate development; these activities will vary from child to child depending on whether the child also demonstrates impairment in other areas, such as hearing or motor skills. The blind infant will not provide the eye contact that parents are looking for, so educate the parents about other indicators that the infant is acknowledging the parents’ presence, such as:

- Increased motor activity
- Eyelid movement
- Changes in breathing pattern
- Making sounds

Encourage the family of a visually impaired child to display affection through touch and tone of voice. Refer

families to support networks and other resources for the blind and visually impaired. Several online resources for families of children who are visually impaired or blind can be found on [thePoint](#).

### Promoting Socialization, Development, and Education

Blind children, since they lack the visual stimulation that children usually receive, may develop self-stimulatory actions in compensation, often called blindisms. Examples of blindisms are eye pressing, rocking, spinning, bouncing, and head banging. These repetitive behaviors may indicate an effort to communicate or alternatively they may interfere with the child's ability to socialize (Hammer, 2011). Work with the parents to determine whether a strategy for the development of alternative behaviors specific to the individual child would be helpful.

Refer the blind or visually impaired child who is younger than 3 years of age to the local district of Early Intervention to establish case management services for the child's developmental needs. After age 3, state laws provide for public education and related services for children with disabilities. An individualized education plan (IEP) should be developed to maximize the child's learning ability. Nurses may be one of the professionals involved in the development of the IEP.

The severely visually impaired or blind child will need to learn to read Braille and will also need to learn to navigate the environment with the use of a cane or via another method.

## INFECTIOUS AND INFLAMMATORY DISORDERS OF THE EARS

Infectious and inflammatory disorders of the ears include several different types of otitis media. Otitis media is defined as inflammation of the middle ear with the presence of fluid. It can be subdivided into two categories: acute otitis media and otitis media with effusion. Acute otitis media (AOM) refers to an acute infectious process of the middle ear that may produce a rapid onset of ear pain and possibly fever. Otitis media with effusion (OME) refers to a collection of fluid in the middle ear space without signs and symptoms of infection. Chronic otitis media with effusion is defined as OME lasting longer than 3 months. Otitis externa refers to inflammation of the external ear canal.

### Acute Otitis Media

AOM is a common illness in children, resulting from infection (bacterial or viral) of fluid in the middle ear. Increased susceptibility in infants and young children may be partly explained by the short length and horizontal

positioning of the Eustachian tube, limited response to antigens, and lack of previous exposure to common pathogens (Yoon et al., 2011). AOM occurs mostly in the fall through spring, with the highest incidence in the winter. AOM often recurs in infants and young children when the fluid in the middle ear becomes reinfected. The most significant risk factors for otitis media are Eustachian tube dysfunction and susceptibility to recurrent upper respiratory infections.

## Pathophysiology

An upper respiratory infection frequently precedes AOM. Fluid and pathogens travel upward from the nasopharyngeal area, invading the middle ear space. Fluid behind the eardrum has difficulty draining back out toward the nasopharyngeal area because of the horizontal positioning of the Eustachian tube. A viral upper respiratory infection may cause AOM or may place the child at risk for bacterial invasion. Pathogens gain access to the Eustachian tube, where they proliferate and invade the mucosa. Fever and pain occur acutely. Increased pressure behind the tympanic membrane may result in perforation. This may result in decreased pain and yield drainage in the ear canal. Most perforations heal spontaneously and are completely benign.

AOM is most commonly caused by viral pathogens, *Streptococcus pneumoniae*, *Haemophilus influenzae*, and *Moraxella catarrhalis*. Viral causes of AOM resolve spontaneously.

After clearance of the infection, fluid remains in the middle ear space behind the tympanic membrane, sometimes for several months (otitis media with effusion). This may occur because of the positioning of the Eustachian tubes, resulting in difficulty in draining fluid back to the nasopharyngeal area. OME may also occur because of the high frequency of upper respiratory infections in infants and young children, which again result in back-up of fluid from the nasopharyngeal area.

The most common complications of AOM include:

- Hearing loss
- Expressive speech delay
- Tympanosclerosis (scarring of the tympanic membrane; usually has no effect on hearing)
- Tympanic membrane perforation (acute with resolution or chronic)
- Chronic suppurative otitis media (chronic drainage via perforation or **tympanostomy** tubes)
- Acute mastoiditis (infection of the mastoid process)
- Intracranial infections, including bacterial meningitis and abscesses

## Therapeutic Management

Viral causes of AOM usually resolve spontaneously, but bacterial causes may require treatment with an antibiotic. It is unreasonable to obtain a culture of middle ear

fluid with every episode of AOM to determine the specific cause. Scientific studies of fluid obtained via tympanostomy in children with AOM have been performed, and clinical decision making is based on this research. There is great concern in the health care community about the development of antibiotic resistance due to the overuse of antibiotics (Sheppard, 2008). For this reason, clinical practice guidelines have been developed for a number of disorders based on large quantities of research.

Certain diagnosis of AOM is based on rapid onset of symptoms, signs of fluid in the middle ear, and signs or symptoms of inflammation in the middle ear (complaint of ear pain or visible erythema of the tympanic membrane) (American Academy of Pediatrics & American Academy of Family Physicians [AAFP], 2004). The choice of antibiotic will depend on the timing, the child's age, and whether the episode is a first or subsequent infection. The current recommendations by the American Academy of Pediatrics and American Academy of Family Physicians allow for a period of observation or "watchful waiting" in certain children. This allows for natural resolution of AOM related to viral causes and decreases the overuse of antibiotics in the pediatric population (AAP & AAFP, 2004).

Recommendations for AOM treatment in previously healthy children are found in Table 39.3. Pain management is also an important component of AOM treatment, as is appropriate follow-up to ensure disease resolution.

## Nursing Assessment

Nursing assessment of the child with AOM consists of health history and physical examination.

### Health History

Elicit a description of the present illness and chief complaint. Note acute, abrupt onset of signs and symptoms. Common signs and symptoms reported during the health history might include:

- Fever (may be low grade or higher)
- Complaints of otalgia (ear pain)
- Fussiness or irritability
- Crying inconsolably, particularly when lying down
- Batting or tugging at the ears (may also occur with teething or OME, or may be a habit)
- Rolling the head from side to side
- Poor feeding or loss of appetite
- Lethargy
- Difficulty sleeping or awakening crying in the night
- Fluid draining from the ear

Determine the child's response to any treatments used thus far. Explore the child's current and past medical history for risk factors such as:

- Young age
- Day care attendance
- Previous history of AOM or OME
- Antecedent or concurrent upper respiratory infection
- Other risk factors (Box 39.2)

**TABLE 39.3** TREATMENT RECOMMENDATIONS FOR ACUTE OTITIS MEDIA

Age and Severity of Illness <sup>a</sup>	Certainty of Diagnosis	Treatment
Younger than 6 months old	Certain or possible	Antibiotics
6 months to 2 years	Certain	Antibiotics
6 months to 2 years with severe illness	Possible	Antibiotics
6 months to 2 years with nonsevere illness	Possible	May observe <sup>b</sup>
Older than 2 years with severe illness	Certain	Antibiotics
Older than 2 years with nonsevere illness	Certain	Observe <sup>b</sup>
Older than 2 years	Possible	Observe <sup>b</sup>

<sup>a</sup>Severe illness is defined as moderate to severe otalgia or fever 39°C or higher. Nonsevere illness is defined as mild otalgia and fever less than 39°C.

<sup>b</sup>Observation is appropriate only when follow-up can be ensured. If symptoms are persistent or become worse, antibiotics may then be started.

Adapted from American Academy of Pediatrics and American Academy of Family Physicians, Subcommittee on Management of Acute Otitis Media. (2004). Clinical practice guidelines: Diagnosis and management of acute otitis media. *Pediatrics*, 113, 1451–1465.

BOX 39.2

**RISK FACTORS FOR ACUTE OTITIS MEDIA**

- Eustachian tube dysfunction
- Recurrent upper respiratory infection
- First episode of acute otitis media (AOM) before 3 months of age
- Day care attendance (increases exposure to viruses causing upper respiratory infections)
- Previous episodes of AOM
- Family history
- Passive smoking
- Crowding in the home or large family size
- Native American, Inuit, or Australian aborigine ethnicity
- Absence of infant breastfeeding
- Immunocompromise
- Poor nutrition
- Craniofacial anomalies
- Presence of allergies (possibly)

Adapted from American Academy of Pediatrics and American Academy of Family Physicians. (2004). Clinical practice guidelines: Diagnosis and management of acute otitis media. *Pediatrics*, 113, 1451–1465; and Yoon, P. J., Kelley, P. E., & Friedman, N. R. (2011). Ear, nose, & throat. In W. W. Hay, M. J. Levin, J. M. Sondheimer, & R. R. Deterding (Eds.), *Current pediatric diagnosis and treatment* (20th ed.). New York, NY: McGraw-Hill.

**Physical Examination and Diagnostic Testing**

The child may complain of pain when the ear is examined. On otoscopic examination, the tympanic membrane will have a dull or opaque appearance and is bulging and/or red (Fig. 39.10). Sometimes pus (greenish or yellowish) may be visible behind the eardrum. Upon

pneumatic otoscopy, the eardrum will be immobile. (A physician or nurse practitioner usually performs the otoscopic examination.) If the tympanic membrane has become perforated, drainage may be present in the ear canal, but the canal will otherwise appear normal. Palpate for possible cervical lymphadenopathy. **Tympanometry** is not as useful in the diagnosis of AOM as it is with OME.

**Nursing Management**

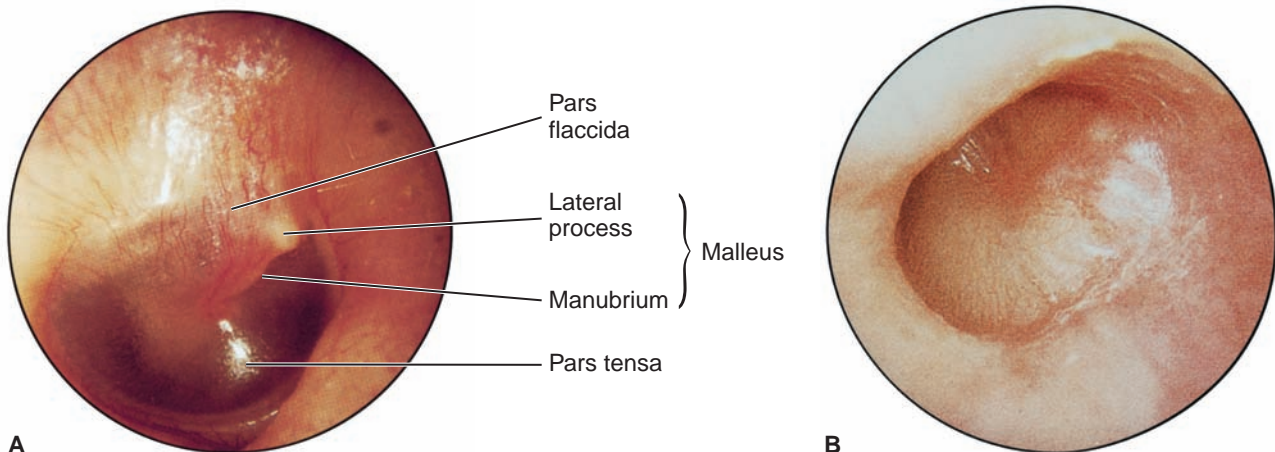

Nursing management of the child with acute otitis media is mainly supportive in nature. It focuses on pain management, family education, and prevention of AOM.

**Managing Pain Associated With Acute Otitis Media**

Analgesics such as acetaminophen and ibuprofen have been shown to be effective at managing mild to moderate pain associated with AOM. They have the added benefit of reducing fever. Narcotic analgesics such as codeine may be prescribed for severe pain. Application of heat or a cool compress may also be helpful. Instruct the family to have the child lie on the affected side with the heating pad or covered ice pack in place to that ear. Numbing eardrops such as benzocaine (Auralgan) may be helpful in the event of acute, severe pain. They should be used in conjunction with analgesics, though, because of the short duration of action (AAP & AAFP, 2004).

**Educating the Family**

If the treatment selected for AOM is observation or watchful waiting, explain the rationale for this to the family. Ensure that the family understands the importance of returning for reevaluation if the child is not improving or if the AOM progresses to severe illness.

**FIGURE 39.10** (A) Normal tympanic membrane. (B) Acute otitis media: note opacity of the tympanic membrane.

When antibiotics are prescribed, the family must understand the importance of completing the entire course of antibiotics. Families are tempted to stop giving the antibiotic because the child is usually vastly improved after taking the medication for 24 to 48 hours. Follow-up for resolution of AOM is necessary for all children and the physician or nurse practitioner will determine the timing of that follow-up. Emphasize the importance of follow-up to the parents, educating them about OME and its potential impact on hearing and speech. See Healthy People 2020.

### HEALTHY PEOPLE 2020

Objective	Nursing Significance
Decrease otitis media in children and adolescents.	<ul style="list-style-type: none"> <li>• Teach children and families the importance of hand washing to avoid the common cold (often a precursor to otitis media).</li> <li>• Teach families the importance of appropriate follow-up for eradication of otitis media.</li> <li>• Educate families about the importance of using antibiotics only for true bacterial infections (in order to decrease the development of resistant organisms, many of which cause otitis media).</li> </ul>

*Healthy People Objectives based on data from <http://www.healthypeople.gov>.*

### Preventing Acute Otitis Media

Breastfed infants have a lower incidence of AOM than formula-fed infants, and breast milk's immunologic benefits are well known (Yoon et al., 2011). Therefore, encourage mothers to breastfeed for at least 6 to 12 months. Instruct families to avoid excess exposure to individuals with upper respiratory infections to decrease the incidence of these infections in their child. Infants and children should not be exposed to second-hand smoke. Encourage parents to stop smoking. If quitting smoking is not possible, then instruct parents not to smoke inside the house or automobile. Encourage the parents to have the child immunized with Prevnar and the influenza vaccine.

Chewing gum that contains xylitol (sucrose substitute) may also be protective (Azarpazhooh, et al., 2011). Children who are old enough may chew xylitol-containing gum. Younger children and infants may be given xylitol syrup. Clinical studies are under way to validate the protective effects of xylitol. Care should be taken to avoid excessive dosing, as xylitol can cause diarrhea.

## Otitis Media With Effusion

Otitis media with effusion refers to the presence of fluid within the middle ear space, without signs or symptoms of infection. It may occur independent of AOM or may persist after the infectious process of AOM has resolved. Risk factors for OME include passive smoking, absence of breastfeeding, frequent viral upper respiratory infections, allergy, young age, male sex, adenoid hypertrophy, Eustachian tube dysfunction, and certain congenital disorders (Yoon et al., 2011). Complications of OME include AOM, hearing loss, and deafness.

### Nursing Assessment

Nursing assessment of the child with OME includes health history, physical examination, and diagnostic testing.

#### Health History

Determine the extent of symptoms. Children may be asymptomatic or may experience a popping sensation or fullness behind the eardrum. Explore the health history for risk factors such as passive smoking, absence of breastfeeding, frequent viral upper respiratory infections, allergy, or recent history of AOM.

#### Physical Examination

Otoscopic examination may reveal a dull, opaque tympanic membrane that may be white, gray, or bluish (Fig. 39.11). If the tympanic membrane is not opaque, a fluid level or air bubble may be visualized. Mobility may be absent or diminished upon pneumatic otoscopy. Tympanometry may be used to confirm the diagnosis of OME.

**FIGURE 39.11** Otitis media with effusion; note dull white tympanic membrane.

## Nursing Management

OME may take several months to resolve. Nursing management during the resolution phase focuses on education and monitoring for hearing loss.

### Educating the Family

Educate the family about the natural history of OME and the anatomic differences in young children that contribute to OME. Inform parents that antihistamines, decongestants, antibiotics, and corticosteroids have not been proven to hasten the resolution of OME and thus are not recommended. OME usually resolves spontaneously, but children should be rechecked every 4 weeks while this resolution is occurring. Teach parents not to feed infants in a supine position and to avoid bottle propping.

### Monitoring for Hearing Loss

When OME persists, the primary concern is its effect on hearing. In the infant or toddler who should be experiencing rapid language development, impaired hearing can depress language acquisition significantly (AAP, 2004). Children with OME who are at risk for speech, language, or learning problems may be referred for evaluation of hearing earlier than a child with OME who is not at risk (Box 39.3). Children with chronic OME (persistent OME of 3 months' duration or longer) should be referred to a specialist for hearing evaluation (AAP, 2004). Children who are not already at risk for speech concerns and are not experiencing difficulty with language acquisition may be reassessed every 3 to 6 months as long as hearing loss is not identified. At-risk children may require treatment earlier.

#### BOX 39.3

#### CHILDREN AT RISK FOR SPEECH, LANGUAGE, OR LEARNING DIFFICULTIES

- Permanent hearing loss (without otitis media with effusion)
- Speech/language delay (suspected or diagnosed)
- Craniofacial disorder that may interfere with speech
- Any pervasive developmental disorder
- Genetic disorders or syndromes associated with speech or learning problems
- Cleft palate
- Blindness or significant visual impairment

Adapted from American Academy of Pediatrics. (2004). Clinical practice guideline: Otitis media with effusion. *Pediatrics*, 113, 1412–1429.

To communicate more effectively with children with OME who have hearing loss:

- Turn off music or television.
- Position yourself within 3 feet of the child before speaking.
- Face the child while speaking.
- Use visual cues.
- Increase the volume of your speech only slightly.
- Speak clearly.
- Request preferential classroom seating.

#### Take Note!

Evaluation of hearing is recommended when OME lasts 3 months or more if language delay, hearing loss, or a learning problem is suspected (AAP, 2004).

### Providing Postoperative Care for the Child With Pressure-Equalizing Tubes

The standard treatment for persistent or problematic OME is surgical insertion of **pressure-equalizing (PE) tubes** into the tympanic membrane (via myringotomy). The tubes stay in place for at least several months and generally fall out on their own (Fig. 39.12). The procedure is usually done as an outpatient surgery and the child returns home in the evening. Teach the parents to administer ear drops postoperatively if prescribed. After PE tube placement, the surgeon may recommend avoiding water entry into the ears. If recommended, advise parents to have the child wear earplugs in the bathtub or while swimming.

Placement of the PE tubes allows for adequate hearing, which in turn encourages appropriate speech development. Placement of PE tubes does not prevent

FIGURE 39.12 Pressure-equalizing tubes in place in the tympanic membrane.

middle ear infection. If the middle ear becomes infected with PE tubes in place, the tubes allow infected fluid to drain from the ear. Tell parents to contact their physician or nurse practitioner if drainage from the ear is noted. After PE tubes are placed, young children often have rapid increases in language acquisition, and parents should observe for this (O'Reilly, 2011).

### Take Note!

Children with PE tubes who swim in a lake must wear earplugs, as lake water is contaminated with bacteria and entry of that water into the middle ear should be avoided (Cincinnati Children's, 2012).

