In asthma, the inflammatory process contributes to increased airway activity. Thus, control or prevention of inflammation is the core of asthma management. Asthma results from a complex variety of responses in relation to a trigger. When the process begins, mast

**TABLE 40.3**

**ASTHMA SEVERITY CLASSIFICATION IN CHILDREN NOT TAKING LONG-TERM CONTROL MEDICATIONS**

Classification	Symptoms	Lung Function	Interference With Normal Activity	Short-Acting $\beta_2$ -Agonist Use for Symptom Control
Intermittent	<ul style="list-style-type: none"> <li>• 1 or 2 times a week</li> <li>• Nighttime symptoms 1 or 2 times a month</li> </ul>	FEV 80% or more of predicted	None	1 or 2 days per week
Mild persistent	<ul style="list-style-type: none"> <li>• Symptoms more than twice a week but less than once a day</li> <li>• Nighttime symptoms 3 or 4 times a month</li> </ul>	FEV 80% or more of predicted, variability	Minor limitation	Greater than twice per week, but not more than once a day
Moderate persistent	<ul style="list-style-type: none"> <li>• Daily symptoms</li> <li>• Nighttime symptoms &gt;1 time a week, but not nightly</li> </ul>	FEV 60% to 80% of predicted	Some limitation	Daily
Severe persistent	<ul style="list-style-type: none"> <li>• Throughout the day</li> <li>• Nighttime symptoms often 7 times per week</li> </ul>	FEV <60% of predicted	Extremely limited	Several times per day

FEV, forced expiratory volume.

**FIGURE 40.12** Note airway edema, mucus production, and bronchospasm occurring with asthma.

cells, T lymphocytes, macrophages, and epithelial cells are involved in the release of inflammatory mediators. Eosinophils and neutrophils migrate to the airway, causing injury. Chemical mediators such as leukotrienes, bradykinin, histamine, and platelet-activating factor also contribute to the inflammatory response. The presence of leukotrienes contributes to prolonged airway constriction. Autonomic neural control of airway tone is affected, airway mucus secretion is increased, mucociliary function changes, and airway smooth muscle responsiveness increases. As a result, acute bronchoconstriction, airway edema, and mucus plugging occur (Fig. 40.12).

In most children, this process is considered reversible and until recently it was not considered to have long-standing effects on lung function. Current research and scientific thought, however, recognize the concept of airway remodeling (Ratcliffe & Kieckhefer, 2010). Airway remodeling occurs as a result of chronic inflammation of the airway. Following the acute response to a trigger, continued allergen response results in a chronic phase. During this phase, the epithelial cells are denuded and the influx of inflammatory cells into the airway continues. This results in structural changes of the airway that are irreversible, and further loss of pulmonary function might occur. The irreversible changes include thickening of the sub-basement membrane, subepithelial fibrosis, airway smooth muscle hypertrophy and hyperplasia, blood vessel proliferation and dilation, and mucous gland hyperplasia and hypersecretion (National Asthma Education and Prevention Program [NAEPP], 2007). In some individuals with poorly controlled asthma, these changes may be permanent, resulting in decreased responsiveness to therapy.

## Therapeutic Management

Current goals of medical therapy are avoidance of asthma triggers and reduction or control of inflammatory episodes. The most recent recommendations by the NAEPP (2007) suggest a stepwise approach to medication man-

agement as well as control of environmental factors (allergens) and comorbid conditions that affect asthma. The NAEPP guidelines stress periodic assessment of asthma control. Treatment decisions may then be made based on the individual's level of asthma control, rather than on the severity at diagnosis. See Healthy People 2020.

The stepwise approach to asthma treatment involves increasing medications as the child's condition worsens, then backing off treatment as he or she improves (Box 40.3).

Short-acting bronchodilators may be used in the acute treatment of bronchoconstriction and long-acting forms may be used to prevent bronchospasm. Exercise-induced bronchospasm may occur in any child with asthma or as the only symptom in the child with mild

### HEALTHY PEOPLE 2020

#### Objective

Reduce activity limitations among persons with current asthma. Reduce the proportion of persons with asthma who miss school or work days. Increase the proportion of persons with current asthma who receive formal patient education.

#### Nursing Significance

- Encourage appropriate physical activity in children with asthma.
- Provide extensive education to children and families about peak flow meter use and its meaning, maintenance and rescue medications, symptoms of asthma exacerbation, and a written plan for how to “step up” and “step down” asthma management.
- Refer children and their families to local or Internet resources and support groups.
- Refer families to formal classes on asthma education.

*Healthy People* Objectives based on data from <http://www.healthypeople.gov>.

## BOX 40.3

**STEPWISE APPROACH TO ASTHMA MANAGEMENT**

All children: child education, environmental control, and management of comorbidities at each step. Consider referral to asthma specialist at step 3. (Step 2 and above are persistent asthma.)

Step 1 (intermittent asthma)

Preferred: short-acting  $\beta_2$ -agonist PRN

Step 2

Preferred: low-dose inhaled corticosteroid  
Alternative: cromolyn or leukotriene modifier

Step 3

Preferred: medium-dose inhaled corticosteroid (all ages) OR low-dose inhaled corticosteroid and leukotriene modifier or long-acting  $\beta_2$ -agonist (children older than 4 years)

Step 4

Preferred: medium-dose inhaled corticosteroids and long-acting  $\beta_2$ -agonist (can use leukotriene modifier in children younger than 4 years)

Step 5

Preferred: high-dose inhaled corticosteroids and long-acting  $\beta_2$ -agonist (or leukotriene modifier or theophylline)

Step 6

Preferred: high-dose inhaled corticosteroids, long-acting  $\beta_2$ -agonist, and oral systemic corticosteroids

Adapted from National Asthma Education and Prevention Program. (2007). *Expert panel report 3: Guidelines for the diagnosis and management of asthma* (NIH Publication No. 07-4051). Bethesda, MD: National Institutes of Health, National Heart, Lung and Blood Institute. These recommendations are intended to be used as a guide in individualized asthma care.

intermittent asthma. Most children may avoid exercise-induced bronchospasm by using a longer warm-up period prior to vigorous exercise and, if necessary, inhaling a short-acting bronchodilator just prior to exercise. Long-term prevention usually involves inhaled steroids. Leukotriene modifiers may be used as an alternative but are not preferred for mild persistent asthma (NAEPP, 2007).

**Take Note!**

Metered-dose inhalers using chlorofluorocarbon (CFC) as the propellant are no longer on the market. Environmentally friendly formulations of hydrofluoroalkane (HFA) are now used in all metered-dose inhalers (Ratcliffe & Kieckhefer, 2010).

**Nursing Assessment**

For a full description of the assessment phase of the nursing process, refer to page 1394. Assessment findings pertinent to asthma are discussed below.

**Health History**

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Cough, particularly at night: hacking cough that is initially nonproductive, becoming productive of frothy sputum
- Difficulty breathing: shortness of breath, chest tightness or pain, dyspnea with exercise
- Wheezing

Explore the child's current and past medical history for risk factors such as:

- History of allergic rhinitis or atopic dermatitis
- Family history of atopy (asthma, allergic rhinitis, atopic dermatitis)
- Recurrent episodes diagnosed as wheezing, bronchiolitis, or bronchitis
- Known allergies
- Seasonal response to environmental pollen
- Tobacco smoke exposure
- Poverty

**Physical Examination**

Physical examination of the child with asthma includes inspection, auscultation, and percussion.

**INSPECTION**

Observe the child's general appearance and color. During mild exacerbations, the child's color might remain pink, but as the child worsens, cyanosis might result. Work of breathing is variable. Some children present with mild retractions, while others demonstrate significant accessory muscle use and eventually head bobbing if not treated effectively. The child may appear anxious and fearful or may be lethargic and irritable. An audible wheeze might be present. Children with persistent severe asthma may have a barrel chest and routinely demonstrate mildly increased work of breathing.

**AUSCULTATION AND PERCUSSION**

A thorough assessment of lung fields is necessary. Wheezing is the hallmark of airway obstruction and might vary throughout the lung fields. Coarseness might also be present. Assess the adequacy of aeration. Breath sounds might be diminished in the bases or throughout. A quiet chest in an asthmatic child can be an ominous sign. With severe airway obstruction, air movement can be so poor that wheezes might not be heard upon auscultation. Percussion may yield hyperresonance.

**Laboratory and Diagnostic Tests**

Laboratory and diagnostic studies commonly ordered for the assessment of asthma include:

- Pulse oximetry: oxygen saturation may be decreased significantly or normal during a mild exacerbation
- Chest radiograph: usually reveals hyperinflation
- Blood gases: might show carbon dioxide retention and hypoxemia
- Pulmonary function tests (PFTs): can be very useful in determining the degree of disease but are not useful during an acute attack. Children as young as 5 or 6 years might be able to comply with spirometry.
- Peak expiratory flow rate (PEFR): is decreased during an exacerbation
- Allergy testing: skin test or RAST can determine allergic triggers for the asthmatic child

## Nursing Management

Initial nursing management of the child with an acute exacerbation of asthma is aimed at restoring a clear airway and effective breathing pattern as well as promoting adequate oxygenation and ventilation (gas exchange). Refer to Nursing Care Plan 40.1. Additional considerations are reviewed below.

### Educating the Child and Family

Asthma is a chronic illness and needs to be understood as such. Teach families of children with asthma, and the children themselves, how to care for the disease. Symptom-free periods (often very long) are interspersed with episodes of exacerbation. Parents and children often do not understand the importance of maintenance medications for long-term control. They may view the episodes of exacerbation (sometimes requiring hospitalization or emergency room visits) as an acute illness and are simply relieved when they are over. Frequently during the periods between acute episodes, children are viewed as disease-free and long-term maintenance schedules are abandoned. The prolonged inflammatory process occurring in the absence of symptoms, primarily in children with moderate to severe asthma, can lead to airway remodeling and eventual irreversible disease.

Each child should have a management plan in place to determine when to step up or step down treatment. Figure 40.13 provides an example of an action plan that may be helpful to families in the management of asthma. The action plan should also be kept on file at the child's school, and relief medication should be available to the child at all times. Children who experience exercise-induced bronchospasm may still participate in physical education or athletics, but may need to be allowed to use their medicine before the activity. Provide appropriate education to the child and family based on the child's individualized stepwise treatment plan. Stress the concept of maintenance medications for the prevention

of future serious disease in addition to controlling or preventing current symptoms.

Educate families and children on the appropriate use of nebulizers, metered-dose inhalers, spacers, dry-powder inhalers, and Diskus, as well as the purposes, functions, and side effects of the medications they deliver. Require return demonstrations of equipment use to ensure that children and families can use the equipment properly (Teaching Guidelines 40.5).

#### Take Note!

The NAEPP (2007) recommends use of a spacer or holding chamber with metered-dose inhalers to increase the bioavailability of medication in the lungs.

In children who have more severe asthma, the NAEPP (2007) recommends the use of the PEFR to determine daily control. PEFR measurements obtained via a home peak flow meter can be very helpful as long as the meter is used appropriately; Teaching Guidelines 40.6 gives instructions on peak flow meter use. The child's "personal best" is determined collaboratively with the physician or nurse practitioner during a symptom-free period. PEFR is measured daily at home using the peak flow meter. The asthma management plan then gives specific instructions based on the PEFR measurement (Table 40.4).

#### Take Note!

Young children with asthma receiving inhaled medications via a nebulizer should use a snugly fitting mask to ensure accurate deposition of medication to the lungs. Discourage "blow-by" via nebulizer, as medication delivery is variable and unreliable (NAEPP, 2007).

Avoidance of allergens is another key component of asthma management. Avoiding known triggers helps to prevent exacerbations as well as long-term inflammatory changes. This can be a difficult task for most families, particularly if the affected child suffers from several allergies. Refer to Teaching Guidelines 40.4 for strategies of allergen avoidance.

#### Take Note!

Teach the child and family that exposure to cigarette smoke increases the need for medications in children with asthma as well as the frequency of asthma exacerbations. Both indoor air quality and environmental pollution contribute to asthma in children (NAEPP, 2007).

Asthma education is a critical component for ensuring optimal health in children with asthma. This education is not limited to the hospital or clinic setting. Nurses can become involved in community asthma education: community-centered education in schools, churches, and day care centers or through peer educators has been

Name: \_\_\_\_\_ Date: \_\_\_\_\_

**ASTHMA ACTION PLAN**

**GREEN ZONE: Doing Well**

- ✓ No coughing, wheezing, chest tightness, or difficulty breathing
- ✓ Can work, play, exercise, perform usual activities without symptoms
- OR
- ✓ Peak flow \_\_\_\_\_ to \_\_\_\_\_ (80% to 100% of personal best)

Take these medicines every day for control and maintenance:

Medicine	How much to take	When and how often

**YELLOW ZONE: Caution/Getting Worse**

- ✓ Coughing, wheezing, chest tightness, or difficulty breathing
- ✓ Symptoms with daily activities, work, play, and exercise
- ✓ Nighttime awakenings with symptoms
- OR
- ✓ Peak flow \_\_\_\_\_ to \_\_\_\_\_ (50% to 80% of personal best)

CONTINUE your Green Zone medicines PLUS take these quick-relief medicines:

Medicine	How much to take	When and how often

**Call your doctor if you have been in the Yellow Zone for more than 24 hours.**

Also call your doctor if: \_\_\_\_\_

**RED ZONE: Alert!**

- ✓ Difficulty breathing, coughing, wheezing not helped with medications
- ✓ Trouble walking or talking due to asthma symptoms
- ✓ Not responding to quick relief medication
- OR
- ✓ Peak flow is less than \_\_\_\_\_ (50% of personal best)

**FOR EXTREME TROUBLE BREATHING/SHORTNESS OF BREATH GET IMMEDIATE HELP!**

Take these quick-relief medicines:

Medicine	How much to take	When and how often

**CALL your doctor NOW.**  
**GO to the hospital/emergency department or CALL for an ambulance NOW!**

This information is for general purposes and is not intended to replace the advice of a qualified health professional. For more information on asthma, visit [www.aaaai.org](http://www.aaaai.org). © 2009 American Academy of Allergy, Asthma & Immunology

**FIGURE 40.13** Asthma action plan. (Used with permission from American Academy of Allergy, Asthma and Immunology, <http://www.aaaai.org/professionals/asthma-action-plan.pdf>.)

shown to be effective. Education should include pathophysiology, asthma triggers, and prevention and treatment strategies. With such a large number of children affected with this chronic disease, community education has the potential to make a broad impact.

School nurses must also become experts in asthma management as well as being committed to ongoing education of the child and family. Resources for schools include:

- Open Airways for Schools: an educational program presented by the American Lung Association or its local chapter, focusing on increasing asthma awareness and compliance with asthma action plans and decreasing asthma emergencies. Contact the local lung association or call 1-800-LUNG-USA.
- Indoor Air Repair at School: a kit available from Allergy and Asthma Network Mothers of Asthmatics (AANMA); and Healthy School Environments Assessment Tool. Links to these and other helpful resources are provided on [thePoint.org](http://thePoint.org).

**Promoting the Child's Self-Esteem**

Fear of an exacerbation and feeling “different” from other children can harm a child’s self-esteem. In qualitative research studies, children have made such statements as “my body shuts down” and “I feel like I’m going to die” (Yoos et al., 2005). The fatigue and fear associated with chronic asthma may reduce the child’s confidence and sense of control over his or her body and life. In addition to coping with a chronic illness, the asthmatic child often also has to cope with school-related issues. Moodiness, acting out, and withdrawal correlate with increases in school absence, which can contribute to poor school performance. To live in fear of an exacerbation or to be unable to participate in activities affects the child’s self-esteem (Yoos et al., 2005).

Through education and support, the child can gain a sense of control. Children need to learn to master their disease. Accurate evaluation of asthma symptoms and improvement of self-esteem may help

## Teaching Guidelines 40.5

**USING ASTHMA MEDICATION DELIVERY DEVICES****Nebulizer**

1. Plug in the nebulizer and connect the air compressor tubing.

2. Add the medication to the medicine cup.

3. Attach the mask or the mouthpiece and hose to the medicine cup.

4. Place the mask on the child OR

5. Instruct the child to close the lips around the mouthpiece and breathe through the mouth.

6. After use, wash the mouthpiece and medicine cup with water and allow to air dry.

**Metered-Dose Inhaler**

1. Shake the inhaler and take off the cap.

2. Attach the inhaler to the spacer or holding chamber.

3. Breathe out completely.

4. Put the spacer mouthpiece in the mouth (or place the mask over the child's nose and mouth, ensuring a good seal).

5. Compress the inhaler and inhale slowly and deeply. Hold the breath for a count of 10.

**Diskus**

1. Hold the Diskus in a horizontal position in one hand and push the thumb grip with the thumb of your other hand away from you until mouthpiece is exposed.

2. Push the lever until it clicks (the dose is now loaded).

3. Breathe out fully.

4. Place your mouth securely around the mouthpiece and breathe in fully and quickly through your mouth.

5. Remove the Diskus, hold the breath for 10 seconds, and then breathe out.

**Turbuhaler**

1. Hold the Turbuhaler upright. Load the dose by twisting the brown grip fully to the right.

2. Then twist it to the left until you hear it click.

3. Breathe out fully.

4. Holding the Turbuhaler horizontally, place the mouth firmly around the mouthpiece and inhale deeply and forcefully.

5. Remove the Turbuhaler from the mouth and then breathe out.

### Teaching Guidelines 40.6 USING A PEAK FLOW METER

- Slide the arrow down to “zero.”
- Stand up straight.
- Take a deep breath and close the lips tightly around the mouthpiece.
- Blow out hard and fast.
- Note the number the arrow moves to.
- Repeat three times and record the highest reading.
- Keep a record of daily readings, being sure to measure peak flow at the same time each day.

Adapted from Ratcliffe, M. M., & Kieckhefer, G. M. (2010). Asthma. In P. J. Allen, J. A. Vessey, & N. A. Schapiro (Eds.), *Primary care of the child with a chronic condition* (5th ed.). St. Louis: Mosby.

the child to experience less panic with an acute episode. Improved self-esteem might also help the child cope with the disease in general and with being different from his or her peers. The school-age child has the cognitive ability to begin taking responsibility for asthma management, with continued involvement on the part of the parents. Transferring control of asthma care to the child is an important developmental process that will increase the child's feeling of control over the illness.

### Promoting Family Coping

Parent denial is an issue in many families. The family, through education and encouragement, can become the

experts on the child's illness as well as advocates for the child's well-being. The resilient child is better able to cope with the challenges facing him or her, including asthma. Cohesiveness and warmth in the family environment can improve a child's resiliency as well as contribute to family hardiness. Parents need to be allowed to ask questions and voice their concerns. A nurse who understands the family's issues and concerns is better able to plan for support and education. Provide culturally sensitive education and interventions that focus on increasing the family's commitment to, and control of, asthma management. As the child and parents become confident in their ability to recognize asthma symptoms and cope with asthma and its periodic episodes, the family's ability to cope will improve.

### Thinking About Development

Ryan Jennings is a 13-year-old male with a history of moderate asthma. He has been prescribed a preventer medication to be taken routinely and a rescue medicine to be used as needed and before exercise. He is a talented pitcher and would like to participate with his school's baseball team.

How will Ryan's developmental stage affect self-care related to his asthma? What is the most appropriate approach for the nurse to take to educate Ryan about his medications and disease process?

How will the nurse foster compliance in Ryan?

TABLE 40.4

## ASSESSMENT OF PEAK EXPIRATORY FLOW RATE (PEFR)

Zone <sup>a</sup>	PEFR	Symptoms	Action
Green: Good control	>80% personal best	None	Take usual medications.
Yellow: Caution	50% to 80% personal best	Possibly present	Take short-acting inhaled $\beta_2$ -agonist right away. Talk to your physician or nurse practitioner.
Red: Medical alert	<50% personal best	Usually present	Take short-acting inhaled $\beta_2$ -agonist right away. Go to office or emergency department.

<sup>a</sup>The National Asthma Education and Prevention Program recommended the “traffic light” approach for educating individuals on PEFRs and management plans.

Adapted from National Asthma Education and Prevention Program. (2007). *Expert panel report 3: Guidelines for the diagnosis and management of asthma* (NIH Publication No. 07-4051). Bethesda, MD: National Institutes of Health, National Heart, Lung and Blood Institute.

## Chronic Lung Disease

Chronic lung disease (formerly termed bronchopulmonary dysplasia) is often diagnosed in infants who have experienced RDS and continue to require oxygen at 28 days of age. It is a chronic respiratory condition seen most commonly in premature infants. It results from a variety of factors, including pulmonary immaturity, acute lung injury, barotrauma, inflammatory mediators, and volutrauma. Epithelial stretching, macrophage and polymorphonuclear cell invasion, and airway edema affect the growth and development of lung structures. Cilia loss and airway lining denudation reduce the normal cleansing abilities of the lung. The number of normal alveoli is reduced by one third to one half. Lower birthweights, white race, and male gender pose increased risk for development of chronic lung disease. Complications include pulmonary artery hypertension, cor pulmonale, congestive heart failure, and severe bacterial or viral pneumonia.

Anti-inflammatory inhaled medications are used for maintenance, and short-acting bronchodilators are used as needed for wheezing episodes. Supplemental long-term oxygen therapy may be required in some infants.

## Nursing Assessment

Tachypnea and increased work of breathing are characteristic of chronic lung disease. After discharge from the neonatal intensive care unit (NICU), these symptoms can continue. Exertion such as activity or oral feeding can cause dyspnea to worsen. Failure to thrive might also be evident. Auscultation might reveal breath sounds that are diminished in the bases. These infants have reactive airway episodes,

so wheezing might be present during times of exacerbation. If fluid overload develops, rales may be heard.

## Nursing Management

If the infant is oxygen dependent, provide education to the parents about oxygen tanks, nasal cannula use, pulse oximetry use, and nebulizer treatments. Often these children require increased-calorie formulas to grow adequately. Fluid restrictions and/or diuretics are necessary in some infants. Follow-up echocardiograms might be used to determine resolution of pulmonary artery hypertension prior to weaning from oxygen. Encourage developmentally appropriate activities. It might be difficult for the oxygen-dependent infant or toddler to reach gross motor milestones or explore the environment because the length of the oxygen tubing limits him or her.

Parental support is also a key nursing intervention. After a long and trying period of ups and downs with their newborn in the intensive care unit, parents find themselves exhausted caring for their medically fragile infant at home.

## Cystic Fibrosis

Cystic fibrosis is an autosomal recessive disorder that affects 30,000 children and adults in the United States (Cystic Fibrosis Foundation [CFF], 2011). A deletion occurring on the long arm of chromosome 7 at the cystic fibrosis transmembrane regulator (CFTR) is the responsible gene mutation. DNA testing can be used prenatally and in newborns to identify the presence of the mutation. The American College of Obstetrics and Gynecology currently recommends screening for cystic fibrosis

to any person seeking preconception or prenatal care. At present, all states include testing for cystic fibrosis as part of newborn screening (CFF, 2011).

Cystic fibrosis is the most common debilitating disease of childhood among those of European descent. Medical advances in recent years have greatly increased the length and quality of life for affected children, with median age for survival being the late 30s (CFF, 2011). Complications include hemoptysis, pneumothorax, bacterial colonization, cor pulmonale, volvulus, intussusception, intestinal obstruction, rectal prolapse, gastroesophageal reflux disease, diabetes, portal hypertension, liver failure, gallstones, and decreased fertility.

## Pathophysiology

In cystic fibrosis, the CFTR mutation causes alterations in epithelial ion transport on mucosal surfaces, resulting in generalized dysfunction of the exocrine glands. The epithelial cells fail to conduct chloride, and water transport abnormalities occur. This results in thickened, tenacious secretions in the sweat glands, gastrointestinal tract, pancreas, respiratory tract, and other exocrine tissues. The increased viscosity of these secretions makes them difficult to clear. The sweat glands produce a larger amount of chloride, leading to a salty taste of the skin and alterations in electrolyte balance and dehydration. The pancreas, intrahepatic bile ducts, intestinal glands, gallbladder, and submaxillary glands become obstructed by viscous mucus and eosinophilic material. Pancreatic enzyme activity is lost and malabsorption of fats, proteins, and carbohydrates occurs, resulting in poor growth and large, malodorous stools. Excess mucus is produced by the tracheobronchial glands. Abnormally thick mucus plugs the small airways, and then bronchiolitis and further plugging of the airways occur. Secondary bacterial infection with *Staphylococcus aureus*, *Pseudomonas aeruginosa*, and *Burkholderia cepacia* often occurs. This contributes to obstruction and inflammation, leading to chronic infection, tissue damage, and respiratory failure. Nasal polyps and recurrent sinusitis are common. Boys have tenacious seminal fluid and experience blocking of the vas deferens, often making them infertile (Hazle, 2010). In girls, thick cervical secretions might limit penetration of sperm. Table 40.5 gives further details of the pathophysiology and resulting respiratory and gastrointestinal clinical manifestations of cystic fibrosis.

## Therapeutic Management

Therapeutic management of cystic fibrosis is aimed toward minimizing pulmonary complications, maximizing lung function, preventing infection, and facilitating growth. All children with cystic fibrosis who have pulmonary involvement require chest physiotherapy

with postural drainage several times daily to mobilize secretions from the lungs. Physical exercise is encouraged. Recombinant human DNase (Pulmozyme) is given daily using a nebulizer to decrease sputum viscosity and help clear secretions. Inhaled bronchodilators and anti-inflammatory agents are prescribed for some children. Aerosolized antibiotics are often prescribed and may be given at home as well as in the hospital. Choice of antibiotic is determined by sputum culture and sensitivity results. Pancreatic enzymes and supplemental fat-soluble vitamins are prescribed to promote adequate digestion and absorption of nutrients and optimize nutritional status. Increased-calorie, high-protein diets are recommended, and sometimes supplemental high-calorie formula, either orally or via feeding tube, is needed. Some children require total parenteral nutrition to maintain or gain weight. Lung transplantation has been successful in some children with cystic fibrosis.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1394. Assessment findings pertinent to cystic fibrosis are discussed below.

### Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history in the undiagnosed child might include:

- A salty taste to the child's skin (resulting from excess chloride loss via perspiration)
- Meconium ileus or late, difficult passage of meconium stool in the newborn period
- Abdominal pain or difficulty passing stool (infants or toddlers might present with intestinal obstruction or intussusception at the time of diagnosis)
- Bulky, greasy stools
- Poor weight gain and growth despite good appetite
- Chronic or recurrent cough and/or upper or lower respiratory infections

Children known to have cystic fibrosis are often admitted to the hospital for pulmonary exacerbations or other complications of the disease. The health history should include questions related to:

- Respiratory status: has cough, sputum production, or work of breathing increased?
- Appetite and weight gain
- Activity tolerance
- Increased need for pulmonary or pancreatic medications
- Presence of fever
- Presence of bone pain
- Any other changes in physical state or medication regimen

TABLE 40.5

**PATHOPHYSIOLOGY OF CYSTIC FIBROSIS AND RESULTANT RESPIRATORY AND GASTROINTESTINAL CLINICAL MANIFESTATIONS**

Defect in the CFTR Gene Affects	Pathophysiology	Clinical Manifestations
Respiratory tract	<ul style="list-style-type: none"> <li>• Infection leads to neutrophilic inflammation.</li> <li>• Cleavage of complement receptors and immunoglobulin G leads to opsonophagocytosis failure.</li> <li>• Chemoattractant interleukin-8 and elastin degradase contribute to inflammatory response.</li> <li>• Thick, tenacious sputum that is chronically colonized with bacteria results.</li> <li>• Air trapping related to airway obstruction occurs.</li> <li>• Pulmonary parenchyma is eventually destroyed.</li> </ul>	<ul style="list-style-type: none"> <li>• Airway obstruction</li> <li>• Difficulty clearing secretions</li> <li>• Respiratory distress and impaired gas exchange</li> <li>• Chronic cough</li> <li>• Barrel-shaped chest</li> <li>• Decreased pulmonary function</li> <li>• Clubbing</li> <li>• Recurrent pneumonia</li> <li>• Hemoptysis</li> <li>• Pneumothorax</li> <li>• Chronic sinusitis</li> <li>• Nasal polyps</li> <li>• Cor pulmonale (right-sided heart failure)</li> </ul>

Adapted from Federico, M. J. (2011). Respiratory tract & mediastinum. In W. W. Hay, M. J. Levin, J. M. Sondheimer, & R. R. Deterding (Eds.), *Current pediatric diagnosis and treatment* (20th ed.). New York: McGraw-Hill; and Hazle, L. A. (2010). Cystic fibrosis. In P. J. Allen, J. A. Vessey, & N. A. Schapiro (Eds.), *Primary care of the child with a chronic condition* (5th ed.). St. Louis: Mosby.

## Physical Examination

The physical examination includes inspection, auscultation, percussion, and palpation.

### INSPECTION

Observe the child's general appearance and color. Check the nasal passages for polyps. Note respiratory rate, work of breathing, use of accessory muscles, position of comfort, frequency and severity of cough, and quality and quantity of sputum produced. The child with cystic fibrosis often has a barrel chest (anterior–posterior diameter

approximates transverse diameter) (Fig. 40.14). Clubbing of the nail beds might also be present. Note whether rectal prolapse is present. Does the child appear small or thin for his or her age? The child might have a protuberant abdomen and thin extremities, with decreased amounts of subcutaneous fat. Observe for the presence of edema (sign of cardiac or liver failure). Note distended neck veins or the presence of a heave (signs of cor pulmonale).

### AUSCULTATION

Auscultation may reveal a variety of adventitious breath sounds. Fine or coarse crackles and scattered or localized

**FIGURE 40.14** (A) Normal chest shape—transverse diameter is greater than anterior–posterior diameter. (B) Barrel chest—transverse diameter equals anterior–posterior diameter.

wheezing might be present. With progressive obstructive pulmonary involvement, breath sounds might be diminished. Tachycardia might be present. Note the presence of a gallop (might occur with cor pulmonale). Note the adequacy of bowel sounds.

#### PERCUSSION

Percussion over the lung fields usually yields hyperresonance due to air trapping. Diaphragmatic excursion might be decreased. Percussion of the abdomen might reveal dullness over an enlarged liver or mass related to intestinal obstruction.

#### PALPATION

Palpation might yield a finding of asymmetric chest excursion if atelectasis is present. Tactile fremitus may be decreased over areas of atelectasis. Note if tenderness is present over the liver (might be an early sign of cor pulmonale).

### Laboratory and Diagnostic Tests

Common laboratory and diagnostic studies ordered for the diagnosis and assessment of cystic fibrosis include:

- Sweat chloride test: considered suspicious if the level of chloride in collected sweat is above 50 mEq/L and diagnostic if the level is above 60 mEq/L

- Pulse oximetry: oxygen saturation might be decreased, particularly during a pulmonary exacerbation
- Chest radiograph: may reveal hyperinflation, bronchial wall thickening, atelectasis, or infiltration
- Pulmonary function tests: might reveal a decrease in forced vital capacity and forced expiratory volume, with increases in residual volume

### Nursing Management

Management of cystic fibrosis focuses on minimizing pulmonary complications, promoting growth and development, and facilitating coping and adjustment by the child and family. In addition to the nursing diagnoses and related interventions discussed in Nursing Care Plan 40.1 for respiratory disorders, interventions common to cystic fibrosis follow.

#### Maintaining Patent Airway

Chest physiotherapy is often used as an adjunct therapy in respiratory illnesses, but for children with cystic fibrosis it is a critical intervention. Chest physiotherapy involves percussion, vibration, and postural drainage, and either it or another bronchial hygiene therapy must be performed several times a day to assist with mobilization of secretions. Nursing Procedure 40.2 gives instructions on the chest physiotherapy technique.

For older children and adolescents, the flutter-valve device, positive expiratory pressure therapy, or a high-frequency chest compression vest may also be used. The flutter valve device provides high-frequency oscillation to the airway as the child exhales into a mouthpiece that contains a steel ball. Positive expiratory pressure therapy involves exhaling through a flow resistor, which creates positive expiratory pressure. The cycles of exhalation are repeated until coughing yields expectoration of secretions. The vest airway clearance system provides high-frequency chest wall oscillation to increase airflow velocity to create repetitive cough-like shear forces and to decrease the viscosity of secretions. Breathing exercises are also helpful in promoting mucus clearance. Encourage physical exercise, as it helps to promote mucus secretion as well as provides cardiopulmonary conditioning. Ensure that Pulmozyme is administered, as well as inhaled bronchodilators and anti-inflammatory agents if prescribed.

#### Preventing Infection

Vigorous pulmonary hygiene for mobilization of secretions is critical to prevent infection. Aerosolized antibiotics can be given at home as well as in the hospital. Children with frequent or severe respiratory exacerbations might require lengthy courses of intravenous antibiotics.

## NURSING PROCEDURE 40.2

## Performing Chest Physiotherapy

1. Provide percussion via a cupped hand or an infant percussion device. Appropriate percussion yields a hollow sound, not a slapping sound.

2. Percuss each segment of the lung for 1 to 2 minutes.

POSITION #1  
UPPER LOBES, Apical segments

POSITION #1, for infants  
UPPER LOBES, Apical segments

LOWER LOBES, Anterior basal segmentsPOSITION #7  
LOWER LOBES, Posterior basal segmentsPOSITION #8 & 9  
LOWER LOBES, Lateral basal segmentsPOSITION #10  
LOWER LOBES, Superior segments

3. Place the ball of the hand on the lung segment, keeping the arm and shoulder straight. Vibrate by tensing and relaxing your arms during the child's exhalation. Vibrate each lung segment for at least five exhalations.

4. Encourage the child to deep breathe and cough.  
5. Change drainage positions and repeat percussion and vibration.

## Maintaining Growth

Pancreatic enzymes must be administered with all meals and snacks to promote adequate digestion and absorption of nutrients. The number of capsules required depends on the extent of pancreatic insufficiency and the amount of food being ingested. The dosage can be adjusted until an adequate growth pattern is established and the number of stools is consistent at one or two per day. Children will need additional enzyme capsules when high-fat foods are being eaten. In the infant or young child, the enzyme capsule can be opened and sprinkled on cereal or applesauce. A well-balanced, high-calorie, high-protein diet is necessary to ensure adequate growth. Some children require up to 1.5 times the recommended daily allowance of calories for children their age. A number of commercially available nutritional formulas and shakes are available for diet supplementation.

In infants, breastfeeding should be continued with enzyme administration. Some infants will require fortification of breast milk or supplementation with high-calorie formulas. Commercially available infant formulas can continue to be used for the formula-fed infant and can be mixed to provide a larger amount of calories if necessary. Supplementation with vitamins A, D, E, and K is necessary. Administer gavage feedings or total parenteral nutrition as prescribed to provide for adequate growth.

## Promoting Family Coping

Cystic fibrosis is a serious chronic illness that requires daily interventions. It can be hard to maintain a schedule that requires pulmonary hygiene several times daily as well as close attention to appropriate diet and enzyme supplementation. Adjusting to the demands that the illness places on the child and family is difficult. Continual adjustments within the family must occur. Children are frequently hospitalized, and this may place an additional strain on the family and its finances. Children with cystic fibrosis may express fear or feelings of isolation, and siblings may be worried or jealous. Encourage the family to lead a normal life through involvement in activities and school attendance during periods of wellness.

### Take Note!

Massage therapy performed by the parent, nurse, or licensed massage therapist may help to improve mood or relieve pain in the child with cystic fibrosis. It may have the added benefit of improving respiratory status, but it does not replace chest physiotherapy (Lee, Holdsworth, Holland, & Button, 2009).

Starting at the time of diagnosis, families often demonstrate significant stress as the severity of the diagnosis and the significance of disease chronicity become real for them. The family should be involved in the child's care

from the time of diagnosis, whether in the outpatient setting or in the hospital. Ongoing education about the illness and its treatments is necessary. Once the initial shock of diagnosis has passed and the family has adjusted to initial care, the family usually learns how to manage the requirements of care. Powerlessness gives way to adaptation. As family members become more comfortable with their understanding of the illness and the required treatments, they will eventually become the experts on the child's care. It is important for the nurse to recognize and respect the family's changing needs over time.

Providing daily intense care can be tiring, and non-compliance on the part of the family or child might occur as a result of this fatigue. Overvigilance may also occur as parents attempt to control the difficult situation and protect the child. Families welcome support and encouragement. Most families eventually progress past the stages of fear, guilt, and powerlessness to a way of living that is different than what they anticipated but is something that they can manage.

Refer parents to a local support group for families of children with cystic fibrosis. The Cystic Fibrosis Foundation has chapters throughout the United States. Links to The Cystic Fibrosis Foundation and other helpful resources can be found on [thePoint](#).

Parents of children with a terminal illness might face the death of their child at an earlier age than expected. Assisting with anticipatory grieving and making decisions related to end-of-life care are other important nursing interventions.

## Preparing the Child and Family for Adulthood With Cystic Fibrosis

With current technological and medication advances, many more children with cystic fibrosis are surviving to adulthood and into their 30s and 40s (CFF, 2011). Lung transplantation is now being used in some children with success, thus prolonging life expectancy (barring transplant complications) (Hazle, 2010). Children with cystic fibrosis should have the goal of independent living as an adult, as other children do. Making the transition from a pediatric medical home to an adult medical home should be viewed as a normal part of growing up, similar to completing school or finding a first job. Pediatric clinics are focused on family-centered care that heavily involves the child's parents, but adults with cystic fibrosis need a different focus, one that views them as independent adults.

Those with cystic fibrosis can make the transition from pediatric to adult care with thoughtful preparation and coordination. They desire and deserve a smooth transition in care that will result in appropriate ongoing medical management of cystic fibrosis in an environment that is geared toward adults rather than children.

Adults with cystic fibrosis are able to find rewarding work and pursue relationships. Most men with cystic

fibrosis are capable of sexual intercourse, though unable to reproduce. Females might have difficulty conceiving, and when they do they should be cautioned about the additional respiratory strain that pregnancy causes. All children of parents with cystic fibrosis will be carriers of the gene.

## Apnea

Apnea is defined as absence of breathing for longer than 20 seconds; it might be accompanied by bradycardia. Sometimes apnea presents in the form of an acute life-threatening event (ALTE), an event in which the infant or child exhibits some combination of apnea, color change, muscle tone alteration, coughing, or gagging. Apnea may also occur acutely at any age as a result of respiratory distress. This discussion will focus on apnea that is chronic or recurrent in nature or that occurs as part of an ALTE.

Apnea in infants may be central (unrelated to any other cause) or may occur with other illnesses such as sepsis and respiratory infection. Apnea in newborns might be associated with hypothermia, hypoglycemia, infection, or hyperbilirubinemia. Apnea of prematurity occurs secondary to an immature respiratory system. Apnea should not be considered a predecessor to sudden infant death syndrome (SIDS). Current research has not proven this theory, and SIDS generally occurs in otherwise healthy young infants (American Academy of Pediatrics [AAP], 2009). Box 40.4 gives more information about SIDS and its prevention.

Therapeutic management of apnea varies depending on the cause. When apnea occurs as a result of another disorder or infection, treatment is directed toward that cause. In the event of apnea, stimulation may trigger the infant to take a breath. If breathing does not resume, rescue breathing or bag-valve-mask ventilation is necessary. Infants and children who have experienced an ALTE or who have chronic apnea may require ongoing cardiac/apnea monitoring. Caffeine or theophylline is sometimes administered, primarily in premature infants, to stimulate respirations (Kelly, 2010).

## Nursing Assessment

Question the parents about the infant's position and activities preceding the apneic episode. Did the infant experience a color change? Did the infant self-stimulate (breathe again on his or her own), or did he or she require stimulation from the caretaker? Assess risk factors for apnea, which may include prematurity, anemia, and history of metabolic disorders. Apnea may occur in association with cardiac or neurologic disturbances, respiratory infection, sepsis, child abuse, or poisoning.

In the hospitalized infant, note absence of respiration, position, color, and other associated findings, such as emesis on the bedclothes. If an infant who is apneic

### BOX 40.4

## SUDDEN INFANT DEATH SYNDROME (SIDS)

### Definition

Sudden death of a previously healthy infant younger than 1 year of age

### Prevention

- Place all infants in the supine position to sleep (even side-lying is not as safe and is not recommended by the AAP).
- Provide a firm sleep surface and avoid soft bedding, excess covers, pillows, and stuffed animals in the crib.
- Avoid maternal prenatal smoking and exposure of the infant to second-hand smoke.
- Ensure the infant sleeps separately from the parents.
- Avoid overbundling or overdressing the infant.
- Encourage pacifier use during naps and at bedtime if the infant is receptive to it (AAP, 2009).

### Support and Information

- Association for SIDS and Infant Mortality Program: [www.asip1.org](http://www.asip1.org)
- National Sudden Infant Death Resource Center: [www.sidscenter.org](http://www.sidscenter.org)
- SIDS Alliance: [www.sidsalliance.org](http://www.sidsalliance.org)
- Sudden Infant Death Syndrome Network, Inc.: <http://sids-network.org/>

fails to be stimulated and does not breathe again, pulselessness will result.

## Nursing Management

When an infant is noted to be apneic, gently stimulate him or her to take a breath again. If gentle stimulation is unsuccessful, then rescue breathing or bag-valve-mask ventilation must be started.

To avoid apnea in the newborn, maintain a neutral thermal environment. Avoid excessive vagal stimulation and taking rectal temperatures (the vagal response can cause bradycardia, resulting in apnea) (Jarvis, 2008). Administer caffeine or theophylline if prescribed and teach families about the use of these medications.

Infants with recurrent apnea or ALTE may be discharged on a home apnea monitor (Fig. 40.15). Provide education on use of the monitor, guidance about when to notify the physician or monitor service about alarms, and training in infant cardiopulmonary resuscitation (CPR). The monitor is usually discontinued after 3 months without a significant event of apnea or bradycardia. In some ways the monitor gives parents peace of mind, but in others it can make them more nervous about the well-being

**FIGURE 40.15** The home apnea monitor uses a soft belt with a Velcro attachment to hold two leads in the appropriate position on the chest.

of their child. Parents often experience disrupted sleep and some may display negative coping patterns (Scollan-Koliopoulos & Koliopoulos, 2010). Providing appropriate education to the parents about the nature of the child's disorder as well as action to take in the event of apnea may give the family a sense of mastery over the situation, thus decreasing their anxiety. Refer families to local support groups such as those offered by Parent to Parent and Parents Helping Parents.

## TRACHEOSTOMY

A **tracheostomy** is an artificial opening in the airway; usually a plastic tracheostomy tube is in place to form a patent airway. Tracheostomies are performed to relieve airway obstruction, such as with subglottic stenosis (narrowing of the airway sometimes resulting from long-term intubation). They are also used for pulmonary toilet and in the child who requires chronic mechanical ventilation. The tracheostomy facilitates secretion removal, reduces work of breathing, and increases the child's comfort. In some cases the tracheostomy facilitates mechanical ventilation weaning. It may be permanent or temporary, depending on the indication. The tracheostomy tube varies in size and type depending on the child's airway size and health and the length of time the child will require the tracheostomy. Silastic tracheostomy tubes are soft and flexible; they are available with a single lumen or may have an outer and inner lumen. Both types have an obturator (the guide used during tube changes). Uncuffed tubes are used more often in the pediatric population (Deutsch, 2010). Figure 40.16 shows various types of tracheostomy tubes.

Complications immediately after surgery include hemorrhage, air entry, pulmonary edema, anatomic damage, and respiratory arrest. At any point in time the tracheostomy tube may become occluded, which compromises ventilation. Complications of chronic tracheostomy include infection, cellulitis, and formation of granulation tissue around the insertion site.

**FIGURE 40.16** Note smaller size and absence of inner cannula on particular brands of pediatric tracheostomy tubes.

## Nursing Assessment

When obtaining the history for a child with a tracheostomy, note the reason for the tracheostomy, as well as the size and type of tracheostomy tube. Inspect the site. The stoma should appear pink and without bleeding or drainage. The tube itself should be clean and free from secretions. The tracheostomy ties should fit securely, allowing one finger to slide beneath the ties (Fig. 40.17). Inspect the skin under the ties for rash or redness. Observe work of breathing.

When caring for the infant or child with a tracheostomy, whether in the hospital, home, or community setting, a thorough respiratory assessment is necessary. Note presence of secretions and their color, thickness, and amount. Auscultate for breath sounds, which should be clear and equal throughout all lung fields. Measure pulse

**FIGURE 40.17** Properly fitting trach ties. One fingerwidth fits between the ties and the child's neck.

oximetry. When infection is suspected or secretions are discolored or have a foul odor, a sputum culture may be obtained.

### Take Note!

Keep small toys (risk of aspiration), plastic bibs or bedding (risk of airway occlusion), and talcum powder (risk of inhalation injury) out of reach of the child with a tracheostomy.

## Nursing Management

In the immediate postoperative period the infant or child may require restraints to avoid accidental dislodgment of the tracheostomy tube. Infants and children who have had a tracheostomy for a period of time become accustomed to it and usually do not attempt to remove the tube. Since air inspired via the tracheostomy tube bypasses the upper airway, it lacks humidification, and this lack of humidity can lead to a mucous plug in the tracheostomy and resultant hypoxia. Provide humidity to either room air or oxygen via a tracheostomy collar or ventilator, depending on the child's need (Fig. 40.18). Box 40.5 lists the equipment that should be available at the bedside of any child who has a tracheostomy.

Tracheostomies require frequent suctioning to maintain patency. The appropriate length for insertion of the suction catheter depends on the size of the tracheostomy and the child's needs. Place a sign at the head of the child's bed indicating the suction catheter size and the length (in centimeters) that it should be inserted for suctioning. Keep an extra tracheostomy tube of the same size and one size smaller at the bedside in the event of an emergency.

Many pediatric tracheostomy tubes do not have an inner cannula that requires periodic removal and cleaning, so periodic removal and replacement of the chronic tracheostomy tube is required. Clean the removed tracheostomy tube with half-strength hydrogen peroxide and pipe cleaners. Rinse with distilled water

**FIGURE 40.18** The trach collar allows for humidification of inspired air or supplemental oxygen.

### BOX 40.5

#### EMERGENCY EQUIPMENT (AVAILABLE AT BEDSIDE)

- Two spare tracheostomy tubes (one the same size and one a size smaller)
- Suction equipment
- Stitch cutter (new tracheostomy)
- Spare tracheostomy ties
- Lubricating jelly
- Bag-valve-mask device
- Call bell within child's/parent's reach

and allow it to dry. The tracheostomy tube can be reused many times if adequately cleaned between uses.

Perform tracheostomy care every 8 hours or per institution protocol. Change the tracheostomy tube only as needed or per institution protocol. Nursing Procedure 40.3 gives information about tracheostomy care. Always

### NURSING PROCEDURE 40.3

#### Tracheostomy Care

1. Gather the necessary equipment:
  - Cleaning solution
  - Gloves
  - Precut gauze pad
  - Cotton-tipped applicators
  - Clean tracheostomy ties
  - Scissors
  - Extra tracheostomy tube in case of accidental dislodgement
2. Position the infant/child supine with a blanket or towel roll to extend the neck.
3. Open all packaging and cut tracheostomy ties to appropriate length if necessary.
4. Cleanse around the tracheostomy site with prescribed solution (half-strength hydrogen peroxide or acetic acid, normal saline or soap and water if at home) and cotton-tipped applicators, working from just around the tracheostomy tube outward.
5. Rinse with sterile water and cotton-tipped applicator in similar fashion.
6. Place the precut sterile gauze under the tracheostomy tube.
7. With the assistant holding the tube in place, cut the ties and remove from the tube.
8. Attach the clean ties to the tube and tie or secure in place with Velcro.

change tracheostomy ties with an assistant to avoid accidental dislodgement of the tube.

If the older child or teen has a tracheostomy tube with an inner cannula, care of the inner cannula is similar to that of an adult. Involve parents in care of the tracheostomy and begin education about caring for the tracheostomy tube at home as soon as the child is stable. The child with a tracheostomy often qualifies for a Medicaid waiver that will provide a certain amount of home nursing care. Refer the family to local support groups. Links for additional helpful resources can be found on [thePoint](#).

### KEY CONCEPTS

- Respiratory infections account for the majority of acute illnesses in children.
- The upper and lower airways are smaller in children than adults, making them more susceptible to obstruction in the presence of mucus, debris, or edema.
- Newborns are obligatory nose breathers.
- The child's highly compliant airway is quite susceptible to dynamic collapse in the presence of airway obstruction.
- Because they have fewer alveoli, children have a higher risk for hypoxemia than adults.
- Generally, disorders of the nose and throat do not result in increased work of breathing or affect the lungs. Thus, if the lungs are involved, lower respiratory disease must be considered.
- Wheezing may be associated with a variety of lower respiratory disorders, such as asthma, bronchiolitis, and cystic fibrosis.
- Pulse oximetry is a useful tool for determining the extent of hypoxia. Findings should be correlated with the child's clinical presentation.
- Rapid streptococcus and rapid influenza tests are very useful for the quick diagnosis of strep throat or influenza so that appropriate treatment may be instituted early in the illness.
- Supplemental oxygen is often necessary in the child who is hospitalized (particularly with lower respiratory disease). Oxygen should be humidified to prevent drying of secretions.
- Suctioning, whether with a bulb syringe or suction catheter, is very effective at maintaining airway patency, especially in the younger child or infant.
- Normal saline nasal wash is an inexpensive, simple, and safe method for decongesting the nose in the case of the common cold, allergic rhinitis, and sinusitis.
- Infants who were born prematurely; children with a chronic illness such as diabetes, congenital heart disease, sickle cell anemia, or cystic fibrosis; and children with developmental disorders such as cerebral palsy tend to be more severely affected with respiratory disorders.
- Passive cigarette smoke exposure increases the infant's and child's risk for respiratory disease.
- Continual swallowing while awake or asleep is an indication of bleeding in the postoperative tonsillectomy child.
- Positioning to ease work of breathing and maintaining a patent airway are priorities for the child with a respiratory disorder.
- To avoid Reye syndrome, aspirin should not be given to treat fever or pain in the infant or child with a viral infection.
- Infants and children at high risk for serious RSV disease should be immunized with Synagis each RSV season. Children older than 6 months of age should be immunized against influenza yearly.
- Children at high risk for exposure to tuberculosis should be screened for infection.
- Promoting airway clearance and maintenance, effective breathing patterns, and adequate gas exchange is the priority focus of nursing intervention in pediatric respiratory disease.
- Children with any degree of respiratory distress require frequent assessment and early intervention to prevent progression to respiratory failure.
- Avoidance of allergens is critical in the treatment plan for the child with allergic rhinitis.
- Avoidance of allergic triggers, control of the inflammatory process, and education of the child and family are the focus of asthma management.
- Chest physiotherapy is extremely useful for mobilizing secretions in any condition resulting in an increase in mucus production and is required in children with cystic fibrosis.
- Children with chronic respiratory disorders and their families often need large amounts of education and psychosocial support: children often experience fear and isolation, while families must learn to balance care of the chronically ill child with other family life.

## MULTIPLE CHOICE QUESTIONS

1. A 5-month-old infant with RSV bronchiolitis is in respiratory distress. The baby has copious secretions, increased work of breathing, cyanosis, and a respiratory rate of 78. What is the most appropriate initial nursing intervention?
  - a. Attempt to calm the infant by placing him in his mother's lap and offering him a bottle.
  - b. Alert the physician to the situation and ask for an order for a stat chest radiograph.
  - c. Suction secretions, provide 100% oxygen via mask, and anticipate respiratory failure.
  - d. Bring the emergency equipment to the room and begin bag-valve-mask ventilation.
2. A toddler has moderate respiratory distress, is mildly cyanotic, and has increased work of breathing, with a respiratory rate of 40. What is the priority nursing intervention?
  - a. Airway maintenance and 100% oxygen by mask.
  - b. 100% oxygen and pulse oximetry monitoring.
  - c. Airway maintenance and continued reassessment.
  - d. 100% oxygen and provision of comfort.
3. The nurse is caring for a child with cystic fibrosis who receives pancreatic enzymes. Which statement by the child's mother indicates an understanding of how to administer the supplemental enzymes?
  - a. "I will stop the enzymes if my child is receiving antibiotics."
  - b. "I will decrease the dose by half if my child is having frequent, bulky stools."
  - c. "Between meals is the best time for me to give the enzymes."
  - d. "The enzymes should be given at the beginning of each meal and snack."
4. Which of these factors contributes to infants' and children's increased risk for upper airway obstruction as compared with adults?
  - a. Underdeveloped cricoid cartilage and narrow nasal passages.
  - b. Small tonsils and narrow nasal passages.
  - c. Cylinder-shaped larynx and underdeveloped sinuses.
  - d. Underdeveloped cricoid cartilage and smaller tongue.
5. Which is the most appropriate treatment for epistaxis?
  - a. With the child lying down and breathing through the mouth, apply pressure to the bridge of the nose.
  - b. With the child lying down and breathing through the mouth, pinch the lower third of the nose closed.

- c. With the child sitting up and leaning forward, apply pressure to the bridge of the nose.
- d. With the child sitting up and leaning forward, pinch the lower third of the nose closed.

## CRITICAL THINKING EXERCISES

1. A 10-month-old girl is admitted to the pediatric unit with a history of recurrent pneumonia and failure to thrive. Her sweat chloride test confirms the diagnosis of cystic fibrosis. She is a frail-appearing infant with thin extremities and a slightly protuberant abdomen. She is tachypneic, has retractions, and coughs frequently. Based on the limited information given here and your knowledge of cystic fibrosis, choose three of the categories below as priorities to focus on when planning her care:
  - a. Prevention of bronchospasm
  - b. Promotion of adequate nutrition
  - c. Education of the child and family
  - d. Prevention of pulmonary infection
  - e. Balancing fluid and electrolytes
  - f. Management of excess weight gain
  - g. Prevention of spread of infection
  - h. Promoting adequate sleep and rest
2. A boy with asthma is admitted to the pediatric unit for the fourth time this year. The mother expresses frustration that he is getting sick so often. Besides information about onset of symptoms and events leading up to this present episode, what other types of information would you ask for while obtaining the history?
3. The mother of the boy in the previous question tells you that she smokes (but never around the boy), the family has a cat that comes inside sometimes, and she always gives her son the medication prescribed. She gives salmeterol and budesonide as soon as he starts to cough. When he is not having an episode, she gives him albuterol before his baseball games. Diphenhydramine helps his runny nose in the springtime. Based on this new information, what advice/instructions would you give the mother?
4. A 7-year-old presents with a history of recurrent nasal discharge. He sneezes every time he visits his cousins, who have pets. He lives in an older home that is carpeted. Tobacco smokers live in the home. His mother reports that he snores and is a mouth breather. She says he has symptoms nearly year-round, but they are worse in the fall and the spring. She reports that diphenhydramine is somewhat helpful with his symptoms, but she doesn't like to give it to him on school

days because it makes him drowsy. Based on the history above, develop a teaching plan for this child.

5. The nurse is caring for a 4-year-old girl who returned from the recovery room after a tonsillectomy 3 hours ago. She has cried off and on over the past 2 hours and is now sleeping. What areas should the nurse assess and focus on for this child?

## STUDY ACTIVITIES

1. While caring for children in the pediatric setting, compare the signs and symptoms of a child with asthma to those of an infant with bronchiolitis. What are the most notable differences? How does the history of the two children differ?
2. A child with asthma has been prescribed Advair (fluticasone and salmeterol), albuterol, and prednisone. Develop a sample teaching plan for the child and family. Include appropriate use of the devices used to deliver the medications, as well as important information about the medications (uses and adverse effects).
3. While caring for children in the pediatric setting, compare the signs and symptoms and presentation of a child with the common cold to those of a child with either sinusitis or allergic rhinitis.
4. While caring for children in the pediatric setting, review the census of children and identify those at risk for severe influenza and thus those who would benefit from annual influenza vaccination.
5. Compare the differences in oxygen administration between a young infant and an older child.

# Nursing Care of the Child With a Cardiovascular Disorder

## Learning Objectives

*Upon completion of the chapter, you will be able to:*

1. Define the key terms used in this chapter.
2. Compare anatomic and physiologic differences of the cardiovascular system in infants and children versus adults.
3. Describe nursing care related to common laboratory and diagnostic tests used in the medical diagnosis of pediatric cardiovascular conditions.
4. Distinguish cardiovascular disorders common in infants, children, and adolescents.
5. Identify appropriate nursing assessments and interventions related to medications and treatments for pediatric cardiovascular disorders.
6. Develop an individualized nursing care plan for the child with a cardiovascular disorder.
7. Describe the psychosocial impact of chronic cardiovascular disorders on children.
8. Devise a nutrition plan for the child with cardiovascular disease.
9. Develop child/family teaching plans for the child with a cardiovascular disorder.

*Logan Bernstein, 6 weeks old, is brought to the clinic by his mother. He presents with poor feeding. His mother states, “Logan falls asleep while feeding, and he’s always very sweaty during feedings.”*

### Words of Wisdom

The heart of the matter is healing the child’s heart so he or she can embrace life to its fullest.

**Cardiovascular** disease is a significant cause of chronic illness and death in children. Typically cardiovascular disorders in children are divided into two major categories—congenital heart disease (CHD) and acquired heart disease.

Congenital heart disease is defined as structural anomalies that are present at birth, though they are often not diagnosed until later in life. CHD accounts for the largest percentage of all birth defects. About 36,000 babies are born annually with a congenital heart defect (American Heart Association [AHA], 2011b).

Acquired heart disease includes disorders that occur after birth. These disorders develop from a wide range of causes, or they can occur as a complication or long-term effect of CHD. Over 100 genes have been identified that may be involved in the development of CHD (Cunningham et al., 2010). Additional noncardiac anomalies occur in about 28% of children with CHD. CHD is also commonly associated with chromosomal abnormalities (Marian, Brugada, & Roberts, 2011). Many congenital heart defects result in heart failure and chronic cyanosis, leading to failure to thrive.

The diagnosis of a cardiovascular disorder in any person can be extremely frightening and overwhelming. Early on, children learn that the heart is necessary for life, so knowing that there is a heart problem can promote feelings of dread. These feelings are compounded by the child's age, the view of the child as being vulnerable and defenseless, and the stressors associated with the disorder itself. The child and parents need much support and reassurance (Cook & Higgins, 2010).

Nurses need to have a sound knowledge base about cardiovascular conditions affecting children so that they can provide appropriate assessment, intervention, guidance, and support to the child and family. Cardiovascular disorders require acute interventions that often have long-term implications for the child's health and growth and development. Due to the potentially overwhelming and devastating effects that cardiovascular disorders can have on children and their families, nurses need to be skilled in assessment and interventions in this area and able to provide support throughout the course of the illness and beyond.

## VARIATIONS IN PEDIATRIC ANATOMY AND PHYSIOLOGY

The cardiovascular system undergoes numerous changes at birth. Structures that were vital to the fetus are no longer needed. Circulation via the umbilical arteries and vein is replaced with the child's own closed independent circulation. Changes in the size of the heart, pulse rate, and blood pressure also occur.

## Circulatory Changes From Gestation to Birth

The fetal heart rate is present on about postconceptual day 17. The four chambers of the heart and arteries are formed during gestational weeks 2 through 8, with maturation of the structures occurring throughout the remainder of gestation. During fetal development, oxygenation of the fetus occurs via the placenta; the lungs, though perfused, do not perform oxygenation and ventilation. The foramen ovale, an opening between the atria, allows blood flow from the right to the left atrium. The ductus arteriosus allows blood flow between the pulmonary artery and the aorta, shunting blood away from the pulmonary circulation (Cunningham et al., 2010). Figure 41.1 illustrates fetal circulation.

With the newborn's first breath, several changes occur in the cardiopulmonary system that enable the newborn to make the transition from fetal circulation to normal circulation. As the newborn breathes for the first time, the lungs inflate, reducing pulmonary vascular resistance to blood flow. As a result, pulmonary artery pressure drops. Subsequently, pressure in the right atrium decreases. Blood flow to the left side of the heart increases the pressure in the left atrium. This change in pressure leads to closure of the foramen ovale. The drop in pressure of the pulmonary artery promotes closure of the ductus arteriosus, which is located between the aorta and pulmonary artery. The ductus venosus, located between the left umbilical vein and the inferior vena cava, closes because of a lack of blood flow and vasoconstriction. The closed ductus arteriosus and ductus venosus eventually become ligaments. With the lack of blood flow to the umbilical arteries and vein, these structures atrophy (Cunningham et al., 2010).

## Structural and Functional Differences

The structure and function of the infant's and child's cardiovascular system differ from those of adults, depending on age. In infants and children younger than 7 years of age, the heart lies more horizontally, resulting in the apex lying higher in the chest, below the fourth intercostal space. As the lungs grow over time, the heart is displaced downward. Between ages 1 and 6 years, the heart is four times the birth size. Between 6 and 12 years of age, the child's heart is 10 times the size it was at birth. However, the heart is smaller proportionally at this time than at any other stage in life. During the school-age years, the heart grows more vertically within the thoracic cavity. During adolescence, the heart continues to grow in relation to the teen's rapid growth.

At birth, the ventricle walls are similar in thickness, but with time the left ventricular wall thickens. The immature myocytes of the infant's heart are thinner and

FIGURE 41.1 Fetal and newborn circulation.

less compliant than those of the adult. Right ventricular function dominates at birth, and over the first few months of life, left ventricular function becomes dominant. The infant's heart at rest exhibits a greater resting tension than the adult's, so volume loading or increased stretch may actually lead to decreased cardiac output. The infant's sarcoplasmic reticulum is less well organized than the adult's, making the infant dependent on serum calcium for contraction. Inotropic response to calcium in the actin and myosin (contractile proteins) increases with age.

The normal heart rate is higher in infancy than in adulthood, limiting the infant's ability to increase cardiac output by increasing the heart rate. The heart's efficiency increases as the child ages and the heart rate drops over time. The normal infant heart rate ranges from 90 to 160 beats per minute (bpm), the toddler's or preschooler's is 80 to 125 bpm, the school-age child's is 70 to 100 bpm, and the adolescent's ranges from 60 to 100 bpm. Innocent murmurs and physiologic splitting of heart sounds may be noted in infancy or childhood. These findings are related to the change in the size of the heart in relation to the thoracic cavity. The infant's and child's blood vessels widen and increase in length over time. The normal infant's blood pressure (BP) is about 80/40 mm Hg. The BP increases over time to the adult level. The toddler or preschooler's BP averages 80 to 100/64 mm Hg, the school-age child's

94 to 112/56 to 60 mm Hg, and the adolescent's 100 to 120/50 to 70 mm Hg (National Institutes of Health, 2008).

## COMMON MEDICAL TREATMENTS

A variety of medications as well as other medical treatments and surgical procedures are used to treat cardiovascular problems in children. Most of these treatments will require a physician's order when the child is in the hospital. The most common treatments and medications are listed in Common Medical Treatments 41.1 and Drug Guide 41.1. The nurse caring for the child with a cardiovascular disorder should be familiar with what the procedures and medications are and how they work as well as common nursing implications related to use of these modalities.

### Take Note!

Give digoxin at regular intervals, every 12 hours, such as at 8 a.m. and 8 p.m., 1 hour before or 2 hours after a feeding. If a digoxin dose is missed and more than 4 hours have elapsed, withhold the dose and give the dose at the regular time; if less than 4 hours have elapsed, give the missed dose. If the child vomits digoxin, do not give a second dose. Monitor potassium levels, as a decrease enhances the effects of digitalis, causing toxicity (Taketokmo, Hodding, & Kraus, 2011).

## COMMON MEDICAL TREATMENTS 41.1

Treatment	Explanation	Indications	Nursing Implications
Oxygen	Supplemented via mask, nasal cannula, hood, tent, or endotracheal/nasotracheal tube	Hypoxemia, respiratory distress, heart failure	Monitor response via work of breathing and pulse oximetry.
Chest physiotherapy (CPT) and postural drainage	Promotes mucus clearance by mobilizing secretions with the assistance of percussion or vibration accompanied by postural drainage (refer to Chapter 40 for additional information related to CPT and postural drainage)	Mobilization of secretions, particularly in postoperative period or with heart failure	May be performed by respiratory therapist in some institutions, by nurses in others. In either case, nurses must be familiar with the technique and able to educate families on its use.
Chest tube	Drainage tube is inserted into the pleural cavity to facilitate removal of air or fluid and allow full lung expansion.	After open heart surgery, pneumothorax	If tube becomes dislodged from container, the chest tube must be clamped immediately to avoid further air entry into the chest cavity.
Pacing	External wiring connected to a small generator used to electrophysiologically correct cardiac arrhythmias or heart block (temporary). Permanent pacing achieved with an implantable internal pacemaker	Bradycardias, heart block, cardiomyopathy, sinoatrial or atrioventricular node malfunction	Provide close observation of the child, pacing unit, and ECG. Maintain asepsis at pacing lead insertion site. Explain to child and family that the permanent pacemaker may be felt under the skin. Advise against participation in contact sports. <sup>a</sup>

<sup>a</sup>Skippen, P., Sanatina, S., Froese, N., & Gow, R. M. (2010). Pacemaker therapy of postoperative arrhythmias after pediatric cardiac surgery. *Pediatric Critical Care Medicine, 11*, 113–138.

## DRUG GUIDE 41.1

Medication	Actions/Indications	Nursing Implications
Alprostadil (Prostin VR: prostaglandin E <sub>1</sub> )	Direct vasodilation of the ductus arteriosus smooth muscle Indicated for temporary maintenance of ductus arteriosus patency in infants with ductal-dependent congenital heart defects	<ul style="list-style-type: none"> <li>• Apnea occurs in 10% to 20% of neonates within first hour of infusion.</li> <li>• Monitor arterial BP, respiratory rate, heart rate, ECG, temperature, and pO<sub>2</sub>; watch for abdominal distention.</li> <li>• Fresh IV solution required every 24 hours.</li> <li>• Reposition catheter if facial or arm flushing occurs.</li> <li>• Use with caution in neonate with bleeding tendency.</li> <li>• Contraindicated in respiratory distress syndrome or persistent fetal circulation.</li> </ul>
Digoxin (Lanoxin)	Increases contractility of the heart muscle by decreasing conduction and increasing force Used for heart failure, atrial fibrillation, atrial flutter, supraventricular tachycardia	<ul style="list-style-type: none"> <li>• Prior to administering each dose, count apical pulse for 1 full minute, noting rate, rhythm, and quality. Withhold if apical pulse is &lt;60 in an adolescent, &lt;90 in an infant.</li> <li>• Avoid giving oral form with meals, as altered absorption may occur.</li> <li>• Monitor serum digoxin levels (therapeutic range: 0.8–2 ng/mL).</li> <li>• Notes signs of toxicity: nausea, vomiting, diarrhea, lethargy, and bradycardia.</li> </ul>

**DRUG GUIDE 41.1** (continued)

Medication	Actions/Indications	Nursing Implications
		<ul style="list-style-type: none"> <li>• Ginseng, hawthorn, and licorice intake increases risk for drug toxicity.</li> <li>• Note contraindications (ventricular fibrillation and hypersensitivity to digitalis).</li> <li>• Avoid rapid IV administration, as this may lead to systemic and coronary artery vasoconstriction.</li> </ul>
Furosemide (Lasix)	<p>Inhibits resorption of sodium and chloride</p> <p>Used to manage edema associated with heart failure, and hypertension in combination with antihypertensives</p>	<ul style="list-style-type: none"> <li>• Administer with food or milk to decrease GI upset.</li> <li>• Monitor BP, renal function, electrolytes (particularly potassium), and hearing.</li> <li>• May cause photosensitivity.</li> </ul>
Heparin	<p>Interferes with conversion of prothrombin to thrombin, preventing clot formation</p> <p>Indicated for the prophylaxis and treatment of thromboembolic disorders, especially after cardiac surgery</p>	<ul style="list-style-type: none"> <li>• Administer SQ, not IM.</li> <li>• Dose is adjusted according to coagulation test results.</li> <li>• Monitor for signs of bleeding, platelet counts.</li> <li>• Ensure that the antidote, protamine sulfate, is available.</li> <li>• Do not administer with uncontrolled bleeding or if subacute bacterial endocarditis is suspected.</li> </ul>
Indomethacin (Indocin)	Inhibits prostaglandin synthesis in order to close patent ductus arteriosus	<ul style="list-style-type: none"> <li>• Monitor heart rate, BP, ECG, and urine output; monitor for murmur.</li> <li>• Monitor serum sodium, glucose, platelet count, BUN, creatinine, potassium, and liver enzymes.</li> <li>• May mask signs of infection.</li> <li>• Note development of edema.</li> </ul>
Spirolactone (Aldactone)	<p>Competes with aldosterone to result in increased water and sodium excretion (saves potassium)</p> <p>Used to manage edema due to heart failure and for treatment of hypertension</p>	<ul style="list-style-type: none"> <li>• Administer with food.</li> <li>• Monitor serum potassium, sodium, and renal function.</li> <li>• May cause drowsiness, headache, and arrhythmia.</li> <li>• May cause false elevations in digitalis level</li> <li>• Teach children to avoid high-potassium diets, salt substitutes, and natural licorice.</li> <li>• Contraindicated in hyperkalemia, renal failure, and anuria.</li> </ul>
<b>Antibiotics</b>		
<p>Penicillin G benzathine (PCN-G)</p> <p>Penicillin V potassium (Pen-VK)</p>	<p>Inhibits bacterial wall synthesis in susceptible organisms</p> <p>Indicated in mild to moderate infections, for prophylaxis of endocarditis and rheumatic fever</p>	<ul style="list-style-type: none"> <li>• Contraindications include hypersensitivity to penicillins.</li> <li>• Report hypersensitivity reactions (chills, fever, wheezing, pruritus, anaphylaxis) immediately.</li> <li>• PCN-G: administer IM.</li> <li>• Pen-VK: administer orally on empty stomach 1 hour prior to or 2 hours after a meal.</li> </ul>

(continued)

**DRUG GUIDE 41.1** (continued)

Medication	Actions/Indications	Nursing Implications
Erythromycin	<p>Inhibits RNA transcription in susceptible organisms</p> <p>Used in children with penicillin allergy, mild to moderate infections, or endocarditis, and for rheumatic fever prophylaxis</p>	<ul style="list-style-type: none"> <li>• Contraindicated in preexisting liver disease.</li> <li>• IV administration may result in CV abnormalities.</li> <li>• Abdominal distress common with oral use.</li> <li>• Fever, dizziness, and rash may occur.</li> </ul>
<b>Antihypertensive Drugs</b>		
Angiotensin-converting enzyme (ACE) inhibitors (captopril [Capoten], enalapril [Vasotec])	<p>Competitive inhibition of ACE for management of hypertension</p> <p>Heart failure management in conjunction with digitalis and diuretics</p>	<ul style="list-style-type: none"> <li>• Monitor BP, renal function, WBC count, and serum potassium.</li> <li>• Discontinue if angioedema occurs.</li> <li>• Captopril: administer orally on empty stomach 1 hour before or 2 hours after meals.</li> <li>• Enalapril: may administer orally without regard to food.</li> </ul>
$\beta$ -Adrenergic blockers (propranolol [Inderal], atenolol [Tenormin], sotalol [Betapace])	<p>Competitively block response to <math>\beta</math>-adrenergic stimulation, decreasing heart rate and force of contraction</p> <p>Used for management of hypertension, arrhythmias, and prevention of myocardial infarction</p>	<ul style="list-style-type: none"> <li>• Monitor ECG and BP.</li> <li>• Propranolol: administer with food.</li> <li>• Atenolol, sotalol: administer without regard to food. Do not stop drug abruptly.</li> <li>• May result in bradycardia, dizziness, nausea and vomiting, dyspnea, and hypoglycemia (propranolol).</li> <li>• Contraindications: heart block, uncompensated heart failure, cardiogenic shock, asthma, or hypersensitivity.</li> </ul>
Hydralazine (Apresoline)	<p>Direct vasodilation of arterioles to manage moderate to severe hypertension, heart failure</p>	<ul style="list-style-type: none"> <li>• Monitor heart rate and BP.</li> <li>• Closely monitor BP with IV use.</li> <li>• Administer oral dose with food.</li> <li>• May cause palpitations, flushing, tachycardia, dizziness, nausea, and vomiting.</li> <li>• Notify physician or nurse practitioner if flu-like symptoms occur.</li> <li>• Contraindicated in rheumatic valvular disease.</li> </ul>

BUN, blood urea nitrogen; CV, cardiovascular; GI, gastrointestinal; IM, intramuscularly;  $pO_2$ , partial pressure of oxygen; SQ, subcutaneously; WBC, white blood cell.

## NURSING PROCESS OVERVIEW FOR THE CHILD WITH A CARDIOVASCULAR DISORDER

Care of the child with a cardiovascular disorder includes all steps of the nursing process: assessment, nursing diagnosis, planning, interventions, and evaluation. There are a number of general concepts related to the nursing process that may be applied to any child with a cardiovascular disorder. The nurse should be knowledgeable about the procedures, treatments, and medications as well as familiar with the nursing implications related to these interventions. With an understanding of these concepts, the nurse can individualize the care based on the child's and family's needs.

**Remember Logan, the 6-week-old with poor feeding? What additional health history and physical examination assessment information should the nurse obtain?**

### Assessment

When assessing a child with a cardiovascular disorder, expect to obtain a health history, perform a physical examination, and prepare the child for laboratory and diagnostic testing.

### Health History

The health history consists of a history of the present illness, past medical history, and family history. Depending on his or her age, the child should be included in the health history interview; the child's age will determine the degree of involvement and the terminology used. Table 41.1 gives examples of typical questions that can be used when obtaining the child's health history.

### HISTORY OF PRESENT ILLNESS

Elicit the history of the present illness, which addresses when the symptoms started and how they have progressed. Inquire about any treatments and medications used at home. Ask parents about history of orthopnea, dyspnea, easy fatigability, growth delays, squatting, edema, dizziness, and/or frequent occurrences of pneumonia, which can be significant signs of pediatric heart disease. The history of present illness may reveal a history of poor feeding, including fatigue, lethargy, and/or vomiting, or failure to thrive, even with adequate caloric intake. The parents may report diaphoresis, which is often seen in early heart failure. The parent or caregiver may also report delays in gross motor development, cyanosis (possibly reported by the parents as more of a gray color than blue), and tachypnea (indicative of heart failure).

**TABLE 41.1** EXAMPLES OF QUESTIONS FOR OBTAINING A CHILD'S HEALTH HISTORY

Questions	Provides Information About
<ul style="list-style-type: none"> <li>• What types and amounts (dosages) of medications has the child received? What were they used for?</li> <li>• Who prescribed them?</li> <li>• Were they effective? Did the child experience any adverse effects?</li> <li>• To whom does the child go for medical evaluation? How often? Were the visits for regular health check-ups or for situational problems? Were there previous hospitalizations? What for?</li> <li>• Has the child experienced any growth delay? Does the child have any problems with activity and coordination?</li> <li>• Does the child's skin color change when crying? If so, what color do you see?</li> <li>• Does the child stop frequently during play to sit or squat?</li> <li>• Does the child have feeding difficulty? Does the child tire easily or sleep excessively?</li> <li>• Does the child frequently develop strep throat?</li> </ul>	<ul style="list-style-type: none"> <li>• Possible underlying conditions that may be related to the child's current status</li> <li>• Other health care personnel involved in the child's care as well as the parents' health care beliefs and patterns</li> <li>• How the medications may be affecting the child's health</li> <li>• The child's health status and the parents' health care knowledge, practices, and beliefs</li> <li>• Problems that may result from impaired cardiac output, adequacy of tissue oxygenation, and concomitant disorders associated with heart disease</li> <li>• Effectiveness of tissue oxygenation. A blue or gray skin color may be due to cyanosis.</li> <li>• The child's exercise tolerance and tissue oxygenation</li> <li>• The child's energy expenditure, ability to tolerate activity, and tissue oxygenation</li> <li>• The child's risk for developing rheumatic fever and heart disease</li> </ul>

Adapted from Park, M. K. (2008). *Pediatric cardiology for practitioners* (5th ed.). St. Louis, MO: Mosby.

## PAST MEDICAL HISTORY

The past medical history includes information about the child as well as the mother's pregnancy history. Assess the child's past medical history for:

- Problems occurring after birth (history of the child's condition after birth may reveal evidence of an associated congenital malformation or other disorder)
- Frequent infections
- Chromosomal abnormalities
- Prematurity
- Autoimmune disorders
- Use of medications, such as corticosteroids

Assess the mother's pregnancy, labor, and delivery history. Be sure to include information about the status of the neonate at birth. Also inquire about maternal use of medications, including illicit or over-the-counter drugs and alcohol; exposure to radiation; presence of hypertension; and maternal viral illnesses such as coxsackievirus, cytomegalovirus, influenza, mumps, or rubella. A history of significant problems related to labor and delivery is also important: stress or asphyxia at birth may be related to cardiac dysfunction and pulmonary hypertension in the newborn.

Assess for additional risk factors such as:

- Family history of heart disease or CHD (investigate the history further if heart disease occurred in a first-degree relative)
- Hyperlipidemia
- Diabetes mellitus
- Obesity
- Inactivity
- Stress
- High-cholesterol diet

## Physical Examination

Physical examination of the child with a cardiovascular condition consists of inspection, palpation, and auscultation. In addition, obtain the child's vital signs and measure the child's height and weight. Plot this information on a standard growth chart to evaluate nutritional status and growth. If the child is younger than 3 years of age, measure and plot the head circumference also.

### INSPECTION

Assess the child's overall appearance. Inspect the color of the skin, noting cyanosis. Inspect the skin for edema. In infants, peripheral edema occurs first in the face, then the presacral region, and then the extremities. Edema of the lower extremities is characteristic of right ventricular heart failure in older children.

### Take Note!

Suspect CHD in the cyanotic newborn who does not improve with oxygen administration (Kattwinkel, 2011).

Inspect the fingers and toes for **clubbing**. Clubbing (which usually does not appear until after 1 year of age) implies chronic hypoxia due to severe congenital heart disease. The first sign of clubbing is softening of the nail beds, followed by rounding of the fingernails, followed by shininess and thickening of the nail ends (see Fig. 40.5 in Chapter 40).

Obtain the child's temperature; fever would suggest infection. Assess respirations, including rate, rhythm, and effort. Note location and severity of retractions if present. Inspect the chest configuration, noting any prominence of the precordial chest wall, which is often seen in infants and children with **cardiomegaly** (abnormal heart enlargement). Note visible pulsations, which may indicate increased heart activity. Also inspect the neck veins for engorgement or abnormal pulsations. Note abdominal distention.

### Take Note!

Children with cardiac conditions resulting in cyanosis will often have baseline oxygen saturations that are relatively low because of the mixing of oxygenated with deoxygenated blood.

### PALPATION

Palpate the right and left radial or brachial pulse to assess cardiac rate and rhythm. Throughout infancy and childhood, the rate may vary. Palpate the femoral pulse; it should be readily palpable and equal in amplitude and strength to the brachial or radial pulse. A femoral pulse that is weak or absent in comparison to the brachial pulse is associated with coarctation of the aorta. Significant variations in pulse occur with activity, so the most accurate heart rate may be determined during sleep. In older children, exercise and emotional factors may influence the heart rate. A bounding pulse is characteristic of patent ductus arteriosus or aortic regurgitation. Diminished pulses may occur with aortic stenosis or cardiomyopathy (Bernstein, 2011). Note tachycardia, bradycardia, rhythm irregularities, diminished peripheral pulses, or thready pulse. Palpate the child's abdomen for hepatomegaly, a sign of right-sided heart failure in the infant and child.

### AUSCULTATION

Auscultate the apical pulse for a full minute to determine heart rate and rhythm. Note irregularities in rhythm, tachycardia, or bradycardia. Auscultate the heart for murmurs. Many children have functional or

innocent murmurs, but all murmurs must be evaluated on the basis of the following characteristics:

- Location
- Relation to the heart cycle and duration
- Intensity: grade I, soft and hard to hear; grade II, soft and easily heard; grade III, loud without thrill; grade IV, loud with a precordial thrill; grade V, loud, with a precordial thrill, audible with a stethoscope partially off chest; grade VI, very loud, audible with a stethoscope or with the naked ear
- Quality: harsh, musical, or rough; high, medium, or low pitch
- Variation with position (sitting, lying, standing) (Bernstein, 2011)

Auscultate for the character of heart sounds. Note distinct, muffled, or distant heart sounds. Abnormal splitting or intensifying of  $S_2$  sounds occurs in children with major heart problems. Ejection clicks, which are high pitched, are related to problems with dilated vessels and/or valve abnormalities. Heard throughout systole, they can be early, moderate, or late. Clicks on the upper left sternal border are related to the pulmonary area. Aortic clicks are best heard at the apex and can be mitral or aortic in origin. A mild to late ejection click at the apex is typical of a mitral valve prolapse. The  $S_3$  heart sound may be heard in children and is associated with cardiac abnormalities. The  $S_4$  heart sound is not normally heard and is always associated with cardiac abnormalities (Lorts, Krawczeski, & Marino, 2009).

Auscultate the BP in the upper extremities and lower extremities and compare the findings; there should be no major differences between the upper and lower extremities. Determine the pulse pressure by subtracting the diastolic pressure from the systolic pressure. The pulse pressure is less than 50 mm Hg, or less than half the systolic pressure. A widened pulse pressure, which usually is accompanied by a bounding pulse, is associated with patent ductus arteriosus, aortic insufficiency, fever, anemia, or complete heart block. A narrowed pulse pressure is associated with aortic stenosis. Note hypotension or hypertension.

#### Take Note!

Alert children and parents if a heart murmur is detected, even if it is benign.

### Laboratory and Diagnostic Testing

Common Laboratory and Diagnostic Tests 41.1 explains the laboratory and diagnostic tests most commonly used when considering cardiovascular disorders in children. The tests can assist the physician in diagnosing the disorder or can be used as guidelines in determining ongoing treatment. Laboratory or nonnursing personnel

obtain some of the tests, while the nurse might obtain others. In either instance the nurse should be familiar with how the tests are obtained, what they are used for, and normal versus abnormal results. This knowledge will also be necessary when providing child and family education related to the testing.

### CARDIAC CATHETERIZATION

Cardiac catheterization is the definitive study for infants and children with cardiac disease and thus deserves special attention in this section on assessment of cardiovascular disorders. Cardiac catheterization has become almost a routine diagnostic procedure and may be performed on an outpatient basis. However, it is highly invasive and not without risks, especially in sick infants and children. Indications for cardiac catheterization include:

- Cardiovascular disease causing cyanosis in infants: these infants need to be catheterized as soon as they are in a reasonably stable condition
- Severe heart failure or progressive problems such as pulmonary edema
- Questionable anatomic or physiologic abnormalities
- Planned cardiac surgery
- Progressive monitoring related to pulmonary hypertension
- Periodic assessment after repair of a cardiac defect
- Therapeutic interventions such as septostomy or balloon valvotomy

Cardiac catheterization may be categorized as diagnostic, interventional, or electrophysiologic. Diagnostic cardiac catheterization typically is used to identify structural defects. Interventional cardiac catheterization is used as a treatment measure to dilate occluded or stenotic structures or vessels or close some defects. Electrophysiologic cardiac catheterization involves the use of electrodes to identify abnormal rhythms and destroy sites of abnormal electrical conduction. The type of catheterization performed varies based on the individual needs of the child. The procedure lasts from 1 to 3 hours (Moller & Johnson, 2008).

### PERFORMING CARDIAC CATHETERIZATION

In cardiac catheterization, a radiopaque catheter is inserted into a blood vessel and is then guided through the vessel to the heart with the aid of fluoroscopy. For a right-sided catheterization, the catheter is threaded to the right atrium via a major vein such as the femoral vein. With a left-sided catheterization, the catheter is threaded to the aorta and heart via an artery. Once the tip of the catheter is in the heart, contrast material is injected via the catheter and radiographic images are taken.

While the catheter is in the heart, several procedures can be performed. The blood pressures, changes in cardiac output or stroke volume, and oxygen

## COMMON LABORATORY AND DIAGNOSTIC TESTS 41.1

Test	Explanation	Indications	Nursing Implications
Arteriogram (angiogram: visualization of arteries or veins)	Radiopaque contrast solution is injected through a catheter and into the circulation. Radiographs are then taken to visualize the structure of the heart and blood vessels	To observe blood flow to parts of body and detect lesions; to confirm a diagnosis. Catheters can be used to remove plaques	<ul style="list-style-type: none"> <li>• Make sure the parent signs a consent form.</li> <li>• Administer premedication as ordered.</li> <li>• Obtain child's weight to determine amount of dye needed.</li> <li>• Keep the child NPO before the procedure according to institutional protocol.</li> <li>• After the procedure, maintain the child on bed rest.</li> <li>• Observe the puncture site for bleeding.</li> <li>• Monitor vital signs frequently and check the pulse distal to the site.</li> </ul>
Ambulatory electrocardiographic monitoring (Holter)	Monitoring of the heart's electrical patterns for 24 hours using a portable compact unit	To identify and quantify arrhythmias in a 24-hour period during normal daily activities	<ul style="list-style-type: none"> <li>• Instruct the child and parent to push the "event button" whenever chest pain, syncope, or palpitations occur.</li> <li>• Normal daily activities should be carried out during the testing period.</li> <li>• Having the child wear a snug undershirt over the leads helps to keep them in place.</li> </ul>
Chest radiograph	A radiographic film of the chest area; will determine size of the heart and its chambers and pulmonary blood flow	Serves as a baseline for comparison with films taken after surgery; used to identify abnormalities of the lungs, heart, and other structures in the chest	<ul style="list-style-type: none"> <li>• Instruct child not to wear jewelry or any metal around neck or on the hospital gown.</li> <li>• Explain to the child and family that no pain or discomfort should result.</li> <li>• If a portable radiograph at bedside is done, remove electrodes temporarily.</li> </ul>
Echocardiogram	Noninvasive ultrasound procedure used to assess heart wall thickness, size of heart chambers, motion of valves and septa, and relationship of great vessels to other cardiac structures	Specific diagnosis of structural defects; determines hemodynamics and detects valvular defects	<ul style="list-style-type: none"> <li>• Assure the child that the echo does not hurt.</li> <li>• Instruct the child about ECG lead placement and use of gel on the scope's wand during the procedure.</li> <li>• Encourage the child to lie still throughout the test.</li> </ul>
Electrocardiogram (ECG)	A graphic record produced by an electrocardiograph (device used to record the electrical activity of the myocardium to detect transmission of the cardiac impulse through the conductive tissues of the muscle). Facilitates evaluation of the heart rate, rhythm, conduction, and musculature	To detect heart rhythm and chamber overload; also serves as a baseline for measuring postoperative complications	<ul style="list-style-type: none"> <li>• Assure the child that monitoring is a painless procedure.</li> <li>• Place electrodes in the appropriate location.</li> <li>• The child must lie still during the ECG recording period (usually about 5 minutes).</li> <li>• Wipe electrode paste or jelly off after procedure.</li> </ul>

**COMMON LABORATORY AND DIAGNOSTIC TESTS 41.1** (continued)

Test	Explanation	Indications	Nursing Implications
Exercise stress test	Monitoring of heart rate, blood pressure, ECG, and oxygen consumption at rest and during exercise	Quantifies exercise tolerance; can be used to provoke symptoms or arrhythmias	<ul style="list-style-type: none"> <li>• Child should be NPO for 4 hours prior to test.</li> <li>• Obtain baseline ECG and vital signs.</li> <li>• Instruct child to verbalize symptoms during testing.</li> <li>• Usually takes about 45 minutes.</li> </ul>
Hemoglobin (Hgb) and hematocrit (Hct)	Measures the total amount of hemoglobin in the blood and indirectly measures the red blood cell number and volume	To detect anemia or polycythemia (may occur with CHD resulting in cyanosis)	<ul style="list-style-type: none"> <li>• False elevations occur with dehydration.</li> <li>• May be obtained quickly via capillary puncture.</li> <li>• Normal values vary with age.</li> </ul>
Partial pressure of oxygen (pO <sub>2</sub> )	Measures the amount of oxygen in the blood	To determine the presence and degree of hypoxia	<ul style="list-style-type: none"> <li>• Most accurate result is with arterial specimen (venous and capillary specimens demonstrate lower levels).</li> <li>• Observe child for cyanosis.</li> <li>• Supplement with oxygen per protocol.</li> </ul>

Adapted from Abdallah, H. (2012). *Pediatric cardiac testing*. Retrieved July 3, 2012, from <http://www.childrenheartinstitute.org/testing/testhome.htm>; and Pagana, K. D., & Pagana, T. J. (2010). *Mosby's manual of diagnostic and laboratory tests* (4th ed.). St. Louis, MO: Mosby.

saturation in each heart chamber and major blood vessels are recorded. With the injection of contrast material, information is revealed about the heart anatomy, ventricular wall motion and ejection fraction, intracardiac pressures and hemodynamic parameters, cardiac valve function, and structural abnormalities. The movement of the contrast material is filmed so that the details of the cardiac procedure are recorded. Samples of heart tissue to evaluate for infection, muscular dysfunction, or rejection after a transplant may also be obtained (Moller & Johnson, 2008).

### NURSING MANAGEMENT OF CARDIAC CATHETERIZATION

For children and parents or guardians, cardiac catheterization can be a source of much anxiety. Therefore, the nurse needs to educate the parents and, if appropriate for age, the child about all aspects of the procedure. The procedure is commonly performed on an outpatient basis, but some physicians or nurse practitioners require the child to be admitted for an overnight stay for observation. Nursing management of the child undergoing cardiac catheterization includes preprocedure nursing assessment and preparation of the child and family, postprocedural nursing care, and discharge teaching.

**Before the Procedure.** A thorough history and physical examination are necessary to establish a baseline. Obtain vital signs. Note fever or other signs and symptoms of infection, which may necessitate rescheduling the procedure. Obtain the child's height and weight to aid in determining medication dosages. Assess the child for any allergies, especially to iodine and shellfish, because some contrast materials contain iodine as a base. Review the child's medications: medications such as anticoagulants are typically withheld for several days or longer prior to the procedure to reduce the child's risk for bleeding. Check the results of any laboratory tests, such as hemoglobin and hematocrit levels.

Perform a complete physical examination. Pay particular attention to assessing the child's peripheral pulses, including pedal pulses. Use an indelible pen to mark the location of the child's pedal pulses so they can be easily assessed after the procedure. Document the location and quality in the child's medical record.

Teach the parents and child, if appropriate, about the procedure. Include information about what the procedure involves, how long it will take, and any special instructions from the physician or nurse practitioner. Use a variety of teaching methods as appropriate, such as videotapes, books, and pamphlets. Adapt these teaching methods to the child's developmental stage.

For example, introduce the younger child to equipment through play therapy. For school-age and older children and their parents, offer a tour of the cardiac catheterization laboratory. Mention sounds and sights they may experience during the procedure. Explain the use of intravenous fluid therapy, sedation, and, if ordered, anesthesia to the child and parents. Tell the child that he or she may feel a sensation of the heart racing when the catheter is inserted. Also warn the older child that he or she may experience a feeling of warmth or stinging when the contrast material is injected. Encourage the child to use familiar ways to help him or her relax. If necessary, teach the child simple relaxation measures.

Typically, food and fluid are withheld for 4 to 6 hours before the procedure. Prescribed medications may be taken with a sip of water. On the day of the procedure, check to ensure that a signed informed consent form is on the child's medical record and that all necessary assessment data have been included. Just before the procedure, ask the child to void and administer a sedative, as ordered. If appropriate and permitted, allow the parents to accompany the child to the catheterization area.

Teach the child and family what to expect after the procedure is completed. Inform the parents of the possible complications that might occur, such as bleeding, low-grade fever, loss of pulse in the extremity used for the catheterization, and development of **arrhythmia** (abnormal heart rhythm). Explain to the child that he or she will have a dressing over the catheter site and that he or she will need to keep the leg straight for several hours after the procedure. Teach the child and parent that frequent monitoring will be required after the procedure (Axton & Fugate, 2009).

**After the Procedure.** Throughout the postprocedure period, closely monitor the child for complications of bleeding, arrhythmia, hematoma, and thrombus formation and infection. After the procedure, evaluate the child's vital signs, the neurovascular status of the lower extremities, and the pressure dressing over the catheterization site every 15 minutes for the first hour and then every 30 minutes for 1 hour. Vital signs should remain within acceptable parameters. Hypotension may signify hemorrhage due to perforation of the heart muscle or bleeding from the insertion site. Expect to monitor cardiac rhythm and oxygen saturation levels via pulse oximetry for the first few hours after the procedure to help identify possible complications.

Assess the child's distal pulses bilaterally for presence and quality. The pulse of the affected extremity may be slightly less than that of the other extremity in the initial postprocedure period, but it should gradually return to baseline. Also assess the color and temperature

of the extremity; pallor or blanching would indicate an obstruction in blood flow. Check capillary refill and sensation to evaluate blood flow to the area.

Maintain bed rest in the immediate postprocedure period. Ensure that the child maintains the extremity in a straight position for approximately 4 to 8 hours, depending on the approach used and the facility's policy. Inspect the pressure dressing frequently. Check to make sure that it is dry and intact, without evidence of bleeding. Reinforce the dressing as necessary and report any evidence of drainage on the dressing. If there is a risk of the dressing becoming soiled or wet, cover it with plastic.

### Take Note!

If bleeding occurs after a cardiac catheterization, apply pressure 1 inch above the site to create pressure over the vessel, thereby reducing the blood flow to the area.

Monitor the child's intake and output closely to ensure adequate hydration. The contrast material has a diuretic effect, so assess the child for signs and symptoms of dehydration and hypovolemia. Typically, the child resumes oral intake as tolerated, beginning with sips of clear liquids and progressing to his or her preprocedure diet. Continue intravenous fluids as ordered and encourage oral fluid intake as allowed and ordered to promote elimination of the contrast material.

Allow the child to talk about the experience and how and what he or she felt. Provide positive reinforcement for the child's actions.

Provide child and family education before the child is discharged home (see Teaching Guidelines 41.1). Areas to address include site care, signs and symptoms of complications (especially within 24 hours after the catheterization, such as fever, bleeding or bruising at the catheterization site, or changes in color, temperature, or sensation in the extremity used), diet, and activity level (Axton & Fugate, 2009).

### Teaching Guidelines 41.1

#### PROVIDING CARE AFTER A CARDIAC CATHETERIZATION

- Change the pressure dressing on the day after the procedure. Apply a dry sterile dressing or adhesive bandage for the next several days. Keep the dressing dry; cover it with plastic if there is a chance that the dressing could become wet or soiled.
- When changing the dressing, inspect the insertion site for redness, irritation, swelling, drainage, and bleeding. Report any of these to the physician or nurse practitioner.

- Check the temperature, color, sensation, and pulses on the child's extremities and compare. Report any changes to the physician or nurse practitioner.
- Resume the child's usual diet after the procedure; report any nausea or vomiting.
- Check the child's temperature at least once a day for approximately 3 days after the procedure. Report any temperature elevation of 100.4°F or greater.
- Avoid giving the child a tub bath for approximately 3 days after the procedure; use sponge baths or showers instead.
- Discourage strenuous exercise or activity for approximately 3 days after the procedure.
- Watch for changes in the child's appearance, such as changes in skin color, reports of the heart "fluttering" or "skipping a beat," fever, or difficulty breathing.
- Give acetaminophen (Tylenol) or ibuprofen (Motrin) for complaints of pain.
- Schedule a follow-up appointment with the physician or nurse practitioner in the time specified.

(2011). *Cardiac catheterization*. Retrieved March 4, 2011, from [http://www.childrensmercy.org/content/uploadedFiles/Care\\_Cards/CMH-99-181p.pdf](http://www.childrensmercy.org/content/uploadedFiles/Care_Cards/CMH-99-181p.pdf)

## Nursing Diagnoses and Related Interventions

Upon completion of a thorough assessment, the nurse might identify several nursing diagnoses. These may include but are not limited to:

- Decreased cardiac output
- Ineffective tissue perfusion
- Imbalanced nutrition, less than body requirements
- Risk for delayed growth and development
- Risk for infection
- Excess fluid volume
- Interrupted family processes
- Activity intolerance
- Pain

**After completing Logan's assessment, the nurse noted the following: poor weight gain, tachypnea with occasional nasal flaring, crackles heard on auscultation, and edema noted in the face, presacral area, and extremities. Based on these assessment findings, what would your top three nursing diagnoses be for Logan?**

Nursing goals, interventions, and evaluation for the child with a cardiovascular disorder are based on the nursing diagnoses. Nursing Care Plan 41.1 can be used as a guide in planning nursing care for the

child with a cardiovascular disorder. The nursing care plan overview should be individualized based on the child's symptoms and needs. Refer to Chapter 36 for detailed information about pain assessment and management. Additional information will be included later in the chapter as it relates to specific disorders.

**Based on your top three nursing diagnoses for Logan, describe appropriate nursing interventions.**

## CONGENITAL HEART DISEASE

In North America, more than 1% of newborn infants have CHD resulting from numerous causes. The prevalence of CHD is about 8 per 1,000 live births; premature infants have a higher rate (Fulton & Brown, 2011). Many chromosome defects are associated with CHD, including Down syndrome, velocardiofacial syndrome, Turner syndrome, trisomy 13, trisomy 18, Williams syndrome, Prader-Willi syndrome, and cri-du-chat (Marian et al., 2011). About one third of infants with CHD will have disease serious enough to result in death or will require cardiac catheterization or cardiac surgery within the first year of life. Complications of CHD include heart failure, hypoxemia, growth retardation, developmental delay, and pulmonary vascular disease. Children with severe anomalies frequently experience failure to thrive.

With advances in palliative and corrective surgery in the past 20 years, many more children are now able to survive into adulthood. As many as 85% of children with CHD grow to be adults, yet many have problems related to education, insurance, and employment (Abdoulhosn & Child, 2011). Hypothermia, cardiopulmonary bypass required during cardiac surgery for CHD, and episodes of hypoxemia may have a long-term impact on the child's cognitive ability and academic function (Fulton & Brown, 2011). Due to the potential long-term effects that CHD may have on these children, nurses must be expertly equipped to care for them.

## Pathophysiology

The exact cause of CHD is unknown. However, the belief is that it results from interplay of several factors, including genetics (e.g., chromosomal alterations) and maternal exposure to environmental factors (e.g., toxins, infections, chronic illnesses, and alcohol).