## Otitis Externa

Otitis externa is defined as an infection and inflammation of the skin of the external ear canal. *Pseudomonas aeruginosa* and *Staphylococcus aureus* are typical causative agents, though fungi such as *Aspergillus* and other bacteria also may be implicated. Moisture in the canal contributes to pathogen growth (Yoon et al., 2011). Otitis externa is commonly known as “swimmer’s ear” since it occurs more frequently in those who swim often (and thus have wet ear canals). Changing the pH in the ear canal contributes to the inflammatory process.

## Nursing Assessment

Nursing assessment of the child with otitis externa focuses on the health history and physical examination.

### Health History

Elicit a description of the present illness and chief complaint. Note history of ear itching or pain, ear drainage, or a feeling of fullness in the ear canal, with possible difficulty hearing. Note onset and progression of symptoms, as well as the child’s response to treatments. Explore the child’s current and past medical history for risk factors such as previous episodes of otitis externa or history of recent swimming in a pool, lake, or ocean.

### Take Note!

The child with otitis externa usually has significant ear pain. Pressure on the tragus should be avoided, as it can worsen the pain.

### Physical Examination

Typically a white or colored discharge can be seen in the ear canal or running from the ear. On otoscopy, the canal is red and edematous, often too swollen for insertion of the speculum and viewing of the tympanic membrane (Fig. 39.13). Diagnosis is based on clinical findings.

FIGURE 39.13 Note edema and erythema of the ear canal as well as purulent discharge in the child with otitis externa.

Occasionally the ear drainage is cultured for bacteria or fungus, particularly if otitis externa is not improving with treatment.

## Nursing Management

The primary goals of nursing management are pain relief, treatment of the infection, and prevention of recurrence.

### Managing Pain

Analgesics (often narcotics) may be administered to manage the pain. A warm compress or heating pad to the affected ear is helpful in some children.

### Treating the Infection

Administer antibiotic or antifungal eardrops as prescribed. In some cases a wick is placed in the ear canal. The wick keeps the antibiotic drops in contact with the skin of the ear canal and promotes healing. Wick insertion can be extremely painful, and younger children will need to be restrained during insertion for their safety.

### Preventing Reinfection

Teach children and their parents about prevention of further episodes once the infection has resolved. Since moisture contributes to otitis externa, explain the importance of keeping the ear canals dry. Encourage the child and parents to use one of the methods described in Teaching Guidelines 39.2 after swimming or showering.

## HEARING LOSS AND DEAFNESS

Infants are ordinarily born with the sense of hearing fully developed. Language development in infancy and early childhood is dependent upon adequate hearing, and

## Teaching Guidelines 39.2

### PREVENTING OTITIS EXTERNA

1. Avoid the use of cotton swabs, headphones, and earphones.
2. Wear earplugs when swimming.
3. Promote ear canal dryness and alternate pH. Use one or more of the following methods:
  - Dry the ear canals using a hair dryer set on a lower setting.
  - Administer solutions that have a drying effect on the auditory canal skin and change the pH of the canal to discourage organism growth in susceptible children. The following solutions can be used:
    - A few drops of Domeboro solution can be placed in the canal, and then allowed to run out.
    - A mixture of half rubbing alcohol and half vinegar (squirted into the canal and then allowed to run out). The alcohol solution should be used only when the ear canals are healthy. Using it while the canals are inflamed will cause stinging and increased pain.

Adapted from Cook, S. P. (2009). *Swimmer's ear*. Retrieved April 4, 2011, from [http://kidshealth.org/parent/infections/ear/swimmer\\_ear.html](http://kidshealth.org/parent/infections/ear/swimmer_ear.html)

even the fluctuating hearing loss associated with intermittent bouts of AOM can hinder language development (AAP, 2004). Hearing loss may be unilateral (involving one ear) or bilateral (involving both ears). The extent of hearing loss is defined based on the softest intensity of sound that is perceived, described in **decibels** (dB). Levels of hearing loss are:

- 0 to 20 dB: normal
- 20 to 40 dB: mild loss
- 40 to 60 dB: moderate loss
- 60 to 80 dB: severe loss
- Greater than 80 dB: profound loss (American Speech-Language-Hearing Association [ASHA], 2012c)

Hearing loss may be congenital or acquired. Congenital hearing loss affects 1 to 6 infants per 1,000 live births in the United States (ASHA, 2012b). Congenital hearing loss accounts for about one half of all the cases of hearing impairment; the remainder are acquired. Premature infants and those with persistent pulmonary hypertension of the newborn are at increased risk for hearing loss compared with other infants. Hearing loss commonly occurs with a large number of congenital or genetic syndromes, as well as in association with anomalies of the head and face. A variety of newborn universal hearing screening mandates have been passed by legislation in 43 states, thus allowing for earlier identification of infants with congenital hearing loss (NCHAM, 2011). See Healthy People 2020.

## HEALTHY PEOPLE 2020

### Objective

Increase the proportion of newborns who are screened for hearing loss no later than age 1 month, have an audiologic evaluation by age 3 months, and are enrolled in appropriate intervention services no later than age 6 months.

*Healthy People* Objectives based on data from <http://www.healthypeople.gov>.

### Nursing Significance

- Encourage appropriate hearing assessments.
- Refer children who are diagnosed with a hearing deficit to local services for the deaf or hearing impaired.

Delayed-onset (acquired) hearing loss may be conductive, sensorineural, or mixed. **Conductive hearing loss** results when transmission of sound through the middle ear is disrupted, as in the case of OME. When fluid fills the middle ear, the tympanic membrane is unable to move properly, and partial or complete hearing loss occurs. **Sensorineural hearing loss** is caused by damage to the hair cells in the cochlea or along the auditory pathway. This may result from kernicterus, use of ototoxic medication, intrauterine infection with cytomegalovirus or rubella, neonatal or postnatal infection such as meningitis, severe neonatal respiratory depression, or exposure to excess noise. Mixed hearing loss occurs when the cause may be attributed to both conductive and sensorineural problems. See Healthy People 2020.

## HEALTHY PEOPLE 2020

### Objective

Increase the use of hearing protection devices. Reduce the proportion of adolescents who have elevated hearing thresholds, or audiometric notches, in high frequencies (3, 4, or 6 kHz) in both ears, signifying noise-induced hearing loss.

*Healthy People* Objectives based on data from <http://www.healthypeople.gov>.

### Nursing Significance

- Educate children and families about the dangers of excess noise and its potential for damaging hearing.
- Encourage appropriate use of ear protection devices.

Regardless of the cause of hearing loss, early intervention can make a difference in the child's ability to communicate.

Once the hearing loss has been determined, intervention can begin. Hearing aids, cochlear implants, communication devices, and speech education may enable these children to communicate verbally. Improved communication beginning in infancy and early childhood may also improve the child's school achievement.

### Take Note!

Earplugs or covers used to block ambient noise in premature infants in the neonatal intensive care unit may decrease the preemie's risk for hearing loss and improve development outcomes (Turk, Williams, & Lasky, 2009).

## Nursing Assessment

Nursing assessment of the child with hearing loss or impairment focuses on the health history, physical examination, and diagnostic hearing testing.

### Health History

Common signs and symptoms reported during the health history might include:

- Infant:
  - Wakes only to touch, not environmental noises
  - Does not startle to loud noises
  - Does not turn to sound by 4 months of age
  - Does not babble at 6 months of age
  - Does not progress with speech development
- Young child:
  - Does not speak by 2 years of age
  - Communicates needs through gestures
  - Does not speak distinctly, as appropriate for his or her age
  - Displays developmental (cognitive) delays
  - Prefers solitary play
  - Displays immature emotional behavior
  - Does not respond to ringing of the telephone or doorbell
  - Focuses on facial expressions when communicating
- Older child:
  - Often asks for statements to be repeated
  - Is inattentive or daydreams
  - Performs poorly at school
  - Displays monotone or other abnormal speech
  - Gives inappropriate answers to questions except when able to view face of speaker
- At any age:
  - Speaks loudly
  - Sits very close to the TV or radio or turns volume up too loud
  - Responds only to moderate or loud voices

Investigate signs of hearing loss as early as possible in order for appropriate intervention to begin.

Explore the child's current and past medical history for risk factors such as congenital anomalies, genetic

syndrome, infection, family history, kernicterus, neonatal ventilator use, ototoxic medication, or exposure to excess noise. Note whether newborn hearing screening was done and, if so, what the results were.

### Physical Examination and Laboratory and Diagnostic Tests

Determine the child's level of interaction with the environment. For preschoolers and older children, administer the whisper test, keeping in mind that this is a gross screening test only. Perform the Weber and Rinne tests (refer to Chapter 32 for further explanation). If further evaluation is needed, the nurse may be responsible for administering an otoacoustic emissions test or auditory brain stem evoked response test, either in the hospital or outpatient office.

## Nursing Management

The primary goal of nursing care for the child with a hearing impairment is to provide education and support to the family and child. Individualize care for the child with a hearing impairment and the family based on their specific responses to the hearing impairment.

### Augmenting Hearing

Compliance with hearing aids and communication curriculums is critical so that the child can develop hearing and speech. Teach the child and family that hearing aids should be cleaned daily with a damp cloth. In addition, it is important to change batteries weekly. When inserting the aid, the volume should be turned down, then adjusted to the appropriate level after insertion. As the infant or child grows, the hearing aid will need to be reassessed for proper fit. Many deaf schools and other organizations provide loaner hearing aids so that the best fit and amplification may be determined prior to purchase. Assist the family to explore this type of option in the local community. See Healthy People 2020.

### HEALTHY PEOPLE 2020

#### Objective

Increase the proportion of persons with hearing impairments who have ever used a hearing aid or assistive listening devices or who have cochlear implants.

#### Nursing Significance

- Know resources available in the local area for the deaf and hearing impaired.
- Refer children with hearing deficits to these resources and to service providers for augmentative devices.

*Healthy People* Objectives based on data from <http://www.healthypeople.gov>.

**TABLE 39.4** COMPARING COMMUNICATION OPTIONS FOR THE HEARING IMPAIRED

<b>Spoken Language</b>	
Oral deaf education (auditory-verbal therapy)	Uses technology to boost auditory potential; teaches children to notice sound and give it meaning. Develops oral speech
Cued speech	A system using hand signs to clarify lip-reading; gives the person clues about the sounds the speaker is making
<b>Signed Language</b>	
American Sign Language (ASL)	Entirely communicated through hand signs, gestures, and facial expressions. Has its own grammar and syntax
Combination: Total Communication	Combines auditory training and teaching of spoken language with SEE (“signing exact English”; corresponds to the words and syntax of English)
<b>Augmentative and Alternative Communication (AAC)</b>	
May use gestural communication	Can also include physical devices such as notebooks, communication boards, charts, or computers. Ranges from very low tech to technologically complex
Adapted from American Speech-Language-Hearing Association. (2012). <i>Augmentative and alternative communication (AAC)</i> . Retrieved July 4, 2012, from <a href="http://www.asha.org/public/speech/disorders/AAC.htm">http://www.asha.org/public/speech/disorders/AAC.htm</a>	

When cochlear implants are used, the nurse focuses on postoperative care of the incision site and pain management.

### Promoting Communication and Education

Families and children need to learn how to communicate effectively with one another. If the child learns American Sign Language, for instance, the parents and siblings should as well. Table 39.4 provides information on communication options for hearing-impaired children and their families. Communication may also be enhanced by the use of text telephone service in the home and closed-caption television. Bells and alarms in the home may use lights rather than sound to alert the child. Provide a sign language interpreter for the child at health care visits if the parent is not present for interpretation.

### Encouraging Education

Refer the child younger than 3 years of age to the local district of Early Intervention for case management of developmental needs. At 3 years of age and beyond, state laws provide for public education and related services for children with disabilities. An IEP should be developed to maximize the child’s learning ability. Nurses may be involved in the development of the IEP.

Some children attend schools specifically geared toward deaf students. The choice of school will depend on the family’s preferences and resources.

### Providing Support

The diagnosis of a significant disability can be extremely stressful for the family. Encourage families to express their feelings and provide emotional support. Ensure that the needs of any siblings are also attended to. When the family is ready, encourage them to network with other families who have children with similar needs. Educate the family about the child’s prescribed plan of care. Refer families to resources and support groups. Several helpful resources are listed on [thePoint](#).

#### KEY CONCEPTS

- Though hearing is fully developed at birth, visual development continues to progress until about age 7 years.
- Binocular vision develops by age 4 months; visual acuity progresses to 20/50 by age 3 years and usually reaches 20/20 by age 7 years.
- The relatively short and horizontally positioned Eustachian tubes of infants and young children make them more susceptible to otitis media than adults.

- To maximize speech and language development, hearing loss should be identified early and intervention begun immediately.
- Children with genetic syndromes or family history are at increased risk of visual and hearing impairments.
- The corneal light reflex test and cover test are useful tools for identifying strabismus and amblyopia.
- Tympanometry is used to determine the presence of fluid behind the eardrum (such as with otitis media with effusion).
- Topical ophthalmic medications are used to treat certain infectious eye disorders.
- Appropriate hand washing is the single most important factor to reduce the spread of acute viral or bacterial conjunctivitis.
- Systemic antibiotics are used for the treatment of periorbital cellulitis.
- Strabismus, glaucoma, and cataracts may all lead to visual impairment if left untreated.
- Asymmetry of the corneal light reflex occurs with true strabismus.
- Amblyopia must be identified early and treated with patching, corrective lenses, or surgery to prevent visual deterioration and promote appropriate vision development.
- A cloudy cornea indicates the presence of cataract.
- Very premature infants are at high risk of developing visual deficits related to retinopathy of prematurity and are also at increased risk of hearing impairment compared to other infants.
- Eye strain, eye rubbing, and headaches may indicate a visual deficit.
- Children with visual disorders should be encouraged to use prescribed corrective lenses.
- Recurrent episodes of acute otitis media may negatively affect the child's hearing.
- Recurrent or constant nasal congestion contributes to otitis media with effusion.
- Otitis externa can be prevented by keeping the ear canal dry and altering canal pH.
- The fluctuating hearing loss associated with recurrent otitis media and the hearing loss associated with chronic otitis media with effusion can both significantly hinder language development in the infant and toddler.
- The child with hearing loss should receive early intervention with hearing aids or other augmentative devices.

## MULTIPLE CHOICE QUESTIONS

- Which situation would cause the nurse to become concerned about possible hearing loss?
  - A 12-month-old who babbles incessantly, making no sense.
  - An 8-month-old who says only “da”.
  - A 3-month-old who startles easily to sound.
  - A 3-year-old who drops the letter “s”.
- A 4-year-old complains of extreme pain when the tragus is touched. Though not diagnostic, this sign is most indicative of which disorder?
  - Acute otitis media.
  - Acute tympanic effusion.
  - Otitis interna.
  - Otitis externa.
- The nurse is caring for an infant who has undergone surgery for infantile glaucoma. What is the priority nursing intervention?
  - Place the child prone postoperatively for comfort.
  - Teach the family use of the contact lens.
  - Place elbow restraints on the infant.
  - Provide a mobile for optical stimulation.
- A 2-year-old has been prescribed eye patching for strabismus 6 hours per day. What teaching does the nurse provide for the mother?
  - Try to patch 6 hours per day, but if you miss some it is OK.
  - Patching is necessary to strengthen vision in the weaker eye.

- Patching will keep the eye from turning in.
- Since the child is so young, patching can be delayed until school age.

## CRITICAL THINKING EXERCISES

- A 16-month-old toddler is being seen for his sixth ear infection. What particular information about his growth and development must the nurse ask about? Be specific about the questions you would ask.
- How would you distinguish allergic conjunctivitis from acute bacterial conjunctivitis?
- A 13-month-old has been diagnosed with severe visual impairment. Develop a list of sample nursing diagnoses for this situation.

## STUDY ACTIVITIES

- Develop a sample plan for teaching a low-literacy parent about the etiology, treatment, and complications of recurrent acute otitis media.
- While in the pediatric clinical setting, compare the play styles of a sighted child with those of a visually impaired child.
- Research hearing and vision resources in your local community.

# Nursing Care of the Child With a Respiratory Disorder

## Learning Objectives

*Upon completion of the chapter, you will be able to:*

1. Define the key terms used in this chapter.
2. Distinguish differences between the anatomy and physiology of the respiratory system in children versus adults.
3. Identify various factors associated with respiratory illness in infants and children.
4. Discuss common laboratory and other diagnostic tests useful in the diagnosis of respiratory conditions.
5. Describe nursing care related to common medications and other treatments used for management and palliation of respiratory conditions.
6. Recognize risk factors associated with various respiratory disorders.
7. Distinguish different respiratory disorders based on their signs and symptoms.
8. Discuss nursing interventions commonly used for respiratory illnesses.
9. Devise an individualized nursing care plan for the child with a respiratory disorder.
10. Develop child/family teaching plans for the child with a respiratory disorder.
11. Describe the psychosocial impact of chronic respiratory disorders on children.

*Alexander Roberts, 4 months old, is brought to the clinic by his mother. He has a cold and has been coughing a great deal for 2 days. Today he has had difficulty taking his bottle and is breathing very quickly. Mrs. Roberts says he seems tired.*

### Words of Wisdom

Restoring a full breath allows a child to participate fully in life's adventures.

**Respiratory** disorders are the most common causes of illness and hospitalization in children. These illnesses range from mild, nonacute disorders (such as the common cold or sore throat) to serious life-threatening conditions (such as epiglottitis). Chronic disorders, such as allergic rhinitis or asthma, can affect quality of life, but frequent acute or recurrent infections also can interfere significantly with the well-being of some children.

Respiratory infections account for the majority of acute illnesses in children (Brady, 2009). The child's age, socioeconomic status, and general health status can influence both the development of respiratory disorders and the course of the illness. For example, low-income children have a higher risk for increased severity or increased frequency of respiratory disease (Quinn, Kaufman, Siddiqi, & Yeats, 2010). Infants and younger children are more likely to deteriorate quickly from a respiratory illness, and children with chronic disorders such as diabetes, congenital heart disease, sickle cell anemia, cystic fibrosis, and cerebral palsy tend to be more severely affected with respiratory disorders.

In addition, the season of the year can influence the development of respiratory disorders and the course of the illness. For example, certain viruses are more prevalent in the winter, whereas allergen-related respiratory diseases are more prevalent in the spring and fall.

Parents may have difficulty determining the severity of their child's condition and might either seek care very early in the course of the illness (when it is still very mild) or wait, presenting to the health care setting when the child is very ill. Nurses must be familiar with respiratory conditions affecting children so that they can provide guidance and support to families. Difficulty with breathing can be very frightening for both the child and parents. Nurses must be able to ask questions that can help establish the severity of the child's illness and determine whether the family should seek care at a health care facility.

Since respiratory illnesses account for the majority of pediatric admissions to general hospitals, nurses caring for children need to have expert assessment and intervention skills in this area. Detection of worsening respiratory status early in the course of deterioration allows for timely treatment and the chance to prevent a minor problem from becoming a critical illness. Nurses are also in a unique position to provide education about respiratory illnesses and to promote efforts to prevent these illnesses.