Congenital heart defects result from some interference in the development of the heart structure during fetal life. Subsequently, the septal walls or valves may fail to develop completely, or vessels or valves may be

## NURSING CARE PLAN 41.1

## Overview for the Child With a Cardiovascular Disorder

**NURSING DIAGNOSIS:** Decreased cardiac output related to structural defect, congenital anomaly, or ineffective heart pumping as evidenced by arrhythmias, edema, murmur, abnormal heart rate, or abnormal heart sounds

### Outcome Identification and Evaluation

Child or infant will demonstrate adequate cardiac output: *will have elastic skin turgor, brisk capillary refill, demonstrate pink color, pulse and blood pressure within normal limits for age, regular heart rhythm, adequate urinary output.*

### Interventions: Increasing Cardiac Output

- Monitor vital signs closely, especially blood pressure (BP) and heart rate, *to detect increases or decreases.*
- Monitor cardiac rhythm via cardiac monitor *to detect arrhythmias quickly.*
- Observe for signs of hypoxia such as tachypnea, cyanosis, tachycardia, bradycardia, dizziness, and/or restlessness *to identify this change early.*
- Administer oxygen as needed *to correct hypoxia.*
- Place child in knee-to-chest or squatting position as needed *to increase systemic vascular resistance.*
- Administer antiarrhythmics, vasopressors, angiotensin-converting enzyme (ACE) inhibitors, beta blockers, corticosteroids, or diuretics as prescribed *to improve cardiac output.*
- Monitor for signs of thrombosis such as restlessness, seizure, coma, oliguria, anuria, edema, hematuria, or paralysis *to identify this condition early.*
- Administer adequate hydration *to decrease possibility of thrombosis formation.*
- Cluster nursing care and other activities *to allow adequate periods of rest.*
- Anticipate child's needs *to decrease the child's stress, thereby decreasing oxygen consumption requirement.*

**NURSING DIAGNOSIS:** Excess fluid volume related to ineffective cardiac muscle function as evidenced by weight gain, edema, jugular vein distention, dyspnea, shortness of breath, abnormal breath sounds, or pulmonary congestion

### Outcome Identification and Evaluation

Child will attain appropriate fluid balance, *will lose weight (fluid), edema or bloating will decrease, lung sounds will be clear, and heart sounds normal.*

### Interventions: Encouraging Fluid Loss

- Weigh daily on same scale in similar amount of clothing: *in children weight is the best indicator of changes in fluid status.*
- Monitor location and extent of edema (measure abdominal girth daily if ascites is present): *decrease in edema indicates positive increase in oncotic pressure.*
- Protect edematous areas from skin breakdown: *edema leads to increased risk for alterations in skin integrity.*
- Auscultate lungs carefully to identify crackles, *indicating pulmonary edema.*
- Assess work of breathing and respiratory rate: *increased work of breathing is associated with pulmonary edema.*
- Assess heart sounds for gallop: *presence of S<sub>3</sub> may indicate fluid overload.*
- Maintain fluid restriction as ordered *to decrease intravascular volume and workload on the heart.*
- Strictly monitor intake and output *to quickly note discrepancies and provide intervention.*
- Provide sodium-restricted diet as ordered: *restricting sodium intake allows better renal excretion of extra fluid.*
- Administer diuretics as ordered and monitor for adverse effects. *Diuretics encourage excretion of fluid and elimination of edema, reduce cardiac filling pressures, and increase renal blood flow. Adverse effects include electrolyte imbalance as well as orthostatic hypotension.*

## NURSING CARE PLAN 41.1

**Overview for the Child With a Cardiovascular Disorder** (continued)

**NURSING DIAGNOSIS:** Imbalanced nutrition, less than body requirements, related to increased energy expenditure and fatigue as evidenced by weight loss or height and weight below accepted standards

**Outcome Identification and Evaluation**

Child will improve nutritional intake resulting in *steady increase in weight and length/height and will feed without tiring easily.*

**Interventions: Promoting Adequate Nutrition**

- Determine body weight and length/height norm for age *to determine goal to work toward.*
- Assess child for food preferences that fall within dietary restrictions: *child will be more likely to consume adequate amounts of foods that he or she likes.*
- Weigh child daily or weekly (according to physician order or institutional standard) and measure length/height weekly *to monitor for increased growth.*
- Offer highest-calorie meals at the time of day when the child's appetite is the greatest *to increase likelihood of increased caloric intake.*
- Provide increased-calorie shakes or puddings within diet restriction: *high-calorie foods increase weight gain.*
- Consult with the pediatric dietician *to provide optimal caloric intake within dietary restrictions.*
- Provide small, frequent feedings *to discourage tiring with feeding.*
- Feed infants with special nipple as needed *to decrease amount of energy expended for sucking.*
- Administer vitamin and mineral supplements as prescribed *to attain/maintain vitamin and mineral balance in the body.*

**NURSING DIAGNOSIS:** Ineffective tissue perfusion related to inadequate cardiac function or cardiac surgery as evidenced by pallor, cyanosis, edema, changes in mental status, prolonged capillary refill, clubbing, or diminished pulses

**Outcome Identification and Evaluation**

Child will demonstrate adequate tissue perfusion: *child will be alert, not restless or lethargic, will have pink color, decrease in edema, normal perfusion, and strong pulses.*

**Interventions: Promoting Tissue Perfusion**

- Assess level of consciousness, pulse, BP, peripheral perfusion, and skin color frequently *to determine baseline and ongoing improvement.*
- Administer cardiac glycosides or vasodilators as ordered *to promote cardiac output necessary for proper perfusion.*
- Monitor pulse oximetry and arterial blood gas results *to assess ability to appropriately oxygenate.*
- Supplement oxygen as needed *to provide oxygen to organs for proper functioning.*
- Monitor hemoglobin and hematocrit *to identify blood loss.*
- Strictly assess intake and output *to determine adequacy of renal perfusion.*
- Position with head of bed elevated *to decrease blood volume returning to heart.*
- Change position every 2 to 4 hours *to promote circulation and avoid skin breakdown in areas of poor perfusion.*

(continued)

## NURSING CARE PLAN 41.1

**Overview for the Child With a Cardiovascular Disorder** (continued)

**NURSING DIAGNOSIS:** Risk for delayed growth and development related to effects of cardiac disease and necessary treatments, inadequate nutrition, or frequent separation from caregivers secondary to illness

**Outcome Identification and Evaluation**

Child will display development appropriate for age: *will display evidence of cognitive and motor function within normal limits (individualized for each child).*

**Interventions: Promoting Appropriate Development**

- Promote adequate caloric intake *to stimulate growth and provide adequate energy.*
- Provide age-appropriate developmental activities *to stimulate development.*
- Consult with the physical or occupational therapist or child life specialist *to determine activities most appropriate for the child within the constraints of the child's illness.*
- Schedule daily activities to allow for essential rest periods *for energy conservation.*
- Encourage parents, teachers, and playmates to be sensitive to child's self-image, using positive comments, *to improve the child's self-concept.*
- As energy allows, encourage participation in all activities as feasible *to allow the child to feel normal.*

**NURSING DIAGNOSIS:** Risk for infection related to need for multiple invasive procedures or cardiac surgery

**Outcome Identification and Evaluation**

Child will remain free from infection: *vital signs will be within normal limits, white blood cell count normal, and cultures negative. Child will exhibit no signs or symptoms of infection.*

**Interventions: Preventing Infection**

- Maintain strict hand hygiene *to prevent spread of infectious organisms to the child.*
- Assess temperature *to detect elevation early in course of infection.*
- Avoid contact with persons with known infections *to prevent risk of becoming ill.*
- Ensure appropriate immunization, including pneumococcal and influenza vaccinations, *to prevent development of common childhood illness.*
- Administer prophylactic antibiotics prior to all dental procedures, surgery, and many invasive procedures *to prevent subacute bacterial endocarditis.*
- Encourage good dental hygiene *to reduce the risk of endocarditis.*

**NURSING DIAGNOSIS:** Interrupted family processes related to crisis associated with heart disease, frequent need for testing and hospitalizations, or stresses associated with care demands, as evidenced by inadequate parental coping, frequent separations of parent and child, or inadequate support

## NURSING CARE PLAN 41.1

**Overview for the Child With a Cardiovascular Disorder** (continued)**Outcome Identification and Evaluation**

Family will maintain functional system of support and will demonstrate adequate coping, adaptation of roles and functions, and decreased anxiety: *parents are involved in child's care, ask appropriate questions, express fears and concerns, and can discuss child's care and condition calmly.*

**Interventions: Promoting Family Processes**

- Provide ongoing support to the child and family to *help them cope.*
- Encourage parents and family members to verbalize concerns related to child's illness, diagnosis, and prognosis: *allows the nurse to identify concerns and areas where further education may be needed and demonstrates family-centered care.*
- Allow families to grieve over the loss of a "perfect" child: *parents must work through those grief feelings so they can be fully "present" for this chronically ill child.*
- Explain therapies, procedures, child's behaviors, and plan of care to parents: *understanding the child's current status and plan of care helps decrease anxiety.*
- Encourage parents to be involved in care: *allows parents to feel needed and valued and gives them a sense of control over their child's health.*
- Identify support system for family and child: *helps nurse identify needs and resources available for coping.*
- Educate family and child on additional resources available to *help them develop a wide base of support.*
- Encourage parents to seek genetic counseling to *provide them with the information required to make an informed decision about having another child.*

**NURSING DIAGNOSIS:** Activity intolerance related to ineffective cardiac muscle function, increased energy expenditure, or inability to meet increased oxygen or metabolic demands as evidenced by squatting positions, shortness of breath, cyanosis, or fatigue

**Outcome Identification and Evaluation**

Child will increase activity level as tolerated: *child participates in play and activities (specify particular activities and level as individualized for each child).*

**Interventions: Promoting Activity**

- Assess level of fatigue and activity tolerance to *determine baseline for comparison.*
- Note extent of dyspnea, oxygen requirement, or color change with exertion to *provide baseline for comparison.*
- Cluster care activities, allowing rest periods in between, to *conserve child's energy.*
- Work with the parent and child to determine a mutually satisfactory daily schedule to *allow adequate rest and energy conservation.*
- Instruct family and child in prescribed activity restrictions to *prevent fatigue while allowing some activity.*
- In the infant, avoid long periods of crying or prolonged nipple feeding: *expends excessive calories.*
- Provide neutral thermal environment to *avoid increased oxygen and energy needs associated with excessive heat or cold.*

stenotic, narrowed, or transposed. Structures that formed to allow fetal circulation may fail to close after birth, altering the pressures necessary to maintain adequate blood flow.

After birth, with the change from fetal to newborn circulation, pressures within the chambers of the right side of the heart are less than those of the left side and pulmonary vascular resistance is less than that for the systemic circulation. These normal pressure gradients are necessary for adequate circulation to the lungs and the rest of the body. However, these pressure gradients become disrupted if a structure has failed to develop, a fetal structure has failed to close, or a narrowing, stenosis, or transposition of a vessel has occurred. For example, blood typically flows from an area of higher pressure to lower pressure. If the ductus arteriosus fails to close, blood will move from the aorta to the pulmonary artery, ultimately increasing right atrial pressure. With this shunting of blood, highly oxygenated blood can mix with less oxygenated blood, interfering with the amount available to the tissues via the systemic circulation. Some of the defects may result in significant hypoxemia, the sequelae of which include clubbing, polycythemia, exercise intolerance, hypercyanotic spells, brain abscess, and cerebrovascular accident (Fulton & Brown, 2011).

Congenital heart defects are categorized based on hemodynamic characteristics (blood flow patterns in the heart):

- Disorders with decreased pulmonary blood flow: tetralogy of Fallot and tricuspid atresia
- Disorders with increased pulmonary blood flow: patent ductus arteriosus (PDA), atrial septal defect (ASD), and ventricular septal defect (VSD)
- Obstructive disorders: coarctation of the aorta, aortic stenosis, and pulmonary stenosis

- Mixed disorders: transposition of the great vessels (TGV), total anomalous pulmonary venous return (TAPVR), truncus arteriosus, and hypoplastic left heart syndrome

## Therapeutic Management

Prenatal education about avoiding certain substances or preventing infection is essential to promote optimal outcomes for the fetus. Encourage parents of children with CHD to receive genetic counseling because of the probability of having subsequent children with a congenital heart defect. Children with small septal defects are urged to lead a normal life and often require no medical intervention. Therapeutic management of other forms of CHD focuses on palliative care or a surgical corrective approach necessary for most of the defects. In newborns and very young infants with severe cyanosis (tricuspid atresia, TGV), a prostaglandin infusion will maintain patency of the ductus arteriosus, improving pulmonary blood flow. Definitive correction of structural disorders requires surgical intervention. Table 41.2 describes the surgical procedures used for the various congenital heart defects and the relevant nursing measures. Nursing management for the child with CHD will be provided following the disorders section. See Evidence-Based Practice 41.1.

### Disorders With Decreased Pulmonary Blood Flow

Defects involving decreased pulmonary blood flow occur when there is some obstruction of blood flow to

#### EVIDENCE-BASED PRACTICE 41.1

#### EFFECTS OF CHRONIC OR INTERMITTENT HYPOXIA ON COGNITION IN CHILDREN

##### STUDY

It is well known that significant hypoxia demonstrates an adverse effect on cognition, yet little is known about the effects of chronic or intermittent hypoxia on cognition in children. Many children with congenital heart disease (CHD) suffer either chronic or intermittent hypoxia. The authors performed a systematic literature review to study this question. Fifty-five studies were included, and a significant proportion of them addressed hypoxia with CHD.

##### Findings

About 80% of the studies reported adverse effects on cognition in children who suffered chronic or intermittent hypoxia, including developmental and academic achievement. Adverse effects were noted at all childhood age

levels except premature infants. The effects were noted even with mild oxygen desaturation.

##### Nursing Implications

It is critical that the developing child be afforded the opportunity to develop optimal cognition. Know the child's normal oxygen saturation so that decreases may be quickly acted upon. Use supplemental oxygen judiciously and within the physician order parameters. Since many children experience improved oxygenation after CHD repair, encourage adequate nutrition so that, in turn, the infant or child will demonstrate growth adequate for safe surgical intervention.

New York, NY: McGraw-Hill and Miyamoto, S. D., Sondheimer, H. M., Fagan, T. E., & Collins, K. K. (2011). Cardiovascular diseases. In W. W. Hay, M. J. Levin, J. M. Sondheimer, & R. R. Deterding (Eds.), *Current pediatric diagnosis and treatment* (20th ed.) New York, NY: McGraw-Hill.

the lungs. As a result of the obstruction, pressure in the right side of the heart increases and becomes greater than that of the left side of the heart. Blood from the higher-pressure right side of the heart then shunts to the lower-pressure left side through a structural defect. Subsequently, deoxygenated blood mixes with oxygenated blood on the left side of the heart. This mixed blood, which is low in oxygen, is pumped via the systemic circulation to the body tissues.

Defects with decreased pulmonary blood flow are characterized by mild to severe oxygen desaturation. Typically, the child exhibits oxygen saturation levels ranging from 50% to 90%, which can produce severe cyanosis. To compensate for low blood oxygen levels, the kidneys produce the hormone erythropoietin to stimulate the bone marrow to produce more red blood cells (RBCs). This increase in RBCs is called **polycythemia**. Polycythemia can lead to an increase in blood volume and possibly blood viscosity, further taxing the workload of the heart. Although the number of RBCs increases, there is no change in the amount of blood that reaches the lungs for oxygenation. Disorders within this classification include tetralogy of Fallot and tricuspid atresia.

## Tetralogy of Fallot

Tetralogy of Fallot is a congenital heart defect composed of four heart defects: pulmonary stenosis (a narrowing of the pulmonary valve and outflow tract, creating an obstruction of blood flow from the right ventricle to the pulmonary artery), VSD, overriding aorta (enlargement of the aortic valve to the extent that it appears to arise from the right and left ventricles rather than the anatomically correct left ventricle), and right ventricular hypertrophy (the muscle walls of the right ventricle increase in size due to continued overuse as the right ventricle attempts to overcome a high-pressure gradient). Surgical intervention is usually required during the first year of life (Fulton & Brown, 2011; Miyamoto, Sondheimer, Fagan, & Collins, 2011).

## Pathophysiology

With pulmonary stenosis, the blood flow from the right ventricle is obstructed and slowed, resulting in a decrease in blood flow to the lungs for oxygenation and a decrease in the amount of oxygenated blood returning to the left atrium from the lungs. The obstructed flow also increases the pressure in the right ventricle. This blood, which is poorly oxygenated, is then shunted across the VSD into the left atrium. Poorly oxygenated blood also travels through the overriding aorta (if it extends to both ventricles). In some cases when the VSD is large, the pressure in the right ventricle may be equal to that of the left ventricle. In this case, the path of blood shunting depends on which circulation is exerting the higher pressure, pulmonary or systemic.

Regardless of which way shunting occurs, a mixing of oxygenated and poorly oxygenated blood occurs, with this blood ultimately being pumped into the systemic circulation. The oxygen saturation of the blood in the systemic circulation is reduced, leading to cyanosis. The degree of cyanosis depends on the extent of the pulmonary stenosis, the size of the VSD, and the vascular resistance of the pulmonary and systemic circulations.

Tetralogy of Fallot is usually diagnosed during the first weeks of life due to the presence of a murmur and/or cyanosis. Some newborns may be acutely cyanotic, while others may exhibit only mild cyanosis that gradually becomes more severe, particularly during times of stress as the child grows older. Most often, infants with tetralogy of Fallot have a PDA at birth, providing additional pulmonary blood flow and thereby decreasing the severity of the initial cyanosis. Later, as the ductus arteriosus closes, such as within the first days of life, more severe cyanosis can occur (Fig. 41.2) (Fulton & Brown, 2011; Miyamoto et al., 2011).

## Nursing Assessment

Nursing assessment consists of the health history, physical examination, and laboratory and diagnostic tests.

### Health History and Physical Examination

Obtain the health history, noting a history of color changes associated with feeding, activity, or crying. Determine if the infant or child is demonstrating hypercyanotic spells. Hypercyanosis develops suddenly and is manifested as increased cyanosis, hypoxemia, dyspnea, and agitation. If the infant's oxygen demand is greater than the supply, such as with crying or during feeding, then the spell progresses to anoxia. When the degree of cyanosis is severe and persistent, the infant may become unresponsive. As the infant gets older, he or she may use specific postures, such as bending at the knees or assuming the fetal position, to relieve a hypercyanotic spell. The walking infant or toddler may squat periodically. These positions improve pulmonary blood flow by increasing systemic vascular resistance. Ask the parents if they have noticed any of these unusual positions. Note history of irritability, sleepiness, or difficulty breathing.

During the physical examination, observe the skin color and note any evidence of cyanosis. Also observe for changes in skin color with positional changes, and inspect the fingers for clubbing. Note if the child has a hypercyanotic spell during the assessment. Count the child's respiratory rate and observe work of breathing, noting retractions, shortness of breath, or noisy breathing. Document oxygen saturation via pulse oximetry; it will likely be decreased. Auscultate the chest for adventitious breath sounds, which may suggest the development of heart failure. Auscultate the heart, noting a loud, harsh murmur characteristic of this disorder.

FIGURE 41.2 Tetralogy of Fallot.

### Laboratory and Diagnostic Tests

Note increased hematocrit, hemoglobin, and RBC count associated with polycythemia. Additional testing may include:

- **Echocardiography** (ultrasound study of structure and motion of heart), possibly revealing right ventricular hypertrophy, decreased pulmonary blood flow, and reduced size of the pulmonary artery
- Electrocardiogram (ECG), indicating right ventricular hypertrophy
- Cardiac catheterization and angiography, which reveal the extent of the structural defects

### Consider This

**Ava Gardener**, 2 weeks old, is brought to the clinic by her mother. She presents with trouble feeding. Her mother states, "When Ava eats, she seems to have trouble breathing, and recently I've noticed a bluish color around her lips." What other assessment information would you obtain?

Ava is to be admitted to the hospital secondary to suspected tetralogy of Fallot. What education and interventions may be necessary for this child and family? How can you assist the family to cope?

### Tricuspid Atresia

Tricuspid atresia is a congenital heart defect in which the valve between the right atrium and right ventricle fails to develop. As a result, there is no opening to allow blood to flow from the right atrium to the right ventricle and subsequently through the pulmonary artery into the lungs (Fulton & Brown, 2011; Miyamoto et al., 2011).

### Pathophysiology

In tricuspid atresia, blood returning from the systemic circulation to the right atrium cannot directly enter the right ventricle due to agenesis of the tricuspid valve. Subsequently, deoxygenated blood then passes through an opening in the atrial septum (either an ASD or through a patent foramen ovale) into the left atrium, never entering the pulmonary vasculature. Thus, deoxygenated blood mixes with oxygenated blood in the left atrium. The blood then travels to the lungs through a PDA. The foramen ovale and ductus arteriosus must remain open for the newborn to maintain minimally adequate oxygenation (Fig. 41.3) (Fulton & Brown, 2011; Miyamoto et al., 2011).

FIGURE 41.3 Tricuspid atresia.

## Nursing Assessment

Nursing assessment consists of the health history, physical examination, and laboratory and diagnostic tests.

### Health History and Physical Examination

Note the infant's history since birth. Document history of cyanosis either at birth or a few days later when the ductus arteriosus closed. Note history of rapid respirations and difficulty with feeding. Inspect the skin for cyanosis or a pale gray color. Observe the apical impulse, noting overactivity. Evaluate the baby's sucking strength (will usually have a weak or poor suck). Count the respiratory rate, noting tachypnea. Note increased work of breathing. Auscultate the lungs, noting crackles or wheezes if heart failure is beginning to develop. Auscultate the heart, noting a murmur. Palpate the skin, noting coolness and clamminess of the extremities. Document the presence of clubbing in the older infant or child.

### Laboratory and Diagnostic Testing

Laboratory and diagnostic testing is similar to that for tetralogy of Fallot. A complete blood cell (CBC) count is needed to assess compensatory increases in hematocrit, hemoglobin, and erythrocyte count (RBC) indicating the development of polycythemia. Pulse oximetry or arterial blood gas tests may be used to determine oxygen

saturation levels (typically reduced). Additional testing may include:

- Echocardiography, revealing absence of tricuspid valve or underdeveloped right ventricle
- ECG, indicating possible heart failure
- Cardiac catheterization and angiography, which reveal the extent of the structural defects

## Disorders With Increased Pulmonary Flow

Most congenital heart defects involve increased pulmonary blood flow. Normally, the left side of the heart has a higher pressure than the right side. Defects with connections involving the left and right sides will shunt blood from the higher-pressure left side to the lower-pressure right side. Even a small pressure gradient such as a 1- to 3-mm difference between the left and right sides will produce a movement of blood from the left to the right. In turn, the increase of blood on the right side of the heart will cause a greater amount of blood to move through the heart. If the amount of blood flowing to the lungs is large, the child may develop heart failure early in life. In addition, right ventricular hypertrophy may result. Sometimes with ventricular hypertrophy the right side of the heart pumps so forcefully that left-to-right shunting is reversed to right-to-left shunting. If this occurs, deoxygenated blood mixes with oxygenated blood, thereby lowering the overall blood oxygen saturation level.

Excessive blood flow to the lungs can produce a compensatory response such as tachypnea or tachycardia. Tachypnea increases caloric expenditure; poor cellular nutrition from decreased peripheral blood flow leads to feeding problems. Subsequently, the infant experiences poor weight gain, which retards overall growth and development. Increased pulmonary blood flow results in decreased systemic blood flow, so sodium and fluid retention may occur. Increased pulmonary blood flow also places the child at higher risk for pulmonary infections. As the child grows, the continuous increased pulmonary blood flow will cause vasoconstriction of the pulmonary vessels, actually decreasing the pulmonary blood flow. This may lead to pulmonary hypertension. For children with congenital defects with increased pulmonary blood flow, oxygen supplementation is not helpful. Oxygen acts as a pulmonary vasodilator. If pulmonary dilation occurs, pulmonary blood flow is even greater, causing tachypnea, increasing lung fluid retention, and eventually causing a much greater problem with oxygenation. Over time, continuous increased pulmonary blood flow may cause pulmonary vasoconstriction and pulmonary hypertension. Therefore, preventing the development of pulmonary disease via early surgical correction is essential.

Examples of defects with increased pulmonary blood flow are ASD, VSD, atrioventricular canal defect, and PDA.

**FIGURE 41.4** Atrial septal defect; note the opening between the two atria.

### Atrial Septal Defect

An ASD is a passageway or hole in the wall (septum) that divides the right atrium from the left atrium (Fig. 41.4). Three types of ASDs are identified based on the location of the opening:

- Ostium primum (ASD1): the opening is at the lower portion of the septum.
- Ostium secundum (ASD2): the opening is near the center of the septum.
- Sinus venosus defect: the opening is near the junction of the superior vena cava and the right atrium.

When the ASD is small, as many as 80% of infants may have a spontaneous closure within the first 18 months of life. If it does not spontaneously close by age 3, the child will most likely need corrective surgery (Fulton & Brown, 2011; Miyamoto et al., 2011).

### Pathophysiology

With ASD, blood flows through the opening from the left atrium to the right atrium due to pressure differences. The shunting increases the blood volume entering the right atrium. This, in turn, leads to increased blood flow into the lungs. If untreated, the defect can cause problems such as pulmonary hypertension, heart failure, atrial

arrhythmias, or stroke (Fulton & Brown, 2011; Miyamoto et al., 2011).

### Nursing Assessment

Most children with ASDs are asymptomatic. However, a very large defect can cause increased blood flow, leading to heart failure, which results in shortness of breath, easy fatigability, or poor growth.

### Health History and Physical Examination

Obtain the health history, noting poor feeding as an infant, decreased ability to keep up with peers, or history of difficulty growing. Observe the child's chest, noting a hyperdynamic precordium. Auscultate the heart, noting a fixed split second heart sound and a systolic ejection murmur, best heard in the pulmonic valve area. Palpate along the left sternal border for a right ventricular heave.

### Laboratory and Diagnostic Tests

Echocardiography is done to confirm the diagnosis. An **electrocardiogram** (graphic recording of the heart's electrical activity) may show normal sinus rhythm or prolonged PR intervals. The chest radiograph may show enlargement of the heart and increased vascularity of the lungs.

### Ventricular Septal Defect

A VSD is an opening between the right and left ventricular chambers of the heart (Fig. 41.5). It is one of the most common congenital heart defects, with a prevalence of 1.5 to 2.5 per 1,000 live births. VSD accounts for 30% of all congenital heart defects. Spontaneous closure of small VSDs occurs in about half of children by age 2 years. Long-term outcomes for surgically repaired VSDs are good. Repair of larger defects by 2 years of age is recommended to prevent the development of pulmonary disease (Fulton & Brown, 2011; Miyamoto et al., 2011).

### Pathophysiology

In VSD, there is an abnormal opening between the right and left ventricles. The opening varies in size, from as small as a pinhole to a complete opening between the ventricles so that the right and left sides are as one. Children with small VSDs may remain asymptomatic. In other children, blood shunts across the opening in the septum. Pulmonary vascular resistance and systemic vascular resistance determine the direction of blood flow. A left-to-right shunt results when pulmonary vascular resistance is low. Increased amounts of blood flowing into the right ventricle are then pumped to the pulmonary circulation, eventually causing an increase in pulmonary vascular resistance. Increased pulmonary vascular resistance leads to increased

**FIGURE 41.5** Ventricular septal defect; note the opening between the ventricles.

pulmonary artery pressure (pulmonary hypertension) and right ventricular hypertrophy. When the pulmonary vascular resistance exceeds the systemic vascular resistance, right-to-left shunting of blood across the VSD occurs, resulting in Eisenmenger syndrome (pulmonary hypertension and cyanosis). Heart failure commonly occurs in children with moderate to severe unrepaired VSDs. Children with VSDs are also at risk for the development of aortic valve regurgitation as well as infective endocarditis (Fulton & Brown, 2011; Miyamoto et al., 2011).

## Nursing Assessment

Initially, the newborn may not exhibit any signs and symptoms at birth because left-to-right shunting is most likely minimal due to the high pulmonary resistance common after birth.

### Health History and Physical Examination

Determine the health history, which commonly reveals signs of heart failure around 4 to 8 weeks of age. Note history of tiring easily, particularly with exertion or feeding. Document the child's growth history, noting difficulty thriving. Ask the parent about color change or diaphoresis with nipple feeding in the infant. Note history of frequent pulmonary infections, shortness of breath, and possibly edema. Inspect the extremities for edema, noting whether pitting is present. Note mild tachypnea.

Auscultate the heart, noting a characteristic holosystolic harsh murmur along the left sternal border. In some instances, a murmur may be noted only with excessive blood flow across the opening. Adventitious lung sounds may be auscultated if the child is experiencing heart failure. Palpate the chest for a thrill.

### Laboratory and Diagnostic Tests

Magnetic resonance imaging (MRI) or echocardiogram with color flow Doppler may reveal the opening as well as the extent of left-to-right shunting. These studies also may identify right ventricular hypertrophy and dilation of the pulmonary artery resulting from the increased blood flow. Cardiac catheterization may be used to evaluate the extent of blood flow being pumped to the pulmonary circulation and to evaluate hemodynamic pressures.

### Atrioventricular Canal Defect

Atrioventricular canal defect (atrioventricular septal defect [AVSD], AV canal, or endocardial cushion defect) accounts for 4% of congenital heart disease. Thirty-five to 40% of children with Down syndrome and CHD have this defect (Fulton & Brown, 2011; Miyamoto et al., 2011).

## Pathophysiology

AV canal defect occurs as a result of failure of the endocardial cushions to fuse (Fig. 41.6). These cushions are needed to separate the central parts of the heart near the tricuspid and mitral (AV) valves. The complete AV canal defect involves atrial and ventricular septal defects as well as a common AV orifice and a common AV valve. Partial and transitional forms of AV canal defect also occur, involving variations of the complete form.

The complete AV canal defect permits oxygenated blood from the lungs to enter the left atrium and ventricle, crossing over the atrial or ventricular septum and returning to the lungs via the pulmonary artery. This recirculation problem, which typically involves a left-to-right shunt, is inefficient because the left ventricle must pump blood back to the lungs and also meet the body's peripheral demand for oxygenated blood. Subsequently, the left ventricle must pump two to three times more blood than in a normal heart. Therefore, this specific type of cardiac defect causes a large left-to-right shunt; an increased workload of the left ventricle; and high pulmonary arterial pressure, resulting in an increased amount of blood in the lungs and causing pulmonary edema (Fulton & Brown, 2011; Miyamoto et al., 2011).

## Nursing Assessment

The infant with a complete AV canal defect commonly exhibits moderate to severe signs and symptoms of heart

FIGURE 41.6 Atrioventricular canal defect.

FIGURE 41.7 Patent ductus arteriosus.

failure. However, for infants with partial or transitional AV canal defects, the signs and symptoms will be subtler.

### Health History and Physical Examination

Obtain the health history, noting frequent respiratory infections and difficulty gaining weight. Ask the parent if the infant has been experiencing difficulty feeding or increased work of breathing.

Inspect the skin, fingernails, and lips for cyanosis. Observe for retractions, tachypnea, and nasal flaring. Auscultate the lungs and heart, noting rales and a loud murmur. The murmur is commonly noted within the first 2 weeks of life. Infants with partial or transitional AV canal defects may display more subtle signs.

### Laboratory and Diagnostic Tests

Echocardiography will reveal the extent of the defect and shunting as well as right ventricular hypertrophy. Electrocardiogram may indicate right ventricular hypertrophy and possible first-degree heart block due to impulse blocking before reaching the AV node.

### Patent Ductus Arteriosus

PDA is failure of the ductus arteriosus, a fetal circulatory structure, to close within the first weeks of life (Fig. 41.7). As a result, there is a connection between the aorta and pulmonary artery. PDA is the second most

common congenital heart defect and accounts for 10% of CHD cases. PDA occurs much more frequently in premature than in term infants and in infants born at high altitudes compared with those born at sea level. Infants with other CHDs that result in right-to-left shunting of blood and cyanosis may additionally display a PDA. In these infants, the PDA allows for some level of oxygenated blood to reach the systemic circulation (Fulton & Brown, 2011; Miyamoto et al., 2011).

### Pathophysiology

Failure of the ductus arteriosus to close leads to continued blood flow from the aorta to the pulmonary artery. Blood returning to the left atrium passes to the left ventricle, enters the aorta, and then travels to the pulmonary artery via the PDA instead of entering the systemic circulation. This altered blood flow pattern increases the workload of the left side of the heart. Pulmonary vascular congestion occurs, causing an increase in pressure. Right ventricular pressure increases in an attempt to overcome this increase in pulmonary pressure. Eventually, right ventricular hypertrophy occurs (Fulton & Brown, 2011; Miyamoto et al., 2011).

### Nursing Assessment

The symptoms of PDA depend on the size of the ductus arteriosus and the amount of blood flow it carries. If it

is small, the infant may be asymptomatic. Some infants demonstrate signs and symptoms of heart failure.

### Health History and Physical Examination

Determine the health history, which may reveal frequent respiratory infections, fatigue, and poor growth and development. On physical examination, note tachycardia, tachypnea, bounding peripheral pulses, and a widened pulse pressure. The diastolic blood pressure typically is low due to the shunting. Auscultate the lungs and heart, noting rales if heart failure is present. Note a harsh, continuous, machine-like murmur, usually loudest under the left clavicle at the first and second intercostal spaces.

### Laboratory and Diagnostic Tests

Echocardiogram reveals the extent of the defective opening and confirms the diagnosis. Electrocardiogram may be normal or it may indicate ventricular hypertrophy, especially if the defect is large. Chest radiography demonstrates cardiomegaly.

## Obstructive Disorders

Another group of congenital heart defects is classified as obstructive disorders. These disorders involve some type of narrowing of a major vessel, interfering with the ability of the blood to flow freely through the vessel. As a result, peripheral circulation or blood flow to the lungs is affected. Increased pressure backing up toward the heart causes an increased workload on the heart. Examples of defects in this group include coarctation of the aorta, aortic stenosis, and pulmonic stenosis.

### Coarctation of the Aorta

Coarctation of the aorta is narrowing of the aorta, the major blood vessel carrying highly oxygenated blood from the left ventricle of the heart to the rest of the body (Fig. 41.8). It accounts for 6% of congenital heart defects and occurs three times more often in males than in females (Fulton & Brown, 2011; Miyamoto et al., 2011).

### Pathophysiology

Coarctation of the aorta occurs most often in the area near the ductus arteriosus. The narrowing can be preductal (between the subclavian artery and ductus arteriosus) or postductal (after the ductus arteriosus). As a result of the narrowing, blood flow is impeded, causing pressure to increase in the area proximal to the defect and to decrease in the area distal to it. Thus, blood pressure is increased in the heart and upper portions of the body and decreased in the lower portions of the body. Left ventricular afterload is increased, and in some children this may lead to heart failure. Collateral circulation also

FIGURE 41.8 Coarctation of the aorta.

may develop as the body attempts to ensure adequate blood flow to the descending aorta. Due to the elevation in blood pressure, the child is also at risk for aortic rupture, aortic aneurysm, and cerebrovascular accident (CVA) (Fulton & Brown, 2011; Miyamoto et al., 2011).

### Nursing Assessment

The extent of the symptoms depends on the severity of the coarctation. Some children with coarctation of the aorta grow well into the school-age years before the defect is discovered.

### Health History and Physical Examination

Determine the health history, noting problems with irritability and frequent epistaxis. In older children, there also may be reports of leg pain with activity, dizziness, fainting, and headaches. Assess pulses throughout, noting full, bounding pulses in the upper extremities with weak or absent pulses in the lower extremities. Determine BP in all four extremities. BP in the upper extremities may be 20 mm Hg or higher than that in the lower extremities. Inspect the school-age child's chest, noting notching of the ribs. Auscultate the heart for a soft or moderately loud systolic murmur, most often heard at the base of the heart.

### Laboratory and Diagnostic Tests

Diagnosis of coarctation of the aorta is based primarily on the history and physical examination. In addition, an

echocardiogram may disclose the extent of narrowing and evidence of collateral circulation. Chest radiography may reveal left-sided cardiac enlargement and rib notching indicative of collateral arterial enlargement. Other tests, such as electrocardiogram, computed tomography, or MRI, may be done to provide additional evidence about the extent of the coarctation and subsequent effects.

## Aortic Stenosis

Aortic stenosis is a condition causing obstruction of the blood flow between the left ventricle and the aorta. The occurrence of aortic stenosis is 4 per 1,000 live births, with 75% of cases occurring in males (Ren, Aggarwal, & Balentine, 2012).

## Pathophysiology

Aortic stenosis can be caused by a muscle obstruction below the aortic valve, an obstruction at the valve itself, or an aortic narrowing just above the valve (Fig. 41.9). The most common type is an obstruction of the valve itself, called aortic valve stenosis. The aortic valve consists of three very pliable leaflets. Normally the leaflets of the aortic valve spread open easily when the left ventricle ejects blood into the aorta. Aortic stenosis occurs when the aortic valve narrows, causing an obstruction between the left ventricle and the aorta. As a result, cardiac output decreases. When the aortic valve does not function properly, the left ventricle must work harder

to pump blood into the aorta. Because of the increased workload, the left ventricular muscle hypertrophies. If this continues, left ventricular failure can occur, leading to a backup of pressure in the pulmonary circulation and pulmonary edema. Heart failure may occur, but this is more commonly seen in the infant (Ren, et al., 2012; Fulton & Brown, 2011).

## Nursing Assessment

Typically, the child with aortic stenosis is asymptomatic. However, it is important to obtain an accurate health history and perform a physical examination.

## Health History and Physical Examination

Obtain the child's health history, noting easy fatigability or complaints of chest pain similar to anginal pain when active. Dizziness with prolonged standing also may be reported. In the infant, note difficulty with feeding. Palpate the child's pulse; if aortic stenosis is severe, the pulses may be faint. Palpate the child's chest, noting a thrill at the base of the heart. Auscultate the heart, noting a systolic murmur best heard along the left sternal border with radiation to the right upper sternal border.

## Laboratory and Diagnostic Tests

The echocardiogram is the most important noninvasive test to identify aortic stenosis. An electrocardiogram may be normal in children with mild to moderate forms of aortic stenosis. For children with severe aortic stenosis, left ventricular hypertrophy may be determined from the electrocardiogram. For children experiencing easy fatigability and chest pain, an exercise stress test may be done to evaluate the degree of cardiac compromise.

## Pulmonary Stenosis

Pulmonary stenosis is a condition that causes an obstruction in blood flow between the right ventricle and the pulmonary arteries. Pulmonary stenosis occurs in 8% to 12% of all cases of CHD (Rao & Pflieger, 2010). It is often associated with other heart anomalies and with genetic syndromes. Children may be asymptomatic, although some children with severe stenosis may exhibit dyspnea and fatigue with exertion (demonstrating hypercyanotic spells similar to those in children with tetralogy of Fallot) (Rao & Pflieger, 2010).

## Pathophysiology

Pulmonary stenosis may occur as a muscular obstruction below the pulmonary valve, an obstruction at the valve, or a narrowing of the pulmonary artery above the valve (Fig. 41.10). Valve obstruction is the most common form of pulmonary stenosis. Normally the pulmonary valve is

FIGURE 41.9 Aortic stenosis.

FIGURE 41.10 Pulmonary stenosis.

constructed with three thin and pliable valve leaflets; they spread apart easily, allowing the right ventricle to eject blood freely into the pulmonary artery. The most common problem causing pulmonary stenosis is that the pulmonary valve leaflets are thickened and fused together along their separation lines, causing the obstruction to blood flow. The right ventricle has an additional workload, causing the muscle to thicken, resulting in right ventricular hypertrophy and decreased pulmonary blood flow. When the pulmonary valve is severely obstructed, the right ventricle cannot eject sufficient blood into the pulmonary artery. As a result, pressure in the right atrium increases, which could lead to a reopening of the foramen ovale. If this occurs, deoxygenated blood would pass through the foramen ovale into the left side of the heart and would then be pumped to the systemic circulation. In some cases, a PDA may be present, thus allowing for some compensation by shunting blood from the aorta to the pulmonary circulation for oxygenation (Fulton & Brown, 2011; Rao & Pflieger, 2010).

## Nursing Assessment

The child with pulmonary stenosis may be asymptomatic or may exhibit signs and symptoms of mild heart failure. If the stenosis is severe, the child may demonstrate cyanosis. Therefore, it is important for the nurse to obtain an accurate health history and physical examination.

## Health History and Physical Examination

Elicit the health history, noting mild dyspnea or cyanosis with exertion. Document the child's growth history, which is typically normal. Carefully palpate the sternal border for a thrill (not always present). Auscultate the heart, noting a high-pitched click following the second heart sound and a systolic ejection murmur loudest at the upper left sternal border.

## Laboratory and Diagnostic Tests

An echocardiogram reveals the extent of obstruction present at the valve, as well as right ventricular hypertrophy. An electrocardiogram also helps to detect right ventricular hypertrophy.

## Mixed Defects

Mixed defects are congenital heart defects that involve a mixing of well-oxygenated blood with poorly oxygenated blood. As a result, systemic blood flow contains a lower oxygen content. Cardiac output is decreased, and heart failure occurs. Examples of mixed defects include transposition of the great vessels, total anomalous pulmonary venous connection, truncus arteriosus, and hypoplastic left heart syndrome.

## Transposition of the Great Vessels (Arteries)

Transposition of the great vessels (TGV) is a congenital heart defect in which the pulmonary artery and the aorta are transposed from their normal positions. The aorta arises from the right ventricle instead of the left ventricle and the pulmonary artery arises from the left ventricle instead of the right ventricle. Transposition of the great vessels accounts for approximately 5% of all CHD cases (Fulton & Brown, 2011; Miyamoto et al., 2011). It is most often diagnosed in the first few days of life when the child manifests cyanosis, which indicates decreased oxygenation. As the ductus arteriosus closes, the symptoms will worsen. Corrective surgery is usually performed by age 4 to 7 days.

## Pathophysiology

TGV creates a situation in which poorly oxygenated blood returning to the right atrium and ventricle is then pumped out to the aorta and back to the body (Fig. 41.11). Oxygenated blood returning from the lungs to the left atrium and ventricle is then sent back to the lungs through the pulmonary artery. Unless there is a connection somewhere in the circulation where the oxygen-rich and oxygen-poor blood can mix, all the organs of the body will be poorly oxygenated. Often the ductus

FIGURE 41.11 Transposition of the great vessels.

arteriosus remains patent, allowing for some mixing of blood. Similarly, if a VSD is also present, mixing of blood may occur and cyanosis will be delayed. However, these associated defects can lead to increased pulmonary blood flow that increases pressure in the pulmonary circulation. This predisposes the child to heart failure (Fulton & Brown, 2011; Miyamoto et al., 2011).

### Nursing Assessment

Significant cyanosis without a murmur in the newborn period is highly indicative of TGV. In some infants, cyanosis will not develop until several days of age as the PDA closes. In infants with septal defects, cyanosis may be further delayed.

### Health History and Physical Examination

Elicit the health history, noting onset of cyanosis with feeding or crying. Observe the infant for cyanosis while active and at rest. Observe the chest, noting a prominent ventricular impulse. Auscultate the heart, noting a loud second heart sound. A murmur may be heard if the ductus remains open or a septal defect is present. If heart failure is present, note edema, tachypnea, and adventitious lung sounds.

### Laboratory and Diagnostic Tests

Echocardiography clearly reveals evidence of the transposition. Cardiac catheterization may be performed to deter-

mine whether oxygen saturation levels are low due to the mixing of the blood.

### Total Anomalous Pulmonary Venous Connection

Total anomalous pulmonary venous connection (TAPVC) is a congenital heart defect in which the pulmonary veins do not connect normally to the left atrium. Instead, they connect to the right atrium, often by way of the superior vena cava. Relatively rare, it occurs in about 1 in 17,000 live births (Fulton & Brown, 2011).

### Pathophysiology

Oxygenated blood that would normally enter the left atrium now enters the right atrium and passes to the right ventricle. As a result, the pressure on the right side of the heart increases, leading to hypertrophy. TAPVC is incompatible with life unless there is an associated defect present that allows for shunting of blood from the highly pressured right side of the heart. A patent foramen ovale or an ASD is usually present. Since none of the pulmonary veins connect normally to the left atrium, the only source of blood to the left atrium is blood that is shunted from the right atrium across the defect to the left side of the heart (Fig. 41.12). The highly oxygenated blood from the lungs completely mixes with the poorly oxygenated blood returning from the systemic circulation. This

FIGURE 41.12 Total anomalous pulmonary venous connection.

causes an overload of the right atrium and right ventricle. The increased blood volume going into the lungs can lead to pulmonary hypertension and pulmonary edema (Fulton & Brown, 2011; Miyamoto et al., 2011).

## Nursing Assessment

The degree of cyanosis present with TAPVC depends on the extent of the associated defects. For example, if the foramen ovale closes or the ASD is small, significant cyanosis will be present. The physical examination findings will vary depending on the type of TAPVC the infant has, whether obstruction is present, and whether other associated cardiac anomalies are present.

## Health History and Physical Examination

Note history of cyanosis, tiring easily, and difficulty feeding. Observe the chest for prominence of the right ventricular impulse and retractions with tachypnea. Auscultate the heart, noting fixed splitting of the second heart sound and a murmur. Palpate the abdomen for hepatomegaly.

## Laboratory and Diagnostic Tests

An echocardiogram will reveal the abnormal connection of the pulmonary veins, enlargement of the right atrium and right ventricle, and an ASD if present. The chest radiograph will demonstrate an enlarged heart and pulmonary edema. Cardiac catheterization can also be useful to visualize the abnormal connection of the pulmonary veins, particularly if an obstruction is present.

## Truncus Arteriosus

Truncus arteriosus is a congenital heart defect in which only one major artery leaves the heart and supplies blood to the pulmonary and systemic circulations. It affects males and females equally and accounts for about 1% all CHD cases (Miyamoto et al., 2011). A VSD may also be present.

## Pathophysiology

The one great vessel contains one valve. This valve consists of two to five leaflets and is positioned over both the left and right ventricles (Fig. 41.13). Due to the location of the valve, blood from the left ventricle mixes with blood from the right ventricle. Pressure in the pulmonary circulation typically is less than that of the systemic circulation, leading to increased blood flow to the lungs. As a result, systemic blood flow is decreased. Over time, the increased pulmonary blood flow can lead to pulmonary vascular disease (Fulton & Brown, 2011; Miyamoto et al., 2011).

## Nursing Assessment

Typically, the infant demonstrates cyanosis in varying degrees, depending on the extent of compromise in the

FIGURE 41.13 Truncus arteriosus.

systemic circulation. Obtain an accurate health history and perform a physical examination.

## Health History and Physical Examination

Elicit the health history, noting history of cyanosis that increases with periods of activity such as feeding. Also note history of tiring easily, difficulty in feeding, and poor growth. Count the respiratory rate, which may be elevated. Observe for nasal flaring, grunting or noisy breathing, retractions, and restlessness. Auscultate the lungs, noting adventitious breath sounds, and the heart, noting a murmur associated with a VSD.

## Laboratory and Diagnostic Tests

An echocardiogram will confirm the presence of truncus arteriosus as the anatomy of the great vessels, the single truncal valve, and the VSD will be seen. On rare occasions a cardiac catheterization may be done to determine pressures in the pulmonary arteries.

## Hypoplastic Left Heart Syndrome

Hypoplastic left heart syndrome (HLHS) is a congenital heart defect in which all of the structures on the left side of the heart are severely underdeveloped (Fig. 41.14). The mitral and aortic valves are completely closed or very small. The left ventricle is nonfunctional. Thus, the left side of the heart is completely unable to supply blood to the systemic circulation. HLHS is the fourth most common congenital heart defect. It appears to have

FIGURE 41.14 Hypoplastic left heart syndrome.

a multifactorial and autosomal recessive inheritance pattern and occurs in up to 4% of cases of CHD (Miyamoto et al., 2011). The options for treatment include palliative care, cardiac transplantation within the first few weeks of life, or palliative reconstructive surgery consisting of three stages, beginning within days to weeks of birth.

## Pathophysiology

With HLHS, the right side of the heart is the main working part of the heart. Blood returning from the lungs into the left atrium must pass through an ASD to the right side of the heart. The right ventricle must then pump blood to the lungs and also to the systemic circulation through the PDA. A few days after birth, when the ductus arteriosus closes, the heart cannot pump blood into the systemic circulation, causing poor perfusion of the vital organs and shock. Death will occur rapidly without intervention (Fulton & Brown, 2011; Miyamoto et al., 2011).

## Nursing Assessment

Initially after birth, the newborn may be asymptomatic because the ductus arteriosus is still patent. However, as the ductus begins to close at a few days of age, the newborn will begin to exhibit cyanosis. Some infants may present with circulatory collapse (shock) and must be resuscitated emergently.

## Health History and Physical Examination

Obtain the health history, noting onset of cyanosis. Note poor feeding and history of tiring easily. Evaluate the vital signs, noting tachycardia, tachypnea, and hypothermia. Observe for increased work of breathing and gradually increasing cyanosis. Note pallor of the extremities and decreased oxygen saturation via pulse oximetry. Auscultate the heart and lungs. Note adventitious breath sounds, a gallop rhythm, a single second heart sound, and a soft systolic ejection or holosystolic murmur.

## Laboratory and Diagnostic Tests

Prenatally, a fetal echocardiogram can diagnose this syndrome, as can a maternal ultrasound. After birth, the echocardiogram illustrates the defect.

## Nursing Management of the Child With Congenital Heart Disease

The child with a congenital heart defect has multiple needs and requires comprehensive, multidisciplinary care. Nurses play a key role in helping the child and family during this intensely stressful time. Nursing care focuses on improving oxygenation, promoting adequate nutrition, assisting the child and family with coping, providing postoperative nursing care, preventing infection, and providing child and family education. An important component of education involves preparing the child and parents for discharge. In addition to the nursing management presented below, refer to Nursing Care Plan 41.1 for additional interventions appropriate for the child with CHD. Individualize nursing care specific to the child's needs.

### Improving Oxygenation

Due to the hemodynamic changes accompanying the underlying structural defect, oxygenation is key. Provide frequent ongoing assessment of the child's cardiopulmonary status. Assess airway patency and suction as needed. Position the child in the Fowler or semi-Fowler position to facilitate lung expansion. Monitor vital signs, especially heart and respiratory rates. Monitor the child's color and oxygen saturation levels closely, using these to guide oxygen administration. Observe for tachypnea and other signs of respiratory distress, such as nasal flaring, grunting, and retractions. Auscultate the lungs for adventitious sounds. Provide humidified supplemental oxygen as ordered, warming it to prevent wide temperature fluctuations. Anticipate the need for assisted ventilation if the child has difficulty maintaining the airway or experiences deterioration in oxygenation capacity. Box 41.1 lists interventions related to relief of hypercyanotic spells.

## BOX 41.1

**RELIEVING HYPERCYANOTIC SPELLS**

- Use a calm, comforting approach.
- Place the infant or child in a knee-to-chest position.
- Provide supplemental oxygen.
- Administer morphine sulfate (0.1 mg/kg IV, IM, or SQ).
- Supply IV fluids.
- Administer propranolol (0.1 mg/kg IV).

IM, intramuscularly; SQ, subcutaneously.

Adapted from Bhimji, S., Setnik, G., Mancini, M. C., Gaeta, T. J., & Donson, D. A. (2012). *Tetralogy of Fallot*. Retrieved July 5, 2012, from <http://emedicine.medscape.com/article/2035949-overview>

**Promoting Adequate Nutrition**

Adequate nutrition is critical to foster growth and development as well as to reduce the risk for infection. Children with congenital heart defects typically have increased nutritional needs due to the increased energy expenditure associated with increased cardiac and respiratory workloads. In addition, many of the defects lead to heart failure, which may affect the child's fluid balance status, further increasing the child's energy expenditure.

Nutrition may be provided orally, enterally, or parenterally. For example, for the newborn or infant, nutrition via breast milk or formula may be provided orally or via gavage feedings. Breastfeeding is usually associated with decreased energy expenditure during the act of feeding, yet some infants in intensive care are not stable enough to breastfeed. Gavage with breast milk is possible, and the use of human milk fortifier (either with breastfeeding or added to the gavage feed) adds additional calories that the infant requires. Formula-fed infants may also require increased-calorie formula, which may be achieved by more concentrated mixing of the formula or through the use of additives such as Polycose or vegetable oil. Consult the nutritionist to determine the individual infant's caloric needs and prescription of appropriate feeding.

Cutting a large hole in the nipple or "cross-cutting" the nipple decreases the work of feeding for some infants. Generally, nipple feedings should be limited to a 20-minute duration, as feeding for longer periods results in excess caloric expenditure. Many infants may feed orally for 20 minutes, receiving the remainder of that feeding via orogastric or nasogastric tube. Offer older children small, frequent feedings to reduce the amount of energy required to feed or eat and to prevent over-tiring the child. When needed, administer and monitor total parenteral nutrition as prescribed.

**Take Note!**

Breastfeeding a child before and after cardiac surgery may boost the infant's immune system, which can help fight postoperative infection. If breastfeeding is not possible, mothers can pump milk and the breast milk may be given via bottle, dropper, or gavage feeding.

**Assisting the Child and Family to Cope**

The diagnosis of CHD is especially overwhelming for the child and the parents. The numerous examinations, diagnostic tests, and procedures are sources of stress for the infant or child regardless of age and for the parents. The parents may fear long-term disability or death or may worry that allowing the child to engage in any activity will worsen his or her status. Thus, the parents may tend to overprotect the child. It is important for the parents to continue parenting the child, even when the child requires extended hospitalizations or intensive care. Explain all that is happening with the child, using language the parents and child can understand. Allow the parents and child to voice their feelings, concerns, or questions. Provide ample time to address these questions and concerns. Encourage the parents and the child, as developmentally appropriate, to participate in the child's care.

If the child is a newborn or infant, encourage attachment and bonding. Emphasize the child's positive attributes, including the normal aspects of the infant. Help the parents to experience the joy of a new infant and see the beauty of the child, no matter how ill the infant is. Urge the parents to touch, stroke, pat, and talk to the infant. Encourage them to hold the infant close, using kangaroo care as appropriate. If the child is older, offer suggestions as to how the parents can meet the child's emotional needs. For example, encourage them to bring a favorite toy or object from home while the child is hospitalized.

Provide developmentally appropriate explanations to the child. Encourage play therapy to help the child understand what is happening.

**Preventing Infection**

Teach parents proper hand hygiene. Provide appropriate dental care. Make sure the child receives prophylaxis for infective endocarditis as needed. Ensure that children 24 months or younger who have hemodynamically significant heart defects receive respiratory syncytial virus (RSV) prophylaxis as recommended during RSV season (Sorce, 2009).

**Providing Care for the Child Undergoing Cardiac Surgery**

Cardiac surgery may be necessary to correct a congenital defect or to provide symptomatic relief. The surgery may

be planned as an elective procedure or done as an emergency. Open heart surgery involves an incision of the heart muscle to repair the internal structures. This may require cardiopulmonary bypass. Closed heart surgery involves structures related to the heart but not the heart muscle itself and may be performed with or without cardiopulmonary bypass.

### PROVIDING PREOPERATIVE CARE

The preoperative nursing assessment complements the history and physical examination and provides important baseline information for comparison during the postoperative period. Establish a relationship with the child and parents. Identify problems that may require particular nursing interventions during the postoperative period. Before cardiac surgery, interview the parents and, if age appropriate, the child. Focus the interview on the history of the present illness, cardiac risk factors, the child's present physical and functional status, additional medical problems, current medications and drug allergies, the child's and family's understanding of the illness and planned procedure, and the family support system.

The preoperative physical assessment includes:

- Temperature and weight measurements
- Examination of extremities for peripheral edema, clubbing, and evaluation of peripheral pulses
- Auscultation of the heart (rate, rhythm, heart sounds, murmurs, clicks, and rubs)
- Respiratory assessment, including respiratory rate, work of breathing, and auscultation of the lungs for breath sounds

Obtain any necessary laboratory and diagnostic tests to establish a baseline. In addition, review the results of any tests done previously. Testing may include CBC count, electrolyte levels, clotting studies, urinalysis, cultures of blood and other body secretions, renal and hepatic function tests, chest radiography, electrocardiogram, echocardiogram, and cardiac catheterization.

In most nonemergent cases, preoperative assessment is performed in an outpatient setting and the child is admitted to the hospital on the day of surgery. Nursing care during this phase focuses on thorough child and parent education. If the surgery is an emergency, teaching must be done quickly, emphasizing the most important elements of the child's care (Beke, Braudis, & Lincoln, 2005).

Child and parent education typically includes the following topics:

- Heart anatomy and its function, including what area is involved with the defect that is to be corrected
- Events before surgery, including any testing or preparation such as a skin scrub
- Location of the child after surgery, such as a pediatric intensive care unit, which may include a visit to the unit if appropriate and explanation of the sights and sounds that may be present

- Appearance of the child after surgery (equipment or devices used for monitoring, such as oxygen administration, electrocardiogram leads, pulse oximeter, chest tubes, mechanical ventilation, or intravenous lines)
- Approximate location of the incision and coverage with dressings
- Postoperative activity level, including measures to reduce the risk of complications, such as coughing and deep-breathing exercises, incentive spirometry, early ambulation, and leg exercises
- Nutritional restrictions, such as nothing by mouth for a specified time before surgery and use of intravenous fluids
- Medications, such as anesthesia, sedation, and analgesics as well as medications the child is taking now that need to be continued or withheld (Beke et al., 2005)

Prepare and educate the child at an age- and developmentally appropriate level. Advise parents to read books with their child about CHD and hospitalization such as:

- *Clifford Visits the Hospital* by N. Bridwell, 2000 (Scholastic Inc.)
- *Franklin Goes to the Hospital* by P. Bourgeois, 2000 (Scholastic Paperbacks)
- *Pump the Bear* by G. O. Whittington, 2000 (Brown Books)
- *Blue Lewis and Sasha the Great* by C. D. Newell, 2005 (Cally Press)
- *Cardiac Kids: A Book for Families Who Have a Child with Heart Disease* by V. Elder, 1994 (Dayton Area Heart and Cancer Association)
- *When Molly Was in the Hospital: A Book for Brothers and Sisters of Hospitalized Children* by D. Duncan, 1994 (Rayve Productions) (siblings)
- *A Night Without Stars* by J. Howe, 1993 (Camelot) (older children)

Additionally, parents may order *It's My Heart*, a parent resource book, free of charge from the Children's Heart Foundation, a link to which is provided on [thePoint](#).

Parents may also help their child by buying a small thrift-store suitcase, spray-painting it, and allowing the child to decorate it with his or her name, pictures of family, stickers, or favorite story characters. This will be the child's "hospital suitcase" that the child may pack with toys and videos to bring to the hospital. Hospital tours are appropriate for school-age children and older children and teens may benefit from an intensive care unit tour before surgery.

Instruct parents to stop food and liquids at the designated time, depending on the child's age, and to give all medications as directed. Some medications may be withheld before surgery. If the child's nutritional status is poor or questionable, nutritional supplementation may be ordered for a period of time preoperatively to ensure that the child has the best possible nutritional status before surgery. When it is time for the child to

be transported to the surgical area, allow the parents to accompany the child as far as possible, depending on the institution's policy. Also reinforce with the child that his or her parents will be present at the bedside when he or she awakens from surgery (Beke et al., 2005).

### PROVIDING POSTOPERATIVE CARE

The child will usually be transported from the operating room to the intensive care unit. Depending on the child's age, postoperative stability, and type of surgery, the child may stay in the intensive care unit for several hours up to several days. Vigilant nursing care aids in the transition of the child and parents after surgery and reduces the risk of complications.

During the postoperative period the nurse should do the following:

- Assess vital signs frequently, as often as every 1 hour, until stable.
- Assess the color of the skin and mucous membranes, check capillary refill, and palpate peripheral pulses.
- Observe cardiac rate and rhythm via electronic monitoring and auscultate heart rate and rhythm and heart sounds frequently.
- Monitor hemodynamic status via arterial and/or central venous lines (left and right atrial and pulmonary artery pressures, pulmonary artery oxygen saturation).
- Provide site care and tubing changes according to the institution's policy.
- Auscultate lungs for adventitious, diminished, or absent breath sounds.
- Assess oxygen saturation levels via pulse oximetry and arterial blood gases as well as work of breathing and level of consciousness frequently.
- Administer supplemental oxygen as needed.
- Monitor mechanical ventilation and suction as ordered.
- Inspect chest tube functioning, noting amount, color, and character of drainage.
- Inspect the dressing (incision and chest tube) for drainage and intactness. Reinforce or change the dressing as ordered.
- Assess the incision for redness, irritation, drainage, or separation.
- Monitor intake and output hourly.
- Maintain accurate intravenous infusion rate; restrict fluids as ordered to prevent hypervolemia.
- Assess for changes in level of consciousness. Report restlessness, irritability, or seizures.
- Obtain ordered laboratory tests, such as CBC count, coagulation studies, cardiac enzyme levels, and electrolyte levels. Report abnormal results.
- Administer medications, such as digoxin or inotropic or vasopressor agents, as ordered, watching the child closely for possible adverse effects.
- Encourage the child to turn, cough, deep breathe, use the incentive spirometer, and splint the incisional area with pillows.

### BOX 41.2

#### POSSIBLE COMPLICATIONS AFTER CARDIAC SURGERY

- Atelectasis
- Bacterial endocarditis
- Cardiac arrhythmias
- Cardiac tamponade
- Cerebrovascular accident
- Heart failure
- Hemorrhage
- Pleural effusion
- Pneumonia
- Pneumothorax
- Postperfusion syndrome
- Postcardiac surgery syndrome
- Pulmonary edema
- Seizures
- Wound infection

Adapted from Bacha, E. A., Cooper, D., Thiagarajan, R., et al. (2008). Cardiac complications associated with the treatment of patients with congenital cardiac disease: Consensus definitions from the Multi-Societal Database Committee for Pediatric and Congenital Heart Disease. *Cardiology in the Young*, 18(Suppl. 2), 196–201.

- Assess the child's pain level and administer analgesics as ordered. Allow time for the child to rest and sleep.
- Assist the child to get out of bed as soon as possible and as ordered.
- Assess daily weights.
- Administer small, frequent feedings or meals when oral intake is allowed.
- Position the child in a comfortable position, one that maximizes chest expansion. Change position frequently.
- Assess the child for complications (Box 41.2).
- Provide emotional and physical support to the child and family, making appropriate referrals such as to social services for assistance.
- Prepare the child and family for discharge (Beke et al., 2005).

#### Take Note!

Abrupt cessation of chest tube output accompanied by an increase in heart rate and increased filling pressure (right atrial) may indicate cardiac tamponade (Beke et al., 2005).

### Providing Child and Family Education

Provide child and family education throughout the child's stay. Initially, teaching focuses on the underlying defect and measures to treat or control the problem. If the child

requires surgery, teaching shifts to preoperative and postoperative events. Emphasize discharge teaching for each admission. Teaching Guidelines 41.2 highlights the major areas to be addressed in child and family education.

### Teaching Guidelines 41.2

#### CARING FOR THE CHILD WITH A CONGENITAL HEART DISEASE

- Give medications, if ordered, exactly as prescribed.
- Weigh the child at least once a week or as ordered, at approximately the same time of the day with the same scale, and wearing the same amount of clothing.
- Allow the child to engage in activity as directed. Provide time for the child to rest frequently throughout the day to prevent overexertion.
- Provide a nutritious diet, taking into account any restrictions for fluids or foods.
- Use measures to prevent infection, such as frequent hand washing, prophylactic antibiotics, and skin care.
- Adhere to schedule for follow-up diagnostic tests and procedures.
- Support the child's growth and development needs.
- Use available community support services.
- Notify the physician or nurse practitioner if the child has increasing episodes of respiratory distress, cyanosis, or difficulty breathing; fever; increased edema of the hands, feet, or face; decreased urinary output; weight loss or difficulty eating or drinking; increased fatigue or irritability; decreased level of alertness; or vomiting or diarrhea.

Adapted from Axton, S. E., & Fugate, T. (2009). *Pediatric nursing care plans for the hospitalized child* (3rd ed.). Upper Saddle River, NJ: Pearson; and Cook, E. H., & Higgins, S. S. (2010). Congenital heart disease. In P. J. Allen, J. A. Vessey, & N. A. Schapiro (Eds.), *Primary care of the child with a chronic condition* (5th ed.). St. Louis: Mosby.

## ACQUIRED CARDIOVASCULAR DISORDERS

Acquired cardiovascular disorders occur in children as a result of an underlying cardiovascular problem or may refer to other cardiac disorders that are not congenital. The most common type of acquired cardiovascular disorder in children is heart failure. Other acquired disorders include rheumatic fever, cardiomyopathy, infective endocarditis, hyperlipidemia, hypertension, and Kawasaki disease.

### Heart Failure

Heart failure occurs most often in children with CHD and is the most common reason for admission to the hospital for children with CHD. Most cases of heart failure in

children with CHD occur by 6 months of age (Miyamoto et al., 2011). Heart failure also occurs secondary to other conditions such as myocardial dysfunction following surgical intervention for CHD, cardiomyopathy, myocarditis, fluid volume overload, hypertension, anemia, or sepsis or as a toxic effect of certain chemotherapeutic agents used in the treatment of cancer. **Heart failure** refers to a set of clinical signs and symptoms that reflect the heart's inability to pump effectively to provide adequate blood, oxygen, and nutrients to the body organs and tissues (Francis, Wilson Tang, & Walsh, 2011; Miyamoto et al., 2011).

The child experiencing heart failure requires a multidisciplinary approach to care. Collaboration is necessary to achieve improved cardiac function, restored fluid balance, decreased cardiac workload, and improved oxygen delivery to the tissues.

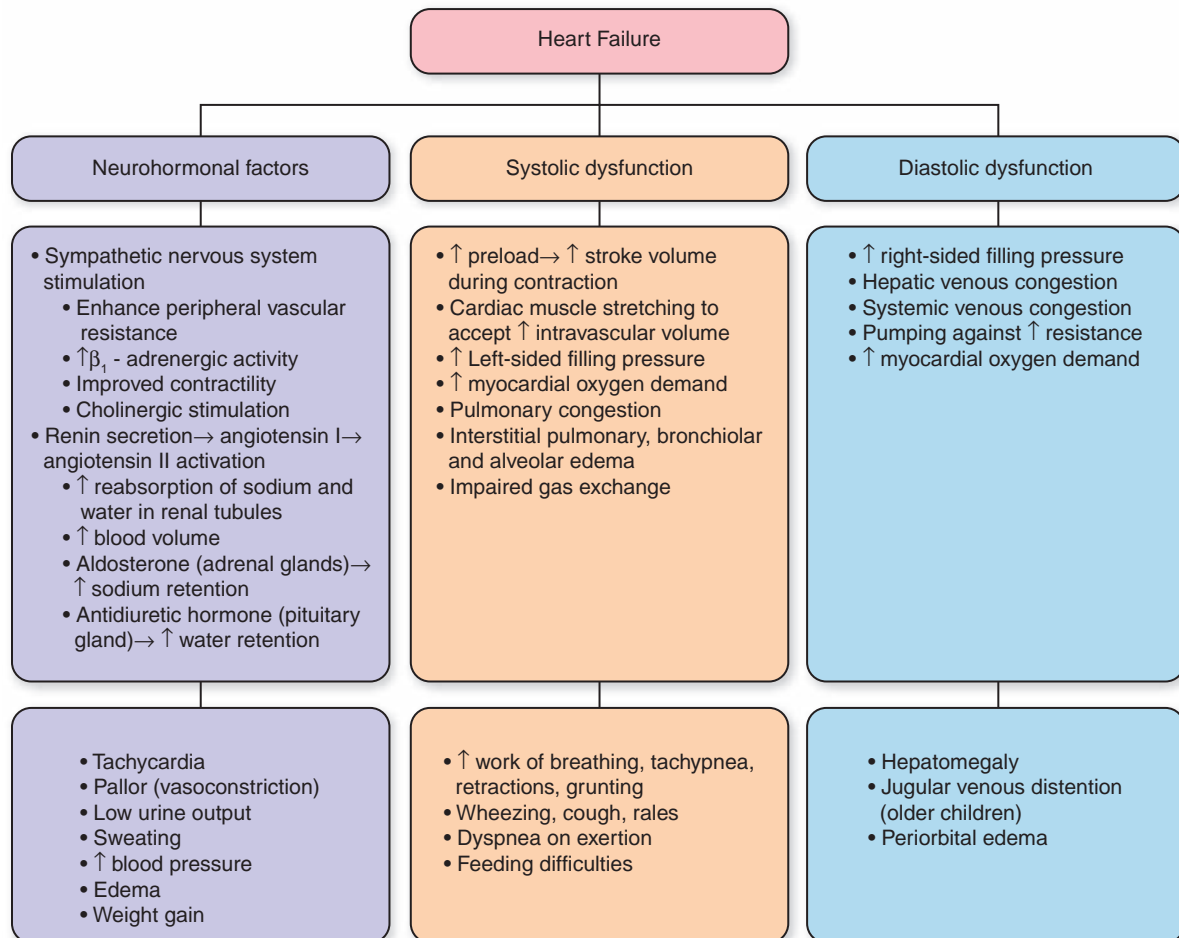

## Pathophysiology

Cardiac output is controlled by preload (diastolic volume), afterload (ventricular wall tension), myocardial contractility (inotropic state), and heart rate. Protracted alterations in any of these factors may lead to heart failure. In the event of reduced cardiac output, multiple compensatory mechanisms are activated. When the ventricular contraction is impaired (systolic dysfunction), reduced ejection of blood occurs, and therefore cardiac output is reduced. Diminished ability to receive venous return (diastolic dysfunction) occurs when high venous pressures are required to support ventricular function. As a result of decreased cardiac output, the renin-angiotensin-aldosterone system is activated as a compensatory mechanism. Fluid and sodium retention as well as improved contractility and vasoconstriction then occur. Initially blood pressure is supported and organ perfusion is maintained, but increased afterload worsens systolic dysfunction. As the heart chambers dilate, myocardial oxygen consumption increases and cardiac output is limited by excessive wall stretch. Over time, the capacity of the heart to respond to these compensatory mechanisms fails, and cardiac output is further decreased (Francis et al., 2011; Miyamoto et al., 2011). Figure 41.15 shows the clinical manifestations that occur related to the mechanisms of heart failure.

## Therapeutic Management

Management of heart failure is supportive. Promotion of oxygenation and ventilation is of utmost importance. Digitalis, diuretics, inotropic agents, vasodilators, antiarrhythmics, and antithrombotics have been widely used in children for palliation of symptoms. Many children with heart failure require management in the intensive care unit until they are stabilized. Augmenting nutrition

**FIGURE 41.15** Pathophysiology of heart failure. (Adapted from Francis, G. S., Wilson Tang, W. H., & Walsh, R. A. [2011]. Pathophysiology of heart failure. In V. Fuster, R. A. Walsh, & R. A. Harrington (Eds.), *Hurst's the heart* (13th ed.). New York, NY: McGraw-Hill.)

and ensuring adequate rest are also key components of management.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1453. Specific assessment findings related to heart failure are discussed below.

### Health History

When obtaining the health history, elicit a description of the present illness and chief complaint. Common complaints reported during the health history might include:

- Failure to gain weight or rapid weight gain
- Failure to thrive
- Difficulty feeding
- Fatigue
- Dizziness, irritability
- Exercise intolerance

- Shortness of breath
- Sucking and then tiring quickly
- Syncope
- Decreased number of wet diapers

Infants with heart failure often display subtle signs such as difficulty feeding and tiring easily. Pay close attention for reports of these problems from the parents. Also be alert for statements such as “The baby drinks a small amount of breast milk (or formula) and stops, but then wants to eat again very soon afterwards”; “The baby seems to perspire a lot during feedings”; or “The baby seems to be more comfortable when he’s sitting up or on my shoulder than when he’s lying flat.” In addition, the parents may report episodes of rapid breathing and grunting.

The child’s current and past medical history also provide additional clues. Question the parents about any history of congenital heart defects and treatments such as surgery to repair the defect. Determine the current medication regimen. Also ask about any recent or past infections, such as streptococcal infections or fever.

## Physical Examination

Weigh the child and note recent rapid weight gain or lack of weight gain. Obtain the child's vital signs, noting tachycardia or tachypnea. These findings are often the first indicators of heart failure in an infant or older child. Measure the BP in the upper and lower extremities, comparing the findings for differences. Note decreased BP, which may be due to impaired cardiac muscle function. Inspect the skin color, noting pallor or cyanosis. Also observe for diaphoresis (profuse sweating). Inspect the face, hands, and lower extremities for edema. Observe for increased work of breathing, such as nasal flaring or retractions. Note the presence of a cough, which may be productive with bloody sputum. Auscultate the apical pulse, noting its location and character. Listen for a murmur, which may suggest a congenital heart defect, a gallop rhythm, or an accentuated third heart sound, suggesting sudden ventricular distention. Auscultate the lungs, noting crackles or wheezes suggestive of pulmonary congestion. Palpate the peripheral pulses, noting weak or thready pulses. Note the temperature and color of the extremities; they may be cool, clammy, and pale.

Assess the child's abdomen, looking for distention indicative of ascites. Gently palpate the abdomen to identify hepatomegaly or splenomegaly.

## Laboratory and Diagnostic Tests

The diagnosis of heart failure is based on the child's signs and symptoms and is confirmed with several laboratory and diagnostic tests. These include:

- Chest radiograph, revealing an enlarged heart and/or pulmonary edema
- Electrocardiogram, indicating ventricular hypertrophy
- Echocardiogram, revealing the underlying cause of heart failure, such as a congenital heart defect

Other tests may be done to support the diagnosis. For example, the CBC count may show evidence of anemia or infection. Electrolyte levels may reveal hyponatremia secondary to fluid retention and hyperkalemia secondary to tissue destruction or impaired renal function. Arterial blood gas results may demonstrate respiratory alkalosis in mild heart failure or metabolic acidosis. Tissue hypoxia may be evidenced by increased lactic acid and decreased bicarbonate levels.

## Nursing Management

Nursing management of the child with heart failure focuses on promoting oxygenation, supporting cardiac function, providing adequate nutrition, and promoting rest.

### Promoting Oxygenation

Position the infant or child in a semi-upright position to decrease work of breathing and lessen pulmonary

congestion. Suction as needed. Chest physiotherapy and postural drainage may also be beneficial. Administer supplemental oxygen as ordered and monitor oxygen saturation via pulse oximetry. Oxygen also serves the function of vasodilator and decreases pulmonary vascular resistance. Occasionally, the infant or child with heart failure may require intubation and positive-pressure ventilation to normalize blood gas tension.

### Take Note!

In a child with a large left-to-right shunt, oxygen will decrease pulmonary vascular resistance while increasing the systemic vascular resistance, which leads to increased left-to-right shunting. Monitor the child carefully and use oxygen only as prescribed.

## Supporting Cardiac Function

Administer digitalis, angiotensin-converting enzyme (ACE) inhibitors, and diuretics as prescribed. Digoxin therapy begins with a digitalizing dose divided into several doses (oral or intravenous [IV]) over a 24-hour period to reach maximum cardiac effect. During digitalization, monitor the electrocardiogram for a prolonged PR interval and decreased ventricular rate. Doses are then administered every 12 hours. Monitor the child for signs of digoxin toxicity. Measure BP before and after administration of ACE inhibitors, holding the dose and notifying the physician if the BP falls more than 15 mm Hg. Observe for signs of hypotension such as lightheadedness, dizziness, or fainting. Weigh the child daily to determine fluid loss. Maintain accurate records of intake and output, restricting fluid intake if ordered. Carefully monitor potassium levels, administering potassium supplements if prescribed. Sodium intake is not usually restricted in the child with heart failure.

## Providing Adequate Nutrition

Due to the increased metabolic rate associated with heart failure, the infant may require as much as 150 calories/kg/day. Older children will also require higher caloric intake than typical children. Offer small, frequent feedings if the child can tolerate them. During the acute phase of heart failure, many infants in particular will require continuous or intermittent gavage feeding to maintain or gain weight. Concentrate infant formula to 24 to 28 calories/ounce as instructed by the nutritionist.

## Promoting Rest

Minimize metabolic needs to decrease cardiac demand. The infant or older child with heart failure will usually limit activities based on energy level. Ensure adequate time for sleep and attempt to limit disturbing

interventions. Provide age-appropriate activities that can be performed quietly or in bed, such as books, coloring or drawing, and video or board games. The older child or adolescent with significant heart failure may require home schooling. As the child improves, a rehabilitation program may be helpful for maximizing activity within the child's cardiovascular status limits.

## Infective Endocarditis

Infective endocarditis is a microbial infection of the endothelial surfaces of the heart's chambers, septum, or valves (most common). Children with congenital heart defects (septum or valve defects) or prosthetic valves are at increased risk of acquiring bacterial endocarditis, which is potentially fatal in these children. Other risk factors for endocarditis include central venous catheters and intravenous drug use. Infective endocarditis occurs when bacteria or fungi gain access to a damaged epithelium. Turbulence in blood flow associated with narrowed or incompetent valves or with a communication between the systemic and pulmonary circulation leads to damage of the endothelium. Thrombi and platelets then adhere to the endothelium, forming vegetations. When a microbe gains access to the bloodstream, it colonizes the vegetation, using the thrombi as a breeding ground. Clumps may separate from the vegetative patch and travel to other organs of the body, causing significant damage (septic emboli). Fungi or more commonly bacteria (particularly  $\alpha$ -hemolytic streptococcus or *Staphylococcus aureus*) are frequently implicated in infective endocarditis (Brusch, 2011; Miyamoto et al., 2011).

Complete antibiotic or antifungal treatment of the causative organism is necessary, and treatment may last 4 to 7 weeks. Prevention of infective endocarditis in the susceptible child with CHD or a valvular disorder is of the utmost importance (Brusch, 2011; Miyamoto et al., 2011).

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 651. Assessment findings related to endocarditis are discussed below.

### Health History

Obtain the health history, noting intermittent, unexplained low-grade fever. Document history of fatigue, anorexia, weight loss, or flu-like symptoms (e.g., arthralgia, myalgia, chills, night sweats). Note history of CHD, valve disorder, or heart failure.

### Physical Examination

Measure the child's temperature, noting low-grade fever. Observe for edema if heart failure is also present. Note

petechiae on the palpebral conjunctiva, the oral mucosa, or the extremities. Inspect for signs of extracardiac emboli:

- Roth spots: splinter hemorrhages with pale centers on sclerae, palate, buccal mucosa, chest, fingers, or toes
- Janeway lesions: painless, flat, red or blue hemorrhagic lesions on the palms or the soles
- Osler nodes: small, tender nodules on the pads of the toes or fingers
- Black lines (splinter hemorrhages) under the nails (Brusch, 2011; Miyamoto et al., 2011)

Evaluate the electrocardiogram for a prolonged PR interval or dysrhythmias. Auscultate the heart for a new or changing murmur. Auscultate the lungs for adventitious breath sounds. Palpate the abdomen for splenomegaly.

## Laboratory and Diagnostic Tests

Diagnosis is usually based on the clinical presentation. Laboratory tests may reveal:

- Blood culture: bacteria or fungus
- CBC count: anemia, leukocytosis
- Urinalysis: microscopic hematuria
- Echocardiogram: cardiomegaly, abnormal valve function, area of vegetation

## Nursing Management

Nursing management focuses on maintaining IV access for at least 4 weeks to appropriately administer the antibiotic or antifungal course of therapy. Monitor the child's temperature and subsequent blood culture results.

Ideally, infective endocarditis in children should be prevented. Children at increased risk for the development of infective endocarditis include those with:

- Prosthetic cardiac valve or prosthetic material used for cardiac valve repair
- Previous endocarditis
- Unrepaired cyanotic congenital heart disease
- Completely repaired congenital heart defect with prosthetic material or device within the first 6 months after the procedure
- Repaired congenital heart disease with residual defects at the site or adjacent to the site of a prosthetic patch or prosthetic device
- Cardiac transplantation recipients who develop cardiac valve abnormalities (Brusch, 2011)

Children at high risk should practice good oral hygiene, including regular tooth brushing and flossing. Instruct parents or the older child to carry emergency medical identification at all times. A wallet card is available from the American Heart Association and a direct link is provided on [thePoint](#). The card may be presented to any physician or nurse practitioner and includes the recommended antibiotic prophylactic regimen (AHA, 2008).

Instruct the parents to notify the primary care provider or cardiologist if the child develops flu-like symptoms or a fever.

High-risk children (as noted above) who are undergoing dental procedures should receive prophylaxis as recommended by the American Heart Association. Antibiotics typically used for prophylaxis may include ampicillin, amoxicillin, gentamicin, or vancomycin.

## Acute Rheumatic Fever

Acute rheumatic fever (ARF) is a delayed sequela of group A streptococcal pharyngeal infection. In the United States this disease occurs more often in school-age children between 5 and 15 years of age in areas where streptococcal pharyngitis is more prevalent, especially during the colder months. It usually develops 2 to 3 weeks after the initial streptococcal infection. Current understanding of the disease process of ARF is that the child develops an antibody response to surface proteins of the bacteria. The antibodies then cross-react with antigens in cardiac muscle and neuronal and synovial tissues, causing carditis, arthritis, and chorea (involuntary random, jerking movements). ARF affects the joints, central nervous system, skin, and subcutaneous tissue and causes chronic, progressive damage to the heart and valves. Most attacks of ARF last 6 to 12 weeks and then are resolved, but rheumatic fever may recur with subsequent streptococcal infections (Chin & Li, 2012).

Diagnosis of ARF is based on the modified Jones criteria (Box 41.3). Therapeutic management is directed toward managing inflammation and fever, eradicating the bacteria, preventing permanent heart damage, and preventing recurrences. A full 10-day course of penicillin therapy (or equivalent) is used along with corticosteroids and nonsteroidal anti-inflammatory drugs. Continuous prophylaxis with monthly intramuscular injections of penicillin G benzathine or daily oral doses of penicillin or erythromycin following the initial illness are recommended to prevent a new streptococcal infection and recurrent ARF. Prophylaxis is continued for 5 years, 10 years, or until age 40 years, depending upon extent of valvular disease (Chin & Li, 2012).

## Nursing Assessment

Elicit a description of the present illness and chief complaint, noting fever and joint pain. Explore the child's recent medical history for risk factors such as documented streptococcal infection or sore throat within the past 2 to 3 weeks, or for past history of ARF. Observe the child for Sydenham chorea, a movement disorder of the face and upper extremities. Inspect the skin for evidence of the classic rash, erythema marginatum, a maculopapular red rash with central clearing and elevated edges. Auscultate the heart, noting a murmur. Palpate the surfaces of the

### BOX 41.3

#### MODIFIED JONES CRITERIA (AMERICAN HEART ASSOCIATION)

Diagnosis of acute rheumatic fever requires the presence of either two major criteria or one major plus two minor criteria.

##### Major Criteria

- Carditis
- Migratory polyarthritis
- Subcutaneous nodules
- Erythema marginatum
- Sydenham chorea

##### Minor Criteria

- Arthralgia
- Fever
- Elevated erythrocyte sedimentation rate or C-reactive protein
- Prolonged PR interval

Adapted from Miyamoto, S. D., Sondheimer, H. M., Fagan, T. E., & Collins, K. K. (2011). Cardiovascular diseases. In W. W. Hay, M. J. Levin, J. M. Sondheimer, & R. R. Deterding (Eds.), *Current pediatric diagnosis and treatment* (20th ed.). New York, NY: McGraw-Hill.

wrist, elbows, and knees for firm, painless, subcutaneous nodules. Note prolonged PR interval on the electrocardiogram. Throat culture will provide definitive diagnosis of current streptococcal infection, while streptococcal antibody tests may yield evidence of recent infection. Echocardiogram is required to determine if carditis is present.

## Nursing Management

Nursing management of the child with ARF focuses on ensuring compliance with the acute course of antibiotics as well as prophylaxis following initial recovery from ARF. Allow the child to verbalize the frustration he or she may be feeling in relation to chorea symptoms. Offer support for dealing with the abnormal movements. Educate the child and others that the sudden jerky movements of chorea will eventually disappear, though they may last as long as several months. Some children may require a neuroleptic agent such as haloperidol (Haldol) for management of chorea. Administer corticosteroids or nonsteroidal anti-inflammatory agents for control of joint pain and swelling.

## Cardiomyopathy

Cardiomyopathy is a condition in which the myocardium cannot contract properly. The incidence of cardiomyopathy among children is increasing; it occurs at a rate of

1 per 100,000 (AHA, 2011a). Cardiomyopathy may occur in children with genetic disorders or congenital heart defects, as a result of an inflammatory or infectious process or hypertension, or after cardiac transplantation or surgery, but most commonly it is idiopathic. Cardiomyopathy occurs predominately in clusters in infancy and adolescence. Three types of cardiomyopathy exist—restrictive, dilated, and hypertrophic. Restrictive cardiomyopathy is rare in children and results in atrial relaxation. Dilated cardiomyopathy is the most common type in childhood and may result in heart failure because of ventricular dilatation with decreased contractility (Kantor, Abraham, Dipchand, Benson, & Redington, 2010). There is some familial tendency toward dilated cardiomyopathy, and it is also associated with Duchenne and Becker muscular dystrophy (Marian et al., 2011). Children with dilated cardiomyopathy may present with heart failure (Kantor et al., 2010). Hypertrophic cardiomyopathy is more common in adolescence and results in hypertrophy of the heart muscle, particularly the left ventricle, affecting the heart's ability to fill. About two thirds of all cases of hypertrophic cardiomyopathy are familial, with some inherited in an autosomal dominant fashion (Marian et al., 2011).

There is no cure for cardiomyopathy, meaning that, currently, heart muscle function cannot be restored. Therapeutic management is directed toward improving heart function and blood pressure. Mechanical ventilation and vasoactive medications are needed in many children. ACE inhibitors, beta blockers, or calcium channel blockers may be used. Pacemakers or surgery is helpful in some children. For severely affected children, heart transplantation is the only viable long-term treatment option (Kantor et al., 2010).

## Nursing Assessment

Explore the health history for risk factors such as:

- Congenital heart defect, cardiac transplantation, or surgery
- Duchenne or Becker muscular dystrophy
- History of myocarditis, HIV infection, or Kawasaki disease
- Hypertension
- Drugs, alcohol, or radiation exposure
- Connective tissue, autoimmune, or endocrine disease
- Maternal diabetes
- Familial history of sudden death

Inquire about a history of respiratory distress, fatigue, poor growth (dilated), chest pain, dizziness, or syncope (hypertrophic). Observe the child for extremity edema and abdominal distention. Note increased work of breathing. Auscultate the heart, noting tachycardia and irregular rhythm. Evaluate heart rhythm via electrocardiogram, noting dysrhythmias or indications of left ventricular hypertrophy.

Chest radiography may reveal cardiomegaly or congested lungs. Echocardiogram demonstrates increased heart size, poor contractility, decreased ejection fraction, or asymmetric septal hypertrophy. Cardiac catheterization is usually performed to aid in the diagnosis.

## Nursing Management

Many children with cardiomyopathy require intensive care initially. Monitor for complications such as blood clots or arrhythmias, which could lead to cardiac arrest. Refer to the previous section on heart failure for nursing interventions related to heart failure, which may be present with dilated cardiomyopathy. Administer vasoactive and other medications as prescribed, monitoring the child closely for response to these therapies as well as for complications. Support the child in choosing activities that fit within the prescribed restrictions. Provide extensive emotional support to the child and family, who may experience significant stress as they realize the severity of this illness.

### Hypertension

Hypertension affects only 1% to 3% of children and adolescents, but often leads to long-term health consequences such as cardiovascular disease and left ventricular hypertrophy (Hollis, 2009). In children, acceptable BP values are based on gender, age, and height. Hypertension is defined as BP persistently greater than the 95th percentile for gender, age, and height. Prehypertension refers to BP that is persistently between the 90th and 95th percentiles. BP is considered normal when the systolic and diastolic values are less than the 90th percentile for gender, age, and height (Brady, Siberry, & Solomon, 2008).

Childhood hypertension may be further defined as primary or secondary. Primary hypertension in children is rare, but its incidence increases with age. Therefore, it is more common in adolescence than in early childhood. Hypertension in children most frequently occurs secondary to an underlying medical problem (most often renal disease). Mild to moderate hypertension in childhood is usually asymptomatic and usually is determined only upon BP screening during a well-child visit or during follow-up for known risk factors.

Therapeutic management depends on the extent of the hypertension and the length of time it has existed. Weight reduction, appropriate diet, and increased physical activity are important components of management of prehypertensive and asymptomatic hypertensive children. Some children are candidates for, and require, anti-hypertensive medications or diuretics (Brady et al., 2008; Hollis, 2009).

## Pathophysiology

The balance between cardiac output and vascular resistance determines the BP. An increase in either of these variables, in the absence of a compensatory decrease in the other, increases the mean BP. Factors regulating cardiac output and vascular resistance include changes in electrolyte balance, particularly sodium, calcium, and potassium (Brady et al., 2008; Hollis, 2009).

## Nursing Assessment

Nursing assessment consists of the health history, physical examination, and laboratory and diagnostic tests.

### Health History

Elicit the health history, determining the presence of risk factors for hypertension such as:

- Family history
- Obesity
- Hyperlipidemia
- Renal disease (including frequent urinary tract infections)
- Systemic lupus erythematosus
- Congenital heart disease
- Neurofibromatosis, Turner syndrome, and other genetic disorders
- Prematurity
- Prolonged neonatal ventilation
- Umbilical artery catheterization
- Diabetes mellitus
- Increased intracranial pressure
- Malignancy
- Solid organ transplant
- Medications known to raise BP

Signs and symptoms reported during the health history might include:

- Growth retardation (with certain chronic medical conditions)
- Obesity
- Signs and symptoms seen particularly in older children
  - Headache
  - Subtle behavioral or school performance changes
  - Fatigue
  - Blurred vision
  - Nosebleed
  - Bell palsy

### Physical Examination

Determine the child's weight and height/length. Plot these growth parameters on the gender-appropriate chart for the child's age. Note the percentile for height/length, as it will be used to determine the BP percentile

(see Appendix H the National Heart Lung and Blood Institute blood pressure charts). Measure the BP in all four extremities (to rule out coarctation of the aorta). Ensure that the child is relaxed and sitting or reclined. Refer to Chapter 32 for specific information related to accurate BP measurement in children.

Inspect the skin for:

- Acne, hirsutism, or striae (associated with anabolic steroid use)
- Café-au-lait spots (associated with neurofibromatosis)
- Malar rash (associated with lupus)
- Pallor, diaphoresis, or flushing (associated with pheochromocytoma)

Observe the extremities for edema (renal disease) or joint swelling (lupus). Inspect the chest for apical heave (ventricular hypertrophy) or wide-spaced nipples (Turner syndrome). Auscultate heart sounds, noting tachycardia (associated with primary hypertension) or murmur (associated with coarctation of the aorta). Palpate the abdomen for a mass or enlarged kidney.

### Laboratory and Diagnostic Testing

Though diagnosis of hypertension is based on BP measurements, additional laboratory or diagnostic tests may be used to evaluate the underlying cause of secondary hypertension, including:

- Urinalysis, blood urea nitrogen, and serum creatinine: may determine presence of renal disease
- Renal ultrasound or angiography: may reveal kidney or genitourinary tract abnormalities
- Echocardiogram: may show left ventricular hypertrophy
- Lipid profile: determines the presence of hyperlipidemia

## Nursing Management

Salt restriction and potassium or calcium supplements have not been scientifically shown to decrease BP in children. However, obese children may benefit from salt restriction, as those children seem to be sensitive to salt intake. Assist the child and family to develop a plan for weight reduction if the child is overweight or obese. Encourage the child and family to control portion sizes, decrease the intake of sugary beverages and snacks, eat more fresh fruits and vegetables, and eat a healthy breakfast. Consult the nutritionist for additional assistance with meal planning. To increase physical activity, encourage the child to find a sport or type of exercise in which he or she is interested. Aerobic activities involving running, walking, or cycling are particularly helpful. When a child requires antihypertensive therapy, teach the child and family how to administer the medication. Caution the parents about side effects related to antihypertensives. Teach the parent to measure the child's BP as determined by the physician or nurse practitioner, as well as to keep appointments for BP follow-up. See Healthy People 2020.

**HEALTHY PEOPLE 2020****Objective**

Reduce the proportion of children and adolescents with hypertension.

**Nursing Significance**

- To prevent development of hypertension and encourage children to maintain a healthy weight and participate in regular exercise.

*Healthy People Objectives based on data from <http://www.healthypeople.gov>.*

**Kawasaki Disease**

Kawasaki disease is an acute systemic vasculitis occurring mostly in infants and young children. It is the leading cause of acquired heart disease among children and occurs more frequently in the winter and spring. Over 4,000 children are hospitalized annually in the United States with Kawasaki disease, and though it affects all ethnic groups, it occurs more frequently in those of Asian or Pacific descent. It is a self-limited syndrome but causes serious cardiovascular sequelae in some affected children (Rowley & Shulman, 2010). Coronary artery aneurysm results in myocardial infarction and death in some children.

Therapeutic management of acute Kawasaki disease focuses on reducing inflammation in the walls of the coronary arteries and preventing coronary thrombosis. Chronic management of children developing aneurysms during the initial phase is directed toward preventing myocardial ischemia. In the acute phase, high-dose aspirin in four divided doses daily and a single infusion of intravenous immunoglobulin (IVIG) are used. Children whose fever persists longer than 48 hours after initiation of aspirin therapy may receive a second dose of IVIG. Pulsed-dose corticosteroid therapy may also be used to prevent or halt coronary dilatation and inhibit progression to aneurysm (Rowley & Shulman, 2010).

**Pathophysiology**

Though the etiology is still unknown, Kawasaki disease may result from an infectious cause. Current thought is that some infectious organism (as yet unidentified) causes disease in genetically susceptible people. Kawasaki disease appears to be an autoimmune response mediated by cytokine-induced endothelial cell surface antigens that leads to vasculitis. Neutrophils, followed by mononuclear cells, T lymphocytes, and immunoglobulin A-producing plasma cells, infiltrate the vessels. Inflammation then occurs in all three layers of the small and medium-sized blood vessels. Edema and smooth muscle necrosis occur in the vessel wall media in severe cases. Generalized

systemic vasculitis occurs in the blood vessels throughout the body due to the inflammation and edema. As elastin and collagen fibers fragment, the structural integrity of the vessel wall is impaired. This mechanism leads to coronary dilatation (ectasia) or aneurysm. Some children never develop coronary artery changes, while others develop an aneurysm in either the acute phase or as a long-term sequela. Infants are at the highest risk for coronary aneurysm or ectasia (Rowley & Shulman, 2010).

**Nursing Assessment**

Nursing assessment consists of determining the health history, physical examination, and laboratory and diagnostic testing.

**Health History**

Elicit the health history, noting any of the following:

- Fever
- Chills
- Headache
- Malaise
- Extreme irritability
- Vomiting
- Diarrhea
- Abdominal pain
- Joint pain

Of particular note is a history of high fever (39.9°C) of at least 5 days' duration that is unresponsive to antibiotics.

**Physical Examination**

Observe for significant bilateral conjunctivitis without exudate. Inspect the mouth and throat for dry, fissured lips; strawberry (cracked and reddened) tongue; and pharyngeal and oral mucosa erythema. Note hyperdynamic precordium. Evaluate the skin for:

- Diffuse, erythematous, polymorphous rash
- Edema of the hands and feet
- Erythema and painful induration of the palms and soles
- Desquamation (peeling) of the perineal region, fingers, and toes, extending to the palms and soles
- Possible jaundice

Palpate the neck for cervical lymphadenopathy (usually unilateral) and the joints for tenderness. Palpate the abdomen for liver enlargement. Auscultate the heart, noting tachycardia, gallop, or murmur.

**Laboratory and Diagnostic Testing**

The CBC count may reveal mild to moderate anemia, an elevated white blood cell count during the acute phase, and significant thrombocytosis (elevated platelet count

[500,000 to 1 million]) in the later phase. The erythrocyte sedimentation rate (ESR) and the C-reactive protein (CRP) level are elevated. Echocardiogram is performed as soon as possible after the diagnosis is confirmed to provide a baseline of a healthy heart or to evaluate for coronary artery involvement. Echocardiograms may be repeated during the illness and as part of long-term follow-up. Occasionally cardiac involvement warrants cardiac catheterization.

## Nursing Management

In addition to the administration of aspirin and immunoglobulin, nursing management of the child with Kawasaki disease focuses on monitoring cardiac status, promoting comfort, and providing family education.

### Monitoring Cardiac Status

Administer intravenous and oral fluids as ordered, evaluating intake and output carefully. Prepare the child for the echocardiogram. Assess frequently for signs of developing heart failure such as tachycardia, gallop, decreased urine output, or respiratory distress. Evaluate quality and strength of pulses. Provide cardiac monitoring as ordered, reporting arrhythmias.

### Promoting Comfort

Provide acetaminophen for fever management and apply cool cloths as tolerated. Keep the environment quiet and cluster nursing care activities to decrease stimulation and hence irritability. Teach parents that irritability is a prominent feature of Kawasaki disease, and support their efforts to console the child. Apply petrolatum jelly or another lubricating ointment to the lips. Encourage the older child to suck on ice chips; the younger child may suck on a cool, moist washcloth. Popsicles are also soothing. Provide comfortable positioning, particularly if the child has joint pain or arthritis.

### Providing Child and Family Education

Teach parents to continue to monitor the child's temperature after discharge until the child has been afebrile for several days. Children with prolonged or recurrent fever may require a second dose of IVIG. Inform parents that irritability may last for up to 2 months after initial diagnosis with Kawasaki disease. Report any toxic effects of aspirin therapy, such as headache, confusion, dizziness, or tinnitus to the physician or nurse practitioner. It is important to avoid nonsteroidal anti-inflammatory agents while aspirin therapy is ongoing. For children with continued arthritis (which resolves in several weeks), range-of-motion exercises with a morning bath may help to decrease stiffness. Instruct parents to avoid measles and varicella vaccination for 11 months after high-dose IVIG

administration. It is critical that the family comply with regularly scheduled cardiology follow-up appointments to determine development or progression of coronary artery ectasia or aneurysm. If the child has severe cardiac involvement, teach the parents about infant and/or child cardiopulmonary resuscitation before discharge from the hospital.

## Hyperlipidemia

Hyperlipidemia refers to high levels of lipids (fats/cholesterol) in the blood. High lipid levels are a risk factor for the development of atherosclerosis, which can result in coronary artery disease, a serious cardiovascular disorder occurring in adults. Children with high lipid levels, though remaining asymptomatic, are likely to have high levels as adults, which increases their risk for coronary artery disease. Therefore, detection, screening, and early intervention are important, especially if there is a family tendency toward heart disease (Daniels, Greer, & the Committee on Nutrition, 2008).

## Pathophysiology

Cholesterol is a building block for hormones and cell membranes. It occurs naturally in foods derived from animals such as eggs, dairy products, meat, poultry, and seafood. Cholesterol is also manufactured in the body. Together, cholesterol and triglycerides are known as lipids. Very-low-density lipoprotein (VLDL) is a lipoprotein composed mainly of triglycerides with only small amounts of cholesterol, phospholipid, and protein. VLDLs are easily converted to low-density lipoproteins (LDLs). Cholesterol is expressed in terms of LDL cholesterol or high-density lipoprotein (HDL) cholesterol. LDLs contain relatively more cholesterol and triglycerides than they do protein. HDLs contain about 50% protein, with the rest being cholesterol, triglyceride, and phospholipid. High levels of cholesterol and triglycerides place a person at risk for atherosclerosis. Elevated VLDL and LDL levels and decreased HDL levels produce a particular increase in the risk for atherosclerosis (Daniels et al., 2008).

## Therapeutic Management

Screening children for hyperlipidemia is of prime importance for early detection, intervention, and subsequent prevention of adult atherosclerosis. The National Cholesterol Education Program recommends screening for hyperlipidemia in children older than 2 years of age if:

- The parent has a total cholesterol level above 240 mg/dL.
- There is a family history of cardiovascular disease in a parent or grandparent before age 55 years.
- The family history is unavailable.

**TABLE 41.3** INTERPRETATION OF CHOLESTEROL LEVELS FOR CHILDREN AGE 2 TO 19 YEARS

Total Cholesterol (mg/dL)	LDL Cholesterol (mg/dL)	Interpretation
<170	<110	Acceptable
170–199	100–129	Borderline
≥200	≥130	Elevated

Adapted from Daniels, S. R., Greer, F. R., & the Committee on Nutrition. (2008). Lipid screening and cardiovascular health in childhood. *Pediatrics*, 122(91), 198–208.

All children should eat a diet with the appropriate amount of fats (see the section on nursing management below) and should participate in physical activity. When diet and exercise are not enough to lower cholesterol to appropriate levels, medications such as resins, fibric acid derivatives, statins, or niacin may be used (Daniels et al., 2008).

## Nursing Assessment

Elicit the health history, noting risk factors such as family history of hyperlipidemia, early heart disease, hypertension, diabetes or other endocrine abnormality, cerebral vascular accident, or sudden death. Note prior lipid levels if available. Measure the child's height and weight, plotting them on standardized growth charts. Note if the child is overweight or obese, as these are risk factors associated with hyperlipidemia. Typically, there are no other particular physical findings associated with hyperlipidemia. Table 41.3 gives details about the interpretation of cholesterol levels.

## Nursing Management

Instruct families that the child must fast for 12 hours before lipid screening (initially and on follow-up samples). Dietary management is the first step in the prevention and management of hyperlipidemia in children older than 2 years of age. The diet should consist primarily of fruits, vegetables, low-fat dairy products, whole grains, beans, lean meat, poultry, and fish. As in adults, fat should account for no more than 30% of daily caloric intake. Fat intake may vary over a period of days, as many young children are picky eaters. Limit saturated fats by choosing lean meats, removing skin from poultry before cooking, and avoiding palm, palm kernel, and coconut oils as well as hydrogenated fats. Teach families to read nutrition labels to determine the content of the food. Limit intake of processed or refined foods as well as high-sugar drinks; these products provide minimal nutrition and significant calories. Children older than

2 years of age should have 60 minutes per day of vigorous play or physical activity. Refer parents to “Healthy Habits for Healthy Kids—A Nutrition and Activity Guide for Parents” published by the American Dietetic Association. (See [thePoint](#) for a direct link.)

If medications are required, teach the child and family about the dose, administration, and possible adverse effects. Assist the family to develop a medication-dosing plan that is compatible with school and work schedules to increase compliance.

## HEART TRANSPLANTATION

Heart transplantation is indicated in children with end-stage heart disease related to cardiomyopathy or inoperable CHD. About 450 children receive a heart transplant each year (Conway & Dipchand, 2010). The 1-year survival rate is 80% to 85% and the overall 20-year rate is 40% (Conway & Dipchand, 2010).

A comprehensive evaluation is performed to determine whether the child is a candidate for heart transplant. The evaluation includes:

- Chest radiograph, electrocardiogram, echocardiogram, exercise stress test, cardiac catheterization, and pulmonary function tests
- CBC count with differential, prothrombin and partial thromboplastin time, serum chemistries and electrolytes, blood urea nitrogen, and creatinine
- Urinalysis and urine creatinine clearance
- Blood, throat, urine, stool, and sputum cultures for bacteria, viruses, fungi, and parasites
- Epstein-Barr virus, cytomegalovirus, varicella, herpes, hepatitis, and HIV titers
- HLA typing and panel reactive antibody typing and titer
- Computed tomography or MRI scan and electroencephalogram
- Consults with neurology, psychology, genetics, social work, nutritionist, physical and occupational therapy, and financial coordinator or case manager (Conway & Dipchand, 2010)

Children with irreversible lung, liver, kidney, or central nervous system disease; recent malignancy (past 5 years); or chronic viral infection may be excluded as candidates.