## VARIATIONS IN PEDIATRIC ANATOMY AND PHYSIOLOGY

Respiratory conditions often affect both the upper and lower respiratory tract, though some affect primarily one or the other. Respiratory dysfunction in children tends to be more severe than in adults, and several differences in the infant's or child's respiratory system account for this increased severity.

## Nose

Newborns are obligatory nose breathers until at least 4 weeks of age. The young infant cannot automatically open his or her mouth to breathe if the nose is obstructed. The nares must be patent for breathing to be successful while feeding. Newborns breathe through their mouths only while crying.

The upper respiratory mucus serves as a cleansing agent, yet newborns produce very little mucus, making them more susceptible to infection. However, the newborn and young infant may have very small nasal passages, so when excess mucus is present, airway obstruction is more likely.

Infants are born with maxillary and ethmoid sinuses present. The frontal sinuses (most often associated with sinus infection) and the sphenoid sinuses develop by age 6 to 8 years. Therefore, younger children are less apt to acquire sinus infections compared to adults.

## Throat

The tongue of the infant relative to the oropharynx is larger than in adults. Posterior displacement of the tongue can quickly lead to severe airway obstruction. Through early school age, children tend to have enlarged tonsillar and adenoidal tissue even in the absence of illness. This can contribute to an increased incidence of airway obstruction.

## Trachea

The airway lumen is smaller in infants and children than in adults. The infant's trachea is approximately 4 mm wide compared with the adult width of 20 mm. When edema, mucus, or bronchospasm is present, the capacity for air passage is greatly diminished. A small reduction in the diameter of a child's airway (resulting from the presence of edema or mucus) will result in an exponential increase in resistance to airflow (Fig. 40.1). Increased **work of breathing** (effort or labor associated with respiration) then occurs.

In teenagers and adults the larynx is cylindrical and fairly uniform in width. In infants and children younger than 10 years old, the cricoid cartilage is underdeveloped, resulting in laryngeal narrowing (Chameides et al., 2011). Thus, in infants and children, the larynx is funnel shaped. Additionally, the larynx and glottis are located higher in the neck, increasing the chance of aspiration of foreign material into the lower airways. Congenital laryngomalacia occurs in some infants and results in the laryngeal structure being weaker than normal, yielding greater collapse on inspiration. Box 40.1 discusses congenital laryngomalacia.

The child's airway is highly compliant, making it quite susceptible to dynamic collapse in the presence of airway obstruction (Chameides et al., 2011). The muscles supporting the airway are less functional than those in the adult. Children have a large amount of soft tissue surrounding the trachea, and the mucous membranes lining the airway

**FIGURE 40.1 (A)** Note the smaller diameter of the child's airway under normal circumstances. **(B)** With 1 mm of edema present, note the exponential decrease in airway lumen diameter as compared with the adult.

are less securely attached as compared with adults. This increases the risk for airway edema and obstruction. Upper airway obstruction resulting from a foreign body, croup, or epiglottitis can result in tracheal collapse during inspiration.

## Lower Respiratory Structures

The bifurcation of the trachea occurs at the level of the third thoracic vertebra in children, compared to the level of the sixth thoracic vertebra in adults. This anatomic difference is important when suctioning children and when endotracheal intubation is required (see Chapter 53 for further discussion) (Chameides et al., 2011). This difference in

placement also contributes to risk for foreign material aspiration. The bronchi and bronchioles of infants and children are narrower in diameter than the adult's, placing them at increased risk for lower airway obstruction (see Fig. 40.1). Lower airway obstruction during exhalation often results from bronchiolitis or asthma or is caused by foreign body aspiration into the lower airway.

Alveoli develop at approximately 24 weeks' gestation. Term infants are born with about 50 million alveoli. After birth, alveolar growth slows until 3 months of age and then progresses until the child reaches 7 or 8 years of age, at which time the alveoli reach the adult number of around 300 million. Alveoli make up most of the lung tissue and are the major sites for gas exchange. Oxygen moves from the alveolar air to the blood, while carbon dioxide moves from the blood into the alveolar air. Smaller numbers of alveoli, particularly in the premature and/or young infant, place the child at a higher risk of **hypoxemia** (deficiency in the concentration of oxygen in arterial blood) and carbon dioxide retention.

## Chest Wall

In older children and adults, the ribs and sternum support the lungs and help keep them well expanded. The movement of the diaphragm and intercostal muscles alters volume and pressure within the chest cavity, resulting in air movement into the lungs. Infants' chest walls are highly compliant (pliable) and fail to support the lungs adequately. Functional residual capacity can be greatly reduced if respiratory effort is diminished. This lack of lung support also makes the tidal volume of infants and toddlers almost completely dependent upon movement of the diaphragm. If diaphragm movement is impaired (as in states of hyperinflation, such as asthma), the intercostal muscles cannot lift the chest wall and respiration is further compromised.

### BOX 40.1

#### CONGENITAL LARYNGOMALACIA

- Inspiratory stridor is present and is intensified with certain positions.
- Suprasternal retractions may be present, but the infant exhibits no other signs of respiratory distress.
- Congenital laryngomalacia is generally a benign condition that improves as the cartilage in the larynx matures. It usually disappears by age 1 year.
- The crowing noise heard with breathing can make parents very anxious. Reassure parents that the condition will improve with time.
- Parents become very familiar with the "normal" sound their infant makes and are often able to identify intensification or change in the stridor. Airway obstruction may occur earlier in infants with this condition, so intensification of stridor or symptoms of respiratory illness should be evaluated early by the physician or nurse practitioner.

## Metabolic Rate and Oxygen Need

Children have a significantly higher metabolic rate than adults. Their resting respiratory rates are faster and their demand for oxygen is higher. Adult oxygen consumption is 3 to 4 liters per minute, while infants consume 6 to 8 liters per minute. In any situation of respiratory distress, infants and children will develop hypoxemia more rapidly than adults (Chameides et al., 2011). This may be attributed not only to the child's increased oxygen requirement but also to the effect that certain conditions have on the oxyhemoglobin dissociation curve.

Normal oxygen transport relies on binding of oxygen to hemoglobin in areas of high partial pressure of oxygen ( $pO_2$ ) (pulmonary arterial beds) and release of oxygen from hemoglobin when the  $pO_2$  is low (peripheral tissues). Normally, a  $pO_2$  of 95 mm Hg results in an oxygen saturation of 97%. A decrease in oxygen saturation results in a disproportionate (much larger) decrease

FIGURE 40.2 Normal hemoglobin dissociation curve (green), shift to the right (red), and shift to the left (blue).

in  $pO_2$  (Fig. 40.2). Thus, a small decrease in oxygen saturation reflects a larger decrease in  $pO_2$ . Conditions such as alkalosis, hypothermia, hypocarbia, anemia, and fetal hemoglobin cause oxygen to become more tightly bound to hemoglobin, resulting in the curve shifting to the left. Common pediatric conditions such as acidosis, hyperthermia, and hypercarbia cause hemoglobin to decrease its affinity for oxygen, further shifting the curve to the right.

## COMMON MEDICAL TREATMENTS

A variety of interventions are used to treat respiratory illness in children. The treatments listed in Common Medical Treatments 40.1 and Drug Guide 40.1 usually require a physician's order when a child is hospitalized.

### COMMON MEDICAL TREATMENTS 40.1

Treatment	Explanation	Indications	Nursing Implications
Oxygen	Supplemented via mask, nasal cannula, hood, or tent or via endotracheal or nasotracheal tube	Hypoxemia, respiratory distress	Monitor response via work of breathing and pulse oximetry.
High humidity	Addition of moisture to inspired air	Common cold, croup, tonsillectomy	Infant may require extra blankets with cool mist, and frequent changes of bedclothes under oxygen hood or tent as they become damp.
Suctioning	Removal of secretions via bulb syringe or suction catheter	Excessive airway secretions (common cold, flu, bronchiolitis, pertussis)	Should be done carefully and only as far as recommended for age or tracheostomy tube size, or until cough or gag occurs.
Chest physiotherapy (CPT) and postural drainage	Promotes mucus clearance by mobilizing secretions with the assistance of percussion or vibration accompanied by postural drainage	Bronchiolitis, pneumonia, cystic fibrosis, or other conditions resulting in increased mucus production. Not effective in inflammatory conditions without increased mucus	May be performed by respiratory therapist in some institutions, by nurses in others. In either case, nurses must be familiar with the technique and able to educate families on its use.
Saline gargles	Relieves throat pain via salt water gargle	Pharyngitis, tonsillitis	Recommended for children old enough to understand the concept of gargling (to avoid choking).
Saline lavage	Normal saline introduced into the airway, followed by suctioning	Common cold, flu, bronchiolitis, any condition resulting in increased mucus production in the upper airway	Very helpful for loosening thick mucus; child may need to be in semi-upright position to avoid aspiration.
Chest tube	Insertion of a drainage tube into the pleural cavity to facilitate removal of air or fluid and allow full lung expansion	Pneumothorax, empyema	Should tube become dislodged from container, the chest tube must be clamped immediately to avoid further air entry into the chest cavity.
Bronchoscopy	Introduction of a bronchoscope into the bronchial tree for diagnostic purposes. Also allows for bronchiolar lavage.	Removal of foreign body, cleansing of bronchial tree	Watch for postprocedure airway swelling, complaints of sore throat.

## DRUG GUIDE 40.1 COMMON DRUGS FOR RESPIRATORY DISORDERS

Medication	Actions/Indications	Nursing Implications
Expectorant (guaifenesin)	Reduces viscosity of thickened secretions by increasing respiratory tract fluid Used for the common cold, pneumonia, and other conditions requiring mobilization and subsequent expectoration of mucus	Encourage deep breathing before coughing in order to mobilize secretions Maintain adequate fluid intake Assess breath sounds frequently
Cough suppressants (dextromethorphan, codeine, hydrocodone)	Relieve irritating, nonproductive cough by direct effect on the cough center in the medulla, which suppresses the cough reflex Used for the common cold, sinusitis, pneumonia, bronchitis	Should be used only with nonproductive coughs in the absence of wheezing
Antihistamines	Treatment of allergic conditions such as allergic rhinitis, asthma	May cause drowsiness or dry mouth
Antibiotics (oral, parenteral)	Treatment of bacterial infections of the respiratory tract such as pharyngitis, tonsillitis, sinusitis, bacterial pneumonia, cystic fibrosis, empyema, abscess, tuberculosis	Check for antibiotic allergies. Should be given as prescribed for the length of time prescribed
Antibiotics (inhaled)	Treatment of bacterial infections of the respiratory tract in children with cystic fibrosis	Can be given via nebulizer
$\beta_2$ -Adrenergic agonists (short acting) (i.e., albuterol, levalbuterol)	Relax airway smooth muscle, resulting in bronchodilation Used for acute and chronic treatment of wheezing and bronchospasm in asthma, bronchiolitis, cystic fibrosis, chronic lung disease. Also used to prevent wheezing in exercise-induced asthma	May be administered orally or via inhalation Can be used for acute relief of bronchospasm May cause nervousness, tachycardia, and jitteriness Inhaled agents result in fewer systemic side effects
$\beta_2$ -Adrenergic agonists (long acting) (i.e., salmeterol)	Long-acting bronchodilator used in chronic asthma management and for prevention of exercise-induced asthma Long-term control in chronic asthma Prevention of exercise-induced asthma	Administered via inhalation Used only for long-term control or for exercise-induced asthma. Not for relief of bronchospasm in an acute wheezing episode
Racemic epinephrine	Produces bronchodilation Indicated for croup	Assess lung sounds and work of breathing Observe for rebound bronchospasm
Anticholinergic (ipratropium)	Produces bronchodilation in asthma or chronic lung disease	In children, generally used as an adjunct to $\beta_2$ -adrenergic agonists for treatment of bronchospasm
Antiviral agents (amantadine, rimantadine, zanamivir, oseltamivir)	Treatment and prevention of influenza A	Amantadine, rimantadine: monitor for confusion, nervousness, and jitteriness. Zanamivir, oseltamivir: well tolerated but expensive
Virazole (Ribavirin)	Treatment of severe lower respiratory tract infection with RSV, usually reserved for ventilated children	Administer via aerosol with the small-particle aerosol generator (SPAG). Suction children on assisted ventilation every 2 hours; monitor pulmonary pressures every 2 to 4 hours. May cause blurred vision and photosensitivity

(continued)

**DRUG GUIDE 40.1 COMMON DRUGS FOR RESPIRATORY DISORDERS** (continued)

Medication	Actions/Indications	Nursing Implications
Corticosteroids (inhaled)	Exert a potent, locally acting anti-inflammatory effect to decrease the frequency and severity of asthma attacks. May also delay pulmonary damage that occurs with chronic asthma. Also used for chronic lung disease and croup syndromes	Not for treatment of acute wheezing Rinse mouth after inhalation to decrease incidence of fungal infections, dry mouth, and hoarseness Minimal systemic absorption makes inhaled steroids the treatment of choice for asthma maintenance program
Corticosteroids (oral, parenteral)	Suppress inflammation and normal immune response Used for acute asthma exacerbations, wheezing with chronic lung disease, and severe croup	May cause hyperglycemia May suppress reaction to allergy tests Consult physician if vaccinations are ordered during course of systemic corticosteroid therapy Short courses of therapy are generally safe. Very effective, but long-term or chronic use can result in peptic ulceration, altered growth, and numerous other side effects. Children on long-term dosing should have growth assessed
Decongestants (e.g., pseudoephedrine)	Treatment of runny or stuffy nose associated with the common cold, sinusitis, or allergic rhinitis in children older than age 6	Assess child periodically for nasal congestion. Some children react to decongestants with excessive sleepiness or increased activity
Leukotriene receptor antagonists (montelukast, zafirlukast, zileuton)	Decrease inflammatory response by antagonizing the effects of leukotrienes to control asthma in children age 1 year and older Montelukast: for allergic rhinitis in children 6 months and older	Given once daily, in the evening Not for relief of bronchospasm during an acute wheezing episode, but may be continued during the episode
Mast cell stabilizers (cromolyn, nedocromil)	Prevent release of histamine from sensitized mast cells, resulting in decreased frequency and intensity of allergic reactions in children with asthma or chronic lung disease. Also used as preexposure treatment for allergens	Administered via inhalation For prophylactic use, not to relieve bronchospasm during an acute wheezing episode. Can be used 10 to 15 minutes prior to exposure to allergen, to decrease reaction to allergen
Methylxanthines (theophylline, aminophylline)	To provide for continuous airway relaxation in moderate or severe asthma in order to achieve long-term control Also indicated for apnea of prematurity (see "Caffeine")	Administered orally or intravenously. Sustained-release oral preparation can be used to prevent nocturnal symptoms Monitor drug levels routinely. Report signs of toxicity immediately: tachycardia, nausea, vomiting, diarrhea, stomach cramps, anorexia, confusion, headache, restlessness, flushing, increased urination, seizures, arrhythmias, insomnia
Caffeine	Stimulates the respiratory center in infants with apnea of prematurity	See "Methylxanthines"
Pulmozyme (dornase alfa)	Enzyme that hydrolyzes the DNA in sputum, reducing sputum viscosity in children with cystic fibrosis	Administered via nebulizer Monitor for dysphonia and pharyngitis
Synagis (palivizumab)	Monoclonal antibody used to prevent serious lower respiratory RSV disease in certain high-risk groups of children	Should be administered monthly during the RSV season Given intramuscularly only

## NURSING PROCESS OVERVIEW FOR THE CHILD WITH A RESPIRATORY DISORDER

Care of the child with a respiratory disorder includes assessment, nursing diagnosis, planning, interventions, and evaluation. There are a number of general concepts related to the nursing process that can be applied to respiratory disorders. From a general understanding of the care involved for a child with respiratory dysfunction, the nurse can then individualize the care based on specifics for the particular child.

### Assessment

Assessment of respiratory dysfunction in children includes health history, physical examination, and laboratory or diagnostic testing.

**Remember Alexander, the 4-month-old with the cold, cough, fatigue, feeding difficulty, and fast breathing? What additional health history and physical examination assessment information should the nurse obtain?**

### Health History

The health history consists of the past medical history, family history, and history of present illness (when the symptoms started and how they have progressed), as well as treatments used at home. The past medical history might be significant for recurrent colds or sore throats, **atopy** (such as asthma or atopic dermatitis), prematurity, respiratory dysfunction at birth, poor weight gain, or history of recurrent respiratory illnesses or chronic lung disease. Family history might be significant for chronic respiratory disorders such as asthma or might reveal contacts for infectious exposure. When eliciting the history of the present illness, inquire about onset and progression; fever; nasal congestion; noisy breathing; presence and description of cough; rapid respirations; increased work of breathing; ear, nose, sinus, or throat pain; ear pulling; headache; vomiting with coughing; poor feeding; and lethargy. Also inquire about exposure to second-hand smoke. Children exposed to environmental smoke have an increased incidence of respiratory illnesses such as asthma, bronchitis, and pneumonia (World Health Organization, 2011). See Healthy People 2020.

### Physical Examination

Physical examination of the respiratory system includes inspection and observation, auscultation, percussion, and palpation.

## HEALTHY PEOPLE 2020

### Objective

Reduce the proportion of nonsmokers (children and adolescents) exposed to second-hand smoke.

### Nursing Significance

- Educate the family about the effects that passive smoking has on children.
- Encourage families to join smoking cessation programs.

*Healthy People Objectives based on data from <http://www.healthypeople.gov>.*

## INSPECTION AND OBSERVATION

**Color.** Observe the child's skin color, noting pallor or cyanosis (circumoral or central). Pallor (pale appearance) occurs as a result of peripheral vasoconstriction in an effort to conserve oxygen for vital functions. **Cyanosis** (a bluish tinge to the skin and mucous membranes) occurs as a result of **hypoxia** (oxygen deficiency). It might first present circumorally (just around the mouth) and progress to central cyanosis. Newborns might have blue hands and feet (acrocyanosis), a normal finding. The infant might have pale hands and feet when cold or when ill, as peripheral circulation is not well developed in early infancy. It is important, then, to note if the cyanosis is central (involving the midline), as this is a true sign of hypoxia. Children with low red blood cell counts might not demonstrate cyanosis as early in the course of hypoxemia as children with normal hemoglobin levels. Therefore, absence of cyanosis or the degree of cyanosis present is not always an accurate indication of the severity of respiratory involvement.

Note the rate and depth of respiration as well as work of breathing. Often the first sign of respiratory illness in infants and children is **tachypnea** (increased respiratory rate).

### Take Note!

A slow or irregular respiratory rate in an acutely ill infant or child is an ominous sign (Chameides et al., 2011). See Chapter 53.

**Nose and Oral Cavity.** Inspect the nose and oral cavity. Note nasal drainage and redness or swelling in the nose. Note the color of the pharynx, presence of exudate, tonsil size, and status and presence of lesions anywhere in the oral cavity.

**Cough and Other Airway Noises.** Note the sound of the cough (Is it wet, productive, dry and hacking, tight? When does the cough occur? Is it only or mainly at night?). Also note if noises associated with breathing are present (e.g., grunting, stridor, or audible wheeze). Grunting occurs on expiration and is produced by premature glottic closure. It is an attempt to preserve or increase

FIGURE 40.3 Location of retractions.

functional residual capacity. Grunting might occur with alveolar collapse or loss of lung volume, such as in **atelectasis** (a collapsed or airless portion of the lung), pneumonia, and pulmonary edema. **Stridor**, a high-pitched, readily audible inspiratory noise, is a sign of upper airway obstruction. Sometimes wheezes can be heard with the naked ear; these are referred to as audible wheezes.

**Respiratory Effort.** Assess respiratory effort for depth and quality. Is breathing labored? Infants and children with significant nasal congestion may have tachypnea, which usually resolves when the nose is cleared of mucus. Mouth breathing may occur when a large amount of nasal congestion is present. Increased work of breathing, particularly if associated with restlessness and anxiety, usually indicates lower respiratory involvement. Assess for the presence of nasal flaring, retractions, or bobbing of the head with each breath. Nasal flaring can occur early in the course of respiratory illness and is an effort to inhale greater amounts of oxygen.

**Retractions** (the inward pulling of soft tissues with respiration) can occur in the intercostal, subcostal, substernal, supraclavicular, or suprasternal regions (Fig. 40.3). Document the severity of the retractions: mild, moderate, or severe. Also note the use of accessory neck muscles. Note the presence of paradoxical breathing (lack of simultaneous chest and abdominal rise with the inspiratory phase; see Fig. 40.4).

### Take Note!

Seesaw (or paradoxical) respirations are very ineffective for ventilation and **oxygenation** (binding of oxygen). The chest falls on inspiration and rises on expiration.

**Anxiety and Restlessness.** Is the child anxious or restless? Restlessness, irritability, and anxiety result from difficulty in securing adequate oxygen. These might be very early signs of respiratory distress, especially if accompanied by tachypnea. Restlessness might progress to listlessness and lethargy if the respiratory dysfunction is not corrected.

**Clubbing.** Inspect the fingertips for the presence of **clubbing**, an enlargement of the terminal phalanx of the finger, resulting in a change in the angle of the nail to the fingertip (Fig. 40.5). Clubbing might occur in children with a chronic respiratory illness. It is the result of increased capillary growth as the body attempts to supply more oxygen to distal body cells.

**Hydration Status.** Note the child's hydration status. Assess the oral mucosa for color and moisture. Note skin turgor, presence of tears, and adequacy of urine output. The child with a respiratory illness is at risk for dehydration. Pain related to sore throat or mouth lesions may prevent the child from drinking properly. Nasal congestion interferes with the infant's ability to suck effectively at the breast or bottle. Tachypnea and increased work of breathing interfere with the ability to safely ingest fluids.

### Auscultation

Assess lung sounds via auscultation. Evaluate breath sounds over the anterior and posterior chest, as well as in the axillary areas. Note the adequacy of aeration. Breath sounds should be equal bilaterally. The intensity and pitch should be equal throughout the lungs; document diminished breath sounds. In the absence of concurrent lower respiratory illness, the breath sounds should be clear throughout all lung fields. During normal respiration, the inspiratory phase is usually softer and longer than the expiratory phase. Prolonged expiration is a sign of bronchial or bronchiolar obstruction. Bronchiolitis, asthma, pulmonary edema, and an intrathoracic foreign body can cause prolonged expiratory phases.

FIGURE 40.4 Seesaw respirations.

**FIGURE 40.5** (A) Normal fingertip. Early clubbing (B) may progress eventually to advanced clubbing (C) as a result of chronic hypoxemia.

Infants and young children have thin chest walls. When the upper airway is congested (as in a severe cold), the noise produced in the upper airway might be transmitted throughout the lung fields. When upper airway congestion is transmitted to the lung fields, the congested-sounding noise heard over the trachea is the same type of noise heard over the lungs but is much louder and more intense. To ascertain if these sounds are truly adventitious lung sounds or if they are transmitted from the upper airway, auscultate again after the child coughs or his or her nose has been suctioned. Another way to discern the difference is to compare auscultatory findings over the trachea to the lung fields to determine if the abnormal sound is truly from within the lung or is actually a sound transmitted from the upper airway.

Note adventitious sounds heard on auscultation.

**Wheezing**, a high-pitched sound that usually occurs on expiration, results from obstruction in the lower trachea or bronchioles. Wheezing that clears with coughing is most likely a result of secretions in the lower trachea. Wheezing resulting from obstruction of the bronchioles, as in bronchiolitis, asthma, chronic lung disease, or cystic fibrosis, does not clear with coughing. **Rales** (crackling sounds) result when the alveoli become fluid filled, such as in pneumonia. Note the location of the adventitious sounds as well as the timing (on inspiration, expiration, or both). Tachycardia might also be present. An increase in heart rate often initially accompanies hypoxemia.

### Percussion

When percussing, note sounds that are not resonant in nature. Flat or dull sounds might be percussed over partially consolidated lung tissue, as in pneumonia. Tympany might be percussed with a pneumothorax. Note the presence of hyperresonance (as might be apparent with asthma).

### Palpation

Palpate the sinuses for tenderness in the older child. Assess for enlargement or tenderness of the lymph nodes of the head and neck. Document alterations in tactile fremitus detected on palpation. Increased tactile fremitus might occur in a case of pneumonia or pleural effusion. Fremitus might be decreased in the case

of barrel chest, as with cystic fibrosis. Absent fremitus might be noted with pneumothorax or atelectasis.

Compare central and peripheral pulses. Note the quality of the pulse as well as the rate. With significant respiratory distress, perfusion often becomes compromised. Poor perfusion might be reflected in weaker peripheral pulses (radial, pedal) when compared to central pulses.

### Laboratory and Diagnostic Testing

Common Laboratory and Diagnostic Tests 40.1 explains the laboratory and diagnostic tests most commonly used for a child with a respiratory disorder. The tests can assist the physician or nurse practitioner in diagnosing the disorder and/or be used as guidelines in determining ongoing treatment. Laboratory or nonnursing personnel obtain some of the tests, while the nurse might obtain others. In either instance it is important for the nurse to be familiar with how the tests are obtained, what they are used for, and normal versus abnormal results. This knowledge will also be necessary when providing child and family education related to the testing.

#### Take Note!

Ambient light may interfere with pulse oximetry readings. When the pulse oximeter probe is placed on the infant's foot or the young child's toe, covering the probe and foot with a sock may help to ensure an accurate measurement (DeMeulenaere, 2007).

### Nursing Diagnoses, Goals, Interventions, and Evaluation

Upon completion of a thorough assessment, the nurse might identify several nursing diagnoses, including:

- Ineffective airway clearance
- Ineffective breathing pattern
- Impaired gas exchange
- Risk for infection
- Pain
- Risk for fluid volume deficit
- Altered nutrition, less than body requirements
- Activity intolerance
- Fear
- Altered family processes

## COMMON LABORATORY AND DIAGNOSTIC TESTS 40.1 RESPIRATORY DISORDERS

Test	Explanation	Indications	Nursing Implications
Allergy skin testing	Suggested allergen is applied to skin via scratch, pin, or prick. A wheal response indicates allergy to the substance. Carries risk of anaphylaxis. (Nursing note: Antihistamines must be discontinued before testing, as they inhibit the test)	Allergic rhinitis, asthma	Close observation for anaphylaxis is necessary. Epinephrine and emergency equipment should be readily available. Some children react to the skin test almost immediately; others take several minutes.
Arterial blood gases	Invasive method (requires blood sampling) of measuring arterial pH, partial pressure of oxygen and carbon dioxide, and base excess in blood	Usually reserved for severe illness, the intubated child, or suspected carbon dioxide retention	Hold pressure for several minutes after a peripheral arterial stick to avoid bleeding. Radial arterial sticks are common and can be very painful. Note if the child is crying excessively during the blood draw, as this affects the carbon dioxide level.
Chest radiograph	Radiographic image of the expanded lungs: can show hyperinflation, atelectasis, pneumonia, foreign body, pleural effusion, abnormal heart or lung size	Bronchiolitis, pneumonia, tuberculosis, asthma, cystic fibrosis, bronchopulmonary dysplasia	Children may be afraid of the x-ray equipment. If a parent or familiar adult can accompany the child, often the child is less afraid. If the child is unable or unwilling to hold still for the x-ray, restraint may be necessary. Restraint should be limited to the amount of time needed for the x-ray.
Fluorescent antibody testing	Determines presence of respiratory syncytial virus (RSV), adenovirus, influenza, parainfluenza, or <i>Chlamydia</i> in nasopharyngeal secretions	Bronchiolitis, pneumonia	To obtain a nasopharyngeal specimen, instill 1 to 3 mL of sterile normal saline into one nostril, aspirate the contents using a small sterile bulb syringe, place the contents in sterile container, and immediately send them to the lab.
Fluoroscopy	Radiographic examination that uses a fluorescent screen—"real-time" imaging	Identification of masses, abscesses	Requires the child to lie still. Equipment can be frightening. Children may respond to presence of parent or familiar adult.
Gastric washings for AFB	Determines presence of AFB (acid-fast bacilli) in stomach (children often swallow sputum)	Tuberculosis	Nasogastric tube is inserted and saline is instilled and suctioned out of the stomach to obtain the specimen.
Peak expiratory flow	Measures the maximum flow of air (in L/second) that can be forcefully exhaled in 1 second	Daily use can indicate adequacy of asthma control.	It is important to establish the child's "personal best" by taking twice-daily readings over a 2-week period while well. The average of these is termed "personal best." Charts based on height and age are also available to determine expected peak expiratory flow.
Pulmonary function tests	Measure respiratory flow and lung volumes	Asthma, cystic fibrosis, chronic lung disease	Usually performed by a respiratory therapist trained to do the full spectrum of tests. Spirometry can be obtained by the trained nurse in the outpatient setting.

**COMMON LABORATORY AND DIAGNOSTIC TESTS 40.1 RESPIRATORY DISORDERS** (continued)

Test	Explanation	Indications	Nursing Implications
Pulse oximetry	Noninvasive method of continuously (or intermittently) measuring oxygen saturation	Can be useful in any situation in which a child is experiencing respiratory distress	Probe must be applied correctly to finger, toe, foot, hand, or ear in order for the machine to appropriately pick up the pulse and oxygen saturation.
Rapid flu test	Rapid test for detection of influenza A or B	Influenza	Should be done in first 24 hours of illness so that medication administration can begin. Have the child gargle with sterile normal saline and then spit into a sterile container. Send immediately to the lab.
Rapid strep test	Instant test for presence of streptococcus A antibody in pharyngeal secretions	Pharyngitis, tonsillitis	Results in 5 to 10 minutes. Negative tests should be backed up with throat culture.
RAST (radioallergosorbent test)	Measures minute quantities of immunoglobulin E in the blood Carries no risk of anaphylaxis but is not as sensitive as skin testing	Asthma (food allergies)	Blood test that is usually sent out to a reference laboratory.
Sinus radiographs, computed tomography (CT), or magnetic resonance imaging (MRI)	Radiologic tests that may show sinus involvement	Sinusitis, recurrent colds	X-ray results are usually received more quickly than CT or MRI results.
Sputum culture	Bacterial culture of invasive organisms in the sputum	Pneumonia, cystic fibrosis, tuberculosis	Must be true sputum, not mucus from the mouth or nose. Child can deep breathe, cough, and spit, or specimen may be obtained via suctioning of the artificial airway.
Sweat chloride test	Collection of sweat on filter paper after stimulation of skin with pilocarpine Measures concentration of chloride in the sweat	Cystic fibrosis	May be difficult to obtain sweat in a young infant.
Throat culture	Bacterial culture (minimum of 24 to 48 hours required) to determine presence of streptococcus A or other bacteria	Pharyngitis, tonsillitis	Can be obtained on separate swab at same time as rapid strep test to decrease trauma to the child (swab both applicators at once). Do not perform immediately after the child has had medication or something to eat or drink.
Tuberculin skin test	Mantoux test (intradermal injection of purified protein derivative)	Tuberculosis, chronic cough	Must be given intradermally; not a valid test if injected incorrectly.

Adapted from Pagana, K. D., & Pagana, T. J. (2010). *Mosby's manual of diagnostic and laboratory tests* (4th ed.). St. Louis: Mosby.

**After completing an assessment of Alexander, the nurse notes the following: lots of clear secretions in the airway, child appears pale, respiratory rate 68, retractions, nasal flaring, wheezing, and diminished breath sounds. Based on these assessment findings, what would your top three nursing diagnoses be for Alexander?**

Nursing goals, interventions, and evaluation for the child with a respiratory disorder are based on the nursing diagnoses. Nursing Care Plan 40.1 can be used as a guide in planning nursing care for the child with a respiratory disorder. The nursing care plan should be individualized based on the child's symptoms and needs; refer to Chapter 36 for detailed information on pain management. Additional information will be included later in the chapter as it relates to specific disorders.

**Based on your top three nursing diagnoses for Alexander, describe appropriate nursing interventions.**

### Providing Oxygen Supplementation

Oxygen may be delivered to the child by a variety of methods (Fig. 40.6). Since oxygen administration is considered a drug, it requires a physician's or nurse practitioner's order, except when following emergency protocols outlined in a health care facility's policies and procedures.

Many health care settings develop specific guidelines for oxygen administration that are often coordinated by respiratory therapists, yet the nurse still remains responsible for ensuring that oxygen is administered properly.

Oxygen sources include wall-mounted systems as well as cylinders. The supply of oxygen available from a wall-mounted source is limitless, but use of a wall-mounted source restricts the child to the hospital room. Cylinders are portable oxygen tanks; the D-cylinder holds a little less than 400 liters of oxygen and the E-cylinder holds about 650 liters of oxygen. Cylinders turn on with a gauge attached to the top of the tank. The cylinder is useful for the child on low-flow oxygen because it allows for mobility.

The tank empties relatively quickly if the child requires a high flow of oxygen, so this is not the best oxygen source in an emergency. Respiratory therapists usually maintain the respiratory equipment that is found in the emergency room or hospital. However, in an outpatient setting the nurse may be responsible for maintaining respiratory equipment and checking the level of oxygen in the office's oxygen tanks each day.

#### Take Note!

Oxygen is highly flammable, so use safety precautions. Post signs ("Oxygen in Use"); inform the family to avoid matches, lighters, and flammable or volatile materials; and use only facility-approved equipment.

The efficiency of oxygen delivery systems is affected by several variables, including the child's respiratory effort, the liter flow of oxygen delivered, and whether the equipment is being used appropriately. In general,

**FIGURE 40.6** (A) Simple oxygen mask provides about 40% oxygen. (B) The nasal cannula provides an additional 4% oxygen per 1 L of oxygen flow (i.e., 1 L will deliver 25% oxygen). (C) The nonrebreather mask provides 80% to 100% oxygen.

## NURSING CARE PLAN 40.1

## Overview for the Child With a Respiratory Disorder

**NURSING DIAGNOSIS:** Ineffective airway clearance related to inflammation, increased secretions, mechanical obstruction, or pain as evidenced by presence of secretions, productive cough, tachypnea, and increased work of breathing

**Outcome Identification and Evaluation**

Child will maintain patent airway, *free from secretions or obstruction, easy work of breathing, respiratory rate within parameters for age.*

**Interventions: Maintaining a Patent Airway**

- Position with airway open (sniffing position if supine) *to allow adequate ventilation.*
- Humidify oxygen or room air and ensure adequate fluid intake (intravenous or oral) *to liquefy secretions for ease in clearance.*
- Suction with bulb syringe or via nasopharyngeal catheter as needed, particularly prior to bottle-feeding, *to promote clearance of secretions.*
- If tachypneic, maintain nothing by mouth (NPO) status *to avoid aspiration.*
- In older child, encourage expectoration of sputum with coughing *to promote airway clearance.*
- Perform chest physiotherapy if ordered *to mobilize secretions.*
- Ensure emergency equipment is readily available *to avoid delay should airway become unmaintainable.*

**NURSING DIAGNOSIS:** Ineffective breathing pattern related to inflammatory or infectious process as evidenced by tachypnea, increased work of breathing, nasal flaring, retractions, diminished breath sounds

**Outcome Identification and Evaluation**

Child will exhibit adequate ventilation: *respiratory rate within parameters for age, easy work of breathing (absence of retractions, accessory muscle use, grunting), clear breath sounds with adequate aeration, oxygen saturation >94% or within prescribed parameters.*

**Interventions: Promoting Effective Breathing Patterns**

- Assess respiratory rate, breath sounds, and work of breathing frequently *to ensure progress with treatment and so that deterioration can be noted early.*
- Use pulse oximetry to monitor oxygen saturation in the least invasive manner *to note adequacy of oxygenation and ensure early detection of hypoxemia.*
- Position for comfort with open airway and room for lung expansion. Use pillows or padding if necessary to maintain position *to ensure optimal ventilation via maximum lung expansion.*
- Administer supplemental oxygen and/or humidity as ordered *to improve oxygenation.*
- Allow for adequate sleep and rest periods *to conserve energy.*
- Administer antibiotics as ordered: *may be indicated in the case of bacterial respiratory infection.*
- Encourage incentive spirometry and coughing with deep breathing (can be accomplished through play) *to maximize ventilation (play enhances the child's participation).*

**NURSING DIAGNOSIS:** Gas exchange, impaired, related to airway plugging, hyperinflation, atelectasis, as evidenced by cyanosis, decreased oxygen saturation, and alterations in arterial blood gases

**Outcome Identification and Evaluation**

Gas exchange will be adequate: *pulse oximetry reading on room air is within normal parameters for age, blood gases within normal limits, absence of cyanosis.*

## NURSING CARE PLAN 40.1

**Overview for the Child With a Respiratory Disorder** (continued)**Interventions: Promoting Adequate Gas Exchange**

- Administer oxygen as ordered *to improve oxygenation.*
- Monitor oxygen saturation via pulse oximetry *to detect alterations in oxygenation.*
- Encourage clearance of secretions via coughing, expectoration, chest physiotherapy, and suctioning *to improve gas exchange.*
- Administer bronchodilators if ordered (albuterol, levalbuterol, and racemic epinephrine) *to treat bronchospasm and improve gas exchange.*
- Provide frequent contact and support to the child and family *to decrease anxiety, which increases the child's oxygen demands.*
- Assess and monitor mental status (confusion, lethargy, restlessness, combativeness): *hypoxemia can lead to changes in mental status.*

**NURSING DIAGNOSIS:** Risk for infection related to presence of infectious organisms as evidenced by fever or presence of virus or bacteria on laboratory screening

**Outcome Identification and Evaluation**

Child will exhibit no signs of secondary infection and will not spread infection to others: *symptoms of infection decrease over time; others remain free from infection.*

**Interventions: Preventing Infection**

- Maintain aseptic technique, practice good hand washing, and use disposable suction catheters *to prevent introduction of further infectious agents.*
- Limit number of visitors and screen them for recent illness *to prevent further infection.*
- Administer antibiotics if prescribed *to prevent or treat bacterial infection.*
- Encourage nutritious diet according to child's preferences and ability to feed orally *to assist body's natural infection-fighting mechanisms.*
- Isolate the child as required *to prevent nosocomial spread of infection.*
- Teach child and family preventive measures such as good hand washing, covering mouth and nose when coughing or sneezing, and proper disposal of used tissues *to prevent nosocomial or community spread of infection.*

**NURSING DIAGNOSIS:** Fluid volume deficit, risk for, related to decreased oral intake, insensible losses via fever, tachypnea, or diaphoresis

**Outcome Identification and Evaluation**

Fluid volume will be maintained: *oral mucosa moist and pink, skin turgor elastic, urine output at least 1 to 2 mL/kg/hour.*

**Interventions: Maintaining Adequate Fluid Volume**

- Administer intravenous fluids if ordered *to maintain adequate hydration in NPO state.*
- When allowed oral intake, encourage oral fluids. Popsicles, favorite fluids, and games can be used *to promote intake.*
- Assess for signs of adequate hydration (elastic skin turgor, moist mucosa, adequate urine output).
- Monitor intake and output *to identify fluid imbalance.*
- Monitor urine specific gravity, urine and serum electrolytes, blood urea nitrogen, creatinine, and osmolality *to determine fluid status.*

(continued)

## NURSING CARE PLAN 40.1

## Overview for the Child With a Respiratory Disorder (continued)

**NURSING DIAGNOSIS:** Nutrition, altered: less than body requirements related to difficulty feeding as evidenced by poor oral intake, tiring with feeding

**Outcome Identification and Evaluation**

Child will maintain adequate nutritional intake: *weight is gained or maintained. Child consumes adequate diet for age.*

**Interventions: Promoting Adequate Nutritional Intake**

- Weigh on same scale at same time daily so that measurements are consistent.
- Perform calorie counts over a 3-day period to determine whether caloric intake is sufficient.
- Encourage child to choose higher-calorie, protein-rich foods to optimize growth potential.
- Coax young children to eat better by playing games and offering favorite foods to improve intake.