Once candidacy is determined, the transplant center registers the child as a potential recipient with the United Network for Organ Sharing (UNOS). Blood type, body size, length of time on the waiting list, and medical urgency are used to evaluate compatibility. Children awaiting transplantation may need continuous or intermittent hospitalization. Coordination of organ procurement and the transplantation procedure is essential.

## Surgical Procedure and Postoperative Therapeutic Management

Most transplantation procedures are **orthotopic**, which means that the recipient's heart is removed and the donor heart is implanted in its place in the normal anatomic position. Cardiopulmonary bypass and hypothermia are used to maintain circulation, protect the brain, and oxygenate the recipient during the procedure. Postoperatively, the child may have near-normal heart function and capacity for exercise and may be able to return to school.

Immunosuppressive therapy is necessary for the rest of the child's life to avoid rejection of the transplanted heart. Usually a three-drug regimen is used that includes calcineurin inhibitors (cyclosporine, tacrolimus), cell toxins (mycophenolate mofetil, azathioprine), and corticosteroids. The cardiologist and transplant surgeon provide ongoing follow-up. Complications of heart transplantation include bacterial, fungal, and viral infection and heart rejection. Neoplasm may occur as a result of chronic immunosuppression.

## Nursing Management

Preoperative nursing care for the child undergoing a heart transplant is similar for children undergoing other types of heart surgery. In addition, the nurse should assist with the comprehensive pretransplant evaluation. Care for the child in the posttransplant period is intense and complex. Evaluate the family's ability to perform the tasks that will be necessary. Teach families about the evaluation and transplantation process, as well as the waiting period. In the immediate preoperative period, perform a thorough history and physical examination and obtain last-minute blood work. Provide preoperative teaching similar to other cardiac surgeries. Older children, adolescents, and parents may enjoy the book *Future Conditional* by J. Hatton (1996, Yorkshire Art Circus), which was written by one of the first heart transplant survivors.

Postoperatively, provide frequent assessments and routine care for cardiac surgery children. In addition, monitor the child closely for infection or signs of rejection.

Acute rejection may be indicated by low-grade fever, fatigue, tachycardia, nausea, vomiting, abdominal pain, and decreased activity tolerance, though some children will be asymptomatic. Maintain strict hand washing techniques and isolate the child from other children with infections. Though live vaccines are contraindicated in immunosuppressed children, inactivated vaccines should be given as recommended (Centers for Disease Control and Prevention, 2012). Teach children and families that the child may return to school and usual activities about 3 months after the transplant. Provide emotional support to the child related to body image changes such as hair growth, gum hyperplasia, weight gain, moon facies, acne, and rashes that occur due to long-term immunosuppressive therapy.

### KEY CONCEPTS

- At birth, when the umbilical cord is cut and the neonate's first breath occurs, the ductus venosus closes with the foramen ovale and the ductus arteriosus closes shortly thereafter. Pulmonary vascular resistance decreases and systemic vascular resistance increases.
- The infant's heart rate averages 120 to 130 beats per minute and decreases throughout childhood, reaching the adult rate in adolescence. Conversely, the infant's and child's blood pressure is significantly lower than the adult's, increasing as the child ages.
- Check the infant's apical pulse prior to digoxin administration and hold the dose if the heart rate is less than 90.
- Poor weight gain, failure to thrive, and increased fatigability commonly occur with congestive heart failure.
- Clubbing of the fingernails occurs as a result of chronic hypoxia in the child with severe congenital heart disease.
- Children with cardiac conditions resulting in cyanosis often have baseline oxygen saturations that are relatively low, because of the mixing of oxygenated with deoxygenated blood.
- Document the presence of a murmur by grading its intensity (I through IV), describing where it occurs within the cardiac cycle, and noting the location where the murmur is best heard.
- Congenital heart disease should be suspected in the cyanotic newborn who does not improve with oxygen administration.
- Cardiac catheterization postprocedure care focuses on evaluation of the child's vital signs and condition of the pressure dressing, as well as

assessment of the distal pulses bilaterally for presence and quality.

- Congenital heart disorders resulting in decreased pulmonary blood flow (tetralogy of Fallot, tricuspid atresia) result in cyanosis.
- Disorders with increased pulmonary blood flow (patent ductus arteriosus, atrial septal defect, and ventricular septal defect) may result in pulmonary edema if the defect is severe.
- A decrease in the lower extremity pulses or blood pressure as compared with the upper extremities may be indicative of coarctation of the aorta.
- It is important to remain calm when an infant or child demonstrates a hypercyanotic spell. Place the child in a knee-chest position, administer oxygen and/or morphine or propranolol, and supply intravenous fluids.
- Children with certain congenital heart defects and/or heart failure require additional calories in order to display adequate growth.
- Children with hypertrophic cardiomyopathy, certain congenital heart defects, valve dysfunction, or prosthetic valves require prophylaxis for infective endocarditis when undergoing procedures or invasive dental work.
- Hypertension in the child or adolescent often leads to long-term health consequences such as cardiovascular disease and left ventricular hypertrophy.
- Kawasaki disease may result in severe cardiac sequelae, so these children need ongoing cardiac follow-up to screen for development of problems.
- It is important to screen for hyperlipidemia in high-risk children.
- Abrupt cessation of chest tube output, accompanied by an increase in the heart rate and increased filling pressure, may indicate cardiac tamponade.

## MULTIPLE CHOICE QUESTIONS

- The nurse is caring for a 5-year-old child with a congenital heart anomaly causing chronic cyanosis. When performing the history and physical examination, what is the nurse least likely to assess?
  - Obesity from overeating.
  - Clubbing of the nail beds.
  - Squatting during play activities.
  - Exercise intolerance.
- A 2-day-old infant was just diagnosed with aortic stenosis. What is the most likely nursing assessment finding?
  - Gallop and rales.
  - Blood pressure discrepancies in the extremities.
  - Right ventricular hypertrophy on ECG.
  - Heart murmur.
- Sam, age 11, has a diagnosis of rheumatic fever and has missed school for a week. What is the most likely cause of this problem?
  - Previous streptococcal throat infection.
  - History of open heart surgery at 5 years of age.
  - Playing too much soccer and not getting enough rest.
  - Exposure to a sibling with pneumonia.
- The nurse is caring for a child after a cardiac catheterization. What is the nursing priority?
  - Allow early ambulation to encourage activity participation.
  - Check pulses above the catheter insertion site for strength and quality.
  - Assess extremity distal to the insertion site for temperature and color.
  - Change the dressing to evaluate the site for infection.
- While assessing a 4-month-old infant, the nurse notes that the baby experiences a hypercyanotic spell. What is the priority nursing action?
  - Provide supplemental oxygen by face mask.
  - Administer a dose of IV morphine sulfate.
  - Begin cardiopulmonary resuscitation.
  - Place the infant in a knee-to-chest position.

## CRITICAL THINKING EXERCISES

- A baby boy was born at 26 weeks' gestation to 15-year-old unmarried parents who abuse drugs. The infant weighed 1.5 kg at birth and was diagnosed with AV canal defect and Down syndrome. Discuss some of the major issues in planning for care. Include a care plan and a list of teaching needs for the family.
- A 4-year-old boy has parents with little education, and the child has Medicaid coverage. Another child is 7 years old and has well-educated parents with private insurance coverage. Both of these children need a heart transplant, and a heart is available that is a very good match for both children. Discuss some of the issues involved in deciding which child should receive the heart.
- A 13-year-old boy was diagnosed with hypertension over 2 years ago. He is noncompliant with his antihypertensive medication regimen. He is 5 feet tall and weighs 170 pounds. His favorite activity is video games. Develop a teaching plan for this teen, providing creative approaches at the appropriate developmental level.

## STUDY ACTIVITIES

- Teach a class of sixth graders about healthy activities to prevent high cholesterol levels, hypertension, and heart disease. Use visual materials.
- Spend the day with a nurse practitioner in the pediatric cardiology clinic. Report to the clinical group your observations about the children's quality of life, growth, and development.
- Observe in the pediatric cardiothoracic intensive care unit or telemetry unit. Note the different cardiac rhythms displayed by children with a variety of cardiovascular disorders.

 regurgitation  
 steatorrhea

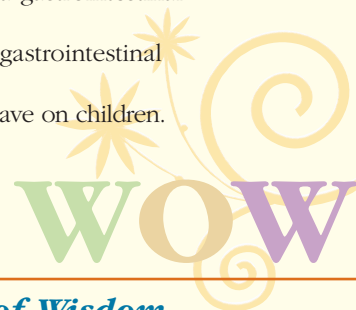

# Nursing Care of the Child With a Gastrointestinal Disorder

## Learning Objectives

Upon completion of the chapter, you will be able to:

1. Define the key terms used in this chapter.
2. Compare the differences in the anatomy and physiology of the gastrointestinal system between children and adults.
3. Discuss common medical treatments for infants and children with gastrointestinal disorders.
4. Discuss common laboratory and diagnostic tests used to identify disorders of the gastrointestinal tract.
5. Discuss medication therapy used in infants and children with gastrointestinal disorders.
6. Recognize risk factors associated with various gastrointestinal illnesses.
7. Differentiate between acute and chronic gastrointestinal disorders.
8. Distinguish common gastrointestinal illnesses of childhood.
9. Discuss nursing interventions commonly used for gastrointestinal illnesses.
10. Devise an individualized nursing care plan for infants/children with a gastrointestinal disorder.
11. Develop teaching plans for family/child education for children with gastrointestinal illnesses.
12. Describe the psychosocial impact that chronic gastrointestinal illnesses have on children.

*Ethan Richardson, 2 months old, is brought to the clinic by his mother. He has been vomiting for the past 3 days. His mother states that she switched formula to see if that would help, but the vomiting worsened. Since last night she has attempted to feed him only Pedialyte. Mrs. Roberts says, "He can't keep anything down and he's very irritable." His weight at birth was 8 lbs 9 ounces, length 21 inches, and head circumference 37 cm. At his 2-month check-up last week he weighed 13 lbs.*

### Words of Wisdom

Children instinctively eat to live, and the nurse can help them devour the joys that life brings.

**Gastrointestinal** (GI) disorders affect children of all ages. GI illnesses range from acute to chronic and from non-life-threatening to life-threatening problems. However, even acute, non-life-threatening illnesses (e.g., diarrhea or vomiting) can become life-threatening without proper nursing assessment and interventions. The most common result of a GI illness is dehydration, requiring fluid therapy at home or, in more extreme cases, in a hospital setting. It is important to take all GI disorders seriously until symptoms are well controlled.

Child and family education related to the treatment of GI disorders is key to preventing the illness from progressing to an emergency situation. Therefore, the nurse's knowledge of the disorders that affect the GI system is crucial. Most often, the parents or child, if the child is older, will contact the physician or nurse practitioner in an outpatient setting to seek help. The nurse is usually the person to triage the phone call to determine the next step in the situation, which may be determining whether the child should be managed at home, brought to the office for assessment, or sent directly to an emergency room for evaluation. The majority of GI disorders can be handled in an outpatient setting to avoid unnecessary hospitalizations. However, some life-threatening problems (e.g., bowel obstruction) require emergency care in the hospital. Again, the knowledge base of the nurse is instrumental in obtaining the proper information by taking a thorough and accurate health history from the parents or child (if the child is older).

## VARIATIONS IN PEDIATRIC ANATOMY AND PHYSIOLOGY

The GI tract includes all of the structures from the mouth to the anus. The primary functions of the GI system are the digestion and absorption of nutrients and water, elimination of waste products, and secretion of various substances required for digestion. Babies are born with immature GI tracts that are not fully mature until age 2. Due to this immaturity, there are many differences between the digestive tract of the young child and that of the older child or adult.

### Mouth

The mouth is highly vascular, making it a common entry point for infectious invaders. In addition, the infant and young child repeatedly bring objects to their mouths and explore them in that fashion. This behavior increases the infant's and young child's risk for contracting infectious agents via the mouth.

### Esophagus

The esophagus provides a passageway from the mouth to the stomach for food. The lower esophageal sphincter (LES)

prevents **regurgitation** (backflow) of stomach contents up into the esophagus and/or oral cavity. The muscle tone of the LES is not fully developed until age 1 month, so infants younger than 1 month of age frequently regurgitate after feedings. Many children younger than 1 year of age continue to regurgitate for several months, but this usually disappears with age. If edema or narrowing of the esophagus occurs in a child with undeveloped esophageal muscle tone, **dysphagia** (difficult or painful swallowing) may occur.

### Stomach

Newborns have a stomach capacity of only 10 to 20 mL. At 2 months of age an infant has the capacity to hold up to 200 mL, though most young infants cannot tolerate 200-mL feedings. By age 16, the stomach capacity is 1,500 mL; by adulthood it is 2,000 to 3,000 mL. Hydrochloric acid, which is found in gastric contents to aid in digestion, reaches the adult level by the time the child is 6 months old.

### Intestines

The small intestine is not functionally mature at birth. A full-term infant has approximately 250 cm of small intestine; an adult has up to 600 cm. Infants who have small bowel loss during early infancy have more problems with absorption and diarrhea than adults who have the same amount of small bowel loss.

### Biliary System

The liver is relatively large at birth, allowing for the smooth edge of the liver to be easily palpated in infancy, as much as 2 cm below the costal margin. The pancreatic enzymes continue to develop postnatally, reaching adult levels around 2 years of age.

### Fluid Balance and Losses

Compared with adults, children exhibit differences in how fluid volume is maintained. These differences are evident in body fluid balance and insensible fluid losses.

#### Body Fluid Balance

Infants and children have a proportionately greater amount of body water than do adults. Infants and young children require a larger relative fluid intake than adults and excrete a relatively greater amount of fluid. This places them at increased risk for fluid loss with illness compared to adults. Until age 2 years, the extracellular fluid, with its larger proportion of sodium and chloride, makes up about half of the child's total body water. Therefore, when potential fluid-loss states occur, water loss occurs more rapidly and in larger amounts than in adults.

## Invisible Fluid Losses

Fever increases fluid loss at a rate of about 7 mL/kg/24-hour period for every sustained 1°C rise in temperature. Since children become febrile with illness more readily and their fevers are higher than those of adults, infants and young children are more apt than adults to experience insensible fluid loss with fever when ill.

Fluid loss via the skin accounts for about two thirds of insensible fluid loss. Infants have a relatively larger body surface area (BSA) compared to older children and adults. The newborn's BSA is about two or three times greater than the adult's, and the preterm infant's is about five times greater than the adult's. This places infants, especially young infants, at increased risk of insensible fluid loss as compared to older children and adults.

The basal metabolic rate in infants and children is higher than that of adults in order to support growth. This higher metabolic rate, even in states of wellness, accounts for increased insensible fluid losses and increased need for water for excretory functions. The young infant's renal immaturity does not allow the kidneys to concentrate urine as well as in older children and adults. This puts infants at particular risk for dehydration or overhydration, depending on the circumstances.

## COMMON MEDICAL TREATMENTS

There are many different forms of medical treatment for GI disorders. In the hospital setting, most medical treatments will require a physician's order. The most common treatments and medications used for GI disorders are listed in Common Medical Treatments 42.1 and Drug Guide 42.1. Both tables provide essential information about medical treatments and medications used in pediatric GI disorders. Refer to these tables as needed while completing the remainder of the chapter.

## NURSING PROCESS OVERVIEW FOR THE CHILD WITH A GASTROINTESTINAL DISORDER

Nursing care of the child with a GI disorder includes nursing assessment, nursing diagnosis, planning, interventions, and evaluation. It is important to individualize each step of this process for each child. A general understanding of the GI tract and the most common disorders can help the nurse to individualize the nursing care plan.

**Remember Ethan, the 2-month-old with vomiting and irritability? What additional health history and physical examination assessment information should you obtain?**

## Assessment

The assessment of the child with a GI disorder includes a health history, physical examination, and laboratory and diagnostic testing.

### Health History

A thorough health history is very important in the assessment of a child with a GI disorder. The health history includes past history (previous illnesses/surgeries), past family history, present illness (when the symptoms began and how this differs from the child's normal status), and how the child's symptoms have been managed up to this point (relevant medical records/home treatments). Detailed knowledge of the past medical and surgical history of the child may reveal bowel resection, previous intestinal infections, and dietary issues and problems.

The child's growth patterns can also be an instrumental part of the health history and may help to generate a timeline for when the current problems appeared. The family history is also extremely important in identifying common genetic or familial GI symptoms or disorders such as irritable bowel syndrome, inflammatory bowel disease, or food allergies. The history of the present illness and symptoms can often distinguish chronic problems from acute disorders. All of these pieces of the health history require descriptive questions and answers from both the nurse and the child, or the child's family. The person providing the history must be able to provide accurate details of the health history.

### Physical Examination

Perform the physical examination of the child from the least invasive part of the examination to the most invasive. It is important for the child to remain as relaxed as possible during this part of the assessment.

### INSPECTION AND OBSERVATION

Inspect and observe the child's color, hydration status, abdominal size and shape, and mental status.

**Color.** First observe the child's skin, eye, and lip color. Pale skin or lips in a child with a GI disorder may be a sign of anemia or dehydration. During liver dysfunction, the bilirubin levels can rise, causing the skin to look jaundiced (yellow). The sclerae can also become **icteric** (yellowed in color), further indicating that the liver is not functioning correctly. Inspect the abdomen for distended veins, which can indicate abdominal or vascular obstruction or distention. As in any part of a physical assessment, watch for areas of ecchymosis (bruising), which may be a sign of abuse.

## COMMON MEDICAL TREATMENTS 42.1

Treatment	Explanation	Indications	Nursing Implications
Cleansing enema	Insertion of fluid into the rectum to soften the stool and stimulate bowel activity	Fecal impaction, severe constipation	Explain procedure to child prior to enema. With multiple enemas, observe for electrolyte imbalances.
Bowel preparation	Use of highly osmotic fluids to induce severe diarrhea to cleanse the entire bowel	Preparation for colonoscopy or bowel surgery	Some children may need to have a nasogastric tube placed so they can consume the needed amounts of fluids. Observe for signs and symptoms of dehydration/electrolyte imbalance.
Feeding tubes	Flexible tubes used for enteral feeding when the infant or child is incapable of swallowing safely or for augmenting nutrition. May be orogastric, nasogastric, gastrostomy, or jejunostomy	Feeding difficulties, failure to thrive, gastroesophageal reflux disease, chronic illness	Orogastric and nasogastric tubes must be checked for placement prior to each use. If required long-term, use a softer, flexible tube intended for long-term use. Stomahesive® or Duoderm® applied to the cheek may decrease risk of skin breakdown from tape. Gastrostomy tubes vary in type. Keep insertion site clean and dry.
Intravenous therapy	Administration of fluids via a catheter that delivers electrolytes and fluids into the venous system	Dehydration, bowel rest, NPO status	Monitor intravenous site for redness, swelling, and pain. Assess urine output to evaluate hydration status.
Ostomy	A portion of the intestine is brought to the level of the skin to allow passage of stool.	Imperforate anus, Hirschsprung disease, necrotizing enterocolitis, Crohn disease, ulcerative colitis	Ostomy contents may be acidic and irritate the skin. Use Stomahesive® or Duoderm® under the pouch to avoid tape irritation to the skin. Pouch should fit the stoma correctly. Assess stoma for pinkness and moist appearance.
Oral rehydration therapy	Administration by mouth of fluids that contain certain amounts of electrolytes and glucose to prevent dehydration and/or promote rehydration	Diarrhea, acute gastroenteritis, vomiting	Fluid administration should begin prior to the onset of dehydration. Urine output should be monitored to evaluate hydration status.
Probiotics (lactobacillus, acidophilus)	Food supplement containing dormant bacteria that when activated may alter the intestinal microflora	Treatment/prevention of diarrhea	Particularly helpful in prevention of or decreasing incidence of antibiotic-induced diarrhea.
Total parenteral nutrition (TPN)	Intravenous complete nutrition. Provides glucose, protein, lipids, vitamins, and minerals	Long-term NPO status, swallowing difficulties, difficulties tolerating enteral feeding (short bowel syndrome, necrotizing enterocolitis)	Higher glucose and protein concentrations and solutions containing calcium require central venous access. Monitor blood glucose levels with initiation, rate changes, and discontinuation. Blood chemistries should be monitored on a regular basis.

**Hydration Status.** The child's hydration status often indicates how severe the current GI illness is. Dehydration can occur rapidly in children, especially in infants and young children. The oral mucosa should be pink and moist. Skin turgor should be elastic. Decreased turgor and tenting indicate dehydration. During crying, especially in infants, the absence of tears may indicate dehydration. Assess the amount of urine output the child has had in the past 24 hours.

**Abdominal Size and Shape.** Inspect the size and shape of the abdomen while the child is standing and while the child is lying supine. The abdomen should be flat when the child is supine. An especially **protuberant** (bulging outward) abdomen suggests the presence of ascites, fluid retention, gaseous distention, or even a tumor. However, many children (toddlers in particular) have a prominent “pot-bellied” abdomen as a normal variation of their anatomy (Weber & Kelley, 2010).

## DRUG GUIDE 42.1 COMMON DRUGS FOR GI DISORDERS

Classification	Actions/Indications	Nursing Implications
Histamine-2 blockers (ranitidine, famotidine, cimetidine, nizatidine)	Decrease histamine production, thereby reducing gastric acid secretion Used for heartburn, esophagitis, GERD, benign duodenal or gastric ulcers	May cause drowsiness or dizziness.
Proton pump inhibitors (omeprazole, lansoprazole, esomeprazole, pantoprazole, rabeprazole)	Block the pump that produces gastric acids Indicated for erosive esophagitis, symptomatic GERD, <i>H. pylori</i> eradication	Adverse effects include headache, nausea, abdominal pain, or diarrhea.
Prokinetics (metoclopramide, cisapride)	Stimulate GI motility to help empty the stomach faster and promote intestinal motility	Metoclopramide may have central nervous system adverse effects. Cisapride available only in limited-access protocol studies.
Antibacterials/antibiotics (metronidazole, vancomycin)	Treatment of bacterial infections of the GI tract Used for suspected or proven bacterial infections of the GI tract, such as <i>Clostridium difficile</i> or parasitic infections	May cause GI upset, diarrhea. Very important to finish entire course of treatment.
Immunosuppressants (6-mercaptopurine, azathioprine)	Suppress the immune system to keep autoimmune disorders in remission such as Crohn disease, ulcerative colitis, autoimmune hepatitis	Drug levels should be checked to determine drug metabolite levels and potential for hepatotoxicity or bone marrow suppression.
Stimulants (senna, docusate sodium)	Stimulate peristalsis in the large intestine to produce a bowel movement Used to relieve constipation	May cause cramping or diarrhea. Stool patterns should be constantly assessed.
Laxatives (polyethylene glycol, milk of magnesia, lactulose)	Soften the stool to allow for easier passage through the colon Used to relieve constipation	Stool patterns should be monitored. Doses may need to be readjusted frequently to find the correct dose for the child.
Antidiarrheals (loperamide, diphenoxylate/atropine)	Decrease peristalsis, thus prolonging transit time of stool through the intestines Indicated to treat diarrhea related to short bowel syndrome, chronic nonspecific diarrhea, irritable bowel syndrome	May cause drowsiness or constipation.
Corticosteroids (prednisone)	Act systemically to reduce inflammation and suppress the normal immune response Used in inflammatory bowel disease, autoimmune disorders	Systemic adverse effects include hirsutism, osteoporosis, GI upset, cushingoid appearance, increased intraocular pressure, irritability, and personality changes. Should be taken as directed. Stopping the medication suddenly may cause adrenal insufficiency.
Antiemetics (promethazine, metoclopramide)	Act on the central nervous system transmitters to prevent nausea and vomiting	May have central nervous system adverse effects, such as drowsiness or irritability.
Anticholinergic/antispasmodics (hyoscyamine, dicyclomine, glycopyrrolate)	Used to control abdominal spasms and cramping associated with irritable bowel syndrome, functional bowel disorders	May cause excessive thirst or dizziness. Encourage plenty of fluids while taking these medications.

**DRUG GUIDE 42.1 COMMON DRUGS FOR GI DISORDERS** (continued)

Classification	Actions/Indications	Nursing Implications
Anti-inflammatories (mesalamine, balsalazide, hydrocortisone enemas/ suppositories, olsalazine, sulfasalazine)	Reduce inflammation in the colon associated with ulcerative colitis, proctitis	Stool output should be monitored to assess for presence of oral medications (indicating poor absorption).
Adapted from Taketokmo, C. K., Hodding, J. H., & Kraus, D. M. (2011). <i>Pediatric and neonatal dosage handbook</i> (18th ed.). Hudson, OH: Lexi-comp.		

A depressed or concave abdomen could indicate a high abdominal obstruction or dehydration. Inspect the umbilicus for color, odor, discharge, inflammation, and herniation.

**Mental Status.** Perform a brief mental status examination of all children with GI complaints. Mental status changes can occur in many instances, such as during severe dehydration, with anaphylactic reactions to foods or medicines, when ammonia levels are elevated with severe liver disease, and with other metabolic disorders. Irritability and restlessness are usually the early signs of mental status changes. **Lethargy** (sluggishness or abnormal drowsiness) and listlessness can occur much more rapidly in children than in adults. It is important to identify this promptly and treat it emergently.

### AUSCULTATION

As with all children, auscultate bowel sounds in all four quadrants. Hyperactive bowel sounds may be noted in children with diarrhea or gastroenteritis. Hypoactive or absent bowel sounds may signify an obstructive process. The nurse can determine absence of bowel sounds after a 5-minute period of auscultation. This can be extremely difficult to perform with children and infants, who may be uncooperative during the examination. Immediately report hypoactive or absent bowel sound findings to the physician or nurse practitioner.

### PERCUSSION

Dullness or flatness is normally found along the right costal margin and 1 to 3 cm below the costal margin of the liver. The area above the symphysis pubis may be dull in young children with full bladders, which is a normal finding. Percussion of the remainder of the abdomen should reveal tympany. Note abnormal findings.

### PALPATION

Reserve palpation for last in the sequence of abdominal examination. First, lightly palpate the abdomen to

assess for areas of tenderness, lesions, muscle tone, turgor, and cutaneous hyperesthesia (a finding in acute peritonitis). Then perform deep palpation from the lower quadrants upward to best feel the liver edge, which should be firm and smooth. In infants and children, palpate the liver during inspiration below the right costal margin. The tip of the spleen may be palpated also during inspiration; it should be 1 to 2 cm below the left costal margin. Palpable kidneys, except in neonates, may indicate tumor or hydronephrosis. The sigmoid colon can be palpated in the left lower quadrant. The cecum may be felt in the right lower quadrant as a soft mass. Areas of firmness or masses may indicate tumor or stool in the abdomen.

Tenderness in the abdomen is not a normal physical finding. Right upper quadrant tenderness could indicate liver enlargement. Right lower quadrant pain, including **rebound tenderness** (pain upon release of pressure during palpation), can be a warning sign of appendicitis; immediately report any positive findings to a physician. Palpate the external inguinal canals for the presence of inguinal hernias, often elicited by having the child turn the head and cough, or blow up a balloon.

### Laboratory and Diagnostic Testing

Common Laboratory and Diagnostic Tests 42.1 gives information about the tests most often ordered by physicians for children with GI illnesses. Some of these tests are ordered in the hospital setting; others are done on an outpatient basis. Typically, the nurse is involved directly in specimen collection while a specifically trained person performs the diagnostic tests. Regardless of who performs the test, nurses must be familiar with preparation guidelines for the child, how each test is performed, and normal and abnormal findings and their significance in order to provide appropriate child and family education. Teaching Guidelines 42.1 gives tips on collecting stool specimens.

## COMMON LABORATORY AND DIAGNOSTIC TESTS 42.1

Test	Explanation	Indications	Nursing Implications
Abdominal ultrasonography	Visualizes abdominal organs and related vessels	Abdominal pain, vomiting, pregnancy, abnormal liver tests, abdominal mass, enlarged organs on palpation	Barium decreases visualization of organs on ultrasound.
Abdominal radiograph (KUB)	Plain radiograph of the abdomen without contrast media	Constipation, abdominal pain, abdominal distention, ascites, foreign body, palpable mass	Usually ordered as flat and upright to allow for free air and fluid levels in the bowel to be detected.
Amylase (serum)	An enzyme that changes starch to sugar, which enters the blood with inflammation of the pancreas	Acute pancreatitis, pancreatic trauma, acute cholecystitis	Increased levels are seen after 3 to 6 hours of the onset of abdominal pain.
Barium enema	After instillation of barium, fluoroscopically allows visualization of the colon	Constipation, rectal prolapse, bleeding, suspected intussusception	Bowel preparation prior to examination may be ordered. Stool will be light colored due to barium for a few days.
Electrolytes (serum)	Sodium, potassium, CO <sub>2</sub> , chloride, blood urea nitrogen (BUN), creatinine	To determine extent of dehydration	BUN and creatinine may be elevated with dehydration. Sodium, potassium, chloride, and CO <sub>2</sub> levels can be greatly affected with dehydration.
Barium swallow/upper GI series	Visualizes the form, position, mucosal folds, peristaltic activity, and motility of the esophagus, stomach, and upper GI tract	Foreign body ingestion, abdominal pain, vomiting, dysphagia, malrotation	Females of reproductive age must be screened for pregnancy. Infants may need to be given barium via syringe.
Small bowel series	Done in conjunction with upper GI series to visualize the small intestine contour, position, and motility	Suspected inflammatory bowel disease (bowel wall thickening), intussusception	Very important to encourage large amounts of water/fluids after test to avoid barium-induced constipation.
Endoscopic retrograde cholangiopancreatography (ERCP)	A fiberoptic endoscope is used to view the hepatobiliary system by instilling contrast to outline the pancreatic and common bile ducts.	Pancreatitis, jaundice, pancreatic tumors, common duct stones, biliary tract disease	Monitor for infection, urinary retention, cholangitis, or pancreatitis after the procedure. Done only occasionally in children.
Esophageal manometry	Tests the esophagus for normal contractile activity and effectiveness of swallowing by measurement of intraluminal pressures and acid sensors	Abnormal esophageal muscle function, dysphagia, chest pain of unknown cause, esophagitis, vomiting	Often done in conjunction with pH probe. The manometric catheter is placed through the nose into the esophagus. May cause nasal irritation/sore throat.
Esophageal pH probe	A single- or double-channelled probe placed into the esophagus to monitor the pH of the contents that are regurgitated into the esophagus from the stomach	Vomiting, gastroesophageal reflux, correlation of symptoms to gastroesophageal reflux events and high risk for problems, as in asthma, apparent life-threatening event, sinusitis, or choking/gagging episodes	24-hour study is most accurate. Special diet during study is often used. Accurate diary of symptoms and feedings during the study is essential. May cause nasal irritation/sore throat.

<b>COMMON LABORATORY AND DIAGNOSTIC TESTS 42.1</b> (continued)			
<b>Test</b>	<b>Explanation</b>	<b>Indications</b>	<b>Nursing Implications</b>
Gastric emptying scan	Assesses the rate at which the stomach empties food into the small intestine by adding isotopes to food and visualizing with scans	Unexplained nausea, vomiting, diarrhea, abdominal cramping	Medications may alter gastric emptying times. Crying or stress during the examination may cause delay in emptying and should be documented.
Hemoccult	Checks for occult blood in the stool	Crohn disease, ulcerative colitis, malabsorption syndromes, diarrhea, abdominal pain	Indicates bleeding in the GI tract.
Hepatobiliary scan (HIDA scan)	Visualizes the gallbladder and determines patency of the biliary system by use of a radionuclide. The amount of radionuclide ejected from the gallbladder (ejection fraction) is calculated.	Differentiate between biliary atresia and neonatal hepatitis; assess liver trauma, right upper quadrant pain, and congenital malformations	Intravenous line will be established to give radionuclide. Pain during injection should be assessed and documented.
Lactose tolerance test	After ingesting lactose, this tests the hydrogen levels in the breath, which will increase with lactose build-up in the intestines.	Postprandial diarrhea, gasiness, bloating, abdominal pain	May produce similar symptoms during the test itself. A positive test will require diet modification and education regarding lactose intolerance.
Lipase (serum)	An enzyme that changes fat to fatty acids and glycerol appearing in the blood with pancreatic change	Pancreatitis, pancreatic carcinoma, cholecystitis, peritonitis	Lipase levels stay elevated longer with acute pancreatitis.
Liver biopsy	A test done to evaluate the microscopic hepatic structures	Hyperbilirubinemia, jaundice, chronic liver disease, hepatitis	Monitor after procedure for bleeding complications; must maintain strict bed rest for up to 8 hours.
Liver function tests (LFTs) (AST/ALT/ GGT)	Enzymes that have high concentrations in the liver	Elevations may indicate the severity of liver disease.	May be affected by drugs or viral illnesses.
Lower endoscopy (colonoscopy)	Allows visualization and biopsies of the lower GI tract from the anus to the terminal ileum with a fiberoptic instrument	Rectal bleeding, lower abdominal pain, suspected tumors or strictures, foreign body removal	The child must undergo a bowel cleansing prior to the examination. Encourage fluids to prevent dehydration. Conscious sedation or anesthesia care; monitor for possible complications of perforation, bleeding, and increased abdominal pain.
Meckel scan	A gamma camera is used to identify gastric mucosa seen in the distal portion of the ileum after injection of radiopharmaceuticals.	Rectal bleeding, anemia, used only to identify a Meckel diverticulum	Gloves are worn by nurse during and after scan when radiopharmaceuticals are given.
Oropharyngeal motility study (OPMS)	A study done with different textures to evaluate the dynamics of swallowing and reveal transient abnormalities	Dysphagia, recurrent aspiration	Usually done in combination with therapists and nutritionist.

(continued)

## COMMON LABORATORY AND DIAGNOSTIC TESTS 42.1 (continued)

Test	Explanation	Indications	Nursing Implications
Rectal suction biopsy	Biopsy is taken of the rectum at different levels to assess for the presence of ganglion cells.	Absence of ganglion cells indicates Hirschsprung disease.	Infants/children should be assessed for rectal bleeding after examination.
Stool culture	Stool is smeared on culture medium and assessed for growth of bacteria over a period of days.	To determine bacterial cause of diarrhea	Requires minimum of 48 hours for growth, several days to weeks in some cases. Can be done with a small amount of stool
Stool for ova and parasites (O&P)	Checks for the presence of parasites or their eggs in the stool	To determine cause of diarrhea or abdominal pain	Requires about 2 tablespoons of stool.
Upper endoscopy (EGD)	Allows visualization and biopsies of the upper GI tract (mouth to upper jejunum) with a fiberoptic instrument	Dysphagia, foreign body removal, epigastric/abdominal pain, suspected celiac disease	Conscious sedation or anesthesia care; monitor for complications of perforation/bleeding.
Urea breath test	Used to detect the presence of <i>H. pylori</i> in the exhaled breath	<i>H. pylori</i> infection	Child must not take proton pump inhibitors for 5 days, all antibiotic therapy and Pepto-Bismol for 14 days.

Adapted from Pagana, K. D., & Pagana, T. J. (2010). *Mosby's manual of diagnostic and laboratory tests* (4th ed.). St. Louis: Mosby.

## Teaching Guidelines 42.1

## STOOL SPECIMEN COLLECTION VARIATIONS

- If the child is in diapers, use a tongue blade to scrape a specimen into the collection container.
- If the child has runny stool, a piece of plastic wrap in the diaper may catch the stool specimen. Very liquid stool may require application of a urine bag to the anal area to collect the stool.
- The older ambulatory child may first urinate in the toilet, and then the stool specimen may be retrieved from the new or clean collection container that fits under the seat at the back of the toilet.
- For the bedridden child, collect the stool specimen from a clean bedpan (do not allow urine to contaminate the stool specimen).
- Send the specimen to the laboratory immediately for accuracy of results.

## Nursing Diagnoses, Goals, Interventions, and Evaluation

Upon completion of a thorough assessment, the nurse might identify several nursing diagnoses, including:

- Risk for deficient fluid volume

- Diarrhea
- Constipation
- Risk for impaired skin integrity
- Imbalanced nutrition: less than body requirements
- Pain
- Ineffective breathing pattern
- Risk for caregiver role strain
- Disturbed body image

**After completing an assessment on Ethan, you note the following: weight 10 lbs, length 23.5 inches, head circumference 40.75 cm. Head is round with sunken anterior fontanel, eyes appear sunken, mucous membranes are dry, heart rate 158, breath sounds clear with respiratory rate of 42, positive bowel sounds in all four quadrants, difficulty palpating abdomen due to crying. Based on these assessment findings, what would your top three nursing diagnoses be for Ethan?**

Nursing goals, interventions, and evaluation for the child with a GI disorder are based on the nursing diagnoses. Nursing Care Plan 42.1 can be used as a guide in

## NURSING CARE PLAN 42.1

## Overview for the Child With a Gastrointestinal Disorder

**NURSING DIAGNOSIS:** Fluid volume, risk for deficit: risk factors may include excessive losses through vomiting or diarrhea, inadequate oral intake, possible NPO status (particularly in the surgical child)

**Outcome Identification and Evaluation**

Child will maintain adequate fluid volume as evidenced by *elastic skin turgor; moist, pink oral mucosa; presence of tears; urine output 1 mL/kg/hour or more.*

**Interventions: Maintaining Fluid Balance**

- Maintain IV line and administer IV fluid as ordered *to maintain fluid volume.*
- Offer small amounts of oral rehydration solution frequently *to maintain fluid volume. Small amounts are usually well tolerated by children with diarrhea and vomiting.*
- When symptoms have lessened or resolved, reintroduce regular diet *to reduce number of stools, provide adequate nutrition, and shorten duration of effects of illness.*
- Avoid high-carbohydrate fluids such as Kool-aid and fruit juice, *as they are low in electrolytes, and increased simple carbohydrate consumption can decrease stool transit time.*
- Assess hydration status (skin turgor, oral mucosa, presence of tears) every 4 to 8 hours *to evaluate maintenance of adequate fluid volume.*
- Assess adequacy of urine output *to assess end-organ perfusion.*
- Maintain strict intake and output record and weigh child daily *to evaluate effectiveness of rehydration.*
- Weigh child daily: *accurate weight is one of the best indicators of fluid volume status in children.*
- Discourage milk products and fluids that contain high levels of sugar during the acute phase of illness, *as these products may worsen diarrhea.*

**NURSING DIAGNOSIS:** Diarrhea; may be related to inflammation of small intestines, presence of infectious agents or toxins, possibly evidenced by loose liquid stools, hyperactive bowel sounds, or abdominal cramping

**Outcome Identification and Evaluation**

Child will experience decrease in diarrhea: *will have bulkier stool as per normal routine.*

**Interventions: Relieving Diarrhea**

- Maintain clear liquid diet no longer than 24 hours, *as prolonged clear liquids will result in continued liquid (“starvation”) stools.*
- Avoid milk products until diarrhea improves: *temporary poor absorption from villus injury follows viral diarrhea.*
- Encourage complex carbohydrate foods *to bulk up the stools.*
- Add fat to carbohydrates *to increase intestinal transit time to encourage water absorption (bulks up stool).*

(continued)

## NURSING CARE PLAN 42.1

## Overview for the Child With a Gastrointestinal Disorder (continued)

**NURSING DIAGNOSIS:** Constipation, related to GI obstructive lesions, pain on defecation, diagnostic procedures, inadequate toileting, or behavioral stool holding, possibly evidenced by change in character or frequency of stools, feeling of abdominal or rectal fullness or pressure, changes in bowel sounds, and abdominal distention

**Outcome Identification and Evaluation**

Child will experience improvement in constipation *by passing daily soft bowel movement without pain or straining.*

**Intervention: Relieving Constipation**

- Palpate for abdominal distention, percuss for dullness, and auscultate for bowel sounds *to assess for signs of constipation.*
- Encourage adequate fluid intake *to soften the stool.*
- Administer medications as ordered *to keep stool moving on daily basis.*
- Encourage activity as tolerated: *immobility contributes to constipation.*
- The child with stool withholding should sit on the toilet twice daily, preferably after breakfast and dinner, *to maximize chances for successful stool passage by taking advantage of the gastrocolic reflex.*
- For behavioral stool holding, use rewards or stickers *to encourage appropriate toileting.*

**NURSING DIAGNOSIS:** Skin integrity, risk for impaired: risk factors include frequent loose stools, poor nutritional status, presence of stoma, acidic gastric contents contact with skin if gastrostomy present

**Outcome Identification and Evaluation**

Infant's skin will remain intact: *buttocks skin will be free from rash, excoriation.* In the child with an ostomy: skin surrounding stoma will remain intact: *free from redness, rash, excoriation.*

**Intervention: Maintaining Skin Integrity**

- Change diapers frequently *to limit acidic stool content contact with skin.*
- Use barrier diaper cream *to protect skin.*
- Assess skin integrity at every diaper change *to recognize skin changes early so that corrective measures can begin.*
- Leave diaper area open to air several times a day if redness is present *so that air can circulate and skin healing can be facilitated.*
- Use plain water or only mild soap to cleanse the skin with diaper changes *to avoid pH changes that contribute to diaper area skin breakdown.*
- Avoid diaper wipes that contain fragrance or alcohol if the skin is red or has a rash, *as both alcohol and perfume cause stinging if used on nonintact skin and can worsen skin breakdown.*

For the child with an ostomy:

- Ensure proper fit of the ostomy appliance/pouch *to avoid acidic stool contact with skin.*
- Use a barrier wafer (e.g., Stomahesive® or Duoderm®) to attach appliance: *avoids repeated pulling of adhesive tape from skin.*
- If redness occurs, use barrier/healing cream or paste on skin around stoma *to promote healing and prevent further skin breakdown.*
- Consult enterostomal therapy nurse as needed *to provide additional support.*

**NURSING DIAGNOSIS:** Nutrition: imbalanced, less than body requirements; may be related to inability to ingest, digest, or absorb nutrients; intestinal pain after eating; decreased transit time through bowel; or psychosocial factors, possibly evidenced by lack of appropriate weight gain or growth, weight loss, aversion to eating, poor muscle tone, or observed lack of intake

## NURSING CARE PLAN 42.1

**Overview for the Child With a Gastrointestinal Disorder** (continued)**Outcome Identification and Evaluation**

Nutritional status will be maximized: *child will maintain or gain weight appropriately.*

**Intervention: Maintaining Appropriate Nutrition**

- Encourage favorite foods (within prescribed diet restrictions if present) *to maximize oral intake.*
- Administer enteral tube feedings as ordered *to maximize caloric intake.*
- Add butter, gravy, or cheese as appropriate to foods (if allowed within diet restrictions) *to increase caloric intake.*
- Encourage high-quality, high-calorie snacks between meals, *so as not to interfere with meal intake.*
- Document response to feeding *to determine feeding tolerance.*
- Limit intake of calorie-free beverages: *beverages should contain nutrients and calories.*
- Consult nutritionist *for appropriate diet supplementation recommendations.*

**NURSING DIAGNOSIS:** Breathing pattern, ineffective, related to postoperative immobility, abdominal pain interfering with breathing, use of narcotic analgesics as evidenced by increased work of or shallow breathing, tachypnea, decreased lung aeration

**Outcome Identification and Evaluation**

Child will demonstrate effective breathing pattern: *respiratory rate normal for age, absence of accessory muscle use, adequate aeration with clear breath sounds throughout all lung fields.*

**Intervention: Promoting Effective Breathing Patterns**

- Turn, cough, and deep breathe every 2 hours *to encourage adequate aeration and discourage fluid pooling in lungs.* In the infant or toddler, turn every 2 hours and use percussor or chest physiotherapy *to prevent pooling of secretions.*
- Play games to encourage deep breathing (blow out penlight, blow cotton ball across bedside table with straw, etc.): *children are more likely to cooperate with interventions if play is involved.*
- In the developmentally able child, encourage incentive spirometer use every 2 hours *to improve lung aeration.*
- Demonstrate/encourage use of pillow splinting with coughing *to decrease abdominal pain and stress on incision.*

**NURSING DIAGNOSIS:** Caregiver role strain, risk for: risk factors may include infant with congenital defect, child with chronic illness, marginal caregiver coping patterns, long-term stress, complexity and quantity of care child requires

**Outcome Identification and Evaluation**

Caregiver will exhibit emotional health: *verbalizes concerns calmly, participates in child's care, and demonstrates knowledge of resources.*

**Intervention: Easing Caregiver Role Strain**

- Assess parental behavior *to identify role strain.*
- Provide emotional support and encourage talking about feelings, fears, and concerns: *to promote trust in nurse as a source of emotional support.*
- Arrange for and/or encourage respite care for child: *provides parent with time away from continual care.*
- Consult social services *to identify community resources available for caregiver support (home health, support group, etc.).*
- Encourage parent to meet own needs and find personal time *to increase energy level and self-esteem, ultimately enhancing the quality of care given.*

(continued)

## NURSING CARE PLAN 42.1

## Overview for the Child With a Gastrointestinal Disorder (continued)

**NURSING DIAGNOSIS:** Body image disturbance; may be related to presence of stoma, loss of control of bowel elimination, scars from multiple surgical procedures, or effects of treatment regimen, possibly evidenced by verbalization of negative feelings about body, refusal to look at stoma or participate in care

**Outcome Identification and Evaluation**

Child or teen will demonstrate acceptance of change in body image *by verbalization of adjustment; looking at, touching, and caring for body; and returning to previous social involvement.*

**Intervention: Promoting Proper Body Image**

- Observe child's coping mechanisms *to reinforce their use in times of stress.*
- Acknowledge denial, anger, and other feelings as normal *to support child/teen through difficult transition.*
- Allow child gradual introduction *to stoma to ease transition.*
- Encourage child/teen to participate in care, *as this sense of control will contribute to positive self-esteem.*

planning nursing care for the child with a GI disorder. Individualize the nursing care plan based on the child's symptoms and needs. Refer to Chapter 36 for detailed information about pain management. Additional information will be included later in the chapter as it relates to specific disorders.

**Based on your top three nursing diagnoses for Ethan, describe appropriate nursing interventions.**

**Stool Diversions**

Children may undergo stool diversions for a variety of GI disorders. Surgical procedures involve the creation

of an ostomy, primarily an *ileostomy* or *colostomy*, by bringing a portion of the small or large intestine to the surface of the abdomen (Fig. 42.1).

Ostomy pouches are worn over the ostomy site to collect stool. The pouch must be of an appropriate size and it should fit around the stoma properly (Fig. 42.2). The pouch may be tucked inside the diaper or underwear or angled to fit outside of the diaper/underwear. Contemporary pouches cannot be seen under most clothing because they are designed to lie flat against the body. Avoid tight or constricting clothing around the stoma site. Teach families to store ostomy supplies in a cool, dry place. Educate parents to inform school staff that the child should be allowed to use the water fountain and the bathroom without restriction, and the school nurse should have extra ostomy supplies available.

**FIGURE 42.1** A colostomy is a stoma from the colon; an ileostomy is a stoma from the ileum.

**FIGURE 42.2** Ensure that the ostomy pouch fits closely around the stoma to prevent irritation of the surrounding skin.

Ostomy care for a child can be challenging due to the child's normal growth and development as well as activity. Empty the ostomy pouch and measure for stool output several times per day. The stool may be semisolid to very liquid in consistency depending on the location of the stoma. Liquid stool output can be acidic, causing irritation and severe burn-like areas on the surrounding skin, so special attention to skin care around the ostomy site is essential. Products such as powders and pastes are available to help protect the skin.

The stoma should be moist and pink or red, demonstrating proper circulation to the intestine (Fig. 42.3). Immediately notify the provider if the stoma is not moist and pink or red. Also notify the provider if the volume of stool output is greatly increased, or if the stoma is prolapsed or retracted.

**FIGURE 42.3** The healthy stoma is pink and moist.

## NURSING PROCEDURE 42.1

### Performing Ostomy Care

1. Set up the equipment:
  - Warm, wet washcloths or paper towels
  - Clean pouch and clamp
  - Skin barrier powder, paste, and/or sealant
  - Pencil or pen
  - Scissors
  - Pattern to measure stoma size
2. Take off the pouch (may need to use adhesive remover or wet washcloth to ease pouch removal).
3. Observe the stoma and surrounding skin. Clean the stoma and skin as needed, allowing it to dry thoroughly.
4. Measure the stoma, mark the new pouch backing, and cut the new backing to size.
5. Apply the new pouch.

Adapted from Children's Hospital Boston. (2011b). *Home care instructions for changing an ostomy pouch (bag or appliance)*. Boston, MA: Author.

Perform ostomy care as needed; pouches usually need to be changed every 1 to 4 days. Refer to Nursing Procedure 42.1 for an explanation of the steps for changing an ostomy pouch.

## STRUCTURAL ANOMALIES OF THE GASTROINTESTINAL TRACT

Structural anomalies of the GI tract include cleft lip and palate, hernias (inguinal and umbilical), and anorectal malformations.

### Cleft Lip and Palate

Cleft lip and palate (Fig. 42.4) is the most common congenital craniofacial anomaly, occurring once in every 700 births worldwide. It occurs frequently in association with other anomalies and has been identified in more than 350 syndromes (Curtin & Boekelheide, 2010). The most common anomalies associated with cleft lip and cleft palate include heart defects, ear malformations, skeletal deformities, and genitourinary abnormality.

Complications of cleft lip and palate include feeding difficulties, altered dentition, delayed or altered speech development, and otitis media. The infant with cleft lip may have difficulty forming an adequate seal

**FIGURE 42.4** The cleft lip may extend all the way through the vermilion border and up into the nostril, or it may be significantly smaller. The cleft palate may be a small opening or may involve the entire palate.

around a nipple in order to create the necessary suction for feeding and may also experience excessive air intake. Gagging, choking, and nasal regurgitation of milk may occur in babies with cleft palate. Excessive feeding time, inadequate intake, and fatigue contribute to insufficient growth. Primary or permanent teeth may be missing, malformed, or unusually positioned. Children with cleft palate may have a nasal quality to the speech as well as delays in speech development. Optimally, speech articulation should be clear by 4 years of age, or additional surgical intervention may be necessary (Curtin & Boekelheide, 2010). The opening in the cleft palate contributes to build-up of fluid in the middle ear (otitis media with effusion), which can lead to an acute infection (acute otitis media). Long-lasting otitis media with effusion leads to temporary and sometimes permanent hearing loss (Curtin & Boekelheide, 2010).

## Pathophysiology

Development of the **cleft** occurs early in pregnancy. The tissue that forms the lip ordinarily fuses by 5 to 6 weeks of gestation, and the palate closes between 7 and 9 weeks of gestation. Therefore, if either the lip or palate does not fuse, then the infant is born with a cleft. Cleft lip or cleft palate may occur in isolation from one another, but 50% of infants born with cleft lip also have cleft palate (Curtin & Boekelheide, 2010). The cleft may be unilateral (the left side is affected more often) or bilateral.

## Therapeutic Management

Babies with cleft lip and cleft palate are usually managed by a specialized team that may include a plastic surgeon or craniofacial specialist, oral surgeon, dentist or orthodontist, prosthodontist, psychologist, otolaryngologist, nurse, social worker, audiologist, and speech-language pathologist.

Many children's hospitals offer these services in one location, such as a craniofacial specialty center. Historically, cleft lip has been repaired surgically around the age of 2 to 3 months and cleft palate at 9 to 18 months. Early repair of the cleft lip restores a normal appearance to the child's face and may improve parent–infant bonding. Regardless of the timing of the surgical repair, however, surgical revision of the palate may be required as the child grows.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1498. Assessment findings pertinent to cleft lip and palate are discussed below.

### Health History

For the newborn, explore pregnancy history for risk factors for development of cleft lip and cleft palate, which include:

- Maternal smoking
- Prenatal infection
- Advanced maternal age
- Use of anticonvulsants, steroids, and other medications during early pregnancy

When an infant or child with cleft lip or palate returns for a clinic visit or hospitalization, inquire about feeding difficulties, respiratory difficulties, speech development, and otitis media.

### Physical Examination

Observe the infant for the presence of the characteristic physical appearance of cleft lip. The cleft may involve the lip only or extend up into the nostril (Fig. 42.5). Cleft palate may be visualized on examination of the mouth. Palpate with a gloved finger to discover mild clefts.

FIGURE 42.5 Cleft lip.

### Laboratory and Diagnostic Tests

Cleft lip may be diagnosed by prenatal ultrasound, but it is diagnosed most commonly at birth by the classic physical appearance.

### Nursing Management

Refer to Nursing Care Plan 42.1 for nursing diagnoses and interventions related to airway maintenance, fluid balance promotion, and restoration of family processes, and to Chapter 36 for pain management. These should be individualized for the particular situation. In addition to the nursing diagnoses and related interventions discussed in Nursing Care Plan 42.1, interventions common to cleft lip and cleft palate follow.

### Preventing Injury to the Suture Line

It is critical to prevent injury to the facial suture line or to the palatal operative sites. Do not allow the infant to rub the facial suture line. To prevent this, position the infant in a supine or side-lying position. It may be necessary to use arm restraints to stop the hands from touching the face or entering the mouth. Clean the suture line as ordered by the surgeon. Possible care options include using petroleum jelly on the facial suture line or a lip-protective device such as a Logan bow (curved thin metal apparatus) or a butterfly adhesive, both of which protect and maintain the suture line. Protect the palate operative site. Avoid putting items in the mouth that might disrupt the sutures (e.g., suction catheter, spoon, straw, pacifier, or plastic syringe).

Prevent vigorous or sustained crying in the infant, because this may cause tension on either suture line. Ways

to prevent crying include administering medications as needed for pain and providing other comfort or distraction measures, such as cuddling, rocking, and anticipation of needs.

### Promoting Adequate Nutrition

Preoperatively, the baby with a cleft lip may demonstrate enhanced growth patterns if breastfed. The contour of the breast against the lip may allow for a better seal to be maintained for adequate sucking (Reilly, Reid, Skeat, & the Academy of Breastfeeding Medicine Clinical Protocol Committee, 2007). Some infants will be fed with a special cleft lip nipple (Fig. 42.6). Parent and surgeon preference will determine the method of feeding. Burp the infant well to expel excess air taken in during difficulty with sucking.

The infant with unrepaired cleft palate is at risk for aspiration with oral feeding. In some instances a prosthodontic device may be created to form a false palate covering. This device may prevent breast milk

FIGURE 42.6 (A) Specialty feeding devices used for infants with cleft lip and cleft palate. (B) An infant uses a Haberman feeder.

or formula from being aspirated. Breastfeeding may be effective in the infant with cleft palate due to the pliability of the breast and the fact that breast tissue may cover the opening in the palate. Postoperatively, some surgeons allow breastfeeding to be resumed almost immediately (Reilly et al., 2007). In the bottle-fed infant special nipples or feeders may have to be used. When the suture line is healed, ordinary feeding may resume.

### Encouraging Infant–Parent Bonding

For some parents, the appearance of a cleft lip is appalling (Curtin & Boekelheide, 2010). Encourage parents to hold the medically stable infant immediately after delivery to encourage bonding. Acknowledge normal feelings of guilt, anger, and sadness. Support the parents in providing care for the infant, particularly feeding, which is viewed as a significant nurturing function. Provide education about the anticipated surgical procedure and eventual normal appearance of the infant's lip.

### Providing Emotional Support

Many families will benefit from support in addition to that received from the craniofacial team. Refer parents to the Cleft Palate Foundation or a parent-to-parent support network, links to which can be found on [thePoint](#). See Healthy People 2020.

#### HEALTHY PEOPLE 2020

Objective	Nursing Significance
Increase the number of states and the District of Columbia that have a system for referral for cleft lips and cleft palates to rehabilitative teams.	<ul style="list-style-type: none"> <li>• Ensure that your office, clinic, or hospital participates in such a system.</li> <li>• If it does not, advocate for such participation.</li> </ul>

*Healthy People* Objectives based on data from <http://www.healthypeople.gov>.

### Anorectal Malformations

Imperforate anus is a congenital malformation of the anorectal opening identified in the newborn period (Levitt & Pena, 2010). Primary repair may occur at birth for infants with uncomplicated low-level lesions. Many newborns receive an ostomy at birth to allow bowel evacuation. The pediatric nurse may encounter the infant with imperforate anus and an ostomy when the child

is admitted to the hospital at several months of age for corrective surgery. Infants often require a staged repair in which the bowel is connected to the anal opening or an anal opening is created (pull-through procedure) (Levitt & Pena, 2012). When the final repair is achieved, the stoma will be closed and the infant will pass stool through the anal opening.

### Nursing Assessment

Preoperatively, perform a thorough physical assessment. In particular note weight, length and head circumference to determine adequate growth. Assess the stoma for pinkness and consistency/volume of stool.

### Nursing Management

Nursing management focuses on preparing infant for surgery and providing postoperative care. Preoperatively, maintain the infant's NPO status and provide bowel cleansing as ordered. Monitor the infant's hydration status. Educate the family about the surgical procedure, immediate postoperative, and follow-up care. Provide support to the parents and family.

Postoperative care includes ensuring adequate pain relief, maintaining NPO status and hydration as well as providing gastric decompression until bowel motility is restored. After the intestinal pull-through procedure is completed, it will be the first time that stool has passed through the anal sphincter. The stool may be quite loose depending on the severity of the imperforate anus. The perianal skin is at significant risk for breakdown. Therefore, use a barrier cream on the area and clean it once daily with soap and water.

Otherwise, wipe liquid stool off the barrier cream with mineral oil and cotton balls. Most of the barrier cream will remain intact, protecting the infant's perianal area. Teach parents appropriate perineal skin care. Refer parents to the Pull-thru Network for additional support and resources (<http://www.pullthrunetwork.org/>).

#### Take Note!

To decrease the drying associated with frequent cleaning, avoid baby wipes and frequent use of soap and water.

### Meckel Diverticulum

Meckel diverticulum is the result of an incomplete fusion of the omphalomesenteric duct during embryonic development. This causes a fibrous band to connect the small intestine to the umbilicus, known as a Meckel diverticulum. It is the most common congenital anomaly of the

GI tract, occurring in 2% of the population (Rabinowitz & Kenawy, 2012). Complications (only seen in about 5% of children) associated with Meckel diverticulum include bleeding, anemia, and intestinal obstruction such as volvulus and intussusception (Rabinowitz & Kenawy, 2012). Surgical correction of the Meckel diverticulum is necessary in children who have complications. The surgery is usually done to remove the diverticulum itself. At times, ileal resection is necessary.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1498. Assessment findings pertinent to Meckel diverticulum are discussed below.

### Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Bleeding
- Anemia
- Severe colicky abdominal pain (in children with associated intestinal obstruction)

### Physical Examination

Assess the child for an acute abdomen. Observe for abdominal distention, auscultate for hypoactive bowel sounds, and then palpate for an abdominal mass, **guarding** (tensing of the abdominal wall muscles), and rebound tenderness.

### Laboratory and Diagnostic Tests

Common laboratory and diagnostic tests ordered for assessment of Meckel diverticulum include:

- Abdominal radiographs to rule out an acute obstructive process
- Meckel scan (conclusive)
- Stool tests for color, consistency, and occult blood (usually positive in Meckel diverticulum)
- Complete blood count (CBC) to assess for anemia

## Nursing Management

If anemia is significant, administer ordered blood products (packed red blood cells) to stabilize the child before surgery. Administer intravenous fluids and maintain NPO status for symptomatic children while further evaluation is being performed. Immediately report an acute abdomen to a physician or nurse practitioner. Postoperative care will vary depending on the surgery that was performed. Provide child and family education as necessary to relieve anxiety related to the diagnosis and surgical

intervention. Refer to the Nursing Care Plan 42.1 for additional information.

## Inguinal and Umbilical Hernias

Inguinal and umbilical hernias are defects that occur during fetal development. Either may be visible at birth, and inguinal hernias may be noted later in life (Sundaram et al., 2011).

### Inguinal Hernia

When the processus vaginalis fails to close completely during embryonal development, an inguinal hernia may occur. This allows the abdominal or pelvic viscera to travel through the internal inguinal ring into the inguinal canal. The hernia sacs that develop most often contain bowel in males and fallopian tubes or ovaries in females. Boys are more likely than girls to develop inguinal hernia and premature infants are particularly susceptible, with an incidence of up to 30% (Sundaram et al., 2011). Surgical correction of the inguinal hernia is usually performed when the infant is several weeks old and has been thriving.

### Nursing Assessment

Assess infants and children with an inguinal hernia for the presence of a bulging mass in the lower abdomen or groin area (Fig. 42.7). It may be possible to visualize the mass, but often the mass is seen only during crying or straining, making it difficult to actually identify in the clinic setting.

### Nursing Management

If a mass is felt upon palpation, the physician or nurse practitioner may attempt to reduce the hernia by pushing it back through the external inguinal ring. The physician or nurse practitioner may ask the nurse to assist in a reduction, most likely helping to hold the child in a position that will allow the physician or nurse practitioner to reduce the hernia. If reduction is not possible even with sedation, the hernia could be incarcerated (Sundaram et al., 2011). An incarcerated hernia could eventually lead to bowel strangulation.

Reduction is only a temporary method of managing inguinal hernias; they must be corrected surgically. The hernia should be manually reduced as needed until the time of the surgery, so teach the family how to reduce the hernia. Instruct the family to contact the surgeon immediately if the hernia becomes irreducible. Provide routine pre- and postoperative care during inguinal hernia surgical repair, including child and family education to relieve anxiety.

A

B

**FIGURE 42.7 (A)** Inguinal hernia: note the bulge in the inguinal (groin) area. **(B)** Umbilical hernia: note the protrusion in the umbilical area.

#### Take Note!

Tell the parents that if the child's inguinal hernia becomes hard, discolored, or painful (evidenced by inconsolable crying), they should immediately call the physician or nurse practitioner to determine the next course of action (office visit or emergency room visit).

## Umbilical Hernia

Umbilical hernia occurs commonly in preterm infants and much more frequently in African Americans compared to Caucasians (Sundaram et al., 2011). An umbilical hernia is caused by an incomplete closure of the umbilical ring, allowing intestinal contents to herniate through the opening. Unlike inguinal hernias, most umbilical hernias are not corrected surgically. Most children will have spontaneous closure of the umbilical hernia by 5 years of age (Sundaram et al., 2011). Surgical correction is necessary only for the largest umbilical hernias that have failed to close by the time the child is 5 years old.

## Nursing Assessment

Assess whether the hernia can be reduced. Notify the surgeon if the hernia will not reduce. Incarceration is extremely rare, but when it does occur, the child will report abdominal pain, tenderness, or redness at the umbilicus (see Fig. 42.7).

## Nursing Management

Since operative repair is not as likely with umbilical hernias as with inguinal hernias, the aim of nursing management is education. Teach the child and family how to reduce the hernia. The child may have some self-esteem issues related to the large protrusion of the unrepaired umbilical hernia. Teach the child coping skills to help relieve anxiety.

#### Take Note!

The use of home remedies to reduce an umbilical hernia should be discouraged because of the risk of bowel strangulation. This includes taping a quarter over a reduced umbilical hernia and the use of "belly bands" (Children's Hospital Boston, 2011a).

## ACUTE GASTROINTESTINAL DISORDERS

Acute GI disorders include dehydration, vomiting, diarrhea, oral candidiasis, oral lesions, hypertrophic pyloric stenosis, necrotizing enterocolitis, intussusception, malrotation and volvulus, and appendicitis.

## Dehydration

Dehydration occurs more readily in infants and young children than it does in adults. The risk is increased in infants and young children because they have an increased extracellular fluid percentage and a relative increase in body water compared to adults. Increased basal metabolic rate, increased body surface area, immature renal function, and increased insensible fluid loss through temperature elevation also contribute to the increased risk for dehydration in infants and young children as compared to adults. Dehydration left unchecked leads to shock, so early recognition and treatment of dehydration is critical to prevent progression to hypovolemic shock. The goals of therapeutic management of dehydration are to restore appropriate fluid balance and to prevent complications.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1498. Assessment findings pertinent to dehydration are discussed below.

## Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history are included in Comparison Chart 42.1, which compares the clinical manifestations of mild, moderate, and severe dehydration.

Explore the child's current and past medical history for risk factors for dehydration such as:

- Diarrhea
- Vomiting
- Decreased oral intake
- Sustained high fever
- Diabetic ketoacidosis
- Extensive burns

### Take Note!

Nurses must be able to assess a child's hydration status accurately and intervene quickly. Children are at higher risk than adults for hypovolemic shock. Dehydrated children may deteriorate very quickly and experience shock.

## Physical Examination and Laboratory and Diagnostic Tests

Assess the child's hydration status, including heart rate, blood pressure, skin turgor, fontanels, oral mucosa, eyes, temperature and color of extremities, mental status, and urine output. Children usually compensate well initially; their heart rate increases in moderate dehydration, but

blood pressure remains normal until it decreases in severe dehydration.

## Nursing Management

Nursing goals for the infant or child with dehydration are aimed at restoring fluid volume and preventing progression to hypovolemia. Provide oral rehydration to children for mild to moderate states of dehydration (see Teaching Guidelines 42.2). Children with severe dehydration should receive intravenous fluids. Initially, administer 20 mL/kg of normal saline or lactated Ringer, and then reassess the hydration status (refer to Chapter 53 for further specifics regarding hypovolemic shock).

Once initial fluid balance is restored, the physician or nurse practitioner may order intravenous fluids at the maintenance rate or as much as 1.5 times maintenance. Maintenance fluid requirements refer to the amount needed under conditions of normal hydration. Maintenance fluid requirements may be determined with the use of the formula found in Box 42.1. In the example provided in Box 42.1, a 23-kg child will need maintenance fluid equivalent to 65 mL/hour.

The same anatomic and physiologic differences that make infants and young children susceptible to dehydration also make them susceptible to overhydration. Thus, continuously evaluate hydration status and be aware of the appropriateness of intravenous fluid orders.

COMPARISON CHART 42.1

### DEHYDRATION

	Mild	Moderate	Severe
<i>Mental status</i>	Alert	Alert to listless	Alert to comatose
<i>Fontanels</i>	Soft and flat	Sunken	Sunken
<i>Eyes</i>	Normal	Mildly sunken orbits	Deeply sunken orbits
<i>Oral mucosa</i>	Pink and moist	Pale and slightly dry	Dry
<i>Skin turgor</i>	Elastic	Decreased	Tenting
<i>Heart rate</i>	Normal	May be increased	Increased, progressing to bradycardia
<i>Blood pressure</i>	Normal	Normal	Normal, progressing to hypotension
<i>Extremities</i>	Warm, pink, brisk capillary refill	Delayed capillary refill	Cool, mottled or dusky, significantly delayed capillary refill
<i>Urine output</i>	May be slightly decreased	<1 mL/kg/hour	Significantly <1 mL/kg/hour

Adapted from Johns Hopkins Hospital, Arcara, K., & Tschudy, M. (2012). *The Harriet Lane handbook* (19th ed.). St. Louis, MO: Mosby; and Takayesu, J. K., et al. (2012). *Pediatrics, dehydration*. Retrieved April 8, 2012, from <http://emedicine.medscape.com/article/801012-overview>

## Teaching Guidelines 42.2

### ORAL REHYDRATION THERAPY

- Oral rehydration solution (ORS) should contain 75 mmol/L sodium chloride and 13.5 g/L glucose (standard ORS solutions include Pedialyte, Infalyte, and Ricelyte).
- Tap water, milk, undiluted fruit juice, soup, and broth are NOT appropriate for oral rehydration.
- Children with mild to moderate dehydration require 50 to 100 mL/kg of ORS over 4 hours.
- After reevaluation, oral rehydration may need to be continued if the child is still dehydrated.
- When rehydrated, the child can resume a regular diet.

Adapted from Stanton, B., Evans, J. B., & Batra, B. (2011). *Oral rehydration therapy*. Retrieved April 8, 2012, from <http://www.uptodate.com/contents/oral-rehydration-therapy>

#### BOX 42.1

#### FORMULA FOR FLUID MAINTENANCE

- 100 mL/kg for first 10 kg
- 50 mL/kg for next 10 kg
- 20 mL/kg for remaining kg
- Add together for total mL needed per 24-hour period.
- Divide by 24 for mL/hour fluid requirement.

Thus, for a 23-kg child:

- $100 \times 10 = 1,000$
- $50 \times 10 = 500$
- $20 \times 3 = 60$
- $1,000 + 500 + 60 = 1,560$

$$1,560/24 = 65 \text{ mL/hour}$$

Adapted from Johns Hopkins Hospital, Arcara, K., & Tschudy, M. (2012). *The Harriet Lane handbook* (19th ed.). St. Louis, MO: Mosby.

## Vomiting

Vomiting is the forceful expulsion of gastric contents through the mouth. It occurs as a reflex with three different phases:

- Prodromal period: nausea and signs of autonomic nervous system stimulation
- Retching
- Vomiting

Vomiting in infants and children has many different causes and is considered to be a symptom of some other condition. Table 42.1 lists common causes of vomiting.

Therapeutic management of vomiting most often involves slow oral rehydration and at times may require administration of antiemetics.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1498. Assessment findings pertinent to vomiting are discussed below.

### Health History

Elicit a description of the present illness and chief complaint. Note onset and progression of symptoms. The assessment of an infant or child with vomiting should include a history of the vomiting events, including:

- Contents/character of the emesis
- Effort and force of vomiting episodes
- Timing (in relation to meals, as well as time of day)

Contents and character of the vomitus may give clues to the cause of vomiting. Bilious vomiting is never considered normal and suggests an obstruction, whereas bloody emesis can signify esophageal or GI bleeding (Sundaram et al., 2011). Assess the effort and force of vomiting to identify whether the episodes are effortful and projectile, as with pyloric stenosis, or effortless, as is often seen in gastroesophageal reflux. The timing of the vomiting also is helpful in determining the cause. Vomiting that occurs several hours past meals could signify delayed gastric emptying. When vomiting occurs upon waking or in the middle of the night, particularly if it is associated with headaches, an intracranial lesion or tumor may be suspected.

Note any events associated with the vomiting, such as diarrhea or pain. Diarrhea may occur with viral gastroenteritis or food poisoning. Pain in the epigastric area could signify peptic ulcer disease, pancreatitis, or cholecystitis.

Assess the child's past medical history to identify preexisting illnesses, drug abuse, trauma, prescribed medications, and previous abdominal surgery. Risk factors for vomiting include exposure to viruses, certain medication use, and overfeeding in an infant.

### Physical Examination

Perform a physical examination, noting the child's general appearance. Note hydration status, as well as mental status changes. Note the quality of bowel sounds upon auscultation. Palpate the abdomen for the presence of abdominal masses, tenderness, or signs of trauma.

### Laboratory and Diagnostic Tests

Laboratory studies may be ordered to assess the child's hydration status or to rule out certain causes of vomiting,

**TABLE 42.1** CAUSES OF VOMITING BY TEMPORAL PATTERN

Category	Acute	Chronic	Cyclic
<b>Infectious</b>	Gastroenteritis, otitis media, pharyngitis, sinusitis (acute), hepatitis, pyelonephritis, meningitis	<i>H. pylori</i> , <i>Giardia</i> , sinusitis (chronic)	Chronic sinusitis
<b>GI</b>	Intussusception, malrotation with volvulus, appendicitis, cholecystitis, pancreatitis	GERD, gastritis, peptic ulcer disease	GERD, malrotation with volvulus
<b>Genitourinary</b>	Ureteropelvic junction obstruction, pyelonephritis	Pregnancy, pyelonephritis	Hydronephrosis
<b>Endocrine/metabolic</b>	Diabetic ketoacidosis	Adrenal hyperplasia	Diabetic ketoacidosis, Addison disease, acute intermittent porphyria
<b>Neurologic</b>	Concussion, subdural hematoma, brain tumor	Brain tumor, Arnold-Chiari malformation	Migraines, Arnold-Chiari malformation, brain tumor
<b>Other</b>	Food poisoning, toxic ingestion	Bulimia, rumination	Cyclic vomiting syndrome

such as urinary tract infection, pancreatitis, or an acute infectious process. Common laboratory and diagnostic tests ordered for assessment of the cause of vomiting include:

- Abdominal ultrasound
- Upper GI series
- Plain abdominal radiographs

## Nursing Management

Nursing management focuses on promoting fluid and electrolyte balance. Oral rehydration is accomplished successfully in most outpatient cases of simple vomiting. Teach the primary caregiver about oral rehydration (refer to Teaching Guidelines 42.2). In the child with mild to moderate dehydration resulting from vomiting, withhold oral feeding for 1 to 2 hours after emesis, after which time oral rehydration can begin. Give the infant or child 0.5 to 2 ounces of oral rehydration solution every 15 minutes, depending on the child's age and size. Most infants and children can retain this small amount of fluid if fed the restricted amount every 15 minutes. As the child improves, larger amounts will be tolerated.

### Take Note!

Homemade oral rehydration solution can be made by combining 1 quart of water (can be water poured from cooking rice if desired), 3 teaspoons sugar, and 1 teaspoon salt.

If oral rehydration is not possible due to continued nausea and vomiting, intravenous fluids will likely

be ordered. In some cases, antiemetics may be used to help control the vomiting. Some antiemetics can cause drowsiness or other side effects and should not be used until a definitive diagnosis is made or severe pathologic processes can be excluded (Sundaram et al., 2011). Educate the family regarding the prevention of vomiting and use of antiemetic therapy.

### Take Note!

Ginger capsules, ginger tea, and candied ginger are generally useful in reducing nausea, are safe for use in children, and usually produce no side effects (White, 2007).

## Diarrhea

Diarrhea is either an increase in the frequency or a decrease in the consistency of stool. Diarrhea in children can either be acute or chronic. Acute infectious diarrhea (gastroenteritis) remains the leading cause of death for children worldwide. In the United States, over 3.5 million infants experience diarrhea yearly, leading to more than 500,000 office visits and 55,000 hospitalizations (Tablang, Grupka, & Wu, 2012).

## Pathophysiology

Acute diarrhea in children is most commonly caused by viruses, but it may also be related to bacterial or parasitic enteropathogens. Viruses injure the absorptive surface of mature villous cells, resulting in decreased fluid absorption

and disaccharidase deficiency. Bacteria produce intestinal injury by directly invading the mucosa, damaging the villous surface, or releasing toxins. Acute diarrhea may be bloody or nonbloody. The viral, bacterial, and parasitic causes of acute infectious diarrhea are discussed in Box 42.2. Diarrhea may also occur in relation to antibiotic use. Risk factors for acute diarrhea include recent ingestion of undercooked meats, foreign travel, day care attendance, and well water use (Tablang et al., 2012).

Though most cases of diarrhea in children are of acute origin, diarrhea may also occur chronically. Chronic diarrhea is diarrhea that lasts for more than 2 weeks. This type of diarrhea is not usually caused by serious illnesses. The causes of chronic diarrhea are listed according to age groups in Box 42.3.

Since most cases of diarrhea are acute and viral in nature, therapeutic management of diarrhea is usually supportive (maintaining fluid balance and nutrition). Probiotic supplementation may decrease the length and extent of diarrhea (Tablang et al., 2012). Bacterial and parasitic causes of diarrhea may be treated with antibiotics or antiparasitic medications, respectively.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1498. Assessment findings pertinent to diarrhea are discussed below.

### Health History

Elicit a description of the present illness and chief complaint. Important information related to the course of the diarrhea includes:

- Number and frequency of stools
- Duration of symptoms
- Stool volume
- Associated symptoms (abdominal pain, cramping, nausea, vomiting, fever)
- Presence of blood or mucus in the stool

Explore the child's current and past medical history for risk factors such as:

- Likelihood of exposure to infectious agents (well water, farm animals, day care attendance)
- Dietary history
- Family history of similar symptoms
- Recent travel
- Child's age (to identify common etiology for that age group)

### Physical Examination

#### INSPECTION

Assess the child with diarrhea for dehydration. Observe the child's general appearance and color. In mild dehydration, the child may appear normal. In moderate

dehydration, the eyes may have decreased tear production or sunken orbits. Mucous membranes may also be dry. Mental status may be compromised with moderate to severe dehydration, as evidenced by listlessness or lethargy. Skin may be nonelastic or exhibit tenting, signifying lack of proper hydration. Abdominal distention or concavity may be present. Urine output may also be decreased if the child is dehydrated. Stool output may be available to assess for color and consistency. Inspect the anal area for presence of redness or rash related to increased stool volumes and increased frequency.

#### AUSCULTATION

Auscultate bowel sounds to assess for presence of hypoactive or hyperactive bowel sounds. Hypoactive bowel sounds may indicate obstruction or peritonitis. Hyperactive bowel sounds may indicate diarrhea/gastroenteritis.

#### PERCUSSION

Percuss the abdomen. Note any abnormalities. The presence of abnormalities on examination for a diagnosis of acute or chronic diarrhea would indicate a pathologic process.

#### PALPATION

Tenderness in the lower quadrants may be related to gastroenteritis. Rebound tenderness or pain should not be found on palpation. If found, it could indicate appendicitis or peritonitis.

### Laboratory and Diagnostic Tests

Common laboratory and diagnostic studies ordered for the assessment of diarrhea include:

- Stool culture: may indicate presence of bacteria
- Stool for ova and parasites (O&P): may indicate the presence of parasites
- Stool viral panel or culture: to determine presence of rotavirus or other viruses
- Stool for occult blood: may be positive if inflammation or ulceration is present in the GI tract
- Stool for leukocytes: may be positive in cases of inflammation or infection
- Stool pH/reducing substances: to see if the diarrhea is caused by carbohydrate intolerance
- Electrolyte panel: may indicate dehydration
- Abdominal radiographs (KUB): presence of stool in colon may indicate constipation or **fecal impaction** (hardened immobile bulk of stool); air–fluid levels may indicate intestinal obstruction

## Nursing Management

Nursing management of the child with diarrhea focuses on restoring fluid and electrolyte balance and providing family education.

## BOX 42.2

## CAUSES OF ACUTE INFECTIOUS DIARRHEA

Viral	Bacterial	Parasitic
Rotavirus: characterized by acute onset of fever and vomiting, followed by loose, watery stools; most common cause of viral diarrhea	Salmonella: usually from ingestion of poultry, meats, or dairy products. Infants are at highest risk. Bacteria are excreted for up to 1 year. Severe cases are treated with antibiotics.	<i>Giardia lamblia</i> : the most common intestinal parasite in the United States; oral–fecal transmission; sudden onset of watery, foul-smelling stool; often causes gassiness and belching; treated with antiparasitic medications
Adenovirus 40 and 41: second most common cause of viral diarrhea illnesses, similar characteristics to rotavirus	<i>Escherichia coli</i> 0157:H7: most often associated with gross bloody stools and abdominal cramping; may lead to hemolytic-uremic syndrome	<i>Entamoeba histolytica</i> : oral–fecal transmission; more common outside of United States; colitis symptoms common
Norwalk virus: more common in older children and adults; characterized by vomiting, nausea, and cramping abdominal pain	Campylobacter: symptoms vary from mild diarrhea to dysentery; severe cases may be treated with antibiotics	<i>Cryptosporidium</i> : spread via farm animals and people; fecal–oral transmission; watery diarrhea, nausea, vomiting, and flu-like symptoms. No definitive treatment
Caliciviruses: affected age usually 3 months to 6 years, seen in day care settings	Shigella: high fevers and bloody stools are common; may cause seizures with fever. Treatment with antibiotics is recommended.	
Astrovirus: affected age usually 1 to 3 years, causing vomiting, diarrhea, fever, and abdominal pain	<i>Clostridium difficile</i> : usually related to antibiotic use; may cause pseudomembranous colitis in severe cases. Infants may be carriers of the bacteria and asymptomatic. Treatment with anti-infective medications may be helpful. Probiotic therapy is usually recommended.	
Cytomegalovirus (CMV): causes other medical problems, but may cause diarrhea with colitis	<i>Yersinia enterocolitica</i> : usually affects children younger than 5 years of age; watery or mucoid diarrhea common, occasionally with gross blood

Deterding (Eds.), *Current pediatric diagnosis and treatment* (20th ed.). New York, NY: McGraw-Hill; and Tablang, M. V., Grupka, M. J., & Wu, G. (2012). *Gastroenteritis, viral*. Retrieved July 6, 2012, from <http://www.emedicine.com/med/topic856.htm>

## BOX 42.3

## CAUSES OF CHRONIC DIARRHEA BY AGE

Infants	Toddlers	School-Age Children
Intractable diarrhea of infancy Milk and soy protein intolerance Infectious enteritis Hirschsprung disease Nutrient malabsorption	Chronic nonspecific diarrhea Viral enteritis <i>Giardia</i> Tumors (secretory diarrhea) Ulcerative colitis Celiac disease	Inflammatory bowel disease Appendiceal abscess Lactase deficiency Constipation with encopresis

## EVIDENCE-BASED PRACTICE 42.1

## EFFECTS OF PROBIOTICS USE ON THE COURSE OF DIARRHEA

## STUDY

Diarrhea (more than three loose, watery stools in a 24-hour period) occurs frequently in children. Most cases of diarrhea are caused by viruses, and symptomatic treatment is the only available therapy. The authors reviewed 23 randomized controlled studies that included a total of over 1,900 participants. The studies evaluated the use of probiotics as compared with placebo or no treatment in relation to the severity and length of diarrhea.

## Findings

A variety of probiotics were noted to reduce diarrhea in infants and children as well as adults. Several of the

studies demonstrated a shortened course of diarrhea when probiotics were used. The results were statistically significant, leading the authors to determine that probiotic therapy during acute diarrhea may be beneficial.

## Nursing Implications

Probiotics are available as supplements: capsules or powder that may be sprinkled on food. Additionally, live culture yogurt contains probiotics. Recommend these additions to the diet of older infants or children with acute diarrhea.

Adapted from Allen, S. J., Okoko, B., Martinez, E., Gregorio, G., & Dans, L. F. (2007). Probiotics for treating infectious diarrhoea. *The Cochrane Library* 2007, 4. Indianapolis, IN: John Wiley & Sons.

### Restoring Fluid and Electrolyte Balance

Continue the child's regular diet if the child is not dehydrated. Initial nursing management of the dehydrated child with diarrhea is focused on fluid and electrolyte balance restoration. Refer to Nursing Care Plan 42.1 on page 1505. Probiotic supplementation while a child is taking antibiotics for other disorders may reduce the incidence of antibiotic-related diarrhea (Land & Martin, 2008) (see Common Medical Treatments 42.1, and Evidence-based Practice 42.1). After rehydration is achieved, it is important to encourage the child to consume a regular diet to maintain energy and growth.

#### Take Note!

Avoid prolonged use of clear liquids in the child with diarrhea because "starvation stools" may result. Also avoid fluids high in glucose, such as fruit juice, gelatin, and soda, which may worsen diarrhea (Fleisher & Matson, 2011).

### Providing Family Education

Teach the parents the importance of oral rehydration therapy (see Teaching Guidelines 42.2). The physician may order medication therapy. In such instances, teach the importance of finishing all prescribed antibiotic therapy. After the cause of the diarrhea is known, teach the child and family how to prevent further occurrences. As most cases of acute diarrhea are infectious, provide education about proper hand-washing techniques and transmission route. Chronic diarrhea is often a result of excessive intake of formula, water, or

fruit juice, so teach the parents about appropriate fluid intake.

### Oral Candidiasis (Thrush)

Oral candidiasis (thrush) is a fungal infection of the oral mucosa. It is most common in newborns and infants. Children at risk for thrush include those with immune disorders, those using corticosteroid inhalers, and those receiving therapy that suppresses the immune system (e.g., chemotherapy for cancer). Antibiotic use may also contribute to thrush. Additionally, fungal infection may be transmitted between the infant and breastfeeding mother.

Therapeutic management includes treatment with oral antifungal agents such as Mycostatin (nystatin) or fluconazole.

### Nursing Assessment

Assess for risk factors for oral candidiasis such as young age, immune suppression, antibiotic use, use of corticosteroid inhalers, or presence of fungal infection in the mother. Inspect the oral mucosa. Thrush appears as thick white patches on the tongue, mucosa, or palate, resembling curdled milk (Fig. 42.8). Unlike milk retained in the mouth, the patches do not easily wipe off with a swab or washcloth. Also assess for the presence of candidal diaper rash (beefy-red rash with satellite lesions). Determine the extent to which the presence of the lesions is interfering with the infant's ability to feed. The lesions may cause significant discomfort.

Diagnosis is usually based on clinical presentation. However, a careful scraping of the lesions can be sent out for fungal culture.

**FIGURE 42.8** Thick white patches in the infant with oral candidiasis (thrush).

## Nursing Management

Nursing management of the child with thrush includes administering medications and providing family education.

### Administering Medications

Ensure appropriate administration of oral antifungal agents. Administer Mycostatin suspension four times per day following feeding to allow the medication to remain in contact with the lesions. In the younger infant, apply Mycostatin to the lesions with a cotton-tipped applicator. The older infant or child can easily swallow the pleasantly flavored suspension. An advantage of fluconazole is its once-daily dosing, but monitor infants and children receiving it for hepatotoxicity. Unlike Mycostatin, it is important to administer fluconazole with food to decrease the side effects of nausea and vomiting.

### Educating the Family

If the mother is also infected, she must receive antifungal treatment as well. Fungal infection of the breast can cause the mother a great deal of pain with nursing, but if appropriately treated breastfeeding can continue without interruption. Stress appropriate hand washing. It is important to keep bottle nipples and pacifiers clean. Infants and young children often mouth their toys, so it is important to clean them appropriately. Explain to parents of infants with thrush the importance of reporting diaper rash because fungal infections in the diaper area often occur concomitantly with thrush and also need to be treated.

#### Take Note!

Geographic tongue is a benign, noncontagious condition. A reduction in the filiform papillae (bumps on the

tongue) occurs in patches that migrate periodically, thus giving a map-like appearance to the tongue, with darker and lighter, higher and lower patches. Do not confuse the lighter patches of geographic tongue with the thick white plaques that form on the tongue with thrush.

## Oral Lesions

A number of oral lesions may affect infants and children. A few of the most common are aphthous ulcers, gingivostomatitis (from herpes simplex virus), and herpangina. Table 42.2 lists the causes of common oral lesions. Regardless of type, oral lesions are often painful and can interfere with the child's ability to eat. Therapeutic management of oral lesions varies depending on the cause.

## Nursing Assessment

Explore the health history for the presence of risk factors such as immune deficiency, cancer chemotherapy treatment, exposure to infectious agents, trauma, stress, or celiac or Crohn disease. Note the onset of the lesion(s) and progression over time. Question the parent or child about the presence of sore throat or dysphagia (occurs with herpangina). Inspect the oral cavity, including the tongue, buccal mucosa, palate, and hypoglossal area. Note the presence of lesions and their distribution. Refer to Table 42.2 for descriptions and illustrations of various oral lesions. Inspect the pharynx, which may be red with herpangina. Generally the diagnosis is based on the history and clinical presentation, but occasionally oral lesions are cultured for herpes simplex virus (HSV).

## Nursing Management

The primary concerns with oral lesions are pain management and maintenance of hydration. A corticosteroid-containing dental paste used for aphthous ulcers is formulated to “stick” to mucous membranes, so the lesion area should be as dry as possible prior to application of the paste. Children do not care for having the paste applied and will often resist. Older children with herpangina or stomatitis can “swish and spit” various formulations of “magic mouthwash” (typically a combination of liquid diphenhydramine, liquid acetaminophen, and milk of magnesia); they may offer some pain relief. Common over-the-counter medications such as Anbesol, Oragel, and Kank-A may be helpful for topical pain relief, though oral analgesics are often necessary.

The child with herpangina is typically a toddler or preschooler (Gompf, Casanas, Carrington, & Cunha, 2012). It may be very difficult to coach a young child to drink fluids when his or her mouth is hurting. Playing games and offering favorite fluids and popsicles may encourage adequate oral intake. It is important to avoid carbonated

**TABLE 42.2** ORAL LESIONS

	<b>Aphthous Ulcers</b>	<b>Gingivostomatitis</b>	<b>Herpangina</b>
<b>Cause</b>	Trauma, vitamin deficiency, celiac disease, Crohn disease	Herpes simplex virus	Enterovirus (Coxsackie)
<b>Appearance</b>	Erythematous border, often yellow appearance to the ulcer, anywhere on oral mucosa or lips 	Vesicular lesions on erythematous base, anywhere in oral cavity, including lips 	Bright-red ulcers, generally in posterior oral cavity 
<b>Fever</b>	Generally absent	May have high fever with initial outbreak	Abrupt onset of high fever (up to 39.4°C to 40.6°C), lasting 1 to 4 days
<b>Length of illness</b>	Generally heal within 7 to 14 days; may recur	10 to 12 days initially; may recur with stress, febrile illness, or intense sunlight exposure (as virus lies dormant in system)	Generally resolves within 5 to 7 days
<b>Therapeutic management</b>	Topical corticosteroid in dental paste may help.	Acyclovir	Supportive treatment only
<p>Adapted from Gompf, S. G., Casanas, B. C., Carrington, M., &amp; Cunha, B. A. (2012). <i>Herpangina</i>. Retrieved June 30, 2012, from <a href="http://emedicine.medscape.com/article/218502-overview">http://emedicine.medscape.com/article/218502-overview</a>; and Plewa, M. C. (2012). <i>Pediatric aphthous ulcers</i>. beverages and citrus juices when oral lesions are present as they can cause further stinging and burning.

**Take Note!**

Viscous lidocaine should be used with caution in younger children as a topical treatment for numbing the lesions or as a swish-and-spit treatment because they may swallow the lidocaine (Taketokmo, Hodding, & Kraus, 2011).

**Hypertrophic Pyloric Stenosis**

Hypertrophic pyloric stenosis is one of the most common conditions requiring surgery in the first 2 months of life (Singh, Kass, & Sinert 2010). In pyloric steno-

sis, the circular muscle of the **pylorus** becomes hypertrophied, causing thickness in the luminal side of the pyloric canal (Fig. 42.9). This thickness creates a gastric outlet obstruction, causing nonbilious vomiting that presents between weeks 2 and 4 of life. The vomiting becomes more frequent and forceful as time goes on and is often projectile. The incidence is 2 to 4 per 1,000 live births, and it occurs more in males than females (4:1), with 30% of all case being in first-born males (Singh et al., 2010). The cause of pyloric stenosis is probably multifactorial.

Pyloric stenosis requires surgical intervention. A pyloromyotomy is performed to cut the muscle of the pylorus and relieve the gastric outlet obstruction (see Fig. 42.7). Postoperative complications are rare.

**FIGURE 42.9 (A)** Hypertrophied pylorus muscle and narrowed stomach outlet. **(B)** In pyloromyotomy, the pylorus is incised, thus increasing the diameter of the pyloric outlet.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1498. Assessment findings pertinent to hypertrophic pyloric stenosis are discussed below.

### Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Forceful, nonbilious vomiting, unrelated to feeding position
- Hunger soon after vomiting episode
- Weight loss due to vomiting
- Progressive dehydration with subsequent lethargy
- Possible positive family history

### Physical Examination and Laboratory and Diagnostic Tests

Palpate for a hard, moveable “olive” in the right upper quadrant (hypertrophied pylorus). If an easily palpable mass is felt, no further testing is necessary and a surgical consult is called. If no mass is identified, a pyloric ultrasound may be ordered to identify a thickened hypoechoic ring in the region of the pylorus. An upper GI series may identify pyloric stenosis as well, but an ultrasound is less invasive and is considered more diagnostic of pyloric stenosis. Assess laboratory values to determine if the infant has metabolic alkalosis resulting from dehydration.

### Take Note!

It may be difficult to examine the infant’s abdomen when pyloric stenosis is suspected because of the infant’s extreme irritability. A pacifier or nipple dipped in glucose water may soothe the infant long enough to perform the abdominal examination.

## Nursing Management

Preoperative management of infants with pyloric stenosis is aimed at fluid management and correcting abnormal electrolyte values. Family anxiety is high during this time because of the impending surgery for an otherwise healthy infant. Provide emotional support to the family. Teach them about the surgical procedure and what to expect postoperatively. After surgery, infants usually resume oral feedings after 1 to 2 days.

## Intussusception

Intussusception is a process that occurs when a proximal segment of bowel “telescopes” into a more distal segment, causing edema, vascular compromise, and, ultimately, partial or total bowel obstruction (Fig. 42.10). Intussusception most often occurs in otherwise healthy infants younger than 1 year of age. It is three times more likely in males than females (Blanco et al., 2012). A lead point (i.e., pathologic point) may cause the telescoping. Examples of lead points are Meckel diverticulum, duplication cysts, polyps, hemangiomas, tumors, or the appendix.

A barium enema is successful at reducing a large percentage of intussusception cases; other cases are reduced surgically. If surgical reduction is unsuccessful or bowel necrosis has occurred, a portion of the bowel must be resected.

**FIGURE 42.10** In intussusception, the intestine telescopes upon itself.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1498. Assessment findings pertinent to intussusception are discussed below.

### Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Sudden onset of intermittent, crampy abdominal pain
- Severe pain (children usually draw up their knees and scream)
- Vomiting
- Diarrhea
- Currant-jelly stools, gross blood, or Hemocult-positive stools
- Lethargy

Typically, symptoms flare and then regress. Between episodes, children may have no symptoms of intussusception. This return to a normal state is due to the intussusception reducing on its own. The child may be asymptomatic and may appear well when presenting to the physician or nurse practitioner or emergency room. Again, this may be a sign that the bowel has reduced spontaneously. Assess the severity of pain, length of time the symptoms have been present, presence of vomiting, and stool patterns and color. Immediately report the presence of bilious vomiting, which occurs only in an obstructive situation. Also assess for signs and symptoms of acute peritonitis. Explore the child's current and past medical history for risk factors, such as cystic fibrosis or celiac disease.

### Physical Examination

Palpate the abdomen for the presence of a sausage-shaped mass in the upper midabdomen; this is a hallmark sign of intussusception. Note any mental status changes.

### Laboratory and Diagnostic Tests

Intussusception is usually diagnosed with an air or barium enema. Use of an enema may show the intussusception and also may reduce it, making the enema therapeutic. A pediatric surgeon should be available at the time the enema is given in case the enema is unsuccessful or perforation (rare) occurs. White blood cell elevation may occur and electrolytes may show signs of dehydration.

## Nursing Management

Administer intravenous fluids and antibiotics before the diagnostic laboratory and radiograph studies are performed. Refer to Nursing Care Plan 42.1 for nursing management of the postoperative child.

The parents may be very fatigued after dealing with a crying infant. They are often quite anxious about surgery in an otherwise healthy child. Offer emotional support and provide appropriate preoperative and postoperative education to the family.

## Malrotation and Volvulus

Intestinal malrotation results from a disruption in embryonic development. When malrotation occurs, the intestine is abnormally attached and the mesentery narrows, twisting on itself (volvulus). If the volvulus involves the entire small bowel, it is termed a midgut volvulus.

The main symptom of malrotation is bilious vomiting. Many children also have abdominal pain, shock symptoms, abdominal distention, tachycardia, and bloody stools. Most cases of malrotation will present in the first few weeks of life, but symptoms may occur in the older infant, child, or adult (Parish & Hatley, 2010).

Therapeutic management of malrotation and volvulus is accomplished surgically. A Ladd procedure is performed, during which the intestine is straightened out and bands contributing to the misalignment are divided. If bowel necrosis has occurred (rare), then an ostomy may be necessary.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1498. Assessment findings pertinent to malrotation and volvulus are discussed below.

### Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include vomiting and abdominal pain. Since obstruction can occur with resulting necrosis of the bowel, immediately inform the physician if obstruction is suspected.

### Physical Examination and Diagnostic and Laboratory Tests

Observe for severity of pain, auscultate for hypoactive bowel sounds, and palpate for abdominal guarding or rebound tenderness. Common laboratory and diagnostic studies ordered for the assessment of malrotation and volvulus include:

- KUB to reveal obstruction
- Upper GI series to identify the location of the duodenojejunal junction and corkscrew appearance of the twisted bowel

## Nursing Management

When diagnostic testing reveals malrotation/volvulus, administer ordered intravenous fluids and intravenous

antibiotics. Often a nasogastric tube is placed to decompress the stomach. Surgery is performed as soon as possible. After surgery, provide postoperative care of the child (see Nursing Care Plan 42.1). Provide continuous emotional support and family education.

## Appendicitis

Appendicitis, an acute inflammation of the appendix, is the most common cause of emergent abdominal surgery in children (Sundaram et al., 2011). It occurs in all age groups; the median age in the pediatric population is 4 to 15 years (Albanese & Sylvester, 2010).

### Pathophysiology

Appendicitis is due to a closed-loop obstruction of the appendix (Fig. 42.11). It is thought that the obstruction is due to fecal material impacted into the relatively narrow appendix, though other causes such as ingested foreign bodies may exist. This causes a subsequent increase in the intraluminal pressure of the appendix, resulting in mucosal edema, bacterial overgrowth, and eventual

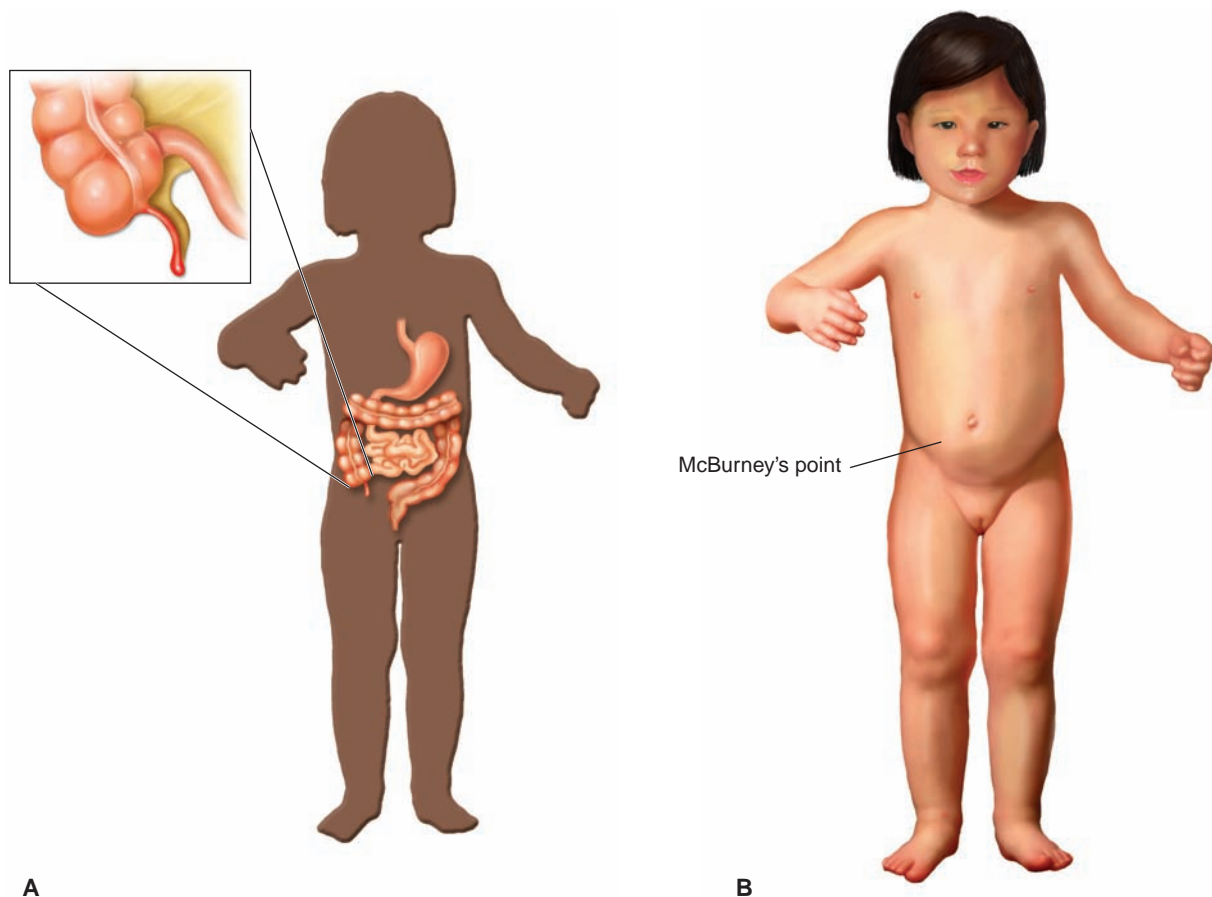

perforation. Due to the fecal material in the appendix, perforation causes inflammatory fluid and bacterial contents to leak into the abdominal cavity, resulting in peritonitis. Diffuse peritonitis is more likely in younger children. Older children and adolescents have a more developed omentum, which walls off the inflamed or perforated appendix, often causing a focal abscess.

### Therapeutic Management

Appendicitis is considered a surgical emergency because if left uncorrected, the appendix may perforate. Surgical removal of the appendix is necessary and is often accomplished via a minimally invasive laparoscopic technique. In the case of perforation, an open surgical procedure is usually required, and lavage of the abdominal cavity may be performed to cleanse it of the infected fluid released from the appendix.

### Nursing Assessment

Early diagnosis and intervention are the key elements to avoid perforation. For a full description of the assessment

**FIGURE 42.11** (A) In appendicitis, the lumen of the appendix is obstructed, resulting in edema and compressed blood vessels. (B) As appendicitis progresses, pain may become localized at McBurney's point (a point midway between the anterior superior iliac crest and the umbilicus).

phase of the nursing process, refer to page 1498. Assessment findings pertinent to appendicitis are discussed below.