**NURSING DIAGNOSIS:** Activity intolerance related to high respiratory demand as evidenced by increased work of breathing and need for frequent rest when playing

**Outcome Identification and Evaluation**

Child will resume normal activity level: *activity is tolerated without difficulty breathing. Pulse oximetry readings and vital signs are within parameters for age and activity level.*

**Interventions: Increasing Activity Tolerance**

- Provide rest periods balanced with periods of activity, and group nursing activities and visits to allow for sufficient rest.
- Provide small, frequent meals to prevent overtiring (energy is expended while eating).
- Encourage quiet activities that do not require exertion to prevent boredom.
- Allow gradual increase in activity as tolerated, keeping pulse oximetry reading within normal parameters, to minimize risk for further respiratory compromise.

**NURSING DIAGNOSIS:** Fear related to difficulty breathing, unfamiliar personnel, procedures, and environment (hospital), as evidenced by clinging, crying, fussing, verbalization, or lack of cooperation

**Outcome Identification and Evaluation**

Fear/anxiety will be reduced: *decreased episodes of crying or fussing, happy and playful at times.*

**Interventions: Relieving Fear**

- Establish trusting relationship with child and family to decrease anxiety and fear.
- Explain procedures to child at developmentally appropriate level to decrease fear of unknown.
- Provide favorite blanket or bear as well as comfort measures preferred by child such as rocking or music for added security.
- Involve parents in care to give child reassurance and decrease fear.

**NURSING DIAGNOSIS:** Family processes, altered, related to child's illness or hospitalization as evidenced by family's presence in hospital, missed work, demonstration of inadequate coping

**Outcome Identification and Evaluation**

Parents demonstrate adequate coping and decreased anxiety: *parents are involved in child's care, ask appropriate questions, and are able to discuss child's care and condition calmly.*

**Interventions: Promoting Adequate Family Processes**

- Encourage parents to discuss their concerns related to child's illness to identify concerns and show parents that the nurse also cares about them, not just the child.
- Explain therapy, procedures, and child's behavior to parents to decrease their anxiety.
- Encourage parents to be involved in care so they feel needed and valued.

oxygen facemasks come in infant, child, and adult sizes. Select the mask that best fits the child. In addition, ensure that the mask is sealed properly to decrease the amount of oxygen that escapes from the mask. Ensure that the liter flow is set according to the manufacturer's recommendations for use with that particular delivery method.

The oxygen flow rate or concentration is usually determined by the physician's or nurse practitioner's order. Whichever method of delivery is used, provide humidification during oxygen delivery to prevent drying of nasal passages and to assist with liquefying secretions. Table 40.1 provides details on oxygen delivery methods.

TABLE 40.1

## OXYGEN DELIVERY METHODS

Delivery Method	Description	Nursing Implications
Simple mask	Provides 35% to 60% oxygen with a flow rate of 6 to 10 L/minute. Oxygen delivery percentage is affected by respiratory rate, inspiratory flow, and adequacy of mask fit.	<ul style="list-style-type: none"> <li>• Must maintain oxygen flow rate of at least 6 L/minute to maintain inspired oxygen concentration and prevent rebreathing of carbon dioxide</li> <li>• Mask must fit snugly to be effective but should not be so tight as to irritate the face.</li> </ul>
Venturi mask	Provides 24% to 50% oxygen by using a special gauge at the base of the mask that allows mixing of room air with oxygen flow	<ul style="list-style-type: none"> <li>• Set oxygen flow rate according to percentage of oxygen desired as indicated on the gauge/dial.</li> <li>• As with simple mask, must fit snugly.</li> </ul>
Nasal cannula	Provides low oxygen concentration (22% to 44%)	<ul style="list-style-type: none"> <li>• Must be used with humidification to prevent drying and irritation of airways.</li> <li>• Can provide very small amounts of oxygen (as low as 25 mL/minute).</li> <li>• Maximum recommended liter flow in children is 4 L/minute.</li> <li>• Children can eat or talk while on oxygen.</li> <li>• Inspired oxygen concentration affected by mouth breathing.</li> <li>• Requires patent nasal passages.</li> </ul>
Oxygen tent	Provides high-humidity environment with up to 50% oxygen concentration	<ul style="list-style-type: none"> <li>• Oxygen level drops when tent is opened.</li> <li>• Must change linen frequently as it becomes damp from the humidity.</li> <li>• Secure edges of tent with blankets or by tucking edges under mattress.</li> <li>• Young children may be fearful and resistant.</li> <li>• Mist may interfere with visualization of child inside tent.</li> </ul>
Oxygen hood	Provides high concentration (up to 80% to 90%) for infants only. Allows easy access to chest and lower body.	<ul style="list-style-type: none"> <li>• Liter flow must be set at 10 to 15 L/minute.</li> <li>• Good method for infant but need to remove for feeding.</li> <li>• Can and should be humidified.</li> </ul>
Partial rebreathing mask	Simple facemask with an oxygen reservoir bag. Provides 50% to 60% oxygen concentration	<ul style="list-style-type: none"> <li>• Must set liter flow rate at 10 to 12 L/minute to prevent rebreathing of carbon dioxide.</li> <li>• The reservoir bag does not completely empty when child inspires if flow rate is set properly.</li> </ul>
Nonrebreathing mask	Simple facemask with valves at the exhalation ports and an oxygen reservoir bag with a valve to prevent exhaled air from entering the reservoir. Provides 95% oxygen concentration	<ul style="list-style-type: none"> <li>• Must set liter flow rate at 10 to 12 L/minute to prevent rebreathing of carbon dioxide.</li> <li>• The reservoir bag does not completely empty when child inspires if flow rate is set properly.</li> </ul>

Adapted from Chameides, L., Samson, R. A., Schexnayder, S. M., & Hazinski, M. F. (Eds.) (2011). *Pediatric advanced life support provider manual*. South Deerfield, MA: Channing Bete Company; and Bowden, V. R., & Greenberg, C. S. (2008). *Pediatric nursing procedures* (2nd ed.). Philadelphia: Lippincott Williams & Wilkins.

**Take Note!**

Monitor vital signs, color, respiratory effort, pulse oximetry, and level of consciousness before, during, and after oxygen therapy to evaluate its effectiveness.

## ACUTE INFECTIOUS DISORDERS

Acute infectious disorders include the common cold, sinusitis, influenza, pharyngitis, tonsillitis, laryngitis, croup syndromes, respiratory syncytial virus (RSV), pneumonia, and bronchitis.

### Common Cold

The common cold is also referred to as a viral upper respiratory infection (URI) or nasopharyngitis. Colds can be caused by rhinoviruses, parainfluenza, RSV, enteroviruses, adenoviruses, and human meta-pneumovirus. Viral particles spread through the air or from person-to-person contact. Colds occur more frequently in the winter. They affect children of all ages and have a higher incidence among children who attend day care and school-age children (Yoon, Kelley, & Friedman, 2011). It is not unusual for a child to have six to nine colds per year. Spontaneous resolution of the common cold occurs after about 7 to 10 days. Potential complications include secondary bacterial infections of the ears, throat, sinuses, or lungs.

Therapeutic management of the common cold is directed toward symptom relief. Nasal congestion may be relieved via humidity and use of normal saline nasal wash or spray followed by suctioning. Antihistamines are not indicated, as they dry secretions further. Over-the-counter cold preparations are available singly and in combinations. These preparations have not been proven to reduce the length or severity of the cold but may offer symptomatic relief in some children older than 6 years of age (they are not recommended in children younger than the age of 4 due to side effects) (Yoon et al., 2011). See Healthy People 2020.

### HEALTHY PEOPLE 2020

#### Objective

Reduce the number of courses of antibiotics prescribed for the sole diagnosis of the common cold.

#### Nursing Significance

- Appropriately educate families that the cause of the common cold is a number of viruses and that antibiotics are inappropriate for the treatment of viral infections.
- Encourage families to use measures such as normal saline nasal washes to decrease symptoms associated with the common cold more quickly.

*Healthy People Objectives based on data from <http://www.healthypeople.gov>.*

**Take Note!**

In 2007, over-the-counter cold preparations containing decongestants intended for use in infants and toddlers were removed from the market. Several research studies have not shown the preparations to be effective and they are known to have potentially serious side effects (U.S. Food and Drug Administration, 2007). Safety of these products in children 2 to 11 years of age remains under review by the Food and Drug Administration.

## Nursing Assessment

The child may have either a stuffy or runny nose. Nasal discharge is usually thin and watery at first but may become thicker and discolored. The color of nasal discharge is not an accurate indicator of viral versus bacterial infection. The child may be hoarse and complain of a sore throat. Cough usually produces very little sputum. Fever, fatigue, watery eyes, and appetite loss may also occur. Symptoms are generally at their worst over the first few days and then decrease over the course of the illness.

Assess for risk factors such as day care or school attendance. Inspect for edema and vasodilation of the mucosa. Diagnosis is based on clinical presentation rather than laboratory or x-ray studies. Comparison Chart 40.1 differentiates causes of nasal congestion.

## Nursing Management

Nursing management of the child with a common cold consists of promoting comfort, providing family education, and preventing spread of the cold.

### Promoting Comfort

Nursing care of the common cold is aimed at supportive measures. Nasal congestion may be relieved with the use of normal saline nose drops, followed by bulb syringe suctioning in infants and toddlers. Older children may use a normal saline nose spray to mobilize secretions. A cool mist humidifier also helps with nasal congestion. Generally, other over-the-counter nose sprays are not recommended for use in children, but they are sometimes prescribed for very short-term use. Promotion of adequate oral fluid intake is important to liquefy secretions.

Educate parents about the use of cold and cough medications. Although they may offer some symptomatic relief, they have not been proven to shorten the length of cold symptoms. Counsel parents to use the appropriate product depending on the symptom relief desired, rather than a combination product. Products containing acetaminophen combined with other “cold symptom” medications may mask a fever in the child who is

## COMPARISON CHART 40.1

## CAUSES OF NASAL CONGESTION

Sign or Symptom	Allergic Rhinitis	Common Cold	Sinusitis
<i>Length of illness</i>	Varies; may have year-round symptoms	10 days or less	Longer than 10 to 14 days
<i>Nasal discharge</i>	Thin, watery, clear	Thick, white, yellow, or green; can be thin	Thick, yellow or green
<i>Nasal congestion</i>	Varies	Present	Present
<i>Sneezing</i>	Varies	Present	Absent
<i>Cough</i>	Varies	Present	Varies
<i>Headache</i>	Varies	Varies	Varies
<i>Fever</i>	Absent	Varies	Varies
<i>Bad breath</i>	Absent	Absent	Varies

developing a secondary bacterial infection. As with all viral infections in children, teach parents that aspirin use should be avoided because of its association with Reye syndrome (Durani, 2011b).

### Providing Family Education

Currently there are no medications available to treat the viruses that cause the common cold, so symptomatic treatment is all that is necessary. Antibiotics are not indicated unless the child also has a bacterial infection. Explain to parents the importance of reserving antibiotic use for appropriate illnesses. Provide education about the use of normal saline nose drops and bulb suctioning to clear the infant's nose of secretions. Normal saline nasal wash using a bulb syringe to instill the solution is also helpful for children of all ages with nasal congestion. Though normal saline for nasal administration is available commercially, parents can also make it at home (Box 40.2). Teaching Guidelines 40.1 gives instructions on use of the bulb syringe.

Counsel parents about how to recognize complications of the common cold, which include:

- Prolonged fever
- Increased throat pain or enlarged, painful lymph nodes

#### BOX 40.2

#### HOMEMADE SALT WATER NOSE DROPS

Mix 8 oz distilled water, a half-teaspoon sea salt, and a quarter-teaspoon baking soda. Keeps for 24 hours in the refrigerator, but should be allowed to come to room temperature prior to use.

- Increased or worsening cough, cough lasting longer than 10 days, chest pain, difficulty breathing
- Earache, headache, tooth or sinus pain
- Unusual irritability or lethargy
- Skin rash

If complications do occur, tell parents to notify the physician or nurse practitioner for further instructions or reassessment.

### Preventing the Common Cold

Teaching about ways to prevent the common cold is a vital nursing intervention. Explain that frequent hand washing helps to decrease the spread of viruses that cause the common cold. Teach parents and family to avoid second-hand smoke as well as crowded places, especially during the winter. Avoid close contact with individuals known to have a cold. Encourage parents and families to consume a healthy diet and get enough rest.

#### Consider This

Corey Davis, a 3-year-old, is brought to the clinic by her mother. She presents with a runny nose, congestion, and a nonproductive cough. Her mother says, "She's miserable."

What other assessment information would be helpful?

Based on the history and clinical presentation, Corey is diagnosed with a common cold. What education would be helpful for this family? Include ways to improve Corey's comfort and ways to prevent the common cold.

## Teaching Guidelines 40.1

**USING THE BULB SYRINGE TO SUCTION NASAL SECRETIONS**

1. Hold the infant on your lap or on the bed with the head tilted slightly back.

2. If using saline, instill several drops of saline solution in one of the infant's nostrils.

3. Compress the sides of the bulb syringe completely. Use only a rubber-tipped bulb syringe. Place the rubber tip in the infant's nose.

4. Release pressure on the bulb.

5. Remove the syringe and squeeze bulb over tissue or the sink to empty it of secretions.

6. Repeat on other nostril if necessary. Using a bulb syringe prior to bottle-feeding or breastfeeding may relieve congestion enough to allow the infant to suck more efficiently.
7. Clean the bulb syringe thoroughly with warm water after each use and allow to air dry.

## Sinusitis

Sinusitis (also called rhinosinusitis) generally refers to a bacterial infection of the paranasal sinuses. The disease may be either acute or chronic in nature. Approximately 5% of upper respiratory infections are complicated with acute sinusitis (DeMuri & Wald, 2010). In young children the maxillary and ethmoid sinuses are the main sites of infection. After age 10 years, the frontal sinuses may be more commonly involved (Yoon et al., 2011). Mucosal swelling, decreased ciliary movement, and thickened nasal discharge all contribute to bacterial invasion of the nose. Nasal polyps also place the child at risk for bacterial sinusitis. Complications include orbital cellulitis and intracranial infections, such as subdural empyemas.

Symptoms lasting less than 30 days generally indicate acute sinusitis, whereas symptoms persisting longer than 4 to 6 weeks usually indicate chronic sinusitis. Sinusitis is managed with antibiotic treatment. The therapeutic management approach varies with chronicity. The course of treatment is usually 14 days. Naturally, chronic sinusitis requires a longer course of treatment than acute sinusitis. Surgical therapy may be indicated for children with chronic sinusitis, particularly if it is recurrent or if nasal polyps are present.

## Nursing Assessment

The most common presentation of sinusitis is persistent signs and symptoms of a cold. Rather than improving after 7 to 10 days, nasal discharge persists. Explore the history for:

- Cough
- Fever
- In preschoolers or older children, halitosis (bad breath)
- Facial pain may or may not be present, so is not a reliable indicator of disease
- Eyelid edema (in the case of ethmoid sinus involvement)
- Irritability
- Poor appetite

Assess for risk factors such as a history of recurrent cold symptoms or a history of nasal polyps.

On physical examination, note eyelid swelling, extent of nasal drainage, and halitosis. Inspect the throat for postnasal drainage. Inspect the nasal mucosa for erythema. Palpate the sinuses, noting pain with mild pressure. The diagnosis may be made based on the history and clinical presentation, augmented by x-ray, computed tomography scan, or magnetic resonance imaging findings in some cases. (Refer to Comparison Chart 40.1, which differentiates the causes of nasal congestion.)

## Nursing Management

Normal saline nose drops or spray, cool mist humidifiers, and adequate oral fluid intake are recommended for children with sinusitis. Teach families the importance of continuing the full course of antibiotics to eradicate the cause of infection. Also educate the family that using decongestants, antihistamines, and intranasal steroids as adjuncts in the treatment of sinusitis has not been shown to be beneficial (DeMuri & Wald, 2010). Normal saline nose spray or nasal washes may promote drainage.

## Influenza

Influenza viral infection (known commonly as the “flu”) occurs primarily during the winter. It is spread through inhalation of droplets or contact with fine-particle aerosols. Infected children shed the virus for 1 to 2 days before symptoms begin and may continue shedding the virus in increased amounts (as compared to adults) for as long as 2 weeks. Average annual infection rates in children range from 20% to 50% (Iskander, Booy, & Lambert, 2007). Influenza viruses primarily affect the upper respiratory epithelium but can cause systemic effects as well. Children with chronic heart or lung conditions, diabetes, chronic renal disease, or immune deficiency are at higher risk for more severe influenza infection compared to other children.

Bacterial infections of the respiratory system commonly occur as complications of influenza infection, severe pneumococcal pneumonia in particular. Otitis media occurs in 18% to 40% of all influenza cases (Iskander et al., 2007). Less common complications include Reye syndrome and acute myositis. Reye syndrome is an acute encephalopathy that has been associated with aspirin use in the influenza-infected child (Durani, 2011b). Acute myositis is particular to children. A sudden onset of severe pain and tenderness in both calves causes the child to refuse to walk. Due to the potential for complications, a prolonged fever or a fever that returns during convalescence should be investigated.

### Take Note!

Current recommendations are for all children older than 6 months of age to be immunized yearly against influenza (Centers for Disease Control and Prevention [CDC], 2012a).

## Nursing Assessment

Children who attend day care or school are at higher risk for influenza infection than those who are routinely at home. Note the presence of risk factors for severe

disease, such as chronic heart or lung disease (such as asthma), diabetes, chronic renal disease, or immune deficiency or children with cancer receiving chemotherapy. School-age children and adolescents experience the illness similarly to adults. Abrupt onset of fever, facial flushing, chills, headache, myalgia, and malaise are accompanied by cough and **coryza** (nasal discharge). About half of infected individuals have a dry or sore throat. Ocular symptoms such as photophobia, tearing, burning, and eye pain are common.

Infants and young children exhibit symptoms similar to other respiratory illnesses. Fever greater than 39.5°C is common. Infants may be mildly toxic in appearance and irritable and have a cough, coryza, and pharyngitis. Wheezing may occur, as influenza also can cause bronchiolitis. An erythematous rash may be present and diarrhea may also occur. The diagnosis may be confirmed by a rapid assay test.

## Nursing Management

Nursing management of influenza is mainly supportive. Symptomatic treatment of cough and fever and maintenance of hydration are the focus of care. Antiviral drugs can reduce the symptoms associated with influenza if they are started within the first 24 to 48 hours of the illness (Iskander et al., 2007).

### Pharyngitis

Inflammation of the throat mucosa (pharynx) is referred to as pharyngitis. A sore throat may accompany nasal congestion and is often viral in nature. A bacterial sore throat most often occurs without nasal symptoms. Group A streptococci account for 15% to 25% of cases, with the remainder being caused by other viruses or bacteria (Martin, 2010).

Suppurative complications of group A streptococcal infection include peritonsillar or retropharyngeal abscess. Peritonsillar abscess may be noted by asymmetric swelling of the tonsils, shifting of the uvula to one side, and palatal edema. Retropharyngeal abscess may progress to the point of airway obstruction, hence requiring careful evaluation and appropriate treatment. Additional complications include acute rheumatic fever (see Chapter 41) and acute glomerulonephritis (see Chapter 43).

Viral pharyngitis is usually self-limited and does not require therapy beyond symptomatic relief. Group A streptococcal pharyngitis requires antibiotic therapy. If either the rapid diagnostic test or throat culture (described below) is positive for group A streptococci, penicillin is generally prescribed. Appropriate alternative

antibiotics include amoxicillin and, for those allergic to penicillin, macrolides and cephalosporins.

### Take Note!

A "strep carrier" is a child who has a positive throat culture for streptococci when asymptomatic. Strep carriers are not at risk for complications from streptococci, as are those who are acutely infected with streptococci and are symptomatic (Martin, 2010).

## Nursing Assessment

Onset of pharyngitis is often quite abrupt. The history may include a fever, sore throat and difficulty swallowing, headache, and abdominal pain. Inquire about recent incidence of viral or strep throat in the family, day care center, or school.

Inspect the pharynx and tonsils, which may demonstrate varying degrees of inflammation (Fig. 40.7). Exudate may be present but is not diagnostic of bacterial infection. Note the presence of petechiae on the palate. Inspect the tongue for a strawberry appearance. Palpate for enlargement and tenderness of the anterior cervical nodes. Inspect the skin for a fine, red, sandpaper-like rash (called scarlatiniform), particularly on the trunk or abdomen, a common finding with streptococcus A infection.

The nurse may obtain a throat swab for rapid diagnostic testing and throat culture. The rapid strep test is a sensitive and reliable measure, rarely resulting in false-positive readings (Blosser, Brady, & Mueller, 2009). If the rapid strep test is negative, the second swab may be sent for a throat culture.

**FIGURE 40.7** Note the redness of the pharynx, tonsillar exudate, and white strawberry tongue coating.

## Atraumatic Care

*When obtaining two swabs for rapid strep testing and throat culture, swab the applicators simultaneously to decrease perceived trauma to the child.*

## Nursing Management

Nursing management of the child with pharyngitis focuses on promoting comfort and providing family education.

### Promoting Comfort

Saline gargles (made with 8 oz of warm water and a half-teaspoon of table salt) are soothing for children old enough to cooperate. Analgesics such as acetaminophen and ibuprofen may ease fever and pain. Sucking on throat lozenges or hard candy may also ease pain. Cool mist humidity helps to keep the mucosa moist in the event of mouth breathing. Encourage the child to ingest popsicles, cool liquids, and ice chips to maintain hydration.

### Providing Family Education

Parents may be accustomed to “sore throats” being treated with antibiotics. However, in the case of a viral cause antibiotics will not be necessary and the pharyngitis will resolve in a few days. For the child with streptococcal pharyngitis, urge parents to have the child complete the entire prescribed course of antibiotics. After 24 hours of antibiotic therapy, instruct the parents to discard the child’s toothbrush to avoid reinfection. Children may return to day care or school after they have been receiving antibiotics for 24 hours; they are considered noncontagious at that point.

## Tonsillitis

Inflammation of the tonsils often occurs with pharyngitis and, thus, may also be viral or bacterial in nature. Viral infections require only symptomatic treatment. Treatment for bacterial tonsillitis is the same as for bacterial pharyngitis. Occasionally surgical intervention is warranted. Tonsillectomy (surgical removal of the palatine tonsils) may be indicated for the child with recurrent streptococcal tonsillitis or massive tonsillar hypertrophy or for other reasons. When hypertrophied adenoids obstruct breathing, then adenoidectomy (surgical removal of the adenoids) may be indicated.

## Nursing Assessment

Note whether fever is present currently or by history. Inquire about the history of recurrent pharyngitis or tonsillitis. Note if the child’s voice sounds muffled or hoarse. Inspect the pharynx for redness and enlargement of the tonsils. As the tonsils enlarge, the child may experience difficulty breathing and swallowing. When tonsils touch at the midline (“kissing tonsils” or 4+ in size), the airway may become obstructed. Also, if the adenoids are enlarged, the posterior nares become obstructed. The child may breathe through the mouth and may snore. Palpate the anterior cervical nodes for enlargement and tenderness. Rapid test or culture may be positive for streptococcus A.

## Nursing Management

Tonsillitis that is medically treated requires the same nursing management as pharyngitis. Nursing care for the child after tonsillectomy is described below.

### Promoting Airway Clearance

Until fully awake, place the child in a side-lying or prone position to facilitate safe drainage of secretions. Once alert, the child may prefer to sit up or have the head of the bed elevated. Suctioning, if necessary, should be done carefully to avoid trauma to the surgical site. Dried blood may be present on the teeth and the nares, with old blood present in emesis. Since the presence of blood can be very frightening to parents, alert them to this possibility.

### Maintaining Fluid Volume

Hemorrhage is unusual postoperatively but may occur any time from the immediate postoperative period to as late as 10 days after surgery. Inspect the throat for bleeding. Mucus tinged with blood may be expected, but fresh blood in the secretions indicates bleeding. Early bleeding may be identified by continuous swallowing of small amounts of blood while awake or sleeping. Other signs of hemorrhage include tachycardia, pallor, restlessness, frequent throat clearing, and emesis of bright red blood.

To avoid trauma to the surgical site, discourage the child from coughing, clearing the throat, blowing the nose, and using straws. Upon discharge, instruct the parents to immediately report any sign of bleeding to the physician or nurse practitioner. To maintain fluid volume postoperatively, encourage children to take any fluids they desire; popsicles and ice chips are particularly soothing. Citrus juice and brown or red fluids should be avoided: the acid in citrus juice may irritate the throat, and red or brown fluids may be confused with blood if vomiting occurs.

## Relieving Pain

For the first 24 hours after surgery, the throat is very sore. Adequate pain relief is essential to establish adequate oral fluid intake. An ice collar may be prescribed, as well as analgesics with or without narcotics. Counsel parents to maintain pain control upon discharge from the facility, not only for the child's sake, but also to enable the child to continue to drink fluids.

## Infectious Mononucleosis

Infectious mononucleosis is a self-limited illness caused by the Epstein-Barr virus. It is characterized by fever, malaise, sore throat, and lymphadenopathy. Mononucleosis is commonly called the “kissing disease” since it is transmitted by oropharyngeal secretions. It can occur at any age but is most often diagnosed in adolescents and young adults (Blosser et al., 2009). Some infected individuals may have concomitant streptococcal pharyngitis. Complications include splenic rupture, Guillain-Barré syndrome, and aseptic meningitis.

## Nursing Assessment

Note any history of exposure to infected individuals. Determine history of fever and onset and progression of sore throat, malaise, and other complaints. Observe for periorbital edema. Inspect the pharynx and tonsils for inflammation and patches of gray exudate. Petechiae may be present on the palate. Palpate for bilateral nontender enlargement of the posterior cervical lymph nodes. After 3 to 5 days of illness, the pharynx may become edematous and the tonsillar exudate more extensive. Lymphadenopathy may progress to include the anterior cervical nodes, which may become tender. Palpate the abdomen for splenomegaly or hepatomegaly. An erythematous maculopapular rash may appear as the illness progresses. Definitive diagnosis may be made by Monospot or Epstein-Barr virus titers.

### Take Note!

The Monospot is usually negative if obtained within the first 7 to 10 days of illness with infectious mononucleosis. Epstein-Barr virus titer is reliable at any point in the illness (Blosser et al., 2009).

## Nursing Management

Nursing management of mononucleosis is primarily symptomatic. The throat may be very sore, so analgesics and salt-water gargles are recommended. Bed rest should be encouraged while the child is febrile. Frequent rest periods

may be necessary for several weeks after the onset of illness, as fatigue may persist as long as 6 weeks. During the acute phase, if tonsillar or pharyngeal edema threatens to obstruct the airway, then corticosteroids may be given to decrease the inflammation. In the presence of splenomegaly or hepatomegaly, strenuous activity and contact sports should be avoided. Appearance of rash or jaundice should be reported to the physician or nurse practitioner.

## Laryngitis

Inflammation of the larynx is termed laryngitis. It may occur alone or in conjunction with other respiratory symptoms. It is characterized by a hoarse voice or loss of the voice (so soft as to make it difficult to hear). Oral fluids might offer relief, but resting the voice for 24 hours will allow the inflammation to subside. Laryngitis alone requires no further intervention.

## Croup

Children between 3 months and 3 years of age are the most frequently affected with croup, though croup may affect any child (Durani, 2012). Croup is also referred to as laryngotracheobronchitis because inflammation and edema of the larynx, trachea, and bronchi occur as a result of viral infection. Parainfluenza is responsible for the majority of cases of croup (Wald, 2010). Other causes include adenovirus, influenza virus A and B, RSV, and rarely measles virus or *Mycoplasma pneumoniae*. The inflammation and edema obstruct the airway, resulting in symptoms. Mucus production also occurs, further contributing to obstruction of the airway. Narrowing of the subglottic area of the trachea results in audible inspiratory stridor. Edema of the larynx causes hoarseness. Inflammation in the larynx and trachea causes the characteristic barking cough of croup.

Symptoms occur most often at night, presenting suddenly, with resolution of symptoms in the morning. Croup is usually self-limited, lasting only about 3 to 5 days. Complications of croup are rare but may include worsening respiratory distress, hypoxia, or bacterial superinfection (as in the case of bacterial tracheitis).

Croup is usually managed on an outpatient basis, with affected children rarely requiring hospitalization. Corticosteroids (usually a single dose) are used to decrease inflammation, and racemic epinephrine aerosols demonstrate the  $\alpha$ -adrenergic effect of mucosal vasoconstriction, helping to decrease edema. Children with croup may be hospitalized if they have significant stridor at rest or severe retractions after a several-hour period of observation. Comparison Chart 40.2 compares croup to epiglottitis.

## COMPARISON CHART 40.2

## CROUP VS. EPIGLOTTITIS

	Spasmodic Croup	Epiglottitis
<i>Preceding illness</i>	None or minimal coryza	None or mild upper respiratory infection
<i>Age group usually affected</i>	3 months to 3 years	1 to 8 years
<i>Onset</i>	Usually sudden, often at night	Rapid (within hours)
<i>Fever</i>	Variable	High
<i>Barking cough, hoarseness</i>	Yes	No
<i>Dysphagia</i>	No	Yes
<i>Toxic appearance</i>	No	Yes
<i>Cause</i>	Viral	<i>Haemophilus influenzae</i> type B

## Nursing Assessment

Note the age of the child; children between 3 months and 3 years of age are most likely to present with viral croup (laryngotracheobronchitis). History may reveal a cough that developed during the night (most common presentation) and that sounds like barking (or a seal). Inspect for the presence of mild URI symptoms. Temperature may be normal or elevated mildly. Listen for inspiratory stridor and observe for suprasternal retractions. Auscultate the lungs for adequacy of breath sounds. Croup is usually diagnosed based on history and clinical presentation, but a lateral neck radiograph may be obtained to rule out epiglottitis.

### Take Note!

The child with fever, a toxic appearance, and increasing respiratory distress despite appropriate croup treatment may have bacterial tracheitis. Notify the physician or nurse practitioner of these findings in a child with croup (Rajan, Emery, & Sood, 2010).

## Nursing Management

If the child's care is being managed at home, advise parents about the symptoms of respiratory distress and instruct them to seek treatment if the child's respiratory condition worsens. Teach parents to expose their child to humidified air (via a cool mist humidifier or steamy bathroom). Though never clinically proven, use of humidified air has long been recommended for alleviating coughing jags and anecdotally has been reported as helpful. Administer dexamethasone if ordered or teach parents about home administration. Explain to parents that the effects of racemic epinephrine last about 2 hours and the child must be observed closely as occasionally a child

will worsen again, requiring another aerosol. Teaching Guidelines 40.2 provides information about home care of croup.

## Teaching Guidelines 40.2

### HOME CARE OF CROUP

- Keep the child quiet and discourage crying.
- Allow the child to sit up (in your arms).
- Encourage rest and fluid intake.
- If stridor occurs, take the child into a steamy bathroom for 10 minutes.
- Administer medication (corticosteroid) as directed.
- Watch the child closely. Call the physician if:
  - The child breathes faster, has retractions, or has any other difficulty breathing
  - The nostrils flare or the lips or nails have a bluish tint
  - The cough or stridor does not improve with exposure to moist air
  - Restlessness increases or the child is confused
  - The child begins to drool or cannot swallow

Adapted from Durani, Y. (2012). *About croup*. Retrieved July 12, 2012, from <http://kidshealth.org/parent/infections/lung/croup.html#>

## Epiglottitis

Epiglottitis (inflammation and swelling of the epiglottis) is most often caused by *Haemophilus influenzae* type b. Extensive use of the Hib vaccine since the 1980s has resulted in a significant decrease in the incidence of epiglottitis (Brady, 2009). Though now rare, epiglottitis most often occurs in children between the ages of 2 and 7 years and can be life-threatening (Brady, 2009). Respiratory arrest and death may occur if the airway becomes

completely occluded. Additional complications include pneumothorax and pulmonary edema. Therapeutic management focuses on airway maintenance and support. Intravenous antibiotic therapy is necessary. The child will be managed in the intensive care unit. See Comparison Chart 40.2 for information comparing croup to epiglottitis.

## Nursing Assessment

Carefully assess the child with suspected epiglottitis. Note sudden onset of symptoms and high fever. The child has an overall toxic appearance. He or she may refuse to speak or may speak only with a very soft voice. The child may refuse to lie down and may assume the characteristic position: sitting forward with the neck extended. Drooling may be present. Note anxiety or a frightened appearance. Note the child's color. Cough is usually absent. A lateral neck radiograph may be performed to determine whether epiglottitis is present. This is done cautiously, so as not to induce airway obstruction with changes in position of the child's neck.

### Take Note!

Do not under any circumstance attempt to visualize the throat; reflex laryngospasm may occur, precipitating immediate airway occlusion (Brady, 2009).

## Nursing Management

Do not leave the child unattended. Keep the child and parents as calm as possible. Allow the child to assume a position of comfort. Do not place the child in a supine position, as airway occlusion may occur. Provide 100% oxygen in the least invasive manner that is acceptable to the child. If the child with epiglottitis experiences complete airway occlusion, an emergency tracheostomy may be necessary. Ensure that emergency equipment is available and that personnel trained in intubation of the pediatric occluded airway and percutaneous tracheostomy are notified of the child's presence in the facility.

### Take Note!

Epiglottitis is characterized by dysphagia, drooling, anxiety, irritability, and significant respiratory distress. Prepare for the event of sudden airway occlusion.

## Bronchiolitis (Respiratory Syncytial Virus)

Bronchiolitis is an acute inflammatory process of the bronchioles and small bronchi. Nearly always caused by a viral pathogen, RSV accounts for the majority of

cases of bronchiolitis, with adenovirus, parainfluenza, and human meta-pneumovirus also being important causative agents. This discussion will focus on RSV bronchiolitis.

The peak incidence of bronchiolitis is in the winter and spring, coinciding with RSV season. RSV season in the United States and Canada generally begins in September or October and continues through April or May. Virtually all children will contract RSV infection within the first few years of life. RSV bronchiolitis occurs most often in infants and toddlers, with a peak incidence around 6 months of age (Goodman, 2011). The severity of disease is related inversely to the age of the child. The frequency and severity of RSV infection decrease with age. Repeated RSV infections occur throughout life but are usually localized to the upper respiratory tract after toddlerhood.

## Pathophysiology

RSV is a highly contagious virus and may be contracted through direct contact with respiratory secretions or from particles on objects contaminated with the virus. RSV invades the nasopharynx, where it replicates and then spreads down to the lower airway via aspiration of upper airway secretions. RSV infection causes necrosis of the respiratory epithelium of the small airways, peribronchiolar mononuclear infiltration, and plugging of the lumens with mucus and exudate. The small airways become variably obstructed; this allows adequate inspiratory volume but prevents full expiration. This leads to hyperinflation and atelectasis. Serious alterations in gas exchange occur, with arterial hypoxemia and carbon dioxide retention resulting from mismatching of pulmonary **ventilation** (gas exchange within the lungs) and perfusion. Hypoventilation occurs secondary to markedly increased work of breathing.

## Therapeutic Management

Management of RSV focuses on supportive treatment. Supplemental oxygen, nasal and/or nasopharyngeal suctioning, oral or intravenous hydration, and inhaled bronchodilator therapy are used. Many infants are managed at home with close observation and adequate hydration. Hospitalization is required for children with more severe disease. The infant with tachypnea, significant retractions, poor oral intake, or lethargy can deteriorate quickly, to the point of requiring ventilatory support, and thus warrants hospital admission.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1394. Assessment findings pertinent to RSV bronchiolitis are discussed below.

## Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Onset of illness with a clear runny nose (sometimes profuse)
- Pharyngitis
- Low-grade fever
- Development of cough 1 to 3 days into the illness, followed by a wheeze shortly thereafter
- Poor feeding

Explore the child's current and past medical history for risk factors such as:

- Young age (younger than 2 years old), more severe disease in a child younger than 6 months old
- Prematurity
- Multiple births
- Birth during April to September
- History of chronic lung disease (bronchopulmonary disease)
- Cyanotic or complicated congenital heart disease
- Immunocompromise
- Male gender
- Exposure to passive tobacco smoke
- Crowded living conditions
- Day care attendance
- School-age siblings
- Low socioeconomic status
- Lack of breastfeeding

## Physical Examination

Examination of the child with RSV involves inspection, observation, and auscultation.