## Health History

Elicit a description of the present illness and chief complaint. Appendicitis may be gradual, but symptoms usually do not come and go; they remain persistent and intensify. Common signs and symptoms reported during the health history might include:

- Vague abdominal pain in the initial stages, localizing to the right lower quadrant over a few hours
- Nausea and vomiting (which usually develop after the onset of pain)
- Small-volume, frequent, soft stools, often confused with diarrhea
- Fever (usually low grade unless perforation occurs, which results in high fever)

## Physical Examination

Children with appendicitis often appear anorexic and ill. They often cannot walk or climb up onto the examination table without assistance. Upon palpation, maximal tenderness occurs over the McBurney point in the right lower quadrant (see Fig. 42.11).

### Take Note!

If the child's abdominal pain is suddenly relieved without intervention, suspect perforation and notify the physician immediately.

Assess the abdomen for acute peritonitis, as indicated by diffuse abdominal tenderness or distention. Immediately report positive findings to a physician or nurse practitioner.

## Laboratory and Diagnostic Tests

Common laboratory and diagnostic studies ordered for the assessment of appendicitis include:

- Abdominal computed tomography (CT) scan: performed to visualize the appendix for further evaluation
- Laboratory testing: may reveal an elevated white blood cell count
- C-reactive protein: may be elevated

## Nursing Management

Provide pre- and postoperative care and child and family education (see Nursing Care Plan 42.1). Care depends on what was found during surgical exploration. A non-ruptured, nongangrenous appendix usually requires no antibiotic therapy, so provide routine surgical care.

In addition to routine surgical care, administer 48 to 72 hours of ordered antibiotics to the child with a

suppurative or gangrenous (nonperforated) appendix to decrease the risk of postoperative infection. The child with a perforated appendix will require 7 to 14 days of intravenous antibiotic therapy in addition to normal postoperative care. Provide family teaching, because the child is often discharged home while still receiving intravenous antibiotic therapy.

## CHRONIC GASTROINTESTINAL DISORDERS

Chronic GI disorders include gastroesophageal reflux, peptic ulcer disease, constipation/encopresis, Hirschsprung disease, short bowel syndrome, inflammatory bowel disease, celiac disease, recurrent abdominal pain, failure to thrive, and chronic feeding problems.

### Gastroesophageal Reflux

Gastroesophageal reflux (GER) is passage of gastric contents into the esophagus. It is considered a normal physiologic process that occurs in healthy infants and children. However, when complications develop from the reflux of gastric contents back into the esophagus or oropharynx, it becomes more of a pathologic process known as gastroesophageal reflux disease (GERD). GER occurs frequently during the first year of life; 85% of infants outgrow reflux by age 12 months (Sundaram et al., 2011). GER is particularly common in premature infants. Other possible diagnoses that can be mistaken for GER include food allergies, formula enteropathies, gastric outlet obstruction, malrotation, cyclic vomiting, and central nervous system lesions.

## Pathophysiology

The process of GER occurs during episodes of transient relaxation of the LES, which can occur during swallowing, crying, or other Valsalva maneuvers that increase intra-abdominal pressure. Delayed esophageal clearance and gastric emptying, highly acidic gastric contents, hiatal hernia (protrusion of the stomach upward into the mediastinal cavity through the esophageal hiatus of the diaphragm), or neurologic disease may also be contributing factors associated with reflux.

The signs and symptoms of GERD are often seen as a result of the damaging components of the refluxate (the pH of the gastric contents, bile acids, and pepsin). The longer the pH of the refluxate is below 4, the higher the risk for development of severe GERD (Weill, 2008). Symptoms of GERD in infants and children are listed below in the health history section.

GERD may cause esophagitis, esophageal stricture, Barrett esophagus (a precancerous condition), or anemia from chronic esophageal erosion. Additionally, complications such as laryngitis, recurrent pneumonia, or asthma may occur.

**FIGURE 42.12** In the Nissen fundoplication, the fundus (upper portion of the stomach) is wrapped around the lower segment of the esophagus.

## Therapeutic Management

Conservative medical management begins with appropriate positioning, such as elevating the head of the bed and keeping the infant or child upright for 30 minutes after feeding. Smaller, more frequent feedings may be helpful. If reflux does not improve with these measures, medications are prescribed to decrease acid production and stabilize the pH of the gastric contents. Also, prokinetic agents may be used to help empty the stomach more quickly, minimizing the amount of gastric contents in the stomach that the child can reflux.

If the GERD cannot be medically managed effectively or requires long-term medication therapy, surgical intervention may be necessary. A Nissen fundoplication is the most common surgical procedure performed for antireflux therapy. The gastric fundus is wrapped around the lower 2 to 3 cm of the esophagus (Fig. 42.12). Laparoscopic funduplications are being performed as a way to minimize the recovery period and reduce potential complications.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1498. Assessment findings pertinent to gastroesophageal reflux are discussed below.

### Health History

Elicit a description of the present illness and chief complaint. Note onset and progression of symptoms. Common signs and symptoms reported during the health history include:

- Recurrent vomiting or regurgitation
- Weight loss or poor weight gain
- Irritability in infants
- Respiratory symptoms (chronic cough, wheezing, stridor, asthma, apnea)
- Hoarseness/sore throat
- Halitosis (mostly in older children)

- Heartburn or chest pain
- Abdominal pain
- Abnormal neck posturing (Sandifer syndrome)
- Hematemesis
- Dysphagia or feeding refusal
- Chronic sinusitis, otitis media
- Poor dentition (caused by acid erosion)

Explore the child's current and past medical history for risk factors such as:

- Prematurity, noting prolonged ventilator use or chronic lung disease
- Dietary habits (e.g., chocolate, coffee, spicy or fatty foods, caffeine, formula-fed or breastfed, overeating or overfeeding)
- Current medications
- Smoking/alcohol use (older children)
- Food allergies
- Other GI disorders (gastric outlet dysfunction/hiatal hernia) or congenital abnormalities
- Feeding positions and patterns (especially important in infants)
- Sleeping positions/patterns
- Other medical history, such as asthma or recurrent infections/pneumonia

## Physical Examination

The physical examination consists of inspection, auscultation, percussion, and palpation.

### INSPECTION

Observe the child's general appearance and color. Infants and children with uncontrolled GER for a period of time may appear underweight or malnourished. Infants may be irritable due to painful regurgitation/reflux events. Note breathing patterns, because reflux-induced asthma may have developed. Acute life-threatening events (ALTEs) and apnea have been associated with severe GERD (Sundaram et al., 2011). Observe the child for cyanosis, altered mental status, and alterations in tone. Inspect emesis for blood or bile.

### AUSCULTATION

Evaluate the lung fields for the presence of complications related to GERD, such as wheezing or pneumonia. No further pathologic findings related to GERD should be auscultated on examination.

### PERCUSSION

Perform routine abdominal percussion, noting any abnormalities. No specific findings should be noted.

### PALPATION

Use caution when palpating the abdomen, especially with infants with GERD, because it may induce vomiting. No abnormalities should be palpated.

### Take Note!

Not all infants with GERD actually vomit. Those with “silent” GERD may only demonstrate irritability associated with feeding or posturing (arching back during or after feeding) and grimacing. Episodes of GERD often cause bradycardia, so if the above signs occur, they should be reported to the physician or nurse practitioner, even if the baby is not vomiting (Weill, 2008).

## Laboratory and Diagnostic Tests

Common laboratory and diagnostic studies ordered for the assessment of gastroesophageal reflux include:

- Upper GI series: though not sensitive or specific to GER, may show some reflux; studies are used to narrow down the differential diagnosis
- Esophageal pH probe study: quantifies GER episodes as they correlate to symptoms
- Esophagogastroduodenoscopy (EGD): shows esophageal and gastric tissue damage from GERD
- Complete blood count: may demonstrate anemia if chronic esophagitis or hematemesis is present
- Hemocult: may be positive if chronic esophagitis is present

## Nursing Management

As with most GI disorders, initial nursing management is aimed at restoring proper fluid balance and nutrition. Refer to Nursing Care Plan 42.1 on page 1505. Additional considerations are reviewed below.

### Promoting Safe Feeding Techniques and Positioning

Feeding adjustments are an essential part of reflux management. Give infants smaller, more frequent feedings using a nipple that controls flow well. Frequently burp the infant during feeds to control reflux. Thickening of the formula with products such as rice or oatmeal cereal can significantly help keep the formula and gastric contents down. Positioning after feedings is important. Keep infants upright for 30 to 45 minutes after feeding by holding them and/or elevating the head of the crib 30 degrees. Placing in infant seats or swings is not recommended as this increases intra-abdominal pressure (Weill, 2008). For older children, elevate the head of the bed as much as possible and restrict meals for several hours before bedtime.

### Maintaining a Patent Airway

GERD symptoms often involve the airway. Maximize reflux precautions to keep the risk of airway involvement to a minimum. In rare instances, GERD causes apnea or an ALTE (Sundaram et al., 2011). In these cases, use an apnea or bradycardia monitor to monitor for such epi-

sodes. The monitor requires a physician's order and can be ordered through a home health company. Teach parents how to deal with these episodes, as their anxiety is very high. Provide cardiopulmonary resuscitation (CPR) instruction to all parents whose children have had an ALTE previously.

### Educating the Family and Child

The goals for the infant and child with gastroesophageal reflux are a decrease in symptoms, a decrease in the frequency and duration of reflux episodes, healing of the injured mucosa, and prevention of further complications of GERD. Teach the parents the signs and symptoms of complications. Explain that reflux is usually limited to the first year of life, though in some cases it persists. If medications are prescribed, thoroughly explain their use and their side effects (see Drug Guide 42.1).

### Providing Postoperative Care

If the child requires fundoplication, a gastrostomy tube is often placed for use in the immediate postoperative period or for long-term feeding. In the immediate postoperative period, assess for pain, abdominal distention, and return of bowel sounds. If a gastrostomy tube is placed, it is often open to straight drain for a period of time postoperatively to keep the stomach empty and allow for the internal incision to heal. When bowel sounds have returned and the infant or child is stable, introduce feedings slowly (typically via the gastrostomy tube). Assess for tolerance of feedings (absence of abdominal distention or pain, minimal residual, and passage of stool). If the abdomen does become distended or the child has discomfort, open the gastrostomy tube to air to decompress the stomach. Assess the insertion site of the gastrostomy tube for redness, edema, or drainage. Keep the site clean and dry per surgeon or hospital protocol. Teach the parents how to care for the gastrostomy tube and insertion site and how to use the tube for feeding.

### Promoting Family and Child Coping

Parents may experience a great deal of anxiety. Teach the family about all aspects of GERD to help promote coping. School-age children often have reflux episodes exhibited by postprandial vomiting, which can be very embarrassing for the children. Notify the school about the medical issues related to GER to minimize the situations for the child.

## Peptic Ulcer Disease

Peptic ulcer disease (PUD) is a term used to describe a variety of disorders of the upper GI tract that result

FIGURE 42.13 Peptic ulcer disease.

from the action of gastric secretions (Fig. 42.13). Mucosal inflammation and subsequent ulceration occur as a result of either a primary or a secondary factor. In children, duodenal ulcers are more common than gastric ulcers (Sundaram et al., 2011). Primary peptic ulcers are usually associated with *Helicobacter pylori*, a gram-negative organism that causes mucosal inflammation and in some cases more severe disease (Sundaram et al., 2011). *H. pylori* is found mostly in the duodenum.

Secondary peptic ulcers may occur as a result of an identifiable factor, such as excess acid production, stress, medications, or the presence of other underlying conditions. Secondary ulcers tend to be gastric in location as opposed to duodenal.

#### Take Note!

Severe stress, such as burns or another illness necessitating critical care, can contribute to the development of a peptic ulcer in children (Sundaram et al., 2011).

## Therapeutic Management

PUD may be treated with antibiotics (if *H. pylori* is verified), histamine agonists, and/or proton pump inhibitors. If the child presents with a severe esophageal or gastric hemorrhage, a nasogastric tube may be placed to decompress the stomach. The child may require intravenous infusion of a histamine-2 receptor antagonist or a proton pump inhibitor initially until the bleeding has stopped and the disease is stabilized.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1498. Assessment findings pertinent to PUD are discussed below.

### Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Abdominal pain
- GI bleeding
- Vomiting

Abdominal pain is the most common complaint of children with PUD. It is important to characterize the abdominal pain, as many other digestive disorders may mimic PUD. The pain tends to be dull and vague, mostly epigastric or periumbilical. Most often, children with PUD have pain that worsens after meals, and the pain may wake them at night. Vomiting may be noted in preschool and school-age children.

Explore the child's current and past medical history for risk factors such as a family history of PUD or other GI diseases, or chronic salicylate or prednisone use.

#### Take Note!

Adolescents at increased risk for the development of PUD include those who use tobacco, alcohol, and caffeine (Sundaram et al., 2011).

## Physical Examination and Laboratory and Diagnostic Tests

Palpate the abdomen for the location of the pain, which is usually epigastric or periumbilical. Note the presence of blood in emesis or stools, as GI bleeding may occur. Common laboratory and diagnostic studies ordered for the assessment of PUD include the following:

- Laboratory studies: to identify anemia or *H. pylori* antibodies
- Urea breath test: to identify *H. pylori* gastritis
- Upper GI series: to detect presence of ulcerations
- Upper endoscopy: the definitive diagnostic test to look for ulceration and nodularity in the upper GI tract
- Biopsies: to assess for *H. pylori*, granulomas, eosinophils, or corrosive agents to identify the primary cause of PUD

## Nursing Management

Hemodynamic stabilization should be the focus of nursing management if significant GI bleeding occurs. Once children are stabilized and tolerating oral feeds, they may

be discharged to home. Provide discharge instructions on the following topics:

- Medications
- Dietary management (especially when allergic gastroenteropathy is found)
- Safety precautions (in cases of ingested substances)
- Stressors
- Prevention of disease recurrence

### Constipation and Encopresis

Constipation is a very common problem seen in a pediatric practice, representing 3% to 10% of all pediatric outpatient visits (Montgomery & Navarro, 2008).

Constipation is usually defined as failure to achieve complete evacuation of the lower colon. It is usually associated with difficulty in passing hard, dry stools but can sometimes be associated with passing small stools the size of marbles. Term newborns should pass a meconium stool within the first 24 hours of life. If this does not occur, the newborn is at risk for developing an underlying GI disorder. The bowel habits of both infants and children vary widely, so assess and treat each child on an individual basis. Breastfed infants may produce a stool with each feeding, though some will skip a few days between stools. Most bottle-fed babies will produce a stool one or two times per day, but they may go 2 to 3 days without producing a stool.

Encopresis is a term used to describe soiling of fecal contents into the underwear beyond the age of

expected toilet training (4 to 5 years of age). Encopresis is often seen as a result of chronic constipation and withholding of stool. As stool is withheld in the rectum, the rectal muscle can stretch over time, and this stretching of the rectum causes fecal impactions. Children who have a stretched rectal vault may experience diarrhea, where leakage occurs around a fecal mass. This is often an embarrassing issue that occurs with school-age children, and the child may hide his or her underwear to avoid punishment. Many psychological issues arise from chronic constipation and encopresis as the child may experience ridicule and shame (Burns, Dunn, Brady, Starr, & Blosser, 2009).

### Pathophysiology

As stool passes through the colon, water is reabsorbed into the colon, resulting in a formed stool by the time it reaches the rectum. At this point, the anal sphincter relaxes to allow the passage of stool from the anus. In constipation, however, this relaxation does not occur.

Most causes of constipation are functional in nature (inorganic) (Montgomery & Navarro, 2008). Children with functional constipation usually present with this problem during the toilet-training years. Children have a painful experience during defecation, which in turn creates a fear of defecation, resulting in further withholding of stool. Organic causes of constipation rarely occur in children. When they do occur, they may be a sign of a disease such as spina bifida or sacral agenesis. The causes of pediatric constipation are discussed in Table 42.3.

**TABLE 42.3 CAUSES OF PEDIATRIC CONSTIPATION BY AGE**

Newborn/Infant	Toddler and Ages 2–4 Years	School Age	Adolescent	Any Age
<ul style="list-style-type: none"> <li>• Meconium plug</li> <li>• Hirschsprung disease</li> <li>• Cystic fibrosis</li> <li>• Congenital anorectal malformations</li> <li>• Pseudo-obstruction</li> <li>• Endocrine: hypothyroidism</li> <li>• Metabolic: diabetes insipidus, renal tubular acidosis</li> <li>• Withholding</li> <li>• Dietary changes</li> </ul>	<ul style="list-style-type: none"> <li>• Anal fissures</li> <li>• Withholding</li> <li>• Toilet refusal</li> <li>• Short-segment Hirschsprung disease</li> <li>• Neurologic disorders</li> <li>• Spinal cord: meningomyelocele, tumors, tethered cord</li> </ul>	<ul style="list-style-type: none"> <li>• Toilet or bathroom access limited or unavailable</li> <li>• Limited ability to recognize physiologic cues, preoccupation with other activities</li> <li>• Tethered cord</li> <li>• Withholding</li> </ul>	<ul style="list-style-type: none"> <li>• Spinal cord injury (accidents, trauma)</li> <li>• Dieting</li> <li>• Anorexia</li> <li>• Pregnancy</li> <li>• Idiopathic slow transit constipation, particularly in females</li> <li>• Laxative abuse</li> <li>• Irritable bowel syndrome, constipation variant</li> </ul>	<ul style="list-style-type: none"> <li>• Medication side effect, dietary, postoperative state</li> <li>• Previous anorectal surgery</li> <li>• Withholding and overflow from chronic rectal distention</li> <li>• Relatively rapid change to sedentary state, dehydration</li> <li>• Hypothyroidism</li> </ul>

Adapted from Montgomery, D. F., & Navarro, F. (2008). Management of constipation and encopresis in children. *Journal of Pediatric Health Care, 22*, 199–204; Sundaram, S., Hoffenberg, E., Kramer, R., Sondheimer, J. M., & Furuta, G. T. (2011). Gastrointestinal tract. In W. W. Hay, M. J. Levin, J. M. Sondheimer, & R. R. Deterding (Eds.), *Current pediatric diagnosis and treatment* (20th ed.). New York, NY: McGraw-Hill; and Tobias, N., Mason, D., Lutkenhoff, M., Stoops, M., & Ferguson, D. (2008). Management principles of organic causes of childhood constipation. *Journal of Pediatric Health Care, 22*, 12–23.

## Therapeutic Management

Once any organic process is ruled out as a cause, constipation may initially be managed with dietary manipulation such as increasing fiber and fluids. However, behavior modification is necessary for most children. Children need to relearn to allow bowel evacuation when stool is present. Children with severe constipation and withholding behaviors may not benefit from dietary management and may require laxative therapy. Sometimes mechanical disimpaction is required initially, followed by the above measures.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1498. Assessment findings pertinent to constipation/encopresis are discussed below.

### Health History

Elicit a description of the present illness and chief complaint. Note the onset of symptoms as described by the parent/child. Common signs and symptoms reported during the health history may include:

- Altered stooling patterns (size, frequency, amount, and color)
- Pain with defecation
- Withholding behaviors (postures to try to withhold the stool, such as crossing the legs, squatting or hiding in a corner, or “dancing”)
- Complaints of abdominal pain and cramping and poor appetite
- Diarrhea leakage
- Soiling of undergarments

It is important to note the duration of the symptoms to determine an acute onset versus a chronic disorder.

Explore the child’s past and current medical history for risk factors such as:

- Family history of GI disorders
- History of rectal bleeding or anal fissures
- Report of first meconium stool after 24 hours of age
- History of sexual abuse

It is important to take an accurate dietary history as well as a history of fluid intake. Also explore current medication or laxative use.

### Physical Examination

Physical examination of the child with constipation consists of inspection, auscultation, percussion, and palpation.

#### INSPECTION

Observe the child’s general appearance. Note whether the abdomen appears distended or rounded. Observe the lower back for a deep pilonidal dimple with hair tuft, which is suggestive of spina bifida occulta. Flat buttocks

may be suggestive of sacral agenesis. Inspect the anus for signs of fissures or soiling. Inspect the child’s underwear for stains or smears, which are indicative of soiling.

#### AUSCULTATION

Auscultate bowel sounds to determine the possibility of an obstruction (hypoactive or absent bowel sounds) in the child with an acute case of constipation.

#### PERCUSSION

Percuss the abdomen to reveal dullness, which would indicate a fecal mass.

#### PALPATION

Palpate the abdomen for any tenderness or masses. The nurse may assist the physician or nurse practitioner with the performance of a rectal examination to assess for rectal tone and rectal vault size.

### Laboratory and Diagnostic Tests

Laboratory and diagnostic tests are not routine with the diagnosis of functional constipation, but if an organic cause is suspected, the following laboratory and diagnostic tests would be ordered:

- Stool for occult blood: the presence of blood could indicate some other disease process
- Abdominal radiograph: large quantities of stool may be seen in the colon
- Sitz marker study: to detect colonic dysmotility
- Barium enema: to rule out a stricture or Hirschsprung disease
- Rectal manometry: to evaluate rectal musculature dysfunction
- Rectal suction biopsy: to rule out Hirschsprung disease

## Nursing Management

Nursing management for the infant or child with constipation is aimed at educating the child and family and promoting child and family coping. Refer to Nursing Care Plan 42.1 on page 1505. Additional considerations are reviewed below.

### Educating the Family and Child

Teach parents how to assess for signs of constipation and withholding behaviors. Also provide guidelines on scheduling and supervising bowel habits in reconditioning the child to use the toilet regularly. Teach parents to use positive reinforcement techniques. For example, when the child produces an adequate-volume bowel movement, reward him or her with stickers, extra playtime or television time, and so on.

Dietary changes may help some children. High-fiber diets help to regulate bowel activity. Increasing fluid intake may also aid in bringing extra water into the bowel, thereby softening the stool. Infants and toddlers with constipation may be experiencing constipation

## NURSING PROCEDURE 42.2

**Administering an Enema**

1. Gather supplies (enema bag, lubricant, enema solution).
2. Wash hands and apply gloves.
3. Position the child:
  - Infant or toddler on abdomen with knees bent
  - Child or adolescent on left side with right leg flexed toward chest
4. Clamp the enema tubing, remove the cap, and apply lubricant to the tip.
5. Insert the tube into the rectum:
  - 2.5 to 4 cm (1 to 1.5 inches) in the infant
  - 5 to 7.5 cm (2 to 3 inches) in the child
6. Unclamp the tubing and administer the prescribed volume of enema solution at a rate of about 100 mL per minute. Recommended volumes:
  - 250 mL or less for the infant
  - 250 to 500 mL for the toddler or preschooler
  - 500 to 1,000 mL for the school-age child
7. Hold the child's buttocks together if needed to encourage retention of the enema for 5 to 10 minutes.

from formula or milk changes. Therefore, manipulating the formula or milk may result in better bowel habits.

Educate families about the importance of compliance with medication use, if medication is ordered. Parents often are very anxious about the use of these medications, but stress to them that compliance is essential. Assess for improper laxative use based on the history of stool patterns.

Many children present to their physician or nurse practitioner with fecal impaction or partial impaction. Teach parents how to disimpact their children at home; this often requires an enema or stimulation therapy. Nursing Procedure 42.2 gives instructions on enema administration in children. Explain the procedure to the child in developmentally appropriate terms. Enema administration can be uncomfortable, but calming measures, such as distraction and praise, provide a comforting environment. After the impaction is removed, promote regular bowel habits to keep the impaction from recurring.

**Promoting Child and Family Coping**

Childhood constipation can be a very stressful process for both the child and family. Behavior modification is necessary for many children. To facilitate daily bowel evacuation, the child should sit on the toilet twice a day (after breakfast and dinner) for 5 to 15 minutes. Instruct the family to keep a “star” or reward chart to encourage compliance. Parents

should award the star for compliance with time sitting on the toilet and should not reserve rewards for successful bowel movements only. Weeks to months may be required to change the stooling pattern (Burns et al., 2009).

Many parents seek counselors to help the entire family deal with the issues. Counseling is geared toward allaying the fears of a child who is afraid to defecate due to pain. Also, children who are older may have behavioral issues that need to be addressed. Psychological evaluation and possible behavioral therapy may need to be implemented if constipation becomes a power struggle.

**Consider This**

Jung Kim, 3 years old, is brought to the clinic by his parents with abdominal pain and a poor appetite. His mother states, “He cries when I put him on the toilet.”

What other assessment information would you obtain?

What education and interventions may be necessary for this child and family?

**Hirschsprung Disease (Congenital Aganglionic Megacolon)**

Hirschsprung disease is the most common cause of neonatal intestinal obstruction (Lee, Shekherdimian, & Dubois, 2012) (Fig. 42.14). The disease is most commonly characterized by constipation in newborns. This is due to a lack of ganglion cells in the bowel, which causes inadequate motility in part of the intestine. These ganglion cells can be absent from the rectosigmoid colon all the way into the small intestine. Hirschsprung disease occurs in 1 of every 5,400 to 7,200 newborns (Lee et al., 2012).

**Therapeutic Management**

Surgical resection of the aganglionic bowel and reanastomosis of the remaining intestine are necessary to promote

**FIGURE 42.14** Enlarged megacolon of Hirschsprung disease.

proper bowel function. There are several types of surgical procedures to correct this, usually performed in stages. The surgical resection requires the child to have an ostomy to divert the stool through a stoma on the abdomen. This allows the area of the resected bowel and anastomosis to heal before it is used. The ostomy is closed at a later date.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1498. Assessment findings pertinent to Hirschsprung disease are discussed below.

### Health History

Elicit a description of the present illness and chief complaint. Newborn stool patterns are a key element in recognizing this diagnosis. Assess whether the newborn passed a meconium stool; most children with Hirschsprung disease do not pass a meconium stool within the first 24 to 48 hours of life. Also, newborns who required rectal stimulation to pass their first meconium stool or who passed a meconium plug should be evaluated for Hirschsprung disease.

Explore the child's current and past medical history for risk factors such as a family history of Hirschsprung disease or Down syndrome, or intestinal **atresia** (lack of a normal opening) (Lee et al., 2009).

### Physical Examination

Inspect and palpate the abdomen. The abdomen is typically distended, and, often, it is possible to palpate stool masses in the abdomen. Perform a rectal examination to assess for rectal tone and the presence of stool in the rectum. Often with Hirschsprung disease, no stool is present in the rectum. However, at the end of the rectal examination, when the finger is being withdrawn, a child with Hirschsprung disease may have a forceful expulsion of fecal material.

### Laboratory and Diagnostic Tests

Common laboratory and diagnostic studies ordered for the assessment of Hirschsprung disease include:

- Barium enema: to look for a narrowing of the intestine
- Rectal suction biopsy: to demonstrate an absence of ganglion cells (definitive diagnosis)

## Nursing Management

Nursing management includes providing postoperative care, performing ostomy care, and providing child and family education.

## Providing Postoperative and Ostomy Care

Provide routine postoperative care and observe for the possible complication of enterocolitis (see Nursing Care Plan 42.1).

The child with Hirschsprung disease may have either a colostomy or ileostomy, depending on the extent of disease in the intestine. In either case, perform proper ostomy care to avoid skin breakdown. Accurately measure stool output to assess the child's fluid volume status.

Observe for the following signs and symptoms of enterocolitis:

- Fever
- Abdominal distention
- Chronic diarrhea
- Explosive stools
- Rectal bleeding
- Straining

If any of the above symptoms are noted, immediately notify the physician or nurse practitioner, maintain bowel rest, and administer intravenous fluids and antibiotics to prevent the development of shock and possibly death.

## Providing Child and Family Education

The family may be anxious and fearful about upcoming surgeries and possible complications. Help to relieve their anxiety by providing information about the diagnosis and the stages of surgical procedures the child will undergo. Provide postoperative teaching to educate parents on proper stoma care as well as medication management (to avoid dehydration, most children with Hirschsprung disease will be prescribed medications to slow stool output). Arrange for the family to consult with a wound care nurse to help them deal with the anxieties and care of newly placed stomas. Provide education about possible postsurgical problems, emphasizing the importance of prompt medical treatment for signs of enterocolitis.

## Short Bowel Syndrome

Short bowel syndrome is a clinical syndrome of nutrient malabsorption and excessive intestinal fluid and electrolyte losses that occurs following massive small intestinal loss or surgical resection. The degree of malabsorption is usually related to the extent of resection of small bowel (Cuffari, 2012). The most common causes of short bowel syndrome are necrotizing enterocolitis, small intestinal atresia, gastroschisis, malrotation with volvulus, and trauma to the small intestine. The extent of malabsorption experienced by an individual child is dependent upon the extent of duodenal, ileal, and/or jejunal loss and the length of small intestine lost, as well as the type.

If the terminal ileum is lost, vitamin B<sub>12</sub> deficiency and bile salt malabsorption may occur. If the ileocecal valve is lost, small bowel bacterial overgrowth is likely to occur, as well as poor intestinal motility.

## Therapeutic Management

The child with short bowel syndrome is at risk for chronic complications. The goals of therapeutic management are to minimize bacterial overgrowth and to maximize the child's nutritional status. Antibiotics may be used to control bacterial overgrowth. Vitamin and mineral supplementation is necessary because the small intestine is usually where fat-soluble vitamins, calcium, magnesium, and zinc are absorbed. Antidiarrheal agents such as loperamide and gastric acid-suppressive medications may be used to decrease stool output. Many children with short bowel syndrome require TPN for extended periods to achieve adequate growth. Progression to enteral feeding may occur extremely slowly, depending on the intestine's response. Despite a markedly improved prognosis for these children, some will not do as well and may ultimately require intestinal and liver transplantation due to irreversible liver damage from long-term use of TPN.

## Nursing Assessment

Elicit the health history, noting diarrhea, which is the primary symptom of short bowel syndrome. Note past history of bowel loss or resection as noted above. Assess the child's hydration state. Inspect the stool for consistency, color, odor, and volume. Review laboratory results, particularly chemistries, to evaluate hydration status, and liver function tests, which may reveal evolving **cholestasis** (impairment of bile flow) secondary to long-term TPN use.

## Nursing Management

Nursing management focuses on encouraging adequate nutrition and promoting effective family coping.

### Encouraging Adequate Nutrition

Treatment for short bowel syndrome can be a slow and tedious process. Most children will require TPN until they can tolerate enteral feeds without significant malabsorption. TPN is usually required for a lengthy time, so most children will require long-term intravenous access. Long-term intravenous access places the child at high risk for infection and resulting sepsis. Therefore, closely monitor for signs and symptoms of infection. Immediately report to the physician or nurse practitioner any fevers or redness or drainage at the intravenous site.

When started, enteral feeding must be administered very slowly to avoid further malabsorption. Usually the

feeding is started continuously, 24 hours per day, via a feeding pump. Most children have long-term feeding tubes, usually gastrostomy tubes. Most of these children will require special formulas to promote absorption. Assess for feeding tube residuals and abdominal distention or discomfort. Strictly monitor intake and output to avoid dehydration. Assess the stool for signs of carbohydrate malabsorption. Administer vitamin and mineral supplementation, antidiarrheals, and antibiotics as ordered. Teach the family about use of enteral feeding tubes, feeding pumps, and medication administration.

### Promoting Effective Family Coping

Children with short bowel syndrome are considered to be medically fragile for a lengthy period. There is much anxiety related to the initial bowel resection that resulted in short bowel. Long-term hospitalization is almost always required, causing parents to miss work and cutting down on the time they have to spend with other children. This can lead to even more anxiety about finances and relationships. Encourage families to become the experts on their child's needs and condition via education and participation in care. Provide teaching so that the family is better able to care for the child in an outpatient setting. Education focuses on information about TPN and central line care, enteral feedings, assessing for hydration status, and managing medications.

#### Take Note!

Maintaining long-term central venous access for TPN in infants can present a challenge. One-piece clothing with the central venous line (CVL) tubing exiting and secured on the back of the outfit can help discourage the infant from pulling on (and subsequently dislodging) the line.

## Inflammatory Bowel Disease

Crohn disease and ulcerative colitis are the two major idiopathic inflammatory bowel diseases of children. The causes are unknown. However, they may be due to an abnormal or uncontrolled genetically determined immunologic or inflammatory response to an environmental antigenic trigger, possibly a virus or bacterium (Haas-Beckert & Heyman, 2010). The features of Crohn disease and ulcerative colitis are listed in Comparison Chart 42.2.

## Therapeutic Management

Medication is used to control inflammation and symptoms. Medications commonly used include 5-aminosalicylates, antibiotics, immunomodulators, immunosuppressives, and anti-tumor necrosis antibody therapy. Dietary manipulation is also very important.

## COMPARISON CHART 42.2

## FEATURES OF CROHN DISEASE AND ULCERATIVE COLITIS

Feature	Crohn Disease	Ulcerative Colitis
<i>Age at onset</i>	10 to 20 years	10 to 20 years
<i>Incidence</i>	4 to 6 per 100,000	3 to 15 per 100,000
<i>Area of bowel affected</i>	Oropharynx, esophagus, and stomach, rare; small bowel only, 25% to 30%; colon and anus only, 25%; ileocolitis, 40%; diffuse disease, 5%	Total colon, 90%; proctitis, 10%
<i>Distribution</i>	Segmental; disease-free skip areas common	Continuous; distal to proximal
<i>Pathology</i>	Full-thickness, acute, and chronic inflammation; noncaseating granulomas (50%), extraintestinal fistulas, abscesses, stricture, and fibrosis may be present	Superficial, acute inflammation of mucosa with microscopic crypt abscess
<i>Radiography findings</i>	Segmental lesions; thickened, circular folds; cobblestone appearance of bowel wall secondary to longitudinal ulcers and transverse fissures; fixation and separation of loops; narrowed lumen; “sting sign”; fistulas	Superficial colitis; loss of haustra; shortened colon and pseudopolyps (islands of normal tissue surrounded by denuded mucosa) are late findings
<i>Intestinal symptoms</i>	Abdominal pain, diarrhea (usually loose with blood if colon involved), perianal disease, enteroenteric or enterocutaneous fistula, abscess, anorexia	Abdominal pain, bloody diarrhea, urgency, tenesmus
<b>Extraintestinal symptoms:</b>		
<i>Arthritis/arthralgia</i>	15%	9%
<i>Fever</i>	40% to 50%	40% to 50%
<i>Stomatitis</i>	9%	2%
<i>Weight loss</i>	90% (mean 5.7 kg)	68% (mean 4.1 kg)
<i>Delayed growth and sexual development</i>	30%	5% to 10%
<i>Uveitis, conjunctivitis</i>	15% (in Crohn colitis)	4%
<i>Sclerosing cholangitis</i>	—	4%
<i>Renal stones</i>	6% (oxalate)	6% (urate)
<i>Pyoderma gangrenosum</i>	1% to 3%	5%
<i>Erythema nodosum</i>	8% to 15%	4%
<i>Laboratory findings</i>	High erythrocyte sedimentation rate; microcytic anemia; low serum iron and total iron-binding capacity; increased fecal protein loss; low serum albumin; antineutrophil cytoplasmic antibodies present in 10% to 20%; <i>Saccharomyces cerevisiae</i> antibodies positive in 60%	High erythrocyte sedimentation rate; microcytic anemia; high white blood cell count with left shift; antineutrophil cytoplasmic antibodies present in 80%

Adapted from Haas-Beckert, B., & Heyman, M. B. (2010). Inflammatory bowel disease. In P. J. Allen, J. A. Vessey, & N. A. Schapiro (Eds.) *Primary care of the child with a chronic condition* (5th ed.). St. Louis, MO: Mosby; and Sundaram, S., Hoffenberg, E., Kramer, R., Sondheimer, J. M., & Furuta, G. T. (2011). Gastrointestinal tract. In W. W. Hay, M. J. Levin, J. M. Sondheimer, & R. R. Deterding (Eds.), *Current pediatric diagnosis and treatment* (20th ed.). New York, NY: McGraw-Hill.

Failure to respond to medical therapy may result in surgical intervention. Many children with ulcerative colitis eventually undergo a total proctocolectomy, with resulting ostomy, as a curative measure. Children or adolescents with Crohn disease may require surgery to relieve obstruction, drain an abscess, or relieve intractable symptoms.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1498. Assessment findings pertinent to Crohn disease and ulcerative colitis are discussed below.

### Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history include:

- Abdominal cramping
- Nighttime symptoms, including waking due to abdominal pain or urge to defecate
- Fever
- Weight loss
- Poor growth
- Delayed sexual development

Children may be reluctant or unwilling to talk about their bowel movements, so explain the importance of doing so. Assess stool pattern history, including frequency, presence of blood or mucus, and duration of symptoms.

Explore the child's current and past medical history for risk factors, such as:

- Family history of inflammatory bowel disease
- Family history of colon cancer
- Family history of immunologic disorders

### Physical Examination

Assess the child's growth using growth charts to identify any poor growth patterns. Perform a full abdominal examination, noting tenderness, masses, or fullness. Inspect the perianal area to look for skin tags or fissures, which would be highly suspicious for Crohn disease. Assist the physician in performing a rectal examination to further assess the rectal area for blood or other lesions.

### Laboratory and Diagnostic Tests

Laboratory test results may be normal. Results for children with Crohn disease and ulcerative colitis are found in Comparison Chart 42.2. Common laboratory and diagnostic studies ordered for the assessment of inflammatory bowel disease include:

- Radiologic studies such as upper GI series with small bowel series: may identify evidence of intestinal inflammation, estimate distribution and extent of disease, and help distinguish between Crohn disease and ulcerative colitis
- CT scan: to rule out suspected abscess
- Colonoscopy: to diagnose inflammatory bowel disease
- Upper endoscopy: to rule out affected mucosal tissue between the mouth and anus in children with upper abdominal complaints

## Nursing Management

Nursing management focuses on teaching about disease management, teaching about nutritional management, teaching about medication therapy, and promoting family and child coping.

### Teaching About Disease Management

The diagnosis of Crohn disease or ulcerative colitis can be very difficult for the child and family to comprehend. Provide teaching about the disease process and medication therapy to help the child and family understand the seriousness of the disease. The physician may discuss surgical options during uncontrolled flare-ups, but the nurse may be the person to whom the family members or child address their questions regarding surgery. Provide the family with information to help answer some of their questions and allay fears.

### Teaching About Nutritional Management

Teach the child and family about nutritional management of the disease. For example, adequate nutrition with a high-protein and high-carbohydrate diet may be recommended. When the disease is active, lactose may be tolerated poorly, and vitamin and iron supplements will most likely be recommended. Explain that in severe cases enteral feeding tubes or TPN may be needed; this is rare but often induces remission.

### Teaching About Medication Therapy

Medications are extremely important in controlling inflammatory bowel disease. Provide information about the following common medications used to control the disease:

- 5-Aminosalicylates (5-ASA): used to prevent relapse (usually used in ulcerative colitis)
- Antibiotics (usually metronidazole and ciprofloxacin): typically used in children who have perianal Crohn disease
- Immunomodulators (usually 6-mercaptopurine [6-MP] or azathioprine): used to help maintain remission. Monitor children for neutropenia and hepatotoxicity.

- Cyclosporine or tacrolimus: used occasionally in conjunction with 6-MP or azathioprine to maintain remission in fulminant ulcerative colitis
- Methotrexate: sometimes used to manage severe Crohn disease
- Anti-tumor necrosis antibody therapy: widely used for children with Crohn disease; occasionally used for children with ulcerative colitis

### Promoting Family and Child Coping

Inflammatory bowel disease is a chronic and often debilitating illness. Many children with this diagnosis can lead normal lives, but frequent illnesses can cause school absences, which in turn add stress to the situation. Because schools have become much less tolerant of absences and tardiness, it may be necessary to write letters to the school explaining the frequent absences or in-school needs. Bathroom privileges should be very flexible for children during flare-ups. Children tend to be of small stature due to the illness itself and steroid use, which stunts growth; this may cause psychological issues, especially for older boys (Haas-Beckert & Heyman, 2010). Children with ostomies as a result of surgical resection may have self-esteem issues related to the presence and care of the ostomy. Arrange for counseling for both the child and family to discuss fears and anxiety related to a chronic disease.

## Celiac Disease

Celiac disease, also known as celiac sprue, is an immunologic disorder in which gluten, a product most commonly found in grains, causes damage to the small intestine. The villi of the small intestine are damaged due to the body's immunologic response to the digestion of gluten. The function of the villi is to absorb nutrients into the bloodstream. When the villi are blunted or damaged, malnutrition occurs.

Celiac disease is one of the most common chronic disorders in Europe and the United States, affecting about 1% of the population (Runge & Nguyen, 2010). Increased incidence occurs in those with a family history of celiac disease and in persons with autoimmune or genetic disorders (Runge & Nguyen, 2010).

The only current treatment for celiac disease is a strict gluten-free diet. Eliminating gluten will cause the villi of the intestines to heal and function normally, with subsequent improvement of symptoms. Even very small amounts of gluten introduced back into the diet can cause damage to the villi, so the child must adhere to the diet throughout life (Runge & Nguyen, 2010).

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1498. Assessment findings pertinent to celiac disease are discussed below. The child with symptoms of celiac disease often presents for evaluation by age 2.

### Health History

Elicit a description of the present illness and chief complaint. The symptoms of celiac disease are very broad and are easily confused with other GI disorders. The classic symptoms of children with celiac disease are:

- Diarrhea
- **Steatorrhea** (fatty stools)
- Constipation
- Failure to thrive or weight loss
- Abdominal distention or bloating
- Poor muscle tone
- Irritability and listlessness
- Dental disorders
- Anemia
- Delayed onset of puberty or amenorrhea
- Nutritional deficiencies

Explore the child's current and past medical history for risk factors such as Caucasian European descent and a family history of celiac disease.

### Physical Examination

Assess for the typical appearance of children with celiac disease: distended abdomen, wasted buttocks, and very thin extremities (Fig. 42.15).

### Laboratory and Diagnostic Tests

Common laboratory and diagnostic studies ordered for the assessment of celiac disease include serologic antibody screening, intestinal biopsy, and genetic testing. The serum antibody markers identify antibodies in the bloodstream that are specific to a child's response to gluten. If antibodies are positive, an intestinal biopsy is taken from the four to six sites in the duodenum during an esophagogastroduodenoscopy performed by a gastroenterologist. Pathology from the biopsy reveals partial or subtotal villous atrophy or blunting of the villi of the small intestine. Genetic testing is also available for celiac disease, looking for certain human leukocyte antigen (HLA) types (Runge & Nguyen, 2010).

## Nursing Management

Providing child and family education is the key nursing role in managing children with celiac disease. The

## Teaching Guidelines 42.3

## DIETARY CONSIDERATIONS IN A GLUTEN-FREE DIET

## Foods Allowed

Potato, soy, rice, or bean flour; rice bran, cornmeal, arrowroot, corn or potato starch, sago, tapioca, buckwheat, millet, flax, teff, sorghum, amaranth, quinoa

Plain, fresh, frozen, or canned vegetables made with allowed ingredients

All fruits and fruit juices

All milk and milk products except those made with gluten additives, aged cheese

All meat, poultry, fish, and shellfish; dried peas and beans, nuts; peanut butter; soybean; cold cuts, frankfurters or sausage without fillers

Butter, margarine, salad dressings, sauces, soups, and desserts with allowable ingredients; sugar, honey, jelly, jam, hard candy, plain chocolate, coconut, molasses, marshmallows, meringues, pure instant or ground coffee, tea, carbonated drinks, wine (from the United States)

## Foods to Avoid

All wheat products; rye, triticale, barley, oats, or oat bran; graham, gluten, spelt, or durum flour, bulgur, farina, or kamut; malt extract; hydrolyzed vegetable protein

Any creamed or breaded vegetables, canned baked beans, some French fries

Some commercial fruit pie fillings and dried fruit

Malted milk, flavored or frozen yogurt

Any meats or poultry prepared with wheat, rye, oats, barley, gluten stabilizers, or fillers for meats; canned meats; self-basting turkey; some egg substitutes

Commercial salad dressings, prepared soups, condiments, sauces, and seasonings made with avoided products; nondairy cream substitutes, flavored instant coffee, alcohol distilled from cereals, licorice

Adapted from Celiac Disease Foundation. (2012). *Diet & Lifestyle*. Retrieved July 3, 2012, from [http://www.celiac.org/index.php?option=com\\_content&view=article&id=11&Itemid=16](http://www.celiac.org/index.php?option=com_content&view=article&id=11&Itemid=16)

**FIGURE 42.15** The child with celiac disease typically displays a distended abdomen and wasted extremities.

child must adhere to a strict gluten-free diet for his or her entire life. This is often very challenging, because gluten is found in most wheat products, rye, barley, and possibly oats. Encourage the parents and child to maintain this gluten-free diet. Often, families consult a dietitian to learn about the gluten-free diet (Teaching Guidelines 42.3).

Provide educational materials and resources to the parents. Many resources are available today about celiac disease because it is becoming more commonly diagnosed. Links to several resources are located on [thePoint](#). These resources can offer information on all aspects of celiac disease, including dietary guidelines and resources for food shopping and eating in restaurants. A reading source appropriate for school-age children is *Gluten-free Friends: An Activity Book for Kids* by Nancy Patin Falini.

### Recurrent Abdominal Pain

Recurrent abdominal pain is a common GI complaint of children and adolescents. It affects children of all ages, and about 2% to 4% of all pediatric outpatient visits are related to recurrent abdominal pain (Noe & Li, 2009). The etiology remains unclear. The Rome Committee is a group of specialists who are focusing on the identification, management, and treatment of both adults and children with these functional GI disorders. The three categories of recurrent abdominal pain in children are functional abdominal pain, nonulcer dyspepsia, and

irritable bowel syndrome. Box 42.4 outlines the Rome Committee's criteria for distinguishing different features of irritable bowel syndrome (Yacob & Di Lorenzo, 2009).

## Pathophysiology

The etiology of recurrent abdominal pain is controversial but most likely multifactorial. It is thought that the autonomic nervous system, which controls the body's response to emotions and stress, and intestinal motility are the two mechanisms. Symptoms may result from an alteration in the transmission of messages between the enteric nervous system and the central nervous system, leading to visceral hypersensitivity. Information from the GI tract is transmitted through bidirectional nerve pathways to the brain. Most neurotransmitters are found in both the brain and the gut, suggesting the potential for integrated effects of pain modulation. As different possibilities exist for the pathophysiology of recurrent abdominal pain, it is clear that there are no structural or biochemical abnormalities that are identifiable.

Therapeutic management most often focuses on increasing the child's coping skills. Some children may need dietary manipulation or medications to control diarrhea (irritable bowel syndrome).

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1498. Assessment findings pertinent to recurrent abdominal pain are discussed below.

### Health History

The diagnosis of recurrent abdominal pain is made on a symptom-based approach. Elicit a description of the present illness and chief complaint. The symptom reported mostly commonly during the health history is abdominal

pain. The child may have difficulty providing a good description of the pain. It is usually periumbilical and is usually described as attacks of pain. It is uncommon for the child to wake up in the middle of the night with this type of pain. In cases of irritable bowel syndrome, the pain may be relieved by defecation. Because diet may play a large role in the symptoms, obtain a dietary history. Take a detailed medication history, because abdominal pain may be an adverse effect of some medications. Identifying social and school stressors is essential.

### Physical Examination

Note the child's body positioning and facial expressions. Interactions with family members during the interview may provide more details regarding social stressors. Palpate the abdomen for tenderness.

### Laboratory and Diagnostic Tests

Common laboratory and diagnostic studies ordered for the assessment of recurrent abdominal pain include:

- Complete blood count: to rule out organic causes of abdominal pain
- Erythrocyte sedimentation rate: to rule out organic causes of abdominal pain
- Urinalysis: to rule out organic causes of abdominal pain
- Complete metabolic panel (CMP): to rule out organic causes of abdominal pain
- Stool studies: to assess for routine pathogens

## Nursing Management

Once the diagnosis of recurrent abdominal pain with no organic cause is made, the majority of the nursing management is focused on promoting coping skills. Often the physician performs a battery of tests to rule out organic causes, especially when child and family anxiety is high. After these tests are complete, teach the family about the factors that exacerbate the pain and how to deal with these factors.

Diet changes may need to be implemented. High-fiber diets help with bowel regulation by keeping motility regular.

Often medications are used to relieve abdominal cramps. Antidiarrheals may be used for children with irritable bowel syndrome that is manifested by diarrhea. Occasionally pain modulators and antidepressants are used to help block the neurotransmitters in the brain-gut connection that cause pain. Encourage compliance with the medication regimen; compliance is needed to achieve beneficial results with many of these medications.

Arrange for counseling, if necessary, for children with social stressors. Children with recurrent abdominal pain may become so debilitated that they cannot function in school, possibly requiring homebound instruction.

#### BOX 42.4

#### ROME COMMITTEE CRITERIA FOR IRRITABLE BOWEL SYNDROME

12 weeks or more of the following symptoms:

- Abdominal pain relieved by defecation
- Onset of pain or discomfort associated with a change in frequency of stool
- Onset of pain or discomfort associated with a change in form of the stool
- No structural or metabolic explanation for this abdominal pain

Adapted from Yacob, D., & Di Lorenzo, C. (2009). Functional abdominal pain: All paths lead to Rome (criteria). *Pediatric Annals*, 38(5), 253–258.

Provide education to the school, with parental permission, regarding the child's illness and how to best deal with it. Explain that this recurrent abdominal pain is a true pain that children feel and is not "in their minds."

## HEPATOBIILIARY DISORDERS

Hepatobiliary disorders include pancreatitis, gallbladder disease, jaundice, biliary atresia, hepatitis, cirrhosis and portal hypertension, and liver transplantation.

### Pancreatitis

Pancreatitis is increasingly being recognized as a childhood problem (Sokol & Narkewicz, 2011). It is classified into two categories—acute and chronic. Acute pancreatitis is an acute inflammatory process that occurs within the pancreas, with variable involvement of localized tissues and remote organ systems. Most common causes of acute pancreatitis include abdominal trauma, drugs and alcohol (though probably rare in children), multisystem disease (such as inflammatory bowel disease or systemic lupus erythematosus), infections (usually viruses such as cytomegalovirus or hepatitis), congenital anomalies (ductal or pancreatic malformations), obstruction (most likely gallstones or tumors in children), or metabolic disorders. Chronic pancreatitis is defined based on the structural and/or functional permanent changes that occur in the pancreas.

When pancreatitis is suspected, the child is placed on immediate bowel rest (NPO). Often, a nasogastric tube placed for suction will be needed to keep the stomach decompressed. Serial monitoring of serum amylase levels will determine when oral feeding may be restarted.

### Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1498. Assessment findings pertinent to pancreatitis are discussed below.

#### Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history include:

- Acute onset of persistent midepigastic and periumbilical abdominal pain, often with radiation to the back or chest
- Vomiting, especially after meals
- Fever

Explore the child's current and past medical history for risk factors such as:

- Cystic fibrosis
- History of gallstones

- Traumatic injury
- Family history of hereditary pancreatitis

#### Physical Examination

On abdominal assessment, the bowel sounds may be diminished, suggesting peritonitis. The abdomen may be tender, and distention may occur in younger children and infants. In severe cases, jaundice, ascites, or pleural effusions may occur. Bluish discoloration around the umbilicus or flanks is seen in the most severe cases of pancreatitis when hemorrhage is present.

#### Laboratory and Diagnostic Tests

Common laboratory and diagnostic studies ordered for the assessment and monitoring of pancreatitis include:

- Serum amylase and/or lipase: levels three times the normal values are extremely indicative of pancreatitis
- Liver profile: often done to check for increased liver functions and/or bilirubin levels
- Blood work: leukocytosis is common with acute pancreatitis. Hyperglycemia and hypocalcemia may also be noted.
- C-reactive protein: levels may be elevated

Diagnostic imaging studies performed to identify malformations or cysts on the pancreas include:

- Plain abdominal radiograph: may show a localized ileus
- Ultrasound: allows direct visualization of the pancreas and the surrounding structures. This is used most frequently with children, as it is less invasive than a CT scan. A CT scan is usually used when there is difficulty in determining the cause of the pancreatitis during ultrasonography.
- Endoscopic retrograde cholangiopancreatography (ERCP): used in some children who may have ductal anomalies, usually with chronic pancreatitis, though complications from this procedure may occur

### Nursing Management

Maintain NPO status and nasogastric tube suction and patency. Administer intravenous fluids to keep the child hydrated and correct any alterations in fluid and electrolyte balance. Pain management is crucial in children with pancreatitis. If hemorrhagic pancreatitis has occurred, blood products and/or intravenous antibiotics may be needed. Oral feedings are restarted only after the serum amylase level has returned to normal (usually in 2 to 4 days). Often, pancreatic enzymes are given with oral feedings if pain occurs after oral feeds are restarted.

Surgery is rarely needed in children with pancreatitis, except in those with severe abdominal trauma or major ductal abnormalities.

Though chronic pancreatitis is rare in children, provide child and family education regarding the signs and symptoms of recurrence and complications.

## Gallbladder Disease

Cholelithiasis is the presence of stones in the gallbladder. Cholesterol stones are usually associated with hyperlipidemia, obesity, pregnancy, birth control pill use, or cystic fibrosis (Schwarz, Hebra, & Miller, 2011). They are seen more often in females than males, and increased risk occurs with age and onset of puberty (Schwarz et al., 2011). These stones occur in the gallbladder and may be found in the common bile duct. Pigment stones are found in prepubertal children and occur about equally in males and females. They are usually found in the common bile duct (associated with bacterial or parasitic infections) or the gallbladder itself (associated with hemolytic anemia or liver cirrhosis).

Cholecystitis is an inflammation of the gallbladder that is caused by the chemical irritation due to the obstruction of bile flow from the gallbladder into the cystic ducts. This inflammation is typically associated with gallstones in children. The most common complication in children with gallstone disease is pancreatitis.

If cholelithiasis results in symptomatic cholecystitis, then surgical removal of the gallbladder (cholecystectomy) will be necessary. This is often accomplished laparoscopically.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1498. Assessment findings pertinent to gallbladder disease are discussed below.

### Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history include:

- Right upper quadrant pain, often radiating substernally or to the right shoulder
- Nausea and vomiting
- Jaundice and fever (with cholecystitis)

Document a detailed diet history as it relates to the presenting symptoms. Pain episodes usually occur after meals (postprandially), especially after the ingestion of fatty or greasy foods. Younger children may present with more nonspecific symptoms, most often due to their lack of ability to communicate their symptoms to others. Explore the child's current and past medical history for risk factors such as chronic TPN use or sickle cell disease.

## Physical Examination

Palpate the abdomen for tenderness. If cholecystitis is present, the gallbladder becomes inflamed, often to the point of causing localized tenderness upon palpation. Assess skin and sclerae color for jaundice. Note presence of fever.

## Laboratory and Diagnostic Tests

Common laboratory and diagnostic studies ordered for the assessment of cholecystitis include:

- Liver function tests, bilirubin, and C-reactive protein: values may be elevated if ductal stones are present
- CBC: may reveal leukocytosis
- Amylase and lipase: may be elevated if pancreatitis is also present
- Plain abdominal radiographs: may reveal radiopaque stones
- Ultrasound of the gallbladder and surrounding structures: to assess the intraluminal contents of the gallbladder as well as any anatomic alterations
- ERCP: to rule out ductal stones
- Hepatobiliary iminodiacetic acid (HIDA) scan: to evaluate the function of the gallbladder

## Nursing Management

The child with symptomatic cholecystitis will usually be hospitalized. Administer intravenous fluids, maintain NPO status and gastric decompression, and administer pain medications. If ordered, administer intravenous antibiotics to treat clinically worsening symptoms of cholecystitis, such as persistent fever. Provide routine postoperative care after cholecystectomy is performed. Provide pre- and postoperative teaching for families of children undergoing gallbladder removal.

## Biliary Atresia

Biliary atresia is an absence of some or all of the major biliary ducts, resulting in obstruction of bile flow. The ensuing obstruction to bile flow causes cholestasis resulting in jaundice and eventual progressive fibrosis with end-stage cirrhosis of the liver. Biliary atresia affects 1 in 10,000 to 15,000 infants (Schwarz, 2011). The etiology of biliary atresia is unknown, but there are several theories, including infectious, autoimmune, or ischemic causes.

## Therapeutic Management

If there is a high suspicion of biliary atresia, the infant will undergo exploratory laparotomy. If biliary atresia is found, a Kasai procedure (hepatopertoenterostomy) is performed to connect the bowel lumen to the bile duct remnants found at the porta hepatis. This procedure is most successful for infants up to 10 weeks of age, as

bile flow restoration after this age is minimal (Schwarz, 2011). Infants who are not identified early enough or those who have failed to respond to the Kasai procedure will need to undergo liver transplantation, usually by age 2 (Schwarz, 2011).

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1498. Assessment findings pertinent to biliary atresia are discussed below.

### Health History

Elicit a description of the present illness and chief complaint. Persistent or recurring jaundice is the most common symptom reported during the health history.

### Physical Examination

In the initial assessment of an infant with cholestasis of unknown origin, assess the stool character. In biliary atresia, stools will be acholic (chalky and white due to the lack of bile pigment). Note jaundice of the skin and sclerae (yellow discoloration caused by bile pigment deposition). Palpate the abdomen; the liver will feel enlarged and hardened. Splenomegaly may occur. In the absence of other congenital malformations, the infant will otherwise appear healthy.

### Laboratory and Diagnostic Studies

Common laboratory and diagnostic studies ordered for the assessment of biliary atresia include:

- Serum bilirubin, alkaline phosphatase, liver enzymes,  $\gamma$ -glutamyl transferase (GGT): elevated
- Ultrasound: to identify anomalies
- Biliary scan: to distinguish whether the cholestasis is intrahepatic or extrahepatic
- Liver biopsy: to confirm the diagnosis

## Nursing Management

Nursing management of infants who have biliary atresia will focus on vitamin and caloric support. Administer fat-soluble vitamins A, D, E, and K. Special formulas containing medium-chain triglycerides are used because significant fat malabsorption occurs when cholestasis is present. Administer feedings via nasogastric tube as needed to ensure increased caloric intake. Identify infections as quickly as possible and administer intravenous antibiotics as ordered. Manage ascites with diuretics and dietary restrictions. Preoperative management before a Kasai procedure is focused on preparation for surgery; infants who have suspected biliary atresia require immediate surgery to optimize outcomes.

Parents and family members of these infants will have extreme anxiety due to the implications of the diagnosis and outcomes. Focus education on the diagnosis and postoperative care. Nursing Care Plan 42.1 gives information about routine postoperative care.

## Hepatitis

Hepatitis is an inflammation of the liver that is caused by a variety of agents, including viral infections, bacterial invasion, metabolic disorders, chemical toxicity, and trauma. The most common viral causes of hepatitis are listed in Table 42.4. Other viruses that may cause hepatitis are cytomegalovirus (CMV), Epstein-Barr virus (EBV), and adenovirus. Fulminant hepatitis is thought to be caused by a non-A, non-B, non-C virus. Children who present with fulminant hepatitis have acute massive hepatic necrosis. The disease progresses rapidly to severe jaundice, coagulopathy, elevated ammonia levels, significantly elevated liver enzyme levels (aspartate aminotransferase [AST] and alanine aminotransferase [ALT]), and progressive coma, resulting in death without liver transplantation. Autoimmune hepatitis is a chronic disorder, affecting mostly adolescent females. The clinical presentation of a child with autoimmune hepatitis includes hepatosplenomegaly, jaundice, fever, fatigue, and right upper quadrant pain.

## Therapeutic Management

Acute hepatitis is treated with rest, hydration, and nutrition. Control of bleeding may also be necessary. Chronic hepatitis often eventually requires liver transplantation. Corticosteroids and immunosuppressants may be used for autoimmune hepatitis. The child with fulminant hepatitis usually requires intensive care with cardiorespiratory support. See Healthy People 2042.

### HEALTHY PEOPLE 2020

#### Objective

Reduce hepatitis A and hepatitis B. Reduce chronic hepatitis B virus infections in infants and young children.

#### Nursing Significance

- Educate families about hepatitis B and its transmission.
- Encourage routine infant and childhood vaccination against hepatitis A and B as recommended.
- For hepatitis A prevention, educate families about appropriate hygiene and hand washing.

*Healthy People Objectives based on data from <http://www.healthypeople.gov>.*

TABLE 42.4

## HEPATITIS VIRUSES A–E

	Hepatitis A (HAV)	Hepatitis B (HBV)	Hepatitis C (HCV)	Hepatitis D (HDV)	Hepatitis E (HEV)
<b>Transmission route</b>	Oral–fecal route, poor sanitation, waterborne	Sexual, intravenous drug use, blood transfusion, perinatally transmitted from mother to infant	Blood product transfusion, intravenous drug use	Same as HBV; HBV markers in serum must be present	Oral–fecal
<b>Incubation period</b>	15 to 30 days	50 to 150 days	30 to 160 days	50 to 150 days	15 to 65 days
<b>Signs and symptoms</b>	Flu-like symptoms Preicteric phase: headache, fatigue, fever, anorexia Icteric phase: jaundice, dark urine, tender liver (right upper quadrant pain)	Some cases are asymptomatic; others present with anorexia, abdominal pain, fatigue, rash, slight fever, visible jaundice, enlarged liver.	Chronic cases usually present asymptotically; others with flu-like symptoms, jaundice, hepatosplenomegaly	Same as HBV	Same as HAV, more severe in pregnant women
<b>Prognosis</b>	Rarely develops into fulminant liver failure; 95% of children recover without sequelae	Chronic disease state likely; increased risk of hepatic cancer	Many will develop chronic hepatitis and cirrhosis.	Same as HBV, but increased likelihood of chronic active hepatitis and cirrhosis	Same as HAV; high mortality in pregnant women

Adapted from Sokol, R., & Narkewicz, M. (2011). Liver & pancreas. In W. W. Hay, M. J. Levin, J. M. Sondheimer, & R. R. Detering (Eds.), *Current pediatric diagnosis and treatment* (20th ed.). New York, NY: McGraw-Hill.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1498. Assessment findings pertinent to hepatitis are discussed below. The nursing assessment for any child who presents with suspected hepatitis should be the same.

### Health History

Elicit a description of the present illness and the chief complaint. Common signs and symptoms reported during the health history include:

- Jaundice
- Fever
- Fatigue
- Abdominal pain

Explore the child's current and past medical history for risk factors such as:

- Recent foreign travel
- Sick contacts
- Medication use
- Abdominal trauma
- Sexual activity
- Intravenous drug use
- Blood product transfusion

Document onset of symptoms as well as all signs and symptoms the child has been experiencing.

### Physical Examination

Observe the skin for jaundice and the sclerae for icterus. Palpate the abdomen to reveal abnormal liver and spleen size or tenderness.

### Laboratory and Diagnostic Studies

Common laboratory and diagnostic studies ordered for the assessment of hepatitis include:

- Liver enzymes, GGT: elevated
- Prothrombin time (PT)/partial thromboplastin time (PTT): prolonged
- Ammonia: elevated in the presence of encephalopathy
- Autoimmune studies, such as antinuclear antibodies, anti-smooth muscle antibodies, and liver-kidney microsomal antibodies: may be used to diagnose autoimmune hepatitis
- Viral studies: to identify viral causes of hepatitis, such as hepatitis A to E antigens and antibodies, CMV, and EBV
- Ultrasound: to assess liver or spleen abnormalities
- Liver biopsy: to determine the type of hepatitis and to assess for damage that has already been done to the liver

## Nursing Management

Acute hepatitis requires rest, hydration, and nutrition. If the child develops vomiting, dehydration, elevated bleeding times (PT/PTT), or mental status changes (encephalopathy), hospitalization may be required. When caring for children with infectious hepatitis, provide education about transmission and prevention, including proper hygiene, safe sexual activity, careful hand-washing techniques, and blood/bodily fluid precautions.

Fulminant hepatitis treatment is aggressive and will require NPO status, nasogastric tube administration of lactulose to decrease ammonia levels that lead to encephalopathic conditions, TPN administration, vitamin K injections to help with coagulopathies, and, ultimately, liver transplantation. Fear and anxiety of the child and parents will likely be very high. Teach the child and family about the diagnosis and what to expect during treatment. Provide immunoglobulin therapy and vaccinations to close contacts of children with infectious hepatitis.

### Cirrhosis and Portal Hypertension

**Cirrhosis** of the liver occurs as a result of the destructive processes that occur during liver damage, leading to the formation of nodules. These nodules can be small (micronodular [less than 3 mm]) or large (macronodular [greater than 3 mm]) and distort the vasculature of the liver, leading to further complications. Causes of cirrhosis in children include biliary malformations,  $\alpha_1$ -antitrypsin deficiency, Wilson disease, galactosemia, tyrosinemia, chronic active hepatitis, and prolonged TPN use (Sokol & Narkewicz, 2011).

Major complications may exist due to cirrhosis of the liver, including portal hypertension. In portal hypertension, the blood flow to, through, or from the liver meets resistance, causing portal blood flow pressures to rise. As these pressures rise, collateral veins form between the portal and systemic venous circulations. The most significant complication of portal hypertension is GI bleeding, from shunting to submucosal veins (varices) in the stomach and esophagus. Esophageal varices may be treated with sclerotherapy during endoscopy to stop acute bleeding. Often blood product administration and vasopressive drugs are needed. In the long term, the only cure for cirrhosis is liver transplantation.

### Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1498. Assessment findings pertinent to cirrhosis and portal hypertension are discussed below.

## Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history include:

- Nausea and vomiting
- Jaundice
- Weakness
- Swelling
- Weight loss

Explore the child's current and past medical history for risk factors such as hepatitis, cystic fibrosis, Wilson disease, hemochromatosis, and biliary atresia. Assess the past medical history to identify possible causes for liver disease.

## Physical Examination

Inspect for jaundice, ascites, spider angiomas, and palmar erythema. Gynecomastia is often seen in males. Palpate the liver; typically it is enlarged and hard, but occasionally it is small and shrunken. Evaluate mental status to determine the presence of hepatic encephalopathy.

## Laboratory and Diagnostic Studies

Laboratory and diagnostic testing will be similar to that of a child with hepatitis. Common laboratory and diagnostic studies ordered for the assessment of cirrhosis or portal hypertension include:

- Liver biopsy: reveals regenerating nodules and surrounding fibrosis
- Upper endoscopy: reveals varices and bleeding

## Nursing Management

Nursing management is very similar to the care of the child with hepatitis. In cases of cirrhosis causing portal hypertension and bleeding varices, GI bleeding must be controlled. This is usually done by replacing blood loss and providing vasopressive therapy to constrict the shunted blood flow. As with all liver disorders and GI bleeding, address and manage family and child anxiety. Be honest about the child's treatment plan and prognosis. Involve the family in the care of the child and educate them as needed.

### Liver Transplantation

Hepatobiliary disorders that result in failure of the liver to function result in the need for liver transplantation. Liver transplantation in children has become increasingly suc-

cessful in the past several years due to advances in immunosuppression, better selection of transplant candidates, and improvements in surgical techniques and postoperative care (Boudi, 2012). Transplant centers now offer both cadaveric and living-related liver transplants for children. Rejection of the transplanted liver is the most significant complication. Most children will require immunosuppressive therapy for a lifetime, putting them at risk for infections.

## Nursing Assessment

Many children will be admitted to a transplant center for a preoperative workup to determine the best possible tissue and blood match for the child. There is much anxiety among family members when a cadaveric transplant is the only possibility for survival. This puts a child on a waiting list that is prioritized based on several criteria. Because there are a limited number of pediatric liver transplant centers throughout the country, there may be many issues regarding transportation, finances, job loss, and lodging. Assess the need for social work intervention; a social worker is almost always involved with these children. A liver transplant coordinator will assist with coordinating the care for pre- and posttransplant children.

## Nursing Management

Preoperatively, assist with the transplant workup and teach the child and family what to expect during and after the liver transplantation. Postoperatively, the child will be in the intensive care unit for several days until he or she is stabilized from the actual surgery (see Nursing Care Plan 42.1). After the child is sent to a regular unit in the hospital, monitor the child for several days to weeks for signs and symptoms of rejection and infection, including fever, increasing liver function test results and GGT, and increasing pain, redness, and swelling at the incision site.

Child and family education is an important element of nursing management in the posttransplant child. Assess and reassess medication knowledge throughout the entire hospitalization, as these children usually require medications for a lifetime.

### KEY CONCEPTS

- The esophagus of the young child exhibits underdeveloped muscle tone compared with the adult.
- A major difference between children and adults is the reduced stomach capacity in the child and the significantly shorter length of the small intestine (250 cm in the child vs. 600 cm in the adult).
- Infants and children have a proportionately greater amount of body water than adults, resulting in a relatively greater fluid intake requirement than

adults and placing infants and children at higher risk for fluid loss as compared with adults.

- The most common result of GI illnesses in infants and children is dehydration.
- The mildly or moderately dehydrated child must be identified and receive rehydration therapy to prevent progression to hypovolemic shock.
- Rehydration is a key medical treatment for dehydration as a result of many different GI disorders. Oral rehydration is most common, but in cases requiring hospitalization intravenous fluid therapy is key.
- Promotion of adequate nutrition is another significant treatment component. The child with a chronic GI disorder may require intravenous TPN or enteral tube feedings to exhibit appropriate growth.
- Surgical intervention is necessary for many acute or congenital GI disorders, such as pyloric stenosis, cleft lip and palate, appendicitis, Hirschsprung disease, and intestinal malrotation.
- Monitoring the blood count, electrolyte levels, and liver function tests is necessary in many pediatric GI disorders.
- Histamine-2 blockers, proton pump inhibitors, and prokinetic agents are used to treat disorders in which gastric acid is a problem, such as esophagitis, GERD, and ulcers.
- Close monitoring for infection is important in children with inflammatory bowel disease, autoimmune hepatitis, or liver transplant who are being treated with immunosuppressants and/or corticosteroids.
- GI stimulants and laxatives may be necessary for treating constipation and encopresis.
- Diarrhea, vomiting, decreased oral intake, sustained high fever, diabetic ketoacidosis, and extensive burns place the infant or child at risk for the development of dehydration.
- Risk factors for vomiting include exposure to viruses, use of certain medications, and overfeeding in the infant.
- Risk factors for acute diarrhea include recent ingestion of undercooked meats, foreign travel, day care attendance, and well water ingestion.
- Vomiting is a symptom and should be characterized in terms of volume, color, relation to meals, duration, and associated symptoms.
- Bleeding may occur as a result of a GI disorder, particularly from the intestine with Meckel diverticulum and from esophageal varices with portal hypertension.
- Acute GI disorders are those that usually have a rapid onset and a short course, which at times may be severe. Examples include dehydration, vomiting, diarrhea, hypertrophic pyloric stenosis, and appendicitis.
- Chronic GI disorders are those that are long lasting or recur over time. Examples include constipation, GER, inflammatory bowel disease, recurrent abdominal pain, and failure to thrive.
- Right lower quadrant pain and rebound tenderness of the abdomen found on physical examination are telltale signs of appendicitis, which is considered a surgical emergency.
- Bilious vomiting is the main symptom of conditions resulting in bowel obstruction, such as malrotation with volvulus.
- The focus of nursing management of the child with diarrhea or vomiting is restoring proper fluid and electrolyte balance through oral rehydration therapy or intravenous fluids if necessary.
- Reduction of inguinal and umbilical hernias should be attempted; if reduction of the hernia is impossible, immediately notify the physician.
- Small, frequent, and thickened feedings and proper positioning after feedings are key elements in the treatment of GER.
- A crucial nursing intervention related to cleft lip and palate repair is protection of the surgical site while it is healing.
- Palpation of the abdomen should be the last part of the physical examination of an infant or child.
- A key element of nursing care for the child with a GI disorder is promotion of appropriate bowel elimination.
- Maximizing nutritional status is a critical nursing function for the child with a GI disorder.
- For the child who has undergone surgical repair for correction of a GI disorder, promoting effective breathing patterns and managing pain are important nursing goals.
- Counseling families about how to manage the child with vomiting or diarrhea at home, including oral rehydration therapy, is a key component of child/family education.
- Education of the child and family regarding the importance of medication compliance for management of inflammatory bowel disease is critical.

- Behavioral therapy and counseling may be necessary for children who have functional constipation and stool withholding.
- The child or adolescent with ineffective bowel control, poor growth, or an ostomy may have poor self-esteem and body image.

## MULTIPLE CHOICE QUESTIONS

1. A mother brings her 6-month-old infant to the clinic. The child has been vomiting since early morning and has had diarrhea since the day before. His temperature is 38° C, pulse 140, and respiratory rate 38. He has lost 6 ounces since his well-child visit 4 days ago. He cries before passing a bowel movement. He will not breast-feed today. What is the priority nursing diagnosis?
  - a. Thermoregulation alteration.
  - b. Pain (abdominal) related to diarrhea.
  - c. Fluid volume deficit related to excessive losses and inadequate intake.
  - d. Alteration in nutrition, less than body requirements, related to decreased oral intake.
2. A child presents with a 2-day history of fever, abdominal pain, occasional vomiting, and decreased oral intake. Which finding would the nurse prioritize for immediate reporting to the physician?
  - a. Temperature 101.9°F.
  - b. Rebound tenderness and abdominal guarding.
  - c. Parents will be leaving the child alone in the hospital.
  - d. Child can tolerate only sips of fluid without nausea.
3. A 3-day-old infant presenting with physiologic jaundice is hospitalized and placed under phototherapy. Which response indicates to the nurse that the parent needs more teaching?
  - a. "My infant is at risk for dehydration."
  - b. "My infant needs to stay under the lights, except during feeding time."
  - c. "My infant can continue to breastfeed during this time."
  - d. "My infant has a serious liver disease."
4. A 3-month-old infant presents with a history of vomiting after feeding. The plan for the infant is to rule out GER. What information from the history would lead the nurse to believe that this infant may need further intervention?
  - a. Poor weight gain.
  - b. Has small "spits" after feeding.
  - c. Sleeps through the night.
  - d. Is difficult to burp.
5. The nurse is caring for a child who has had diarrhea and vomiting for the past several days. What is the priority nursing assessment?
  - a. Determine the child's weight.
  - b. Ask if the family has traveled outside of the country.
  - c. Assess circulation and perfusion.
  - d. Send a stool specimen to the lab.

## CRITICAL THINKING EXERCISES

1. A 6-month-old baby is brought to the physician's office with a history of diarrhea. She has had six watery stools in the past 18 hours. She is vomiting her formula. Her mother states that she has had no fever.
  - a. Upon completion of the history and physical examination, what signs and symptoms would you expect to find that would indicate that the baby is experiencing mild dehydration?
  - b. What is the priority nursing diagnosis for this infant?
  - c. Identify a plan for this nursing diagnosis; include a teaching plan for the mother.
2. A 14-kg child with moderate dehydration has received two boluses of normal saline in the emergency room prior to being admitted to the pediatric nursing unit. The physician orders D5 ½ NS @ 1½ maintenance.
  - a. What would the intravenous fluid rate be?
  - b. What will the nurse assess for to determine whether the child is becoming overhydrated?
3. An infant requires a temporary colostomy. What discharge instructions would you provide to the parents about how to take care of the colostomy and when to call their child's physician or nurse practitioner?

## STUDY ACTIVITIES

1. In the clinical setting, compare the growth records of a child with celiac disease to those of a similar-aged child without disease.
2. While caring for children in the clinical setting, compare and contrast the medical history, signs and symptoms of illness, and prescribed treatment for a child with Crohn disease and one with ulcerative colitis.
3. In the clinical setting, observe the behavioral responses of an infant or young child with inorganic failure to thrive.

#### KEY TERMS

anasarca  
 anuria  
 bacteriuria  
 dysuria  
 enuresis  
 hematuria  
 oliguria  
 proteinuria

 urinary frequency

# Nursing Care of the Child With a Genitourinary Disorder

## Learning Objectives

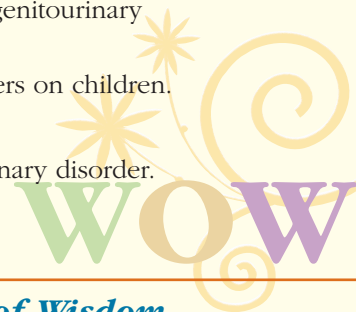

*Upon completion of the chapter, you will be able to:*

1. Define the key terms used in this chapter.
2. Compare anatomic and physiologic differences of the genitourinary system in infants and children versus adults.
3. Describe nursing care related to common laboratory and diagnostic testing used in the medical diagnosis of pediatric genitourinary conditions.
4. Distinguish genitourinary disorders common in infants, children, and adolescents.
5. Identify appropriate nursing assessments and interventions related to medications and treatments for pediatric genitourinary disorders.
6. Develop an individualized nursing care plan for the child with a genitourinary disorder.
7. Describe the psychosocial impact of chronic genitourinary disorders on children.
8. Devise a nutrition plan for the child with renal insufficiency.
9. Develop child/family teaching plans for the child with a genitourinary disorder.

*Corey Bond, 5 years old, is brought to the clinic by her mother. She presents with fever and lethargy for the past 24 hours. Her mother states, “Corey has had a few accidents in her pants over the past few days, which is unusual for her. She also has been getting up at night more often to use the bathroom.”*

## Words of Wisdom

A child's essential bodily processes of elimination can be a major event of wonder and creative accomplishment.

**Genitourinary** (GU) disorders in children and adolescents may occur as a result of abnormalities in fetal development, infectious processes, trauma, neurologic deficit, genetic influences, or other causes.

Congenital disorders account for a large proportion of GU disorders in infants. External GU malformations are easily identified at birth, but internal structural defects may not be identified until later in infancy or childhood when symptoms or complications arise. Enuresis and urinary tract infection (UTI) also occur in a significant number of children.

Some GU disorders directly involve the kidney from the outset, while others involve other parts of the urinary tract and may have a long-term effect on the kidneys and renal function, particularly if left untreated or treated inadequately.

Disorders affecting the reproductive organs often require early diagnosis and management to preserve future reproductive capabilities.

Nurses must be knowledgeable about pediatric GU conditions to provide prompt recognition, nursing care, education, and support to children and their families. Though some disorders are acute and resolve quickly, many have a long-term effect on quality of life and will require more intense, extended support.

Management of acute or common pediatric GU disorders may be provided in the pediatric or family practice outpatient setting, while specialists such as pediatric nephrologists or urologists usually manage chronic or involved GU disorders.

## VARIATIONS IN PEDIATRIC ANATOMY AND PHYSIOLOGY

Though all of the urinary tract and reproductive organs are present at birth, their functioning is immature initially. The infant or child is at increased risk for the development of certain GU disorders because of the anatomic and physiologic differences between children and adults.

### Structural Differences

The kidney is large in relation to the size of the abdomen until the child reaches adolescence. Due to this increased size, the kidneys of the child are less well protected from injury by the ribs and fat padding than they are in the adult. The urethra is naturally shorter in all ages of females compared to males, placing them at increased risk for the entrance of bacteria into the bladder via the urethra. In the female infant or young child, this risk is compounded by the physical proximity of the urethral opening to the rectum. The young

male's urethra is much shorter than the adult male's, placing the male infant or young child at increased risk of urinary tract infection compared with the adult male.

### Urinary Concentration

Blood flow through the kidneys (glomerular filtration rate [GFR]) is slower in the infant and young toddler compared with the adult (Lum, 2011). The kidney is less able to concentrate urine and reabsorb amino acids, placing the infant and young toddler at increased risk for dehydration during times when fluid loss or decreased fluid intake occurs. The normal range for serum blood urea nitrogen (BUN) and creatinine of the healthy infant or young toddler is usually less than the older child's or adult's. The renal system usually reaches functional maturity at around 2 years of age.

### Urine Output

Bladder capacity is about 30 mL in the newborn; it increases to the usual adult capacity of about 270 mL by 1 year of age. The expected urine output in the infant and child is 0.5 to 2 mL/kg/hour, with the average 1-year-old voiding about 400 to 500 mL per day. The average urine output for a teenager is about 800 to 1,400 mL per day. The infant and toddler may void as often as 9 or 10 times per day. By age 3 the average number of voids per day is the same as the adult's (three to eight).

### Reproductive Organ Maturity

The reproductive organs are also immature at birth. The gonads are not mature until adolescence in most children. The hormonal changes that occur with puberty account for some of the reproductive concerns, particularly for female adolescents.

## COMMON MEDICAL TREATMENTS

A variety of medications as well as other medical treatments and surgical procedures are used to treat GU problems in children. Most of these treatments will require a physician's or nurse practitioner's order when the child is in the hospital. The most common treatments and medications are listed in Common Medical Treatments 43.1 and Drug Guide 43.1. The nurse caring for the child with a GU disorder should be familiar with what the procedures are, how the treatments and medications work, and common nursing implications related to use of these modalities.

## COMMON MEDICAL TREATMENTS 43.1

Treatment	Explanation	Indications	Nursing Implications
Urinary diversion	Surgical diversion of ureters to the abdominal wall. Continent diversion uses a piece of intestine to create a bladder that can be catheterized. Noncontinent diversion involves a stoma on the abdominal wall that requires use of an ostomy pouch.	Any situation in which the bladder needs to be removed or does not function correctly (bladder exstrophy or prune belly)	Meticulous skin care is necessary to prevent breakdown around stoma. Teach families how to care for ostomy pouch or how to catheterize continent stoma. Expect mucus in urine if intestine is used for urinary reservoir. Monitor for signs of urinary tract infection.
Foley catheter	An indwelling urinary catheter stays in place by means of an inflated balloon.	Usually used only during the postoperative period	Monitor for urethral drainage or irritation. Keep area clean and dry. Monitor color, consistency, clarity, and amount of urine in drainage bag. Monitor for infection, checking results of urinalysis and urine cultures.
Ureteral stent	A thin catheter temporarily placed in the ureter to drain urine. Removed via cystoscopy when it is time for discontinuation	Urinary tract anomalies	Monitor urine output carefully. Check for bleeding postoperatively.
Nephrostomy tube	Tube placed directly into the kidney to drain urine externally to a bag	Urinary tract anomalies	Monitor urine output carefully.
Suprapubic tube	Catheter placed in the bladder via the abdominal wall above the symphysis pubis	Postoperative urine drainage with reconstructive surgeries	Monitor for blood in urine, adequate urine output. Minimize manipulation of suprapubic tube to avoid triggering bladder spasms.
Vesicostomy	Stoma in the abdominal wall to the bladder	Urinary tract anomalies, neurogenic bladder	Constant urine drainage requires diaper use. Monitor urine output. Assess skin around stoma for breakdown.
Appendicovesicostomy (Mitrofanoff procedure)	Uses appendix to create a stoma on the abdominal wall that allows for catheterization of the bladder	Urinary tract anomalies, neurogenic bladder	Allows for urinary continence, which improves the child's self-esteem. Teach family and child how to catheterize stoma.
Bladder augmentation	Uses a piece of stomach or intestine to enlarge bladder capacity	Decreased bladder capacity	Since a portion of the GI tract is used, urine is often mucus-like.

## NURSING PROCESS OVERVIEW FOR THE CHILD WITH A GENITOURINARY DISORDER

Care of the child with a GU disorder includes assessment, nursing diagnosis, planning, interventions, and evaluation. There are a number of general concepts related to the nursing process that may be applied to GU disorders. From a general understanding of the care involved for a child with urinary, renal, or reproductive dysfunction, the nurse can then individualize the care based on specifics for that child.

## Assessment

Assessment of urinary tract, renal, or reproductive dysfunction includes health history, physical examination, and laboratory and diagnostic testing.

**Remember Corey, the 5-year-old with fever and lethargy? What additional health history and physical examination assessment information should you obtain?**

### DRUG GUIDE 43.1 COMMON DRUGS FOR GU DISORDERS

Medication	Actions/Indications	Nursing Implications
Anticholinergic agents (oxybutynin, propanteline bromide, belladonna & opium suppository)	Cause smooth muscle relaxation of the bladder, used for urinary tract spasms or contractions related to surgical procedure or use of catheters. Control of nocturnal enuresis	Increase fluid intake (limit to during the day in the child with nocturnal enuresis). Avoid use in febrile child.
Antibiotics (oral, parenteral)	Kill bacteria or arrest their growth. Used for urinary tract infection	Check for antibiotic allergies. Should be given as prescribed for the length of time indicated
Desmopressin (DDAVP)	Antidiuretic hormone effects by causing renal tubule to absorb more water, decreasing volume of urine in children with nocturnal enuresis	Nasal spray may cause nasal irritation, nausea, flushing, or headache. Administer at bedtime; alternate nares. Associated with a high relapse rate.
Human chorionic gonadotropin (hCG)	Stimulates production of gonadal steroids to precipitate testicular descent	Monitor for signs of precocious puberty if used long term.
Corticosteroids	Anti-inflammatory and immunosuppressive action to induce remission and promote diuresis in nephrotic syndrome. High-dose intravenous therapy used when nephrotic syndrome is resistant to conventional doses	Administer with food to decrease GI upset. May mask signs of infection. Do not stop treatment abruptly, or acute adrenal insufficiency may occur. Monitor for Cushing syndrome.
Cytotoxic drugs (cyclophosphamide [Cytoxan] and chlorambucil [Leukeran])	Interfere with normal function of DNA by alkylation. Used to induce prolonged remission in nephrotic syndrome	Doses may be tapered over time. Monitor for hypertension during infusion. Causes bone marrow suppression. Monitor for signs of infection. Cyclophosphamide: administer in the morning; provide adequate hydration; have child void frequently during and after infusion to decrease risk of hemorrhagic cystitis. Chlorambucil: administer with nonspicy, non-acidic foods; rarely seizures occur.
Immunosuppressant drugs (cyclosporine A [CyA], azathioprine, tacrolimus, mycophenolate)	Cause immune suppression to prevent rejection of renal transplants. CyA and tacrolimus may be used for steroid-dependent nephrotic syndrome.	Monitor complete blood count, serum creatinine, potassium, and magnesium. Monitor blood pressure and observe for signs of infection. Blood levels should be drawn prior to morning dose. CyA: do not give with grapefruit juice. Azathioprine and mycophenolate: give on empty stomach; do not open capsule or crush tablet. Tacrolimus: give on empty stomach; assess for development of hyperglycemia. Relapse of nephrotic syndrome may occur after withdrawal of CyA or tacrolimus therapy.
Muromonab-CD3 (Orthoclone OKT3)	Removal of all CD3 molecules from T-lymphocyte surface so it has inability to act. Used for treatment of acute renal transplant rejection	Monitor for development of pulmonary edema. First-dose effect may cause fever, chills, chest tightness, wheezing, nausea, and vomiting.

**DRUG GUIDE 43.1 COMMON DRUGS FOR GU DISORDERS** (continued)

Medication	Actions/Indications	Nursing Implications
Angiotensin-converting enzyme (ACE) inhibitors (captopril, enalapril)	Potent vasoconstrictor, prevent conversion of angiotensin I to angiotensin II. Used to treat renal causes of hypertension	Monitor blood pressure frequently. May cause cough, hyperkalemia. Captopril: administer on empty stomach. Enalapril: administer without regard to food.
Imipramine (Tofranil) (tricyclic antidepressant)	Increases the synaptic concentration of serotonin and/or norepinephrine. Treatment of enuresis	Monitor for urinary retention. May cause decreased appetite.
Diuretics: furosemide (Lasix), hydrochlorothiazide (HCTZ)	Inhibit resorption of sodium and chloride leading to increased excretion of water and electrolytes. Used in nephrotic syndrome, acute glomerulonephritis, hemolytic-uremic syndrome, or other instances of fluid overload with renal sufficiency	Administer with food or milk to decrease GI upset. Monitor blood pressure, renal function, and electrolytes (particularly potassium). May cause photosensitivity.
Vasodilators: hydralazine (Apresoline), minoxidil	Direct vasodilation of arterioles, resulting in decreased systemic resistance. Used to treat renal causes of hypertension	May cause fluid retention. Hydralazine: administer with food. Monitor heart rate and blood pressure (closely with intravenous use). Minoxidil: may be administered without regard to food. May cause dizziness.
Calcium channel blocker: nifedipine (Procardia)	Prevents calcium from entering voltage-sensitive channels, resulting in coronary vasodilation. Used to treat renal causes of hypertension	Administer with food; avoid grapefruit juice. Insoluble shell of extended-release tablet may pass in stool. Use caution when administering liquid-filled capsule sublingually or by bite-and-swallow method, as significant hypotension may occur.
Albumin (intravenous)	Increases intravascular oncotic pressure, resulting in movement of fluid from interstitial to intravascular space. Indicated for fluid volume excess associated with nephrotic syndrome	May require a filter depending on brand used. Rapid infusion can result in vascular overload. Monitor vital signs; observe for pulmonary edema and cardiac failure.

Adapted from Taketokmo, C. K., Hodding, J. H., & Kraus, D. M. (2011). *Pediatric and neonatal dosage handbook* (18th ed.). Hudson, OH: Lexi-comp.

### Health History

The health history consists of the past medical history, including the mother's pregnancy history; family history; and history of present illness (when the symptoms started and how they have progressed), as well as medications and treatments used at home. The past medical history may be significant for maternal polyhydramnios, oligohydramnios, diabetes, hypertension, or alcohol or cocaine ingestion. Neonatal history may include the presence of a single umbilical artery or an abdominal mass, chromosome abnormality, or congenital

malformation. Document past medical history of UTI or other problems with the GU tract. Family history may be significant for renal disease or uropathology, chronic UTIs, renal calculi, or a history of parental enuresis. Determine age of successful toilet training, pattern of incontinent episodes (having "accidents"), and toileting hygiene self-care routines. Note myelomeningocele or other spinal disturbance that may affect the child's ability to urinate. Note previous urologic surgeries or ongoing renal interventions (e.g., dialysis). For the adolescent girl, obtain a thorough menstrual history, including sexual behavior and pregnancy history.

When determining the history of the present illness, inquire about the following:

- Burning on urination
- Changes in voiding patterns
- Foul-smelling urine
- Vaginal or urethral discharge
- Genital pain, irritation, or discomfort
- Blood in the urine
- Edema
- Masses in the groin, scrotum, or abdomen
- Flank or abdominal pain
- Cramps
- Nausea and/or vomiting
- Poor growth
- Weight gain
- Fever
- Infectious exposure (particularly *Streptococcus A* or *Escherichia coli*)
- Trauma

Record medications used for acute or chronic conditions, or for contraception.

### Physical Examination

Physical examination of the GU system includes inspection and observation, auscultation, percussion, and palpation.

#### INSPECTION AND OBSERVATION

Observe the child's general appearance, noting growth retardation or unusual weight gain. Inspect the skin for the presence of pruritus, edema (generalized or periorbital), or bruising. Note pallor of the skin or dysmorphic features (associated with genetic conditions). Document the presence of lethargy, fatigue, rapid respirations, confusion, or developmental delay. Observe the external genitalia area for infant diaper rash, constant urine dribble, displaced urethral opening, reddened urethral opening, or discharge. In females, note vaginal irritation or labial fusion. In males, observe the scrotal sac for enlargement or discoloration. Note the condition of a urinary stoma or diversion if present. With the child lying flat, observe the abdomen for distention, ascites, or slack abdominal musculature.

#### AUSCULTATION

Listen carefully to heart sounds, as a flow murmur may be present in the anemic child with a renal disorder (Klein, 2010). Note elevated heart rate. Auscultate blood pressure with the appropriate-size cuff, noting elevation or depression. In the edematous child, carefully auscultate the lungs, noting the presence of adventitious sounds. Note the absence of bowel sounds, as this may indicate peritonitis. In the child who receives chronic hemodialysis, auscultate the

fistula for the presence of a bruit (desired normal finding).

#### Take Note!

Use the bell of the stethoscope when auscultating the infant's or child's blood pressure so that you can hear the softer Korotkoff sounds more accurately.

#### PERCUSSION

Percuss the abdomen. Note unusual dullness or flatness (dullness is usually heard over the spleen at the right costal margin, over the kidneys, and 1 to 3 cm below the left costal margin). A full bladder may yield dullness above the symphysis pubis.

#### PALPATION

Palpate the abdomen. Note the presence of palpable kidneys (indicating enlargement or mass, as they are usually difficult to palpate in the older infant or child). Note the presence of abdominal masses or a distended bladder. Document tenderness to palpation or along the costovertebral angle. Palpate the scrotum for the presence of descended testicles, masses, or other abnormalities. Note whether the foreskin, if present, can be retracted. In the child who receives chronic hemodialysis, palpate the fistula or graft for the presence of a thrill (desired normal finding).

### Laboratory and Diagnostic Testing

Common Laboratory and Diagnostic Tests 43.1 offers an explanation of the most commonly used laboratory and diagnostic tests for a child suspected of having a GU disorder. The test results can help the physician or nurse practitioner to diagnose the disorder or to determine treatment. Laboratory or nonnursing personnel obtain some of the tests, while the nurse might obtain others. In either instance the nurse should be familiar with how the tests are obtained, what they are used for, and normal versus abnormal results. This knowledge will also be necessary when providing child and family education related to the tests and results.

Urine specimens may be collected using a variety of different methods in infants and children. Suprapubic aspiration is a useful method for obtaining a sterile urine specimen from the neonate or young infant. A sterile needle is inserted into the bladder through the anterior wall of the abdomen and the urine is then aspirated. The physician or nurse practitioner generally performs this method. Infants and toddlers who are not toilet trained may require a urine bag for urine collection. A sterile urine bag is required for a urine culture, a clean bag for routine urinalysis. A 24-hour urine collection bag is also available. Nursing Procedure 43.1 gives details on the use of the urine bag.

## COMMON LABORATORY AND DIAGNOSTIC TESTS 43.1 GENITOURINARY DISORDERS

Test	Explanation	Indications	Nursing Implications
Complete blood count	Evaluate hemoglobin and hematocrit, white blood cell count, and platelet count	Any condition in which anemia, infection, or thrombocytopenia is suspected	Normal values vary according to age and gender. White blood cell count differential is helpful in evaluating source of infection.
Blood urea nitrogen (BUN) (serum)	Indirect measurement of renal function and glomerular filtration in the presence of adequate liver function	Nephrotic syndrome, hemolytic-uremic syndrome, renal failure, acute glomerulonephritis, or other renal diseases	BUN may be elevated with high-protein diet or dehydration, may be decreased with overhydration or malnutrition.
Creatinine (serum)	A more direct measurement of renal function, only minimally affected by liver function. Generally, doubling of the creatinine level is suggestive of a 50% reduction in glomerular filtration rate.	Used to diagnose impaired renal function	A diet high in meat may cause a transient though not pronounced increase in creatinine. There are also slight diurnal variations in levels. Draw at same time each day if serial evaluations are ordered.
Creatinine clearance (urine and serum)	A 24-hour urine collection is evaluated for the presence of creatinine, then compared with the serum creatinine level to determine creatinine clearance.	Used to diagnose impaired renal function	Discard the first void and then begin the 24-hour urine collection. Keep the specimen on ice during the collection period. Collect ALL urine passed in the 24-hour period. Ensure that a venous blood sample is drawn during the 24-hour period. The urine specimen should be sent promptly to the laboratory at the end of the 24-hour period.
Potassium (serum)	Measures the concentration of potassium in the blood	Any suspected renal disease; followed routinely in renal failure	Avoid hemolysis and allowing child to open and close the hand with a tourniquet in place, as these can cause elevation in potassium levels. Evaluate the child with increased or decreased potassium levels for cardiac arrhythmias. Immediately notify physician or nurse practitioner of critically high potassium levels.
Total protein, globulin, albumin (serum)	Protein electrophoresis separates the various components into zones according to their electrical charge.	Used to diagnose, evaluate, and monitor chronic renal disease	Significantly low levels of albumin contribute to extent of edema, as albumin is necessary in the blood to maintain colloidal osmotic pressure.
Calcium (serum)	Measurement of calcium level in the blood; half of all calcium is protein-bound, so the level will decrease with hypoalbuminemia.	Renal diseases associated with hypoalbuminemia and edema	Avoid prolonged tourniquet use during blood draw, as this may falsely increase the calcium level.
Phosphorus (serum)	Measurement of phosphate level in the blood. Phosphorus levels are inversely related to calcium levels (they increase when calcium levels decrease).	Renal disease, ongoing monitoring, particularly in the child with hypocalcemia	Child should be NPO past midnight prior to the morning of the blood draw. Avoid hemolysis, as it can falsely elevate the phosphate level.
Urinalysis (urine)	Evaluates color, pH, specific gravity, and odor of urine. Also assess for presence of protein, glucose, ketones, blood, leukocyte esterase, red and white blood cells, bacteria, crystals, and casts.	Reveals preliminary information about the urinary tract. Useful in children with fever, dysuria, flank pain, urgency, or hematuria. Proteinuria may be noted in renal disorders.	Be aware of the many drugs affecting urine color and notify laboratory if child is taking one. Notify laboratory if female is menstruating. Refrigerate specimen if not processed promptly. While proteinuria may occur with various renal disorders, it may also occur as either transient or orthostatic proteinuria, both of which are benign events.
Cystoscopy	Endoscopic visualization of the urethra and bladder	Evaluate hematuria, recurrent urinary tract infection; determine ureteral reflux; measure bladder capacity	Encourage fluids. Monitor vital signs. Child may feel burning with voiding after procedure. Pink tinge to urine is common after procedure.

(continued)

**COMMON LABORATORY AND DIAGNOSTIC TESTS 43.1 GENITOURINARY DISORDERS** (continued)

Test	Explanation	Indications	Nursing Implications
Urine culture and sensitivity	Urine is plated in the laboratory and evaluated every day for the presence of bacteria. A final report is usually issued after 48 to 72 hours. Sensitivity testing is performed to determine the best choice of antibiotic.	Used to diagnose urinary tract infection	Obtain culture specimen prior to starting antibiotics if at all possible. Avoid contamination of the specimen with stool. May be obtained by catheterization, clean-catch specimen, or sterile U-bag. In some institutions, suprapubic tap is performed in neonates and young infants by the physician or nurse practitioner.
Urodynamic studies	Measure the urine flow during micturition via a urine flow meter	Dysfunctional voiding	The child must have a full bladder. The child then urinates into the urine flow meter. There is no discomfort associated with the test.
Voiding cystourethrogram (VCUG)	The bladder is filled with contrast material via catheterization. Fluoroscopy is performed to demonstrate filling of the bladder and collapsing after emptying.	Hematuria, urinary tract infections, vesicoureteral reflux, suspected structural anomalies	Just prior to the test, insert the Foley catheter. Ensure that the adolescent female is not pregnant. After the test, encourage the child to drink fluids to prevent bacterial accumulation and aid in dye elimination.
Intravenous pyelogram (IVP)	Radiopaque contrast material is injected intravenously and filtered by the kidneys. X-ray films are obtained at set intervals to show passage of the dye through the kidneys, ureters, and bladder.	Urinary outlet obstruction, hematuria, trauma to the renal system, suspected kidney tumor	Contraindicated in children allergic to shellfish or iodine. If the dye infiltrates at the intravenous site, hyaluronidase (Wydase) may be used to speed absorption of the iodine. Ensure adequate hydration before and after the test. Some institutions require enema or laxative evacuation of the bowel prior to the study to ensure adequate visualization of the urinary tract.
Renal biopsy	Usually a percutaneous specimen is obtained by inserting a needle through the skin and into the kidney. The sample of kidney tissue obtained is then microscopically examined.	Diagnosis of renal disease or assessment of renal transplant rejection	After the biopsy, carefully assess for signs or symptoms of bleeding: increased heart rate, pale color, flank pain or backache, shoulder pain, lightheadedness. Inspect urine for gross hematuria. Child will be on bed rest, preferably supine for 24 hours.
Renal ultrasound	Reflected sound waves allow visualization of the kidneys, ureters, and bladder.	Useful in determining kidney size (as with hydronephrosis and polycystic kidney), presence of cysts or tumors, or rejection of kidney transplant	No fasting is required prior to the procedure. Does not require contrast material. The child should feel no discomfort during the ultrasound.

Adapted from Pagana, K. D., & Pagana, T. J. (2010). *Mosby's manual of diagnostic and laboratory tests* (4th ed.). St. Louis, MO: Mosby.

## Atraumatic Care

*When examining the genital area or performing urinary catheterization of the young female, allow the girl to sit with her mother on the examination table to decrease anxiety. Have the girl lie back on her mother's chest, seated on the table between the mother's legs. Encourage the mother to console and hug the girl while the invasive examination or procedure is being performed.*

- Sterile urinary catheterization is performed like that in adults. The size of the catheter varies depending on the size of the child. General size recommendations are:
  - 6 French: Birth to 2 years old
  - 6 to 8 French: 2 to 5 years old
  - 8 to 10 French: 5 to 10 years old
  - 10 to 12 French: 10 to 16 years old (Bowden & Greenberg, 2012)

## NURSING PROCEDURE 43.1

## Applying the Urine Bag

1. Cleanse the perineal area well and pat dry (Figure A). If a culture is to be obtained, cleanse the genital area with povidone-iodine (Betadine) or per institutional protocol.
2. Apply benzoin around the scrotum or the vulvar area to aid with urine bag adhesion.
3. Allow the benzoin to dry.
4. Apply the urine bag.
  - For boys: Ensure that the penis is fully inside the bag; a portion of the scrotum may or may not be inside the bag, depending on scrotal size.
  - For girls: Apply the narrow portion of the bag on the perineal space between the anal and vulvar areas first for best adhesion, and then spread the remaining adhesive section (Figure B).
5. Tuck the bag downward inside the diaper to discourage leaking.
6. Check the bag frequently for urine (Figure C).

**Take Note!**

Use familiar terms such as “pee-pee,” “tinkle,” or “potty” to explain to the child what is needed and to gain his or her cooperation.

## Nursing Diagnoses and Related Interventions

Upon completion of a thorough assessment, the nurse might identify several nursing diagnoses, such as:

- Impaired urinary elimination
- Fluid volume excess
- Imbalanced nutrition, less (or more) than body requirements
- Risk for infection
- Deficient knowledge of the child or family
- Urinary retention
- Activity intolerance
- Interrupted family processes
- Disturbed body image

**After completing an assessment of Corey, you note the following: foul-smelling urine, abdominal tenderness, redness in her perineal area, and slightly blood-tinged, cloudy urine. Based on these assessment findings, what would your top three nursing diagnoses be for Corey?**

Nursing goals, interventions, and evaluation for the child with a GU disorder are based on the nursing diagnoses. Nursing Care Plan 43.1 can be used as a guide in planning nursing care for the child with a GU disorder. The care plan overview includes nursing diagnoses and interventions for urinary tract disorders as well as genital (or reproductive system) disorders. It is important to individualize it based on the child's symptoms and needs. Refer to Chapter 36 for detailed information about pain management. Additional information will

## NURSING CARE PLAN 43.1

## Overview for the Child With a Genitourinary Disorder

**NURSINGS DIAGNOSIS:** Activity intolerance related to generalized edema, anemia, or generalized weakness as evidenced by verbalization of weakness or fatigue; elevated heart rate, respiratory rate, or blood pressure with activity; complaint of shortness of breath with play or activity

### Outcome Identification and Evaluation

Child will display increased activity tolerance, desire to play without developing symptoms of exertion.

### Intervention: *Promoting Activity*

- Encourage activity or ambulation per physician's or nurse practitioner's orders: *early mobilization results in better outcomes.*
- Observe child for symptoms of activity intolerance such as pallor, nausea, lightheadedness, or dizziness or changes in vital signs *to determine level of tolerance.*
- If child is on bed rest, perform range-of-motion exercises and frequent position changes, *as negative changes to the musculoskeletal system occur quickly with inactivity and immobility.*
- Cluster nursing care activities and plan for periods of rest before and after exertional activities *to decrease oxygen need and consumption.*
- Refer the child to physical therapy *for exercise prescription to increase skeletal muscle strength.*

**NURSING DIAGNOSIS:** Excess fluid volume related to decreased protein in the bloodstream, decreased urine output, sodium retention, possible inappropriate fluid intake, or altered hormone levels inducing fluid retention as evidenced by edema, bloating, weight gain, oliguria, azotemia, or changes in heart and lung sounds

### Outcome Identification and Evaluation

Child will attain appropriate fluid balance, will lose weight (fluid), edema or bloating will decrease, lung sounds will be clear and heart sounds normal.

### Intervention: *Encouraging Fluid Loss*

- Weigh child daily on same scale in similar amount of clothing: *in children, weight is the best indicator of changes in fluid status.*
- Monitor location and extent of edema (measure abdominal girth daily if ascites present): *decrease in edema indicates positive increase in oncotic pressure.*
- Auscultate lungs carefully to determine presence of crackles (*indicating pulmonary edema*).
- Assess work of breathing and respiratory rate: *increased work of breathing is associated with pulmonary edema.*
- Assess heart sounds for presence or absence of gallop: *presence of S<sub>3</sub> may indicate fluid overload.*
- Maintain fluid restriction as ordered *to decrease intravascular volume and workload on the heart.*
- Strictly monitor intake and output *to quickly note discrepancies and provide intervention.*
- Provide sodium-restricted diet as ordered: *restricting sodium in the diet allows for better renal excretion of extra fluid.*
- Administer diuretics as ordered and monitor for side effects of those medications. *Diuretics encourage excretion of fluid and elimination of edema, reduce cardiac filling pressures, and increase renal blood flow. Side effects include electrolyte imbalance as well as orthostatic hypotension.*

## NURSING CARE PLAN 43.1

**Overview for the Child With a Genitourinary Disorder** (continued)

**NURSING DIAGNOSIS:** Imbalanced nutrition: less than body requirements related to anorexia and protein loss as evidenced by weight, length/height, and/or BMI below average for age

**Outcome Identification and Evaluation**

Child will improve nutritional intake, resulting in steady increase in weight and length/height.

**Intervention: Promoting Adequate Nutrition**

- Determine body weight and length/height norm for age *to determine goal to work toward.*
- Assess child for food preferences that fall within dietary restrictions, *as the child will be more likely to consume adequate amounts of foods that he or she likes.*
- Weigh daily or weekly (according to physician or nurse practitioner order or institutional standard) and measure length/height weekly *to monitor for increased growth.*
- Offer highest-calorie meals at the time of day when the child's appetite is the greatest *to increase likelihood of increased caloric intake.*
- Provide increased-calorie shakes or puddings within diet restriction: *high calorie foods increase weight gain.*
- Administer vitamin and mineral supplements as prescribed *to attain/maintain vitamin and mineral balance in the body.*

**NURSING DIAGNOSIS:** Imbalanced nutrition: more than body requirements related to increased appetite secondary to steroid therapy as evidenced by weight greater than 95th percentile for age or recent increase in weight

**Outcome Identification and Evaluation**

Child will demonstrate balanced nutritional intake, will maintain current weight or steadily lose excess weight.

**Intervention: Encouraging Appropriate Nutritional Intake**

- Determine ideal body weight and body mass index for age *to determine goal to work toward.*
- Consult dietitian *for guidance in planning nutrient-rich diet in context of restrictions.*
- Evaluate for emotional/psychological reasons for overeating *to address these concerns.*
- Formulate a contract with the child *to involve him or her in the planning process and encourage compliance with the plan.*
- With the child, plan for daily exercise/activity to expend excess calories: *it is important to involve the child in planning, in order to increase compliance.*
- Instruct the child/parent about appropriate nutrient-rich foods to choose within the constraints of diet and fluid restrictions *to provide basis for ongoing diet management at home.*
- Weigh child twice weekly on same scale *to determine progress toward goal.*

**NURSING DIAGNOSIS:** Impaired urinary elimination related to urinary tract infection or other urologic condition, or other factors such as ignoring urge to void at appropriate time as evidenced by urinary retention or incontinence, dribbling, urgency, or dysuria

(continued)

## NURSING CARE PLAN 43.1

**Overview for the Child With a Genitourinary Disorder** (continued)**Outcome Identification and Evaluation**

Child will maintain continence, will void in the toilet.

**Intervention: Promoting Adequate Urinary Elimination**

- Assess the child's usual voiding pattern and success within that pattern *to determine baseline*.
- Develop a schedule for bladder emptying *to encourage voiding in the toilet*.
- Maintain adequate hydration, *as dehydration irritates the bladder*.
- Avoid constipation, *as constipation is associated with inability to adequately empty bladder*.
- Teach parents to restrict child's fluid intake after dinner *to avoid bedwetting*.
- Ensure child voids prior to going to bed *to avoid bedwetting*.
- Teach bladder-stretching exercises as prescribed per physician or nurse practitioner *to increase bladder capacity*.

**NURSING DIAGNOSIS:** Urinary retention related to anatomic obstruction, sensory motor impairment, or dysfunctional voiding as evidenced by dribbling, inadequate bladder emptying

**Outcome Identification and Evaluation**

Child's bladder will empty adequately, according to preestablished quantities and frequencies individualized for the child (usual urine output is 0.5 to 2 mL/kg/hour).

**Intervention: Promoting Successful Bladder Emptying**

- Assess child's ability to adequately empty bladder via history focused on character and duration of lower urinary symptoms *to establish baseline*.
- Assess for history of fecal impaction or encopresis, *as alterations in bowel elimination may have a negative impact on urinary elimination*.
- Assess for bladder distention by palpation or urinary retention by postvoid residual obtained via catheterization or bladder ultrasound *to determine extent of retention*.
- Maintain adequate hydration *to avoid irritating effects of dehydration on the bladder*.
- Schedule voiding *to decrease bladder overdistention*.
- In the child with significant urinary retention, teach parents/child the technique of clean intermittent catheterization, *which allows for regular complete bladder emptying*.

**NURSING DIAGNOSIS:** Disturbed body image related to anatomic differences, short stature, or effects of long-term corticosteroid use as evidenced by verbalization of dissatisfaction with the child's or adolescent's looks

**Outcome Identification and Evaluation**

Child or adolescent will display appropriate body image, will look at self in mirror and participate in social activities.

## NURSING CARE PLAN 43.1

## Overview for the Child With a Genitourinary Disorder (continued)

**Intervention: Promoting Body Image**

- Acknowledge feelings of anger over body changes and illness: *venting feelings is associated with less body image disturbance.*
- Support the child's or teen's choices of comfortable, fashionable clothing *that may disguise anatomic abnormalities and dialysis tubing.*
- Involve the child and especially the teen in the decision-making process, *as a sense of control of his or her own body will improve body image.*
- Encourage children or teens to spend time with others their own age who have short stature or other effects of renal disorders: *a peer's opinions are often better accepted than those of persons in authority, such as parents or health care professionals.*

**NURSING DIAGNOSIS:** Knowledge deficit related to lack of information regarding complex medical condition, prognosis, and medical needs as evidenced by verbalization, questions, or actions demonstrating lack of understanding regarding child's condition or care

**Outcome Identification and Evaluation**

Child and parents will verbalize accurate information and understanding about condition, prognosis, and medical needs: *child and parents demonstrate knowledge of condition and medications and will demonstrate therapeutic procedures the child requires.*

**Intervention: Educating the Child and Parents**

- Assess child's and parents' willingness to learn: *child and parents must be open to learning for teaching to be effective.*
- Provide parents with time to adjust to diagnosis: *will facilitate adjustment and ability to learn and participate in child's care.*
- Teach in short sessions: *many short sessions are found to be more helpful than one long session.*
- Repeat information: *allows parents and child time to learn and understand.*
- Individualize teaching to the parents' and child's level of understanding (depends on age of child, physical condition, memory) *to ensure understanding.*
- Provide reinforcement and rewards *to facilitate the teaching/learning process.*
- Use multiple modes of learning involving many senses (written, verbal, demonstration, and videos) when possible: *child and parents are more likely to retain information when it is presented in different ways using many senses.*

be included later in the chapter as it relates to specific disorders.

**Based on your top three nursing diagnoses for Corey, describe appropriate nursing interventions.**

**Structural Disorders**

Numerous urologic conditions are congenital (present at birth) and occur as a result of altered fetal development. Many of these defects are apparent at birth, yet some are not recognized until later in infancy or childhood when symptoms or complications arise.

**URINARY TRACT AND RENAL DISORDERS**

The urinary tract and renal disorders discussed below include structural disorders, UTI, enuresis, and acquired disorders that result in altered renal function.

**Bladder Exstrophy**

Bladder exstrophy is a structural defect that requires surgical repair and creation of urinary stoma. Refer to chapter 24 for nursing assessment and preoperative care of bladder exstrophy.

## Providing Postoperative Care

Nursing management in the postoperative period focuses on preventing infection. Keep the infant supine and quickly change soiled diapers to prevent contamination of the incision with stool. Surgical reconstruction of the bladder within the pelvic cavity and reconstruction of a urethra are done if enough bladder tissue is present. An indwelling urethral catheter or suprapubic tube will allow urinary drainage, allowing the bladder to rest in the initial postoperative period. Ensure that catheters drain freely and do not become kinked. Sometimes tubes or catheters used in the postoperative period require irrigation. Refer to the institution's policy and the surgeon's orders for specifics related to urinary catheter irrigation.

Manage bladder spasms with oxybutynin (Ditropan) or belladonna and opioid (B & O) suppositories as ordered. Note blood-tinged urine upon return from surgery, with clearing of urine within hours to days. If orthopedic surgery is also involved in the repair due to a malformed pubic arch, follow through with recommended positioning or bracing to prevent further separation of the pubic arch.

## Catheterizing the Stoma

If bladder tissue is insufficient for repair, then the bladder is removed and a continent urinary reservoir is created. The ureters are connected to a portion of the small intestine that is separated from the gastrointestinal (GI) tract, thus creating a urinary reservoir. The intestines are reanastomosed to leave the GI tract intact and separate from the GU tract. A stoma is created on the abdominal wall; it provides access to the urinary reservoir (Fig. 43.1). The stoma is catheterized about four times per day to empty the reservoir of urine. Urine from an intestine-based urinary reservoir tends to be mucus-like and is often cloudier than urine from a urinary bladder. Teach parents the procedure for catheterizing the urinary reservoir and instruct them to call the child's urologist or physician or nurse practitioner if signs or symptoms of UTI occur.

### Take Note!

Children with congenital urologic malformations are at high risk for the development of latex allergy (Behrman, 2011). Latex allergy can result in anaphylaxis. Primary prevention of latex allergy is warranted in all children with urologic malformations, so use latex-free gloves, tubes, and catheters in these children.

## Hypospadias/Epispadias

Hypospadias is a urethral defect in which the opening is on the ventral surface of the penis rather than at the end of the penis (Fig. 43.2). Epispadias is a urethral

**FIGURE 43.1** The abdominal stoma allows for urinary continence and requires catheterization.

defect in which the opening is on the dorsal surface of the penis. In either case, the opening may be near the glans of the penis, midway along the penis or near the base. If left uncorrected, the boy may not be capable of appropriately aiming a urinary stream from a standing position. In addition, the abnormal placement of the urethral opening may interfere with the deposition of sperm during intercourse, leaving the man infertile. Also, if left uncorrected, the boy's self-esteem and body image may be damaged by the abnormal appearance of his genitalia (Pfeil & Lindsay, 2010). For these reasons, the defect is usually repaired sometime after about 1 year of age. The goal of surgical correction for either condition is to provide for an appropriately placed meatus that allows for normal voiding and ejaculation. The meatus is moved to the glans penis and the urethra is reconstructed as needed. Most repairs are

**FIGURE 43.2** (A) Hypospadias: the urethral opening is located on the ventral side of the penis. (B) Epispadias: the urethral opening is located on the dorsal side of the penis.

accomplished in one surgery. More extensive reconstructions may require two stages.

## Nursing Assessment

Note history of an unusual urine stream. Inspect the penis for placement of the urethral meatus: it may be slightly off center of the glans or may be present somewhere along the shaft of the penis. Inspect for chordee, a fibrous band causing the penis to curve downward. Palpate for the presence or absence of testicles in the scrotal sac, because cryptorchidism (undescended testicles) often occurs with hypospadias, as do hydrocele and inguinal hernia.

## Nursing Management

The newborn with hypospadias or epispadias should not undergo circumcision until after surgical repair of the urethral meatus. In more extreme cases, the surgeon may need to use some of the excess foreskin while reconstructing the meatus. Nursing management of the infant who has undergone a hypospadias or epispadias repair focuses on providing routine postoperative care and parent education.

### Providing Postoperative Care

Postoperatively, assess urinary drainage from the urethral stent or drainage tube, which allows for discharge of urine without stress along the surgical site. Ensure that the urinary drainage tube remains carefully taped

with the penis in an upright position to prevent stress on the urethral incision. The penile dressing is usually a compression type, used to decrease edema and bruising. Administer antibiotics if prescribed. Assess for pain, which is usually not extensive, and administer analgesics or antispasmodics (oral oxybutynin or B & O suppository) as needed for bladder spasms.

### Take Note!

Bladder spasms may also be managed effectively through the use of epidural analgesia, which is being used more frequently in the postoperative period in the pediatric population (Ellis, Martelli, LaMontagne, & Splinter, 2007).

Double diapering is a method used to protect the urethra and stent or catheter after surgery; it also helps keep the area clean and free from infection. The inner diaper contains stool and the outer diaper contains urine, allowing separation between the bowel and bladder output. Nursing Procedure 43.2 details the double-diapering technique. Change the outside (larger) diaper when the child is wet; change both diapers when the child has a bowel movement.

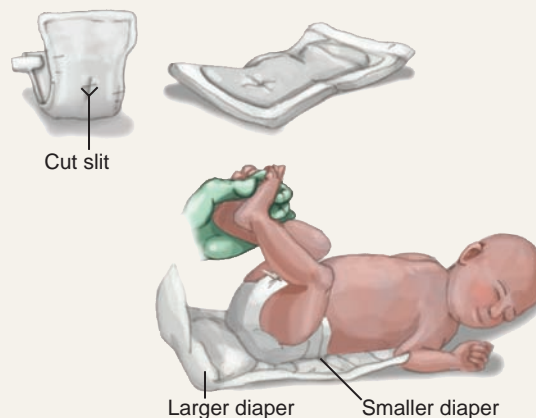

### Educating the Family

If the child is to be discharged with the urinary catheter in place (which is common), teach the parents how to care for the catheter and drainage system. Have parents demonstrate their ability to irrigate the catheter should a mucus plug occur. Tub baths are generally prohibited until it is time to remove the penile dressing. Roughhousing, ride-on

## NURSING PROCEDURE 43.2

### Double Diapering

1. Cut a hole or a cross-shaped slit in the front of the smaller diaper.
2. Unfold both diapers and place the smaller diaper (with the hole) inside the larger one.
3. Place both diapers under the child.
4. Carefully bring the penis (if applicable) and catheter/stent through the hole in the smaller diaper and close the diaper.
5. Close the larger diaper, making sure the tip of the catheter/stent is inside the larger diaper.

Adapted from Liu, D. B., & Edmondson, J. D. (2011). Antenatal hydronephrosis. Retrieved April 1, 2012, from <http://medicine.medscape.com/article/1016305-overview>; and Lum, G. M. (2011). Kidney & urinary tract. In W. W. Hay, M. J. Levin, J. M. Sondheimer, & R. R. Deterding (Eds.), *Current pediatric diagnosis and treatment* (20th ed.). New York, NY: McGraw-Hill.

toys, or any activity involving straddling is not allowed for 2 to 3 weeks.

## Obstructive Uropathy

Obstructive uropathy is an obstruction at any level along the upper or lower urinary tract. This discussion will focus on congenital structural defects, though obstruction can also occur as a result of other disease processes (acquired obstructive uropathy). The most common sites of obstruction are listed in Table 43.1. The defect may be unilateral or bilateral and can cause partial or complete obstruction of urine flow, resulting in dilation of the affected kidney (hydronephrosis). Complications include recurrent UTI, renal insufficiency, and progressive damage to the kidney resulting in renal failure.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1551. Assessment findings pertinent to obstructive uropathy are discussed below.

## Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Recurrent UTI
- Incontinence
- Fever
- Foul-smelling urine
- Flank pain
- Abdominal pain
- **Urinary frequency** (needing to void often)
- Urinary **urgency** (urge to void immediately)
- **Dysuria** (difficulty or pain with voiding)
- **Hematuria** (blood in the urine)

Explore the child's current and past medical history for risk factors such as:

- “Prune belly” syndrome
- Chromosome abnormalities
- Anorectal malformations
- Ear defects

## Physical Examination and Laboratory and Diagnostic Tests

Palpate the abdomen for the presence of an abdominal mass (hydronephrotic kidney). Assess the blood pressure; elevation may occur if renal insufficiency is present. Many cases of obstructive uropathy may be diagnosed with prenatal ultrasound if the obstruction has been significant enough to cause hydronephrosis or dilatation elsewhere along the urinary tract.

## Nursing Management

Surgical correction is specific to the type of obstruction and generally consists of removal of the obstruction, reimplantation of the ureters as necessary, and, occasionally, creation of a urinary diversion. Postoperatively, assess urine output via vesicostomy, nephrostomy, suprapubic tube, or urethral catheter for color, clots, clarity, and amount. Encourage fluids once the child can tolerate them orally. Administer analgesics and/or antispasmodics as needed for bladder spasms. Teach parents care of vesicostomy or drainage tubes, with which the child may be discharged.

### Take Note!

Upon return from surgery, most children have intravenous fluids without added potassium infusion. Potassium is withheld from the intravenous fluid until adequate urine output is established postoperatively to avoid the development of hyperkalemia should the kidneys fail to function properly (Browne, Flanigan, McComiskey, & Pieper, 2013).

## Hydronephrosis

Hydronephrosis is a condition in which the pelvis and calyces of the kidney are dilated (Fig. 43.3). Hydronephrosis may occur as a congenital defect, as a result of obstructive uropathy, or secondary to vesicoureteral reflux. Congenital hydronephrosis may be revealed on prenatal ultrasound. Complications of hydronephrosis include renal insufficiency, hypertension, and eventually renal failure.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1551. Assessment findings pertinent to hydronephrosis are discussed below.

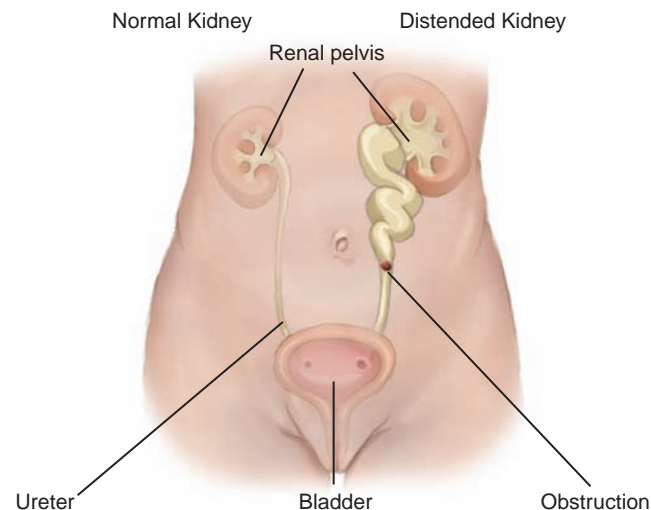

FIGURE 43.3 Hydronephrosis.

## Health History

Elicit a description of the present illness and chief complaint. The infant may be asymptomatic, but signs and symptoms reported during the health history might include:

- Failure to thrive
- Intermittent hematuria
- Presence of an abdominal mass
- Signs and symptoms associated with a UTI such as fever, vomiting, poor feeding, and irritability

Explore the child's current and past medical history for risk factors such as:

- Maternal oligohydramnios or polyhydramnios (congenital hydronephrosis)
- Elevated levels of serum  $\alpha$ -fetoprotein (congenital hydronephrosis)

## Physical Examination and Diagnostic and Laboratory Tests

Monitor the blood pressure of infants and children suspected of having hydronephrosis. Palpation of the abdomen may reveal enlarged kidney(s) or a distended bladder. A voiding cystourethrogram (VCUG) will be performed to determine the presence of a structural defect that may be causing the hydronephrosis. Other diagnostic tests, such as a renal ultrasound or an intravenous pyelogram, may also be performed to clarify the diagnosis.

## Nursing Management

Teach the parents signs and symptoms of UTI and sepsis, as these complications may occur. Explain to the parents that they should observe the child for adequacy of urine output and hydration status. Teach the parents to perform appropriate perineal hygiene and to avoid using irritants in the genital area. The infant or child with hydronephrosis will need follow-up with a pediatric nephrologist or urologist.

## Vesicoureteral Reflux

Vesicoureteral reflux (VUR) is a condition in which urine from the bladder flows back up the ureters. This reflux of urine occurs during bladder contraction with voiding (Fig. 43.4). Reflux may occur in one or both ureters. If reflux occurs when the urine is infected, the kidney is exposed to bacteria and pyelonephritis may result. The increased pressure placed upon the kidney with reflux can cause renal scarring and lead to hypertension later in life and, if severe, renal insufficiency or failure.

Primary VUR results from a congenital abnormality at the vesicoureteral junction that results in incompetence

**FIGURE 43.4** Note retrograde flow of urine up the ureter upon bladder contraction.

of the valve. Secondary VUR is related to other structural or functional problems such as neurogenic bladder, bladder dysfunction, or bladder outlet obstruction. As many as 70% of all children diagnosed with UTI have VUR (Nelson & Koo, 2012).

VUR is graded according to its severity, from grade I, which is characterized by minor dilatation of the proximal ureter, to grade V, which is characterized by severe dilatation of the ureter and pelvis of the kidney. Grade I and II VUR cases usually resolve spontaneously, but grade III through V cases are generally associated with recurrent UTIs, hydronephrosis, and progressive renal damage (Nelson & Koo, 2012).

The goal of therapeutic management of VUR is prevention of pyelonephritis and subsequent renal scarring, which may contribute to the development of hypertension later in life (Nelson & Koo, 2012). Management includes antibiotic prophylaxis and hygiene/voiding practices to prevent UTI. Serial urine cultures are used to determine recurrence of UTI. Biannual, annual, or biennial radio-nuclide VCUGs are performed to determine the status of VUR.

Grade III, IV, and V cases usually warrant surgical intervention. The ureters are resected from the bladder and reimplanted elsewhere in the bladder wall to regain functionality.

### Take Note!

The keys to prevention of long-term sequelae such as hypertension in children with urologic conditions are early diagnosis and intervention, prevention of infection, and close clinical follow-up. Nurses play a key role in monitoring and education.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1551. Assessment findings pertinent to VUR are discussed below.

## Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Fever
- Dysuria
- Frequency or urgency
- Nocturia
- Hematuria
- Pain in the back, abdomen, or flank

Explore the child's current and past medical history for risk factors such as:

- Recurrent UTI in the female
- Single episode of UTI in the male
- Congenital defect
- Family history of VUR

For the child who is receiving ongoing follow-up for VUR, determine whether UTIs have occurred since the last visit, as well as the name and dose of prophylactic antibiotic.

## Physical Examination

Monitor the blood pressure for elevation. Palpate the abdomen for presence of a mass (if hydronephrosis is present). VCUG may be used to diagnose VUR.

## Nursing Management

Nursing management for the child with VUR includes preventing infection and providing postoperative care.

### Preventing Infection

When VUR is present, the goal is to avoid urine infection so that infected urine cannot gain access to the kidneys. Initially, most cases of VUR are managed medically. Teach the child to empty the bladder completely. Teach the child and parents appropriate perineal hygiene as well as toileting hygiene to prevent recurrence of UTI. Teach parents about the antibiotic therapy prescribed; the child will be maintained on a low daily dose to prevent UTI. The drug is most effective when given at bedtime because of urinary stasis overnight. Inform parents of the schedule for serial urine cultures and follow-up VCUG.

### Providing Postoperative Care

If VUR is severe or if UTI is recurrent, surgical correction will be necessary. In the first 24 to 48 hours after surgery, maintain the intravenous fluid rate at 1.5 times maintenance to encourage a high urinary output. Monitor urine

output via the Foley catheter; urine should be bloody initially, clearing within 2 to 3 days. If ureteral stents are present, monitor urine output from those as well. Administer analgesics for incisional pain relief and antispasmodics or B & O suppositories as needed for bladder spasms. Encourage ambulation and advancement of diet as ordered to promote return of appropriate bowel function. Teach parents that prophylactic antibiotics will be given until 1 to 2 months after surgery, when the VCUG demonstrates absence of reflux.

### Take Note!

When caring for the child who has undergone urologic surgery, avoid manipulating the Foley or suprapubic catheter: catheter manipulation contributes to bladder spasms.

## Urinary Tract Infection

UTI is an infection of the urinary tract, most commonly affecting the bladder. UTI occurs most often as a result of bacteria ascending to the bladder via the urethra. The incidence of UTI in children is nearly 3% and is most common in infants and young children. It occurs more frequently in males than females during infancy, but after 1 year of age it is more common in females (Fisher, 2012). One explanation for the more common occurrence in females is that the female's shorter urethra allows bacteria to have easier access to the bladder. The urethra is also located quite close to the vagina and anus in females, allowing spread of bacteria from those areas. The sexually active female adolescent is at risk for the development of UTI, as bacteria may be forced into the urethra by pressure from intercourse. The adolescent male may be somewhat protected from UTI by the antibacterial properties of prostate secretions.

UTI presents differently in infants than it does in children. Infants may exhibit fever, irritability, vomiting, failure to thrive, or jaundice. Children may also experience fever and vomiting, but also may have dysuria, frequency, hesitancy, urgency, and/or pain.

## Pathophysiology

*E. coli* most commonly causes UTI, as it is usually found in the perineal and anal region, close to the urethral opening. Other organisms include *Klebsiella*, *Staphylococcus aureus*, *Proteus*, *Pseudomonas*, and *Haemophilus*. Numerous factors may contribute to bacterial proliferation. Urinary stasis contributes to the development of a UTI once the bacteria have gained entry. Urine that remains in the bladder after voiding allows bacteria to grow rapidly. A decreased fluid intake also contributes to bacterial growth, as the bacteria become more

concentrated. If the urine is alkaline, bacteria are better able to flourish. Untreated bladder infection may allow reflux of infected urine up the ureters to the kidneys and result in pyelonephritis, a more serious infection.

## Therapeutic Management

UTIs are treated with either oral or intravenous antibiotics, depending on the severity of the infection. Urine culture and sensitivity determines the appropriate antibiotic. A 7- to 14-day course of antibiotics is often prescribed, though 2- to 5-day courses may be as effective. Adequate fluid intake is necessary to flush the bacteria from the bladder. Fever management may also be needed. (See Evidence-based Practice 43.1.)

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1551. Assessment findings pertinent to UTI are discussed below.

### Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Fever
- Nausea or vomiting
- Chills
- Abdomen, back, or flank pain
- Lethargy
- Jaundice (in the neonate)

- Poor feeding or “just not acting right” (in the infant)
- Urinary urgency or frequency
- Burning or stinging with urination (the infant may cry with urination, the toddler may grab the diaper)
- Foul-smelling urine
- Poor appetite (child)
- Enuresis or incontinence in a previously toilet-trained child
- Blood in the urine

Explore the child’s current and past medical history for risk factors such as:

- Previous UTI
- Obstructive uropathy
- Inadequate toileting hygiene (often occurs with preschool girls)
- VUR
- Constipation
- Urine holding or dysfunctional voiding
- Neurogenic bladder
- Uncircumcised male
- Sexual intercourse
- Pregnancy
- Chronic illness

### Physical Examination

In the neonate or young infant, observe for jaundice or increased respiratory rate. In infants and children, inspect the perineal area for redness or irritation. Observe the urine for visible blood, cloudiness, dark color, sediment, mucus, or foul odor. Note pallor, edema, or elevated blood pressure. Palpate the abdomen. Note distended bladder, abdominal mass, or tenderness, particularly in the flank area.

## EVIDENCE-BASED PRACTICE 43.1

### ANTIBIOTICS AND URINARY TRACT INFECTIONS IN CHILDREN

#### STUDY

Urinary tract infections (UTIs) commonly occur in children, causing frequent and painful urination. Traditionally, 7- to 10-day courses have been recommended for treating UTI in children. In the search for options to decrease side effects and improve costs, short courses of antibiotics may provide the solution. The authors included 10 randomized and quasi-randomized trials with a total of 652 participants. Participants included were low risk, between the ages of 3 months and 18 years with culture-proven UTI. The studies assessed the benefits and harms of short-course (2 to 4 days) antibiotic treatment compared with that of standard duration (7 to 14 days).

#### Findings

The authors found that a 2- to 4-day course of oral antibiotics appears to be as effective as the traditional

long course (7 to 14 days) in eradicating UTI in children. Additionally, there was no statistical significance demonstrated in terms of repeat UTI within 1 to 15 months after the original infection.

#### Nursing Implications

Shorter courses of antibiotic treatment are much easier for families to comply with and complete, yet families may be accustomed to longer courses of antibiotic treatment and need further education. Educate families that the shorter course is indeed effective in treating UTI. Nurses should advocate for short-course antibiotic treatment in low-risk children with UTI.

Adapted from Michael, M., Hodson, E. M., Craig, J. C., Martin, S., & Voyer, V. A. (2007). Short versus standard duration oral antibiotic therapy for acute urinary tract infection in children. *The Cochrane Library* 2007, 4. Indianapolis, IN: John Wiley & Sons.

## Laboratory and Diagnostic Tests

Common laboratory and diagnostic studies ordered for the assessment of UTI include:

- Urinalysis (clean-catch, suprapubic, or catheterized): may be positive for blood, nitrites, leukocyte esterase, white blood cells, or bacteria (**bacteriuria**)
- Urine culture: will be positive for infecting organism
- Renal ultrasound: may show hydronephrosis if child also has a structural defect
- VCUG: not usually performed until the child has been treated with antibiotics for at least 48 hours, as infected urine tends to reflux up the ureters anyway. VCUG performed once the urine has regained sterility may be positive for VUR.

Renal ultrasound, VCUG, and other nuclear medicine scans such as the technetium dimercaptosuccinic acid (DMSA) scan may be indicated in certain populations. The physician or nurse practitioner will determine the need for radiologic testing.

## Nursing Management

Goals for nursing management include eradicating infection, promoting comfort, and preventing recurrence of infection.

### Eradicating Infection

The child who can tolerate oral intake will be prescribed an oral antibiotic. The child who has protracted vomiting related to the UTI or who has suspected pyelonephritis will require hospitalization and intravenous antibiotics. Any infant younger than 8 weeks of age with fever, UTI, and a concerning history should also be hospitalized for administration of intravenous antibiotics (Fisher, 2012). Administer oral or intravenous antibiotics as prescribed. Urge the parent to complete the entire course of oral antibiotic at home, even though the child is feeling better. Administer intravenous fluids as ordered or encourage generous oral fluid intake to help flush the bacteria from the bladder.

### Promoting Comfort

Administer antipyretics such as acetaminophen or ibuprofen to reduce fever. A heating pad or warm compress may help relieve abdomen or flank pain. If the child is afraid to urinate due to burning or stinging, encourage voiding in a warm sitz or tub bath.

### Preventing Recurrence of Infection

Encourage the parents to return as ordered for a repeat urine culture after completion of the antibiotic course to ensure eradication of bacteria. Teaching Guidelines 43.1 gives further information on preventing UTI.

## Teaching Guidelines 43.1

### PREVENTING URINARY TRACT INFECTION IN FEMALES

- Drink enough fluid (to keep urine flushed through bladder).
- Drink cranberry juice to acidify the urine. Avoid colas and caffeine, which irritate the bladder.
- Urinate frequently and do not “hold” urine (to discourage urinary stasis).
- Avoid bubble baths (they contribute to vulvar and perineal irritation).
- Wipe from front to back after voiding (to avoid contaminating the urethra with rectal material).
- Wear cotton underwear (to decrease the incidence of perineal irritation).
- Avoid wearing tight jeans or pants.
- Wash the perineal area daily with soap and water.
- While menstruating, change sanitary pads frequently to discourage bacterial growth.
- Void immediately after sexual intercourse.

## Enuresis

**Enuresis** is continued incontinence of urine past the age of toilet training. Box 43.1 gives further definitions related to enuresis. Nocturnal enuresis generally subsides by 6 years of age; if it does not, further investigation and treatment may be warranted. Occasional daytime wetting or dribbling of urine is usually not a cause for concern, but frequent daytime wetting concerns both the child and the parents. Nocturnal enuresis may persist in some children into late childhood and adolescence, causing significant distress for the affected child and family.

In some children, enuresis may occur secondary to a physical disorder such as diabetes mellitus or insipidus, sickle cell anemia, ectopic ureter, or urethral obstruction. Other causes common to both diurnal and nocturnal enuresis include a urine-concentrating defect, UTI, constipation, and emotional distress (sometimes serious). The most frequent cause of daytime enuresis is dysfunctional voiding or holding of urine, though giggle

### BOX 43.1

#### DEFINITIONS RELATED TO ENURESIS

- **Primary enuresis:** enuresis in the child who has never achieved voluntary bladder control
- **Secondary enuresis:** urinary incontinence in the child who previously demonstrated bladder control over a period of at least 3 to 6 consecutive months
- **Diurnal enuresis:** daytime loss of urinary control
- **Nocturnal enuresis:** nighttime bedwetting

incontinence and stress incontinence also occur. Nocturnal enuresis may be related to a high fluid intake in the evening, obstructive sleep apnea, sexual abuse, a family history of enuresis, or inappropriate family expectations. Physical causes of enuresis must be treated; further management of the disorder focuses on behavioral training, which may be augmented with the use of enuresis alarms or medications.

## Nursing Assessment

Elicit a description of the present illness and chief complaint. Determine the age of toilet training and when or if the child achieved successful daytime and nighttime dryness. Inquire about urine-holding behaviors such as squatting, dancing, or staring as well as rushing to the bathroom (diurnal enuresis). Inquire about the amount and types of fluid the child typically consumes before bedtime (nocturnal enuresis). Assess for risk factors such as:

- Family disruption or other stressors
- Chronic constipation (carefully assess bowel movement patterns)
- Excessive family demands related to toileting patterns
- History of being difficult to arouse from sleep
- Family history of enuresis

Assess the child's cognitive status: developmentally delayed children may take significantly longer to achieve urine continence than their typical same-age peers. Assess for short stature or elevated blood pressure, as these may occur when renal abnormalities are present.

## Nursing Management

For the child with diurnal enuresis, encourage him or her to increase the amount of fluid consumed during the day in order to increase the frequency of the urge to void. Set a fixed schedule for the child to attempt to void throughout the day. These practices will usually be sufficient to retrain the child's voiding patterns. The child with nocturnal enuresis without a physiologic cause for bedwetting may require a varied approach (Cox, 2009).

### Educating the Child and Family About Nocturnal Enuresis

Teach the family that the child is not lazy, nor does he or she wet the bed intentionally. Encourage the child and family to read books such as *Dry All Night: The Picture Book Technique That Stops Bedwetting* by Alison Mack or *Waking Up Dry: A Guide to Help Children Overcome Bedwetting* by Dr. Howard Bennett. Encourage the parents to limit intake of bladder irritants such as chocolate and caffeine. Teach parents to limit fluid intake after dinner and ensure that the child voids just before going

to bed. Waking the child to void at 11 p.m. may also be helpful. Teach the parents to use bed pads and to make the bed with two sets of sheets and pads to decrease the workload in the middle of the night. When sleeping at home, the child should wear his or her usual underwear or pajamas. If away on a family vacation, pull-ups may decrease the stress on both the child and the parents.

### Providing Support and Encouragement

It is important for the child to understand that he or she is not alone. Depending on the child's developmental level, explain that as many as 5 million people have enuresis (this can be done in terms the child can relate to, such as a proportion within a school or 100 times the number of children in one school, etc.). It is not only "little kids" who wet the bed, and all kids who wet the bed need help overcoming this problem. Parents should include the child in plans for nighttime urinary control; this helps to increase the child's motivation to become dry. Parents should set up a reward system for dry nights. Parents should include the child in bed linen changes when he or she does wet the bed, but should do so in a matter-of-fact manner rather than in a punitive way; in fact, it is important to always avoid punishment for bedwetting.

With patience, consistency, and time, dryness will be achieved. Provide ongoing emotional support and positive reinforcement to the child and family.

### Decreasing Nighttime Voiding

Teach the family using an enuresis alarm system how to use the alarm as well as the previously mentioned techniques (Fig. 43.5). (Also see links to resources on [thePoint](#).) Most of these devices work by sounding an alarm when the first few drops of urine appear; the child then awakens and stops the urine flow. Over time the child becomes conditioned to either awaken when the bladder is full or stop the urine flow when sleeping.

#### Consider This

Antonio Cruise, a 7-year-old boy, is brought to the clinic by his mother for his annual examination. During your assessment the mother brings up concerns that Antonio continues to wet the bed at night. She states, "I was hoping this would end on its own, but now I'm concerned that there is a problem."

What further assessment information would you obtain?

What education and interventions may be necessary for this child and family?

What can you do to provide support and encouragement for Antonio and his family?

**FIGURE 43.5** Some children and families find great success with the use of an enuresis alarm. The alarm wakes the child at the first sign of wetness. Over time, the child learns to awaken at night in response to the sensation of a full bladder.

When behavioral and motivational therapies are unsuccessful, particularly in the older child, medications may be prescribed. Teach the child and parents about the use of medications such as oxybutynin, imipramine, and desmopressin (DDAVP) if these are prescribed (refer to Drug Guide 43.1).

#### Take Note!

Enuresis is a source of shame and embarrassment for children and adolescents. It affects the child's life emotionally, behaviorally, and socially. The family's life is also significantly affected. Treatment failures for enuresis have been correlated with adolescent low self-esteem (Martin & Volkmar, 2007).

### Acquired Disorders Resulting in Altered Renal Function

A number of acquired disorders are responsible for alterations in renal function. They may occur as an autoimmune response or in relation to a bacterial infection. Renal dysfunction may also occur as a result of obstructive disorders or repeated VUR, as discussed earlier. Left untreated, these disorders may lead to renal failure. Even when treated appropriately, sometimes the appropriate response is not achieved and acute or chronic renal failure develops. Renal disorders are the most frequent cause of hypertension in children.

#### Take Note!

Severe hypertension (blood pressure higher than the 99th percentile for age and sex) may lead to damage of the eye or vital organs (kidney, brain, or heart), or even death

(Flynn & Tullus, 2009). Nurses must be adept at accurately measuring blood pressure in children.

### Nephrotic Syndrome

Nephrotic syndrome occurs as a result of increased glomerular basement membrane permeability, which allows abnormal loss of protein in the urine. Nephrotic syndrome generally occurs in three forms—congenital, idiopathic, and secondary.

Congenital nephrotic syndrome is an inherited disorder; it is rare and occurs primarily in families of Finnish descent. The prognosis is poor, though some success has occurred with early, aggressive treatment and with the advances in kidney transplantation in infants (Jalanko, 2009). Nephrotic syndrome may also occur secondary to another condition such as systemic lupus erythematosus, Henoch-Schönlein purpura, or diabetes.

Idiopathic nephrotic syndrome is the most commonly occurring type in children and is often termed minimal change nephrotic syndrome (MCNS) (Lane, 2011). MCNS occurs more frequently in males than females, with 70% of cases occurring by age 5 years (Lane, 2011). This discussion will focus primarily on MCNS. Complications of nephrotic syndrome include anemia, infection, poor growth, peritonitis, thrombosis, and renal failure.

### Pathophysiology

Increased glomerular permeability results in the passage of larger plasma proteins through the glomerular basement membrane. This results in excess loss of protein (albumin) in the urine (**proteinuria**) and decreased protein and albumin (hypoalbuminemia) in the bloodstream. Protein loss in nephrotic syndrome tends to be almost exclusively albumin. Hypoalbuminemia results in a change in osmotic pressure, and fluid shifts from the bloodstream into the interstitial tissue (causing edema). This decrease in blood volume triggers the kidneys to respond by conserving sodium and water, leading to further edema. The liver senses the protein loss and increases production of lipoproteins. Hyperlipidemia then develops as the excess lipids cannot be excreted in the urine. Hyperlipidemia associated with nephrotic syndrome may be quite severe, yet cholesterol levels may decrease when the nephrotic syndrome is in remission, only to rise significantly again with a relapse.

Children with nephrotic syndrome are at increased risk for clotting (thromboembolism) because of the decreased intravascular volume. They are also at increased risk for the development of serious infection, most commonly pneumococcal pneumonia, sepsis, or spontaneous peritonitis. Steroid-resistant nephrotic syndrome may result in acute renal failure.

## Therapeutic Management

Medical management of MCNS usually involves the use of corticosteroids. Intravenous albumin may be used in the severely edematous child. Diuretics are also required in the edematous phase. Long-term therapy is usually required to induce remission. The nephrologist will determine the length of therapy based on the child's response. Children who have steroid-responsive MCNS generally have a favorable prognosis. Some children with MCNS exhibit a minimal response to steroid therapy or experience remissions and the MCNS is steroid resistant (Lane, 2011). Immunosuppressive therapy such as cyclophosphamide, cyclosporine A, or mycophenolate mofetil may be necessary.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1551. Assessment findings pertinent to MCNS are discussed below.

### Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Nausea or vomiting (may be related to ascites)
- Recent weight gain
- History of periorbital edema upon waking, progressing to generalized edema throughout the day
- Weakness or fatigue
- Irritability or fussiness

Explore the child's current and past medical history for risk factors such as:

- Intrauterine growth retardation
- Young age (younger than 3 years)
- Male sex

### Physical Examination

The physical assessment of the child with nephrotic syndrome includes inspection and observation, auscultation, and palpation.

Observe the child for edema (periorbital, generalized [**anasarca**], or abdominal ascites). As the disease progresses, the edema also progresses to become more generalized, eventually becoming severe. Inspect the skin for a stretched, tight appearance; pallor; or skin breakdown related to significant edema (Fig. 43.6). Document height (or length) and weight. Note increased respiratory rate or increased work of breathing related to ascites and edema.

Note the blood pressure; it may be elevated in the child with nephrotic syndrome, though it is most often

FIGURE 43.6 Note marked edema associated with nephrotic syndrome.

either normal or decreased unless the child is progressing to renal failure. Auscultate heart and lung sounds, noting abnormalities related to fluid overload. Palpate the skin, noting tautness. Palpate the abdomen and document the presence of ascites.

### Laboratory and Diagnostic Tests

Urine dipstick will reveal marked proteinuria. Infrequently, mild hematuria is also present. Serum protein and albumin levels will be low (often markedly so). Serum cholesterol and triglyceride levels are elevated. With continued nephrotic syndrome, creatinine and BUN may become elevated.

## Nursing Management

Goals for nursing management include promoting diuresis, preventing infection, promoting adequate nutrition, and educating the parents about ongoing care at home. As with other chronic disorders, provide ongoing emotional support to the child and family.

### Promoting Diuresis

Administer corticosteroids as ordered. Tapering or weaning doses are required when the time comes to stop corticosteroid therapy. Administer diuretics if ordered, usually furosemide (Lasix). Children may develop hypokalemia because of potassium loss as an adverse effect of furosemide. Those children may require potassium supplementation or a diet higher in potassium-containing foods. Monitor urine output and the amount of protein in the urine (by dipstick). Weigh the child daily on the same scale either naked or wearing the same amount of clothing. Assess for resolution of edema. Measure pulse

rate and blood pressure every 4 hours to detect hypovolemia resulting from excessive fluid shifts. Enforce oral fluid restrictions if ordered.

In cases of severe hypoalbuminemia, intravenous albumin may be administered. Increases in the serum albumin level cause fluid to shift from the subcutaneous spaces back into the bloodstream. A diuretic such as furosemide administered immediately after the albumin infusion allows for optimal diuresis and prevents fluid overload. Refer to Drug Guide 43.1 for the nursing implications related to use of these medications.

### Preventing Infection

Monitor the child's temperature. Administer pneumococcal vaccine as prescribed (see Chapter 31 for information on immunizations). Administer prophylactic antibiotics, if prescribed. Delay administering live vaccines until at least 2 weeks after corticosteroid or other immunosuppressive medication therapy ceases. Teach parents that if the child is unimmunized and is exposed to chickenpox, the parents should notify the child's pediatrician, nurse practitioner or nephrologist immediately so that the child may receive varicella zoster immunoglobulin.

### Encouraging Adequate Nutrition and Growth

Encourage a nutrient-rich diet within prescribed restrictions. Fluid restriction is reserved for children with massive edema. Sodium intake may be restricted in the edematous child in an effort to prevent further fluid retention. Consultation with the dietitian is often helpful in meal planning because many of the foods that children like are high in sodium. Encourage protein-rich snacks. Consult with the child and family in planning meals and snacks that the child likes and will be likely to consume. Use of nutritional supplement shakes may be helpful for some children.

### Educating the Family

Teach parents how to give medications and monitor for adverse effects. Demonstrate the urine dipstick technique for detecting protein, and encourage the family to keep a chart of dipstick results. The child may return to school but should avoid contact with sick playmates. If the child is exposed to another child with an infectious illness, explain to the parents that they should monitor temperature and urine dipstick results more frequently to identify a relapse in nephrotic syndrome early so that treatment can begin.

### Providing Emotional Support

Nephrotic syndrome is often a chronic condition, and children who are responsive to steroid treatment may enter remission only to experience relapse. This cycle

of relapse and remission takes an emotional toll on the child and family. Frequent hospitalizations require the child to miss school and the parents to miss work; this creates further stress for the family. The child may experience social isolation because he or she must avoid exposure to infections or because of self-esteem problems. The child may be dissatisfied with his or her appearance because of edema and weight gain, short stature, and the classic "moon face" associated with chronic steroid use.

Provide emotional support to the child and family. Encourage them in their efforts to maintain the treatment plan. Introduce the child to other youngsters with chronic renal conditions. Refer families to the National Kidney Foundation, a link to which can be found on [thePoint](#), for information about local support groups and resources.

### Acute Poststreptococcal Glomerulonephritis

Acute poststreptococcal glomerulonephritis (APSGN) is a condition in which immune processes injure the glomeruli. Immune mechanisms cause inflammation, which results in altered glomerular structure and function in both kidneys. It often occurs following an infection, usually an upper respiratory or skin infection. APSGN is caused by an antibody-antigen reaction secondary to an infection with a nephritogenic strain of group A  $\beta$ -hemolytic streptococcus. APSGN occurs more frequently in males than females and with a peak prevalence occurring around 5 to 6 years of age (Bhimma, 2011). The most serious complication is progression to uremia and renal failure (either acute or chronic).

There is no specific medical treatment for APSGN. Treatment is aimed at maintaining fluid volume and managing hypertension. If there is evidence of a current streptococcal infection, antibiotic therapy will be necessary.

### Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1551. Assessment findings pertinent to acute glomerulonephritis are discussed below.

### Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Fever
- Lethargy
- Headache
- Decreased urine output
- Abdominal pain
- Vomiting
- Anorexia

Assess the child's current and past medical history for risk factors such as a recent episode of pharyngitis or other streptococcal infection, age older than 2 years, or male sex.

### Physical Examination and Laboratory and Diagnostic Tests

Assess the child's blood pressure for elevation, which is common. Note the presence of mild edema. Observe for signs of cardiopulmonary congestion such as increased work of breathing or cough. Auscultate the lungs for crackles and the heart for gallop. The urine dipstick test will reveal proteinuria as well as hematuria. Inspect the urine for gross hematuria, which will cause the urine to appear tea colored, cola colored, or even a dirty green color. Serum creatinine and BUN may be normal or elevated, the serum complement level is depressed, and the erythrocyte sedimentation rate is elevated. Laboratory findings specific to streptococcus include an elevated antistreptolysin (ASO) titer and an elevated DNAase B antigen titer.

## Nursing Management

Administer antihypertensives such as labetalol or nifedipine and diuretics as ordered. Monitor blood pressure frequently. Maintain sodium and fluid restrictions as prescribed during the initial edematous phase. Weigh the child daily on the same scale wearing the same amount of clothing. Monitor increasing urine output and note improvement in the urine color. Document resolution of edema. Provide a careful neurologic evaluation, as hypertension may cause encephalopathy and seizures. Children with APSGN generally are fatigued and choose bed rest during the acute phase. Provide the child with age-appropriate activities and cluster care to allow rest periods.

Some children may be managed at home if edema is mild and they are not hypertensive. Teach the family to monitor urine output and color, take blood pressure measurements, and restrict the diet as prescribed. The child cared for at home should not participate in strenuous activity until proteinuria and hematuria are resolved. If renal involvement progresses, dialysis may become necessary.

#### Take Note!

Avoid use of nonsteroidal anti-inflammatory drugs (NSAIDs) in children with questionable renal function, as the antiprostaglandin action of NSAIDs may cause a further decrease in the glomerular filtration rate (Solomon, 2012).

## Hemolytic-Uremic Syndrome

Hemolytic-uremic syndrome (HUS) is defined by three features—hemolytic anemia, thrombocytopenia, and acute renal failure. Typical HUS features an antecedent diarrheal

illness. Other causes of HUS include idiopathic, inherited, drug-related, association with malignancies, transplantation, and malignant hypertension. This discussion will focus on typical HUS, the type preceded by a diarrheal illness. Watery diarrhea progresses to hemorrhagic colitis, then to the triad of HUS. The features of HUS, as well as effects on other organs, are caused primarily by microthrombi and ischemic changes within the organs. The thrombotic events in the small blood vessels of the glomerulus lead to occlusion of the glomerular capillary loops and glomerulosclerosis, resulting in renal failure.

A verotoxin-producing strain of *E. coli*, O157:H7, causes the majority of cases, though *Streptococcus pneumoniae*, *Shigella dysenteriae*, and other bacteria may also be the cause (Tan & Silverberg, 2010). It is thought that antibiotic treatment for the bacteria may contribute to release of the verotoxin. Undercooked ground beef accounts for most cases of *E. coli* O157:H7 infection, but it is also transmitted via the feces of numerous animals as well as unpasteurized dairy and fruit products. Transmission also occurs via human feces, and cases have been linked to public swimming pools. HUS occurs most often in children age 6 months to 4 years (Tan & Silverberg, 2010). Complications include chronic renal failure, seizures and coma, pancreatitis, intussusception, rectal prolapse, cardiomyopathy, congestive heart failure, and acute respiratory distress syndrome.

Therapeutic management of HUS is directed toward maintaining fluid balance; correcting hypertension, acidosis, and electrolyte abnormalities; replenishing circulating red blood cells; and providing dialysis if needed.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1551. Assessment findings pertinent to HUS are discussed below.

### Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include watery diarrhea accompanied by cramping and sometimes vomiting. After several days, the diarrhea becomes bloody and eventually improves.

Explore the child's current and past medical history for risk factors such as ingestion of ground beef, visits to a water park or to a petting zoo before the onset of the diarrheal illness, or use of antidiarrheal medications or antibiotics.

### Physical Examination

Observe the child for pallor, toxic appearance, edema, **oliguria** (decreased urine output), or **anuria** (absent urine output). Assess for elevated blood pressure and

tenderness in the abdomen. Assess the child for neurologic involvement, which may include irritability, altered level of consciousness, seizures, posturing, or coma.

### Laboratory and Diagnostic Tests

Urinalysis may reveal the presence of blood, protein, pus, and/or casts. Serum laboratory abnormalities are numerous and may include:

- Elevated BUN and creatinine
- Moderate to severe anemia (with the presence of Burr cells, schistocytes, spherocytes, or helmet cells), mild to severe thrombocytopenia
- Increased reticulocyte count
- Increased bilirubin and lactic dehydrogenase (LDH) levels
- Negative Coombs test (except in cases of *Streptococcus pneumoniae* infection)
- Leukocytosis with left shift
- Hyponatremia
- Hyperkalemia
- Hyperphosphatemia
- Metabolic acidosis

### Nursing Management

Nursing management of the child with HUS focuses on close observation and monitoring of the child's status. Institute and maintain contact precautions to prevent spread of *E. coli* O157:H7 to other children (bacteria are shed for up to 17 days after resolution of the diarrhea). Close attention must be paid to fluid volume status. Prevention of HUS is also an important nursing function.

### Maintaining Appropriate Fluid Volume Balance

Maintain strict intake and output monitoring and recording to evaluate the progression toward renal failure. Carefully monitor intravenous infusions and blood chemistries. Administer diuretics as ordered. Assess blood pressure frequently and report elevations to the physician or nurse practitioner. Administer antihypertensives as ordered and monitor their effectiveness. Encourage adequate nutritional intake within the constraints of prescribed dietary restrictions. Monitor for bleeding as well as for fatigue and pallor. Follow the institutional protocol for transfusion of packed red blood cells and/or platelets (platelets are usually transfused only if active bleeding or severe thrombocytopenia occurs). Report progressive deterioration in laboratory findings to the physician or nurse practitioner. Some children with HUS will require dialysis for at least several days.

### Preventing Hemolytic-Uremic Syndrome

Proper hand washing is necessary. Teach children to wash their hands after using the bathroom, before eating, and after petting farm animals. Encourage the use of "swim diapers," which contain feces, for children who are not toilet trained. Teach parents to thoroughly cook all meats to a core temperature of 155°F, or until the meat is gray or brown throughout and the juices from the meat are clear rather than pink. Wash all fruits and vegetables thoroughly. Ensure that drinking water and water used for recreation are treated appropriately. Avoid unpasteurized dairy products and fruit juices (including cider).

### Renal Failure

Renal failure is a condition in which the kidneys cannot concentrate urine, conserve electrolytes, or excrete waste products. As in adults, renal failure in children may occur as an acute or chronic condition. Some cases of acute renal failure resolve without further complications, while dialysis is necessary in other children. When acute renal failure continues to progress, it becomes chronic (also known as end-stage renal disease [ESRD]). Dialysis and kidney transplantation are treatment modalities used for ESRD.

### Acute Renal Failure

Acute renal failure is defined as a sudden, often reversible, decline in renal function that results in the accumulation of metabolic toxins (particularly nitrogenous wastes) as well as fluid and electrolyte imbalance. Fluid overload may lead to hypertension, pulmonary edema, and congestive heart failure. Additional complications include hyperkalemia, metabolic acidosis, hyperphosphatemia, and uremia. In children, acute renal failure most commonly occurs as a result of decreased renal perfusion, as occurs in hypovolemic or septic shock. It may also occur in children with hemolytic anemia or as a result of nephrotoxicity from medications. Complications include anemia, hyperkalemia, hypertension, pulmonary edema, cardiac failure, and altered level of consciousness or seizures. In addition, acute renal failure may also progress to a chronic state.

Therapeutic management is aimed at treating the underlying cause, managing the fluid and electrolyte disturbances, and decreasing blood pressure.

#### Take Note!

Medications commonly used in children can reduce renal function. Cephalosporins may cause a transient increase in BUN and creatinine. Truly nephrotoxic drugs often used in children include aminoglycosides, sulfonamides, vancomycin, and NSAIDs. Make sure that potentially nephrotoxic

drugs are administered according to published safe guidelines (dosage, frequency, rate of administration) (Taketokmo, Hodding, & Kraus, 2011).

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1551. Assessment findings pertinent to acute renal failure are discussed below.

### Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Nausea
- Vomiting
- Diarrhea
- Lethargy
- Fever
- Decreased urine output

Assess the child's current and past medical history for risk factors such as history of shock, trauma, burns, urologic abnormalities, renal disease, use of nephrotoxic medications, or severe blood transfusion reaction.

### Physical Examination and Laboratory and Diagnostic Tests

Note decreased skin elasticity, dry mucous membranes, or edema. Auscultate the lungs for crackles, which may occur with pulmonary edema. Document tachypnea. Note cardiac rhythm disturbances. Evaluate the child's level of consciousness. Laboratory tests will reveal increased serum creatinine levels and possible electrolyte disturbances, such as hyperkalemia or hypocalcemia. Urinalysis may reveal proteinuria or hematuria.

#### Take Note!

Monitor the infant or child with renal failure carefully for signs of congestive heart failure, such as edema accompanied by bounding pulse, presence of an  $S_3$  heart sound, adventitious lung sounds, and shortness of breath.

## Nursing Management

Nursing care focuses on managing hypertension, restoring fluid and electrolyte balance, and educating the family.

### Managing Hypertension

Carefully monitor the child's blood pressure. Administer antihypertensives as prescribed. When a fast-acting drug such as nifedipine (Procardia) sublingually or labetalol intravenously is used, stay with the child and frequently monitor blood pressure. Immediately notify the physician

or nurse practitioner if high blood pressure is resistant to medication and the blood pressure remains elevated.

### Restoring Fluid and Electrolyte Balance

Monitor vital signs frequently and assess urine specific gravity. Maintain strict records of intake and output. Administer diuretics as ordered. When urine output is restored, diuresis may be significant. Monitor for signs of hyperkalemia (weak, irregular pulse; muscle weakness; abdominal cramping) and hypocalcemia (muscle twitching or tetany). Administer polystyrene sulfonate (Kayexalate) as ordered orally, rectally, or through a nasogastric tube to decrease potassium levels. Kayexalate removes potassium primarily by exchanging sodium for it, which is then eliminated in the feces. Administer packed red blood cell transfusions as ordered (may need to be followed by a dose of diuretic). Dialysis may become necessary if oliguria is sustained and leads to significant fluid overload, the electrolyte imbalance reaches dangerous levels, or uremia results in depression of the central nervous system.

### Providing Family Education

Educate the family about the plan of care and the need for fluid restriction, if ordered. Instruct the family to save all voids for observation and measurement by the nurse. Provide education about the use of dialysis if relevant.

### End-Stage Renal Disease

ESRD is chronic renal failure requiring long-term dialysis or renal transplantation. Chronic renal failure in children most often results from congenital structural defects such as obstructive uropathy (Klein, 2010). It may also be caused by an inherited condition such as familial nephritis or may result from an acquired problem such as glomerulonephritis; it may follow an infectious process such as pyelonephritis or HUS (Klein, 2010). This is in contrast to chronic renal failure in adults, which primarily results from diabetes or hypertension.

Uremia, hypocalcemia, hyperkalemia, and metabolic acidosis occur. Complications of ESRD are many. Uremic toxins deplete erythrocytes and the failing kidneys cannot produce erythropoietin, so severe anemia results. Hypertension is common and heart failure may occur. Hypocalcemia results in renal rickets (brittle bones). Growth is retarded and sexual maturation may be delayed or absent. Many children with ESRD experience depression, anxiety, impaired social interaction, and poor self-esteem (Klein, 2010). See Healthy People 2020.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1551. Assessment findings pertinent to ESRD are discussed below.

**HEALTHY PEOPLE 2020****Objective**

Reduce the rate of new cases of end-stage renal disease (ESRD).

*Healthy People* Objectives based on data from <http://www.healthypeople.gov>.

**Nursing Significance**

- Encourage compliance with medical regimens related to urinary tract disorders in order to prevent progression to chronic renal failure.

**Take Note!**

Carefully assess children with ESRD for worsening uremia or metabolic acidosis. Uremia may result in central nervous system symptoms such as headache or coma, or gastrointestinal or neuromuscular disturbances. Metabolic acidosis causes lethargy, dull headache, and confusion.

**Nursing Management**

Nursing goals for the child with ESRD include promoting growth and development, removing waste products and maintaining fluid balance via dialysis, encouraging psychosocial well-being, and supporting and educating the family.

**Health History**

Explore the health history for low birthweight (associated with kidney dysfunction and anatomic alterations), poor growth (weight, length/height, and head circumference), and regimen of dialysis. Note decreased appetite or energy level, dry or itchy skin, or bone or joint pain.

**Physical Examination and Laboratory and Diagnostic Tests**

Perform a thorough physical assessment, noting any abnormalities (may vary from child to child). If present, assess the peritoneal catheter site for absence of drainage, bleeding, or redness. If the child undergoes hemodialysis, assess the fistula or graft site for the presence of a bruit and a thrill. Laboratory tests may reveal low hemoglobin and hematocrit, increased serum phosphorus and potassium levels, and decreased sodium, calcium, and bicarbonate levels. BUN, uric acid, and creatinine levels will be elevated. A 24-hour urine creatinine clearance test will show increased amounts of creatinine in the urine, reflecting decreasing kidney function.

**Promoting Growth and Development**

Encourage the child to choose foods he or she likes that are within the imposed dietary restrictions. Daily protein requirements for adequate growth range from 0.9 to 1.5 grams of protein per kilogram of weight. Sodium and/or potassium restrictions may also be necessary. Enforce fluid restrictions if prescribed. Administer medications such as erythropoietin, growth hormone, and vitamin and mineral supplements to augment nutritional status and promote growth. Table 43.2 lists medications and supplements used to support growth.

**Encouraging Psychosocial Well-Being**

The child with chronic renal failure and particularly ESRD often suffers from depression and anxiety. Refer children and their families to the hospital social worker or counselor as needed for depression or anxiety issues. The chronic need for dialysis (daily with peritoneal dialysis or three or four times per week with hemodialysis) confers long-term stress on the child and family. The child usually demonstrates poor growth and often suffers from body image disturbance. Frequent medical appointments

**TABLE 43.2****MEDICATIONS AND SUPPLEMENTS COMMONLY USED TO TREAT ESRD COMPLICATIONS**

Medication or Supplement	Purpose
Vitamin D and calcium	Correction of hypocalcemia and hyperphosphatemia
Ferrous sulfate	Treatment of anemia
Bicitra or sodium bicarbonate tablets	Correction of acidosis
Multivitamin	Augment nutritional status
Erythropoietin injections	Stimulate red blood cell growth
Growth hormone injections	Stimulate growth in stature

Adapted from Klein, M. S. (2010). Kidney disease, chronic. In P. J. Allen, J. A. Vessey, and N. A. Schapiro (Eds.), *Primary care of the child with a chronic condition* (5th ed.). St. Louis, MO: Mosby.

and hospitalizations interfere with the child's scholastic achievements. Introduce the child to other children with ESRD (this often happens anyway at the hemodialysis center).

Ensure that the family is aware of financial and support resources within the community and refer them to the National Kidney Foundation. Also suggest the American Kidney Fund, which provides financial aid and access to summer camps for children with renal problems. Links to both of these resources are located on [thePoint](#). Camp is an excellent way for children to demonstrate that they have mastered some of the loss-of-control issues related to their disease.

Several websites provide forums for children and teens with kidney failure or transplantation so they can learn about their disease, access resources, and/or communicate with other children. Links to such websites are available on [thePoint](#).

## Dialysis and Transplantation

Peritoneal dialysis or hemodialysis is required on a long-term basis for children with chronic renal failure or ESRD. Once the child has progressed to ESRD, kidney transplantation is needed in order for the child to progress with normal growth and development.

### Peritoneal Dialysis

Peritoneal dialysis uses the child's abdominal cavity as a semipermeable membrane to help remove excess fluid and waste products (Figs. 43.7 and 43.8). The parent or caregiver performs peritoneal dialysis at home after completing a training course. The process is either completed

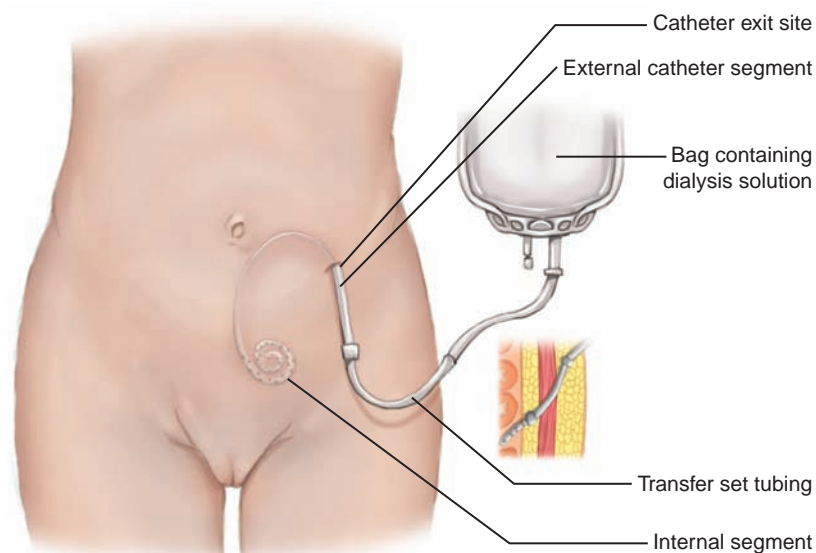

overnight with the use of a machine (continuous cyclic peritoneal dialysis) or in increments throughout the day for a total of 4 to 8 hours (continuous ambulatory peritoneal dialysis). Comparison Chart 43.1 compares these two methods of peritoneal dialysis.

The advantages of peritoneal dialysis over hemodialysis include improved growth as a result of more dietary freedom, increased independence in daily activities, and a steadier state of electrolyte balance. However, the risk for infection (peritonitis and sepsis) is a continual concern with peritoneal dialysis (Klein, 2010). Dialysate exchange protocols, care of the catheter in the abdomen, and dressing changes must all be performed using sterile technique to avoid introducing microorganisms into the peritoneal cavity. Box 43.2 lists additional risks associated with peritoneal dialysis.

### Hemodialysis

Hemodialysis removes toxins and excess fluid from the blood by pumping the child's blood through a hemodialysis machine and then reinfusing the blood into the child. Needles to remove and reinfuse the blood are inserted into an arteriovenous fistula or graft, usually located in the child's arm (Figs. 43.9 and 43.10).

Hemodialysis frees the parent from the need to perform daily dialysis, but the procedure, which takes 3 to 6 hours, must be done two to four times per week (usually three) at a pediatric hemodialysis center. This requires time away from school and other activities for the child and from work and other family responsibilities for the parent. Since hemodialysis is usually performed only every other day, larger amounts of waste products build up in the child's blood (uremia), placing the child at higher risk for seizures. The access site may become infected, and occlusion is also possible. The

**FIGURE 43.7** The peritoneal dialysis catheter is tunneled under the skin into the peritoneal cavity.

**FIGURE 43.8** (A) During the “fill” phase of peritoneal dialysis, dialysate fluid is instilled into the peritoneal cavity. (B) During the “dwell” phase, the child may be up out of bed with the empty dialysate bag folded up with the tubing under his clothing. (C) During the “drain” phase, the old dialysate is drained from the peritoneum by gravity, bringing with it waste products and excess fluid. The dialysate bags are weighed prior to filling and after draining to determine the amount of fluid removed from the child.

### COMPARISON CHART 43.1

#### METHODS OF PERITONEAL DIALYSIS

	Continuous Ambulatory Peritoneal Dialysis (CAPD)	Continuous Cyclic Peritoneal Dialysis (CCPD)
<i>When performed</i>	Throughout the day, with exchanges every 3 to 6 hours. Fluid is usually allowed to dwell overnight to allow child to sleep	Usually overnight while child is sleeping
<i>Method</i>	Manual instillation and draining and changing of dialysate bags with each exchange	Automated via CCPD machine; bags and tubing are attached when started, then disconnected in the morning
<i>Dwell time</i>	3 to 6 hours	Usually 30 minutes to 1 hour
<i>Mobility</i>	Allows for mobility and permits child to participate in activities between exchanges	Child is confined to bed during the night while CCPD is ongoing but completely mobile while off CCPD during the day

child must follow a stricter diet between hemodialysis treatments, though dietary restrictions are usually lifted while the child is actually undergoing the treatment.

### Nursing Assessment

Refer to the section on nursing assessment of the child with chronic renal failure/ESRD, as it is similar to assessment of the child undergoing dialysis. Assess for alterations in blood pressure and laboratory values following dialysis. Monitor for signs and symptoms of infection.

Assess the child receiving peritoneal dialysis for toleration of the fluid volume instilled within the peritoneum. The abdomen will remain distended while the fluid is indwelling and will be significantly flatter when the fluid is drained. Assess the Tenckhoff catheter site for signs of infection. Monitor the child's temperature. Inspect the dialysate effluent for fibrin or cloudiness, which may indicate infection. Weigh the child daily (in the drain phase if on peritoneal dialysis).

For the child who receives hemodialysis, assess the arteriovenous fistula or graft site with each set of vital

**BOX 43.2**

**RISKS ASSOCIATED WITH PERITONEAL DIALYSIS**

- Hypertension and other cardiac complications
- Seizures
- Obstructed catheter
- Dialysate leakage
- Hyperglycemia
- Increased triglyceride levels
- Increased protein loss
- Parental stress and burnout related to repetitive nature of daily intervention

signs. Auscultate the site for the presence of a bruit and palpate for the presence of a thrill. Notify the physician or nurse practitioner immediately if either is absent.

**Take Note!**

Avoid taking blood pressure, performing venipuncture, or using a tourniquet in the extremity with the arteriovenous fistula or graft; these procedures may cause occlusion and subsequent malfunction of the fistula or graft. Teach parents and children to inform all health care providers they come in contact with about the presence of the fistula or graft.

**Nursing Management**

Specially trained and certified nurses perform both peritoneal dialysis and hemodialysis. The general pediatric nurse’s role is related to the ongoing care of the child. The child undergoing peritoneal dialysis usually is allowed a more liberal diet and intake of fluid than the child undergoing hemodialysis. Peritoneal dialysis removes waste and excess fluids on a daily basis, whereas hemodialysis occurs about every other day. Most routine medications are withheld on the morning that hemodialysis is scheduled, since they would be filtered out through the dialysis process anyway. Administer these medications as soon as the child returns from the dialysis unit. See Healthy People 2020.

**FIGURE 43.9** (A) Arteriovenous fistula. (B) Arteriovenous graft.

**Renal Transplantation**

Renal transplantation is the optimal treatment for ESRD and offers the best opportunity for the child to live a normal life. Vigilant medication administration is necessary

**HEALTHY PEOPLE 2020**

**Objective**

Increase the proportion of new hemodialysis patients who use arteriovenous fistulas as the primary mode of vascular access. Increase the proportion of dialysis patients registered on the waiting list for transplantation.

**Nursing Significance**

- Educate families about the benefits of an arteriovenous fistula over other methods of hemodialysis access.
- Advocate for the child to obtain an arteriovenous fistula.
- Educate families about transplantation, and if no living-related match is available, encourage the family to seek placement on the organ transplant waiting list.

*Healthy People* Objectives based on data from <http://www.healthypeople.gov>.

**FIGURE 43.10** Pediatric hemodialysis.

### Thinking About Development

Trevon Smith is a 17-year-old male football player who was on track for a college scholarship. Following an episode of acute glomerulonephritis, Trevon has progressed to chronic renal failure and is dependent upon hemodialysis. He is listed for a kidney transplant.

How will Trevon's developmental stage affect his desire to comply with the medical regimen? What types of psychosocial issues might Trevon be experiencing and how can the nurse best support Trevon at this time?

How will the nurse educate Trevon about self-care?

after the transplant to prevent organ rejection. The child achieves improved renal function with the transplant and may demonstrate improved growth, enhanced cognitive development, and improved psychosocial development and quality of life.

Kidneys are obtained from a cadaver (a patient declared brain-dead who had previously given consent to organ donation) or from a blood relative (living-related). The transplanted kidney must match the child's blood type and the child's human leukocyte antigens (HLAs). The cadaver kidney or living-related kidney is implanted surgically in the abdomen and the blood vessels are anastomosed to the aorta and superior vena cava.

Generally, living-related transplants have a decreased rejection rate compared to cadaver transplants (Klein & Martin, 2010). Living-related kidney donation and subsequent transplantation can be planned ahead and scheduled in advance. In contrast, cadaver kidneys become available suddenly, leaving less time for preoperative preparation. For either type, last-minute blood tissue typing is required before the final decision is made to move forward with transplantation. Often the child's native kidneys are removed before or at the time of the renal transplant because of their association with hypertension in the child (Klein & Martin, 2010).

#### Take Note!

Cadaver kidneys are allocated to potential recipients based on the age of the child with renal failure, the time that he or she has been awaiting a transplant, blood type, HLA antibody matching, panel reactive antibodies, and region of the country (so that the donated kidney can be received expeditiously).

### Nursing Assessment

A thorough physical assessment is warranted for any child undergoing renal transplant, whether in the initial postoperative period, at a clinic visit, or when admitted

to the hospital, to rule out transplant rejection. Note recent health history, medications and their doses, and any symptoms the child has been having. In the initial postoperative period, assess the incision for redness, edema, or drainage. If any of these signs of infection or rejection occur, notify the transplant surgeon and nephrologist immediately. Monitor blood pressure and other vital signs closely. Document resolution of edema. Record intake and output accurately. Assess for signs and symptoms of transplant rejection such as malaise, fever, unexplained weight gain, or pain over the transplant area.

### Nursing Management

Postoperative care focuses on preventing rejection, monitoring renal function, maintaining fluid and electrolyte balance, and educating the child and family.

#### Take Note!

Encourage the child with a renal transplant to wear a medical alert necklace or bracelet, and urge the parents to inform community emergency services of the child's transplant status.

### Preventing Rejection and Promoting Renal Function

Administer immunosuppressants accurately and in a timely fashion. Obtain and monitor serum levels of these medications per protocol. Immediately report significant alterations in vital signs or edema at the surgical site, as they may indicate transplant rejection. Maintain strict documentation of intake and output. Once adequate urine output is established, intake is usually liberalized.

### Educating the Child and Family

Develop a schedule to cluster care so that the child may receive the rest needed for recovery despite the many and frequent assessments and interventions. With the family, develop a medication schedule that will be compatible with the family's life at home as well as the restrictions related to some medications. Begin teaching with the family as soon as the child's condition is stable. Accurate medication administration and home monitoring are necessary to prevent rejection. The child may return to school when discharged from the hospital, but the family will need to communicate closely with the school nurse about the child's immunosuppressed status. The American Nephrology Nurses Association has developed a renal transplant fact sheet that can be shared with the school nurse. A link to the association's website is located on [thePoint](#).

**Take Note!**

Tell the parents to inform their child's physician or nurse practitioner about the child's long-term corticosteroid use and/or immunosuppressed status, as the child should not receive any live vaccines.

## REPRODUCTIVE ORGAN DISORDERS

A number of disorders may occur within the female or male genitalia and internal reproductive organs in children. These problems may be structural or infectious.

### Female Disorders

Disorders of the female reproductive organs that occur in children and adolescents include structural disorders, infectious disorders, and menstrual disorders. Menstrual disorders are discussed in chapter 4 and pelvic inflammatory disease is covered in chapter 5.

#### Labial Adhesions

Labial adhesion or labial fusion is partial or complete adherence of the labia minora (Fig. 43.11). UTI may result from urinary stasis behind the labia; if the adhesions are left untreated, the vaginal orifice may become inaccessible, presenting difficulty with sexual intercourse in the future.

#### Nursing Assessment

Younger girls have a higher risk of adhesions (3 months to 4 years) (Nepple & Cooper, 2011). Assess the history for dysuria or urinary frequency. Inspect the genitalia for fusion or adherence of the labia minora.

**FIGURE 43.11** Labial adhesions. Note fusion of the labia minora. Copyrighted 2011. UBM Medica LLC. 82486:1111JM

## Nursing Management

Administer topical estrogen cream as prescribed, usually once or twice daily. Teach the parents to continue cream application until the labia separate. Encourage use of petroleum jelly daily for 1 month following labial separation to prevent recurrence of adhesion.

### Vulvovaginitis

Vulvovaginitis is inflammation of the vulva and vagina. Inflammation may occur as a result of bacterial or yeast overgrowth or from chemical factors such as bubble bath, soaps, or perfumes found in personal care products. Poor hygiene may also cause vulvovaginitis. Tight clothing may cause a heat rash in the perineal area. Persistent scratching of the irritated area may result in the complication of superficial skin infection.

#### Nursing Assessment

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history may include itching or burning in the perineal area. Explore the child's current and past medical history for risk factors, which may include:

- Young age (toilet-trained preschooler)
- Poor hygiene
- Sexual activity
- Immune disorders
- Diabetes mellitus

Inspect the perineum for redness, edema, irritation, rash, or vaginal discharge (note color, consistency, and odor).

#### Nursing Management

Teach appropriate hygiene (daily and toileting). Girls (or their parents) should wash the genital area thoroughly on a daily basis with mild soap and water. Rinse the area well. Encourage girls to wipe after urinating and after bowel movements to wipe in a front-to-back motion. The girl should wear cotton underwear and should change it at least once a day. Administer topical or oral medications as ordered. Table 43.3 lists treatments related to specific types of vulvovaginitis.

### Male Disorders

Male reproductive disorders include structural disorders and disorders caused by infection or inflammation. Circumcision will also be discussed below.

TABLE 43.3

## VULVOVAGINITIS: TYPES AND TREATMENTS

Cause	Assessment Findings	Treatment
Unhygienic practices	Irritation of labia and vaginal opening May have foul brownish-green discharge if infected with bacteria from rectum	Good hygiene. Sometimes a mild anti-inflammatory cream is prescribed. Assess for signs and symptoms of UTI, which may occur as a complication.
<i>Candida albicans</i>	Red bumpy perineal rash in infants White cottage-cheese–like discharge Intense itching	Antifungal cream or vaginal suppository. Prevent by ingesting probiotics (found in yogurt and kefir) daily and supplementing with a probiotic such as Lactinex when taking antibiotics.
<i>Bordetella, Gardnerella</i>	Thin gray vaginal discharge with fishy odor	Flagyl (metronidazole) orally.
<i>Trichomonas vaginalis</i>	Foul yellow-gray or green vaginal discharge	Flagyl (metronidazole) orally. Sexually transmitted, so can be prevented with the use of condoms.

Adapted from Neinstein, L. S., Gordon, C. M., Katzman, D. K., Rosen, D. S., & Woods, E. R. (2009). *Handbook of adolescent health care*. Philadelphia, PA: Lippincott Williams & Wilkins.

## Phimosis and Paraphimosis

In phimosis, the foreskin of the penis cannot be retracted. Although this is normal in the newborn, it can be pathologic later. Over time, the prepuce (foreskin) naturally becomes retractable. Local irritation, balanitis, or UTI may occur if urine is retained within the foreskin after voiding. Paraphimosis (Fig. 43.12) is a more serious disorder characterized by retraction of the phimotic prepuce, which causes a constricting band behind the glans of the penis and results in incarceration if left untreated.

Topical steroid cream applied twice a day for 1 month may be prescribed for phimosis. Paraphimosis requires reduction of the prepuce or a small dorsal incision to release the foreskin. Circumcision may be used to treat either condition.

FIGURE 43.12 Paraphimosis: note the swollen prepuce. Copyrighted 2011. UBM Medica LLC. 82486:1111JM

## Nursing Assessment

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Irritation or bleeding from the opening of the prepuce (phimosis)
- Dysuria (phimosis)
- Pain (paraphimosis)
- Swollen penis (paraphimosis)

Determine the onset of symptoms and inspect the penis for irritation, erythema, edema, or discharge.

### Take Note!

A swollen, reddened penis (paraphimosis) is a medical emergency and can quickly result in necrosis of the tip of the penis if left untreated.

## Nursing Management

Apply topical steroid medication as prescribed for phimosis, following gentle retraction to stretch the foreskin back. Topical vitamin E cream may also help to soften the phimotic ring. When surgical intervention is necessary, provide routine postprocedural care and pain management (refer to the section on circumcision below). Teach the parents and uncircumcised boy proper hygiene, which will help to prevent phimosis and paraphimosis (Teaching Guidelines 43.2).

## Circumcision

Circumcision is the removal of the excess foreskin of the penis. Some newborn boys are circumcised shortly after birth before going home from the hospital. Some

## Teaching Guidelines 43.2

### HYGIENE IN THE UNCIRCUMCISED MALE

- The foreskin does not normally retract in the newborn boy, so do not force it to do so.
- Change the diaper frequently and wash the penis daily with water and mild soap.
- When the infant is older and the foreskin easily retracts, gently retract the foreskin and clean around the glans with water and mild soap once a week.
- Dry the area prior to replacing the foreskin.
- Always replace the foreskin after retraction.
- Teach the preschool-age boy to retract the foreskin and clean the penis during each bath or shower.

parents elect not to have their newborn boy circumcised at that time but may desire it later. Neonatal circumcision may be performed in the newborn nursery, hospital unit treatment room, or outpatient office. Circumcision is indicated later for the conditions of phimosis and paraphimosis. Circumcision done after the newborn period usually requires general anesthesia.

The benefits of circumcision include a decreased incidence of UTI, sexually transmitted diseases, AIDS, and penile cancer, and in female partners a decreased occurrence of cervical cancer. Complications of circumcision include alterations in the urinary meatus, unintentional removal of excessive amounts of foreskin, or damage to the glans penis (American Academy of Pediatrics [AAP], 2005).

Whether to circumcise or not is a personal decision and often based on religious beliefs or social or cultural customs. Nurses should support and educate the parents in either case.

## Nursing Assessment

Prior to the procedure, assess for normal placement of the urinary meatus on the glans penis (in boys with hypospadias, circumcision should be delayed until evaluation by the pediatric urologist). After the circumcision, assess for redness, edema, or active bleeding. Note signs of infection, such as purulent drainage. Assess pain level.

## Nursing Management

Nursing care of the boy undergoing circumcision focuses on managing pain, providing postprocedural care, and educating the parents.

### Managing Pain

Whether circumcision is performed in the obstetric area of the hospital before newborn discharge or in the outpatient setting at a few days of age, pain management during the

procedure must not be neglected. Advocate for appropriate pain management for the infant undergoing circumcision. The American Academy of Pediatrics recommends using a subcutaneous ring block with lidocaine or a dorsal nerve block to the penis. The AAP also recommends the use of EMLA (eutectic mixture of local anesthetic) cream topically to decrease pain during the circumcision (2005). Playing calming music during the procedure may also help to soothe the infant, providing distraction. A sucrose-dipped pacifier may also be used as adjuvant therapy for pain management. To increase a sense of comfort during the procedure, restrain the infant in a padded circumcision chair with blankets covering the legs and upper body (Kraft, 2003). This allows the infant to be in a semi-upright position during the procedure while still allowing for a sterile procedural field. If a padded restraint chair is not available, provide atraumatic care by padding the circumcision board and covering the infant as previously described.

### Providing Postprocedural Care

Usual care after circumcision depends on the type of appliance used (Gomco or Mogen clamp or Plastibell apparatus). Cleanse the penis with clear water for the first few days and avoid using alcohol-containing wipes. To avoid irritation to the penis, fasten diapers loosely. Notify the physician or nurse practitioner if excessive redness, active bleeding, or purulent discharge occurs. Assess for the first void following the procedure, or if performed in the outpatient setting instruct parents to call the physician or nurse practitioner if the infant has not voided by 6 to 8 hours after the circumcision. Apply antibiotic ointment or petroleum jelly to the penile head with each diaper change as prescribed, based on the circumcision method used and the preference of the physician or nurse practitioner.

#### Take Note!

If excess bleeding occurs after the circumcision, apply direct pressure and notify the physician or nurse practitioner immediately.

### Educating the Parents

Instruct parents to give sponge baths until the circumcision is healed. Describe the normal granulation tissue that will be present during the healing process. Teach parents to apply ointment or petroleum jelly if indicated. Instruct the parents to call the physician or nurse practitioner if any of the following occur:

- The infant does not urinate within 6 to 8 hours after the procedure.
- Heavy bleeding occurs (more than small spots on the diaper or bleeding that requires direct pressure to stop it).
- There is purulent or serous drainage from the circumcised area.
- There is redness or swelling of the penile shaft.

**Take Note!**

If the Plastibell is used, teach parents NOT to use petroleum jelly, as it may cause the ring to be dislodged. A yellowish crust may form that should be allowed to fall off on its own after several days.

## Cryptorchidism

Cryptorchidism (also known as undescended testicles) occurs when one or both testicles do not descend into the scrotal sac. Ordinarily the testes, which in the fetus develop in the abdomen, make their descent into the scrotal sac during the seventh month of gestation. The cause for this failure to descend may be mechanical, hormonal, chromosomal, or enzymatic. The disorder may occur unilaterally or bilaterally. Up to 3% of term male infants exhibit cryptorchidism (Ashley, Barthold, & Kolon, 2010).

Complications associated with cryptorchidism that is allowed to progress into the school-age years include sterility and an increased risk for testicular cancer in adolescence or the young adult years. Therapeutic management is surgical. An orchiopexy is performed to release the spermatic cord, and the testes are then pulled into the scrotum and tacked into place.

## Nursing Assessment

Explore the health history for risk factors such as:

- Prematurity
- First-born child
- Cesarean birth
- Low birthweight
- Hypospadias

Palpate for the presence (or absence) of both testes in the scrotal sac.

**Take Note!**

A retractile testis is one that may be brought into the scrotum, remains for a time, and then retracts back up the inguinal canal. This should not be confused with true cryptorchidism.

## Nursing Management

If the testes are not descended by 6 months of age, the infant should be referred for surgical repair (Ashley et al., 2010). Postoperatively, observe the incision for signs of bleeding or infection.

## Hydrocele and Varicocele

Hydrocele (fluid in the scrotal sac) is usually a benign and self-limiting disorder. It is usually noted early in infancy and often resolves spontaneously by 1 year of age. Varicocele (a venous varicosity along the spermatic

cord) is often noted as a swelling of the scrotal sac. Complications of varicocele include low sperm count or reduced sperm motility, which can result in infertility.

## Nursing Assessment

Elicit a description of the present illness and chief complaint. The boy with hydrocele will have an enlarged scrotum that may decrease in size when he is lying down. Inspect the scrotum for a fluid-filled appearance.

The boy with varicocele will have a mass on one or both sides of the scrotum and bluish discoloration. Inspect the scrotum for masses; the spermatic vein feels worm-like on palpation. The boy with varicocele may have pain.

## Nursing Management

Both hydrocele and painless varicocele require watchful waiting, as these conditions will usually resolve spontaneously. If they do not resolve, or if the difference in testicular volume is marked in the boy with varicocele, refer the child to a urologist, as surgery may be indicated. Reassure parents that hydrocele is not associated with the development of infertility. Varicocele may lead to infertility if left untreated, so instruct parents to seek care if pain occurs or if there is a large difference in testicular size. Either condition may be surgically corrected on an outpatient basis. Provide routine postoperative care following either surgery.

## Testicular Torsion

In testicular torsion, a testicle is abnormally attached to the scrotum and twisted. It requires immediate attention because ischemia can result if the torsion is left untreated, leading to infertility. Testicular torsion may occur at any age but most commonly occurs in boys aged 12 to 18 years (Dufour, 2008).

## Nursing Assessment

Elicit a description of the present illness and chief complaint. Signs and symptoms of testicular torsion include sudden, severe scrotal pain. Inspect the affected side for significant swelling, which may appear hemorrhagic or blue-black.

## Nursing Management

Surgical correction is necessary immediately. Administer pain medication prior to surgery. Reassure the child and family that surgery will alleviate the problem and is performed to restore adequate blood flow to the testicle. After surgical repair, provide routine postoperative care.

**Take Note!**

Testicular torsion is considered a surgical emergency, as necrosis of the testis may occur and gangrene may set in.

## Epididymitis

Epididymitis (inflammation of the epididymis) is caused by infection with bacteria. It is the most common cause of pain in the scrotum. It rarely occurs before puberty, but if it does it may occur as a result of a urethral or bladder infection related to a urogenital anomaly. Therapeutic management is directed toward eradicating the bacteria. If left untreated, a scrotal abscess, testicular infarction, or infertility may occur.

## Nursing Assessment

Note history of painful swelling of the scrotum, which may be gradual or acute. If the boy is sexually active, explore history of sexual encounters prior to the onset of symptoms. Document history of dysuria or urethral discharge. Note fever, which may last from days to weeks. On inspection, note edema and erythema of the scrotum. Gently palpate the scrotum for a hardened and tender epididymis. Note urethral discharge if present. Palpate the inguinal lymph nodes for enlargement. Urinalysis may be positive for bacteria and white blood cells. The culture of urethral discharge may be positive for a sexually transmitted infection such as gonorrhea or *Chlamydia*. The complete blood count may reveal an elevated white blood cell count.

## Nursing Management

Encourage the boy to rest in bed with the scrotum elevated. Ice packs to the scrotum may help with pain relief. Administer pain medications such as NSAIDs or other analgesics as needed.

Administer antibiotics as prescribed. Educate the boy and his family to complete the entire course of antibiotics as prescribed to eradicate the infection. Advise the child and family to notify the physician or nurse practitioner if the condition is not improving or if the pain and swelling worsen.

### KEY CONCEPTS

- Though present at birth, the reproductive organs do not reach functional maturity until puberty.
- The short length of the urethra in girls and its proximity to the vagina and anus place the young girl at higher risk for the development of urinary tract infections compared with the adult.
- The urinary tract is immature in infants and young children, with a slower glomerular filtration rate and a decreased ability to concentrate urine and reabsorb amino acids compared with the adult.
- The expected urine output in the infant and child is 0.5 to 2 mL/kg/hour.
- Obtaining a clean or sterile urine specimen is necessary for accurate urine culture results.
- A urinary catheter must be inserted just prior to the voiding cystourethrogram.
- Close monitoring of serum blood counts and electrolytes is a critical component of nursing care related to renal disorders.
- Certain congenital urologic anomalies may require multiple surgeries as well as urinary diversion; urine drains through a stoma on the abdominal wall that is either pouched or catheterized.
- The treatment for nocturnal enuresis may include the use of desmopressin nasal spray and/or an enuresis alarm to train the child to awaken to the sensation of a filling bladder.
- Nephrotic syndrome results in significant proteinuria and edema.
- Acute glomerulonephritis most often follows a group A streptococcal infection and commonly results in hematuria, proteinuria, and hypertension.
- The most common cause of hemolytic-uremic syndrome is infection with *E. coli* O157:H7. It can be prevented by adequately cooking ground meat, washing hands and produce well, and making sure that an appropriate chemical balance is maintained in public recreational water sources such as swimming pools and water parks.
- Corticosteroids can cause gastrointestinal upset. If used on a long-term basis, they should be tapered rather than discontinued abruptly to avoid adrenal crisis.
- In children, chronic kidney disease is most often the result of congenital structural defects, or infectious, inflammatory, or immune processes that damage the kidney, whereas in adults it usually results from hypertension or diabetes.
- Children taking immunosuppressants for nephrotic syndrome or for renal transplant are at increased risk for the development of overwhelming infection.
- Peritoneal dialysis may be accomplished at home by the parent. Close attention to sterile technique is needed.
- Hemodialysis requires an arteriovenous fistula or graft that is accessed with needles three or four

times per week at a hemodialysis center. This is disruptive to the child's academic, social, and family lives.

- Renal transplantation is the best option for the treatment of end-stage renal disease in children, but vigilant medication administration is needed to prevent organ rejection.
- Children with renal failure experience anemia, poor growth, depression, anxiety, and low self-esteem.
- The diet for a child with a renal disorder must be individualized according to prescribed sodium, fluid, and/or protein restrictions.
- Postoperative care for the child undergoing urologic surgery includes pain management, avoidance or treatment of bladder spasms, and monitoring of urine output.

## MULTIPLE CHOICE QUESTIONS

1. The nurse is performing education for the parents of an infant with bladder exstrophy. Which statement by the parents would indicate an understanding of the child's future care?
  - a. "Care will be no different than that of any other infant."
  - b. "My infant will only need this one surgery."
  - c. "My child will wear diapers all his life."
  - d. "We will need to care for the urinary diversion."
2. A 4-year-old girl presents with recurrent urinary tract infection. A prior workup did not reveal any urinary tract abnormalities. What is the priority nursing action?
  - a. Obtain a sterile urine sample after completion of antibiotics.
  - b. Teach appropriate toileting hygiene.
  - c. Prepare the child for surgery to reimplant the ureters.
  - d. Administer antibiotics intramuscularly.
3. A 5-year-old who had a renal transplant 9 months ago and has no history of chickenpox presents to the pediatric clinic for his vaccinations. Which is the most appropriate set to give?
  - a. DTaP, IPV.
  - b. DTaP, IPV, MMR, varicella.
  - c. DTaP, IPV, varicella.
  - d. IPV only.
4. When the nurse is caring for a child with hemolytic-uremic syndrome or acute glomerulonephritis and the child is not yet toilet trained, which action by the nurse would best determine fluid retention?
  - a. Test urine for specific gravity.
  - b. Weigh child daily.
  - c. Weigh the wet diapers.
  - d. Measure abdominal girth daily.

## CRITICAL THINKING EXERCISES

1. Devise a meal plan for a 5-year-old child with a renal disorder that requires a 2-g sodium restriction per day. Keep in mind the child's developmental level and feeding idiosyncrasies at this age.
2. Develop a discharge teaching plan for a 3-year-old with nephrotic syndrome who will be taking corticosteroids long term.
3. Devise a developmental stimulation plan for an 11-month-old who has had significant urinary tract reconstruction surgery and is facing a prolonged period of confinement to the crib.

## STUDY ACTIVITIES

1. In the clinical setting, compare the growth and development of two children the same age, one with chronic renal failure and one who has been healthy.
2. While caring for children in the clinical setting, compare and contrast the medical history, signs and symptoms of illness, and prescribed treatments for a child with nephrotic syndrome and one with acute glomerulonephritis.
3. Observe peritoneal dialysis in the hospital or hemodialysis in a hospital or outpatient center. Record observations about the children's psychosocial and developmental status.

# Nursing Care of the Child With a Neuromuscular Disorder

## Learning Objectives

*Upon completion of the chapter, you will be able to:*

1. Define the key terms used in this chapter.
2. Compare differences between the anatomy and physiology of the neuromuscular system in children versus adults.
3. Identify nursing interventions related to common laboratory and diagnostic tests used in the diagnosis and management of neuromuscular conditions.
4. Identify appropriate nursing assessments and interventions related to medications and treatments used for childhood neuromuscular conditions.
5. Distinguish various neuromuscular illnesses occurring in childhood.
6. Devise an individualized nursing care plan for the child with a neuromuscular disorder.
7. Develop child/family teaching plans for the child with a neuromuscular disorder.
8. Describe the psychosocial impact of chronic neuromuscular disorders on the growth and development of children.

### Words of Wisdom

Enhancing a child's abilities may enhance his or her strength to overcome anything.

*Frederick Stevens, 4 years old, seems to be falling often and has started to have difficulty climbing the stairs on his own. His mother states, "Recently he hasn't been able to keep up with his 6-year-old sister when we're playing at the park. He usually ends up sitting on the bench with me." She is concerned about the changes she has seen in her son.*

A variety of neuromuscular disorders may affect children, but the result of each is muscular dysfunction. Some of the disorders result from a neurologic insult such as trauma or hypoxia to the brain or spinal cord. Others occur as a result of genetic dysfunction or structural abnormality. Still others may be autoimmune in nature, often following a simple viral infection. Many neuromuscular disorders are chronic, lasting the child's entire life and resulting in handicaps.

The nurse caring for a child with neuromuscular dysfunction plays an important role in the management of these disorders. Not only must the nurse provide direct intervention in response to health alterations that result, but also the nurse is often part of the larger multidisciplinary team and may serve as the coordinator of many specialists or interventions. Understanding the most common responses to these disorders gives the nurse the foundation required to plan care for any child with any neuromuscular disorder.

## VARIATIONS IN PEDIATRIC ANATOMY AND PHYSIOLOGY

The neuromuscular system is the combination of the nervous system and the muscles working together to create movement. Anatomic and physiologic differences in infants and children, such as the immaturity of the neurologic and musculoskeletal systems, place them at increased risk for the development of a neuromuscular disorder.

### Brain and Spinal Cord Development

Early in gestation, around 3 to 4 weeks, the neural tube of the embryo begins to differentiate into the brain and spinal cord. If the fetus suffers infection, trauma, malnutrition, or teratogen exposure during this critical period of growth and differentiation, brain or spinal cord development may be altered. The premature infant's central nervous system is less mature than the term newborn's. Such immaturity in the preterm infant places him or her at a higher risk of central nervous insult within the neonatal period, which may result in delayed motor skill attainment or cerebral palsy. Compared with the adult, the child's spine is very mobile, especially the cervical spine region, resulting in a higher risk for cervical spine injury.

### Myelination

Though development of the structures of the nervous system is complete at birth, myelination is incomplete. Myelination continues to progress and is complete by about 2 years of age. Myelination proceeds in a cephalocaudal and proximodistal fashion, allowing the infant

to gain head and neck control before becoming able to control the trunk and the extremities. As myelination proceeds, the speed and accuracy of nerve impulses increase.

## Muscular Development

The muscular system, including tendons, ligaments, and cartilage, arises from the mesoderm in early embryonic development. At birth (term or preterm), the muscles, tendons, ligaments, and cartilage are all present and functional. The newborn infant is capable of spontaneous movement but lacks purposeful control. Full range of motion is present at birth. Healthy infants and children demonstrate normal muscle tone; **hypertonia** (increased muscle tone) or **hypotonia** (low muscle tone) is an abnormal finding. Deep tendon reflexes are present at birth and are initially brisk in the newborn and progress to average over the first few months. Sluggish deep tendon reflexes indicate an abnormality. As the infant matures and becomes mobile, the muscles develop further and become stronger. The adolescent boy, in response to testosterone release, experiences a growth spurt, particularly in the trunk and legs, and develops bulkier muscles at that time.

## COMMON MEDICAL TREATMENTS

A variety of medications as well as other medical treatments are used to treat neuromuscular disorders in children. Most of these treatments will require a physician's or nurse practitioner's order when the child is in the hospital. The most common treatments and medications are listed in Common Medical Treatments 44.1 and Drug Guide 44.1. The nurse caring for the child with a neuromuscular disorder should become familiar with what these procedures are and how they work as well as common nursing implications related to use of these modalities.

## NURSING PROCESS OVERVIEW FOR THE CHILD WITH A NEUROMUSCULAR DISORDER

Care of the child with a neuromuscular disorder includes assessment, nursing diagnosis, planning, interventions, and evaluation. There are a number of general concepts related to the nursing process that may be applied to neuromuscular dysfunction in children. From a general understanding of the care involved for a child with a neuromuscular disorder, the nurse can then individualize the care based on specifics particular for that child.