### INSPECTION AND OBSERVATION

Observe the child's general appearance and color (centrally and peripherally). The infant with RSV bronchiolitis might appear air-hungry, exhibiting various degrees of cyanosis and respiratory distress, including tachypnea, retractions, accessory muscle use, grunting, and periods of apnea. Cough and audible wheeze might be heard. The infant might appear listless and uninterested in feeding, surroundings, or parents.

### AUSCULTATION

Auscultate the lungs, noting adventitious sounds and determining the quality of aeration of the lung fields. Earlier in the illness, wheezes might be heard scattered throughout the lung fields. In more serious cases, the chest might sound quiet and without wheeze. This is due to significant hyperexpansion with very poor air exchange.

## Laboratory and Diagnostic Tests

Common laboratory and diagnostic studies ordered for the assessment of RSV bronchiolitis include:

- Pulse oximetry: oxygen saturation might be decreased significantly
- Chest radiograph: might reveal hyperinflation and patchy areas of atelectasis or infiltration
- Blood gases: might show carbon dioxide retention and hypoxemia
- Nasal-pharyngeal washings: positive identification of RSV can be made via enzyme-linked immunosorbent assay (ELISA) or immunofluorescent antibody (IFA) testing

## Nursing Management

RSV infection is usually self-limited, and nursing diagnoses, goals, and interventions for the child with bronchiolitis are aimed at supportive care. Children with less severe disease might require only antipyretics, adequate hydration, and close observation. They can often be successfully managed at home, provided the primary caregiver is reliable and comfortable with close observation. Teach parents or caregivers to watch for signs of worsening and to seek care quickly should the child's condition deteriorate.

Hospitalization is required for children with more severe disease, and children admitted with RSV bronchiolitis warrant close observation. In addition to the nursing diagnoses and related interventions discussed in Nursing Care Plan 40.1 for respiratory disorders, interventions common to bronchiolitis follow.

### Take Note!

Currently no safe and effective antiviral drug is available for definitive treatment of RSV. Aerosolized ribavirin is recommended only for the highest-risk, most severely ill children. Routine antibiotic use is discouraged in RSV bronchiolitis treatment because the secondary bacterial infection rate of the lower airway is very low (Cecchia, 2011).

## Maintaining Patent Airway

Infants and young children with RSV tend to have copious secretions. Position the child with the head of the bed elevated to facilitate an open airway. These children often require frequent assessment and suctioning to maintain a patent airway. Use a Yankauer or tonsil-tip suction catheter to suction the mouth or pharynx of older infants or children, rinsing the catheter after each suctioning. Nasal bulb suctioning may be sufficient to clear the airway in some infants, while others will require nasopharyngeal suctioning with a suction catheter. Nursing Procedure 40.1 gives further information. Adjust the pressure ranges for

## NURSING PROCEDURE 40.1

**Nasopharyngeal or Artificial Airway Suction Technique**

1. Make sure the suction equipment works properly before starting.
2. After washing your hands, assemble the equipment needed:
  - Appropriate-size sterile suction catheter
  - Sterile gloves
  - Supplemental oxygen
  - Sterile water-based lubricant
  - Sterile normal saline if indicated
3. Don sterile gloves, keeping dominant hand sterile and nondominant hand clean.
4. Preoxygenate the infant or child if indicated.
5. Apply lubricant to the end of the suction catheter.
6. If indicated for loosening of secretions, instill sterile saline.
7. Maintaining sterile technique, insert the suction catheter into the child's nostril or airway.
  - Insert only to the point of gagging if inserting via the nostril.
  - Insert only 0.5 cm further than the length of the artificial airway.
8. Intermittently apply suction for no longer than 10 seconds while twisting and removing the catheter.
9. Supplement with oxygen after suctioning.

suctioning infants and children between 60 and 100 mm Hg (40 and 60 mm Hg for premature infants).

**Promoting Adequate Gas Exchange**

Infants and children with RSV bronchiolitis might deteriorate quickly as the disease progresses. In the child ill enough to require oxygen, the risk is even greater. Assessment should include work of breathing, respiratory rate, and oxygen saturation. The percentage of inspired oxygen (FiO<sub>2</sub>) should be adjusted as needed to maintain oxygen saturation within the desired range. Positioning the infant with the head of the bed elevated may also improve gas exchange. Frequent assessment is necessary for the hospitalized child with bronchiolitis.

**Take Note!**

In the tachypneic infant, slowing of the respiratory rate does not necessarily indicate improvement: often, a slower respiratory rate is an indication of tiring, and carbon dioxide retention may soon be followed by apnea (Chameides et al., 2011).

**Reducing Risk for Infection**

Since RSV is easily spread through contact with droplets, isolate inpatients according to hospital policy to decrease the risk of nosocomial spread to other children. Children with RSV can be safely cohorted. Attention to hand washing is necessary, as droplets might enter the eyes, nose, or mouth via the hands.

**Providing Family Education**

Educate parents so they can recognize signs of worsening distress. Tell parents to call the physician or nurse practitioner if the child's breathing becomes rapid or more difficult or if the child cannot eat secondary to tachypnea. Children who are younger than 1 year of age or who are at higher risk (those who were born prematurely or who have chronic heart or lung conditions) might have a longer course of illness. Instruct parents that cough can persist for several days to weeks after resolution of the disease, but infants usually act well otherwise.

**Preventing Respiratory Syncytial Virus Disease**

Strict adherence to hand washing policies in day care centers and when exposed to individuals with cold symptoms is important for all age groups. Though generally benign in healthy older children, RSV can be devastating in young infants or children with preexisting risk factors. Palivizumab (Synagis) is a monoclonal antibody that can prevent severe RSV disease in those who are most susceptible (Cecchia, 2011). It is given as an intramuscular injection once a month throughout the RSV season. Though quite costly, it is covered by most insurance policies and Medicaid for those who qualify. It is generally indicated for use in certain qualifying children younger than 2 years of age. Qualifying factors include:

- Prematurity
- Chronic lung disease (bronchopulmonary dysplasia) requiring medication or oxygen
- Certain congenital heart diseases
- Immunocompromise (Cecchia, 2011).

Links to additional information related to Synagis are located on [thePoint](#).

**Pneumonia**

Pneumonia is an inflammation of the lung parenchyma. It can be caused by a virus, bacteria, *Mycoplasma*, or a fungus. Respiratory viruses are the most common cause of pneumonia in younger children and the least common cause in older children. Viral pneumonia is usually better tolerated in children of all ages. Children with bacterial pneumonia are more apt to present with a toxic

appearance, but they generally recover rapidly if appropriate antibiotic treatment is instituted early. *Streptococcus pneumoniae* is a common cause of bacterial pneumonia in all ages of children, and *M. pneumoniae* is a common causative agent in the school-age child and adolescent. Fungal infection may also result in pneumonia. Aspiration pneumonia may result from aspiration of foreign material into the lower respiratory tract. Pneumonia occurs more often in winter and early spring. It is common in children but is seen most frequently in infants and young toddlers.

### Take Note!

Community-acquired pneumonia (CAP) refers to pneumonia in a previously healthy person that is contracted outside of the hospital setting. CAP is a common cause of lower respiratory infection in North America (Don, Canciani, & Korppi, 2010).

Pneumonia is usually a self-limited disease. A child who presents with recurrent pneumonia should be evaluated for chronic lung disease such as asthma or cystic fibrosis. Potential complications of pneumonia include bacteremia, pleural effusion, empyema, lung abscess, and pneumothorax. Excluding bacteremia, these complications are often treated with thoracentesis and/or chest tubes as well as antibiotics if appropriate. Pneumatoceles (thin-walled cavities developing in the lung) might occur with certain bacterial pneumonias and usually resolve spontaneously over time.

Therapeutic management of children with less severe disease includes antipyretics, adequate hydration, and close observation. Even bacterial pneumonia can be successfully managed at home if the work of breathing is not severe and oxygen saturation is within normal limits. However, hospitalization is required for children with more severe disease. The child with tachypnea, significant retractions, poor oral intake, or lethargy might require hospital admission for the administration of supplemental oxygen, intravenous hydration, and antibiotics. See Healthy People 2020.

## HEALTHY PEOPLE 2020

Objective	Nursing Significance
Reduce invasive pneumococcal infections.	<ul style="list-style-type: none"> <li>• Provide accurate information to families about pneumococcal disease.</li> <li>• Encourage pneumococcal immunization per recommendations.</li> </ul>

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1394. Assessment findings pertinent to pneumonia are discussed below.

### Health History

Elicit a description of the present illness and chief complaint. Note onset and progression of symptoms. Common signs and symptoms reported during the health history include:

- Antecedent viral URI
- Fever
- Cough (note type and whether productive or not)
- Increased respiratory rate
- History of lethargy, poor feeding, vomiting, or diarrhea in infants
- Chills, headache, dyspnea, chest pain, abdominal pain, and nausea or vomiting in older children

Explore the child's past and current medical history for risk factors known to be associated with an increase in the severity of pneumonia, such as:

- Prematurity
- Malnutrition
- Passive smoke exposure
- Low socioeconomic status
- Day care attendance
- Underlying cardiopulmonary, immune, or nervous system disease (Brady, 2009)

### Physical Examination

Physical examination consists of inspection, auscultation, percussion, and palpation.

#### INSPECTION

Observe the child's general appearance and color (centrally and peripherally). Cyanosis might accompany coughing spells. The child with bacterial pneumonia may appear ill. Assess work of breathing. Children with pneumonia might exhibit substernal, subcostal, or intercostal retractions. Tachypnea and nasal flaring may be present. Describe cough and quality of sputum if produced.

#### AUSCULTATION

Auscultation of the lungs might reveal wheezes or rales in the younger child. Local or diffuse rales may be present in the older child. Document diminished breath sounds.

#### PERCUSSION AND PALPATION

In the older child, percussion might yield local dullness over a consolidated area. Percussion is much less valuable in the infant or younger child. Tactile fremitus felt upon palpation may be increased with pneumonia.

## Laboratory and Diagnostic Tests

Common laboratory and diagnostic studies ordered for the assessment of pneumonia include:

- Pulse oximetry: oxygen saturation might be decreased significantly or within normal range
- Chest radiograph: varies according to child age and causative agent. In infants and young children, bilateral air trapping and perihilar **infiltrates** (collection of inflammatory cells, cellular debris, and foreign organisms) are the most common findings. Patchy areas of consolidation might also be present. In older children, lobar consolidation is seen more frequently
- Sputum culture: may be useful in determining causative bacteria in older children and adolescents
- White blood cell count: might be elevated in the case of bacterial pneumonia

## Nursing Management

Nursing diagnoses, goals, and interventions for the child with pneumonia are primarily aimed at providing supportive care and education about the illness and its treatment. Prevention of pneumococcal infection is also important. Children with more severe disease will require hospitalization. Refer to Nursing Care Plan 40.1 for nursing diagnoses and related interventions. In addition to the interventions listed there, the following should be noted.

### Providing Supportive Care

Ensure adequate hydration and assist in thinning of secretions by encouraging oral fluid intake in the child whose respiratory status is stable. In children with increased work of breathing, intravenous fluids may be necessary to maintain hydration. Allow and encourage the child to assume a position of comfort, usually with the head of the bed elevated to promote aeration of the lungs. If pain due to coughing or pneumonia itself is severe, administer analgesics as prescribed. Provide supplemental oxygen to the child with respiratory distress or hypoxia as needed.

### Providing Family Education

Educate the family about the importance of adhering to the prescribed antibiotic regimen. Antibiotics may be given intravenously if the child is hospitalized. Oral antibiotics are used upon discharge or if the child is managed on an outpatient basis.

Teach the parents of a child with bacterial pneumonia to expect that following resolution of the acute illness. For 1 to 2 weeks the child might continue to tire easily and the infant might continue to need small,

frequent feedings. Cough may also persist after the acute recovery period but should lessen over time.

If the child is diagnosed with viral pneumonia, parents might not understand that their child does not require an antibiotic. Pneumonia is often perceived by the public as a bacterial infection, so most parents will need an explanation related to treatment of viral infections. As with bacterial pneumonia, the child may experience a week or two of weakness or fatigue following resolution of the acute illness.

The young child is at risk for the development of aspiration pneumonia. Parents need to understand that the child might be at risk for injury related to his or her age and developmental stage. To prevent recurrent or further aspiration, teach the parents the safety measures in Teaching Guidelines 40.3.

### Teaching Guidelines 40.3

#### PREVENTING ASPIRATION

- Keep toxic substances such as lighter fluid, solvents, and hydrocarbons out of reach of young children. Toddlers and preschoolers cannot distinguish safe from unsafe fluids due to their developmental stage.
- Avoid oily nose drops and oil-based vitamins or home remedies to avoid lipid aspiration into the lungs.
- Avoid oral feedings if the infant's respiratory rate is 60 or greater to minimize the risk of aspiration of the feeding.
- Discourage parents from "force-feeding" in the event of poor oral intake or severe illness to minimize the risk of aspiration of the feeding.
- Position infants and ill children on their right side after feeding to minimize the risk of aspirating emesis or regurgitated feeding.

## Preventing Pneumococcal Infection

Children at high risk for severe pneumococcal infection should be immunized against it. This includes all children between 0 and 23 months of age, as well as children between 24 and 59 months of age who either never received the vaccine before age 2 or did not receive a booster dose between 12 and 23 months of age. Additionally, children between 24 and 59 months of age with certain conditions such as immune deficiency, sickle cell disease, asplenia, chronic cardiac conditions, chronic lung problems, cerebrospinal fluid leaks, chronic renal insufficiency, diabetes mellitus, and organ transplants should receive the vaccine (CDC, 2012b). For additional information on immunization, refer to Chapter 31.

## Bronchitis

Bronchitis is an inflammation of the trachea and major bronchi. It is often associated with a URI. Bronchitis is usually viral in nature, though *M. pneumoniae* and other bacterial organisms are causative in about 10% of cases (Carolan, 2011). Recovery usually occurs within 5 to 10 days. Therapeutic management involves mainly supportive care. Expectorant administration and adequate hydration are important. If bacterial infection is the cause, antibiotics are indicated.

## Nursing Assessment

The illness might begin with a mild URI. Fever develops, followed by a dry, hacking cough that might become productive in older children. The cough might wake the child at night. Auscultation of the lungs might reveal coarse rales. Respirations remain unlabored. The chest radiograph might show diffuse alveolar hyperinflation and perihilar markings.

## Nursing Management

Nursing management is aimed at providing supportive care. Teach parents that expectorants will help loosen secretions and antipyretics will help reduce the fever, making the child more comfortable. Encourage adequate hydration. Antibiotics are prescribed only in cases believed to be bacterial in nature. Discourage the use of cough suppressants; it is important for accumulated sputum to be raised.

## Tuberculosis

Tuberculosis (TB) is a highly contagious disease caused by inhalation of droplets of *Mycobacterium tuberculosis* or *Mycobacterium bovis*. Children usually contract the disease from an immediate household member. Homeless and impoverished children are at higher risk, as are those exposed to an adult with TB infection (Federico, 2011). After exposure to an infected individual, the incubation period is 2 to 10 weeks. The inhaled tubercle bacilli multiply in the alveoli and alveolar ducts, forming an inflammatory exudate. The bacilli are spread by the bloodstream and lymphatic system to various parts of the body. Though pulmonary tuberculosis is the most common, children may also have infection in other parts of the body, such as the gastrointestinal tract or central nervous system.

In the case of drug-sensitive tuberculosis, the American Academy of Pediatrics recommends a 6-month course of oral therapy. The first 2 months consist of isoniazid, rifampin, and pyrazinamide given daily. This is followed by twice-weekly isoniazid and rifampin; administration must be observed directly (usually by a public health

nurse). In the case of multidrug-resistant tuberculosis, ethambutol or streptomycin is given via intramuscular injection (Pickering, 2009). See Healthy People 2020.

## HEALTHY PEOPLE 2020

### Objective

Reduce tuberculosis. Increase treatment completion rate of all children with tuberculosis who are eligible to complete therapy. Increase the treatment completion rate of contacts to sputum smear-positive cases who are diagnosed with latent tuberculosis infection (LTBI) and started LTBI treatment.

### Nursing Significance

- Assess the health history of all infants, children, and adolescents for risk factors for tuberculosis infection.
- Provide tuberculosis screening as recommended.
- Refer all tuberculosis infections to the local public health department.
- Educate families about the importance of completing medication therapy as prescribed for active and latent tuberculosis, and the need for appropriate follow-up and retesting for tuberculosis infection.

*Healthy People* Objectives based on data from <http://www.healthypeople.gov>.

## Nursing Assessment

Routine screening for tuberculosis infection is not recommended for low-risk individuals, but children considered to be at high risk for contracting tuberculosis should be screened using the Mantoux test. Children considered to be at high risk are those who:

- Are infected with HIV
- Are incarcerated or institutionalized
- Have a positive recent history of latent tuberculosis infection
- Are immigrants from or have a history of travel to endemic countries
- Are exposed at home to HIV-infected or homeless persons, illicit drug users, persons recently incarcerated, migrant farm workers, or nursing home residents (Federico, 2011)

The presentation of tuberculosis in children is quite varied. Children can be asymptomatic or exhibit a broad range of symptoms. Symptoms may include fever, malaise, weight loss, anorexia, pain and tightness in the chest, and rarely hemoptysis. Cough may or may not be present and usually progresses slowly over several weeks to months. As tuberculosis progresses, the respiratory rate increases and the lung on the affected side is poorly expanded. Dullness to percussion might be present, as well as diminished breath sounds and crackles. Fever persists and pallor, anemia, weakness, and weight loss are present. Diagnosis is confirmed with a positive Mantoux

test, positive gastric washings for acid-fast bacillus, and/or a chest radiograph consistent with tuberculosis.

## Nursing Management

Hospitalization of children with tuberculosis is necessary only for the most serious cases. Nursing management is aimed at providing supportive care and encouraging adherence to the treatment regimen. Most nursing care for childhood tuberculosis is provided in outpatient clinics, schools, or a public health setting. Supportive care includes ensuring adequate nutrition and adequate rest, providing comfort measures such as fever reduction, preventing exposure to other infectious diseases, and preventing reinfection.

### Providing Care for the Child With Latent Tuberculosis Infection

Children who test positive for tuberculosis but who do not have symptoms or radiographic/laboratory evidence of disease are considered to have latent infection. These children should be treated with isoniazid for 9 months to prevent progression to active disease. Follow-up and appropriate monitoring can be achieved via the child's physician or nurse practitioner or local health department.

### Preventing Infection

Tuberculosis infection is prevented by avoiding contact with the tubercle bacillus. Thus, hospitalized children with tuberculosis must be isolated according to hospital policy to prevent nosocomial spread of tuberculosis infection. Promotion of natural resistance through nutrition, rest, and avoidance of serious infections does not prevent infection. Pasteurization of milk has helped to decrease the transmission of *M. bovis*. Administration of bacille Calmette-Guérin (BCG) vaccine can provide incomplete protection against tuberculosis, and it is not widely used in the United States (Pickering, 2009).