## COMMON MEDICAL TREATMENTS 44.1

Treatment	Explanation	Indications	Nursing Implications
Skeletal or cervical traction	Traction is used to immobilize the cervical spine. Halo traction will be applied in stable injuries and allows the child greater mobility. Cervical traction is applied by a jacket-like apparatus, and the child can get out of bed, use a wheelchair, and even ambulate.	To minimize or prevent trauma to the spinal cord	Monitor neurologic status closely. Assess for signs and symptoms of infection or impaired skin integrity. Provide appropriate pin site care.
Physical therapy, occupational therapy, or speech therapy	Physical therapy focuses on attainment or improvement of gross motor skills. Occupational therapy focuses on refinement of fine motor skills, feeding, and activities of daily living. Speech therapy is warranted for the child with a speech impairment or feeding difficulty related to oral muscular issues.	Cerebral palsy, spina bifida, spinal cord injury, muscular dystrophy, spinal muscular atrophy	Provide follow-through with prescribed exercises or supportive equipment. Success of therapy is dependent upon continued compliance with the prescribed regimen. Ensure that adequate communication exists within the interdisciplinary team.
Orthotics, braces	Adaptive positioning devices specially fitted for each child by the physical or occupational therapist or orthotist. Used to maintain proper body or extremity alignment, improve mobility, and prevent contractures	Cerebral palsy, spinal cord injury, spina bifida, muscular dystrophy, spinal muscular atrophy	Provide frequent assessments of skin covered by the device to avoid skin breakdown. Follow the therapist's schedule of recommended "on" and "off" times. Encourage families to comply with use.

## DRUG GUIDE 44.1 COMMON DRUGS FOR NEUROMUSCULAR DISORDERS

Medication	Actions/Indications	Nursing Implications
Benzodiazepines (diazepam, lorazepam)	Anticonvulsant; enhance the inhibition of GABA Used adjunctively for relief of skeletal muscle spasm associated with cerebral palsy and paralysis resulting from spinal cord injury	Monitor sedation level. Assess for improvements in spasticity.
Baclofen (oral or intrathecal)	Central-acting skeletal muscle relaxant; precise mechanism unknown Used to treat painful spasms and decrease spasticity in children with motor neuron lesions, such as cerebral palsy and spinal cord injury	Assess motor function. Monitor for a decrease in spasticity. Observe for mental confusion, depression, or hallucinations. Dosage must be tapered before discontinuing because withdrawal symptoms may occur.
Corticosteroids	Anti-inflammatory and immunosuppressive action Duchenne muscular dystrophy, myasthenia gravis, dermatomyositis	Administer with food to decrease GI upset. May mask signs of infection Do not stop treatment abruptly or acute adrenal insufficiency may occur. Monitor for Cushing syndrome. Dosage may be tapered over time.
Botulin toxin	Neurotoxin produced by <i>Clostridium botulinum</i> that blocks neuromuscular conduction Relief of spasticity in cerebral palsy, occasionally for torticollis	Injected into the muscle by an advanced provider. May cause dry mouth

GABA,  $\gamma$ -aminobutyric acid; GI, gastrointestinal.

Adapted from Karch, A. (2010). *2010 Lippincott's nursing drug guide*. Philadelphia: Wolters Kluwer Health/Lippincott Williams & Wilkins and Taketomo, C. K., Hodding, J. H., & Kraus, D. M. (2010). *Lexi-comp's Drug Reference Handbook: Pediatric & Neonatal Dosage Handbook* (18th ed.). Hudson, OH: Lexi-comp, Inc.

## Assessment

Assessment of neuromuscular dysfunction in children includes health history, physical examination, and laboratory and diagnostic testing.

**Remember Frederick, the 4-year-old who has been falling and having difficulty climbing stairs and who seems to tire easily when playing with his sister? What additional health history and physical examination assessment information should the nurse obtain?**

### Health History

The health history consists of the past medical history, including the mother's pregnancy history; family history; and history of present illness (when the symptoms started and how they have progressed), as well as treatments used at home. The past medical history might be significant for prematurity, difficult birth, infection during pregnancy, changes in gait, falls, delayed development, or poor growth. Family history might be significant for neuromuscular disorders that are genetic. When eliciting the history of the present illness, inquire about the following:

- Changes in gait
- Recent trauma
- Poor feeding
- Lethargy
- Fever
- Weakness
- Alteration in muscle tone

Determine the child's history of attainment of developmental milestones. Note the age that milestones such as sitting, crawling, and walking were attained, and determine whether the pace of attainment of milestones has decreased. Some children may progress normally at first and then demonstrate decreased velocity of development of achievements or even loss of abilities. Obtain a clear description of weakness; is it fatigue, or is the child truly not as strong as he or she was in the past?

### Physical Examination

Physical examination of the nervous and musculoskeletal systems consists of inspection, observation, and palpation. It should also include auscultation of the heart and lungs, as the function of these organs may be affected by certain neuromuscular conditions.

#### INSPECTION AND OBSERVATION

Observe the infant or child playing with toys, crawling, or walking to obtain significant information about

cranial nerve, cerebellar, and motor function. Observe the child's general appearance, noting any asymmetry in muscle development. When extremities are not used, muscular **atrophy** develops, so a shortened limb may indicate chronic hemiparesis. Note symmetry of spontaneous movement of extremities as well as facial muscles. Determine cranial nerve function (refer back to Chapter 38 for a complete description of assessment of cranial nerves). Inspect the spine for cutaneous abnormalities such as dimples or hair tufts, which may be associated with spinal cord abnormalities. Observe the child's level of consciousness (LOC), noting a decrease or significant changes. Note the presence of lethargy. Refer to Chapter 38 for a complete description of evaluation of LOC.

**Motor Function.** Observe spontaneous activity, posture, and balance, and assess for asymmetric movements. In the infant, observe resting posture, which will normally be a slightly flexed posture. The infant should be able to extend extremities to a normal stretch. Note position of comfort of the infant's or child's neck.

**Reflexes.** Note sluggish or brisk deep tendon reflexes. Note persistence of primitive reflexes in the older infant or child, such as Moro or tonic neck. Assess for development of protective reflexes, which is often delayed in infants with motor disorders.

**Sensory Function.** Alterations in sensory function accompany many neuromuscular disorders. Assess sensory function in a similar fashion to that used in the adult. The sensory functions of light touch, pain, vibration, heat, and cold are distinguishable by a child. In the infant, assess for response to light touch or pain. The usual response to pain will be withdrawal from the stimulus. Always prepare the child for the sensory examination in order to gain cooperation. The pinprick test may be particularly frightening, but most children will cooperate if educated appropriately.

#### PALPATION

Assess muscle strength and tone in the infant or child. Compare strength and tone bilaterally. Evaluate neck tone by pulling the infant from a supine position to a sitting position (Fig. 44.1). By 4 to 5 months the infant should be able to maintain the head in a neutral position. Perform passive range of motion of the neck. Alterations in range of motion may indicate a neuromuscular disorder or torticollis. Note trunk tone in the infant by holding the infant under the axillae and palpating for trunk tone. The hypotonic infant will feel as though he or she is slipping through the examiner's hands. Generalized hypotonia is a common sign of neuromuscular disease in the infant and young child (Sarnat, 2011). The hypertonic infant will feel rigid, extending the trunk and legs. Assess leg tone in the infant

FIGURE 44.1 Assessing neck tone in an infant.

by placing the infant in the vertical position with the feet on a flat surface; the 4-month-old infant should be able to momentarily support his or her weight (Fig. 44.2). Assess the strength of the infant or young child by noting ability to move the muscles against gravity. In older children, have the child push against the examiner's hand with the sole of the foot to determine muscle strength (Fig. 44.3). Note any hypertonia or **spasticity**, which is involuntary muscle contractions that are not coordinated with other muscles (e.g., when you stretch out your forearm the triceps contract and

FIGURE 44.2 Assessing leg tone in an infant.

FIGURE 44.3 Assessing leg strength of the child.

the biceps stretch; in spasticity they both contract at the same time). These may be an early indication of cerebral palsy or another neuromuscular disorder.

#### Take Note!

In cases of trauma or suspected trauma, do not perform any assessment that involves movement of the head and neck until cervical injury is ruled out. Maintain complete immobilization of the cervical spine until that time.

### AUSCULTATION

Auscultate the child's lungs; adventitious sounds are often present when respiratory muscle function is impaired.

### Laboratory and Diagnostic Testing

Common Laboratory and Diagnostic Tests 44.1 offers an explanation of the laboratory and diagnostic tests most commonly used in neuromuscular disorders. The tests can assist the physician or nurse practitioner in diagnosing the disorder and/or be used as guidelines in determining ongoing treatment. Laboratory or non-nursing personnel perform some of the tests, while the nurse might perform others. In either instance the nurse should be familiar with how the tests are performed, what they are used for, and normal versus abnormal results. This knowledge will also be necessary when providing child and family education related to the testing.

### Nursing Diagnoses, Goals, Interventions, and Evaluations

Upon completion of a thorough assessment, the nurse might identify several nursing diagnoses, including:

- Impaired physical mobility
- Imbalanced nutrition: less than body requirements

## COMMON LABORATORY AND DIAGNOSTIC TESTS 44.1

Test	Explanation	Indications	Nursing Implications
Cervical spine x-rays	Radiographic image of the cervical spine	Detection of spinal fractures	In the trauma victim, the cervical spine should remain immobilized until cleared after cervical spine radiographs.
Fluoroscopy	Radiographic examination that uses continuous x-rays to show live, real-time images	Assessment of cervical spine instability during movement	Children may be afraid of the x-ray machine but will need to cooperate with flexion and extension of the neck. Allow a parent or family member to accompany the child.
Myelography	X-ray study of the spinal cord allowing visualization of the cord, nerve roots, and surrounding meninges	Detection of space-occupying lesions of the spinal cord; visualization of neural tube defects; evaluation of traumatic injury	Involves injection of contrast medium into the CSF via lumbar puncture. Most common contrast used is water-soluble iodine, but there is also oil and air contrast. Postprocedure interventions vary based on type of contrast medium; therefore, determine which one was used. After the procedure, bedrest is necessary for 4 to 24 hours; keep head of bed elevated for several hours. Encourage hydration. Observe for signs of meningeal irritation.
Ultrasound	Use of sound waves to locate the depth and structure within soft tissues and fluid	Assessment of spinal abnormalities	Better tolerated by nonsedated children than CT or MRI Can be performed with a portable unit at bedside
Computed tomography (CT)	Noninvasive x-ray study that looks at tissue density and structures. Images a "slice" of tissue	Evaluation of congenital abnormalities such as neural tube defects, fractures, demyelination, or inflammation	Machine is large and can be frightening to children. Procedure can be lengthy and child must remain still. If unable to do so, sedation may be necessary. If performed with contrast medium, assess for allergy. Encourage fluids after procedure if not contraindicated.
Magnetic resonance imaging (MRI)	Based on how hydrogen atoms behave in a magnetic field when disturbed by radiofrequency signals. Does not require ionizing radiation. Provides a 3D view of the body part being scanned	Assessment of inflammation, congenital abnormalities such as neural tube defects	Remove all metal objects from the child. Child must remain motionless for entire scan; parent can stay in room with child. Younger children will require sedation in order to be still. A loud thumping sound occurs inside the machine during the procedure, which can be frightening to children.
Creatine kinase	Reflects muscle damage: it leaks from muscle into plasma as muscles deteriorate.	Diagnosis of muscular dystrophy, spinal muscular atrophy	Draw sample before electromyogram or muscle biopsy, as those tests may lead to release of creatine kinase.
Electromyography	A recording electrode is placed in the skeletal muscle and electrical activity is recorded.	Differentiates muscular disorders from those that are neurologic in origin	Requires insertion of short needles into the muscles. Sedation or analgesia may be ordered.

**COMMON LABORATORY AND DIAGNOSTIC TESTS 44.1** (continued)

Test	Explanation	Indications	Nursing Implications
Nerve conduction velocity	Measures the speed of nerve conduction. Patch-like electrodes are attached to the skin at various nerve locations	Differentiation of muscular disorders	Feels like mild electric shocks
Muscle biopsy	Removal of a piece of muscular tissue either by needle or by open biopsy	Determination of type of muscular dystrophy or spinal muscular atrophy	Postbiopsy care is similar to that for other types of biopsy. Involves a small incision with one or two sutures
Dystrophin	A normal intracellular plasma membrane protein in the muscle	Determination of specific type of muscular dystrophy	Absent in Duchenne muscular dystrophy, decreased in Becker muscular dystrophy
Genetic testing	Tests for presence of the gene for the disease or for carrier status	Determination of disease or carrier status of inherited muscular disorder	Entire family should be tested, even those unaffected, because carrier status should be determined and genetic counseling related to reproduction provided.

- Urinary retention
- Constipation
- Self-care deficit (specify)
- Risk for impaired skin integrity
- Chronic sorrow
- Risk for injury
- Deficient knowledge (specify)
- Family processes, interrupted

**After completing an assessment of Fredrick, the nurse noted the following: he started walking at 2 years of age, he has difficulty jumping, his gait has a waddling appearance, and he does not rise from the floor in the usual fashion. Based on these assessment findings, what would your top three nursing diagnoses be for Fredrick?**

Nursing goals, interventions, and evaluation for the child with neuromuscular dysfunction are based on the nursing diagnoses (see Nursing Care Plan 44.1). The nursing care plan may be used as a guide in planning nursing care for the child with a neuromuscular disorder. The care plan includes many nursing diagnoses that are applicable to the child or adolescent. Children's responses to neuromuscular dysfunction and its treatment will vary, and nursing care should be individualized based on the child's and family's responses to illness; see Healthy People 2020. Additional information

**HEALTHY PEOPLE 2020****Objective**

Increase the proportion of children with special health needs who have access to a medical home.

**Nursing Significance**

- Educate the family that specialist care (though often consisting of frequent and multiple visits) does not replace primary care through the medical home.
- Encourage families to find a physician or nurse practitioner with whom they feel comfortable for well-child check-ups and routine childhood illnesses.

*Healthy People Objectives based on data from <http://www.healthypeople.gov>.*

about nursing management will be included later in the chapter as it relates to specific disorders.

**Based on your top three nursing diagnoses for Fredrick, describe appropriate nursing interventions.**

## NURSING CARE PLAN 44.1

**Overview for the Child With a Neuromuscular Disorder**

**NURSING DIAGNOSIS:** Impaired physical mobility related to muscle weakness, hypertonicity, impaired coordination, loss of muscle function or control as evidenced by an inability to move extremities, to ambulate without assistance, to move without limitations

**Outcome Identification and Evaluation**

Child will be able to engage in activities within age parameters and limits of disease: *child is able to move extremities, move about environment, and participate in exercise programs within limits of age and disease.*

**Interventions: Maximizing Physical Mobility**

- Encourage gross and fine motor activities to facilitate motor development.
- Collaborate with physical therapy, occupational therapy, and speech therapy to strengthen muscles and promote optimal mobility to facilitate motor development.
- Use passive and active range-of-motion (ROM) exercises and teach child and family how to perform them to prevent contractures, facilitate joint mobility and muscle development (active ROM), and help increase mobility.
- Praise accomplishments and emphasize child's abilities to improve self-esteem and encourage feeling of confidence and competence.

**NURSING DIAGNOSIS:** Nutrition, imbalanced, less than body requirements, related to difficulty feeding secondary to deficient sucking, swallowing, or chewing; difficulty assuming normal feeding position; inability to feed self as evidenced by decreased oral intake, impaired swallowing, weight loss, or plateau

**Outcome Identification and Evaluation**

Child will exhibit signs of adequate nutrition *as evidenced by appropriate weight gain, intake and output within normal limits, and adequate ingestion of calories.*

**Intervention: Promoting Adequate Nutrition**

- Monitor height and weight: *insufficient intake will lead to impaired growth and weight gain.*
- Monitor hydration status (moist mucous membranes, elastic skin turgor, adequate urine output): *insufficient intake can lead to dehydration.*
- Use techniques to promote caloric and nutritional intake and teach family about these techniques (e.g., positioning, modified utensils, soft or blended foods, allowing extra time) to facilitate intake.
- Assess respiratory system frequently to assess for aspiration.
- Assist family to help child assume as normal a feeding position as possible to help increase oral intake.

**NURSING DIAGNOSIS:** Urinary retention related to sensory motor impairment as evidenced by dribbling, inadequate bladder emptying

**Outcome Identification and Evaluation**

Child's bladder will empty adequately, *according to preestablished quantities and frequencies individualized for the child (usual urine output is 0.5 to 2 mL/kg/hour).*

## NURSING CARE PLAN 44.1

**Overview for the Child With a Neuromuscular Disorder** (continued)**Intervention: Promoting Successful Bladder Emptying**

- Assess child's ability to empty bladder via history focused on character and duration of lower urinary symptoms *to establish baseline*.
- Assess for history of fecal impaction or constipation, *as alterations in bowel elimination may hinder urinary elimination*.
- Assess for bladder distention by palpation or urinary retention by postvoid residual obtained via catheterization or bladder ultrasound *to determine extent of retention*.
- Maintain adequate hydration *to avoid irritating effects that dehydration has on the bladder*.
- Schedule voiding to *decrease bladder overdistention*.
- Teach the family (and the child if old enough) with significant urinary retention the technique of clean intermittent catheterization *to allow regular, complete bladder emptying*.

**NURSING DIAGNOSIS:** Risk for constipation related to immobility, loss of sensation

**Outcome Identification and Evaluation**

Child will demonstrate adequate stool passage: *will pass soft, formed stool every 1 to 3 days without straining or other adverse effects*.

**Intervention: Promoting Appropriate Bowel Elimination**

- Assess usual pattern of stooling *to determine baseline and identify potential problems with elimination*.
- Palpate for abdominal fullness and auscultate for bowel sounds *to assess for bowel function and presence of constipation*.
- Encourage fiber intake *to increase frequency of stools*.
- Ensure adequate fluid intake *to prevent formation of hard, dry stools*.
- Encourage activity within child's limits or restrictions: *even minimal activity increases peristalsis*.
- Administer medications or enemas as ordered *to promote bowel training/evacuation (especially in child with myelomeningocele or spinal cord injury)*.

**NURSING DIAGNOSIS:** Self-care deficit related to neuromuscular impairments, cognitive deficits as evidenced by an inability to perform hygiene care and transfer self independently

**Outcome Identification and Evaluation**

Child will demonstrate ability to care for self within age parameters and limits of disease: *child is able to feed, dress, and manage elimination within limits of disease and age*.

**Intervention: Maximizing Self-Care**

- Introduce child and family to self-help methods as soon as possible *to promote independence from the beginning*.
- Encourage family and staff to allow child to do as much as possible *to allow child to gain confidence and independence*.
- Teach specific measures for bowel and urinary elimination as needed *to promote independence and increase self-care abilities and self-esteem*.
- Collaborate with physical therapy, occupational therapy, and speech therapy to provide child and family with appropriate tools to modify environment and methods to promote transferring and self-care *to allow for maximum functioning*.
- Praise accomplishments and emphasize child's abilities *to improve self-esteem and encourage feelings of confidence and competence*.
- Balance activity with periods of rest *to reduce fatigue and increase energy for self-care*.

(continued)

## NURSING CARE PLAN 44.1

**Overview for the Child With a Neuromuscular Disorder** (continued)

**NURSING DIAGNOSIS:** Risk for impaired skin integrity related to immobility, use of braces or adaptive devices

**Outcome Identification and Evaluation**

Child's skin will remain intact, *without evidence of redness or breakdown.*

**Intervention: Promoting Skin Integrity**

- Monitor condition of entire skin surface at least daily *to provide baseline and allow for early identification of areas at risk.*
- Avoid excessive friction or harsh cleaning products *that may increase risk of breakdown in child with susceptible skin.*
- Keep child's skin free from stool and urine *to decrease risk of breakdown.*
- Change child's position frequently *to decrease pressure to susceptible areas.*
- Monitor skin condition affected by braces or adaptive equipment frequently *to prevent skin breakdown related to poor fit.*

**NURSING DIAGNOSIS:** Chronic sorrow related to presence of chronic disability as evidenced by child's or family's expression of sadness, anger, disappointment, or feeling overwhelmed

**Outcome Identification and Evaluation**

Child and/or family will accept situation: *child/family will appropriately identify feelings, function at a normal developmental level, and plan for the future.*

**Intervention: Easing Sorrow**

- Assess degree of sorrow *to provide baseline for intervention.*
- Identify problems with eating or sleeping, *often affected when grief or sorrow is present.*
- Spend time with the child and family: *an empathetic presence is valued by suffering families.*
- Encourage the use of positive coping techniques: *taking action, expressing feelings, and intentional attempts at coping are helpful techniques.*
- Refer to appropriate support groups: *can be helpful to talk to others in similar situations.*
- Refer for spiritual counseling as desired: *many families experience grief resolution in a more timely fashion if spiritual needs are addressed.*

**NURSING DIAGNOSIS:** Risk for injury related to muscle weakness

**Outcome identification and evaluation**

Child will remain free from injury: *child will not fall or experience other injury.*

**Intervention: Preventing Injury**

- Ensure that side rails of bed are elevated when caregiver is not directly at bedside *to prevent fall from bed.*
- Use appropriate safety restraints with adaptive equipment and wheelchairs *to prevent fall or slipping from equipment.*
- Do not leave child unattended in tub *as weakness may cause the child to slip under the water.*
- Avoid restraint use if at all possible: *close observation is more appropriate.*

## NURSING CARE PLAN 44.1

**Overview for the Child With a Neuromuscular Disorder** (continued)

**NURSING DIAGNOSIS:** Deficient knowledge related to lack of information regarding complex medical condition, prognosis, and medical needs as evidenced by verbalization, questions, or actions demonstrating lack of understanding regarding child's condition or care

**Outcome Identification and Evaluation**

Child and family will verbalize accurate information and understanding about condition, prognosis, and medical needs: *child and family demonstrate knowledge of condition and prognosis and medical needs, including possible causes, contributing factors, and treatment measures.*

**Intervention: Providing Child and Family Teaching**

- Assess child's and family's willingness to learn: *child and family must be willing to learn for teaching to be effective.*
- Provide family with time to adjust to diagnosis to *facilitate adjustment and ability to learn and participate in child's care.*
- Repeat information *to allow family and child time to learn and understand.*
- Teach in short sessions: *many short sessions are more helpful than one long session.*
- Gear teaching to the level of understanding of the child and family (depends on age of child, physical condition, memory) *to ensure understanding.*
- Provide reinforcement and rewards *to facilitate the teaching/learning process.*
- Use multiple modes of learning involving many senses (provide written, verbal, demonstration, and videos) when possible: *child and family are more likely to retain information when it is presented in different ways using many senses.*

**NURSING DIAGNOSIS:** Family processes, interrupted, related to child's illness, hospitalization, diagnosis of chronic illness in child, and potential long-term effects of illness as evidenced by family's presence in hospital, missed work, demonstration of inadequate coping

**Outcome Identification and Evaluation**

Family will maintain functional system of support and demonstrate adequate coping and adaptation of roles: *parents are involved in child's care, ask appropriate questions, express fears and concerns, and are able to discuss child's care and condition calmly.*

**Intervention: Promoting Appropriate Family Functioning**

- Encourage parents and family to verbalize concerns related to child's illness, diagnosis, and prognosis: *allows the nurse to identify concerns and areas where further education may be needed; demonstrates family-centered care.*
- Explain therapies, procedures, child's behaviors, and plan of care to parents: *understanding of the child's current status and plan of care helps decrease anxiety.*
- Encourage parental involvement in care *to allow parents to feel needed and valued and to have a sense of control over their child's health.*
- Identify support system for family and child: *support system is often needed by stressed families to assist with coping.*
- Educate family and child on additional resources available *to help them develop a wide base of support.*

## CONGENITAL NEUROMUSCULAR DISORDERS

Several disorders with neuromuscular effects are congenital in nature. These include neural tube defects and genetic neuromuscular disorders. The structural disorders are spina bifida occulta, meningocele, and myelomeningocele (neural tube defects). The genetic neuromuscular disorders include the various types of muscular dystrophy and spinal muscular atrophy. These disorders are not always recognized at birth because signs and symptoms are not evident until months or even years after birth. However, they are still considered to be congenital as they have a genetic basis.

### Neural Tube Defects

Neural tube defects account for the majority of congenital anomalies of the central nervous system. The neural tube closes between the third and fourth week of gestation. The cause of neural tube defects is not known, but many factors, such as drugs, malnutrition, chemicals, and genetics, can hinder normal central nervous system development. Strong evidence exists that maternal pre-conception supplementation of folic acid can decrease the incidence of neural tube defects in pregnancies at risk by 50% to 70% (Centers for Disease Control and Prevention, 2011; Kinsman & Johnston, 2011). Beginning in 1992 and continuing until today, the U.S. Public Health Service along with the Centers for Disease Control and Prevention (CDC) recommends that all women of child-bearing age who are capable of becoming pregnant take 0.4 mg (400 mcg) of folic acid daily (Centers for Disease Control and Prevention, 2011). Pregnant women who had a previous child with a neural tube defect are rec-

ommended to take a higher dosage and should consult with their physician or nurse practitioner (Centers for Disease Control and Prevention, 2011). Prenatal screening of maternal serum for  $\alpha$ -fetoprotein (AFP) and ultrasound examination at 16 to 18 weeks' gestation can help identify fetuses at risk. Neural tube defects primarily affecting spinal cord development include spina bifida occulta, meningocele, and myelomeningocele (Fig. 44.4). Neural tube defects primarily affecting brain development are discussed in Chapter 38.

### Spina Bifida Occulta

*Spina bifida* is a term that is often used to refer to all neural tube disorders that affect the spinal cord. This can be confusing and a cause of concern for parents. There are well-defined degrees of spinal cord involvement, and it is important for health care professionals to use the correct terminology.

Spina bifida occulta is a defect of the vertebral bodies without protrusion of the spinal cord or meninges. This defect is not visible externally and in most cases has no adverse effects (see Fig. 44.4). Spina bifida occulta is a common anomaly. It is estimated that it affects 10% to 20% of otherwise healthy people (Spina Bifida Association, 2011a). Children with spina bifida occulta need no immediate medical intervention. Complications are rare, but may include more significant abnormalities of the spinal cord such as tethered cord, syringomyelia, or diastematomyelia.

### Nursing Assessment

In most cases, spina bifida occulta is benign and asymptomatic and produces no neurologic signs. In fact, it may be considered a normal variant (Spina Bifida Association, 2011a). The defect, which is usually present in the

FIGURE 44.4 (A) Normal spine. (B) Spina bifida occulta. (C) Meningocele. (D) Myelomeningocele.

lumbosacral area, often goes undetected. However, there may be noticeable dimpling, abnormal patches of hair, or discoloration of skin at the defect site. If so, further investigation, including magnetic resonance imaging (MRI), may be warranted.

## Nursing Management

Nursing care will focus on educating the family. Inform parents of its presence and what the diagnosis means. Many times parents will confuse this diagnosis with spina bifida cystica, a much more serious defect. Occasionally, children with spina bifida occulta eventually need surgical intervention due to degenerative changes or involvement of the spine and nerve roots resulting in complications such as tethered cord, syringomyelia, or diastematomyelia. When these associated problems occur, the condition is often termed “occult spinal dysraphism” to avoid confusion.

## Meningocele

Meningocele, the less serious form of spina bifida cystica, occurs when the meninges herniate through a defect in the vertebrae. The spinal cord is usually normal and there are typically no associated neurologic deficits. Treatment for meningocele involves surgical correction of the lesion (see Fig. 44.4).

## Nursing Assessment

Initial assessment after delivery will reveal a visible external sac protruding from the spinal area. It is most often seen in the lumbar region but can be anywhere along the spinal canal. Most are covered with skin and pose no threat to the child. However, assessment to ensure that the sac covering is intact remains important. Assess neurologic status carefully. Most children will be asymptomatic, with no neurologic deficits (Kinsman & Johnston, 2011; Liptak, 2008). Before surgical correction the infant will be thoroughly examined to determine whether there is any neural involvement or associated anomalies. Diagnostic procedures such as computed tomography (CT), MRI, and ultrasound may be performed.

## Nursing Management

If the skin covering the sac is intact and the child has normal neurologic functioning, surgical correction may be delayed (Kinsman & Johnston, 2011). However, as in a child with myelomeningocele, immediately report any evidence of leaking cerebrospinal fluid (CSF) to ensure prompt intervention to prevent infection. Nursing management will be supportive. Provide preoperative and postoperative care similar to the child with myelomeningocele to prevent rupture of the sac, to prevent infection,

and to provide adequate nutrition and hydration. Monitor for symptoms of constipation or bladder dysfunction that may result due to increasing size of the lesion. Resulting hydrocephalus has been associated with some cases of meningocele (Kinsman & Johnston, 2011). Therefore, monitor head circumference and watch for signs and symptoms of increased intracranial pressure (ICP).

## Myelomeningocele

Myelomeningocele, the most severe form of neural tube defect, occurs in approximately 1 in 4,000 live births (Kinsman & Johnston, 2011). Myelomeningocele is a type of spina bifida cystica, and clinically the term “spina bifida” is often used to refer to myelomeningocele. It may be diagnosed in utero via ultrasound. Otherwise it is visually obvious at birth. The newborn with myelomeningocele is at increased risk for meningitis, hypoxia, and hemorrhage.

In myelomeningocele, the spinal cord often ends at the point of the defect, resulting in absent motor and sensory function beyond that point (see Fig. 44.5). Therefore, the long-term complications of paralysis, orthopedic deformities, and bladder and bowel incontinence are often seen in children with myelomeningocele. The presence of **neurogenic** bladder and frequent catheterization puts the child at an increased risk for urinary tract infections, pyelonephritis, and hydronephrosis, which may result in long-term renal damage if managed inappropriately. Accompanying hydrocephalus associated with type II Chiari defect is seen in 80% of children with myelomeningocele (Kinsman & Johnston, 2011). Due to the improper development and the downward displacement of the brain into the cervical spine, CSF flow is blocked, resulting in hydrocephalus. The lower the deformity is on the spine, the lower the risk of developing hydrocephalus (Kinsman & Johnston, 2011).

Children with myelomeningocele usually require multiple surgical procedures. In addition, due to frequent catheterizations, these children are at an increased

**FIGURE 44.5** Usually a sac covers the deformity of myelomeningocele and is visible at birth.

risk of developing a latex allergy (Kinsman & Johnston, 2011; Zak & Chan, 2010). Learning problems and seizures are more common in these children than in the general population, but 70% of those surviving with myelomeningocele have normal intelligence (Kinsman & Johnston, 2011). Ambulation is possible for some children, depending on the level of the lesion. Due to advances in medical treatment the life expectancy of children with this disorder has increased. For children born with a myelomeningocele who receive aggressive treatment, the mortality rate is 10% to 15%; most deaths occur before the age of 4 years (Kinsman & Johnston, 2011).

## Pathophysiology

The cause of myelomeningocele is unknown, but risk factors are consistent with other neural tube defects, such as maternal drug use, malnutrition, and a genetic predisposition (Kinsman & Johnston, 2011). In myelomeningocele, the neural tube fails to close at the end of the fourth week of gestation. As a result, an external sac-like protrusion that encases the meninges, spinal fluid, and in some cases nerves is present on the spine (see Fig. 44.4). A myelomeningocele can be located anywhere along the spinal cord, but 75% are located in the lumbosacral region (Kinsman & Johnston, 2011). The degree of neurologic deficit will depend on the location (Kinsman & Johnston, 2011). An increase in neurologic deficit is seen as the myelomeningocele extends into the thoracic region.

## Therapeutic Management

Surgical closure will be performed as soon as possible after birth, especially if a CSF leak is present or if there is a danger of the sac rupturing. The goal of early surgical intervention is to prevent infection and to minimize further loss of function, which can result from the stretching of nerve roots as the meningeal sac expands after birth. A new option is becoming available but remains experimental. In utero fetal surgery to repair the myelomeningocele has been performed in the United States, with the first randomized trial showing improved outcomes for the fetuses compared to postnatal surgery (Robinson, 2011). Ongoing management of this disorder remains complex. A multidisciplinary approach is needed, involving specialists in neurology, neurosurgery, urology, orthopedics, therapy, and rehabilitation along with intense nursing care. The chronic nature of this disorder necessitates lifelong follow-up.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1592. Assessment findings pertinent to myelomeningocele are discussed below.

## Health History

High-risk deliveries should be identified. Explore the pregnancy history and past medical history for risk factors such as:

- Lack of prenatal care
- Lack of preconception and/or prenatal folic acid supplementation
- Previous child born with neural tube defect or family history of neural tube defects
- Maternal consumption of certain drugs that antagonize folic acid, such as anticonvulsants (carbamazepine and phenobarbital)

The older infant or child with a history of myelomeningocele requires numerous surgical procedures and lifelong follow-up. In an infant or child returning for a clinic visit or hospitalization, the health history should include questions related to:

- Current mobility status and any changes in motor abilities
- Genitourinary function and regimen
- Bowel function and regimen
- Signs or symptoms of urinary infections
- History of hydrocephalus with presence of shunt
- Signs or symptoms of shunt infection or malfunction (refer to section on hydrocephalus in Chapter 38)
- Latex sensitivity
- Nutritional status, including changes in weight
- Any other changes in physical or cognitive state
- Resources available and used by the family

## Physical Examination

Initial assessment after delivery will reveal a visible external sac protruding from the spinal area (Fig. 44.5). Observe the baby's general appearance and assess whether the sac covering is intact. Assess neurologic status and look for associated anomalies. Assess for movement of extremities and anal reflex, which will help determine the level of neurologic involvement. Flaccid paralysis, absence of deep tendon reflexes, lack of response to touch and pain stimuli, skeletal abnormalities such as club feet, constant dribbling of urine, and a relaxed anal sphincter may be found.

In the older infant or child, perform a thorough physical examination and focus on the functional assessment. Note the level of paralysis or paresthesia. Inspect skin for breakdown. Determine the child's motor capabilities.

## Laboratory and Diagnostic Tests

A myelomeningocele may be detected prenatally around 16 to 18 weeks' gestation by ultrasound, by a blood test that detects AFP increases, or by analysis of amniotic fluid for AFP increases. Common laboratory and diagnostic studies ordered for the assessment of myelomeningocele include:

- MRI
- CT

- Ultrasound
- Myelography

These diagnostic tests are used to evaluate brain and spinal cord involvement (refer to Common Laboratory and Diagnostic Tests 44.1).

## Nursing Management

Initial nursing management of the child with myelomeningocele involves preventing trauma to the meningeal sac and preventing infection before surgical repair of the defect. Refer to the Nursing Care Plan Overview in this chapter. Additional considerations are reviewed below.

### Preventing Infection

Risk for infection related to the presence of the meningeal sac and potential for rupture is a central nursing concern in the newborn with myelomeningocele. Until surgical intervention occurs, the goal is to prevent rupture or leakage of CSF from the sac. Keeping the sac from drying out is important, as is preventing trauma or pressure on the sac. Use sterile saline-soaked nonadhesive gauze or antibiotic-soaked gauze to keep the sac moist. Immediately report any seepage of clear fluid from the lesion, as this could indicate an opening in the sac and provide a portal of entry for microorganisms. Position the infant in the prone position or supported on the side to avoid pressure on the sac. To keep the infant warm, place the infant in a warmer or isolette to avoid the use of blankets, which could exert too much pressure on the sac. Pay special attention while the infant is in a warmer or isolette because the radiant heat can cause drying and cracking of the sac.

Keep the lesion free of feces and urine to help avoid infection. Position the infant so that urine and feces flow away from the sac (e.g., prone position, or place a folded towel under the abdomen) to help prevent infection. Placing a piece of plastic wrap below the meningocele is another way of preventing feces from coming into contact with the lesion. After surgery, position the infant in the prone or side-lying position to allow the incision to heal. Continue with precautions to prevent urine or feces from coming into contact with the incision.

### Promoting Urinary Elimination

Children with myelomeningocele often have bladder incontinence, though some children may achieve normal urinary continence. The level of the lesion will influence the amount of dysfunction. Myelomeningocele remains one of the most common causes of neurogenic bladder in children. Therefore, evaluation of renal function by a

pediatric urologist should be performed on each child with myelomeningocele.

Neurogenic bladder refers to the failure of the bladder to either store urine or empty itself of urine. Children with neurogenic bladder have loss of control over voiding. The spastic type of neurogenic bladder is hyperreflexive and yields frequent release of urine, but with incomplete emptying. The hypotonic neurogenic bladder is flaccid and weak and becomes stretched out; it can hold very large amounts of urine, resulting in continuous dribbling of urine from the urethra. Urinary stasis and retention occur in both types, placing the child at risk for urinary tract infection as well as reflux of bladder contents back up into the ureters and kidneys, resulting in renal scarring and insufficiency.

The goals of neurogenic bladder management are to promote optimal urinary continence and prevent renal complications. Interventions for neurogenic bladder include clean intermittent catheterization to promote bladder emptying; medications such as oxybutynin chloride (Ditropan) to improve bladder capacity; prompt recognition and treatment of infections; and in some children surgical interventions such as a continent urinary reservoir or vesicostomy to facilitate urinary elimination. Clean intermittent catheterization is addressed below. In the child with a spastic or rigid bladder, teach parents how to administer antispasmodic medications such as oxybutynin. Teach the parents that the medication is used to increase the bladder capacity and reduce the potential for reflux. Refer to Chapter 43 for additional information on nursing care related to the surgical procedures.

### ASSESSING URINARY FUNCTION

Determine the child's pattern and success of toilet training, both for bladder and bowel. Assess the child's cognitive/developmental level. Observe the genital area for dribbling of urine from the urethra, noting odor of urine if present. Note redness of the urethra or excoriation in the diaper area. Inspect the abdomen for scars from prior surgeries and the presence of urinary diversion or continent stoma. Palpate the abdomen for presence of distended bladder, fecal mass, or enlarged kidneys. Determine the child's level of paralysis or paresthesia.

### PERFORMING CLEAN INTERMITTENT CATHETERIZATION

Depending on the level of paralysis at birth in the child with myelomeningocele, clean intermittent catheterization may be started at that time. In other children with spina bifida and in children who suffer spinal cord injury, catheterization may be started at a later age. Teach parents the technique of clean intermittent catheterization via the urethra, unless a urinary diversion or continent stoma has been created (Teaching Guidelines 44.1).

## Teaching Guidelines 44.1

### CLEAN INTERMITTENT CATHETERIZATION

- Wash hands with soap and water or use waterless antibacterial cleanser.
- Have supplies within reach and place child on his or her back, on toilet, or in wheelchair.
- Clean genitalia with a washcloth or disposable wipe (on girls separate labia and wipe front to back; on boys clean the tip of the penis; if uncircumcised, pull back foreskin so tip of penis is visible).
- Apply generous amount of water-based lubricant to catheter.
- Perform catheterization. Insert catheter only as far as needed to obtain urine flow (about 2 to 3 inches for females, about 4 to 6 inches for males). Hold catheter there until urine flow stops. Move catheter slightly, press on lower abdomen, or have child lean forward to tense abdominals to ensure no more urine is in the bladder.
- Wash reusable catheter after use with soapy water inside and out; rinse well (a syringe can be used to flush the catheter) and allow to dry.
- When dry, store in zip-top plastic bag or other clean storage container.
- Sterilize daily (time frames and procedure may vary based on institution policy and procedures); soak the catheter in a 1:1 vinegar and water solution for about 30 minutes, rinsing well before next use, or place the catheter in boiling water for 10 minutes. Allow to dry very well before storing.
- Replace the catheter when it becomes cloudy, stiff, rough, cracked, or damaged.
- Teach the child to self-catheterize when he or she is developmentally ready.

Adapted from Bozic, D., & Daniels, C. (2009). *AboutKidsHealth clean intermittent catheterization (CIC): Step by step instructions for boys*. Retrieved July 12, 2012, from <http://www.aboutkidshealth.ca/en/healthaz/testsandtreatments/medicaldevices/pages/clean-intermittent-catheterization-cic-step-by-step-instructions-for-boys.aspx>

Teaching the parents the techniques of clean intermittent catheterization is an important step in preserving renal functioning, preventing infection, and helping the family gain some control over the child's physical condition. Until the child is able to self-catheterize, the parents will be responsible for this procedure. Children with normal intelligence and upper extremity motor skills usually learn to self-catheterize at the age of 6 or 7 years (Zak & Chan, 2010). Educating the child to self-catheterize the urethra or stoma as appropriate empowers the child, gives him or her a sense of control, and allows for appropriate urinary elimination when the

child is away from the parents (e.g., at school). See Evidence-Based Practice 44.1.

Offer support and appropriate referrals to the child and family. Refer families to vendors in the local area for catheterization supplies.

### Promoting Bowel Elimination

Children with myelomeningocele often have bowel incontinence as well; the level of the lesion affects the amount of dysfunction. Many children with myelomeningocele can achieve some degree of bowel continence. Bowel training with the use of timed enemas or suppositories along with diet modifications can allow for defecation at predetermined times once or twice a day. Although bowel incontinence can be difficult for children as they grow older due to social concerns and self-esteem and body image disturbances, it does not pose the same health risks as urinary incontinence.

#### Take Note!

Use only latex-free catheters and gloves for catheterization of children with myelomeningocele and/or neurogenic bladder, as these children exhibit a high incidence of latex allergy (Zak & Chan, 2010).

### Promoting Adequate Nutrition

The risk for altered nutrition, less than body requirements, related to the restrictions on positioning of the infant before and after surgery is another nursing concern. Assist the family in assuming as normal a feeding position as possible. Preoperatively, the risk of rupture may be too high to warrant holding. Therefore, the infant's head can be turned to the side or the infant can be placed in the side-lying position to facilitate feeding. If the infant is held, special care needs to be taken to avoid pressure on the sac or postoperative incision. Encourage the parents to interact as much as possible with the infant by talking to and touching the infant during feeding to help promote intake. If the mother was planning on breastfeeding the infant, assist her in meeting this goal, if possible. If the infant can be held, encourage her to do this, or assist her in pumping and saving breast milk to be given to the infant via bottle until the infant is able to be held. Feeding an infant in an unusual position can be difficult, and it is the nurse's role to provide support, education, and modeling for the parents and family when needed.

### Preventing Latex Allergic Reaction

Sensitivity to latex or natural rubber is very common among children with myelomeningocele. They are at an increased risk of developing an allergy to latex related to the multiple exposures to latex products during surgical

**EVIDENCE-BASED PRACTICE 44.1****SELF-INTERMITTENT CATHETERIZATION AMONG FEMALE CHILDREN WITH MYELOMENINGOCELE AND THE POTENTIAL FOR INCREASED COMPLICATIONS****STUDY**

The authors reviewed the medical records of 31 females with myelomeningocele followed from the start of clean intermittent catheterization (CIC). Between all subjects, CIC was used for 459 patient-years. In all cases, the girls used noncoated polyvinyl chloride catheters.

**Findings**

Over the total 459 patient-years, 13 females experienced a total of 20 episodes of complications among them. These included hematuria, urethral polyps, and difficulties in

catheterization. Complications were increased if assisted CIC was used or if a smaller-bore catheter was utilized.

**Nursing Implications**

There are few complications occurring in females with myelomeningocele who self-catheterize using clean technique. Encourage the use of large-size noncoated polyvinyl catheters. Teach females when developmentally capable to perform self-CIC. This function is safe and yields greater independence in this special population.

Adapted from Lindehall, B., Abrahamsson, K., Jodal, U., Olsson, I., & Sillen, U. (2007). Complications of clean intermittent catheterization in young females with myelomeningocele: 10 to 19 years of followup. *Journal of Urology*, 178(3), 1053–1055.

procedures and bladder catheterizations. Research has shown that up to 73% of children who require repeat surgeries due to spina bifida are sensitive to latex (Spina Bifida Association, 2011b). A latex-free environment should be created for all procedures performed on children with myelomeningocele to prevent latex allergy. Also, children with a known latex allergy must be identified and managed in a latex-free environment. The nurse must ensure that these children do not come into direct contact with latex or equipment and supplies that contain latex. Be familiar with those products and equipment at your facility that contain latex and those that are latex-free. The Food and Drug Administration (FDA) now requires that all medical supplies be labeled if they contain latex (FDA Talk Paper, 1997), but this is not the case for consumer products. Many resources exist that list products that are latex-free, and each hospital should have such a list readily available to health care professionals. For an updated list of latex-containing products and other helpful information for parents regarding consumer products, contact the Spina Bifida Association of America, a link to which can be found on [thePoint](#).

Children who are at a high risk for latex sensitivity should wear medical alert identification. Education programs regarding latex sensitivity and ways to prevent it need to be directed at those who care for high-risk children, including teachers, school nurses, relatives, babysitters, and all health care professionals.

**Maintaining Skin Integrity**

Address the risk for altered skin integrity related to the infant's prone position and impaired mobility. The prone position puts constant pressure on the knees and elbows, and it may be difficult to keep the infant clean of urine

and feces. Diapering may be contraindicated preoperatively to avoid pressure on the sac. Therefore, ensure that the infant is kept as clean and dry as possible. This is made more difficult by the constant dribbling of stool and urine that may be present. Placing a pad beneath the diaper area and changing it frequently is important. Perform meticulous skin care. Place the infant on a special care mattress and place synthetic sheepskin under the infant to help reduce friction. Special attention to the infant's legs needs to occur when positioning them, since paralysis may be present. Using a folded diaper between the legs can help reduce pressure and friction from the legs rubbing together.

**Educating and Supporting the Child and Family**

Myelomeningocele is a serious disorder that affects multiple body systems and produces varying degrees of deficits. It is a disorder that has lifelong effects. Thanks to medical advances and technology most children born with myelomeningocele can expect to live a normal life, but challenges remain for the family and child as they learn to cope and live with this physical condition. Adjusting to the demands this condition places on the child and family is difficult. Parents may need time to accept their infant's condition, but as soon as possible they should be involved in the infant's care.

Teaching should begin immediately in the hospital. Teaching should include positioning, preventing infection, feeding, promoting urinary elimination through clean intermittent catheterization, preventing latex allergy, and identifying the signs and symptoms of complications such as increased ICP. Due to the chronic nature of this condition, long-term

planning needs to begin in the hospital. These children usually require multiple surgical procedures and hospitalizations, and this can place stress on the family and their finances. The nurse has an important role in providing ongoing education about the illness and its treatments and the plan of care. As the family becomes more comfortable with the condition, they will become the experts in the child's care. Respect and recognize the family's changing needs. Providing intense daily care can take its toll on a family, and continual support and encouragement are needed. Referral to the Spina Bifida Association and a local support group for families of children with myelomeningocele is appropriate. See Healthy People 2020.

### HEALTHY PEOPLE 2020

#### Objective

Increase the proportion of children and youth with disabilities who spend at least 80% of their time in regular education programs.

#### Nursing Significance

- Become familiar with local schools' offerings and capabilities so that you can refer families to an educational site appropriate for their child.

*Healthy People Objectives based on data from <http://www.healthypeople.gov>.*

### Consider This

Turner Wilson was just born with an obvious defect on his spine. Upon assessment, the nurse notes flaccid extremities and a distended bladder. The parents are devastated.

Identify additional assessments the nurse should make.

Describe nursing care for this neonate.

What teaching will the nurse do with this infant's family?

## Muscular Dystrophy

Muscular **dystrophy** refers to a group of inherited conditions that result in progressive muscle weakness and wasting. The muscles affected are primarily the skeletal (voluntary) muscles. Nine types of muscular dystrophy exist. All include muscle weakness over the lifetime; it is progressive in all cases but more severe

in others. The various muscular dystrophies are most often diagnosed in childhood and affect a variety of muscle groups. The inheritance pattern for muscular dystrophy differs for each type but may be X-linked, autosomal dominant, or recessive. The genetic mutation in muscular dystrophy results in absence or decrease of a specific muscle protein that prevents normal function of the muscle. The skeletal muscle fibers are affected, yet there are no structural abnormalities in the spinal cord or the peripheral nerves. Table 44.1 gives specifics related to the various types of muscular dystrophy.

Duchenne muscular dystrophy, the most common neuromuscular disorder of childhood, is universally fatal (usually by age 20 to 25) (Sarnat, 2011; Zak & Chan, 2010). The incidence is about 1 in 3,600 live male births (Sarnat, 2011). For these reasons, this discussion will focus on Duchenne muscular dystrophy.

## Pathophysiology

The gene mutation in Duchenne muscular dystrophy results in the absence of dystrophin, a protein that is critical for maintenance of muscle cells. The gene is X-linked recessive, meaning that mainly boys are affected and they receive the gene from their mothers (women are carriers but have no symptoms). Absence of dystrophin leads to generalized weakness of voluntary muscles, and the weakness progresses over time. The hips, thighs, pelvis, and shoulders are affected initially; as the disease progresses, all voluntary muscles as well as cardiac and respiratory muscles are affected. Rarely, males with Duchenne muscular dystrophy may survive beyond the early 30s (Muscular Dystrophy Association, 2009b).

Boys with Duchenne muscular dystrophy are often late in learning to walk. As toddlers, they may display pseudohypertrophy (enlarged appearance) of the calves. During the preschool years they fall often and are quite clumsy. The affected child has difficulty climbing stairs and running and cannot get up from the floor in the usual fashion. The school-age child walks on the toes or balls of the feet with a rolling or waddling gait. Balance is disturbed significantly, and the child's belly may stick out when the shoulders are pulled back to stay upright and keep from falling over. During the school-age years it also becomes difficult for the child to raise his or her arms. Sometime between the ages of 7 and 12 years nearly all boys with Duchenne muscular dystrophy lose the ability to ambulate, and by the teen years any activity of the arms, legs, or trunk requires assistance or support (Muscular Dystrophy Association, 2009b). Most boys with Duchenne muscular dystrophy have normal intelligence, but many may exhibit a specific learning disability (Sarnat, 2011).

TABLE 44.1

## TYPES OF MUSCULAR DYSTROPHY

Type	Onset	Inheritance	Muscle Involvement
Duchenne (pseudohypertrophic)	Early childhood (usually 3 to 6 years)	X-linked recessive	Generalized weakness, muscle wasting; limb and trunk first
Becker	Adolescence or adulthood	X-linked recessive	Similar but less severe than Duchenne
Congenital	At birth	Autosomal dominant or recessive	Generalized muscular weakness, possible joint deformities
Emery-Dreifuss	Childhood to early teens (usually by 10 years)	X-linked recessive or autosomal dominant	Weakness, wasting of shoulder, upper arm, and shin muscles
Limb-girdle	Childhood to middle age	Autosomal dominant or recessive	Weakness, wasting of shoulder and pelvic girdles first
Facioscapulohumeral	Childhood to early adulthood (usually by age 20)	Autosomal dominant	Facial muscles weaken first, then shoulders and upper arms
Myotonic	Teen or adult years	Autosomal dominant	Generalized weakness, wasting of face, feet, hands, and neck first Delayed relaxation of muscles after contraction
Oculopharyngeal	Early adulthood to middle age	Autosomal dominant or recessive	Affects muscles of eyelid and throat first
Distal	Childhood to adult	Autosomal dominant or recessive	Weakness, wasting of hand, forearm, lower leg muscles

Adapted from Zak, M., & Chan, V. W. (2010). Pediatric neurologic disorders. In S. M. Nettina (Ed.), *Lippincott manual of nursing practice* (9th ed., pp. 1543–1573). Philadelphia: Lippincott Williams & Wilkins; and Muscular Dystrophy Association. (2011a). *MUSCULAR DYSTROPHIES: Duchenne muscular dystrophy (DMD) (also known as pseudohypertrophic); Becker muscular dystrophy (BMD); congenital muscular dystrophy (CMD); Emery-Dreifuss muscular dystrophy (EDMD); limb-girdle muscular dystrophy (LGMD); facioscapulohumeral muscular dystrophy (FSH or FSHD) (also known as Landouzy-Dejerine); myotonic dystrophy (MMD) (also known as DM or Steinert disease); oculopharyngeal muscular dystrophy (OPMD); distal muscular dystrophy (DD) (Miyoshi)*. Retrieved June 28, 2011, from <http://www.mdaua.org/disease/>

## Therapeutic Management

There is no cure for Duchenne muscular dystrophy. However, the use of corticosteroids may slow the progression of the disease (Muscular Dystrophy Association, 2009b; Sarnat, 2011; Zak & Chan, 2010). It is thought that prednisone helps by protecting muscle fibers from damage to the sarcolemma (defective in the absence of dystrophin). Numerous studies have shown that boys treated with prednisone demonstrate improved strength and function. The side effects of corticosteroids are many, including weight gain, osteoporosis, and mood changes (Palmieria & Sblendorio, 2007; Sarnat, 2011). Calcium supplements are prescribed to prevent osteoporosis, and antidepressants may be helpful when depression occurs related to the chronicity of the disease and/or as an effect of corticosteroid use (Muscular Dystrophy Association, 2009b); see Healthy People 2020. Braces or orthoses and mobility and positioning aids are necessary.

## HEALTHY PEOPLE 2020

### Objective

Reduce the proportion of children and adolescents with disabilities who are reported to be sad, unhappy, or depressed.

### Nursing Significance

- Use every encounter with the child or adolescent with a disability as an opportunity to screen for mental health concerns.
- Refer these children and teens as appropriate for mental health assessment and intervention.

*Healthy People Objectives based on data from <http://www.healthypeople.gov>.*

### Take Note!

Gene therapy clinical trials for the treatment of Duchenne muscular dystrophy are in progress (Muscular Dystrophy Association, 2009b; Muscular Dystrophy Association, 2011b).

As the muscles deteriorate, joints may become fixated, resulting in **contractures**. Contractures restrict flexibility and mobility and cause discomfort. Sometimes contractures require surgical tendon release. Spinal curvatures result over time. The boy with Duchenne muscular dystrophy who can still walk may develop lordosis. More frequently, scoliosis or kyphosis develops with this disorder. Surgical spinal fixation with rod implantation is often required by adolescence (Muscular Dystrophy Association, 2009b). Additional complications include pulmonary, urinary, or systemic infections; depression; learning or behavioral disorders; aspiration pneumonia (as oropharyngeal muscles become affected); cardiac dysrhythmias; and, eventually, respiratory insufficiency and failure (as weakness of the chest muscles and diaphragm progresses).

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1592. Assessment findings pertinent to Duchenne muscular dystrophy are discussed below.

### Health History

Examine the health history for a family history of neuromuscular disorders. Note pregnancy and delivery history, as this information may be useful in ruling out a pregnancy problem or birth trauma as a cause for the motor dysfunction. Determine status of developmental milestone achievement. Boys with Duchenne muscular dystrophy learn to walk but over time become unable to do so. If the child was previously diagnosed with muscular dystrophy, determine progression of disease. Inquire about functional status and need for assistive or adaptive equipment such as braces or wheelchairs. Determine skills related to activities of daily living. Note history of cough or frequent respiratory infections, which occur as the respiratory muscles weaken. While talking with the child and family, determine whether psychosocial issues such as decreased self-esteem, depression, alterations in socialization, or altered family processes might be present.

### Physical Examination

Perform a thorough physical examination on the child with suspected muscular dystrophy or the child with known history of the disorder. Particular findings related to inspection, observation, auscultation, and palpation are presented below.

## INSPECTION AND OBSERVATION

Observe the child's ability to rise from the floor. A hallmark finding of Duchenne muscular dystrophy is the presence of the Gowers sign: the child cannot rise from the floor in standard fashion because of increasing weakness (Fig. 44.6). Observe the child's gait. Determine effectiveness of cough.

## AUSCULTATION AND PALPATION

Auscultate the heart and lungs. Note tachycardia, which develops as the heart muscle weakens. Note adequacy of breath sounds, which may diminish with decreasing respiratory function. Note muscle strength with resistance testing. Palpate muscle tone.

## Laboratory and Diagnostic Tests

Electromyography (EMG) demonstrates that the problem lies in the muscles, not in the nerves. Serum creatine kinase levels are elevated early in the disorder, when significant muscle wasting is actively occurring. Muscle biopsy provides definitive diagnosis, demonstrating the absence of dystrophin. DNA testing reveals the presence of the gene.

## Nursing Management

Nursing management is aimed at promoting mobility, maintaining cardiopulmonary function, preventing complications, and maximizing quality of life. Interventions directed at maintaining mobility and cardiopulmonary function also help to prevent complications. Refer to Nursing Care Plan 44.1, and individualize nursing care based on the child's and family's response to the illness. Additional specifics related to care of the child with muscular dystrophy are discussed below.

### Promoting Mobility

Administer corticosteroids and calcium supplements as ordered. Encourage at least minimal weight bearing in a standing position to promote improved circulation, healthier bones, and a straight spine. Boys with Duchenne muscular dystrophy may use a standing walker or standing frame to maintain an upright position. Perform passive stretching or strengthening exercises as recommended by the physical therapist. These exercises preserve mobility and may help to prevent muscle atrophy. Use orthotic supports such as hand braces or ankle-foot orthoses (AFOs) to prevent contractures of joints. Schedule activities during the part of the day when the child has the most energy. Teach parents the use of positioning, exercises, orthoses, and adaptive equipment.

**FIGURE 44.6** The Gower sign. **(A)** First the child must roll onto his hands and knees. **(B)** Then he must bear weight by using his hands to support some of his weight, while raising his posterior. **(C–E)** The boy then uses his hands to “walk” up his legs to assume an upright position.

### Maintaining Cardiopulmonary Function

Assess respiratory rate, depth of respirations, and work of breathing. Auscultate the lungs to determine whether aeration is sufficient and to assess clarity of breath sounds. Position the child for maximum chest expansion, usually in the upright position. Teach the child and family deep-breathing exercises to strengthen or maintain respiratory muscles and encourage coughing to clear the airways. Perform chest physical therapy or assist with

chest percussion. Monitor the results of pulmonary function testing. Use of intermittent positive-pressure ventilation and mechanically assisted coughing will become necessary in the teen years for some boys, possibly later for others. Teach parents monitoring of respiratory status and use of these modalities in conjunction with the respiratory therapist. Monitor cardiac status closely to identify heart failure early. Assess for edema, weight gain, or crackles. Strictly monitor fluid intake and output.

### Maximizing Quality of Life

Long periods of bed rest may contribute to further weakness. Work with the family and child to develop a schedule for diversional activities that provide appropriate developmental stimulation but avoid overexertion or frustration (related to inability to perform the activity). Periods of adequate rest must be balanced with activities. Walking or riding a stationary bike is appropriate for the child who has upper extremity involvement. For the child with lower extremity involvement, a wheelchair may become necessary for mobility, and the child may participate in crafts, drawing, and computer activities. Participating in the Special Olympics may be appropriate for some children. Visit [thePoint\\*](#) for a link to the Special Olympics website. Do not place limits on the child but encourage activities he or she is interested in that can be modified as needed to fit his or her abilities.

Provide emotional support to the child and family. Long-term direct care is stressful for families and becomes more complex as the child gets older. Families often need respite from continual caregiving duties. When a child is hospitalized, the caregiver may feel comfortable allowing nurses and other health care professionals to assume more of the child’s daily care; this can be an opportunity for the caregiver to obtain respite from daily care. Respite care may also be offered in the home by various community services, so explore these resources with families.

Assess the child’s educational status. Some children attend school; others may opt for home schooling. Administer antidepressants as ordered; managing depression may

increase the child’s desire to participate in activities and self-care. Refer the child and family to the Muscular Dystrophy Association (a link to which is located on [thePoint\\*](#)), which provides multidisciplinary care via clinics located throughout the United States. The association is also a clearinghouse for resources for individuals with muscular dystrophy. Ensure that families receive genetic counseling for family planning purposes as well as determining which family members may be carriers for muscular dystrophy.

### Spinal Muscular Atrophy

Spinal muscular atrophy (SMA) is a genetic motor neuron disease that affects the spinal nerves’ ability to communicate with the muscles. It is inherited via an autosomal recessive mechanism. The motor neuron protein SMN (survival of motor neurons) is deficient as a result of a faulty gene on chromosome 5. The motor neurons are located mostly in the spinal cord. Without adequate SMN, the signals from the neurons to the muscles instructing them to contract are ineffective, so the muscles lose function and over time atrophy. The proximal muscles, those closer to the body’s center, are usually more affected than the distal muscles. Emotional and mental development as well as sensation are unaffected by the disease (Muscular Dystrophy Association, 2009c).

There are several types of SMA, including type 1 (Werdnig-Hoffmann disease, infantile SMA), type 2 (intermediate), and type 3 (Kugelberg-Welander disease or juvenile SMA). Their usual progression and prognosis are compared in Table 44.2.

**TABLE 44.2** FEATURES OF SPINAL MUSCULAR ATROPHY

Features	Type 1 SMA (Werdnig-Hoffman Disease, Infantile SMA)	Type 2 SMA (Intermediate SMA)	Type 3 SMA (Kugelberg-Welander Disease, Juvenile SMA)
Onset	Before birth to 6 months of age	6 to 18 months of age	After 18 months of age; child has started walking or has taken at least five independent steps
Symptoms	<ul style="list-style-type: none"> <li>• Generalized weakness; cannot sit without support</li> <li>• Weak cry</li> <li>• Difficulty sucking, swallowing, and breathing</li> </ul>	<ul style="list-style-type: none"> <li>• Proximal muscles are more affected; i.e., thighs are weaker than lower legs; legs tend to be weaker than arms.</li> <li>• Respiratory muscles may be involved.</li> <li>• Scoliosis may occur.</li> </ul>	<ul style="list-style-type: none"> <li>• Weakness that is most severe in the shoulders, hips, thighs, and upper back</li> <li>• Respiratory muscles may be involved.</li> <li>• Scoliosis may occur.</li> </ul>
Progression	Rapidly progresses to early childhood death. Use of ventilators and gastrostomy feeding tubes may prolong life expectancy.	Slower progression. Survival into adulthood common if respiratory status maintained appropriately	Slow progression. Life span usually unaffected. Walking ability maintained until at least adolescence; may need wheelchair later in life

Adapted from Muscular Dystrophy Association. (2009c). *Facts about spinal muscular atrophy (SMA)*. Retrieved July 12, 2012, from <http://www.mda.org/publications/PDFs/FA-SMA.pdf>

Respiratory muscle weakness may occur with all types of SMA and is usually the cause of death in type 1 and type 2 SMA (Muscular Dystrophy Association, 2009c). The increasing availability of more effective and more portable ventilation devices has led to some children with SMA living many years more than expected; some children even live into their teenage years (Muscular Dystrophy Association, 2009c). Upper respiratory tract infections and aspiration related to dysphagia or gastroesophageal reflux often develop into pneumonia and eventual respiratory failure, as the affected child cannot effectively cough independently in order to clear the airway. Many children with severe type 1 SMA are ventilator dependent. Pectus excavatum develops in children with type 1 and 2 SMA who exhibit paradoxical breathing (use of the diaphragm without intercostal muscle support). The chest becomes funnel shaped and the xiphoid process is retracted (pectus excavatum), further restricting respiratory development. Inability to appropriately suck and swallow leads to difficulty feeding in the child with type 1 SMA. Weak back muscles affect the developing spine, resulting in the complication of scoliosis, kyphosis, or both.

Therapeutic management of SMA is supportive, aimed at promoting mobility, maintaining adequate nutrition and pulmonary function, and preventing complications. Spinal fusion may be performed in older children with significant scoliosis. Supplementation with creatine and/or coenzyme Q10 is under investigation (Muscular Dystrophy Association, 2009c).

Since the discovery of the disease-causing gene for SMA, further research and improved diagnostic techniques have occurred. The Spinal Muscular Atrophy Project is a National Institute of Neurological Disorders and Stroke (NINDS)–funded collaborative program focused on the development of drug therapies, potential leads for further drug discovery, and clinical testing (NINDS, 2011d). The International Standard of Care Committee for SMA published guidelines for care of the child with SMA in 2007 due to the wide variation of care and clinical outcomes seen in children with SMA (Wang et al., 2007). The guidelines discussed diagnostic testing and care of the child with newly diagnosed SMA, consensus on pulmonary care, consensus on gastrointestinal and nutritional care, consensus on orthopedic care, and rehabilitation and palliative care issues (Wang et al., 2007).

## Nursing Assessment

Note history of attainment of developmental milestones, as well as loss of milestones. SMA should be suspected in a child showing symmetric weakness that is more proximal than distal and greater in the legs than arms, diminished or absent tendon reflexes, and preserved sensation (Wang et al., 2007). In the infant or child with known SMA, assess for recent hospitalizations or respiratory illness. Determine the respiratory support

**FIGURE 44.7** Note the very narrow chest, beginning xiphoid depression, and relatively enlarged appearance of the abdomen in this infant with type 1 spinal muscular atrophy (SMA).

regimen used at home (if any). Note level of motor ability, and identify the orthoses or adaptive equipment used. Elicit history related to feeding patterns at home. Assess for floppy appearance in the infant with SMA. Note decreased ability to initiate spontaneous muscle movement. In the infant or young child with SMA, note narrow chest with decreased excursion, relatively protuberant abdomen, and paradoxical breathing pattern (Fig. 44.7). Observe the chest for formation of pectus excavatum. Auscultate the lungs for diminished or adventitious breath sounds. Monitor laboratory testing, which may include:

- Creatine kinase (CK): elevated when muscular damage is occurring
- Genetic testing: identifies presence of gene for SMA
- Muscle biopsy: shows the muscle abnormality
- Nerve conduction velocity test and electromyogram: to determine extent of involvement

## Nursing Management

Nursing management of type 2 and type 3 SMA focuses on promoting mobility, maintaining pulmonary function, and preventing complications. Children with type 1 SMA need additional interventions related to prevention of complications from immobility and assistance with nutrition. Refer to Nursing Care Plan 44.1 for interventions related to these areas. Individualize the nursing plan of care based on the individual child's responses to the disorder.

**FIGURE 44.8** Use of noninvasive positive-pressure monitoring via a mask can maximize respiration and may help prevent pulmonary complications.

Promote mobility through the use of range-of-motion exercises, lightweight orthotics, standing frames, and wheelchair use as appropriate. Support parents in their efforts to comply with physical and occupational therapy regimens. Older children may exercise with assistance in a warm pool. Position the child in a fashion that maintains appropriate body alignment.

Provide airway clearance techniques such as manual or mechanical cough assistance, chest percussion, and postural drainage to assist with clearance of secretions. In collaboration with respiratory therapy, teach families the use of noninvasive ventilation support, in which positive pressure is delivered to the lungs through a mask or mouthpiece (Fig. 44.8). Provide routine tracheostomy care if the child has a tracheostomy (refer to tracheostomy section of Chapter 40).

Administer gastrostomy tube feedings if ordered, and teach families gastrostomy tube care. Use bracing as prescribed to prevent spinal curvature. Make frequent inspections for skin breakdown in areas affected by bracing.

## Cerebral Palsy

Cerebral palsy is a term used to describe a range of non-specific clinical symptoms characterized by abnormal motor pattern and postures caused by nonprogressive abnormal brain function. The majority of causes occur before delivery, but can also occur in the natal and post-natal periods (Johnston, 2011; Zak & Chan, 2010) (Box 44.1); see Healthy People 2020. Cerebral palsy is the most common movement disorder of childhood; it is a lifelong condition and one of the most common causes of physical disability in children (Johnston, 2011). The

## HEALTHY PEOPLE 2020

### Objective

Reduce preterm births.

### Nursing Significance

- Encourage appropriate birth control use among adolescents to decrease the incidence of teen pregnancy (teens have an increased incidence of preterm delivery).
- If an adolescent does become pregnant, encourage early appropriate prenatal care.
- Discourage substance use among pregnant teens.
- Teach pregnant teens about an appropriate diet.

*Healthy People* Objectives based on data from <http://www.healthypeople.gov>.

incidence is about 3.6 in every 1,000 live births (Johnston, 2011).

Most affected children will develop symptoms in infancy or early childhood. There is a large variation in symptoms and disability. For some children it may be as mild as a slight limp; for others it may result in severe motor and neurologic impairments (NINDS, 2011a). Primary signs include motor impairments such as spasticity, muscle weakness, and **ataxia**, which is lack of coordination of muscle movements during voluntary movements such as walking or picking up objects. Complications include mental impairments, seizures, growth problems, impaired vision or hearing, abnormal sensation or perception, and hydrocephalus. Most children can survive into adulthood, but function and quality of life can vary from near normal to substantial impairments (NINDS, 2011a).

## Pathophysiology

Cerebral palsy is a disorder caused by abnormal development of, or damage to, the motor areas of the brain, resulting in a neurologic lesion. It is difficult to establish an exact location of the neurologic lesion, but it causes a disruption in the brain's ability to control movement and posture. The lesion itself does not change over time; thus, the disorder is considered nonprogressive since the brain injury does not progress. However, the clinical

## BOX 44.1

**CAUSES OF CEREBRAL PALSY****Prenatal**

- Congenital malformation
- Hypoxia
- Maternal fever
- Maternal seizures
- Maternal bleeding
- Exposure to radiation
- Environmental toxins
- Genetic abnormalities
- Metabolic disorders
- Intrauterine growth restriction
- Intrauterine infection, such as cytomegalovirus and toxoplasmosis
- Nutritional deficits
- Preeclampsia
- Multiple births
- Prematurity
- Low birthweight
- Malformation of brain structure
- Abnormalities of blood flow to the brain
- Abdominal insults

**Perinatal**

- Prematurity (<32 weeks)
- Asphyxia
- Hypoxia
- Abnormal fetal presentation
- Sepsis or central nervous system infection
- Placental complications
- Electrolyte disturbance
- Cerebral hemorrhage
- Chorioamnionitis (infection of the placental tissues and amniotic fluid)

**Postnatal**

- Kernicterus (a type of brain damage that may result from neonatal hyperbilirubinemia)
- Asphyxia
- Head trauma (e.g., motor vehicle accidents, abuse)
- Seizures
- Toxins
- Viral or bacterial infection of the central nervous system (e.g., meningitis)
- Cerebral infarcts
- Intraventricular hemorrhage

manifestations of the lesion change as the child grows. Some children may improve, but many either plateau in their attainment of motor skills or demonstrate worsening of motor abilities because it is difficult to maintain the ability to move over time.

Cerebral palsy is classified in several ways. One common way is by the type of movement disturbance (Table 44.3).

**Therapeutic Management**

Management of cerebral palsy involves multiple disciplines, including a primary physician, specialty physicians such as a neurologist and an orthopedic surgeon, nurses, physical therapists, occupational therapists, speech therapists, dietitians, psychologists, counselors, teachers, and parents. There is no standard treatment for all children. The overall focus of therapeutic management will be to assist the child to gain optimal development and function within the limits of the disease. Treatment is mainly preventative, symptomatic, and supportive. Spasticity management will be a primary concern and will be determined by clinical findings.

Medical management is focused on promoting mobility through the use of therapeutic modalities and medications. Surgical management is often required and is used to correct deformities related to spasticity.

**Physical, Occupational, and Speech Therapy**

The use of therapeutic modalities such as physical therapy, occupational therapy, and speech therapy will be essential in promoting mobility and development in the child with cerebral palsy. The earlier the treatment begins, the better chance the child has of overcoming developmental disabilities (NINDS, 2011a).

Physical therapists work with children to assist in the development of gross motor movements such as walking and positioning, and they help the child develop independent movement. They also assist in preventing contractures, and they instruct children and caregivers in the use of assistive devices such as walkers and wheelchairs. Occupational therapists may be responsible for fashioning orthotics and splints. AFOs are the most common orthotic used by children with cerebral palsy (Cervasio, 2011) (Fig. 44.9). AFOs help prevent deformity from conditions such as contractures and help reduce the effects of existing deformities. They can help improve a child's mobility by assisting in control of alignment and helping to increase the efficiency of the child's gait. Spinal orthotics such as braces are used in young children with cerebral palsy to combat scoliosis that develops due to spasticity. These braces are used to delay surgical management of the scoliosis until the child reaches skeletal maturity. Splinting is used to maintain muscle length. Serial casting may also be used to increase muscle and tendon length.

Occupational therapy also assists in the development of fine motor skills and will help the child to perform optimal self-care by working on skills such as activities of daily living. Speech therapy assists in the development of receptive and expressive language and addresses the

TABLE 44.3

## CLASSIFICATION OF CEREBRAL PALSY

Types	Description	Characteristics
Spastic	Hypertonicity and permanent contractures; different types based on which limbs are affected: <ul style="list-style-type: none"> <li>• Hemiplegia: both extremities on one side</li> <li>• Quadriplegia: all four extremities</li> <li>• Diplegia or paraplegia: lower extremities</li> </ul>	<ul style="list-style-type: none"> <li>• Most common form</li> <li>• Poor control of posture, balance, and movement</li> <li>• Exaggeration of deep tendon reflexes</li> <li>• Hypertonicity of affected extremities</li> <li>• Continuation of primitive reflexes</li> <li>• In some children, failure to progress to protective reflexes</li> </ul>
Athetoid or dyskinetic	Abnormal involuntary movements	<ul style="list-style-type: none"> <li>• Infant is limp and flaccid.</li> <li>• Uncontrolled, slow, worm-like writhing or twisting movements</li> <li>• Affects all four extremities and possible involvement of face, neck, and tongue</li> <li>• Movements increase during periods of stress.</li> <li>• Dysarthria and drooling may be present.</li> </ul>
Ataxic	Affects balance and depth perception	<ul style="list-style-type: none"> <li>• Rare form</li> <li>• Poor coordination</li> <li>• Unsteady gait</li> <li>• Wide-based gait</li> </ul>
Mixed	Combination of the above	Most common is spastic and athetoid.

use of appropriate feeding techniques in the child who has swallowing problems. Speech therapists may teach augmented communication strategies to children who are nonverbal or who have articulation problems. Many children may not communicate verbally but can use alternative means such as communication books or boards and

computers with voice synthesizers to make their desires known or to participate in conversation.

### Pharmacologic Management

Various pharmacologic options are available to manage spasticity (see Drug Guide 44.1). Oral medications used to treat spasticity include baclofen, dantrolene sodium, and diazepam. Children with athetoid cerebral palsy may be given anticholinergics to help decrease abnormal movements.

Parenterally administered medications such as botulin toxins and baclofen are also used to manage spasticity. Botulinum toxin is injected into the spastic muscle to balance the muscle forces across joints and to decrease spasticity. It is useful in managing focal spasticity in which the spasticity is interfering with function, producing pain, or contributing to a progressive deformity. Botulin toxin injection is performed by the physician or nurse practitioner and can be done in the clinic or outpatient setting.

**FIGURE 44.9** The child with cerebral palsy may benefit from wearing ankle-foot orthotics (AFOs) to provide support needed for independent or assisted walking.

#### Take Note!

Pathologic drooling is a problem for many children with cerebral palsy. It can lead to dehydration, dental enamel erosion, and maceration of the skin, and an odor can result, along with social stigmatization. Recent research has shown that intraglandular injection of botulinum toxin type A can improve drooling with few side effects in children with neurologic disorders (Fairhurst & Cockerill, 2011; Ong, Wong, & Hamid, 2009).

Intrathecal administration of baclofen has been shown to decrease tone, but it must be infused continuously due to its short half-life. Surgical placement of a baclofen pump will be considered in children with general spasticity that is limiting function, comfort, activities of daily living, and endurance. To test whether it is a suitable option, an intrathecal test dose of baclofen will be administered. If the trial is successful, a baclofen pump will be implanted. Once inserted, delivery of the drug can be individualized to meet the child's unique needs. The pump needs to be replaced every 5 to 7 years and must be refilled with medication approximately every 3 months, depending on the type of pump. Complications with baclofen pump placement include infection, rupture, dislodgement, or blockage of the catheter.

Medications are also used to treat seizure disorders in children with cerebral palsy (refer to Chapter 38 for information related to seizure management).

### Surgical Management

Many children will require surgical procedures to correct deformities related to spasticity. Multiple corrective surgeries may be required; they usually are orthopedic or neurosurgical. Surgery may be used to correct contractures that are severe enough to cause movement limitations. Common orthopedic procedures include tendon lengthening procedures, correction of hip and adductor muscle spasticity, and fusion of unstable joints to help improve locomotion, correct bony deformities, decrease painful spasticity, and maintain, restore, or stabilize a spinal deformity. Neurosurgical interventions may include placement of a shunt in children who have developed hydrocephalus, or surgical interventions to decrease spasticity. Selective dorsal root rhizotomy is used to decrease spasticity in the lower extremities by reducing the amount of stimulation that reaches the muscles via the nerves.

### Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1592. Assessment findings pertinent to cerebral palsy are discussed below.

### Health History

Elicit a description of the present illness and chief complaint. Obtain a detailed account of gestational and perinatal events (refer to Box 44.1). Common signs and symptoms reported during the health history of the undiagnosed child might include:

- History of head trauma
- Delayed attainment of developmental milestones
- Muscle weakness or rigidity
- Poor feeding
- Hips and knees feel rigid and unbending when pulled to a sitting position
- Seizure activity
- Subnormal learning
- Abnormal motor performance, scoots on back instead of crawling on abdomen, walks or stands on toes

Children known to have cerebral palsy are often admitted to the hospital for corrective surgeries or other complications of the disease, such as aspiration pneumonia and urinary tract infections. The health history should include questions related to:

- Respiratory status: Has a cough, sputum production, or increased work of breathing developed?
- Motor function: Has there been a change in muscle tone or increase in spasticity?
- Presence of fever
- Feeding and weight loss
- Any other changes in physical state or medication regimen

### Physical Examination

Observe general appearance. Pay close attention to the neurologic assessment and motor assessment. Assess for delayed development, size for age, and sensory alterations such as strabismus, vision problems, and speech disorders. Abnormal postures may be present. While lying supine, the infant may demonstrate scissor crossing of the legs with plantar flexion. In the prone position the infant may raise his or her head higher than normal due to arching of the back, or the opisthotonic position may be noted. The infant may also abnormally flex the arms and legs under the trunk. Primitive reflexes may persist beyond the point at which they disappear in a healthy infant. Evolution of protective reflexes may be delayed. Watch the infant or child play, crawl, walk, or climb to determine motor function and capability. Note any movement disorder. Infants with cerebral palsy may demonstrate abnormal use of muscle groups such as scooting on their back instead of crawling or walking.

Assess active and passive range of motion. Pay particular attention to muscle tone. Though an increased or decreased resistance may be noted with passive movements, **hypertonicity** is most often seen. Increased resistance to dorsiflexion and passive hip abduction are the most common early signs. Sustained **clonus** may be present after forced dorsiflexion. Lift the child by placing your hands in the infant's or child's axillary area to assess shoulder girdle function and tone. Infants with cerebral palsy often demonstrate prolonged standing on their toes when supported in an upright standing position in this fashion. Lift the young child off the ground while the child holds your thumbs to test hand strength. Observe

for presence of limb deformity, as decreased use of an extremity (as in the case of hemiparesis) may result in shortening of the extremity compared to the other one.

### Laboratory and Diagnostic Tests

A complete history, physical examination, and ancillary investigations are the primary modality for establishing a diagnosis of cerebral palsy. The following laboratory and diagnostic tests will help determine whether cerebral palsy is the likely cause or whether another condition may be the cause of the child's symptoms. These tests also will be important in evaluating the severity of the child's physical disabilities. Common supplementary laboratory and diagnostic tests ordered for the diagnosis and assessment of cerebral palsy include:

- Electroencephalogram: usually abnormal but the pattern is highly variable
- Cranial radiographs or ultrasound: may show cerebral asymmetry
- MRI or CT: may show area of damage or abnormal development but may be normal
- Screening for metabolic defects and genetic testing may be performed to help determine the cause of cerebral palsy.

### Nursing Management

In addition to the nursing diagnoses and related interventions discussed in the Nursing Care Plan 44.1, nursing management focuses on promoting growth and development by promoting mobility and maintaining optimal nutritional intake. Providing support and education to the child and family is also an important nursing function.

#### Promoting Mobility

Mobility is critical to the development of the child with cerebral palsy. Treatment modalities to promote mobility include physiotherapy, pharmacologic management, and surgery. Surgical procedures are discussed above. Physical or occupational therapy as well as medications may be used to address musculoskeletal abnormalities, to facilitate range of motion, to delay or prevent deformities such as contractures, to provide joint stability, to maximize activity, and to encourage the use of adaptive devices. The nurse's role in relation to the various therapies is to provide ongoing follow-through with prescribed exercises, positioning, or bracing.

#### Take Note!

Therapeutic horseback riding has been demonstrated to improve gross motor function in children with cerebral palsy. If available in the local area, refer the child and family to the North American Riding for the Handicapped Association (NARHA) (Sterba, 2007; Elliott, Funderburk, & Holland, 2008).

When casting, splinting, or orthotics are used, assess skin integrity frequently. Pain management may also be necessary. Nursing management of children receiving botulin toxin focuses on assisting with the procedure and providing education and support to the child and family. Nursing interventions related to baclofen include assisting with the test dose and providing preoperative and postoperative care if a pump is placed, as well as providing support and education to the child and family. Teaching Guidelines 44.2 gives information related to baclofen pump insertion.

#### Teaching Guidelines 44.2

##### BACLOFEN PUMP: CHILD/FAMILY EDUCATION

- Check the incisions daily for redness, drainage, or swelling.
- Notify the physician or nurse practitioner if the child has a temperature greater than 101.5°F, or if the child has persistent incision pain.
- Avoid tub baths for 2 weeks.
- Do not allow the child to sleep on the stomach for 4 weeks after pump insertion.
- Discourage twisting at the waist, reaching high overhead, stretching, or bending forward or backward for 4 weeks.
- When the incisions have healed, normal activity may be resumed.
- Wear loose clothing to prevent irritation at the incision site.
- Carry implanted device identification and emergency information cards at all times.

#### Promoting Nutrition

Children with cerebral palsy may have difficulty eating and swallowing due to poor motor control of the mouth, tongue, and throat. This may lead to poor nutrition and problems with growth. The child may require a longer time to eat because of poor motor control. Special diets, such as soft or puréed, may make swallowing easier. Proper positioning during feeding is essential to facilitate swallowing and reduce the risk of aspiration. Speech or occupational therapists can assist in working on strengthening swallowing muscles as well as assisting in developing accommodations to facilitate nutritional intake. Consult a dietitian to ensure adequate nutrition for children with cerebral palsy. In children with severe swallowing problems or malnutrition, a feeding tube such as a gastrostomy tube may be placed.

#### Providing Support and Education

Cerebral palsy is a lifelong disorder that can result in severe physical and cognitive disability. In some cases

disability may require complete intensive daily care of the child. Adjusting to the demands of this multifaceted illness is difficult. Children are frequently hospitalized and need numerous corrective surgeries, which places strain on the family and its finances. From the time of diagnosis, the family should be involved in the child's care. It is important to include parents in the planning of interventions and care of this child. In most cases they are the primary caregivers and will assist the child in development of functioning and skills as well as providing daily care. They will provide essential information to the health care team and will be advocates for their child throughout his or her life. It is important that nurses provide ongoing education for the child and family.

As the child grows, the needs of the family and child will change. Recognize and respect these needs. Providing daily intense care can be demanding and tiring. When a child with cerebral palsy is admitted to the hospital, this may serve as a time of respite for family and primary caregivers. Encourage respite care and provide support and encouragement. Because cerebral palsy is a lifelong condition, children will need meaningful education programs that emphasize independence in the least restrictive educational environment. Refer caregivers to local resources, including education services and support groups. Links to United Cerebral Palsy, a national organization, and Easter Seals, an organization that helps children with disabilities and special needs and provides support to families, can be accessed on [thePoint](#).

Refer children younger than age 3 years to the local early intervention service. Early intervention provides case management of developmental services for children with special needs. Each state has a coordinator for early intervention. The office of the early intervention coordinator can then direct the health care professional to the local or district early intervention office. The website 4MyChild (a link to which is available on [thePoint](#)) provides a comprehensive list of contact information based on the state you live in.

Additional links to resources for families of young children with special needs are available on [thePoint](#). For additional reading, recommend the book *Children With Cerebral Palsy: A Parent's Guide* by E. Geralis (published by Woodbine House).

## ACQUIRED NEUROMUSCULAR DISORDERS

A number of neuromuscular disorders may be acquired during childhood or adolescence. These include disorders resulting from trauma as well as those that are autoimmune and infectious in nature. Trauma or unintentional injury is a leading cause of childhood morbidity

and mortality in the United States (Centers for Disease Control and Prevention, 2009). The child is at increased risk for trauma based on the developmental factors of physical and emotional immaturity; additionally, adolescents often display belief of invincibility. The developing neuromuscular system, if injured, may be irreparable, so the injury may result in life-threatening or lifelong effects. Neuromuscular trauma includes spinal cord injury and birth trauma (refer to chapter 24 for information related to birth trauma). Autoimmune neuromuscular disorders include Guillain-Barré syndrome, myasthenia gravis, and dermatomyositis. Botulism, though uncommon in developed countries, is an important neuromuscular disorder resulting from infection.

### Spinal Cord Injury

Spinal cord injury is damage to the spinal cord that results in loss of function. Frequent causes are trauma, such as car accidents, falls, diving into shallow water, gunshot or stab wounds, sports injuries, child abuse, or birth injuries. Spinal cord injuries are relatively uncommon in children, but when they do occur they have a devastating impact on the child's physical and functional status, social and emotional development, and family functioning. More spinal cord injuries are seen in people 16 to 30 years of age due to their increased incidence of accidents, particularly motor vehicle accidents (Mayo Clinic Staff, 2009).

Spinal cord injury is a medical emergency and immediate medical attention is required. Cervical traction is often used initially and surgical intervention is sometimes necessary. Ongoing medical treatment will be based on the child's age and overall health and the extent and location of the injury. Therapeutic management focuses on rehabilitation and prevention of complications. Spinal cord injury in children is managed similarly to that in adults.

### Nursing Assessment

Symptoms vary based on the location and severity of the injury. Common signs and symptoms associated with spinal cord injury include:

- Inability to move or feel extremities
- Numbness
- Tingling
- Weakness

Paralysis depends on the location of the injury to the spinal cord; the higher the injury in the spinal cord, the more extensive the damage and the greater the loss of function. High cervical injury will result in damage to the phrenic nerve, which innervates the diaphragm. Damage to this nerve will leave the child unable to breathe without assistance.

The diagnosis of spinal cord injury is made by clinical signs and diagnostic tests, which may include radiographs, CT scans, and MRI.

## Nursing Management

Any child who requires hospitalization due to trauma should be considered at risk for a spinal cord injury. Immobilization of the spine is essential until full evaluation of the injury is complete and spinal cord damage is ruled out. Nursing management will be similar to management of the adult with a spinal cord injury and will focus on optimizing mobility, promoting bladder and bowel management, promoting adequate nutritional status, preventing complications associated with extreme immobility such as contractures and muscle atrophy, respiratory complications, managing pain, and providing support and education to the child and family. Refer to the myelomeningocele section of this chapter for information related to urinary and bowel elimination.

The nurse plays an important role not only in the acute care of children with spinal cord injury but also during rehabilitation. Recovery from a spinal cord injury requires long-term hospitalization and rehabilitation. An interdisciplinary team of physicians, nurses, therapists, social workers, and case managers will work to manage the child's complex and long-term needs. Promoting communication among the interdisciplinary team is essential and will be a key nursing function. Rehabilitation will need to focus on the ever-changing developmental needs of the child as he or she grows.

Prevention of spinal cord injuries is an important nursing consideration. Educate the public on vehicular safety, including seat belt use and the proper use of age-appropriate safety seats. Additional education topics include bicycle, sports, and recreation safety; prevention of falls; violence prevention including gun safety; and water safety, including the risk of diving. This education can help decrease the incidence of spinal cord injury in children.

### Guillain-Barré Syndrome

Guillain-Barré syndrome (also called acute inflammatory demyelinating polyradiculoneuropathy or polyneuropathy) is an uncommon disorder in which an immune response within the body attacks the peripheral nervous system but does not usually affect the brain or spinal cord. Guillain-Barré syndrome results in inflammation and demyelination of the peripheral nerves. It is not fully understood why this occurs, but it is believed to be an autoimmune condition that most commonly is triggered by a previous viral or bacterial infection, usually described as an influenza-like upper respiratory tract infection or an acute gastroenteritis with fever (NINDS, 2011b; Sivadon-Tardy et al., 2009). In rare cases it has

occurred after the child has had an immunization or surgery (NINDS, 2011b). In many cases the causative agent remains unidentified (Sivadon-Tardy et al., 2009).

## Therapeutic Management

Treatment of Guillain-Barré syndrome is symptomatic and focuses on lessening the severity and speeding recovery. Management may include plasma exchange and administration of intravenous immunoglobulins, especially in severe cases. The goal of treatment is to keep the body functioning until the nervous system recovers. Guillain-Barré syndrome is a life-threatening condition, and some children will die during the acute phase due to respiratory failure. Most children will make a full recovery, but a few may have residual damage.

## Nursing Assessment

Early diagnosis and prompt treatment are essential since the disorder can quickly lead to respiratory failure and death from muscle paralysis. For a full description of the assessment phase of the nursing process, refer to page 797. Assessment findings pertinent to Guillain-Barré syndrome are discussed below.

### Health History

Elicit a description of the present illness and chief complaint. The clinical presentation of Guillain-Barré syndrome is fairly similar in children and adults. It can occur a few days or weeks after the causative infection or event. Guillain-Barré syndrome has a quick onset and begins with muscle weakness and paresthesias such as numbness and tingling. Classically it initially affects the legs and progresses in an ascending manner. Occasionally it affects the arms or face first and proceeds in a descending manner. Progression is usually complete in 2 to 4 weeks, followed by a stable period leading to the recovery phase, which lasts for a few weeks to months in most cases but can take years. Severity of the disorder ranges from mild weakness to total paralysis.

In children, pain, especially of the lower extremities, as the initial presentation preceding motor involvement has been reported. Other symptoms seen during the course of the illness include:

- Fairly symmetric flaccid weakness or paralysis
- Ataxia
- Sensory disturbances

### Physical Examination and Laboratory and Diagnostic Tests

Physical examination findings may include decreased or absent tendon reflexes. Facial weakness or difficulty swallowing may also be present. Diagnosis is usually

based on clinical findings of paralysis. CSF analysis may reveal an increased level of protein, but this may not be evident until after the first week of the illness.

### Take Note!

Tickling may be a successful technique for assessing the level of paralysis in the child with Guillain-Barré syndrome, either initially or in the recovery phase.

## Nursing Management

Nursing management is supportive. In severe cases the child may require intensive nursing care along with mechanical ventilation. Observe the child closely for the extent of paralysis and monitor for respiratory involvement. Nursing care focuses on the same concerns as in any child with extreme immobility or paralysis.

Prevention of complications associated with immobility is a central concern and involves maintaining skin integrity, preventing respiratory complications and contractures, maintaining adequate nutrition, and managing pain. Interventions include turning and repositioning every 2 hours, assessing the skin for redness or breakdown, performing range-of-motion exercises, keeping the skin clean and dry, encouraging intake of fluids to maintain hydration status, and encouraging coughing and deep breathing every 2 hours and as needed. Enteral feeding or parenteral nutrition may be indicated if swallowing becomes impaired. Physical therapy may be helpful in preventing complications and promoting motor skill recovery. Provide support and education to the parent and child. The rapid onset and long recovery can be difficult and can cause strain on the family and its finances. If residual disability occurs, the family will need help adjusting and caring for their child.

### Take Note!

Serial measurement of tidal volumes may reveal respiratory deterioration in the child with Guillain-Barré syndrome.

## Myasthenia Gravis

Myasthenia gravis is an autoimmune disease that may be inherited as a rare genetic disease, may be acquired by infants born to mothers with myasthenia gravis, or may develop later in childhood. The cause is unclear but the thymus gland sometimes plays a role and it is suspected that viral or bacterial infection can trigger it (Muscular Dystrophy Association, 2009d). The acetylcholine receptor at the neuromuscular junction is affected, inhibiting normal neuromuscular transmission. The result is progressive weakness and fatigue of the skeletal muscles.

Though no gene has been discovered as responsible for myasthenia gravis, autoimmune diseases do demonstrate a genetic predisposition.

Myasthenia gravis usually reaches maximum severity within 1 to 3 years of onset, and with proper treatment children can remain physically active (Muscular Dystrophy Association, 2009d). However, there is no cure for myasthenia gravis. Symptoms can be controlled, but it is a lifelong condition, with early detection being the key to managing the disorder successfully. The disease may be aggravated by stress, exposure to extreme temperatures, and infections, resulting in a myasthenic crisis. Myasthenic crisis is a medical emergency with symptoms including sudden respiratory distress, dysphagia, dysarthria, ptosis, diplopia, tachycardia, anxiety, and rapidly increasing weakness.

Therapeutic management generally involves the use of anticholinesterase medications such as pyridostigmine, which blocks the breakdown of acetylcholine at the neuromuscular junction and enhances neuromuscular transmission. If weakness is not controlled, additional medications may include corticosteroids and other immunosuppressants. Other treatments include plasmapheresis, which removes antibodies from the blood; intravenous immunoglobulin, and thymectomy (however, the role of the thymus gland in the disease process is unclear; therefore, this procedure may or may not improve the child's symptoms).

## Nursing Assessment

Note history of fatigue and weakness; difficulty chewing, swallowing, or holding up the head; or pain with muscle fatigue. In the verbal child, note complaints of double vision. Observe the child for ptosis (droopy eyelids) or altered eye movements from partial paralysis. The neonate may display inadequate suck, weak cry, floppy extremities, and, possibly, respiratory insufficiency. Note increased work of breathing. Laboratory testing may involve the edrophonium (Tensilon) test, in which a short-acting cholinesterase inhibitor is used. Acetylcholine receptor (AChR) antibodies may be present in elevated quantities in the serum.

## Nursing Management

The goals of nursing management include prevention of respiratory problems and providing adequate nutrition. Administer anticholinergic or other medications as ordered, teaching children and families about the use of these drugs. Anticholinergic drugs should be given 30 to 45 minutes before meals, on time and exactly as ordered. Encourage families to seek prompt medical treatment for suspected infections. Encourage appropriate stress management and avoidance of extreme temperatures. Teach families that physical activities should be performed

during times of peak energy; rest periods are needed for energy conservation. Teach families to call their neurologist immediately if signs and symptoms of myasthenic crisis or cholinergic crisis, which results from overmedication with anticholinergic medications, appear. Myasthenic crisis and cholinergic crisis have a similar presentation: rapidly increasing muscle weakness with resultant respiratory distress. Encourage children to wear a medical alert bracelet.

### Take Note!

Signs and symptoms of myasthenic crisis include severe muscle weakness, respiratory difficulty, tachycardia, and dysphagia. Signs and symptoms of cholinergic crisis include severe muscle weakness, sweating, increased salivation, bradycardia, and hypotension.

## Dermatomyositis

Dermatomyositis is an autoimmune disease that results in inflammation of the muscles or associated tissues. It occurs more often in girls and is generally diagnosed between the ages of 5 and 14 years (Muscular Dystrophy Association, 2009a). The autoimmune response may be triggered by exposure to a virus or to certain medications (Muscular Dystrophy Association, 2009a). As with other autoimmune diseases, a genetic predisposition is present. The inflammatory cells of the immune system cause a vasculitis that affects the skin, muscles, kidneys, retinas, and gastrointestinal tract.

Therapeutic management involving the use of corticosteroids or other immunosuppressants is necessary to prevent the complications of painful calcium deposits under the skin, as well as joint contractures. With appropriate treatment, children may recover completely, though some children experience relapses (Muscular Dystrophy Association, 2009a).

## Nursing Assessment

Elicit a health history, which commonly involves history of fever, fatigue, and rash, usually followed by muscle pain and weakness. Determine onset and progression of muscle weakness. Inspect the skin for presence of rash involving the upper eyelids and extensor surfaces of the knuckles, elbows, and knees. The rash is initially a reddish-purplish color, and then progresses to scaling with resulting roughness of the skin. Test muscle strength, noting particularly weakness in the pelvic and shoulder girdles. Laboratory and diagnostic testing may include muscle enzyme levels, a positive antinuclear antibody (ANA) test, and an electromyogram to distinguish muscular weakness from other causes.

## Nursing Management

Administer medications as ordered and teach families about their use; instruct them to monitor for side effects. Educate the family about the importance of maintaining the medication regimen in order to prevent calcinosis (calcium deposits) and joint deformity in the future. Encourage compliance with physical therapy regimens. Ensure that children are excused from physical education classes while the disease is active.

## BOTULISM

Botulism is a disease that is caused by a toxin produced in the immature intestines of young children resulting from infection with the bacterium *Clostridium botulinum*. It is rare but can cause serious paralytic illness. Botulism can be a food-borne infection but can also be contracted through wound infections or intestinal infections in infants, which is the most common form in the United States (Arnon, 2011). *C. botulinum* is common in soil and can also be found in a variety of foods, such as improperly preserved home-canned foods. It generally occurs in infants younger than 6 months of age (Arnon, 2011). It has been associated with feeding honey and corn syrup to infants; thus, these should be avoided in children younger than 1 year of age (Vorvick, Vyas, & Zieve, 2009). The disease is not infectious; to become infected, the child must ingest the bacterial spores. These spores then multiply in the intestinal tract and produce the toxin, which is absorbed in the immature intestines of the infant. It is generally not a problem for older children because the bacteria do not grow well in mature intestines due to the presence of the normal intestinal flora. Prognosis is good, but if treatment is not initiated, paralysis of the arms, legs, trunk, and respiratory system can develop. Therapeutic management is usually supportive but may involve administration of botulinum toxin.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1592. Assessment findings pertinent to botulism are discussed below.

### Health History

Elicit a description of the present illness and chief complaint. Signs and symptoms usually occur soon after ingestion of the bacteria. Common signs and symptoms in infants reported during the health history might include:

- Constipation
- Poor feeding

- Listlessness
- Generalized weakness
- Weak cry

Common signs and symptoms in older children reported during the health history might include:

- Double vision
- Blurred vision
- Drooping eyelids
- Difficulty swallowing
- Slurred speech
- Muscle weakness

### Physical Examination and Laboratory and Diagnostic Tests

Assess for a diminished gag reflex, which is indicative of botulism. Diagnostic tests include cultures of stool and serum. Botulism is a rare disease and is difficult to diagnose since its symptoms are similar to those of other neuromuscular diseases. Therefore, assessment may include diagnostic tests to help rule out other diseases, such as Guillain-Barré syndrome, stroke, and myasthenia gravis.

### Nursing Management

Treatment is mainly supportive and focuses on maintaining respiratory status and nutritional status. If ordered, administer botulinum toxin early in the disease to reduce its severity and progression.

#### KEY CONCEPTS

- Muscles, tendons, ligaments, and cartilage are all present and functional at birth, though intentional, purposeful movement develops only as the infant matures.
- The spine is very mobile in the newborn and infant, especially the cervical spine region, resulting in a high risk for cervical spine injury.
- The nurse's role in laboratory and diagnostic testing for neuromuscular disorders is mainly that of educating the child and family about and preparing the child for the test or procedure.
- Assessment of range of motion and muscle tone is critical in the child with a neuromuscular disorder. Hypertonia or hypotonia is an abnormal finding in the infant or child.
- Determining attainment of developmental milestones and subsequent progression or loss of those milestones is useful in distinguishing various neuromuscular disorders.

- The nurse reinforces and carries out the exercise plans and adaptive equipment use as prescribed by the physical or occupational therapist in order to maintain neuromuscular function and to prevent complications.
- Nursing management of a child with myelomeningocele focuses on preventing infection, promoting bowel and urinary elimination, promoting adequate nutrition, preventing latex allergy reaction, maintaining skin integrity, providing education and support to the family, and recognizing complications, such as hydrocephalus or increased ICP, associated with the disorder.
- Cerebral palsy may result in significant motor impairment. Children with cerebral palsy require ongoing physical therapy as well as nutritional intervention.
- Boys with Duchenne muscular dystrophy initially learn to walk but later lose this ability.
- Respiratory compromise occurs in muscular dystrophy and spinal muscular atrophy and eventually leads to death.
- Children with spinal cord injury require intense nursing management and lengthy rehabilitation to maintain or regain function.
- Children with neuromuscular disorders often suffer depression related to the chronic nature of the disorder.
- School attendance and participation in activities such as the Special Olympics are important for children with neuromuscular dysfunction.

## MULTIPLE CHOICE QUESTIONS

1. A boy with Duchenne muscular dystrophy is admitted to the pediatric unit. He has an ineffective cough. Lung auscultation reveals diminished breath sounds. What is the priority nursing intervention?
  - a. Apply supplemental oxygen.
  - b. Notify the respiratory therapist.
  - c. Monitor pulse oximetry.
  - d. Position for adequate airway clearance.
2. A 7-year-old child with cerebral palsy has been admitted to the hospital. Which information is most important for the nurse to obtain in the history?
  - a. Age that the child learned to walk
  - b. Parents' expectations of the child's development
  - c. Functional status related to eating and mobility
  - d. Birth history to identify cause of cerebral palsy
3. The nurse is caring for a 2-year-old with myelomeningocele. When teaching about care related to neurogenic bladder, what response by the parent would indicate that additional teaching is required?
  - a. "Routine catheterization will decrease the risk of infection from urine staying in the bladder."
  - b. "I know it will be important for me to catheterize my child for the rest of her life."
  - c. "I will make sure that I always use latex-free catheters."
  - d. "I will wash the catheter with warm soapy water after each use."
4. The nurse is caring for a child with cerebral palsy who requires a wheelchair to attain mobility. Which intervention would help the child achieve a sense of normality?
  - a. Encourage follow-through with physical therapy exercises.
  - b. Restrict the child to a special needs classroom.
  - c. Encourage after-school activities within the limits of the child's abilities.
  - d. Ensure the school is aware of the child's capabilities.
5. What is the priority nursing intervention for the child recently admitted with Guillain-Barré syndrome?
  - a. Perform range-of-motion exercises.
  - b. Take temperature every 4 hours.
  - c. Monitor respiratory status closely.
  - d. Assess skin frequently.

## CRITICAL THINKING EXERCISES

1. A 5-year-old girl, diagnosed with myelomeningocele, is admitted to the hospital for a corrective surgical procedure. Choose four questions from below that the nurse should ask when obtaining the health history that would assist in planning the child's care.
  - a. What is the child's current mobility status?
  - b. Is there a family history of myelomeningocele?
  - c. What is the child's genitourinary and bowel function and regimen?
  - d. Does this child have a history of hydrocephalus with presence of shunt?
  - e. Does she have known latex sensitivity?
  - f. Were there any complications during the pregnancy or birth of this child?
  - g. Did the mother take prenatal folic acid supplementation?
2. Based on the case in the above question, develop a nursing care plan for the child with myelomeningocele.
3. A 5-year-old child is admitted to the pediatric unit with a history of cerebral palsy sustained at birth. The child is admitted for a scheduled tendon lengthening procedure. Based on your knowledge about the effects of cerebral palsy, list three priorities to focus on when planning her care. Compare this to a child admitted for surgical correction of a broken femur with no significant past medical history.

## STUDY ACTIVITIES

1. In the clinical setting, compare the growth of a child with muscular dystrophy, spinal muscular atrophy, or cerebral palsy to the growth of a similar-age child who has been healthy. What differences or similarities do you find? What are the explanations for your findings?
2. Identify the role of the registered nurse in the multidisciplinary care of the child with a debilitating neuromuscular disorder.
3. In the clinical setting, interview the parent of a child with Duchenne muscular dystrophy, myelomeningocele, spinal muscular atrophy, or severe cerebral palsy. Determine the parent's feelings about the ongoing care that he or she is responsible for. Reflect upon this interview in your clinical journal.
4. In the clinical setting, compare the cognitive abilities of two children with a severe neuromuscular disorder. What are the reasons for the similarities or differences that you find?

# Nursing Care of the Child With a Musculoskeletal Disorder

## Learning Objectives

*Upon completion of the chapter, you will be able to:*

1. Define the key terms used in this chapter.
2. Compare the anatomy and physiology of the musculoskeletal system in children versus adults.
3. Identify nursing interventions related to common laboratory and diagnostic tests used in the diagnosis and management of musculoskeletal disorders.
4. Identify appropriate nursing assessments and interventions related to medications and treatments for common childhood musculoskeletal disorders.
5. Distinguish various musculoskeletal disorders occurring in childhood.
6. Devise an individualized nursing care plan for the child with a musculoskeletal disorder.
7. Develop child/family teaching plans for the child with a musculoskeletal disorder.
8. Describe the impact of chronic musculoskeletal disorders on the growth and development of children.

*Dakota Dawes, 2 years old, is brought to the clinic by his mother. She states, “Last night Dakota said his arm hurt, but he didn’t have any complaints during the day. Today when he was playing I noticed he wasn’t using his right arm.”*

### Words of Wisdom

Nursing care that helps children to take wobbly steps, run, jump, fall, and get up again provides life itself in a child’s world.

**Musculoskeletal** disorders in children may occur as a congenital malformation or a genetic disorder that is present from birth but may not be identified until later in childhood or adolescence. Other disorders are developmental and still others result from trauma. Infants and young children have resilient soft tissue, so sprains and strains are less common in this age group. Older school-age children and adolescents often participate in sports, resulting in an increased risk of injuries such as sprains, fractures, and torn ligaments.

The immobility associated with most musculoskeletal disorders may affect the child's development and acquisition of motor skills, leading to motor dysfunction.

Understanding the most common responses to these disorders gives the nurse the foundation required to plan care for any child with any musculoskeletal disorder.

## VARIATIONS IN PEDIATRIC ANATOMY AND PHYSIOLOGY

The musculoskeletal system provides the body with form, support, stability, protection, and the ability to move. It is made up of bones, muscles, cartilage, tendons, ligaments, joints, and connective tissue. The musculoskeletal system in infants and children is immature compared with adults; thus, when a musculoskeletal problem occurs in childhood, the child's growth and movement may be hindered.

### Myelination

Myelination of the central nervous system continues to progress after birth and is complete by about 2 years of age. Myelination proceeds in a cephalocaudal and proximal–distal fashion, allowing voluntary muscle control to progress as myelination occurs. As myelination proceeds, the speed and accuracy of nerve impulses increase. Primitive reflexes are replaced with voluntary movement.

### Muscle Development

The muscular system, including tendons, ligaments, and cartilage, arises from the mesoderm in early embryonic development. At birth (term or preterm), the muscles, tendons, ligaments, and cartilage are all present and functional. The newborn infant is capable of spontaneous movement but lacks purposeful control. Full range of motion is present at birth. Healthy infants and children demonstrate normal muscle tone. As the infant matures and becomes mobile, the muscles develop further and become stronger and their mass increases. The infant's muscles account for approximately 25% of total body weight, as compared with the adult's muscle mass, which accounts for about 40% of total body weight (Bechard,

Wroe, & Ellis, 2008). Muscles grow rapidly in adolescence; this contributes to clumsiness, which places the teen at increased risk for injury. In response to testosterone release, the adolescent boy experiences a growth spurt, particularly in the trunk and legs, and develops bulkier muscles. Female infants tend to have laxer ligaments than male infants, possibly due to the presence of female hormones, placing them at increased risk for developmental dysplasia of the hip (Sankar, Horn, Wells, & Dormans, 2011).

### Skeletal Development

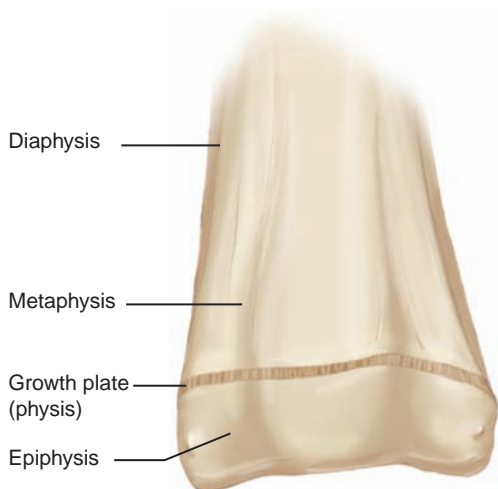

The infant's skeleton is not fully ossified at birth. The infant and young child's bones are more flexible and more porous and have a lower mineral content than the adult's. These structural differences of a young child's bones allow for greater shock absorption, so the bones will often bend rather than break when an injury occurs. The thick, strong periosteum of the child's bones allows for a greater absorption of force than is seen in adults. As a result, the cortex of the bone does not always break, sometimes buckling or bending only. The skeleton contains increased amounts of cartilage compared with adolescents and adults. **Ossification**, the conversion of cartilage to bone, continues throughout childhood and is complete at adolescence.

During fetal development the spine displays **kyphosis**, an outward curvature. Cervical **lordosis**, inward curvature, develops as the infant starts to hold the head up. When the infant or toddler assumes an upright position, the primary and secondary curves of the spine begin to develop. The balance of the curves allows the head to be centered over the pelvis. During the toddler years, the period of early walking, lumbar lordosis may be significant (also termed toddler lordosis), and the toddler appears quite swaybacked and potbellied. As the child develops, the spine takes on more adult-like curves. During adolescence thoracic kyphosis may become evident. This is most often a postural effect, and as the teen matures, the posture appears similar to that of an adult.

### Growth Plate

The ends of the bones in young children are composed of the **epiphysis**, the end of a long bone, and the **physis**, in combination termed the growth plate. In infants, the epiphyses are cartilaginous and ossify over time. In children, the epiphysis is the secondary ossification center at the end of the bone. The physis is a cartilaginous area between the epiphysis and the metaphysis. Growth of the bones occurs primarily in the epiphyseal region. This area is vulnerable and structurally weak. Traumatic force applied to the epiphysis during injury may result in fracture in that area of the bone. Epiphyseal injury

**FIGURE 45.1** Anatomic areas of growing bone.

may result in early, incomplete, or partial closure of the growth plate, leading to deformity or shortening of the bone. Epiphyseal growth continues until skeletal maturity is reached during adolescence. Production of androgens in adolescence gradually causes the growth plates to fuse, and thus long bone growth is complete (Fig. 45.1).

## Bone Healing

The child's bones have a thick, strong periosteum with an abundant blood supply. Bone healing occurs in the same fashion as in the adult, but because of the rich nutrient supply to the periosteum, it occurs more quickly in children. Children's bones produce callus more rapidly and in larger quantities than do adults'. As new bone cells quickly form, a bulge of new bone growth occurs at the site of the fracture. The younger the child, the more quickly the bone heals. Also, the closer the fracture is to the growth plate (epiphysis), the more quickly the fracture heals. The capacity for remodeling (the process of breaking down and forming new bone) is increased in children as compared with adults. This means that straightening of the bone over time occurs more easily in children.

## Positional Alterations

The lower extremities of the infant tend to have a bowed appearance, attributed to in utero positioning. In utero, the fetus' hips are usually flexed, abducted, and externally rotated, with the knees also flexed and the lower limbs inwardly rotated. This normal developmental variation is termed internal tibial torsion. The legs straighten with passive motion, and internal tibial torsion should not be confused with "bowlegs" (Fig 45.2). Internal tibial torsion usually resolves independently some time in the second or third year of life as the toddler bears weight and the lower extremity muscles and bones mature. The

**FIGURE 45.2** Internal tibial torsion with metatarsus adductus—normal findings in the infant.

bowlegged appearance is sometimes also referred to as genu varum. As internal tibial torsion or genu varum resolves, physiologic genu valgum occurs. Children usually demonstrate symmetric genu valgum (knock-knees) by the age of 2 to 3 years. In genu valgum, when the knees are touching, the ankles are significantly separated, with the lower portion of the legs angled outward (Fig. 45.3). By age 7 or 8 years, genu valgum gradually resolves in most children.

The newborn's feet also display in-toeing (metatarsus adductus) as a result of in utero positioning (see Fig. 45.2). The feet remain flexible and may be passively

**FIGURE 45.3** Genu valgum (knock-knees): note knees touching at midline and outward angle of the lower half of the legs.

moved to midline and in a straight position. This also resolves as the infant's musculoskeletal system matures. Pes planus (flat feet) is noted in infants when they begin to walk. The long arch of the foot is not yet developed and makes contact with the floor, resulting in a medial bulge. As the child grows and the muscles become less lax, the arch generally develops. Some children may continue with flexible flat feet, and this is considered a normal variation.

### Take Note!

Fractures are rare in children younger than 1 year of age. Carefully evaluate the infant who presents with a fracture for child abuse or an underlying musculoskeletal disorder (Grewal & Ahier, 2010).

## COMMON MEDICAL TREATMENTS

A variety of medications as well as other medical treatments are used to treat musculoskeletal disorders in children. Most of these treatments will require a physician's or nurse practitioner's order when the child is in the hospital. The most common treatments and medications are listed in Common Medical Treatments 45.1 and Drug Guide 45.1. The nurse caring for the child with a musculoskeletal disorder should become familiar with what the procedures are, how they work, and common nursing implications related to use of these modalities. The treatment of musculoskeletal disorders often involves immobilization via casting, bracing, splinting, or traction to allow healing with the bones in appropriate alignment. The length of treatment with these immobilization methods varies from weeks to months depending on the type of disorder being treated and its severity. Complications related to casting and traction include neurovascular compromise, skin integrity impairment, soft tissue injury, **compartment syndrome**, and, with skeletal traction, pin site infection or osteomyelitis.

### Casts

Casts are used to **immobilize** a bone that has been injured or a diseased joint. When a fracture has occurred, a cast serves to hold the bone in reduction, thus preventing deformity as the fracture heals. Casts are constructed of a hard material, traditionally plaster but now more commonly fiberglass. The hard nature of the cast keeps the bone aligned so that healing may occur more quickly. In a fracture that would heal on its own without specific immobilization, a cast may be used to reduce pain and to allow the child increased mobility. The choice of cast material and type of cast will be determined by the physician or nurse practitioner or orthopedic surgeon. Figure 45.4 shows selected casts used in children.

### Take Note!

Gore-Tex is a special material that can be used to line casts and make them waterproof. These casts can get completely wet in the bath, in the shower, or during swimming. These casts cannot be used for all types of fractures, fractures where skin pins are in place under the cast, or recently manipulated fractures (Cincinnati's Children's, 2010). These casts also have an increased cost that may not be covered by insurance.

### Traction

**Traction**, another common method of immobilization, may be used to reduce and/or immobilize a fracture, to align an injured extremity, and to allow the extremity to be restored to its normal length. Traction may also reduce pain by decreasing the incidence of muscle spasm. In running traction, the weight pulls directly on the extremity in only one plane. This may be achieved with either skin or skeletal traction. In balanced suspension traction, additional weights are used to provide a counterbalance to the force of traction. This allows for constant pull on the extremity even if the child changes position somewhat. Comparison Chart 45.1 discusses skin versus skeletal traction.

### External Fixation

**External fixation** may be used for complicated fractures, especially open fractures with soft tissue damage. A series of pins or wires are inserted into bone and then attached to an external frame. The fixator apparatus may be adjusted as needed by the physician or nurse practitioner. Once the desired level of correction is achieved, no further adjustment occurs and the bone is allowed to heal. Advantages of external fixation include increased comfort for the injured child and improved function of muscles and joints when complicated fracture occurs.

## NURSING PROCESS OVERVIEW FOR THE CHILD WITH A MUSCULOSKELETAL DISORDER

Care of the child with a musculoskeletal disorder includes assessment, nursing diagnosis, planning, interventions, and evaluation. There are a number of general concepts related to the nursing process that may be applied to musculoskeletal dysfunction in children. The nursing care of immobilized children is similar to that of adults, yet developmental and age-appropriate effects must be taken into account. Prevention of complications is a key nursing function. Nursing Care Plan 45.1 gives interventions related to prevention of complications. Particular care related to casts, traction, and fixators is discussed below.

Treatment	Explanation	Indications	Nursing Implications
Traction	Application of a pulling force on an extremity or body part	Fracture reduction, dislocations, correction of deformities	<p>To maintain even, constant traction:</p> <ul style="list-style-type: none"> <li>• Ensure weights hang free at all times and ropes remain in the pulley grooves.</li> <li>• Keep weights out of child's reach.</li> <li>• Maintain prescribed weight.</li> <li>• Elevate head or foot of bed only with physician order.</li> </ul> <p>Monitor for complications:</p> <ul style="list-style-type: none"> <li>• Perform neurovascular checks at least every 4 hours.</li> <li>• Assess for skin impairment.</li> </ul>
Casting	Application of plaster or fiberglass material to form a rigid apparatus to immobilize a body part	Fracture reduction, dislocations, correction of deformities	<p>Assess frequently for neurovascular compromise, skin impairment at cast edges.</p> <p>Protect cast from moisture.</p> <p>Teach family how to care for cast at home.</p>
Splinting	Temporary stiff support of injured area	Temporary fracture reduction, immobilization and support of sprains	<p>Similar to cast care. Some splints are removable and are replaced when the child is up out of bed.</p> <p>Teach family appropriate use of splints.</p>
Fixation	Surgical reduction of a fracture or skeletal deformity with an internal or external pin or fixation device	Fractures, skeletal deformities	<p>No additional care for internal fixation</p> <p>External fixation: perform pin care as prescribed by the surgeon.</p> <p>Assess for excess drainage or pin slippage, notifying physician or nurse practitioner if this occurs.</p> <p>Velcro or snaps on sleeves and pant legs help with dressing.</p>
Cold therapy	Application of ice bags, commercial cold packs, or cold compresses	Most often used in acute injuries to cause vasoconstriction, thereby decreasing pain and swelling	<p>Apply for 20 to 30 minutes, then remove for 1 hour, and then reapply for 20 to 30 minutes.</p> <p>Discontinue when numbness occurs.</p> <p>Place a towel between the cold pack and the skin to prevent thermal injury.</p>
Crutches	Ambulatory devices that transfer body weight from lower to upper extremities	Used whenever weight bearing is contraindicated	<p>Top of crutch should reach 2 to 3 fingerbreadths below the axillae to prevent nerve palsy.</p> <p>Teach child appropriate ambulation with crutches or reinforce teaching if performed by physical therapist.</p>
Physical therapy, occupational therapy	Physical therapy focuses on attainment or improvement of gross motor skills. Occupational therapy focuses on refinement of fine motor skills, feeding, and activities of daily living.	Restore function after injury or surgery; promote developmental activities when limb use is compromised, as in limb deficiency	<p>Provide follow-through with prescribed exercises or supportive equipment.</p> <p>Success of therapy is dependent upon continued compliance with the prescribed regimen.</p> <p>Ensure adequate communication exists within the interdisciplinary team.</p>
Orthotics, braces	Adaptive positioning devices specially fitted for each child by the physical or occupational therapist or orthotist. Used to maintain proper body or extremity alignment, improve mobility, and prevent contractures.	Used to immobilize a body part or prevent deformity through positioning. Used to treat developmental dysplasia of the hip and scoliosis; also may be used for a period of time after cast removal.	<p>Provide frequent assessments of skin covered by the device to avoid skin breakdown.</p> <p>Cotton undergarment worn under the brace helps to maintain skin integrity.</p> <p>Follow the therapist's schedule of recommended "on" and "off" times.</p> <p>Encourage families to comply with use.</p>

## DRUG GUIDE 45.1 COMMON DRUGS FOR MUSCULOSKELETAL DISORDERS

Medication	Actions	Indications	Nursing Implications
Benzodiazepines (diazepam, lorazepam)	Antianxiety drugs that also have the effect of skeletal muscle relaxation	Treatment of muscle spasms associated with traction or casting	Monitor sedation level. May cause dizziness Paradoxical excitement may occur. Assess for improvements in spasms.
Acetaminophen	Blocks pain impulses in response to inhibition of prostaglandin synthesis	Relief of mild pain if used alone, moderate or severe pain if used with a narcotic analgesic	Often combined with a narcotic such as codeine or oxycodone for increased analgesic effect Monitor pain levels and response to medication.
Narcotic analgesics	Act on receptors in the brain to alter perception of pain	Relief of moderate to severe pain associated with injuries, orthopedic procedures	Assess pain location, quality, intensity, and duration. Assess respiratory rate prior to and periodically after administration. Monitor sedation level. May cause nausea, vomiting, constipation, pupil constriction
Nonsteroidal anti-inflammatory drugs (NSAIDs: ibuprofen, ketorolac)	Inhibit prostaglandin synthesis, having a direct inhibitory effect on pain perception and resulting in antiinflammatory and antipyretic activities	Relief of mild to moderate pain, treatment of Legg-Calvé-Perthes disease	Monitor for nausea, vomiting, diarrhea, and constipation. Administer with water or food to decrease GI upset.
Bisphosphonate: IV—pamidronate, zoledronic acid; oral—alendronate, risedronate	Increase bone mineral density	Decrease incidence of fractures in moderate to severe osteogenesis imperfecta	IV: given at 4-month intervals, causes a decrease in serum calcium level, influenza-like reaction with first IV dose Oral: side effects include heartburn, regurgitation, and upper abdominal discomfort.

GI, gastrointestinal; IV, intravenously.

(2010). *Lexi-comp's Drug Reference Handbook: Pediatric & Neonatal Dosage Handbook* (18th ed.). Hudson, OH: Lexi-comp, Inc.

### Assessment

Assessment of musculoskeletal dysfunction in children includes health history, physical examination, and laboratory and diagnostic testing.

**Remember Dakota, the 2-year-old with right arm pain and refusal to use his arm? What additional health history and physical examination assessment information should the nurse obtain?**

### Health History

The health history consists of the past medical history, family history, and history of present illness (when the symptoms started and how they have progressed), as well as treatments used at home. The past medical history might

be significant for musculoskeletal congenital anomaly or orthopedic injury during the birthing process. Breech delivery may be associated with developmental dysplasia of the hip. Determine history related to attainment of developmental milestones, such as walking and whether or not the child participates in sports. Inquire about the child's usual level of physical activity, participation in sports, and use of protective equipment. Family history may be positive for orthopedic problems. When eliciting the history of the present illness, inquire about the following:

- Limp or other changes in gait
- Recent trauma (determine the mechanism of injury)
- Recent strenuous exercise
- Fever
- Weakness
- Alteration in muscle tone
- Areas of redness or swelling

FIGURE 45.4 Selected casts used in children.

### Physical Examination

Physical examination of the musculoskeletal system consists of inspection, observation, and palpation.

#### INSPECTION AND OBSERVATION

Observe the child's posture and alignment of the trunk. Inspect the extremities for symmetry and positioning and for absence, duplication, or webbing of any digits. Note any obvious extremity deformity or limb-length discrepancy. Inspect the skin for redness, warmth, bruises, and puncture sites. Observe gait in the child

who has achieved the developmental skill of walking. Note refusal to walk, limping, in-toeing, out-toeing, or foot slap. Inspect injured joints for ecchymosis or swelling. In the injured extremity, note the color of the fingertips or toes. Observe spontaneous range of motion. Perform scoliosis screening to determine spinal alignment. Note symmetry of thigh folds.

#### PALPATION

Palpate the clavicles in the newborn or young infant for tenderness or a bump that indicates callus formation

### COMPARISON CHART 45.1

#### SKIN VERSUS SKELETAL TRACTION

	Skin Traction	Skeletal Traction
<i>Application of force</i>	To the skin via strips or tapes secured with Ace bandages or traction boots	To the body part directly by fixation into or through the bone
<i>Length of treatment</i>	Usually limited	Allows for longer periods of traction
<i>Amount of force</i>	Less	More

with clavicle fracture. Perform active range of motion to determine if a joint position is fixed (e.g., clubfoot). Palpate the affected joint or extremity to detect warmth or tenderness. In the injured child or the child with a cast or splint, thoroughly assess the neurovascular status of the affected extremities. Palpate the fingers or toes for warmth. Determine the capillary refill time. Note the presence of sensation or motion. Evaluate muscle strength. Palpate pulses distal to the injury, noting their strength and quality. Perform the Ortolani and Barlow maneuvers (see section on developmental dysplasia of the hip later in this chapter) to assess for developmental dysplasia of the hip.

### Take Note!

Assess the injured site last, and do so gently.

## Laboratory and Diagnostic Testing

Common Laboratory and Diagnostic Tests 45.1 explains the laboratory and diagnostic tests most commonly used when considering musculoskeletal disorders. The tests can assist the physician or nurse practitioner in diagnosing a disorder and/or be used as guidelines in determining ongoing treatment. Some of the tests are obtained by laboratory or nonnursing personnel, while others might be obtained by the nurse. In either instance the nurse should be familiar with how the tests are obtained, what they are used for, and normal versus abnormal results. This knowledge will also be necessary when providing child and family education related to the tests.

## Nursing Diagnoses, Goals, Interventions, and Evaluation

Upon completion of a thorough assessment, the nurse might identify several nursing diagnoses, including:

- Pain (see Chapter 36)
- Impaired physical mobility
- Risk for constipation
- Self-care deficit (specify)
- Risk for impaired skin integrity
- Deficient knowledge (specify)
- Risk for delayed development

**After completing an assessment of Dakota, the nurse noted the following: the history revealed that he had been sledding with his older brother the day before. Upon examination, bruising and swelling of the right arm are noted, with point tenderness at the wrist. Based on the assessment findings, what would your top three nursing diagnoses be for Dakota?**

Nursing goals, interventions, and evaluation for the child with musculoskeletal dysfunction are based on the nursing diagnoses (see Nursing Care Plan 45.1). Nursing Care Plan 45.1 may be used as a guide in planning nursing care for the child with a musculoskeletal disorder. The care plan includes many nursing diagnoses that are applicable to the child or adolescent. Children's responses to musculoskeletal dysfunction and its treatment will vary, and nursing care should be individualized based on the child's and family's responses to illness.

The nursing care of immobilized children is similar to that of adults, but developmental and age-appropriate effects must be taken into account. Prevention of complications is a key nursing function. Refer to Nursing Care Plan 45.1 for interventions related to prevention of complications. Additional information about nursing care related to certain disorders will be included later in the chapter as it relates to specific disorders. Refer to Chapter 36 for nursing interventions related to pain management. Particular care related to casts, traction, and external fixation is discussed below.

**Based on your top three nursing diagnoses for Dakota, describe appropriate nursing interventions.**

## Assisting With Cast Application

Before cast or splint application, perform baseline neurovascular assessment for comparison after immobilization. Include:

- Color (note cyanosis or other discoloration)
- Movement (note inability to move fingers or toes)
- Sensation (note whether loss of sensation is present)
- Edema
- Quality of pulses

Enlist the cooperation of the child and reduce his or her fear by showing the child the cast materials and using an age-appropriate approach to describe cast application. Premedicate as ordered to reduce pain when manual traction is applied to align the bone. Use distraction throughout cast application and assist with application of the cast or splint (Fig. 45.5).

### Take Note!

Modern fiberglass cast materials are available in a variety of colors, as well as a few patterns. Allowing the child to choose the color will increase the child's cooperation with the procedure.

After the cast or splint is applied, drying time will vary based on the type of material used. Splints and fiberglass casts usually take only a few minutes to dry

**COMMON LABORATORY AND DIAGNOSTIC TESTS 45.1**

Test	Explanation	Indications	Nursing Implications
Radiographs	Radiographic image; usually two views are obtained of the affected extremity (lateral and anteroposterior)	To detect fractures and other anomalies	Child must cooperate and hold still. Enlist the family's help in calming the child.
Ultrasound	Use of sound waves to locate the depth and structure within soft tissues and fluid	To diagnose toxic synovitis, Legg-Calvé-Perthes disease, slipped capital femoral epiphysis, osteomyelitis, fractures, ligament or soft tissue injuries Monitoring and follow-up of fractures and remodeling	Better tolerated by nonsedated children than CT or MRI Can be performed with a portable unit at bedside
Computed tomography (CT)	Noninvasive x-ray study that looks at tissue density and structures. Images a "slice" of tissue	To evaluate the extent of osteomyelitis, Legg-Calvé-Perthes disease, or slipped capital femoral epiphysis or to rule out other problems	Machine is large and can be frightening to children. Procedure can be lengthy and child must remain still. If unable to do so, sedation may be necessary. If performed with contrast medium, assess for allergy. Encourage fluids after the procedure if not contraindicated.
Magnetic resonance imaging (MRI)	Based on how hydrogen atoms behave in a magnetic field when disturbed by radiofrequency signals. Does not require ionizing radiation. Provides a 3D view of the body part being scanned	To assess hard and soft tissue, as well as bone marrow; to evaluate extent of osteomyelitis, Legg-Calvé-Perthes disease, or slipped capital femoral epiphysis; or to rule out other problems	Remove all metal objects from the child. Child must remain motionless for entire scan; parent can stay in room with child. Younger children will require sedation in order to be still. A loud thumping sound occurs inside the machine during the scan procedure, and this can be frightening to children.
Arthrography	Multiple radiographic images of a joint after direct injection with a radiopaque substance	To assess ligaments, muscles, tendons, and cartilage, particularly after injury	Should not be performed if joint infection is present. The joint should be rested for 12 hours. Apply cold therapy afterward and assess for swelling and pain. Crepitus may be present in the joint for 1 to 2 days after procedure.
Complete blood count	Evaluates hemoglobin and hematocrit, white blood cell count, platelet count	To evaluate hemoglobin and hematocrit with fracture with potential bleeding. To determine infection in osteomyelitis, septic arthritis, and toxic synovitis	Normal values vary according to age and gender. White blood cell count differential is helpful in evaluating for infection. May be affected by myelosuppressive drugs
Erythrocyte sedimentation rate	Nonspecific test used to determine presence of infection or inflammation	To evaluate for osteomyelitis or septic arthritis	Send sample to laboratory immediately; if allowed to stand for longer than 3 hours, may produce falsely low result
C-reactive protein	Measures acute-phase reactant protein indicative of inflammatory process	To evaluate for osteomyelitis or septic arthritis	Anti-inflammatory drugs may cause decreased levels. More sensitive and rapidly responsive than erythrocyte sedimentation rate

*(continued)*

COMMON LABORATORY AND DIAGNOSTIC TESTS 45.1 (continued)			
Test	Explanation	Indications	Nursing Implications
Blood culture	To determine presence of bacteria in blood	May be positive with septic arthritis or osteomyelitis	Transport specimen to laboratory within 30 minutes. Avoid skin contamination of specimen while obtaining it. Cultures should usually be drawn before starting antibiotics, as partial antibiotic treatment may result in negative culture.
Joint fluid aspiration (arthrocentesis)	Aspirated joint fluid is examined for presence of pus and white blood cells; culture is performed.	To evaluate for septic arthritis	Use cold therapy to decrease swelling after aspiration. Apply pressure dressing to prevent hematoma formation or fluid re-collection. Assess for fever and joint pain or edema, which may indicate infection. Positive fluid culture indicates a bacterial infection in the joint. May also be used to relieve pressure in the joint space

Adapted from Fischbach, F. T., & Dunning III, M. B. (2009). *A manual of laboratory and diagnostic tests* (8th ed.). Philadelphia: Lippincott Williams & Wilkins.

and will cause a very warm feeling inside the cast, so warn the child that it will begin to feel very warm. Plaster requires 24 to 48 hours to dry. Take care not to cause depressions in the plaster cast while drying, as those may cause skin pressure and breakdown. Instruct the child and family to keep the cast still, positioning it with pillows as needed.

### Caring for the Child With a Cast

Perform frequent neurovascular checks of the casted extremity to identify signs of compromise early. These signs include:

- Increased pain
- Increased edema

- Pale or blue color
- Skin coolness
- Numbness or tingling
- Prolonged capillary refill
- Decreased pulse strength (or absence of pulse)

Notify the physician or nurse practitioner of changes in neurovascular status or odor or drainage from the cast.

Fiberglass casts usually have a soft fabric edge, so they usually do not cause skin rubbing at the edges of the cast. On the other hand, plaster casts require special treatment of the cast edge to prevent skin rubbing. This may be accomplished through a technique called petaling: cut rounded-edge strips of moleskin or another soft material with an adhesive backing and apply them to the edge of cast, as shown in Figure 45.6.

FIGURE 45.5 Assist with cast application by distracting or comforting the child.

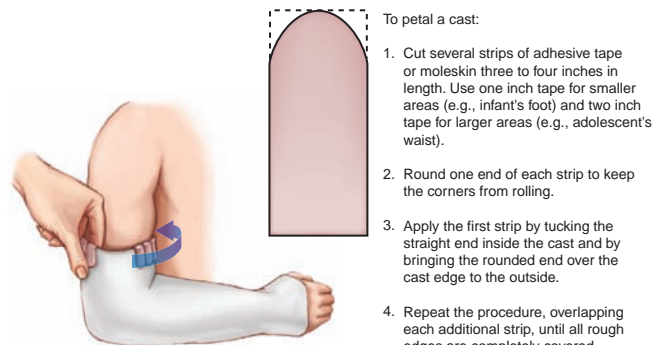

FIGURE 45.6 Petaling the cast.

## NURSING CARE PLAN 45.1

## Overview for the Child With a Musculoskeletal Disorder

**NURSING DIAGNOSIS:** Impaired physical mobility related to injury, pain, or weakness as evidenced by inability to move an extremity, to ambulate, or to move without limitations

### Outcome Identification and Evaluation

Child will engage in physical activities within limits of injury or disease: *child will assist with transfers and positioning in bed and/or participate in prescribed bed exercises.*

### Intervention: Maximizing Physical Mobility

- Assess child's ability to move based on injury or disease and within limits of prescribed treatment *to determine baseline.*
- Prior to prescribed exercise or major position changes, ensure that pain medication is given: *relief of pain increases child's ability to tolerate and participate in activity.*
- Use passive and active range-of-motion exercises and teach child and family how to perform them *to facilitate joint mobility and muscle development (active ROM) and to help increase mobility (within limits of restrictions related to injury or prescribed treatment).*
- Collaborate with physical therapy and occupational therapy as needed to provide child and family with appropriate exercises and methods to promote mobility. Support therapy activities by using same equipment and technique *to help rehabilitate musculoskeletal deficits, improve mobility, and allow for maximum functioning.*
- Praise accomplishments and emphasize child's abilities *to improve self-esteem and encourage feelings of confidence and competence.*
- Teach child and family necessary care related to mobility issues *so the family can continue with these measures at home.*

**NURSING DIAGNOSIS:** Risk for constipation related to immobility and/or use of narcotic analgesics

### Outcome Identification and Evaluation

Child will demonstrate adequate stool passage, *will pass soft, formed stool every 1 to 3 days without straining or other adverse effects.*

### Intervention: Promoting Appropriate Bowel Elimination

- Assess usual pattern of stooling *to determine baseline and identify potential problems with elimination.*
- Palpate for abdominal fullness and auscultate for bowel sounds *to assess for bowel function and presence of constipation.*
- Encourage fiber intake *to increase frequency of stools.*
- Ensure adequate fluid intake *to prevent formation of hard, dry stools.*
- Encourage activity within child's limits or restrictions *as even minimal activity increases peristalsis.*

**NURSING DIAGNOSIS:** Self-care deficit related to immobility as evidenced by inability to perform hygiene care and transfer self independently

### Outcome Identification and Evaluation

Child will demonstrate ability to care for self within age parameters and limits of disease: *child is able to feed, dress, and manage elimination within limits of injury or disease and age.*

(continued)

## NURSING CARE PLAN 45.1

**Overview for the Child With a Musculoskeletal Disorder** (continued)**Intervention: Maximizing Self-Care**

- Introduce child and family to self-help methods as soon as possible *to promote independence from the beginning.*
- Encourage family and staff to allow child to do as much as possible *to allow child to gain confidence and independence.*
- Collaborate with physical therapy and occupational therapy as needed to provide child and family with appropriate tools to modify environment and methods to promote transferring and self-care *to allow for maximum functioning.*
- Praise accomplishments and emphasize child's abilities *to improve self-esteem and encourage feelings of confidence and competence.*
- Balance activity with periods to rest *to reduce fatigue and increase energy available for self-care.*

**NURSING DIAGNOSIS:** Risk for impaired skin integrity related to immobility, casting, traction, use of braces or adaptive devices

**Outcome Identification and Evaluation**

Child's skin will remain intact, *without evidence of redness or breakdown.*

**Intervention: Promoting Skin Integrity**

- Monitor condition of entire skin surface at least daily *to provide baseline and allow for early identification of areas at risk.*
- Avoid excessive friction or harsh cleaning products *that may increase risk of breakdown in child with susceptible skin.*
- Keep child's skin free from stool and urine *to decrease risk of breakdown.*
- Keep linen clean, dry, and free from food crumbs and wrinkles *to prevent pressure areas from forming.*
- Change child's position frequently *to decrease pressure on susceptible areas.*
- Monitor condition of skin affected by braces or adaptive equipment frequently *to prevent skin breakdown related to poor fit.*

For the child in traction:

- Pad bony prominences with cotton padding before applying traction *to protect skin from injury.*
- Gently massage child's back and sacrum with lotion *to stimulate circulation.*

For the child in a spica cast:

- Apply plastic wrap to the perineal edges of the cast *to prevent soiling of cast edges, which can contribute to cast breakdown.*
- Use a fracture bedpan *to facilitate toileting without soiling cast.*
- For the child still in diapers, tuck a smaller diaper under the perineal edges of cast and cover with a larger diaper *to prevent cast soiling.*

**NURSING DIAGNOSIS:** Deficient knowledge related to cast care, activity restrictions, or other prescribed treatment as evidenced by verbalization, questions, or actions demonstrating lack of understanding regarding child's condition or care

**Outcome Identification and Evaluation**

Child and family will demonstrate accurate understanding about condition and course of treatment *through verbalization and return demonstration.*

## NURSING CARE PLAN 45.1

## Overview for the Child With a Musculoskeletal Disorder (continued)

**Intervention: Providing Child and Family Teaching**

- Assess child's and family's willingness to learn: *child and family must be willing to learn for teaching to be effective.*
- Provide teaching at an appropriate level for the child and family (depends on age of child, physical condition, memory) *to ensure understanding.*
- Teach in short sessions: *many short sessions are more helpful than one long session.*
- Repeat information *to give family and child time to learn and understand.*
- Provide reinforcement and rewards *to facilitate the teaching/learning process.*
- Use multiple modes of learning involving many senses (provide written, verbal, demonstration, and videos) when possible: *child and family are more likely to retain information when presented in different ways using many senses.*

**NURSING DIAGNOSIS:** Risk for delayed development related to immobility, alterations in extremities

**Outcome Identification and Evaluation**

Development will be enhanced: *child will make continued progress toward developmental milestones and will not show regression in abilities.*

**Intervention: Promoting Development**

- Screen for developmental capabilities *to determine child's current level of functioning.*
- Offer age-appropriate toys, play, and activities (including gross motor) *to encourage further development.*
- Perform exercises or interventions as prescribed by physical or occupational therapist: *repeat participation in those activities helps to promote function and acquisition of developmental skills.*
- Provide support to families: *immobility and extremity deficits may lead to slow progress in achieving developmental milestones, so ongoing motivation is needed.*

**Take Note!**

If a cast is lined with Gore-Tex do not petal it.

Position the child with the casted extremity elevated on pillows. Ice may be applied during the first 24 to 48 hours after casting if needed. Teaching the child to use crutches is an important nursing intervention for any child with lower extremity immobilization so that the child can maintain mobility (Fig. 45.7). Provide home care instructions to the family about cast care. (See Teaching Guidelines 45.1.)

**Take Note!**

Persistent complaints of pain may indicate compromised skin integrity under the cast.

**FIGURE 45.7** Reinforce appropriate crutch walking for children with lower extremity immobilization.

## Teaching Guidelines 45.1

### HOME CAST CARE

- For the first 48 hours, elevate the extremity above the level of the heart and apply cold therapy for 20 to 30 minutes, then off 1 hour, and repeat.
- Assess for swelling, and have the child wiggle the fingers or toes hourly.
- For itching inside the cast:
  - Never insert anything into the cast for the purposes of scratching.
  - Blow cool air in from a hair dryer set on the lowest setting or tap lightly on the cast.
  - Do not use lotions or powders.
- Protect the cast from wetness.
  - Apply a plastic bag around cast and tape securely for bathing or showering. Continue to avoid placing the cast directly in water (unless it is Gore-Tex lined).
  - Cover it when your child eats or drinks.
  - If a cast become soiled it can be wiped clean with a slightly damp clean cloth.
  - If the cast gets wet, dry it with a blow dryer on the cold setting (if warm setting is used the child could get burned).
- If the child has a large cast, change position every 2 hours during the day and while sleeping change position as often as possible.
- Check the skin for irritation.
  - Press the skin back around edges of the cast.
  - Use a flashlight to look for reddened or irritated areas.
  - Feel for blisters or sores.
- Call the physician or nurse practitioner if:
  - The casted extremity is cool to the touch, pale, blue, or very swollen.
  - The child cannot move the fingers or toes.
  - Severe pain occurs when the child attempts to move the fingers or toes.
  - Persistent numbness or tingling occurs.
  - Drainage or a foul smell comes from under the cast.
  - Severe itching occurs inside the cast.
  - The child runs a fever greater than 101.5°F for longer than 24 hours.
  - Skin edges are red and swollen or exhibit breakdown.
  - Child complains of rubbing or burning under cast.
  - The cast gets wet or is cracked, split, or softened.

Adapted from Bowden, V. R., & Greenberg, C. S. (2008). *Pediatric nursing procedures*. Philadelphia: Lippincott Williams & Wilkins; and American Academy of Family Physicians. (2010). *Cast care*. Retrieved July 12, 2012, from <http://familydoctor.org/online/famdocen/home/healthy/firstaid/after-injury/094.html>

**FIGURE 45.8** The loud noise of the cast saw may frighten the child.

### Assisting With Cast Removal

Children may be frightened by cast removal. Prepare the child using age-appropriate terminology:

- The cast cutter will make a loud noise (Fig. 45.8).
- The skin or extremity will not be injured (demonstrate by touching the cast cutter lightly to your palm).
- The child will feel warmth or vibration during cast removal.

Teaching Guidelines 45.2 gives instructions related to skin care after cast removal.

## Teaching Guidelines 45.2

### SKIN CARE AFTER CAST REMOVAL

- Brown, flaky skin is normal and occurs as dead skin and secretions accumulate under the cast.
- New skin may be tender.
- Soak with warm water daily.
- Wash with warm soapy water, avoiding excessive rubbing, which may traumatize the skin.
- Discourage the child from scratching the dry skin.
- Apply moisturizing lotion to relieve dry skin.
- Encourage activity to regain strength and motion of extremity.

## Caring for the Child in Traction

Nursing care of the child in any type of traction focuses not only on appropriate application and maintenance of traction but also on promoting normal growth and development and preventing complications (see Table 45.1). Apply skin traction over intact skin only so that the pull of the traction is effective. Prepare the skin with an appropriate adhesive before applying the traction tapes to ensure that the tapes adhere well, preventing skin friction. After application of the traction tapes, apply the elastic bandage or use the foam boot. Attach the traction spreader block and then apply the prescribed amount of weight via a rope attached to the spreader block. Ensure that the rope moves without obstruction and that the weights hang freely without touching the floor.

In skeletal traction, apply weight via ropes attached to the skeletal pins. Treat the pin sites as surgical wounds (see section on pin site care). Protect the exposed ends of the pins to avoid injury. Whether skin or skeletal traction is used, be sure that constant and even traction is maintained.

### Take Note!

Avoid sudden bumping or movement of the bed: this can disturb traction alignment and cause additional pain to the child as the weights are jostled.

## Preventing Complications

Refer to Nursing Care Plan 36.1 for interventions related to pain management and Nursing Care Plan 45.1 for interventions related to the prevention of complications of immobility such as skin integrity impairment. To prevent contractures and atrophy that may result from disuse of muscles, ensure that unaffected extremities are exercised. Assist the child to exercise the unaffected joints and to use the unaffected extremity if this does not disrupt traction alignment. Promote use of a trapeze if not contraindicated to involve the child in repositioning and assist with movement. Encourage deep-breathing exercises to prevent the pulmonary complications of long-term immobilization.

Promote normal growth and development by:

- Placing age-appropriate toys within the child's reach
- Encouraging visits from friends
- Providing diversional activities such as drawing, coloring, or video games (Fig. 45.9)

### Take Note!

Ongoing, careful neurovascular assessments are critical in the child with a cast or in skeletal traction.

**FIGURE 45.9** Provide age-appropriate diversional activities and schoolwork for children confined to bed in traction.

Notify the physician or nurse practitioner immediately if these signs of compartment syndrome occur: extreme pain (out of proportion to the situation), pain with passive range of motion of digits, distal extremity pallor, inability to move digits, or loss of pulses.

## Caring for the Child With an External Fixator

Care of an external fixator involves maintaining skin integrity, preventing infection, and preventing injury. Routine neurovascular and skin assessment is essential. Skin care is similar to a child in skeletal traction and includes pin care daily. Elevation of the extremity can help prevent swelling. The fixator may be moved by grasping the frame, as the fixator can tolerate ordinary movement. Encourage weight bearing as prescribed. Provide appropriate education to the child and family. Encourage the child to look at the apparatus. Teach the child not to pick or manipulate the pins. Baggy or loose clothing can be worn over the device. Velcro sewn into the seams can be helpful and allows clothes to slip over the device.

## Providing Pin Care

Whether pins are inserted for skeletal traction or as part of an external fixator (see section on fractures), keeping the pin sites clean is important to prevent infection. (See Evidence-Based Practice 45.1.) Cleaning of the pin sites prevents infection by promoting comfort and preventing healing skin from adhering to the metal pin. Notify the orthopedic surgeon if signs of pin site infection are present or if pin slippage occurs.

TABLE 45.1

## TYPES OF TRACTION AND NURSING IMPLICATIONS

Type of Traction	Description	Nursing Implications
<p>Bryant traction</p> 	<p>Both legs are extended vertically, with child's weight serving as countertraction. Skin traction is applied to both legs. Used to reduce femur fracture in children younger than 2 years or with developmental dysplasia of the hip.</p>	<p>Maintain appropriate position. Ensure heels and ankles are free from pressure. Assess condition and position of elastic bandages every shift and rewrap elastic bandages as ordered.</p>
<p>Russell traction</p> 	<p>Skin traction for femur fracture, hip, and specific types of knee injuries or contractures. Uses a knee sling. In split Russell traction, a portion of the traction weight may be redistributed via a pulley from the sling to the head of the bed (used for femur fracture, Legg-Calvé-Perthes disease, slipped capital femoral epiphysis).</p>	<p>Wrap bandages from ankle to thigh on children younger than age 2 years, from ankle to knee on children older than 2 years. Use a foot support to prevent foot drop. Ensure heel is free from bed. Assess popliteal region for skin breakdown from the sling. Mark leg to ensure proper replacement of sling.</p>
<p>Buck traction</p> 	<p>Skin traction for hip and knee contractures, Legg-Calvé-Perthes disease, slipped capital femoral epiphysis. Used to rest an injured limb or to prevent spasms of injured muscles or joints. Traction force delivered in straight line.</p>	<p>Remove traction boot every 8 hours to assess skin. Leg may be slightly abducted.</p>
<p>Cervical skin traction</p> 	<p>Skin traction applied with a skin strap (head halter). Used for neck sprains/strains, torticollis, or nerve trauma.</p>	<p>Ensure that head halter or skin strap does not place pressure on ears or throat. Limit of 5 to 7 lbs of weight.</p>
<p>Side-arm 90-90</p> 	<p>Skin traction for humerus fractures and injuries to the shoulder girdle. Used to treat fractures of the humerus and injuries in or around the shoulder girdle.</p>	<p>Maintain elbow flexed at 90 degrees. Fingers and hand may feel cool because of elevation. Child may turn to affected side only.</p>

TABLE 45.1

## TYPES OF TRACTION AND NURSING IMPLICATIONS (continued)

Type of Traction	Description	Nursing Implications
Dunlop side-arm 00-90 	Skeletal traction through an olecranon screw or pin in distal humerus. Lower arm is held in balanced suspension.	See side-arm 90-90. In addition, provide appropriate pin site care.
90-90 traction 	For femur fracture reduction when skin traction is inadequate. Skeletal traction with force applied through pin in distal femur	A foam boot may be used for suspension of the lower leg. Force of traction applied to femur via the pin. The amount of weight used is just enough to hold lower limb suspended.
Cervical skeletal tongs 	Tongs attached to skull via pins. Used with fractures or dislocations of the cervical or high thoracic vertebrae	Assess frequently for increased pain, respiratory distress, and spinal cord, cranial nerve, or brachial plexus injury. Place on Stryker frame or specially equipped bed to ease positioning without disruption of alignment.
Halo traction 	Metal halo attached to skull via pins. Used for cervical or high thoracic vertebrae fracture or dislocation and for postoperative immobilization following cervical fusion	Refer to nursing implications for cervical tongs. Tape small wrench to front of brace so that front panel can be quickly removed in an emergency. May become ambulatory in this type of traction; will be top-heavy so may need assistance with balance. Assess pin sites and provide pin care as ordered.
Balanced suspension traction 	Used for femur, hip, or tibial fracture. Thomas splint suspends the thigh while the Pearson attachment allows knee flexion and supports the leg below the knee.	Avoid pressure to popliteal area.

**EVIDENCE-BASED PRACTICE 45.1****PIN SITE CLEANING METHODS AND INFECTION PREVENTION****STUDY**

External fixation (metal pins) is used to immobilize bones while fractures heal. By the nature of pin insertion into the bone, pin sites place the child at risk for development of an infection. Numerous studies have been conducted to evaluate the effectiveness of pin site care. To date, pin site care is usually determined by physician, nurse practitioner, or institution preference. The authors reviewed randomized controlled studies that evaluated the effect on infection and other complication rates of different methods of cleansing or dressing of pin sites. The interventions reviewed compared any type of cleaning method versus no cleaning, different cleansing solutions, site care performed daily or weekly, and varying dressing regimens.

**Findings**

The results were inconclusive. No particular method of pin site care was determined to be statistically significant

Adapted from Lethaby, A., Temple, J., & Santy, J. (2008). Pin site care for preventing infections associated with external bone fixators and pins. *Cochrane Database of Systematic Reviews*, 4. Retrieved July 31, 2010, from <http://www2.cochrane.org/reviews/en/ab004551.html>

in reducing infection or other complication rates from orthopedic pins.

**Nursing Implications**

Despite the lack of clear insight from this study, it remains important for nurses to continue vigilance regarding pin site care. Ongoing assessment of pin sites for signs of infection and monitoring of the child's temperature are particularly important. Provide pin site care according to the physician's or nurse practitioner's preference or institution's protocol. With the lack of conclusive evidence related to pin site care, nurses caring for orthopedic children with orthopedic disorders are in a prime position to develop and execute a well-designed research study related to pin site care.

Thus far, there is insufficient evidence that supports a particular strategy of pin care. More randomized trials are needed. The National Association of Orthopaedic Nurses has published minimal guidelines, which include:

- Perform pin care daily or weekly after the first 48 to 72 hours.
- The most effective solution for pin site care may be chlorhexidine 2 mg/mL but 0.9% sodium chloride solution is an alternative.
- Teach children and their families pin site care along with instructions on the signs and symptoms of infection before discharge (Holmes, Brown, & Pin Site Care Expert Panel, 2005; Bonner, 2009).

Since the research available is minimal, these recommendations are made tentatively (Holmes et al., 2005). Therefore, interventions for pin care need to be individualized based on the child's condition and response to treatment and according to institutional policy or the physician's or nurse practitioner's orders. Certain physicians or nurse practitioners prefer the site to be cleaned with normal saline; others choose a solution with antibacterial properties. Some institutions recommend removal of all crusts formed on the skin around the pin; others do not. The rationale for crust removal is to promote free drainage and prevent the surrounding skin from adhering to the pin. A keyhole dressing may be necessary around the pin if drainage is present. No matter

which procedure is ordered or preferred, perform pin care as necessary to prevent infection at the pin site. The Ilizarov fixator uses wires that are thinner than ordinary pins, so simply cleansing by showering is usually sufficient to keep the pin site clean. If drainage is present, cleanse the skin around the wires with a dry gauze pad.

**CONGENITAL AND DEVELOPMENTAL DISORDERS**

Congenital anomalies of the musculoskeletal system are usually readily identified at birth. Congenital structural anomalies involving the skeleton include pectus excavatum, pectus carinatum, limb deficiencies, polydactyly or syndactyly, metatarsus adductus, congenital clubfoot, and osteogenesis imperfecta. A developmental anomaly that may be diagnosed at birth or later in life is developmental dysplasia of the hip. A muscular condition, torticollis, most often presents as a congenital condition but may also develop after birth. Tibia vara is a developmental disorder affecting young children. Rarely, a developmental positional alteration such as genu varum, genu valgum, or pes planus will persist past the usual age of resolution or cause the child pain. If those situations occur, bracing, orthotics, or surgical correction may become necessary.

## Pectus Excavatum

Pectus excavatum and pectus carinatum are anterior chest wall deformities. Pectus excavatum, a funnel-shaped chest, accounts for greater than 90% of all congenital chest wall deformities (Boas, 2011). A depression that sinks inward is apparent at the xiphoid process (Fig. 45.10). Pectus carinatum, a protuberance of the chest wall, accounts for only 5% to 15% of anterior chest wall deformities (Boas, 2011). The remainder are mixed deformities.

Pectus excavatum does not resolve as the child grows; rather, it progresses with growth. The chest depression may be minimal or marked. When the pectus is more pronounced, cardiac and pulmonary compression occurs. Symptoms of this compression most often present during puberty, when the pectus quickly worsens. Children may complain of shortness of breath, withdraw from physical activities, and have a poor body image.

## Therapeutic Management

Therapeutic management of pectus excavatum is based on the severity and physiologic compromise. Options include observation, use of physical therapy to work on musculoskeletal compromise, and surgical correction, preferably before puberty, when the skeleton is more pliable. Various surgical techniques may be used and generally involve either the placement of a surgical steel bar or using a piece of bone in the rib cage to lift the depression. This discussion will focus on care of the child who undergoes surgical steel bar placement for pectus correction.

**FIGURE 45.10** Pectus excavatum: note the depression in the chest wall at the xiphoid process.

## Nursing Assessment

Elicit the health history, noting progression of the defect and effects on the child's cardiopulmonary function. Note shortness of breath, exercise intolerance, or chest pain. Observe the child's chest for anterior wall deformity, noting depth and severity. Auscultate the lungs to determine the adequacy of aeration. Radiographs, computed tomography (CT), or magnetic resonance imaging (MRI) may be used to determine the extent of the anomaly and compression of inner structures.

## Nursing Management

Prepare the child preoperatively by allowing a tour of the surgical area and the pediatric intensive care unit. Introduce the child to the pain scale that will be used in the postoperative period.

Postoperatively, nursing management focuses on assessment, protection of the surgical site, and pain management. Auscultate lung sounds frequently to determine the adequacy of aeration and to monitor for development of the complication of pneumothorax. Assess for signs of wound infection that would necessitate removal of the curved bar. During the first few postoperative days positioning is challenging; do not allow the child to roll in bed, lie on either side, or rotate or flex the spine (these positions may disrupt the bar's position). Administer analgesics as needed either intravenously or via the epidural catheter. Teach families that the child will not be allowed to lie on his or her side at home for 4 weeks after the surgery to ensure that the band does not shift. Encourage aerobic activity at home after being cleared by the surgeon (this will increase the child's vital capacity, previously hindered by the pectus). The bar will be removed 2 to 4 years after the initial placement.

## Limb Deficiencies

Limb deficiencies, either complete absence of a limb or a portion of it or deformity, occur as the fetus is developing. These defects are attributed to an amniotic band constricting the limb, resulting in either incomplete development or amputation of the limb. Many children born with limb deformities also have congenital anomalies such as craniofacial abnormalities and cardiac and genitourinary defects (Morrissy, Giavedoni, & Coulter-O'Berry, 2006; Polousky & Eilert, 2009).

Therapeutic management is aimed at improving the child's functional ability. Physical therapy and occupational therapy may be helpful. Adaptive equipment such as a prosthesis may also be prescribed.

## Nursing Assessment

Note the extent of limb deformity, providing an accurate description of the presence or absence of a portion of the arm or leg, or missing fingers or toes. Assess the child's ability to use the extremity as a helper (arms) or in ambulation (legs). Determine status of acquisition of developmental skills.

## Nursing Management

Reinforce prescribed activities that are meant to improve the child's function. Provide activities in which the child is capable of participating. If the limb deficiency is significant, refer the infant to the local early intervention office as soon as possible after birth. Early intervention, available in all 50 states, is designed to promote development from birth to age 3 years. Absence of a limb or a significant portion of a limb will have a considerable impact on the child's ability to meet developmental milestones as expected.

### Polydactyly/Syndactyly

Polydactyly is the presence of extra digits on the hand or foot (Fig. 45.11). It affects African Americans more frequently (Kaneshiro & Zieve, 2009). One third of the time, polydactyly occurs in both the hand and foot (Hosalkar, Spiegel, & Davidson, 2011). It usually involves digits at the border of the hand or foot, but can also occur by a central digit (Hosalkar, Spiegel, et al., 2011). Syndactyly is webbing of the fingers and toes. Both polydactyly and syndactyly can be inherited and associated with other genetic syndromes (Carrigan, 2011; Hosalkar, Spiegel, et al., 2011; Kaneshiro & Zieve, 2009).

FIGURE 45.11 Note additional digits (toes) of polydactyly.

Therapeutic management includes tying off the additional digit until it falls off or surgical removal of the digit. No treatment is usually required for syndactyly, though surgical repair is sometimes performed for cosmetic reasons.

## Nursing Assessment

Inspect the hands and feet for the presence of extra digits. Note whether the additional digits are soft (without bone) or are full or partial digits with bone present. Note location of webbing.

## Nursing Management

If the digit is tied off, observe for expected necrosis of tissue and eventually loss of the extra digit. When surgical removal is necessary, provide routine pre- and post-operative care as appropriate.

### Metatarsus Adductus

Metatarsus adductus, a medial deviation of the forefoot, is one of the most common foot deformities of childhood (Fig. 45.12). It occurs most commonly as a result of in utero positioning (Hosalkar, Spiegel, et al., 2011). Half of all cases occur bilaterally (Hosalkar, Spiegel, et al., 2011). The degree of flexibility is important and determines treatment. If the forefoot is flexible past neutral manipulation passively, observation is often sufficient. If the forefoot is flexible only to neutral manipulation, stretching exercises may be beneficial. If the forefoot is rigid and is not flexible to neutral manipulation, serial casting, preferably before the age of 8 months, may be required (Hosalkar, Spiegel, et al., 2011). Surgical intervention is rarely needed.

FIGURE 45.12 Metatarsus adductus: note medial deviation of the forefoot.

## Nursing Assessment

The deformity is usually noted at birth. Note inward deviation of the forefoot. The great and second toes might be separated. Determine forefoot flexibility. Range of motion of the ankle, hindfoot, and midfoot is normal in all three types. Accompanying hip dysplasia may be seen; therefore, careful examination of the hips is warranted (Wells & Sehgal, 2011).

## Nursing Management

Nursing care for children with type I and II metatarsus adductus is aimed at education and reassurance of the parents. Nursing care for the child with type III metatarsus adductus is similar to that of the child with clubfoot (see below).

### Congenital Clubfoot

Congenital clubfoot (also termed congenital talipes equinovarus) is a congenital anomaly that occurs in 1 of 1,000 live births (Hosalkar, Spiegel, et al., 2011). Clubfoot consists of:

- Talipes varus (inversion of the heel)
- Talipes equinus (plantarflexion of the foot; the heel is raised and would not strike the ground in a standing position)
- Cavus (plantarflexion of the forefoot on the hindfoot)
- Forefoot adduction with supination (the forefoot is inverted and turned slightly upward)

The foot resembles the head of a golf club (Fig. 45.13). Half of all cases occur bilaterally (Hosalkar, Spiegel, et al., 2011). Males are affected more frequently than females (Gunta, 2009; Hosalkar, Spiegel, et al., 2011). The exact etiology of clubfoot is unknown.

**FIGURE 45.13** Note inverted heel, ankle equinus, and forefoot adduction in this infant with bilateral clubfoot.

Clubfoot may be classified into four categories: postural, neurogenic, syndromic, and idiopathic. Postural clubfoot often resolves with a short series of manipulative casting. Neurogenic clubfoot occurs in infants with myelomeningocele. Clubfoot in association with other syndromes (syndromic) is often resistant to treatment. Idiopathic clubfoot occurs in otherwise normal healthy infants. The approach to treatment is similar regardless of the classification.

## Therapeutic Management

The goal of therapeutic management of clubfoot is achievement of a functional foot; treatment starts as soon after birth as possible. Weekly manipulation with serial cast changes is performed; later, cast changes occur every 2 weeks. Other infants require corrective shoes or bracing. In some infants surgical release of soft tissue may be necessary. Following surgery, the foot is immobilized with a cast for up to 12 weeks, and then ankle-foot orthoses or corrective shoes are used for several years.

Complications of clubfoot and its treatment include residual deformity, rocker-bottom foot, awkward gait, weight bearing on the lateral portion of the foot if uncorrected, and disturbance to the epiphysis.

## Nursing Assessment

Note family history of foot deformities and obstetric history of breech position. Inspect the foot for position at rest. Perform active range of motion, noting inability to move foot into normal positioning at midline. Radiographs are obtained to determine bony abnormality and note progress during treatment.

## Nursing Management

Perform neurovascular assessment and cast care for infants requiring casting. Provide emotional support, as treatment often begins in the newborn period and families may have a difficult time adjusting to the diagnosis and treatment required for their new baby. Teach families cast care and about the use of orthotics or braces as prescribed.

### Osteogenesis Imperfecta

Osteogenesis imperfecta is a genetic bone disorder that results in low bone mass, increased fragility of the bones, and other connective tissue problems such as joint hypermobility, resulting in instability of the joints. All of these contribute to fracture occurrence. Dentinogenesis imperfecta may also occur. This is characterized by the tooth enamel wearing easily and brittle and discolored teeth.

The disorder usually occurs as a result of a defect in the collagen type 1 gene, usually through an autosomal dominant inheritance pattern but some types are inherited in a recessive manner (Gunta, 2009). The types of osteogenesis imperfecta range from mild to severe connective tissue and bone involvement (Table 45.2). Subtypes A and B exist depending on (A) the absence or (B) the presence of dentinogenesis imperfecta (Marini, 2011). In children with moderate to severe disease, fractures are more likely to occur, and short stature is common. In addition to multiple fractures, additional complications include early hearing loss, acute and chronic pain, scoliosis, and respiratory problems.

**Take Note!**

Blue sclera is not diagnostic of osteogenesis imperfecta, but it is a common finding (Gunta, 2009). However, there are some individuals with blue sclerae who do not have osteogenesis imperfecta. Keep in mind that the sclerae of newborns tend to be bluish, progressing to white over the first few weeks of life.

**Therapeutic Management**

The goal of medical and surgical management is to decrease the incidence of fractures and maintain mobility. Bisphosphonate administration is used for moderate

**TABLE 45.2 CLASSIFICATION OF OSTEOGENESIS IMPERFECTA**

Classification	Characteristics
I	Mild Accounts for 50% of OI cases <sup>a</sup> Blue sclera Hearing loss Frequent shoulder and elbow dislocations Recurrent fractures in childhood After growth is complete incidence of fractures diminishes dramatically. Average or slightly shorter stature compared to family members Gross motor development delays
II	Most severe form Lethal in perinatal period or die within first year of life Low birthweight, very short limbs, small chest, and soft skull Intrauterine fractures evident Very dark blue/gray sclera
III	Most severe nonlethal form Sclera ranges from white to blue Fractures in utero and at birth with progressive deformity Bone fragility and fracture rate vary Results in significant disability Marked short stature
IV	Moderately severe Sclera may be light blue in infancy and lighten to white during childhood Fragile bones May present at birth with in utero fractures or bowing of lower long bones Height may be less than average for age
V and VI	Clinically within type IV but microscopic studies reveal distinct bone patterns; do not involve deficits of type I collagen Moderate in severity Similar to type IV in degree of fractures and skeletal deformity Type VI is extremely rare
VII and VIII	Recessive inheritance patterns Type VII resembles type IV or III, except infants have white sclera: stature is short. Type VIII resembles type II or III, except for white sclera; growth deficiency is severe.

<sup>a</sup>Osteogenesis Imperfecta Foundation. (2007). *Types of OI*. Retrieved July 12, 2012, from [http://www.oif.org/site/PageServer?pagename=AOL\\_Types](http://www.oif.org/site/PageServer?pagename=AOL_Types)

Adapted from Marini, J. C. (2011). Chapter 692: Osteogenesis imperfecta. In R. M. Kliegman, B. F. Stanton, J. W. St. Geme, N. F. Schor, & R. E. Behrman, (Eds.), *Nelson's textbook of pediatrics* (19th ed., p. 2437–40). Philadelphia: Saunders.

to severe disease. Fracture care is often required. Physical therapy and occupational therapy prevent contractures and maximize mobility. Standing with bracing is encouraged. Lightweight splints or braces may allow the child to bear weight earlier. Severe cases may require surgical insertion of rods into the long bones.

## Nursing Assessment

Elicit a health history, which may reveal a family history of osteogenesis imperfecta, a pattern of frequent fractures, or screaming associated with routine care and handling of the newborn. Inspect the eyes for sclerae that have a blue, purple, or gray tint. Note abnormalities of the primary teeth. Inspect skin for bruising and note joint hypermobility with active range of motion. Laboratory tests may include a skin biopsy (which reveals abnormalities in type 1 collagen) or DNA testing (locating the genetic mutation).

## Nursing Management

Handle the child carefully and teach the family to avoid trauma (Teaching Guidelines 45.3). Refer families to the Osteogenesis Imperfecta Foundation (a link to which can be found on [thePoint](#)), which provides access to multiple resources as well as clinical trials. An excellent book for families of children with osteogenesis imperfecta is *Children With OI: Strategies to Enhance Performance* by H. L. Cintas and L. H. Gerber.

### Teaching Guidelines 45.3

#### PREVENTING INJURY IN CHILDREN WITH OSTEOGENESIS IMPERFECTA

- Never push or pull on an arm or leg.
- Do not bend an arm or leg into an awkward position.
- Lift a baby by placing one hand under the legs and buttocks and one hand under the shoulders, head, and neck.
- Do not lift a baby's legs by the ankles to change the diaper.
- Do not lift a baby or small child from under the armpits.
- Provide supported positioning.
- If fracture is suspected, handle the limb minimally.

Encourage safe mobility. Reinforce physical and occupational therapists' recommendations for promotion of fine motor skills and independence in activities of daily living, as well as use of adaptive equipment and appropriate promotion of mobility. Adapted physical education is important to promote mobility and maintain

bone and muscle mass. If the child is ambulatory, even with adaptive equipment use, walking is a good form of exercise. Swimming and water therapy are appropriate, allowing independent movement with little fracture risk.

### Take Note!

Use caution when inserting an intravenous line or taking a blood pressure measurement, as pressure on the arm or leg can lead to bruising and fractures.

## Developmental Dysplasia of the Hip

Developmental dysplasia of the hip (DDH) refers to abnormalities of the developing hip that include dislocation, subluxation, and dysplasia of the hip joint. In DDH, the femoral head has an abnormal relationship to the acetabulum. Frank dislocation of the hip may occur, in which there is no contact between the femoral head and acetabulum. Subluxation is a partial dislocation, meaning that the acetabulum is not fully seated within the hip joint. Dysplasia refers to an acetabulum that is shallow or sloping instead of cup shaped. DDH may affect just one or both hips. The dysplastic hip may be provoked to subluxation or dislocated and then reduced again (Fig. 45.14).

## Pathophysiology

While dislocation may occur during a growth period in utero, the laxity of the newborn's hip allows dislocation and relocation of the hip to occur. The hip can develop normally only if the femoral head is appropriately and deeply seated within the acetabulum. If subluxation and periodic or continued dislocation occur, then structural changes in the hip's anatomy occur. Continued dysplasia of the hip leads to limited abduction of the hip and contracture of muscles. DDH is more common in females, probably due to the greater susceptibility of the female

FIGURE 45.14 Developmental dysplasia of the hip.

newborn to maternal hormones that contribute to laxity of the ligaments (Sankar, Horn, Wells, & Dormans, 2011). Mechanical factors such as breech positioning or the presence of oligohydramnios also contribute to the development of DDH. Genetic factors also play a role: there is an increased incidence of DDH among persons of Native American and Eastern Europe descent, with very low rates among people of African or Chinese heritage (Sankar, Horn, Wells, & Dormans, 2011). Complications of DDH include avascular necrosis of the femoral head, loss of range of motion, recurrently unstable hip, femoral nerve palsy, leg-length discrepancy, and early osteoarthritis.

## Therapeutic Management

The goal of therapeutic management is to maintain the hip joint in reduction so that the femoral head and acetabulum can develop properly.

Treatment varies based on the child's age and the severity of DDH. Infants younger than 6 months of age may be treated with a Pavlik harness, which reduces and stabilizes the hip by preventing hip extension and adduction and maintaining the hip in flexion and abduction (Sankar, Horn, Wells, & Dormans, 2011; Polousky & Eilert, 2009). The Pavlik harness is successful in the treatment of DDH in the majority of infants younger than 6 months of age if it is used on a full-time basis and applied properly (Weinstein, 2006). Children from 6 months to 2 years of age often require closed reduction (Sankar, Horn, Wells, & Dormans, 2011; Polousky & Eilert, 2009). Skin or skeletal traction may be used first to gradually stretch the associated soft tissue structures. Closed reduction occurs under general anesthesia, with the hip being gently maneuvered back into the acetabulum. A spica cast worn for 12 weeks maintains reduction of the hip. After the cast is removed, the child must wear an abduction brace full time (except for baths) for 2 months (Sankar, Horn, Wells, & Dormans, 2011). Then the brace is worn at night and during naps until development of the acetabulum is normal. Children older than 2 years of age or those who have failed to respond to prior treatment require an open surgical reduction followed by a period of casting (Sankar, Horn, Wells, & Dormans, 2011; Weinstein, 2006). Follow-up continues until the age of skeletal maturity.

## Nursing Assessment

Nursing assessment of children with DDH includes obtaining a health history and inspecting, observing, and palpating for findings common to DDH.

### Health History

Assess the health history for risk factors such as:

- Family history of DDH
- Female gender

- Oligohydramnios or breech birth
- Native American or Eastern European descent
- Associated lower limb deformity, metatarsus adductus, hip asymmetry, torticollis, or other congenital musculoskeletal deformity

Previously undiagnosed older children may complain of hip pain.

### Physical Assessment

The physical examination for DDH includes inspection, observation, and palpation. Since DDH is a developmental process, ongoing screening assessments are required throughout at least the first several months of the infant's life.

#### INSPECTION AND OBSERVATION

Ensure that the infant is on a flat surface and is relaxed. Note asymmetry of thigh or gluteal folds with the infant in a prone position. Document shortening of the affected femur observed as limb-length discrepancy. Older children may exhibit **Trendelenburg gait**. Figure 45.15 illustrates these assessments.

#### PALPATION

Note limited hip abduction while performing passive range of motion. Abduction should ordinarily occur to 75 degrees and adduction to within 30 degrees with the infant's pelvis stabilized. Perform Barlow and Ortolani tests, feeling for, or noting, a palpable "clunk" as the femoral head dislocates (positive Barlow) or reduces (positive Ortolani) back into the acetabulum. Force is not necessary when performing the Barlow and Ortolani maneuvers (see Fig. 45.15 and Nursing Procedure 45.1).

#### Take Note!

A higher-pitched "click" sound or sensation may occur with flexion or extension of the hip. When assessing for DDH, do not confuse this benign, adventitial sound with a true "clunk."

### Laboratory and Diagnostic Testing

Ultrasound of the hip allows for visualization of the femoral head and the outer edge of the acetabulum. Plain hip radiographs may be used in the infant or child older than 6 months of age.

## Nursing Management

Earlier recognition of hip dysplasia with earlier harness use results in better correction of the anomaly. Excellent assessment skills and reporting of any abnormal findings are critical. Initially, the infant will need to wear the Pavlik harness continuously (Fig. 45.16). The physician or nurse practitioner makes all appropriate adjustments

**FIGURE 45.15** Assessment techniques for developmental dysplasia of the hip. **(A)** Assess for asymmetry of thigh and gluteal folds. **(B)** Assess for unequal knee height related to femur shortening. **(C)** Note limitation in hip abduction. **(D)** Positive Trendelenburg sign: note pelvis/hip drops when leg is raised. **(E)** Feel for “clunk” when adduction and depression of femur dislocates hip (Barlow’s test). Assess for “clunk” when the dislocated hip is abducted and relocated (Ortolani sign).

to the harness when applied so that the hips are held in the optimal position for appropriate development. Teach parents use of the harness and assessment of the baby’s skin. If started early, harness use usually continues for about 3 months (Teaching Guidelines 45.4). Breast-feeding can continue throughout the harness treatment

#### Teaching Guidelines 45.4

##### CARING FOR A CHILD IN A PAVLIK HARNESS

- Do not adjust the straps without checking with the physician or nurse practitioner first.
- Until your physician or nurse practitioner instructs you to take the harness off for a period of time each day, it must be used continuously (for the first week or sometimes longer).
- Change your baby’s diaper while he or she is in the harness.
- Place your baby to sleep on his or her back.
- Check skin folds, especially behind the knees and diaper area, for redness, irritation, or breakdown. Keep these areas clean and dry.

- Once the baby is permitted to be out of the harness for a short period, you may bathe your baby while the harness is off.
- Long knee socks and an undershirt are recommended to prevent rubbing of the skin against the brace.
- Note location of the markings on the straps for appropriate placement of the harness.
- Wash the harness with mild detergent by hand and air dry. If using the dryer, use *only* the air fluffing setting (no heat).
- Call the doctor if:
  - Your baby’s feet are swollen or bluish.
  - The harness appears too small.
  - Skin is raw or a rash develops.
  - Your baby is unable to actively kick his or her legs.

period, but creative positioning of the infant may be needed.

For infants or children diagnosed later than 6 months of age or those who do not improve with harness use, surgical reduction may be performed after a period of traction (Sankar, Horn, Wells, & Dormans, 2011). Postoperative casting followed by bracing or orthotic use is common. Caring for the child in the postoperative period is

## NURSING PROCEDURE 45.1

## Performing Ortolani and Barlow Maneuvers

**Purpose: To Detect Congenital Developmental Dysplasia of the Hip**

**Ortolani Maneuver**

1. Place the newborn in the supine position and flex the hips and knees to 90 degrees at the hip.
2. Grasp the inner aspect of the thighs and abduct the hips (usually to approximately 180 degrees) while applying upward pressure.

3. Listen for any sounds during the maneuver. There should be no “clunk” heard or felt when

the legs are abducted. Such a sound indicates the femoral head hitting the acetabulum as the femoral head reenters the area. This suggests developmental hip dysplasia.

**Barlow Maneuver**

1. With the newborn still lying supine and grasping the inner aspect of the thighs (as just mentioned), adduct the thighs while applying outward and downward pressure to the thighs.

2. Feel for the femoral head slipping out of the acetabulum; also listen and feel for a “clunk.”

**FIGURE 45.16** Pavlik harness used to keep the knees flexed and hips abducted to allow the hips to grow normally in a child with developmental dysplasia of the hip.

similar to care of any child in a cast. Pain management and monitoring for bleeding are priority activities. Teach families care of the cast at home.

### Tibia Vara (Blount Disease)

Tibia vara (Blount disease) is a developmental disorder affecting young children. There are three types: infantile (1 to 3 years), juvenile (4 to 10 years), and adolescent (11 years or older) (Wells & Sehgal, 2011). Infantile is the most common and is discussed here (Wells & Sehgal, 2011). The normal physiologic bowing or genu varum becomes more pronounced in the child with tibia vara. The cause of tibia vara is unknown, but it is considered to be a developmental disorder because it occurs most frequently in children who are early walkers. Most cases occur in African American females and both extremities are affected (Wells & Sehgal, 2011). In addition to early walking, obesity is also a risk factor. If left untreated, the growth plate of the upper tibia ceases bone production. Asymmetric growth at the knee then occurs and the bowing progresses. Severe degenerative arthritis of the knee is an additional long-term complication.

**FIGURE 45.17** Note extreme bowing of the legs in tibia vara.

Therapeutic management is aimed at stopping the progression of the disease through bracing or surgical treatment. Medical or surgical treatment should begin early, before 4 years of age.

## Nursing Assessment

Elicit a health history and determine the age at which the child started walking. Assess growth parameters to determine whether the risk factor of obesity is present. Note significant bowing of the legs while the child is standing and ambulating (Fig. 45.17).

## Nursing Management

Bracing may include a modified knee–ankle–foot orthosis that relieves the compression forces on the growth plate, allowing bone growth resumption and correction of bowlegs. To be successful, bracing must be continued for months to years and the brace must be worn 23 hours per day. Compliance is the most significant barrier to successful treatment. Parents have a difficult time forcing their toddler to stay in a brace that inhibits mobility for the bulk of the day (particularly a bilateral brace). Support parents by encouraging and praising their compliance with bracing. Teach parents to assess for potential skin impairment from brace rubbing.

When surgical treatment is required, the leg(s) will be immobilized in a long-leg bent knee or spica cast

after the osteotomy is performed. Perform routine cast care. Refer to Nursing Care Plan 45.1 for additional interventions related to care of the immobilized child.

## Torticollis

Torticollis is a painless muscular condition presenting in infants or in children with certain syndromes. Congenital muscular torticollis may result from in utero positioning or difficult birth. Preferential turning of the head to one side while in the supine position after birth may also lead to torticollis. Torticollis results from tightness of the sternocleidomastoid muscle, resulting in the infant's head being tilted to one side.

Therapeutic management involves passive stretching exercises. These exercises should be effective in 95% of cases of congenital torticollis, especially if treatment is started within the first 4 months of life (Spiegel & Dormans, 2011). Physical therapy may be prescribed and a tubular orthosis for torticollis (TOT) collar may also be used. Medications used include baclofen and injection of botulinum toxin, which can provide temporary relief with repeat injections needed every 3 months (Vorvick & Zieve, 2010). Surgery is not common but may be done in the preschool years if other methods have been unsuccessful. Plagiocephaly may result from the continued pressure on the side of the skull to which the neck is turned.

## Nursing Assessment

Note history of head tilt and infant's lack of desire to turn the head in the opposite direction. Observe the infant for wryneck (tilting of the head to one side; Fig. 45.18). Note limited movement of the neck while performing passive range of motion. Palpate the neck, noting a mass in the sternocleidomastoid muscle on the affected side. Examine the head for evidence of plagiocephaly. Accompanying hip dysplasia is seen in 20% of cases. Therefore, careful examination of the hips is warranted (Polousky & Eilert, 2009).

## Nursing Management

Teach parents gentle neck-stretching exercises to be performed several times a day. While immobilizing the shoulder on the affected side, gently sustain a side-to-side stretch toward the unaffected side, holding the stretch for 10 to 30 seconds. Repeat 10 to 15 times per session. Perform an ear-to-shoulder stretch in a similar fashion. To prevent the development of torticollis in the unaffected infant, prevent positional plagiocephaly. Prevent flatness of one side of the head by varying the infant's head position, and do not always turn the infant's head to one side while he or she is in the infant seat, in

**FIGURE 45.18** Note wryneck or head tilt in the infant with torticollis.

the swing, or lying supine. Refer families to the Infant Torticollis Organization, a parent support network, and Torticollis Kids, links to which can be found on [thePoint](#).

## ACQUIRED DISORDERS

Several acquired musculoskeletal disorders may affect children. Nutritional deficits or malabsorption of fats may lead to rickets. Slipped capital femoral epiphysis and Legg-Calvé-Perthes disease affect mainly school-age and adolescent boys. Osteomyelitis, septic arthritis, and toxic synovitis are common infectious musculoskeletal disorders. Spinal curvature may occur as a result of a neuromuscular disorder or idiopathically.

### Rickets

Rickets is a condition in which there is softening or weakening of the bones. Childhood rickets may occur as a result of nutritional deficiencies such as inadequate consumption of calcium or vitamin D or limited exposure to sunlight (required for adequate production of vitamin D). Rickets caused by vitamin D deficiency is a preventable condition but cases continue to be reported in infants, children, and adolescents (Wagner, Greer, & the Section on Breastfeeding and Committee on Nutrition, 2008). Rickets may also occur

if the body cannot regulate calcium and phosphorus in the appropriate balance, such as in chronic renal disease. Gastrointestinal disorders in which fat absorption is altered (e.g., Crohn disease, celiac disease, and cystic fibrosis) may lead to rickets, as vitamin D is a fat-soluble vitamin.

Calcium is primarily laid down in the bones of the fetus during the third trimester. Premature infants miss this period of calcium accumulation and also suffer from inadequate calcium intake in the neonatal period. Thus, premature infants often demonstrate rickets of prematurity. Regardless of the underlying cause, rickets is most likely to occur during periods of rapid growth.

Vitamin D regulates calcium absorption from the small intestine and levels of calcium and phosphate in the bones. When calcium and phosphate levels in the blood are imbalanced, then calcium is released from the bones into the blood, resulting in loss of the supportive bony matrix.

## Therapeutic Management

Treatment of rickets is aimed at correcting the calcium imbalance so that the skeleton may develop properly and without deformity. Calcium and phosphorus supplements are given, and some children also require vitamin D supplements. If rickets is not corrected while the child is still growing, permanent skeletal deformities and short stature may result.

### Take Note!

The Academy of Pediatrics currently recommends all infants and children, including adolescents, have a minimum daily intake of 400 IU of vitamin D beginning soon after birth (Wagner et al., 2008).

## Nursing Assessment

Obtain a health history, determining risk factors such as:

- Limited exposure to sunlight
- Strict vegetarian diet or lactose intolerance (either one without milk product ingestion)
- Exclusive breastfeeding by a mother who has a vitamin D deficiency
- Dark-pigmented skin
- Prematurity
- Malabsorptive gastrointestinal disorder
- Chronic renal disease

Note history of fractures or bone pain. Observe for dental deformities and bowlegs. Decreased muscle tone may also be present. Note low serum calcium and phosphate levels and high alkaline phosphatase levels. Radiographs may show changes in the shape and structure of the bone.

## Nursing Management

Administer calcium and phosphorus supplements at alternate times to promote proper absorption of both of these supplements. Encourage exposure to moderate amounts of sunlight and administer vitamin D supplements as prescribed. Teach families that good dietary sources of vitamin D are fish, liver, and processed milk.

### Slipped Capital Femoral Epiphysis

Slipped capital femoral epiphysis (SCFE) is a condition in which the femoral head dislocates from the neck and shaft of the femur at the level of the epiphyseal plate. The epiphysis slips downward and backward. SCFE occurs most frequently in obese males, 11 to 16 years of age, and is more common in African American boys compared to Caucasians (Sankar, Horn, Wells, & Dormans, 2011). The left hip is more often affected (Sankar, Horn, Wells, & Dormans, 2011). The exact cause is unknown, but it is thought that during the teenage growth spurt the femoral growth plate weakens and becomes less resistant to stressors. Hormonal alterations during this period may also play a role.

SCFE is classified based on its severity and whether the slip is acute or chronic. Chronic SCFE may lead to shortening of the affected leg and thigh atrophy.

## Therapeutic Management

Promptly refer the child with SCFE to an orthopedic surgeon, as early surgical intervention will decrease the risk of long-term deformity. The goals of therapeutic management are to prevent further slippage, minimize deformity, and avoid the complications of cartilage necrosis (chondrolysis) and avascular necrosis of the femoral head. Surgical intervention may include in situ pinning, in which a pin or screw is inserted percutaneously into the femoral head to hold it in place. Osteotomy may be used for more severe cases. Osteoarthritis may be a long-term complication of SCFE.

## Nursing Assessment

Elicit a health history, determining the onset and extent of pain. In acute SCFE, the pain is usually sudden in onset and results in inability to bear weight. Chronic SCFE may present with an insidious onset of pain and limp. Note risk factors for SCFE, including age 9 to 16 years, African American race, sedentary lifestyle, rapid growth spurt, and being overweight or obese (Grewal & Ahier, 2010; Sankar, Horn, Wells, & Dormans, 2011). Observe ambulation, noting Trendelenburg gait. Assess for pain that is in the hip or that is referred to the groin, medial thigh, or knee. Note decreased range of motion in the affected hip with external rotation. Radiographs will be obtained to

confirm the diagnosis (anteroposterior and lateral frog-leg views of hips). Bone scan can rule out avascular necrosis, and CT scan helps define the extent of slippage.

### Take Note!

Do not attempt to perform passive range of motion to determine the extent of limitation in the child with SCFE; this may cause worsening of the condition.

## Nursing Management

Enforce bed rest and activity restriction. If traction is used for a period before surgery, perform routine traction care and neurovascular assessments. If surgery is performed, provide routine preoperative and postoperative care. Assess pain and administer analgesics as needed. After in situ pinning, assist the child with crutch walking. Teach the family that weight bearing is usually resumed about a week after the surgery and that the pin will be removed later. Prolonged immobility may isolate the adolescent from usual peer interactions, so encourage phone calls and visits with friends. Provide books, games, electronic devices, and magazines for distraction during the period of immobility. Provide education and support to the child and family.

### Legg-Calvé-Perthes Disease

Legg-Calvé-Perthes disease is a self-limiting condition that involves avascular necrosis of the femoral head. It most often affects children between 4 and 8 years of age, but it can occur as early as 18 months and up until skeletal maturity (Hoffmeister, 2008). The disease affects males more often (Grewal & Ahier, 2010). The etiology is unknown, but interruption of the blood supply to the femoral head results in bone death, and the spherical shape of the femoral head may be lost. Swelling of the soft tissues around the hip may occur. As new blood vessels develop, the area is supplied with circulation, allowing bone resorption and deposition to take place. During this period of revascularization, which takes 18 to 24 months, the bone is soft and more likely to fracture. Over time, the femoral head reforms.

## Therapeutic Management

The goal of therapeutic management is to maintain normal femoral head shape and to restore appropriate motion. Treatment of Legg-Calvé-Perthes disease includes anti-inflammatory medication to decrease muscle spasms around the hip joint and to relieve pain. Activity limitation may be prescribed, and sometimes bracing, casting, or traction is recommended to contain the femoral head. Serial x-ray follow-up determines progress of the

disease. If surgery becomes warranted, which is rarely done, then osteotomy may be performed. Complications include joint deformity, early degenerative joint disease, persistent pain, loss of hip motion or function, and gait disturbance.

## Nursing Assessment

Explore the health history for short stature, delayed bone maturation, related trauma, or a family history of Legg-Calvé-Perthes disease. Note painless limp, which may be intermittent over a period of months. Mild hip pain may result and may be referred to the knee or the thigh. Pain may be aggravated by exercise. Observe the child walking and note Trendelenburg gait. Perform range of motion, noting internal rotation of the hip and limited abduction. Muscle spasm may result with hip extension and rotation. Hip radiographs are obtained to evaluate the extent of epiphyseal involvement. MRI or bone scan may also be used to differentiate Legg-Calvé-Perthes disease from other disorders. Ultrasound and arthrograms may also be useful.

## Nursing Management

Nursing care of Legg-Calvé-Perthes disease is highly variable and depends on the stage of the disease and its severity. Administer anti-inflammatory medications, noting their effect on pain. If activities are restricted, exercise the unaffected body parts. Assist families with use of the brace if prescribed. The brace may be wiped with a damp cloth if it becomes dirty. Some children will be prescribed no treatment other than avoidance of contact or high-impact sports. Swimming and bicycle riding help to maintain range of motion with little risk. If mobility equipment is needed, educate the child and family on its use. If osteotomy is performed, provide routine postoperative care, including education and support of the child and family.

### Osteomyelitis

Osteomyelitis is a bacterial infection of the bone and soft tissue surrounding the bone. The long bone metaphysis is the most common location (Grewal & Ahier, 2010). *Staphylococcus aureus* is the most common infecting organism with methicillin-resistant *S. aureus* (MRSA) infections on the rise (Grewal & Ahier, 2010; Polousky & Eilert, 2009). Additional causes in infants include group B streptococcus and *Escherichia coli*; in children, *Streptococcus pyogenes* and *Haemophilus influenza* (which is now rare due to improvements in immunizations) are also implicated. Children usually present for evaluation within a few days to a week of onset of symptoms, though some may present later.

FIGURE 45.19 In osteomyelitis, bacterial invasion leads to infection within the bone.

Osteomyelitis is acquired hematogenously. Bacteria from the bloodstream mainly invade the most rapidly growing portion of the bone. The invading bacteria trigger an inflammatory response, formation of pus and edema, and vascular congestion. Small blood vessels thrombose and the infection extends into the metaphyseal marrow cavity. As the infection progresses the inflammation extends throughout the bone and blood supply is disrupted, resulting in death of the bone tissues (Fig. 45.19).

## Therapeutic Management

Aspiration is necessary to confirm diagnosis and identify specific microorganisms. Treatment includes a 4- to 6-week course of antibiotics. Some children may receive 1 to 2 weeks of intravenous antibiotics and then be switched to oral antibiotics for the remainder of the course. Surgical débridement is rarely necessary. Early treatment may prevent the complications of bone destruction, fracture, and growth arrest. Additional complications include recurrent infection, septic arthritis, and systemic infection.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1630. Assessment findings pertinent to osteomyelitis are discussed here.

Explore the health history for risk factors and symptoms. Risk factors include impetigo, infected varicella lesions, furunculosis, recent trauma, infected burns, and

prolonged intravenous line use. Obtain history of current or recent antibiotic therapy and response. Note history of irritability, lethargy, possible fever, and onset of pain or change in activity level. The child usually refuses to walk and demonstrates decreased range of motion in the affected extremity. Inspect the affected extremity for swelling. Palpate for local warmth and tenderness. Note point tenderness over affected bone.

Laboratory and diagnostic testing may reveal:

- Elevated white blood cell count, erythrocyte sedimentation rate, and C-reactive protein level
- Positive blood cultures
- Deep soft tissue swelling on radiography
- Changes on ultrasound or CT scan

## Nursing Management

Nursing management of the child with osteomyelitis focuses on assessment, pain management, and maintenance of intravenous access for administration of antibiotics. Individualize care based on the child's and family's response to the illness; see Nursing Care Plan 45.1. Maintain bed rest initially to prevent injury and promote comfort. Administer antipyretics as ordered if the child is febrile in the initial stage of the illness. Encourage the use of unaffected extremities by providing developmentally appropriate toys and games. Instruct the child and family on safe and proper use of crutches or walker if prescribed. Some children will be discharged home on intravenous antibiotics, while others will finish an oral antibiotic course. Teach parents proper administration of medications and maintenance of a peripherally inserted central catheter or central line at home if the child is finishing the antibiotic course intravenously.

### Septic Arthritis

Acute septic arthritis is a condition in which bacteria invade the joint space, most often the hip or knee. It can occur at any age but usually occurs in children younger than 3 years old (Dugdale, Vyas, & Zieve, 2009). Usually bacteria gain access to the joint through the bloodstream but can be due to direct puncture from injections, venipuncture, wound infection, surgery, or injury.

*S. aureus* is the most common causative organism with community-acquired MRSA on the rise (Schwentker, 2009). Various streptococci species, *Pseudomonas aeruginosa*, pneumococci, *Neisseria meningitidis* (with or without an associated meningitis), *Escherichia coli*, *Klebsiella* species, and *Enterobacter* species are also responsible organisms. *Haemophilus influenzae* used to be a common cause, but is now rare due to improvements in immunizations (Schwentker, 2009). Sepsis of the hip joint may cause avascular necrosis of the femoral head due to

pressure on blood vessels and cartilage within the joint space. Septic arthritis is considered a medical emergency, as destruction of the joint cartilage may occur within just a few days. Additional complications of septic arthritis include permanent deformity, leg-length discrepancy, and long-term decreased range of motion and disability.

The goals of treatment of septic arthritis are to prevent destruction of the joint cartilage and maintain function, motion, and strength. Septic arthritis is treated rapidly with joint aspiration or arthrotomy, followed by intravenous antibiotic therapy while in the hospital and oral antibiotics at home.

## Nursing Assessment

Note history of predisposing factors such as respiratory infection or otitis media, skin or soft tissue infections, or, in the neonate, traumatic puncture wounds and femoral venipunctures. The history is usually significant for sudden onset of fever and moderate to severe pain.

Upon physical examination, the infant or child appears ill. Note extent of fever, reports of pain, refusal to bear weight or straighten the joint, and limited range of motion (the child usually maintains the joint in flexion and will not allow the leg to be straightened). The child will generally hold the joint in a position of comfort and the child or infant will appear without pain as long as the joint is immobile. Any attempt at passive range of motion will reveal pain. Palpate the affected joint for warmth and swelling.

Laboratory findings may include:

- White blood cell count normal or elevated with elevated neutrophil counts
- Elevated erythrocyte sedimentation rate and C-reactive protein levels
- Fluid from joint aspiration demonstrates elevated white blood cell count; culture determines responsible organism.
- Joint radiograph may show subtle soft tissue changes or increase in the joint space.
- Positive blood culture for the causative organism (15% of cases)

## Nursing Management

Refer to Nursing Care Plan 45.1 for interventions related to musculoskeletal disorders. Assess aspiration wound for signs of infection. Monitor vital signs for resolution of fever. Pain management with ibuprofen or acetaminophen will be sufficient for some children; others may initially require codeine or morphine. Assess the affected joint for a decrease in swelling, increasing range of motion, and decreasing or absent pain. The child may be discharged after 72 hours of intravenous antibiotics following joint aspiration if he or she is improving and can tolerate oral antibiotics. At discharge, if the child cannot

ambulate, physical therapy may be consulted for short-term use of crutches or a wheelchair. Teach families how to assess for signs and symptoms of wound infection, how to administer oral antibiotics and pain medication, and how to assist their child with crutch walking.

### Transient Synovitis of the Hip

Transient synovitis of the hip (also termed toxic synovitis) is the most common cause of hip pain and limping in children in the United States (Polousky & Eilert, 2009). It occurs in children as young as 9 months of age through adolescence, most commonly affecting children between 3 and 8 years old (Sankar, Horn, Wells, & Dormans, 2011). Boys are affected twice as often as girls (Polousky & Eilert, 2009). The exact cause is unclear, but it is thought to be associated with recent or active infection, trauma, or allergic hypersensitivity (Sankar, Horn, Wells, & Dormans, 2011; Whitelaw & Schikler, 2012). It is a self-limiting disease and most cases resolve within a week, but it may last as long as 4 weeks. Usually septic arthritis and osteomyelitis must be excluded before diagnosis can be confirmed.

Therapeutic management involves nonsteroidal anti-inflammatory medications, analgesics, and bed rest to relieve weight bearing on the affected hip joint.

### Nursing Assessment

Explore the health history for risk factors such as antecedent trauma, concurrent or recent upper respiratory tract infection, pharyngitis, or otitis media. Note sudden acute onset of moderate to severe pain of one hip. Sometimes pain is referred to the anterior thigh or knee. Pain is usually the worst upon arising in the morning, and the child refuses to walk; pain then decreases throughout the day. Temperature will be normal or low grade (less than 38°C). Observe for a limp or for refusal to bear weight. Observe position of the affected hip: it will be held in a flexed and externally rotated position. Note restricted range of motion for abduction and internal rotation.

## Nursing Management

Nursing care focuses on educating the family including instructions on administering nonsteroidal anti-inflammatory medications, analgesics, and bed rest. Parents are very concerned when their child refuses to walk; therefore, provide significant support and reassure the child and family of the self-limiting nature of the disease.

### Scoliosis

Scoliosis is a lateral curvature of the spine that exceeds 10 degrees. It may be congenital, associated with other disorders, or idiopathic. Table 45.3 explains the types of scoliosis. Idiopathic scoliosis, with the majority of cases occurring during adolescence, is the most common scoliosis (Spiegel & Dormans, 2011). Hence, this discussion will focus on adolescent idiopathic scoliosis. The etiology of idiopathic scoliosis is not known, but genetic factors, growth abnormalities, and bone, muscle, disc, or central nervous system disorders may contribute to its development. Early screening and detection of scoliosis result in improved outcomes.

### Pathophysiology

In the rapidly growing adolescent, the involved vertebrae rotate around a vertical axis, resulting in lateral curvature. The vertebrae rotate to the convex side of the curve, with the spinous processes rotating toward the concave side. Wedge-shaped vertebral bodies and discs develop because growth is suppressed on the concave side of the curve (Grewal & Ahier, 2010). As the curve progresses, the shape of the thoracic cage changes and respiratory and cardiovascular compromise may occur (the main complications of severe scoliosis).

### Therapeutic Management

Treatment of scoliosis is aimed at preventing progression of the curve and decreasing the impact on pulmonary

**TABLE 45.3** TYPES OF SCOLIOSIS

Type	Associated Factors
Idiopathic	Unknown cause Infantile: occurs in the first 3 years of life Juvenile: diagnosed between age 4 and 10 years, or prior to adolescence Adolescent: age 11 to 17 years
Neuromuscular	Associated with neurologic or muscular disease such as cerebral palsy, myelomeningocele, spinal cord tumors, spinal muscular atrophy, muscular dystrophies
Congenital	Results from anomalous vertebral development

## BOX 45.1

**TYPES OF BRACES USED TO TREAT SCOLIOSIS**

- Underarm (thoracolumbosacral orthosis [TLSO], Boston, Wilmington): for low thoracic and thoracolumbar curves; less conspicuous, no visible neckpiece
- Milwaukee: for thoracic or major double curves; traditional, standard, has a visible neckpiece with chin rest
- Nighttime bending (Charleston): creates a curve so severe that walking is not possible, so can be worn only at night

and cardiac function. Treatment is based on the age of the child, expected future growth, and severity of the curve. Observation with serial examinations and spine radiographs is used to monitor curve progression. For curves of 25 to 40 degrees, bracing may be sufficient to decrease progression of the curve (Grewal & Ahier, 2010). Box 45.1 describes types of scoliosis braces and Figure 45.20 shows examples of braces. The choice of brace will depend on the location and severity of the curve. Some curves will progress despite appropriate bracing and compliance.

Surgical correction is often required for curves greater than 45 degrees; it is achieved with rod placement and bone grafting (Grewal & Ahier, 2010; Whitelaw & Schikler, 2012). Partial spinal fusion accompanies many of the corrective surgeries. Multiple surgical approaches and techniques with various instrumentation methods exist for fusion and rod placement. The surgical approach

may be anterior, posterior, or both. Traditional rod placement (Harrington rod) involved a single rod fused to the vertebrae, resulting in curve correction but also a flat-backed appearance. Newer rod instrumentations allow for scoliosis curve correction with maintenance of normal back curvature. The rods are shorter, and several are wired or grafted to the appropriate vertebrae to achieve correction. Figure 45.21 shows one example of surgical rod instrumentation.

**Nursing Assessment**

For a full description of the assessment phase of the nursing process, refer to page 1630. Assessment findings pertinent to scoliosis are discussed below.

**Health History**

Determine why the child is presenting for evaluation of scoliosis. Commonly the child or adolescent will not report back pain; only mild discomfort is associated with idiopathic scoliosis until the curve becomes severe. Often the family recognizes asymmetry in the hips or shoulders or the child is screened for scoliosis at school and determined to be at risk. Explore the child's current and past medical history for risk factors such as:

- Family history of scoliosis
- Recent growth spurt
- Physical changes related to puberty

Determine the age of development of secondary sex characteristics and the age of menarche, as these signs of pubertal development indicate the expected velocity and length of remaining growth.

**FIGURE 45.20** (A) Boston brace. (B) Milwaukee brace. (C) Nighttime bending brace.

**FIGURE 45.21** Rods are fused to the vertebrae and connected to a distracting rod to rotate the vertebral column (Cotrel-Dubousset method is shown).

### Physical Examination

The physical assessment of a child with possible or actual scoliosis involves mainly inspection and observation. Auscultate the heart and lungs to determine compromise related to severe curvature.

Observe the child at rest, sitting, and standing for evidence of poor posture. Inspect the child's back in a standing position. Note asymmetries such as shoulder elevation,

prominence of one scapula, uneven curve at the waistline, or a rib hump on one side. Measure shoulder levels from the floor to the acromioclavicular joints. Note the difference between the height of the high and low shoulder in centimeters. Measure heights of anterior and posterior iliac spines and note the difference in centimeters. View the child from the side, noting abnormalities in the spinal curve. With the child bending forward, arms hanging freely, note asymmetry of the back (pronounced hump on one side). Figure 45.22 shows scoliosis noted upon visual inspection. Note leg-length discrepancy if present. During the neurologic examination, balance, motor strength, sensation, and reflexes should all be normal.

### Laboratory and Diagnostic Tests

Full-spine radiographs are necessary to determine the degree of curvature. The radiologist will determine the extent of the curve based on specific formulas and techniques of measurement.

### Nursing Management

Nursing Care Plan 45.1 lists general interventions. Tailor nursing care based on the adolescent's response to the disease and its treatment. Additional nursing interventions specific to scoliosis are discussed here.

### Encouraging Compliance With Bracing

Bracing is intended to prevent progression of the curve but does not correct the current curve. Although modern

**FIGURE 45.22 (A)** Note right shoulder, scapula, and hip elevation as well as discrepancy in waist curvature. **(B)** Note right upper back hump.

braces display an improved appearance, with no visible neckpiece, and can be worn under clothes, many adolescents are not compliant with brace wear. The brace must be worn 23 hours per day to prevent curve progression. Many factors may contribute to noncompliance, including the discomfort associated with brace wear such as pain, heat, and poor fit. The family environment may not be conducive to compliance with brace wear, and teenagers are very concerned about body image.

Inspect the skin for evidence of rubbing by the brace that may impair skin integrity. Teach families appropriate skin care and recommend they check the brace daily for fit and breakage. Encourage the teen to shower during the 1 hour per day that the brace is off and to ensure that the skin is clean and dry before putting the brace back on. Wearing a cotton T-shirt under the brace may decrease some of the discomfort associated with brace wear. Exercises to strengthen back muscles may prevent muscle atrophy from prolonged bracing and maintain spine flexibility.

### Promoting Positive Body Image

Encourage the teen to express his or her feelings or concerns about wearing the brace. Give the teen ways to explain scoliosis and its treatment to his or her peers. Wearing stylish baggy clothes may help the teen to conceal the brace if desired. Refer teens and their families to the National Scoliosis Foundation for additional support. A link to the National Scoliosis Foundation is provided on [thePoint](#).

### Providing Preoperative Care

If the curve progresses despite bracing or causes pulmonary or cardiac compromise, surgical intervention will be warranted. In the preoperative period, teach the teen the importance of turning, coughing, and deep breathing in the postoperative period. Explain the tubes and lines that will be present immediately after the surgery. Review positioning guidelines: back flexion or extension will not be allowed. Introduce the child to the patient-controlled analgesia pump and explain pain scales. There is a high risk for significant blood loss with spinal fusion and instrumentation, so if possible arrange for preoperative autologous blood donation.