## ACUTE NONINFECTIOUS DISORDERS

Acute noninfectious disorders include epistaxis, foreign body aspiration, acute respiratory distress syndrome, pneumothorax, and respiratory distress syndrome (RDS). RDS is a condition unique to newborn infants and is discussed in Chapter 24.

### Epistaxis

Epistaxis (a nosebleed) occurs most frequently in children before adolescence. Bleeding of the nasal mucosa occurs most often from the anterior portion of the

septum. Epistaxis may be recurrent and idiopathic (meaning there is no cause). The majority of cases are benign, but in children with bleeding disorders or other hematologic concerns, epistaxis should be further investigated and treated.

#### Take Note!

The child with recurrent epistaxis or epistaxis that is difficult to control should be further evaluated for underlying bleeding or platelet concerns.

## Nursing Assessment

Explore the child's history for initiating factors such as local inflammation, mucosal drying, or local trauma (usually nose picking). Inspect the nasal cavity for blood.

## Nursing Management

The presence of blood often frightens children and their parents. The nurse and parents should remain calm. The child should sit up and lean forward (lying down may allow aspiration of the blood). Apply continuous pressure to the anterior portion of the nose by pinching it closed. Encourage the child to breathe through the mouth during this portion of the treatment. Ice or a cold cloth applied to the bridge of the nose may also be helpful. The bleeding usually stops within 10 to 15 minutes. Apply petroleum jelly or water-soluble gel to the nasal mucosa with a cotton-tipped applicator to moisten the mucosa and prevent recurrence.

### Foreign Body Aspiration

Foreign body aspiration occurs when any solid or liquid substance is inhaled into the respiratory tract. It is common in infants and young children and can present in a life-threatening manner. The object may lodge in the upper or lower airway, causing varying degrees of respiratory difficulty. Small, smooth objects such as peanuts are the most frequently aspirated, but any small toy, article, or piece of food smaller than the diameter of the young child's airway can be aspirated.

#### Take Note!

Items smaller than 1.25 inches (3.2 cm) can be aspirated easily. A simple way for parents to estimate the safe size of a small item or toy piece is to gauge its size against a standard toilet paper roll, which is generally about 1.5 inches in diameter (Safe Kids, 2012).

Foreign body aspiration occurs most frequently in children between 6 months and 4 years of age (Federico, 2011). Children this age are growing and developing

rapidly. They tend to explore things with their mouths and can easily aspirate small items.

The child often coughs out foreign bodies from the upper airway. If the foreign body reaches the bronchus, then it may need to be surgically removed via bronchoscopy. Postoperative antibiotics are used if an infection is also present. Complications of foreign body aspiration include pneumonia or abscess formation, hypoxia, respiratory failure, and death.

## Nursing Assessment

The infant or young child might present with a history of sudden onset of cough, wheeze, or stridor. Stridor suggests that the foreign body is lodged in the upper airway. Sometimes the onset of respiratory symptoms is much more gradual. When the item has traveled down one of the bronchi, then wheezing, rhonchi, and decreased aeration can be heard on the affected side. A chest radiograph will demonstrate the foreign body only if it is radiopaque (Fig. 40.8).

## Nursing Management

The most important nursing intervention related to foreign body aspiration is prevention. Anticipatory guidance for families with 6-month-olds should include a discussion of aspiration avoidance. Repeat this information at each subsequent well-child visit through age 5. Tell parents to avoid letting their child play with toys with small parts and to keep coins and other small objects out of the reach of children. Teach parents not to feed peanuts and popcorn to their child until he or she

**FIGURE 40.8** Foreign body is noted in the bronchus on a chest radiograph.

is at least 3 years old (Federico, 2011). When children progress to table food, teach parents to chop all foods so that they are small enough to pass down the trachea should the child neglect to chew them up thoroughly. Carrots, grapes, and hot dogs should be cut into small pieces. Harmful liquids should be kept out of the reach of children.

### Take Note!

Prevent young children from playing with latex balloons. When popped, small pieces pose an aspiration danger (Durani, 2011a).

## Acute Respiratory Distress Syndrome

Acute respiratory distress syndrome (ARDS) occurs following a primary insult such as sepsis, viral pneumonia, smoke inhalation, or near drowning. Respiratory distress and hypoxemia occur acutely within 72 hours of the insult in infants and children with previously healthy lungs (Thilo & Rosenberg, 2011). The alveolar–capillary membrane becomes more permeable and pulmonary edema develops. Hyaline membrane formation over the alveolar surfaces and decreased surfactant production cause lung stiffness. Mucosal swelling and cellular debris lead to atelectasis. Gas diffusion is impaired significantly. Some children have residual lung disease and some recover completely. However, ARDS can progress to respiratory failure and death.

Therapeutic management is aimed at improving oxygenation and ventilation. Mechanical ventilation is used, with special attention to lung volumes and positive end-expiratory pressure (PEEP). Newer treatment modalities show promise for improving outcomes of ARDS (see Table 40.2).

## Nursing Assessment

Tachycardia and tachypnea occur over the first few hours of the illness. Significantly increased work of breathing with nasal flaring and retractions develops. Auscultate the breath sounds, which might range from normal to high-pitched crackles throughout the lung fields. Hypoxemia develops. Bilateral infiltrates can be seen on a chest radiograph.

## Nursing Management

Nursing care of the child with ARDS is mainly supportive and occurs in the intensive care unit. Closely monitor respiratory and cardiovascular status. Comfort measures such as hygiene and positioning as well as pain and anxiety management, maintenance

**TABLE 40.2** ALTERNATIVES TO TRADITIONAL MECHANICAL VENTILATION

Mode	Description	Additional Information
High-frequency ventilators (high-frequency, oscillating, or jet)	Provide very high respiratory rates (up to 1,200 breaths per minute) and very low tidal volumes	May decrease risk of barotrauma associated with ventilator pressures
Nitric oxide	Causes pulmonary vasodilation, helping to increase blood flow to alveoli	Safe; no long-term developmental risks
Liquid ventilation	Perfluorocarbon liquid acts as a surfactant. Provides an effective medium for gas exchange and increases pulmonary function	Virtually no reported physiologic sequelae
Extracorporeal membrane oxygenation (ECMO)	Blood is removed from body via catheter, warmed and oxygenated in the ECMO machine, and then returned to infant.	Labor-intensive. Risk of bleeding is great.

of nutrition, and prevention of infection are also key nursing interventions. (See Evidence-Based Practice 18-1.) The acute phase of worsening respiratory distress can be frightening for a child of any age, and the nurse can be instrumental in soothing the child's fears. As the disease worsens and progresses, especially when ventilatory support is required, it is especially important to provide psychological support of the family as well as education about the intensive care unit procedures.

## Pneumothorax

A collection of air in the pleural space is called a pneumothorax. It can occur spontaneously in an otherwise healthy child or as a result of chronic lung disease, cardiopulmonary resuscitation, surgery, or trauma. Trapped air consumes space within the pleural cavity, and the affected lung suffers at least partial collapse. Needle aspiration and/or placement of a chest

### EVIDENCE-BASED PRACTICE 40.1

#### VARIOUS BODY POSITIONS AND THEIR EFFECTS ON HOSPITALIZED INFANTS AND YOUNG CHILDREN WITH ACUTE RESPIRATORY DISTRESS

##### STUDY

Prone positioning has been found to improve ventilation in some adults with acute respiratory distress and in premature infants with respiratory distress syndrome, but due to the risk of sudden infant death syndrome (SIDS), infants are generally positioned supine. The authors reviewed 21 studies that evaluated the effect of positioning (supine, prone, lateral, elevated, and flat positions) on respiratory function (oxygen saturation, partial pressure of arterial oxygen, oxygenation index, thoracoabdominal synchrony, and episodes of oxygen desaturation) in infants and young children with acute respiratory distress.

##### Findings

The only position found to produce a statistically significant improvement in respiratory function was the prone position. The prone position was better in

terms of improving ventilation and oxygenation. The other positions did not demonstrate statistically significant differences.

##### Nursing Implications

Nurses should critically consider the result of this review. Certainly, if an alternate position is used, the infant must be closely monitored and the position changed should any level of deterioration occur. If hospitalized infants with acute respiratory distress are placed in the prone position, continuous cardiopulmonary and oxygenation saturation monitoring must be provided because of the risk of SIDS in this age group. Do not encourage families to use the prone position at home when an infant is ill with a respiratory condition.

Adapted from Wells, D. A., Gillies, D., & Fitzgerald, D. A. (2007). Positioning for acute respiratory distress in hospitalised infants and children. *The Cochrane Library* 2007, 4. Indianapolis: John Wiley & Sons.

tube are used to evacuate the air from the chest. Some small pneumothoraces resolve independently, without intervention.

## Nursing Assessment

Primary pneumothorax (spontaneous) occurs most often in adolescence (Gluckman & Forti, 2011). The infant or child with a pneumothorax might have a sudden or gradual onset of symptoms. Chest pain might be present as well as signs of respiratory distress such as tachypnea, retractions, nasal flaring, or grunting. Assess risk factors for acquiring a pneumothorax, including chest trauma or surgery, intubation and mechanical ventilation, or a history of chronic lung disease such as cystic fibrosis. Inspect the child for a pale or cyanotic appearance. Auscultate for increased heart rate (tachycardia) and absent or diminished breath sounds on the affected side. The radiograph reveals air within the thoracic cavity (Fig. 40.9).

## Nursing Management

The child with a pneumothorax requires frequent respiratory assessments. Pulse oximetry might be used as an adjunct, but clinical evaluation of respiratory status is most useful. In some cases, administration of 100% oxygen hastens the reabsorption of air, but it is generally used only for a few hours (Gluckman & Forti, 2011). If a chest tube is connected to a dry suction or water seal apparatus, provide care of the drainage apparatus as appropriate (Fig. 40.10). A pair of hemostats should be kept at the bedside to clamp the tube should it become dislodged from the drainage

**FIGURE 40.10** The chest tube is connected to a suction or water seal via a drainage container.

container. The dressing around the chest tube is occlusive and is not routinely changed. If the tube becomes dislodged from the child's chest, apply Vaseline gauze and an occlusive dressing, immediately perform appropriate respiratory assessment, and notify the physician or nurse practitioner.

## CHRONIC RESPIRATORY DISORDERS

Chronic respiratory disorders include allergic rhinitis, asthma, chronic lung disease (bronchopulmonary dysplasia), cystic fibrosis, and apnea.

### Allergic Rhinitis

Allergic rhinitis is a common chronic condition in childhood, affecting a significant number of children. Aller-

**FIGURE 40.9** (A) Pneumothorax. (B) Note reinflation of the lung when the chest tube is present.

gic rhinitis is associated with atopic dermatitis and asthma. Perennial allergic rhinitis occurs year-round and is associated with indoor environments. Allergens commonly implicated in perennial allergic rhinitis include dust mites, pet dander, cockroach antigens, and molds. Seasonal allergic rhinitis is caused by elevations in outdoor levels of allergens. It is typically caused by certain pollens, trees, weeds, fungi, and molds. Complications from allergic rhinitis include exacerbation of asthma symptoms, recurrent sinusitis and otitis media, and dental malocclusion.

## Pathophysiology

Allergic rhinitis is an intermittent or persistent inflammatory state that is mediated by immunoglobulin E (IgE). In response to contact with an airborne allergen protein, the nasal mucosa mounts an immune response. The antigen (from the allergen) binds to a specific IgE on the surface of mast cells, releasing the chemical mediators of histamine and leukotrienes. The release of mediators results in acute tissue edema and mucus production. Late-phase mediators are released and more inflammation results. IgE binds to receptors on the surfaces of mast cells and basophils, creating the sensitization memory that causes the reaction with subsequent allergen exposures. Allergen exposure then results in mast cell degranulation and release of histamine and other chemotactic factors. Histamine and other factors cause nasal vasodilation, watery **rhinorrhea** (runny nose), and nasal congestion. Irritation of local nerve endings by histamine produces pruritus and sneezing. Treatment of allergic rhinitis is aimed at decreasing response to these allergic mediators as well as treating inflammation.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1394. Assessment findings pertinent to allergic rhinitis are discussed below.

### Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Mild, intermittent to chronic nasal stuffiness
- Thin, runny nasal discharge
- Sneezing
- Itching of nose, eyes, palate
- Mouth breathing and snoring

Determine the seasonality of symptoms. Are they perennial (year-round) or do they occur during certain seasons only? What types of medications or other treatments have been used, and what was the child's response?

Explore the history for the presence of risk factors such as:

- Family history of atopic disease (asthma, allergic rhinitis, or atopic dermatitis)
- Known allergy to dust mites, pet dander, cockroach antigens, pollens, or molds
- Early childhood exposure to indoor allergens
- Early introduction to foods or formula in infancy
- Exposure to tobacco smoke
- Environmental air pollution
- Recurrent viral infections (Sheikh & Najib, 2012)

Nonwhite race and higher socioeconomic status have also been noted as risk factors.

### Physical Examination

Physical examination of the child with allergic rhinitis includes inspection, observation, and auscultation.

#### INSPECTION AND OBSERVATION

Observe the child's facies for red-rimmed eyes or tearing, mild eyelid edema, "allergic shiners" (bluish or grayish cast beneath the eyes), and "allergic salute" (a transverse nasal crease between the lower and middle thirds of the nose that results from repeated nose rubbing) (Fig. 40.11). Inspect the nasal cavity. The turbinates may be swollen and gray/blue. Clear mucoid nasal drainage may be observed. Inspect the skin for rash. Listen for nasal phonation with speech.

**FIGURE 40.11** Allergic shiners beneath the eyes and allergic salute across the nose.

## AUSCULTATION

Auscultate the lungs for adequate aeration and clarity of breath sounds. In the child who also has asthma, exacerbation with wheezing often occurs with allergic rhinitis.

## Laboratory and Diagnostic Tests

The initial diagnosis is often made based on the history and clinical findings. Common laboratory and diagnostic studies ordered for the assessment of allergic rhinitis may include:

- Nasal smear (positive for eosinophilia)
- Positive allergy skin test
- Positive *radioallergosorbent test* (RAST)

To distinguish between the causes of nasal congestion, refer to Comparison Chart 40.1.

## Nursing Management

In addition to the nursing diagnoses and related interventions discussed in Nursing Care Plan 40.1 for disorders of the nose, mouth, and throat, interventions common to allergic rhinitis follow.

## Maintaining Patent Airway

The constant nasal obstruction that occurs with allergic rhinitis can be very problematic for some children. Performing nasal washes with normal saline may keep the nasal mucus from becoming thickened. Thickened, immobile secretions often lead to a secondary bacterial infection. The nasal wash also decongests the nose, allowing for improved nasal airflow. Anti-inflammatory (corticosteroid) nasal sprays can decrease the inflammatory response to allergens. A mast cell stabilizing nasal spray such as cromolyn sodium may decrease the intensity and frequency of allergic responses. Oral antihistamines are now available in once-daily dosing, providing convenience for the family. Some children may benefit from a combined antihistamine/nasal decongestant if nasal congestion is significant. Leukotriene modifiers such as montelukast may also be beneficial for some children.

## Providing Family Education

One of the most important tools in the treatment of allergic rhinitis is learning to avoid known allergens. Teaching Guidelines 40.4 gives information on educating families about avoidance of allergens. Children may be referred to a specialist for allergen desensitization (allergy shots). Products helpful with control of allergies are available from a number of vendors. Links to such vendors can be found on [thePoint](#).

## Teaching Guidelines 40.4

### CONTROLLING EXPOSURE TO ALLERGENS

#### Tobacco

- Avoid all exposure to tobacco smoke.
- If parents cannot quit, they must not smoke inside the home or car.

#### Dust Mites

- Use pillow and mattress covers.
- Wash sheets, pillowcases, and comforters once a week in 130°F water.
- Use blinds rather than curtains in bedroom.
- Remove stuffed animals from bedroom.
- Reduce indoor humidity to <50%.
- Remove carpet from bedroom.
- Clean solid-surface floors with wet mop each week.

#### Pet Dander

- Remove pets from home permanently.
- If unable to remove them, keep them out of bedroom and off carpet and upholstered furniture.

#### Cockroaches

- Keep kitchen very clean.
- Avoiding leaving food or drinks out.
- Use pesticides if necessary, but ensure that the asthmatic child is not inside the home when the pesticide is sprayed.

#### Indoor Molds

- Repair water leaks.
- Use dehumidifier to keep basement dry.
- Reduce indoor humidity to <50%.

#### Outdoor Molds, Pollen, and Air Pollution

- Avoid going outdoors when mold and pollen counts are high.
- Avoid outdoor activity when pollution levels are high.

Bethesda, MD: National Institutes of Health, National Heart, Lung and Blood Institute; and Ratcliffe, M. M., & Kieckhefer, G. M. (2010). Asthma. In P. J. Allen, J. A. Vessey, & N. A. Schapiro (Eds.), *Primary care of the child with a chronic condition* (5th ed.). St. Louis: Mosby.

## Asthma

Asthma is a chronic inflammatory airway disorder characterized by airway hyperresponsiveness, airway edema, and mucus production. Airway obstruction resulting from asthma might be partially or completely reversed. Severity ranges from long periods of control with infrequent acute exacerbations in some children to the presence

**HEALTHY PEOPLE 2020**

Objective	Nursing Significance
Reduce asthma deaths, hospitalizations for asthma, and hospital emergency department visits for asthma.	<ul style="list-style-type: none"> <li>• Appropriately educate children with asthma and their families about the ongoing management of asthma.</li> <li>• Provide appropriate education and triage to families of children with asthma, particularly when the child is experiencing symptoms or a decreased peak flow rate.</li> </ul>

*Healthy People* Objectives based on data from <http://www.healthypeople.gov>.

of persistent daily symptoms in others. It is the most common chronic illness of childhood and affects over 6 million American children (Tippets & Guilbert, 2009). A small percentage of children with asthma account for a large percentage of health care use and expense. Asthma accounts for almost 13 million lost school days per year and 14.5 million lost workdays on the part of parents (Tippets & Guilbert, 2009). The incidence and severity of asthma are increasing; this might be attributed to

increased urbanization, increased air pollution, and more accurate diagnosis. See Healthy People 2020.

Severity ranges from symptoms associated only with vigorous activity (exercise-induced bronchospasm) to daily symptoms that interfere with quality of life. Table 40.3 discusses classification of asthma severity. Though uncommon, childhood death related to asthma is also on the rise worldwide. Air pollution, allergens, family history, and viral infections might all play a role in asthma (Ratcliffe & Kieckhefer, 2010). Many children with asthma also have gastroesophageal disease, though the relationship between the two diseases is not clearly understood.

A significant long-term complication, chronic airway remodeling, may result from recurrent asthma exacerbation and inflammation. Children with asthma are more susceptible to serious bacterial and viral respiratory infections (Ratcliffe & Kieckhefer, 2010). Acute complications also include status asthmaticus and respiratory failure.