### Providing Postoperative Care

The goal of nursing management in the postoperative period after spinal fusion with or without instrumentation is to avoid complications. Perform neurovascular checks with each set of vital signs. When turning the child, use the log-roll technique to avoid flexion of the back (Fig. 45.23). Provide proper pain management and medicate for pain before repositioning and ambulation.

**FIGURE 45.23** Log-roll the postoperative spinal fusion child to prevent spine flexion.

Administer prophylactic intravenous antibiotics if ordered. Assess for drainage from the operative site and for excess blood loss via the Hemovac or other drainage tube. Maintain Foley patency, as the child will be confined to bed for the first couple of days. Maintain strict recording of fluid intake and output. Administer transfusions of packed red blood cells if ordered. Ambulation, once ordered, should be done slowly to avoid orthostatic hypotension. Assist the family with arrangements to continue the teen's schoolwork while hospitalized and/or arrange for home tutoring during the several-week recovery period.

### Consider This

Angela Hernandez, a 15-year-old girl, is being seen in the clinic after she was found to be at high risk for scoliosis during a school screening. Upon assessment the nurse notes asymmetry of the hips, with shoulder elevation and prominence of one scapula. She is visibly upset and wants to know what caused this and what can be done. How would you address her concerns?

Angela's plan of care will include wearing of a brace. What education will be necessary and how can you promote compliance?

Describe nursing care for Angela if surgical correction becomes necessary.

## INJURIES

Injuries throughout childhood are inevitable. Trauma often occurs as a result of motor vehicle injury. The bulk of trauma resulting from physical activity or sports in children is due to running, skateboarding, and climbing trees. Only about one third of sports injuries in children occur during organized sports; the rest occur in physical education

class or nonorganized sports (Busch, 2006). Younger children tend to suffer contusions, sprains, and simple upper extremity fractures; adolescents more frequently experience lower extremity trauma. As the number of children participating in youth sports increases and the intensity of training and the level of competition also increase, the incidence of injury is also likely to increase.

Many types of musculoskeletal injuries exist. This discussion will focus on fractures, sprains, overuse syndromes, and dislocated radial head.

## Fracture

Fractures occur frequently in children and adolescents; 42% of boys and 27% of girls will suffer a fracture during childhood (Grewal & Ahier, 2010). The most common fractures in children occur in the forearm and wrist (Grewal & Ahier, 2010). Greenstick and buckle fractures account for about half of pediatric fractures, and only about 20% of childhood fractures require reduction (Price, Phillips, & Devito, 2006). Midclavicular, humerus, or femur fractures can occur as a result of birth trauma. They typically heal well but may require limiting mobility or splinting.

Fractures in children result most frequently from accidental trauma (Grewal & Ahier, 2010). Nonaccidental trauma (child abuse) and other disease processes are the other causes of fractures. In children younger than 2 years, most fractures that occur are the result of another person causing the injury (Grewal & Ahier, 2010).

### Take Note!

Fracture in the newborn (with the exception of birth trauma) or infant should raise a high index of suspicion for abuse, as fractures are very unusual in children who cannot yet walk (Grewal & Ahier, 2010).

## Pathophysiology

The growth plate is the most vulnerable portion of the child's bone and is frequently the site of injury. The Salter-Harris classification system is used to describe fractures involving the growth plate (Table 45.4). The thicker, more elastic periosteum in children yields to the force encountered with trauma, resulting more frequently in nondisplaced fractures in children. The increased vascularity and decreased mineral content make the child's bones more flexible. Plastic or bowing deformities and buckle and greenstick fractures are the result. Complete fractures do occur in children, but they tend to be more stable than in the adult, resulting in improved healing and function. Spiral, pelvic, and hip fractures are rare in children. Table 45.5 explains common types of fractures in children.

Fractures in children heal more rapidly and result in less disability and deformity than adults. The younger

the child, the more quickly the bone heals. However, plastic deformity and Salter-Harris type IV fractures may result in an angular deformity. Though healing of fractures is usually quick and without incident in children, delayed union, nonunion, or malunion can occur. Additional complications include infection, avascular necrosis, bone shortening from epiphyseal arrest, vascular or nerve injuries, fat embolism, reflex sympathetic dystrophy, and compartment syndrome, which is an orthopedic emergency. Later in life, osteoarthritis may occur as a long-term complication from childhood fracture (Dugdale & Zieve, 2010).

### Take Note!

Any type of fracture can be the result of child abuse but spiral femur fractures, rib fractures, and humerus fractures, particularly in the child younger than 2 years of age, should always be thoroughly investigated to rule out the possibility of abuse (Wells, Sehgal, & Dormans, 2011).

## Therapeutic Management

The vast majority of childhood fractures would heal well with splinting only, but casting of these fractures is performed to provide further comfort to the child and to allow for increased activity while the fracture is healing. Displaced fractures require manual traction to align the bones, followed by casting. More severe fractures may require traction for a period of time, usually followed by casting. Severe or complicated fractures may alternatively require open reduction and internal fixation for healing to occur. Complex fractures are often treated with external fixation (Fig. 45.24).

### Take Note!

Significant swelling may occur initially after immobilization with a splint. Delaying casting for a few days provides time for some of the swelling to subside, allowing for successful casting a few days after the injury.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1630. Assessment findings pertinent to fractures are discussed below.

## Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include recent injury, trauma, or fall; complaint of pain; difficulty bearing weight; limp; or refusal to use an extremity. Young children often demonstrate sudden onset of irritability and refusal to bear

TABLE 45.5

TYPES OF FRACTURES IN CHILDREN

Fracture Type	Description	Illustration
Plastic or bowing deformity	Significant bending without breaking of the bone	
Buckle fracture	Compression injury; the bone buckles rather than breaks.	
Greenstick fracture	Incomplete fracture of the bone	
Complete fracture	Bone breaks into two pieces.	

**FIGURE 45.24** (A) External fixation is required for complicated fractures. (B) The Ilizarov fixator is a circular apparatus usually used for complicated lower extremity fractures. The pins are smaller in diameter, more like wires, than those used in other fixators.

weight. Ask about the mechanism of injury and obtain a description of the traumatic event. Be alert to inconsistencies between the history and the clinical picture or mechanism of injury; inconsistency may be an indicator of child abuse. Explore the child's current and past medical history for risk factors such as:

- Rickets
- Renal osteodystrophy
- Osteogenesis imperfecta
- Participation in sports, particularly contact sports
- Failure to use protective equipment as recommended for various physical activities and sports (e.g., wrist guards while rollerblading)

### Physical Examination

Perform the physical examination of the child with a potential fracture carefully, so as not to cause further pain or trauma. The physical examination particular to fractures includes inspection, observation, and palpation.

#### Take Note!

Do not attempt to straighten or manipulate an injured limb.

### INSPECTION AND OBSERVATION

Inspect the skin for bruising, erythema, or swelling. Observe the extremities for deformity. Note neglect of an

extremity or an inability to bear weight. If ambulating, note any limp.

### PALPATION

Carefully palpate the joint or injured part. Distract the young child with a toy or activity while palpating. Note point tenderness, which is a reliable indicator of fracture in children. Assess neurovascular status, noting distal extremity temperature, spontaneous movement, sensation, numbness, capillary refill time, and quality of pulses. The neurovascular assessment is critical to providing a baseline so that any changes associated with compartment syndrome can be identified quickly.

### Laboratory and Diagnostic Tests

Usually plain x-ray films are all that is required to identify a simple fracture. Complicated fractures that require surgical intervention may require further evaluation with CT or MRI.

## Nursing Management

Immediately after the injury, immobilize the limb above and below the site of injury in the most comfortable position with a splint. Use cold therapy to reduce swelling in the first 48 hours after injury. Elevate the injured extremity above the level of the heart. Perform frequent neurovascular checks.

#### Take Note!

Assess the injured, splinted, or casted extremity frequently for the "5 P's," which may indicate compartment syndrome: pain (increased out of proportion), pulselessness, pallor, paresthesia, and paralysis. Report these findings immediately.

Assess pain level and administer pain medications as needed. Utilize nonpharmacologic methods of pain relief as needed. Administer tetanus vaccine in the child with an open fracture if he or she has not received a tetanus booster within the past 5 years. Additional nursing interventions include providing family education and teaching on fracture prevention.

### Providing Family Education

Unless bed rest is prescribed, children with upper extremity casts and "walking" leg casts can resume increased levels of activity as the pain subsides. Children who require crutches while in a cast may return to school, but those in spica casts will be at home for several weeks. Providing distraction and finding ways to keep up with school work are important. Teach families to care for the cast (see Teaching Guidelines 45.1).

## Preventing Fractures

Discourage risky behavior such as climbing trees and performing tricks on bicycles. Provide appropriate supervision, particularly with outdoor activity. Encourage appropriate use of protective equipment, such as wrist guards with rollerblading and shin guards with soccer. Ensure that playground equipment is in good working order and intact; there should not be protruding screws or unbalanced portions of equipment, which may increase the risk for falling.

### Sprains

Sprains result from a twisting or turning motion of the affected body part. The tendons and ligaments stretch excessively and may tear slightly. They are uncommon in young children as their growth plates are weaker than their muscles and tendons, making them more prone to fracture. They may occur at any joint, but the most common are ankle and knee sprains. Therapeutic management of sprains includes rest, ice, compression, and elevation (RICE). Other treatment options may include activity restrictions, splints or casts, crutches or wheelchair, and physical therapy. On initial evaluation, sprains need to be differentiated from torn ligaments and meniscal tears, as those conditions are more serious and may require surgical intervention.

## Nursing Assessment

Elicit a health history, determining the mechanism of injury (whether it occurred during sports or simply a

misstep or fall). Determine what treatment the family has used so far. Inspect the affected body part for edema, which is frequently present, and bruising, which sometimes occurs. Note limp or inability to bear weight. Do not attempt to perform passive range of motion on the affected body part. Assess neurovascular status distal to the injury (usually normal).

## Nursing Management

Instruct the child and family in appropriate treatment of sprains, which includes:

- Rest: limit activity.
- Ice: apply cold packs for 20 to 30 minutes, remove for 1 hour, and repeat (for the first 24 to 48 hours).
- Compression: apply an Ace wrap or other elastic bandage or brace; check skin for alterations when rewrapping.
- Elevation: elevate the injured extremity above the level of the heart to decrease swelling (Fig. 45.25).

The child may require instruction in crutch walking as well. Teach families that to prevent sprains during sports, it is important for the child to perform appropriate stretching and warm-up activities.

### Take Note!

If the child's fingers or toes become increasingly swollen or discolored, remove the Ace wrap immediately.

## RICE

Rest

Ice

Compression

Elevation

FIGURE 45.25 RICE (rest, ice, compression, elevation) is the appropriate treatment for sprains.

## Overuse Syndromes

The term “overuse syndrome” refers to a group of disorders that result from repeated force applied to normal tissue. The connective tissues fail in response to repetitive stress, leading to a small amount of tissue breakdown. They develop over the course of weeks to months. There is usually no identifiable injury associated with overuse syndromes. Pain is usually associated with the activity and worsens with continued participation in the activity. The incidence of overuse injuries in the young athlete has increased as participation of youths in organized sports has grown along with children today participating in sports year-round and sometimes in multiple sports simultaneously (Brenner & the Council on Sports Medicine and Fitness, 2011). The young athlete is at risk for more serious overuse injuries due to the following:

- The growing bones of the young athlete cannot handle as much stress as mature bones in adults.
- The child is just learning the proper mechanisms for skills, such as throwing a baseball.
- The child is unable to recognize vague signs of injury such as fatigue and poor performance (Brenner & the Council on Sports Medicine and Fitness, 2011).

Table 45.6 gives details on several common overuse syndromes. Therapeutic management is aimed at reassurance, pain management, and limiting rather than eliminating activity.

## Nursing Assessment

Elicit a health history to determine the extent of involvement in sports. Note onset of pain, duration, intensity, aggravating factors, and treatments used at home. Examine the painful part, noting findings similar to those noted for each syndrome in Table 45.6.

## Nursing Management

Initially, apply ice when pain is severe. Anti-inflammatory medications such as ibuprofen may be helpful. Encourage the child to limit exercise and participate in a different activity. After a few weeks, most overuse syndromes resolve; at that point, the athlete may resume the prior activity. Osgood-Schlatter disease is the exception and may require 12 to 24 months to resolve (Gunta, 2009). Using pads or braces that are appropriate to the painful body part is also helpful. Supporting the arm with a

TABLE 45.6

OVERUSE DISORDERS

Disorder	Anatomic Area Affected	Most Commonly Occurs in	Symptoms
Osgood-Schlatter disease	Partial avulsion of the ossification center of the tibial tubercle	Active adolescents, most often boys. Most frequently during periods of rapid growth	<ul style="list-style-type: none"> <li>• Mild to moderate pain, activity related</li> <li>• Tibial tubercle is tender when palpated</li> <li>• Painful swelling or prominence of the anterior portion of the tibial tubercle</li> </ul>
Epiphysiolysis of proximal humerus	Proximal humerus (widening of growth plate)	Occurs with rigorous upper extremity activity, such as baseball pitching	<ul style="list-style-type: none"> <li>• Tenderness in the shoulder or proximal humerus</li> <li>• Pain with active internal rotation</li> <li>• Full shoulder range of motion continues</li> </ul>
Epiphysiolysis of distal radius	Distal radius (widening of growth plate)	Occurs with overuse of the distal radius, such as in gymnasts	<ul style="list-style-type: none"> <li>• Wrist pain that worsens with activity</li> </ul>
Sever disease (calcaneal apophysitis)	Calcaneus (heel)	Usually in 9- to 14-year-olds	<ul style="list-style-type: none"> <li>• Pain over the posterior aspect of the calcaneus</li> <li>• Limited active and passive dorsiflexion of foot</li> </ul>
Shin splints	Refer to a variety of overuse syndromes associated with the shin (stress fracture, tibial stress, muscular issues)	Occur with activities that place repeated exertion on the lower leg, as in runners, ballerinas, elite soccer players	<ul style="list-style-type: none"> <li>• Exercise-induced pain of the anterior aspect of the middle part of the lower leg</li> <li>• May be sharp pain</li> <li>• Worsens with exercise</li> <li>• With stress fracture, may have a limp that worsens with activity</li> </ul>

sling may relieve stress on the proximal humerus when epiphysiolysis occurs. Heel cups used in athletic shoes help relieve stress on the heels associated with Sever disease. To prevent overuse syndromes, encourage athletes to perform appropriate stretching exercises during a 20- to 30-minute warm-up period before each practice or game. Also encourage several weeks of conditioning training before the season begins.

There is currently limited research pertaining to overuse injuries in the young athlete. The American Academy of Pediatrics has developed some guidelines to help prevent these injuries such as the following: encourage 1 to 2 days off per week of competitive athletics, sports training, and competitive practice; encourage 2 to 3 months away from a specific sport during the year; and educate to increase weekly training time, number of repetitions, or total distance by no more than 10% a week (Brenner & the Council on Sports Medicine and Fitness, 2011).

### Take Note!

“Energy healing” such as therapeutic touch and Reiki may provide a nonpharmacologic adjunct to pain management for musculoskeletal injuries.

## Radial Head Subluxation

Subluxation of the radial head (“nursemaid’s elbow”) occurs when a pulling motion on the arm causes the annular ligament surrounding the radial head to stretch or tear, therefore displacing the radial head. The ligament becomes entrapped within the joint, preventing spontaneous reduction. It usually occurs in children younger than 7 years of age and is a common injury in children aged 2 to 5 years (Rodts, 2009). In most cases a parent, sibling, or caregiver inadvertently injures the child while holding or pulling on a pronated upper extremity. Radiologic examination may be done, especially if the mechanism of injury is not clear, to rule out fracture or dislocation. To reduce the injury, the elbow is flexed to 90 degrees and then the forearm is fully and firmly supinated, causing the ligament to snap back into place. With appropriate reduction of the radial head, no complications result.

## Nursing Assessment

Elicit a health history to help determine the mechanism of injury. Common precipitators of this injury include pulling on the child’s arm while leading him or her in one direction, helping the child up the stairs, a child dropping or falling to the ground while an adult is holding the hand, or swinging or lifting the child by the hands. Assess neurovascular status and examine the extremity.

The child will hold the arm slightly flexed at the side or across the abdomen and refuse to move it. When the arm is still, the child apparently has no discomfort. Neurovascular status is normally intact with no bruising or swelling present.

## Nursing Management

After treatment, usually hyperpronation to reduce the dislocation, assess the child’s ability to use the arm without pain. Typically after reduction the child will demonstrate less pain almost immediately. Educate parents that once a radial head subluxation occurs it may recur. Teach parents to avoid excessive pulling or pulling up on the child’s arm, particularly in an abrupt jerking fashion, to prevent recurrence. Encourage parents and caregivers to always lift the child under the arms.

### KEY CONCEPTS

- At birth, muscles, tendons, ligaments, and cartilage are all present and functional.
- Rapid muscle growth in the adolescent years places the teenager at increased risk for injury compared with other age groups.
- The bones of the infant and young child are more flexible and have a thicker periosteum and more abundant blood supply than the adult’s; as a result, bending occurs more frequently than breaking of the bone, and the fractured bone heals more quickly.
- The epiphysis of long bones is the growth center of the bones in children. Injury to this area may result in long-term extremity deformity.
- Plain radiographs are usually sufficient for diagnosing injuries in children. If CT or MRI scans are required, the nurse may need to help the child stay calm and still during the procedure.
- Apply a pressure dressing following joint aspiration to prevent hematoma formation or fluid recollection.
- Perform frequent assessments of pain status and the effect of pain medication in the child with a musculoskeletal disorder.
- Diazepam (Valium) may be helpful in relieving muscle spasm associated with traction.
- Maintain traction and the appropriate amount of weight as ordered.
- The bulk of cast care occurs in the home. Teach the family of a child with a cast to perform neurovascular assessments, prevent the cast from getting wet, and care for the skin appropriately.

- Assessment of neurovascular status is an essential component of care for a child with a neuromuscular disorder.
- Children with chronic disorders such as osteogenesis imperfecta may demonstrate slower or lesser growth than other children and may also be unable to participate in certain activities because of bone fragility.
- Congenital or developmental disorders such as DDH or clubfoot require bracing or casting for correction and to prevent deformity later in life.
- Fractures may occur as a result of unintentional or intentional injury, or because the bones are fragile, as in rickets or osteogenesis imperfecta.
- Sprains, fractures, and overuse syndromes occur frequently in young athletes. Appropriate warm-up and stretching may help prevent some of these injuries.
- Rest, ice, compression, and elevation is the appropriate treatment for sprains.
- Torticollis may be treated by teaching the family to perform daily neck muscle stretching exercises.
- To prevent complications after a spinal fusion for scoliosis correction, use the log-roll method for turning the child so that back flexion is avoided.

## MULTIPLE CHOICE QUESTIONS

- The nurse is evaluating a parent's understanding of treatment for torticollis. Which response best indicates that the parent understands the appropriate treatment?
  - Encourages the infant to turn the head to the unaffected side
  - States that prone positioning for sleep will be needed
  - Places the infant on the affected side
  - Stretches the infant's neck to the opposite side and holds it for 5 seconds
- The nurse is providing education related to use of a brace that the orthopedic surgeon has ordered as treatment for idiopathic scoliosis in an adolescent girl. Which statement by the teen best indicates an understanding of appropriate use of the brace?
  - "I can take my brace off only for special occasions."
  - "I will take my brace off for only 1 hour per day, for showering."
  - "I do not need to wear my brace at night while I am sleeping."
  - "It is most important for me to wear my brace during the day, while I am upright."
- The nurse is caring for orthopedic children who are in the postoperative period following spinal fusion. What is the most appropriate activity to delegate to unlicensed assistive personnel?
  - Ambulate the children twice daily to promote mobility.
  - Encourage commode use to promote bowel function.
  - Provide diversionary activities, as the children must stay flat on their backs.
  - Assist with log-rolling the children every 2 hours.
- The nurse is caring for a child with a fractured left femur who has been in skeletal traction for several days. Upon assessment, she notes that the left foot is pale, with a nonpalpable pedal pulse. What is the priority nursing intervention?
  - Release the traction, as there may be too much weight on it.
  - Nothing; alterations in circulation are expected with skeletal traction.
  - Immediately notify the physician or nurse practitioner of this abnormal finding.
  - Massage the foot immediately to increase circulation.

## CRITICAL THINKING EXERCISES

- Develop a teaching plan for the family of an infant with developmental dysplasia of the hip or clubfoot.
- Develop a discharge teaching plan for a 2-year-old who will be in a hip spica cast for 10 more weeks at home.
- Devise a developmental/education plan for a child who will be confined to traction for 6 weeks. Choose a child in the clinical area whom you have cared for or choose a particular age group and develop the plan.

## STUDY ACTIVITIES

- In the clinical setting, compare the growth and development of a child with osteogenesis imperfecta or rickets with that of a typical healthy child. What differences or similarities do you find? What are the explanations for your findings?
- Attend a pediatric orthopedic clinic or the local clinic of Children's Medical Services. Identify the role of the registered nurse in this setting.

#### KEY TERMS

annular  
dermatitis  
erythema  
macule  
papule  
pruritus  
scaling  
vesicle

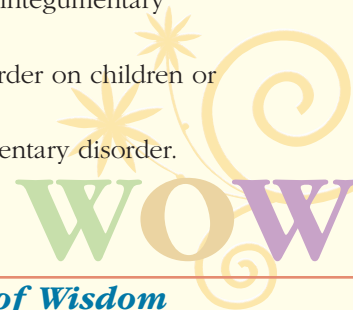

## Nursing Care of the Child With an Integumentary Disorder

### Learning Objectives

*Upon completion of the chapter, you will be able to:*

1. Define the key terms used in this chapter.
2. Compare anatomic and physiologic differences of the integumentary system in infants and children versus adults.
3. Describe nursing care related to common laboratory and diagnostic tests used in the medical diagnosis of integumentary disorders in infants, children, and adolescents.
4. Distinguish integumentary disorders common in infants, children, and adolescents.
5. Identify appropriate nursing assessments and interventions related to pediatric integumentary disorders.
6. Develop an individualized nursing care plan for the child with an integumentary disorder.
7. Describe the psychosocial impact of a chronic integumentary disorder on children or adolescents.
8. Develop child/family teaching plans for the child with an integumentary disorder.

*Eva Lopez, 1 year old, is brought to the clinic by her mother, who states, “Eva has dry patches of skin, her wrists bleed from her scratching, and she’s having trouble sleeping at night.”*

### Words of Wisdom

To a nurse the child's skin is life's gift-wrapping, but to the child the skin is the space suit for life.

**Integumentary** disorders occur often in children and are caused by exposure to infectious microorganisms, hypersensitivity reactions, hormonal influences, and injuries. Some integumentary disorders are as mild and self-limited as a minor abrasion. Others, such as atopic dermatitis, are chronic and must be managed consistently. Finally, some integumentary disorders can be severe and even life-threatening, such as full-thickness burns. If the integumentary disorders are chronic or severe, they can have a major impact on the child's physiologic or psychological status (Magin, Adams, Heading, Pond, & Smith, 2008). Nurses who care for children need to be familiar with common skin disorders of infancy, childhood, and adolescence so they can effectively intervene with children and their families.

## VARIATIONS IN PEDIATRIC ANATOMY AND PHYSIOLOGY

Skin is the largest organ of the body and serves to protect the underlying tissues from trauma and invasion by microorganisms. The skin's health reflects the internal well-being of the body (Burns, Dunn, Brady, Starr, & Blosser, 2009). The skin is also important for the perception of pain, heat, and cold and for the regulation of body temperature.

### Differences in the Skin Between Children and Adults

The infant's epidermis is thinner than the adult's, and the blood vessels lie closer to the surface because there is a decreased amount of subcutaneous fat. Thus, the infant loses heat more readily through the skin's surface than the older child or adult does. The thinness of the infant's skin also allows substances to be absorbed through the skin more readily than they would be in an adult. Bacteria can gain access via the infant's and younger child's skin more readily than they can through the adult's skin. The infant's skin contains more water than the adult's, and the epidermis is loosely bound to the dermis. This means that friction may easily cause separation of the layers, resulting in blistering or skin breakdown. The infant's skin is also less pigmented than that of the adult (in all races), placing the infant at increased risk of skin damage from ultraviolet radiation. Over time, the infant's skin toughens and becomes less hydrated and thus is less susceptible to microorganism invasion. The skin thickness and characteristics reach adult levels in the late teenage years.

### Differences in Dark-Skinned Children

Children with dark skin tend to have more pronounced cutaneous reactions compared to children with lighter skin. Hypopigmentation or hyperpigmentation in the affected area following healing of a dermatologic condition is

**FIGURE 46.1** Keloid formation is more common in dark-skinned than light-skinned children.

common in dark-skinned children. This change in pigmentation may be temporary (a few months following a superficial skin disorder) or permanent (following a more involved skin condition). Dark-skinned children tend to have more prominent **papules** (rounded, nonpustular elevation on the skin), follicular responses, lichenification, and vesicular or bullous reactions than lighter-skinned children with the same disorder. Hypertrophic scarring and keloid formation (Fig. 46.1) occur more often in dark-skinned children (Burns et al., 2009).

### Sebaceous and Sweat Glands

Sebaceous glands function immaturely at birth. The sebum secreted serves to lubricate the skin and hair. Sebum production increases in the preadolescent and adolescent years, which is why acne develops at that time. The infant's eccrine sweat glands are somewhat functional and will produce sweat as a response to emotional stimuli and heat. They become fully functional in the middle childhood years. Until that time, temperature regulation is less effective compared to older children and adults. The apocrine sweat glands are small and nonfunctional in the infant. They mature during puberty, at which time body odor develops in response to the fluid secreted by these glands.

## COMMON MEDICAL TREATMENTS

A variety of medications as well as other medical treatments are used to treat integumentary disorders in children. Most of these treatments will require a physician's or nurse practitioner's order when the child is in the hospital. The most common treatments and medications are listed in Common Medical Treatments 46.1 and Drug Guide 46.1. The nurse caring for the child with an integumentary disorder should be familiar with the procedures and medications, how they work, and common nursing implications related to their use.

## COMMON MEDICAL TREATMENTS 46.1

Treatment	Explanation	Indications	Nursing Implications
Wet dressing	Dressing moistened with lukewarm water (sterile water may be required in certain cases)	In the presence of itching, crusting, or oozing—helps to remove crusts	May use Burow, Domeboro, or saline solutions in certain cases. Provide atraumatic care by giving premedication before dressing change.
Sunscreen	Lotion, gel, or cream with a sun-protective factor (SPF)	All children older than 6 months of age	Use a fragrance-free, para-aminobenzoic acid (PABA)-free preparation with an SPF of 15 or higher. Apply at least 30 minutes prior to sun exposure. Reapply at least every 2 hours while exposed (every 60 to 80 minutes while in the water). Sweat- and water-resistant preparations are available yet still require reapplication as noted above. Use daily in summer and in warm climates, even on overcast and cloudy days.
Bathing	Use of lukewarm water (with or without soap) to bathe	Itchy and irritating skin conditions	Recommend fragrance-free, dye-free soaps such as Dove, Aveeno, Basis, Lubriderm. Colloid (oatmeal baths) are especially helpful. Pat the child dry; do not rub the skin. Leave the child moist before applying medication, dressing, or moisturizer.

## DRUG GUIDE 46.1 COMMON DRUGS FOR INTEGUMENTARY DISORDERS

Medication	Actions/Indications	Nursing Implications
Antibiotics (topical)	Decrease skin colonization with bacteria Indicated for mild acne vulgaris, impetigo, folliculitis	Apply as prescribed to clean skin or a cleansed wound. Be alert for neomycin allergy.
Antibiotics (systemic)	Bactericidal or bacteriostatic against a variety of organisms, depending on the preparation Used for moderate to severe acne vulgaris, extensive impetigo, cellulitis, scalded skin syndrome	Check for medication allergies prior to administration. Teach families to finish entire course of antibiotics.
Corticosteroids (topical)	Anti-inflammatory effect in atopic dermatitis and certain kinds of contact dermatitis	Do not use moderate- or high-potency corticosteroid preparations on the face or genitals. Do not cover with an occlusive dressing. Absorption is increased in the young infant.
Antifungals (topical)	Fungicidal used to treat tinea, candidal diaper rash	Apply a thin layer as prescribed. Comply with length of treatment as prescribed to prevent reemergence of the rash.
Antifungals (systemic): griseofulvin, ketoconazole	Kill fungus; bind to human keratin, making it resistant to fungus Indicated for tinea capitis and severe or widespread fungal skin infections	Griseofulvin: give with fatty food to increase absorption. Requires minimum 4-week course Monitor liver function tests and CBC. May cause photosensitivity Ketoconazole: administer with food to decrease GI upset.

**DRUG GUIDE 46.1 COMMON DRUGS FOR INTEGUMENTARY DISORDERS** (continued)

Medication	Actions/Indications	Nursing Implications
Benzoyl peroxide	Decreases colonization of <i>P. acnes</i> in mild acne vulgaris	Available in combination with topical antibiotics. Apply sparingly. Shake before application. Avoid contact with eyes and mucous membranes.
Retinoids (topical): tretinoin, adapalene, tazarotene	Anticomedogenic activity in moderate to severe acne vulgaris	Adverse effects: dryness, burning, photosensitivity Instruct child to use SPF 15 or higher sunscreen.
Topical immune modulators (tacrolimus, pimecrolimus)	Inhibit T-lymphocyte action at the skin level Used for moderate to severe atopic dermatitis, or in conditions resistant to topical steroids	Use only in children older than 2 years old. Avoid sunlight exposure. May cause burning, pruritus, flu-like symptoms, or headache.
Antihistamines (diphenhydramine, chlorpheniramine, hydroxyzine)	Antihistaminic effect, results in sedation Indicated for hypersensitivity reactions, atopic dermatitis or contact dermatitis that is severely pruritic	May give three or four times a day unless sedation effect interferes with activities of daily living or school.
Systemic corticosteroids (prednisone, dexamethasone, methylprednisolone)	Anti-inflammatory and immunosuppressive action Used in severe contact dermatitis	Administer with food to decrease GI upset. May mask signs of infection. Monitor blood pressure, urine for glucose. Do not stop treatment abruptly or acute adrenal insufficiency may occur. Monitor for Cushing syndrome. Doses may be tapered over time.
Isotretinoin (Accutane)	Reduces sebaceous gland size, decreases sebum production, and regulates cell proliferation and differentiation Indicated for cystic acne or severe acne that is resistant to 3 months of treatment with oral antibiotics	Ensure that the adolescent girl is not pregnant and does not become pregnant. Monitor CBC, lipid profiles, liver function tests, and $\beta$ -human chorionic gonadotropin monthly. Monitor for suicide risk.
Coal tar preparations	Antipruritic and anti-inflammatory effect Useful in psoriasis, atopic dermatitis	May stain fabrics; strong and unpleasant odor. Apply at bedtime and rinse off in the morning to improve compliance.
Silver sulfadiazine 1% (Silvadene)	Bactericidal against gram-positive and gram-negative bacteria and yeasts Indicated for burns	Cover with occlusive dressing. Apply BID. Do not use in children with sulfa allergy. Forms a gel on the burn that is painful to remove. May cause transient neutropenia. Do not use on the child's face or on an infant younger than 2 months of age.

CBC, complete blood count; GI, gastrointestinal.

Adapted from Taketokmo, C. K., Hodding, J. H., & Kraus, D. M. (2011). *Pediatric and neonatal dosage handbook* (18th ed.). Hudson, OH: Lexi-comp.

## NURSING PROCESS OVERVIEW FOR THE CHILD WITH AN INTEGUMENTARY DISORDER

Nursing management of the child with an integumentary disorder requires astute assessment skills, development of accurate nursing diagnoses and expected outcomes, implementation of appropriate interventions, and evaluation of the entire process. Many skin rashes may be associated with other, often serious illnesses, so the nurse must use comprehensive and excellent assessment skills when evaluating rashes in children. Certain integumentary conditions are chronic and require ongoing care related to health maintenance, education, and psychosocial needs.

### Assessment

Nursing assessment of the child with an integumentary disorder includes obtaining the health history and performing a physical examination. Assisting with or obtaining laboratory tests may also be necessary.

**Remember Eva, the 1-year-old with the dry patches, itching, and trouble sleeping? What additional health history and physical examination assessment information should the nurse obtain?**

### Health History

Determine the child's or parent's chief complaint, which is most often related to pruritus, **scaling** (dry, flaky skin), or a cosmetic disruption. Document the history of the present illness, noting onset, location, duration, characteristics, other symptoms, and relieving factors, particularly as related to a rash or lesion. Also ask about the quantity and quality of any discharge from the rash or lesions. Document accompanying symptoms. Note the child's general state of health, history of chronic medical conditions, recent surgeries, hospitalizations, medications, or immunizations. Has there been a recent change in the child's food intake or environment? Is there a family history of chronic or acute skin conditions? Does anyone in the home have a similar concern at this time? Does the family have pets that go outdoors? Does the child play in the woods or garden? Note usual skin care routines, as well as types of soaps, cosmetics, or other skin care products used. Determine the amount of daily sun exposure and whether the child consistently uses sunscreen.

### Physical Examination

Perform a complete physical examination, noting any abnormalities. Perform a focused and thorough examination of the skin. The best lighting for examination of the skin is natural daylight. Look at the skin in general, noting distribution of any obvious rashes or lesions. Inspect the mucous membranes, noting and describing lesions if present. Examine all surfaces of the skin and scalp carefully. Note temperature, moisture, texture, and fragility of the skin. If a rash or lesions are present, note their location and provide a detailed description of them. Describe whether a rash is macular, papular, pustular, or vesicular.

Provide a description of vascular lesions if present. If lesions are present on the scalp, has hair loss in that region occurred? Describe lesions according to the following criteria:

- Linear: in a line
- Shape: are the lesions round, oval, or **annular** (ring around central clearing)?
- Morbilliform: a rosy, maculopapular rash
- Target lesions: like a bull's-eye

If drainage is present, describe it as clear, purulent, honey colored, or otherwise. Note scaling or lichenification of the skin. Palpate for regional lymphadenopathy.

### Laboratory and Diagnostic Testing

Common Laboratory and Diagnostic Tests 46.1 details the laboratory and diagnostic tests most commonly used when considering integumentary disorders. The tests can assist the physician or nurse practitioner in diagnosing the disorder or can be used as guidelines in determining ongoing treatment. Some of the tests are obtained by laboratory or nonnursing personnel, while others might be obtained by the nurse. In either instance the nurse should be familiar with how the tests are obtained, what they are used for, and normal versus abnormal results. This knowledge will also be necessary when providing child and family education related to the testing.

### Nursing Diagnoses and Related Interventions

Upon completion of a thorough assessment, the nurse might identify several nursing diagnoses, such as:

- Impaired skin integrity
- Pain
- Risk for infection
- Disturbed body image
- Risk for fluid volume deficit
- Altered nutrition

Desired outcomes and interventions are based on the nursing diagnoses. Nursing Care Plan 46.1 can be used

## COMMON LABORATORY AND DIAGNOSTIC TESTS 46.1

Test	Explanation	Indications	Nursing Implications
Complete blood count (CBC) with differential	Evaluate hemoglobin and hematocrit, WBC count (particularly the percentage of individual WBCs), and platelet count	Infection or inflammatory process	Normal values vary according to age and gender. WBC differential is helpful in evaluating source of infection. May be affected by myelosuppressive drugs. Eosinophils may be elevated in the child with atopic dermatitis.
Erythrocyte sedimentation rate (ESR)	Nonspecific test used to detect presence of infection or inflammation	Infection or inflammatory process	Send sample to laboratory immediately; if allowed to stand for longer than 3 hours, may result in falsely low result.
Potassium hydroxide (KOH) prep	Reveals branching hyphae (fungus) when viewed under microscope	To identify fungal infection	Place skin scrapings on a microscope slide and add KOH 20% drop.
Culture of wound or skin drainage	Allows for microbial growth and organism identification	Identification of specific organism	Note sensitivities.
Immunoglobulin E (IgE)	Measurement of serum IgE	Atopic dermatitis	Often elevated in allergic or atopic disease, though this is a nonspecific finding. May be increased if the child takes systemic corticosteroids.
Patch or skin testing	Needle prick testing with allergens	Atopic or contact dermatitis	Have emergency equipment available in the event of anaphylaxis (rare).

Adapted from Pagana, K. D., & Pagana, T. J. (2010). *Mosby's manual of diagnostic and laboratory tests* (4th ed.). St. Louis, MO: Mosby.

**After completing an assessment of Eva, the nurse noted the following: hypopigmentation of the skin behind her knees, dry patches on her wrists and face, and slight wheezing heard bilaterally on auscultation. Based on these assessment findings, what would your top three nursing diagnoses be for Eva?**

as a guide in planning nursing care for the child with an integumentary disorder. Individualize the plan of care based on the child's and family's responses to the health alteration. See Chapter 36 for information about pain management. Additional information will be included later in the chapter as it relates to specific disorders.

**Based on your top three nursing diagnoses for Eva, describe appropriate nursing interventions.**

## INFECTIOUS DISORDERS

Infectious disorders of the skin include those caused by viral, bacterial, or fungal infection. The viral exanthems are discussed in Chapter 37. Bacterial and fungal infections of the skin are discussed below.

### Bacterial Infections

Bacterial infections of the skin include bullous and nonbullous impetigo, folliculitis, cellulitis, and staphylococcal scalded skin syndrome. These bacterial skin infections are often caused by *Staphylococcus aureus* and group A  $\beta$ -hemolytic streptococcus, which are ordinarily normal flora on the skin. Impetigo, folliculitis, and cellulitis are usually self-limited disorders that rarely become severe.

Impetigo is a readily recognizable skin rash (Fig. 46.2). Nonbullous impetigo generally follows some type of skin trauma or may arise as a secondary bacterial infection of

## NURSING CARE PLAN 46.1

## Overview for the Child With an Integumentary Disorder

**NURSING DIAGNOSIS:** Impaired skin integrity related to infectious process, hypersensitivity reaction, injury, or mechanical factors as evidenced by rash, inflammation, abrasion, laceration, or disrupted epidermis

**Outcome Identification and Evaluation**

Integrity of skin surface will be restored: *rash, abrasion, laceration, or other skin disruption will heal.*

**Interventions: Restoring Skin Integrity**

- Assess site of skin impairment to *determine extent of involvement and plan care.*
- Monitor skin impairment every shift for changes in color, warmth, redness, or other signs of infection to *identify problems early.*
- Determine the child's and family's skin care practices to *establish need for education related to skin care.*
- Individualize the child's skin care regimen depending on the child's particular skin condition to *most appropriately care for skin in light of the child's disorder.*
- In the immobile child, use a risk assessment tool (such as a modified Norton or Braden scale) to *identify risk for skin breakdown.*
- Position the child on the opposite side of the skin impairment to *avoid further skin breakdown.*
- Encourage appropriate nutritional intake as *adequate nutrients are necessary for appropriate immune function and skin healing.*
- Consult the wound and ostomy care nurse specialist to *determine the best approach for individualized wound care.*
- Provide dressing change and wound care as prescribed to *promote wound or burn healing.*

**NURSING DIAGNOSIS:** Risk for infection related to disruption in protective skin barrier

**Outcome Identification and Evaluation**

Child will remain free from local or systemic infection, will remain afebrile, *without additional redness or warmth at skin disruption site.*

**Interventions: Preventing Infection**

- Use appropriate hand hygiene to *decrease transmission of infectious organisms.*
- Assess the skin impairment site for increased warmth, redness, discharge, or new purulence to *identify infection early.*
- Assess temperature every 4 hours or more frequently if needed, as *children develop fever quickly in response to infection.*
- Note white blood cell (WBC) count and culture results, reporting unexpected values to the physician or nurse practitioner so *that appropriate treatment may be started.*
- Follow prescribed therapies for skin alteration to *maintain skin moisture and prevent further breakdown, which may lead to infection.*
- Encourage appropriate nutritional intake as *adequate nutrients are necessary for appropriate immune function and skin healing.*

**NURSING DIAGNOSIS:** Disturbed body image related to chronic skin changes caused by disease process, burns, or other skin alteration as evidenced by child's verbalization, reluctance to participate in activities, or social withdrawal

## NURSING CARE PLAN 46.1

**Overview for the Child With an Integumentary Disorder** (continued)**Outcome Identification and Evaluation**

Child will verbalize or demonstrate acceptance of alteration in body, *will return to previous level of social involvement.*

**Interventions: Promoting Appropriate Body Image**

- Assess child or teen for feelings about alteration in skin *to determine baseline.*
- Acknowledge feelings of anger or depression related to skin changes *to provide an outlet for feelings.*
- Encourage the child or teen to participate in skin care *to give some sense of control over what is occurring.*
- Help the child or teen to accept self *as the perception of self is tied to knowing oneself and identifying what the self values.*

**NURSING DIAGNOSIS:** Risk for deficient fluid volume related to burns**Outcome Identification and Evaluation**

Fluid volume status will be balanced, *child will maintain urine output of 1 to 2 mL/kg/hour, oral mucosa will be moist and pink, heart rate will remain within age- and situation-specific parameters.*

**Interventions: Promoting Fluid Balance**

- Assess fluid volume status at least every shift, more frequently if disrupted, *to obtain baseline for comparison.*
- Strictly monitor intake and output *to detect imbalance or need for additional fluid intake.*
- Weigh the child daily on the same scale, at the same time, in the same amount of clothing *as changes in weight are an accurate indicator of fluid volume status in children.*
- Provide intravenous fluid resuscitation in initial period, followed by encouragement of oral fluid intake in the burned child, *to compensate for fluid loss through burned areas.*

**NURSING DIAGNOSIS:** Imbalanced nutrition, less than body requirements, related to increased metabolic state (burns) as evidenced by poor wound healing, difficulty gaining or maintaining body weight**Outcome Identification and Evaluation**

Child will demonstrate balanced nutritional state, *will maintain or gain weight as appropriate for situation, will demonstrate improvement in wound healing.*

**Interventions: Promoting Nutrition**

- Assess the child's food preferences and ability to eat *to provide a baseline for planning nursing care.*
- Consult the nutritionist *because nutritional needs are increased related to altered metabolic state as a result of burns.*
- Collaborate with the nutritionist, child, and parents to plan meals that appeal to the child *to increase the child's intake.*
- Administer vitamin and mineral preparations as prescribed *to supplement nutrients.*
- Provide smaller, more frequent meals and snacks *to promote increased intake.*
- Weigh the child daily *to determine progress.*

**FIGURE 46.2** Note honey-colored crusting with impetigo.

another skin disorder, such as atopic dermatitis. Bullous impetigo demonstrates a sporadic occurrence pattern and develops on intact skin, resulting from toxin production by *S. aureus*.

Folliculitis, infection of the hair follicle, most often results from occlusion of the hair follicle. It may occur as a result of poor hygiene, prolonged contact with contaminated water, maceration, a moist environment, or use of occlusive emollient products.

Cellulitis is a localized infection and inflammation of the skin and subcutaneous tissues and is usually preceded by skin trauma of some sort (Fig. 46.3).

Staphylococcal scalded skin syndrome results from infection with *S. aureus* that produces a toxin, which then causes exfoliation. It has an abrupt onset and results in diffuse **erythema** (reddening of the skin) and skin tenderness (Fig. 46.4). Scalded skin syndrome is most common in infancy and rare beyond 5 years of age (Marino & Fine, 2009).

**FIGURE 46.3** Note erythema and edema associated with cellulitis.

**FIGURE 46.4** Staphylococcal scalded skin syndrome (SSSS) with ruptured bullae. (Used with permission from Goodheart, H.P. *Goodheart's photoguide to common skin disorders: Diagnosis and management* [3rd ed.]. Philadelphia, PA: Lippincott Williams & Wilkins, 2009.)

Of particular concern are community-acquired bacterial skin infections caused by methicillin-resistant *S. aureus* (CA-MRSA) (So & Farrington, 2008). CA-MRSA most commonly occurs as a skin or soft tissue infection, such as cellulitis or an abscess. Risk factors for CA-MRSA are turf burns, towel sharing, participation in team sports, or attendance at day care or outdoor camps. If the child presents with a moderate to severe skin infection or with an infection that is not responding as expected to therapy, it is important to culture the infected area for MRSA.

Therapeutic management of bacterial skin infections includes topical or systemic antibiotics and appropriate hygiene (Table 46.1).

## Nursing Assessment

Obtain the history as noted in the nursing process overview section. Note history of skin disruption such as a cut, scrape, or insect or spider bite (nonbullous impetigo and cellulitis). Note body piercing in the adolescent, which can lead to impetigo or cellulitis. Measure the child's temperature. Fever may occur with bullous impetigo or cellulitis and is common with scalded skin syndrome. Inspect the skin, noting abnormalities, documenting their location and distribution, and describing drainage if present. Table 46.1 gives specific clinical manifestations of the various bacterial skin infections. Palpate for regional lymphadenopathy, which may be present with impetigo or cellulitis. Blood cultures are indicated in the child with cellulitis with lymphangitic streaking and in all cases of periorbital or orbital cellulitis.

## Nursing Management

Administer antibiotics topically or systemically as prescribed. Teach the family about antibiotic administration and care of the lesions or rash. Soak impetiginous lesions

TABLE 46.1 BACTERIAL SKIN INFECTIONS

Disorder	Skin Findings	Usual Treatment
Nonbullous impetigo	<ul style="list-style-type: none"> <li>• <b>Papules</b> progressing to vesicles, then painless pustules with a narrow erythematous border</li> <li>• Honey-colored exudate when the vesicles or pustules rupture, which forms a crust on the ulcer-like base (see Fig. 46.2)</li> </ul>	<ul style="list-style-type: none"> <li>• Limited amount: treat topically with mupirocin ointment.</li> <li>• If numerous lesions, oral first-generation cephalosporin is indicated.</li> <li>• Clindamycin may be needed for MRSA.</li> <li>• Remove honey-colored crust with cool compresses BID.</li> </ul>
Bullous impetigo	<ul style="list-style-type: none"> <li>• Red macules and bullous eruptions on an erythematous base</li> <li>• Size may be from a few millimeters to several centimeters.</li> </ul>	<ul style="list-style-type: none"> <li>• Oral first-generation cephalosporin.</li> <li>• Good hygiene.</li> </ul>
Folliculitis	<ul style="list-style-type: none"> <li>• Red, raised hair follicles</li> </ul>	<ul style="list-style-type: none"> <li>• Treat with aggressive hygiene: warm compresses after washing with soap and water several times a day.</li> <li>• Topical mupirocin is indicated; occasionally oral antibiotics are required.</li> </ul>
Cellulitis	<ul style="list-style-type: none"> <li>• Localized reaction: <b>erythema</b>, pain, edema, warmth at site of skin disruption (see Fig. 46.3)</li> </ul>	<ul style="list-style-type: none"> <li>• Mild cases are usually treated with cephalexin or amoxicillin/clavulanic acid.</li> <li>• More severe cases and periorbital or orbital cellulitis require IV cephalosporins.</li> </ul>
Staphylococcal scalded skin syndrome	<ul style="list-style-type: none"> <li>• Flattish bullae that rupture within hours</li> <li>• Red, weeping surface is left, most commonly on face, groin, neck, and axillary region (see Fig. 46.4)</li> </ul>	<ul style="list-style-type: none"> <li>• Mild to moderate cases are treated with oral cephalexin, dicloxacillin, or amoxicillin/clavulanic acid.</li> <li>• Severe cases are managed similar to burns with aggressive fluid management and IV oxacillin or clindamycin.</li> </ul>

Adapted from Burch, J. M., & Morelli, J. G. (2011). Skin. In W. W. Hay, M. J. Levin, J. M. Sondheimer, & R. R. Deterding (Eds.), *Current pediatric diagnosis and treatment* (20th ed.). New York, NY: McGraw-Hill; and Lewis, L. S. & Friedman, F. A. *Impetigo*. Retrieved July 7, 2012, from <http://emedicine.medscape.com/article/965254-overview>.

with cool compresses or Burow solution to remove crusts before applying topical antibiotics. Though impetigo is considered a contagious disorder among vulnerable populations, removal from school or day care is not necessary unless the condition is widespread or actively weeping. Prevent transmission of nosocomial MRSA by appropriately isolating children according to the institution's policy when the child is hospitalized. In children with scalded skin syndrome, reduce the risk of scarring by minimal handling, avoiding corticosteroids, and applying soothing ointments as the skin heals.

Educate the family about prevention of bacterial skin infections. Stress the importance of cleanliness and hygiene. Teach the family to keep the child's fingernails cut short and to clean the nails with a nail brush at bath time. When a skin disruption such as a cut, scrape, or insect bite occurs, teach the family to clean the area well to prevent the development of cellulitis. Folliculitis may be prevented with diligent hygiene and avoidance

of occlusive emollients. Table 46.1 gives additional information about specific treatments for bacterial skin infections.

## Fungal Infections

Fungi also cause infections on children's skin. *Tinea* is a fungal disease of the skin occurring on any part of the body. The part of the body affected determines the second word in the name. Examples of tinea infections occurring on various parts of the body include:

- Tinea pedis: fungal infection on the feet
- Tinea corporis: fungal infection on the arms or legs
- Tinea versicolor: fungal infection on the trunk and extremities
- Tinea capitis: fungal infection on the scalp, eyebrows, or eyelashes
- Tinea cruris: fungal infection on the groin

TABLE 46.2

## MANIFESTATIONS AND MANAGEMENT OF FUNGAL INFECTIONS

Disorder	Skin Findings	Usual Treatment
Tinea corporis (ringworm)	<ul style="list-style-type: none"> <li>Annular lesion with raised peripheral scaling and central clearing (looks like a ring) (see Fig. 46.5)</li> </ul>	<ul style="list-style-type: none"> <li>Topical antifungal cream is required for at least 4 weeks.</li> </ul>
Tinea capitis	<ul style="list-style-type: none"> <li>Patches of scaling in the scalp with central hair loss</li> <li>Risk of kerion development (inflamed, boggy mass that is filled with pustules) (see Fig. 46.6)</li> </ul>	<ul style="list-style-type: none"> <li>Oral griseofulvin for 4 to 6 weeks.</li> <li>Selenium sulfide shampoo may be used to decrease contagiousness (adjunct only).</li> <li>No school or day care for 1 week after treatment initiated.</li> </ul>
Tinea versicolor	<ul style="list-style-type: none"> <li>Superficial tan or hypopigmented oval scaly lesions, especially on upper back and chest and proximal arms</li> <li>More noticeable in the summer with tanning of unaffected areas (see Fig. 46.7)</li> </ul>	<ul style="list-style-type: none"> <li>Apply selenium sulfide shampoo all over body (from face to knees) and allow to stay on skin overnight, rinsing in the morning, once a week for 4 weeks (this may cause skin irritation).</li> <li>Topical antifungals in the imidazole family may be used instead.</li> </ul>
Tinea pedis (athlete's foot)	<ul style="list-style-type: none"> <li>Red, scaling rash on soles and between the toes (see Fig. 46.8)</li> </ul>	<ul style="list-style-type: none"> <li>Topical antifungal cream, powder, or spray.</li> <li>Appropriate foot hygiene.</li> </ul>

Diaper candidiasis (also called monilia diaper rash)	<ul style="list-style-type: none"> <li>Fiery red lesions, scaling in the skin folds, and satellite lesions (located further out from the main rash) (see Fig. 46.9)</li> </ul>	<ul style="list-style-type: none"> <li>Topical nystatin with diaper changes for several days.</li> <li>See section on diaper dermatitis for additional information.</li> </ul>

Adapted from Burch, J. M., & Morelli, J. G. (2011). Skin. In W. W. Hay, M. J. Levin, J. M. Sondheimer, & R. R. Deterding (Eds.), *Current pediatric diagnosis and treatment* (20th ed.). New York, NY: McGraw-Hill.

The three organisms most often responsible for tinea are *Epidermophyton*, *Microsporum*, and *Trichophyton*, though *Malassezia furfur* causes tinea versicolor. *Candida albicans* may cause an infection of the skin, particularly in a warm, moist area such as the diaper area. In fact, 80% of diaper rashes lasting longer than 4 days are colonized with *C. albicans* (Marino & Fine, 2009). All fungal skin infections may occur year-round, but tinea versicolor is more common in warm weather.

Therapeutic management of fungal infections involves appropriate hygiene and administration of an antifungal agent. Table 46.2 gives further information about treatment. See EBP 46.1

## Nursing Assessment

Elicit the health history, noting exposure to another person with a fungal infection or exposure to a pet (fungi are often carried by pets). Note onset of the rash and whether it is itchy. Determine if the child has recently visited the barber (tinea capitis). Note contact with damp areas such as locker rooms and swimming pools, use of

nylon socks or nonbreathable shoes, or minor trauma to the feet (tinea pedis). Document a history of wearing tight clothing or participating in a contact sport such as wrestling (tinea cruris). Inspect the skin and scalp, noting the location, description, and distribution of the rash or lesions (Figs. 46.5, 46.6, 46.7, 46.8, and 46.9). Table 46.2 describes the clinical findings associated with various types of tinea.

Scraping and KOH preparation show branching hyphae. For tinea capitis, the Wood lamp will fluoresce yellow-green if it is caused by *Microsporum*, but not with *Trichophyton*. A fungal culture of a plucked hair is more reliable for diagnosis of tinea capitis.

## Nursing Management

Maintain appropriate hygiene and administer antifungal agents as prescribed (see Table 46.2). Additional specifics related to the individual fungal disorders are as follows:

- Tinea corporis is contagious, but the child may return to day care or school once treatment has begun. Identify and treat family members or other contacts.

**FIGURE 46.5** Tinea corporis: note raised scaly border with clearing in center.

**FIGURE 46.8** Tinea pedis. The interdigital pattern of tinea pedis is common. (Used with permission from Goodheart, H.P. *Goodheart's photoguide to common skin disorders: Diagnosis and management* [3rd ed.]. Philadelphia, PA: Lippincott Williams & Wilkins, 2009.)

**FIGURE 46.6** Note hair breakage and loss with tinea capitis.

**FIGURE 46.7** Tinea versicolor. Hypopigmented scaly lesions on the back of a darkly pigmented adolescent. (Used with permission from Goodheart, H.P. *Goodheart's photoguide to common skin disorders: Diagnosis and management* [3rd ed.]. Philadelphia, PA: Lippincott Williams & Wilkins, 2009.)

- Counsel the child with tinea capitis and parents that hair will usually regrow in 3 to 12 months. Wash sheets and clothes in hot water to decrease the risk of the infection spreading to other family members.
- Instruct the child with tinea pedis to keep the feet clean and dry. Rinse feet with water or a water/vinegar mixture and dry them well, especially between the toes. Encourage the child to wear cotton socks and shoes that allow the feet to breathe. Going barefoot at home is allowed, but flip-flops should be worn around swimming pools and in locker rooms.
- Inform the child with tinea versicolor that return to normal skin pigmentation may take several months.
- Counsel the child or adolescent with tinea cruris to wear cotton underwear and loose clothing. It is important to maintain good hygiene, particularly after sports practice or a sporting event.
- For management of diaper candidiasis, follow the suggestions listed below in the section on diaper dermatitis.

**FIGURE 46.9** A bright red rash with satellite lesions occurs with diaper candidiasis.

**EVIDENCE-BASED PRACTICE 46.1****EFFECTIVENESS OF VARIOUS SYSTEMIC ANTIFUNGAL DRUGS IN TREATING TINEA CAPITIS IN CHILDREN****STUDY**

Tinea capitis (fungal infection of the scalp) affects a large number of children. Traditionally, a 6- to 8-week course of oral griseofulvin was required to eradicate the infection. The authors evaluated 21 randomized controlled studies that included a total of 1,812 participants. The studies determined the effectiveness of terbinafine, itraconazole, fluconazole, and griseofulvin at eradicating dermatophytes in tinea capitis.

**Findings**

The authors found that shorter courses (2 to 4 weeks) with terbinafine, itraconazole, or fluconazole were as effective

at treating tinea capitis as the traditional longer course with griseofulvin.

Adapted from González, U., Seaton, T., Bergus, G., Jacobson, J., & Martínez-Monzón, C. (2007). Systemic antifungal therapy for tinea capitis in children. *The Cochrane Library* 2007, 4. Indianapolis, IN: John Wiley & Sons.

**Nursing Implications**

Shorter courses of treatment will improve compliance, although the drugs may be more expensive. Educate families that the shorter course will be simpler to complete and result in fewer side effects and decreased need for laboratory evaluation of their child. Assist families with any paperwork needed to encourage insurance coverage for these drugs if needed.

**INFLAMMATORY SKIN CONDITIONS**

Inflammatory skin conditions may be either acute or chronic. Acute hypersensitivity reactions may cause diaper dermatitis, contact dermatitis, erythema multiforme, and urticaria. Atopic dermatitis is a chronic hypersensitivity disorder. Seborrhea and psoriasis are chronic inflammatory skin disorders that do not occur as a result of hypersensitivity.

**Diaper Dermatitis**

**Dermatitis** refers to an inflammatory reaction of the skin. Diaper dermatitis refers to an inflammatory reaction of the skin in the area covered by a diaper. It is a nonimmunologic response to a skin irritant that results in skin cell hydration disturbance. Prolonged exposure to urine and feces may lead to skin breakdown (Fig. 46.10). Diaper wearing increases the skin's pH, activating fecal enzymes that further contribute to skin maceration.

FIGURE 46.10 Diaper dermatitis.

**Nursing Assessment**

Determine from the history whether the infant or child wears diapers. Ask about the onset and progression of the rash, as well as any treatments and response. Inspect the skin in the diaper area for erythema and maceration (see Fig. 46.10). Ordinary diaper dermatitis does not usually result in a bumpy rash, but starts as a flat red rash in the convex skin creases. It may appear red and shiny and may or may not also have papules. Untreated, it may become more widespread or severe. Some cases of diaper dermatitis are caused by overgrowth of *C. albicans* (see Fig. 46.9 and the section on fungal infections).

**Nursing Management**

Prevention is the best management of diaper dermatitis. Topical products such as ointments or creams containing vitamins A, D, and E; zinc oxide; or petrolatum are helpful to provide a barrier to the skin. Teaching Guidelines 46.1 gives further information on prevention and management of diaper dermatitis. See above for treatment of diaper rash caused by *C. albicans* infection.

**Teaching Guidelines 46.1****PREVENTION AND MANAGEMENT OF DIAPER DERMATITIS**

- Change diapers frequently. Change stool-soiled diapers as soon as possible.
- Avoid rubber pants.
- Gently wash the diaper area with a soft cloth, avoiding harsh soaps.
- Use baby wipes in most children, but avoid wipes that contain fragrance or preservatives.

- Once a rash has occurred, follow all the prevention tips above and add the following:
  - Allow the infant or child to go diaperless for a period of time each day to allow the rash to heal.
  - Blow-dry the diaper area/rash area with the dryer set on the warm (not hot) setting for 3 to 5 minutes.

### Take Note!

Discourage parents from using any type of baby powder to avoid the risk of aspiration; inhalation of talcum-containing powders may result in pneumonitis (Garlich & Nelson, 2011).

## Atopic Dermatitis

Atopic dermatitis (eczema) is one of the disorders in the atopy family (along with asthma and allergic rhinitis). Atopic dermatitis affects 10% to 20% of U.S. children and up to 90% of children with atopic dermatitis develop symptoms before 5 years of age (Tofte, 2008). About half of the children who have atopic dermatitis will also develop allergic rhinitis and/or asthma (Marino & Fine, 2009; Ogles, 2008).

The chronic itching associated with atopic dermatitis causes a great deal of psychological distress. The child's self-image may be affected, particularly if the rash is extensive. Difficulty sleeping may occur because of the itching. The child is irritable and has difficulty concentrating, and family life is disrupted. Parents' stress related to the child's condition may increase the child's anxiety and lead to an increase in itching and scratching. The child may outgrow atopic dermatitis, its severity may decrease as the child approaches adulthood, or the child may continue to have difficulties into the adult years. Bacterial superinfection may occur as a complication.

Therapeutic management includes good skin hydration, application of topical corticosteroids or immune modulators, oral antihistamines for sedative effects, and antibiotics if secondary infection occurs.

## Pathophysiology

Atopic dermatitis is a chronic disorder characterized by extreme itching and inflamed, reddened, and swollen skin. It has a relapsing and remitting nature. The skin reaction occurs in response to specific allergens, usually food (especially eggs, wheat, milk, and peanuts) or environmental triggers (e.g., molds, dust mites, and cat dander). Other factors, such as high or low ambient temperatures, perspiring, scratching, skin irritants, or stress, may contribute to flare-ups. When the child encounters a triggering antigen, antigen-presenting cells stimulate interleukins to begin the inflammatory process. The skin begins to feel pruritic and the child starts to scratch.

The sensation of itchiness comes first, and then the rash becomes apparent. The scratching causes the rash to appear. Sweating causes atopic dermatitis to worsen, as does excessively humid or dry environments.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1674. Assessment findings pertinent to atopic dermatitis are discussed below.

### Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Wiggling or scratching
- Dry skin
- Scratch marks noticed by the parents
- Disrupted sleep
- Irritability

Explore the child's current and past medical history for risk factors such as:

- Family history of atopic dermatitis, allergic rhinitis, or asthma
- Child's history of asthma or allergic rhinitis
- Food or environmental allergies

Determine the onset of the rash; its location, progression, and severity; and response to treatments used so far. Note medications used to treat the rash, as well as other medications the child may be taking.

### Physical Examination

Physical examination consists of inspection and observation and auscultation.

#### INSPECTION AND OBSERVATION

Observe whether the infant is wiggling or the child is actively scratching. Carefully inspect the skin. Document dry, scaly, or flaky skin, as well as hypertrophy and lichenification (Fig. 46.11). If lesions are present they may be dry lesions or weepy papules or **vesicles** (fluid-filled lesions). In children younger than 2 years old, the rash is most likely to occur on the face, scalp, wrists, and extensor surfaces of the arms or legs. In older children it may occur anywhere on the skin, but is found more commonly on the flexor areas. Note erythema or warmth, which may indicate associated secondary bacterial infection. Document areas of hyperpigmentation or hypopigmentation, which may have resulted from a prior exacerbation of atopic dermatitis or its treatment. Inspect the eyes, nose, and throat for symptoms of allergic rhinitis.

**FIGURE 46.11** Atopic dermatitis rash is red, dry, and scaly.

### AUSCULTATION

Auscultate the lungs for wheezing (commonly found in the associated condition of asthma).

### Laboratory and Diagnostic Tests

Serum immunoglobulin E (IgE) levels may be elevated in the child with atopic dermatitis. Skin prick allergy testing may determine the food or environmental allergen to which the child is sensitive.

### Nursing Management

Nursing management of the child with atopic dermatitis focuses on promoting skin hydration, maintaining skin integrity, and preventing infection.

#### Promoting Skin Hydration

First and foremost, avoid hot water and any skin or hair product containing perfumes, dyes, or fragrance. Bathe the child twice daily in warm (not hot) water. Use a mild soap to clean only the dirty areas. Recommended mild soaps or cleansing agents include:

- Unscented Dove or Dove for sensitive skin
- Tone
- Caress
- Oil of Olay
- Cetaphil
- Aquanil

Slightly pat the child dry after the bath, but do not rub the skin with the towel. Leave the child moist. Apply prescribed topical ointments or creams to the affected area. Apply fragrance-free moisturizer over the prescribed topical medication and all over the child's body. Recommended moisturizers include:

- Eucerin, Moisturel, Curel (cream or lotion)
- Aquaphor

- Vaseline
- Crisco

#### Take Note!

Vaseline or generic petrolatum is an inexpensive, readily available moisturizer.

Apply moisturizer multiple times throughout the day. Avoid clothing made of synthetic fabrics or wool. Avoid triggers known to exacerbate atopic dermatitis.

Taking evening primrose oil and other essential fatty acids as an oral supplement over a period of at least 6 weeks may produce an improvement in the atopic dermatitis (Senapati, Banerjee, & Gangopadhyay, 2008). If not initially recommended by the physician or nurse practitioner, the parent should consult with him or her first before starting these supplements. Headache and nausea are rare adverse effects of these supplements and, if they occur, are usually mild. Chamomile preparations for topical use may also be effective and are generally considered safe.

### Maintaining Skin Integrity and Preventing Infection

Cut the child's fingernails short and keep them clean. Avoid tight clothing and heat. Use 100% cotton bed sheets and pajamas. In addition to keeping the child's skin well moisturized, it is extremely important to prevent the child from scratching. Scratching causes the rash to appear and further scratching may lead to secondary infection. Antihistamines given at bedtime may sedate the child enough to allow him or her to sleep without awakening because of itching.

During the waking hours, behavior modification may help to keep the child from scratching. Have the parent keep a diary for 1 week to determine the pattern of scratching. Help the parent to determine specific strategies that may raise the child's awareness of scratching. A hand-held clicker or counter may help to identify the scratching episode for the child, thus raising awareness. The use of diversion, imagination, and play may help to distract the child from scratching. The parent and child may create a game together that results in the child participating in a behavior rather than scratching. Pressing the skin or clenching the fist may replace scratching. It is important for the child to stay active to distract his or her mind from the itching. It is important for the parent to positively reinforce and reward the desired behaviors.

### Contact Dermatitis

Contact dermatitis is a cell-mediated response to an antigenic substance exposure. The first exposure is the sensitization phase. The antigen attaches to cells

that migrate to regional lymph nodes and have contact with T lymphocytes, where recognition of antigen is developed. During the second phase, elicitation, contact with the antigen results in T-lymphocyte proliferation and release of inflammatory mediators. An allergic response occurs within 24 to 48 hours after contact with the substance.

Contact dermatitis may occur as a result of allergy to nickel or cobalt found in clothing hardware and dyes, and chemicals found in many hygiene products and cosmetics. One of the more common causes of contact dermatitis in children results from exposure to highly allergenic plants such as *Toxicodendron radicans* (poison ivy), *Toxicodendron quercifolium* (Eastern poison oak), *Toxicodendron diversilobum* (Western poison oak), and *Toxicodendron vernix* (poison sumac).

Direct or indirect contact with the plant's oleoresin found in the leaves, stems, and roots results in an allergic reaction. Even contact with dormant plants or plants perceived to be dead may cause an allergic response. The rash is extremely pruritic and may last for 2 to 4 weeks; lesions continue to appear during the illness. Contact dermatitis is not contagious and does not spread either to other parts of the affected child's skin or to other people. Scratching does not spread the rash, but it may cause skin damage or secondary infection. Complications of contact dermatitis include secondary bacterial skin infections and lichenification or hyperpigmentation, particularly in dark-skinned people.

Therapeutic management is directed toward management of itching and the use of topical corticosteroids. Moderate-potency topical glucocorticoid cream or ointment is used for mild to moderate contact dermatitis, and high-potency preparations are used for more severe cases. Some severe cases of contact dermatitis may require the use of systemic steroids.

## Nursing Assessment

Elicit the health history, noting onset, description, location, and progression of the rash, which may be intensely pruritic and vesicular if caused by allergenic plant exposure (see Fig. 46.12). Rashes caused by other allergenic exposure may be quite variable in their appearance and intensity of pruritus. Document treatment used thus far, and the child's response to it. Examine the skin, noting rash that may vary from maculopapular in nature to an erythematous papulovesicular rash at the site of contact. Some lesions may be weeping; others may erupt and form a crust. The lesions are often distributed in an asymmetric linear pattern on exposed body parts if caused by allergenic plant exposure. If the child's shirt came in contact with the plant and then the shirt was removed by pulling it over the head, there may be widespread lesions over both sides of the face. Lesions near the eyes often cause significant eyelid edema.

**FIGURE 46.12** Note vesicular rash in linear formation characteristic of poison ivy.

### Take Note!

Nickel dermatitis may occur from contact with jewelry, eyeglasses, belts, or clothing snaps. Infants may display a small red circle with scaling at the site of contact with sleeper snaps.

## Nursing Management

Contact dermatitis may be prevented by avoiding contact with the allergen. When the condition does occur, nursing management focuses on relieving the discomfort associated with the rash. Administer topical or systemic corticosteroids as prescribed and teach the family about use of the medications. Teaching Guidelines 46.2 gives more information about the treatment and prevention of contact dermatitis.

### Teaching Guidelines 46.2

#### PREVENTION AND TREATMENT OF CONTACT DERMATITIS

##### Prevention

- Wear long sleeves and long pants on outings in the woods.
- Identify and remove offending plants in the yard by using a commercial weed or underbrush killer.
- Vinyl gloves (not rubber or latex) are an effective barrier.
- The plant's oil residue may be on clothes, pets, garden and sports equipment, and toys; wash those well with soap and water.
- If contact occurs, wash vigorously with soap and water within 10 minutes of contact.

- Zanfel and Tecnu Oak-N-Ivy Outdoor Skin Cleanser (both soap mixtures) may prevent rash if used to wash the skin soon after exposure.
- Ivy Block (an organoclay) is the only U.S. Food and Drug Administration–approved preventive treatment for contact dermatitis related to poison ivy, oak, or sumac. (Visit [thePoint\\*](#) for web links that will provide additional information.) It is applied to the skin before possible exposure.

#### Treatment

- Wash lesions daily with mild soap and water.
- Mildly débride crusted lesions.
- Tepid baths (colloidal oatmeal such as Aveeno) are helpful to decrease itching.
- Avoid hot baths or showers, as they aggravate itching.
- Apply corticosteroid preparations topically as directed (if using high-potency preparations, do not cover with an occlusive dressing).
- Weeping lesions may be wrapped lightly; avoid occlusion.
- Burow or Domeboro solutions with a dressing applied twice daily for 20 minutes may help to dry weepy lesions.
- Over-the-counter preparations such as calamine lotion or Ivy Rest may reduce itching and help the lesions to dry.
- Do not use topical antihistamines, benzocaine, or neomycin because of the potential for sensitization.

## Erythema Multiforme

Erythema multiforme, though uncommon in children, is an acute, self-limiting hypersensitivity reaction. It may occur in response to viral infections, such as adenovirus or Epstein-Barr virus; *Mycoplasma pneumoniae* infection; or a drug (especially sulfa drugs, penicillins, or immunizations) or food reaction. Stevens-Johnson syndrome is the most severe form of erythema multiforme and most often occurs in response to certain medications or to *Mycoplasma* infection (Box 46.1). Therapeutic management of erythema multiforme is generally supportive because it resolves on its own.

## Nursing Assessment

Note history of fever, malaise, and achiness (myalgia). Determine onset and progression of rash, and presence of **pruritus** (itchiness) and burning. Document the child's temperature upon assessment. Inspect the skin for lesions, which most commonly occur over the hands and feet and extensor surfaces of the extremities, with spread to the trunk. Lesions progress from erythematous **macules** (flat reddened areas) to papules, plaques,

### BOX 46.1

#### STEVENS-JOHNSON SYNDROME

- 1- to 14-day history of fever, malaise, headache, generalized aching, emesis, and diarrhea
- Sudden onset of high fever with rash appearing
- Rash is characteristic of erythema multiforme with the addition of inflammatory bullae on at least two types of mucosa (lips, oral mucosa, bulbar conjunctivae, or anogenital region).
- Mortality rate of 10% (Marino & Fine, 2009), particularly when the genitourinary, gastrointestinal, and respiratory tracts are involved
- Treatment: hospitalization, isolation, fluid and electrolyte support, treatment of secondary infection of the lesions
- Ophthalmologic consult to determine if corneal ulceration, keratitis, uveitis, or panophthalmitis is present

vesicles, and target lesions over a period of days (hence the name *multiforme*) (Fig. 46.13).

## Nursing Management

Discontinue the medication or food if it is identified as the cause. Ensure that treatment for *Mycoplasma* is instituted if present. Encourage oral hydration. Administer analgesics and antihistamines as needed to promote comfort. If oral lesions are present, encourage soothing mouthwashes or use of topic oral anesthetics in the older child or teen. Oral lesions may be débrided with hydrogen peroxide.

## Urticaria

Urticaria, commonly called hives, is a type I hypersensitivity reaction caused by an immunologically mediated antigen–antibody response of histamine release from

FIGURE 46.13 Erythema multiforme.

mast cells. Vasodilation and increased vascular permeability result, and erythema and wheals then occur. Urticaria usually begins rapidly and may disappear in a few days or may take up to 6 to 8 weeks to resolve. The most common causes of this reaction are foods, drugs, animal stings, infections, environmental stimuli (e.g., heat, cold, sun, tight clothes), and stress. Therapeutic management focuses on identifying and removing the cause as well as providing antihistamines or steroids.

## Nursing Assessment

Obtain a detailed history of new foods, medications, symptoms of a recent infection, changes in environment, or unusual stress. Inspect the skin, noting raised, edematous hives anywhere on the body or mucous membranes (Fig. 46.14). The hives are pruritic, blanch when pressed, and may migrate. Angioedema may also be present and is identifiable as subcutaneous edema and warmth, occurring most frequently on the extremities, face, or genitalia. Carefully assess airway and breathing, as hypersensitivity reactions may affect respiratory status.

## Nursing Management

Identify and remove the offending trigger. Discontinue antibiotics. Administer antihistamines, corticosteroids, and topical antipruritics as prescribed. Inform the child and family that the episode should resolve within a few days. If it lasts up to 6 weeks, the child should be reevaluated (Burns et al., 2009). Advise the family to obtain a medical alert bracelet for the child if the reaction is severe.

**FIGURE 46.14** Ill-appearing child with urticaria. (Used with permission from Fleisher GR, Ludwig S, Baskin MN. *Atlas of pediatric emergency medicine*. Philadelphia, PA: Lippincott Williams & Wilkins, 2004:88).

### Take Note!

In an emergency situation when airway and breathing are compromised, subcutaneous epinephrine followed by intravenous (IV) diphenhydramine and corticosteroids is necessary.

## Seborrhea

Seborrhea is a chronic inflammatory dermatitis that may occur on the skin or scalp. In infants it occurs most often on the scalp and is commonly referred to as cradle cap. Infants may also manifest seborrhea on the nose or eyebrows, behind the ears, or in the diaper area. It usually resolves over a period of weeks to months (Shelov & Altman, 2009). Adolescents manifest seborrhea on the scalp (dandruff) and on the eyebrows and eyelashes, behind the ears, and between the shoulder blades.

It is thought that seborrhea is an inflammatory reaction to the fungus *Pityrosporum ovale* and is worsened by sebaceous involvement related to maternal hormones in the infant and androgens in the adolescent.

Therapeutic management includes treating the skin lesions with corticosteroid creams or lotions. Antidandruff shampoos containing selenium sulfide, ketoconazole, or tar are used to treat the scalp.

## Nursing Assessment

Elicit the health history, determining onset and progression of skin and scalp changes. Note response to treatment used so far. In the infant, inspect the scalp and forehead, behind the ears, and the neck, trunk, and diaper area for thick or flaky greasy yellow scales (Fig. 46.15).

**FIGURE 46.15** Severe cradle cap (yellow, greasy-appearing plaques).

In the adolescent, note mild flakes in the hair with yellow greasy scales on the scalp, forehead, and eyebrows; behind the ears; or between the scapulae.

## Nursing Management

Wash or shampoo the affected areas with a mild soap. Apply anti-inflammatory cream to skin lesions if prescribed. In the infant, apply mineral oil to the scalp, massage it in well with a washcloth, and then shampoo 10 to 15 minutes later, using a brush to gently lift the crusts; do not forcibly remove the crusts. If needed, selenium sulfide shampoo may safely be used on the infant, following the aforementioned procedure. The adolescent may require daily shampooing with an antidandruff shampoo.

### Psoriasis

Psoriasis is a chronic inflammatory skin disease with periods of remission and exacerbation; control is possible with conscientious therapy. The incidence of psoriasis depends on climate and genetics. For example, it is less common in tropical areas and dark-skinned people. About 10% to 15% of new cases are diagnosed in children younger than 10 years of age annually (Meffert et al., 2011).

Hyperproliferation of the epidermis occurs, with a rash developing at sites of mechanical, thermal, or physical trauma. Therapeutic management includes skin hydration, use of tar preparations, ultraviolet light, or tazarotene (a topical retinoid). Narrow-band ultraviolet light has been used with some success in children with severe psoriasis.

## Nursing Assessment

Note family history of psoriasis. Determine onset and progression of rash, as well as treatments used and the response to treatment. Question the child about pruritus, which is usually absent with psoriasis. Inspect the skin for erythematous papules that coalesce to form plaques, most frequently found on the scalp, elbows, genital area, and knees (Fig. 46.16). Facial plaques may also occur and are more common in children than adults. The plaques have a silvery or yellow-white scale and sharply demarcated borders. Layers of scale may be present, which, when removed, result in pinpoint bleeding (referred to as the Auspitz sign). Plaques on the scalp may result in alopecia. Examine the palms and soles, noting fissures and scaling. Skin biopsy, though rarely needed for diagnosis, will show hyperplastic epidermis, with thinning of the papillary dermis.

**FIGURE 46.16** Psoriasis. (Used with permission from Goodheart, H.P. *Goodheart's photoguide to common skin disorders: Diagnosis and management* [3rd ed.]. Philadelphia, PA: Lippincott Williams & Wilkins, 2009.)

## Nursing Management

Exposure to sunlight may promote healing, but take care not to allow the child to become sunburned. Apply skin moisturizers or emollients daily to prevent dry skin and flare-ups. Apply topical anti-inflammatory creams as prescribed during flare-ups. Apply tar shampoos or skin preparations. Use mineral oil and warm towels to soak and remove thick plaques.

### Thinking About Development

Emily Wilson is a 15-year-old female with a history of moderate psoriasis. She experiences significant scaling along her hairline, forehead, scalp, and arms. Hypopigmentation and striae are beginning to occur on her arms as a result of topical medication use. She is a talented ballerina but expresses increasing concerns about her skin alterations showing while she is performing.

How does Emily's developmental stage affect self-care related to her psoriasis?

What is the most appropriate approach for the nurse to take to educate Emily about control of her psoriasis?

How will the nurse best promote an appropriate body image for Emily?

## ACNE

Acne, the most common skin condition occurring in childhood (Burch & Morelli, 2011), is a disorder that affects the pilosebaceous unit. It affects males and females, as well as all ethnic groups. Overall, males tend to have more severe disease than females, probably because of the androgen influence (Burch & Morelli, 2011). Acne that

persists past the usual course of time for infantile or adolescent acne may be caused by endocrine abnormalities. It may also occur in response to the use of certain types of drugs such as corticosteroids, androgens, phenytoin, and others. The usual presentation and nursing management of acne neonatorum and acne vulgaris is presented below.

### Acne Neonatorum

Acne neonatorum occurs as a response to the presence of maternal androgens and affects about 20% of newborns (O'Connor, McLaughlin, & Ham, 2008). It generally appears between 2 and 4 weeks of age and lasts up to 4 to 6 months, sometimes lasting until 2 to 3 years of age (O'Connor et al., 2008). Neonatal acne affects boys more often than girls and tends to be more severe in boys. Usually no treatment is necessary, but in severe cases there is a risk of scarring, so a topical preparation may be prescribed.

### Nursing Assessment

Note oily face or scalp. Examine the face (especially the cheeks), upper chest, and back for inflammatory papules and pustules. Document absence of fever.

### Nursing Management

Instruct parents to avoid picking or squeezing the pimples; to do so places the infant at risk for secondary bacterial infection and cellulitis. Teach parents to wash the affected areas daily with clear water. Avoid using fragranced soaps or lotions on the area with acne. Inform the parents that as the newborn's hormones stabilize over time, the acne usually resolves without additional intervention.

### Acne Vulgaris

Acne vulgaris affects 50% to 85% of adolescents between the ages of 12 and 16 years, and endogenous androgens play a role in its development (Burch & Morelli, 2011). It occurs most frequently on the face, chest, and back. Risk factors for the development of acne vulgaris include preadolescent or adolescent age, male gender (due to the presence of androgens), an oily complexion, Cushing syndrome, or another disease process resulting in increased androgen production.

### Pathophysiology

The sebaceous gland produces sebum and is connected by a duct to the follicular canal that opens on the skin's

surface. Androgenous hormones stimulate sebaceous gland proliferation and production of sebum. These hormones exhibit increased activity during the pubertal years. Abnormal shedding of the outermost layer of the skin (the stratum corneum) occurs at the level of the follicular opening, resulting in a keratin plug that fills the follicle. The sebaceous glands increase sebum production. Bacterial overgrowth of *Propionibacterium acnes* occurs because the presence of sebum and keratin in the follicular canal creates an excellent environment for growth. Inflammation occurs as the follicular wall perforates, allowing the contents to leak into nearby tissue.

### Therapeutic Management

Therapeutic management focuses on reducing *P. acnes*, decreasing sebum production, normalizing skin shedding, and eliminating inflammation. Teach the adolescent to cleanse the skin gently twice a day. Medication therapy may include a combination of benzoyl peroxide, salicylic acid, retinoids, and topical or oral antibiotics. Isotretinoin (Accutane) may be used in severe cases. Drug Guide 46.1 gives further information on these medications. In girls, oral contraceptives may help lessen acne by decreasing the effects of androgens on the sebaceous glands. Diode laser or blue ultraviolet light therapy may also be used. CO<sub>2</sub> lasers and dermabrasion may be used to treat pitted scarring.

### Nursing Assessment

Note history of onset of acne lesions, as well as family history of acne. Determine medication use; certain medications may hasten the onset of acne or worsen it when already present. In particular, note use of corticosteroids, androgens, lithium, phenytoin, and isoniazid. Document history of an endocrine disorder, particularly one that results in hyperandrogenism. In girls, note worsening of acne 2 to 7 days before the start of the menstrual period. Inspect the skin for lesions (particularly on the face and upper chest and back, which are the areas of highest sebaceous activity). Note presence, distribution, and extent of noninflammatory lesions, such as open and closed comedones, as well as inflammatory lesions such as papules, pustules, nodules, or cysts (open comedones are commonly referred to as blackheads and closed comedones as whiteheads; see Fig. 46.17). Examine the skin for hypertrophic scarring resulting from inflammatory lesions. Table 46.3 explains the acne classification. Note oily skin and oily hair, which result from increased sebum production. Determine remedies that have been used and the extent of success of those treatments. Assess the child's or teen's feelings about the disorder.

FIGURE 46.17 Acne vulgaris.

## Nursing Management

Avoid oil-based cosmetics and hair products, as their use may block pores, contributing to noninflammatory lesions. Look for cosmetic products labeled as noncomedogenic. Headbands, helmets, and hats may exacerbate the lesions by causing friction. Dryness and peeling may occur with acne treatment, so encourage the child to use a humectant moisturizer. Mild cleansing with soap and water twice daily is appropriate. Avoid excessive scrubbing and harsh chemical or alcohol-based cleansers. Avoid picking or squeezing the lesions. Using a noncomedogenic sunscreen with an SPF of 30 or higher may reduce the risk of postinflammatory discoloration from acne lesions (Burns et al., 2009). Teach adolescents that the prescribed topical medications must be used daily and that it may take 4 to 6 weeks to see results. Avoid the use of over-the-counter preparations because they are irritating and aggravate the drying effect of prescription acne treatments. Instruct boys to shave gently and avoid using dull razors, so as not

### BOX 46.2

#### DECREASING RISK OF FETAL EXPOSURE TO ISOTRETINOIN: IPLEDGE

- As of 2006, physicians, pharmacists, and patients are required to register in the iPLEDGE program before they prescribe, dispense, or receive isotretinoin (Accutane).
- The iPLEDGE program is a central registry requiring monthly input as noted below in order to continue isotretinoin treatment.
- Monthly input includes the following:
  - Females of childbearing age are using two forms of contraception.
  - Pregnancy test results are negative.
  - Isotretinoin users do not donate blood during treatment or for 1 month after completion of treatment.
  - Additional links are provided on [thePoint](#).

Adapted from U.S. Food and Drug Administration, Center for Drug Evaluation and Research. (2010). *iPledge 2007 update*. Retrieved July 7, 2012, from <http://www.fda.gov/Drugs/DrugSafety/PostmarketDrugSafetyInformationforPatientsandProviders/ucm094306.htm>

to further irritate the condition. Adolescent girls taking isotretinoin (Accutane) who are sexually active must be on a pregnancy prevention program because the drug causes defects in fetal development (Fulton, 2012) (Box 46.2).

Adolescents interested in complementary medicine approaches may try topical use of a tea tree oil preparation. Fewer adverse effects may occur with tea tree oil preparations than with benzoyl peroxide preparations, but local reactions may still occur (Leopold, 2010).

If the acne is severe, depression may occur as a result of body image disturbances. Provide emotional support to adolescents undergoing acne therapy. Refer teens for counseling if necessary.

TABLE 46.3

CLASSIFICATION OF ACNE

Classification	Manifestations
Mild acne	Primarily noninflammatory lesions (comedones)
Moderate acne	Comedones plus inflammatory lesions such as papules or pustules (localized to face or back)
Severe acne	Lesions similar to moderate acne, but more widespread, and/or presence of cysts or nodules. Associated more frequently with scarring

#### Take Note!

Chocolate, skim milk, and French fries have not been proven to contribute to the incidence or severity of acne. However, advise teens to wash their hands after eating greasy finger foods to avoid spreading additional oil to the surface of the face (Burch & Morelli, 2011).

#### Consider This

Paxton Herman, age 16, comes to the clinic with complaints of acne on his face and back. What assessment information should the nurse obtain? What education will be important for Paxton?

## INJURIES

Children, by their inquisitive natures, developmental immaturity, and skin's properties, are prone to experience a variety of skin injuries. Pressure ulcers are most likely to occur in hospitalized or otherwise immobile children. Typical healthy, active children are likely to suffer cuts, abrasions, foreign body penetration, burns and other thermal injuries, bites, and stings.

### Pressure Ulcers

Skin breakdown involves changes in intact skin, which may range from blanchable erythema to deep pressure ulcers. The term "pressure ulcer" refers to damage to the skin resulting in skin loss and development of a crater that may range from mild to deep. The incidence of pressure ulcers in critically ill children is 18% to 27% (Schindler et al., 2011). Pressure ulcers develop from a combination of factors, including immobility or decreased activity, decreased sensory perception, increased moisture, impaired nutritional status, inadequate tissue perfusion, and the forces of friction and shear. Common sites of pressure ulcers in hospitalized children include the occiput and toes, while children who require wheelchairs for mobility have pressure ulcers in the sacral or hip area more frequently.

### Nursing Assessment

Note history of immobility (chronic, related to a condition such as paralysis) or lengthy hospitalization, particularly in intensive care. Inspect the skin for areas of erythema or warmth. Note ulceration of the skin. Use the facility's wound assessment scale to document the extent of the ulcer. Take a photo of the ulcer if possible.

### Nursing Management

Position the child to alleviate pressure on the area of the ulcer. Use specialized beds or mattresses to prevent further pressure areas from developing. Perform prescribed wound care meticulously, noting the formation of granulation tissue as the ulcer begins to heal. Prevent pressure ulcers in the child who is hospitalized for long periods of time by turning the child frequently, assessing the entire surface of the child's skin at least every shift, using pressure-alleviating beds and mattresses, and maintaining the child's nutritional status.

### Minor Injuries

Children suffer minor injuries very frequently. Because of their developmental immaturity and inquisitive

nature, children often attempt tasks they are not yet capable of or take risks that an adult would not, often resulting in a fall or other accident. Minor injuries include minor cuts and abrasions, as well as skin penetration of foreign bodies such as splinters or glass fragments. The break in the skin allows an entry point for bacteria, and the complication of cellulitis may occur. Treatment is directed at cleaning the wound and preventing infection.

### Nursing Assessment

Obtain the history from the child or caregiver to determine whether dirt or a foreign object may be present in the wound. Inspect the wound, noting depth of injury, a foreign body, and bleeding.

### Nursing Management

Cleanse the wound with mild soap and water or with an antibacterial cleanser. Wet gauze helps to scrub away fine and large sand particles. Remove pieces of loose skin with sterile scissors, foreign particles with sterile forceps, and road tar with petrolatum. Small abrasions and minor, well-approximated cuts may be left open to the air. Apply a small amount of antibacterial ointment and cover large abrasions with a loose dressing. Change the dressing 12 hours later and redress after cleaning the wound. Leave it open to air after 24 hours have passed from the time of injury.

Calendula preparations are presumed to be safe for topical use and may speed wound healing. Chamomile may help to dry a weeping wound, and allergic reactions to the herb are rare (Ehrlich, 2010). Assess the wound daily for signs of infection, which include purulence, warmth, edema, increasing pain, and erythema that extends past the margin of the cut or abrasion.

### Burns

Burns are a common preventable mechanism of injury among children and adolescents. Young children are at highest risk for burns and the mortality rate from burns is highest in children younger than 6 years of age (Bergen, Chen, Warner, & Fingerhut, 2008). Specifically, burns are the third-leading cause of death from unintentional injury in children between 1 and 4 years of age (Bergen et al., 2008). Most pediatric burn-related injuries do not result in death, but injuries from burns often cause extreme pain and extensive burns can result in serious disfigurement. Children younger than 10 years of age are at highest risk of scald and contact burns (accidental touching or intentional child abuse) and from burns

related to fire (Quilty, 2010). Children 10-to-18 years of age often suffer scald burns when cooking or fire-related burns due to lack of judgment based on developmental level (Quilty, 2010). Carbon monoxide poisoning often occurs in conjunction with burns as a result of smoke inhalation, and infants and children are at greater risk for carbon monoxide poisoning than adults. See Healthy People 2020.

### HEALTHY PEOPLE 2020

#### Objective

Reduce residential fire deaths. Increase functioning residential smoke alarms.

#### Nursing Significance

- Question all families about smoke detectors and if they are working.
- Provide families with resources related to fire prevention.

*Healthy People Objectives based on data from <http://www.healthypeople.gov>.*

Great advances have been made in the care of children with serious burns. As a result of improved burn care, children who in the past would have died as a result of burns over large body surface areas have a much greater chance of survival (Quilty, 2010).

Conventional wisdom is that children with severe burns should be transferred to a specialized burn unit. The Committee on Trauma of the American College of Surgeons has developed the following criteria for referral of burned persons to a burn unit:

- Partial thickness burns greater than 10% of total body surface area
- Burns that involve the face
- Burns that involve the hands and feet, genitalia, perineum, or major joints
- Electrical burns, including lightning injury
- Chemical burns
- Inhalation injury
- Burn injury in children who have preexisting conditions that might affect their care
- Persons with burns and traumatic injuries
- Persons who will require special social, emotional, or long-term rehabilitative care
- Burned children in a hospital without qualified personnel or equipment for the care of children (Gamelli, 2007)

The old terms used to describe the depth of burns as first, second, and third degree have been replaced by contemporary terminology. Burns are now classified according to the extent of injury and the terminology used to describe each type includes superficial, partial thickness, deep partial thickness, and full thickness

(Quilty, 2010). Superficial burns involve only epidermal injury and usually heal without scarring or other sequelae within 4 to 5 days. In partial-thickness burns, injury occurs not only to the epidermis but also to portions of the dermis. These burns usually heal within about 2 weeks and carry a minimal risk of scar formation. Deep partial-thickness burns take longer to heal, may scar, and result in changes in nail and hair appearance as well as sebaceous gland function in the affected area. They may require surgical intervention. Full-thickness burns result in significant tissue damage as they extend through the epidermis, dermis, and hypodermis. Extensive scarring results, as hair follicles and sweat glands are destroyed. Full-thickness burns require a significant time to heal. If underlying tendons and/or bone are involved, the burn may be termed fourth degree. Contractures and limited function may occur as a complication of full-thickness burns. Skin grafting is usually necessary. Full or partially circumferential burns may result in ischemia from loss of blood flow related to progressive swelling of the area.

## Pathophysiology

Burned tissue begins to coagulate after the injury, and direct coagulation and microvascular reactions in the adjacent dermis may extend the burn. The blood vessels demonstrate increased capillary permeability, resulting in vasodilatation. This leads to increased hydrostatic pressure in the capillaries, causing water, electrolytes, and protein to leak out of the vasculature and result in significant edema. Edema forms very rapidly in the first 18 hours after the burn, peaking at around 48 hours. Capillary permeability then returns to normal between 48 and 72 hours after the burn and the lymphatics can reabsorb the edema fluid. Diuresis occurs, ridding the body of the excess fluid. Fluid loss from burned skin occurs at an amount that is 5 to 10 times greater than that from undamaged skin, and this fluid loss continues until the damaged surface is healed or grafted.

Initially, the severely burned child experiences a decrease in cardiac output, with a subsequent hypermetabolic response during which cardiac output increases dramatically. During this heightened metabolic state, the child is at risk for insulin resistance and increased protein catabolism. Children who are burned during an indoor or chemical fire are at an increased risk of respiratory injury. Children who have aspirated hot liquids are particularly at risk for airway-altering edema.

## Therapeutic Management

Therapeutic management of burns focuses on fluid resuscitation, wound care, prevention of infection, and

restoration of function. Burn infections are treated with antibiotics specific to the causative organism. If invasive burn damage occurs, surgery may be necessary.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1674. Upon arrival, evaluate the child with burns to determine if he or she will require intensive management. Remove any smoldering clothing. Obtain a brief history of the burn circumstances while you are assessing the child and providing care.

## Health History

If the burn is severe or there is a potential for respiratory compromise, obtain a brief history while simultaneously evaluating the child and providing emergency care. If the burn does not appear to pose an immediate life-threatening risk, obtain an in-depth history. Elicit a description of how the burn occurred, noting date, time, and cause. Determine if smoke inhalation or an associated fall may have occurred. Document treatment that the parent or caregiver has provided to the child's burn so far. Note the child's recent health status, current medications, recent or chronic illness, and immunization status, in particular noting the date of the most recent tetanus vaccination.

Determine whether the history being given sounds consistent with the type of burn injury that has occurred. Inquire about what caused the burn and if the event was witnessed by anyone. Spatter-type burns resulting from the child pulling a source of hot fluid onto himself or herself usually yield a nonuniform, asymmetric distribution of injury. In contrast, intentional scald injuries usually yield a uniform "stocking" or "glove" distribution when the child's extremity is held under very hot water as punishment (Giardino & Giardino, 2012). It is important for the nurse to pick up on clues in the health history that may indicate that the burn is a result of child abuse, rather than an accident (Box 46.3). Children are also burned by curling irons, gasoline, fireworks, room heaters, ovens, and ranges. Obtain a detailed history about the circumstances surrounding these types of burns. Ask the parent what the home hot water heater temperature is.

## Physical Examination

Emergency examination of the burned child consists of a primary survey followed by a secondary survey. The primary survey includes evaluation of the child's airway, breathing, and circulation. The secondary survey focuses on evaluation of the burns and other injuries. Box 46.4 gives information about emergency assessment of the

### BOX 46.3

#### SIGNS OF CHILD ABUSE-INDUCED BURNS

- Inconsistent history given when caregivers are interviewed separately
- Delay in seeking treatment by caregiver
- Uniform appearance of the burn, with clear delineation of burned and nonburned area (as with a hot object applied to the skin)
- In the case of a scald-induced burn, lack of spattering of water but evidence of so-called "porcelain-contact sparing," where the portion of the child's skin that was in contact with the tub or sink is not burned (commonly seen with a forced immersion in extremely hot water used as punishment)
- Flexor-sparing burns or burns that involve the dorsum of the hand
- A stocking/glove pattern on the hands or feet (circumferential ring appearing around the extremity, resulting from a caregiver forcefully holding the child under extremely hot water)

Adapted from Giardino, A. P., & Giardino, E. R. (2012). *Physical child abuse clinical presentation*. Retrieved July 7, 2012, from <http://emedicine.medscape.com/article/915664-overview>

burned child. Inspect the child's skin, noting erythema, blistering, weeping, or eschar (charred skin).

Classify the burn according to its severity. Superficial burns are painful, red, dry, and possibly edematous (Fig. 46.18). Partial-thickness and deep partial-thickness burns are very painful and edematous and have a wet appearance or blisters (Fig. 46.19). Full-thickness burns may be very painful or numb or pain-free in some areas. They appear red, edematous, leathery, dry, or waxy and may display peeling or charred skin (Fig. 46.20). Note whether the burn is circumferential (encircling a body part) or partially circumferential.

#### Take Note!

Due to overlying blistering, it is difficult to accurately distinguish between partial- and full-thickness burns. In addition, in the case of third-degree burns, it is difficult to estimate burn depth during the initial evaluation.

## Laboratory and Diagnostic Tests

In the child with more extensive burns, electrolytes and complete blood count are used to measure fluid and electrolyte balance and to determine the possibility of infection, respectively. If wound infection is suspected, culture of the drainage will determine the particular bacteria. Nutritional indices such as albumin, transferrin, carotene, retinol, copper, cholesterol, calcium, thiamine, riboflavin, pyridoxine, and iron may be evaluated when

## BOX 46.4

**EMERGENCY ASSESSMENT OF THE BURNED CHILD****Primary Survey**

- Assess the child's airway, noting whether it is patent, maintainable, or unmaintainable.
- Suspect airway injury from burn or smoke inhalation if any of the following are present: burns around the mouth, nose, or eyes; carbonaceous (black-colored) sputum; hoarseness or stridor.
- Evaluate the child's skin color, respiratory effort, symmetry of breathing, and breath sounds.
- Determine the pulse strength, perfusion status, and heart rate. Note extent and location of edema.

**Secondary Survey**

- Determine burn depth.
- Estimate burn extent by determining the percentage of body surface area affected. Use a chart for estimation (see Fig. 46.21) or rapidly estimate by using the child's palm size, which is equivalent to about 1% of the child's body surface area.
- Inspect the child for other traumatic injuries (children who have jumped or fallen from a house fire may suffer cervical spine or internal injuries).

Adapted from Jenkins, J. A. & Schraga, E. D. (2011). *Emergent management of thermal burns*. Retrieved July 7, 2012, from <http://emedicine.medscape.com/article/769193-overview#aw2aab6b2>

the child has severe or extensive burns. Pulmonary status may be evaluated via pulse oximetry and end-tidal CO<sub>2</sub> monitoring, arterial blood gases, carboxyhemoglobin levels, and chest radiography. Fiberoptic bronchoscopy

**FIGURE 46.18** Superficial burn—painful but without blisters.

**FIGURE 46.19** Partial-thickness burn—very painful, with blistering.

and xenon ventilation–perfusion scanning may be used to evaluate inhalation injury. Electrocardiographic monitoring is important for the child who has suffered an electrical burn to identify cardiac arrhythmias, which can be noted for up to 72 hours after a burn injury.

**Nursing Management**

Nursing management of the child who has been burned focuses first on stabilizing the child. Place the child on a cardiac/apnea monitor, measure the child with the Broselow tape, monitor pulse oximetry, and apply an end-tidal CO<sub>2</sub> monitor if the child is ventilated. Further management focuses on cleansing the burn, pain management, and prevention and treatment of infection. Fluid status and nutrition are important components of burn care, particularly in the early stages. Rehabilitation of the child with severe burns is also an important nursing function. Providing child and family education about the prevention of burns as well as care of burns at home is critical. Nursing Care Plan 46.1 gives additional interventions related to fluid and nutritional management.

**FIGURE 46.20** Full-thickness burn—color ranges from red to charred, or white, minimal pain, marked edema.

**Promoting Oxygenation and Ventilation**

Institute emergency airway management as needed. If the child requires intubation, make sure that the tracheal tube is taped in a very secure manner, as reintubations in these children will become increasingly difficult as the edema spreads. The burned child's respiratory status warrants vigilant evaluation and reevaluation, as airway edema that is secondary to a burn may not become evident until 2 days after the injury. Administer 100% oxygen via nonrebreather mask or bag-valve-mask ventilation to all children with severe burns. Continue to reassess the child's pulmonary status, adjusting the interventions as necessary (refer to Chapter 53 for further information about respiratory emergency care).

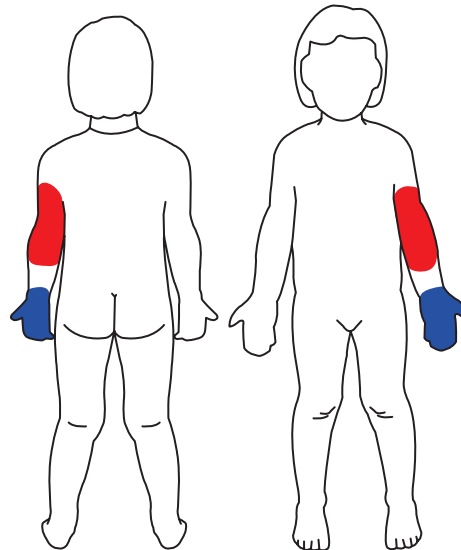

**Take Note!**

High levels of carboxyhemoglobin as a result of smoke inhalation may contribute to falsely high pulse oximetry readings (Jenkins & Schraga, 2011).

**Restoring and Maintaining Fluid Volume**

Several formulas are available for the calculation of resuscitative fluids in children. Most experts recommend that pediatric burn therapy include:

- Fluid calculation based on the body surface area burned (Fig. 46.21)
- Use of a crystalloid (Ringer lactate) during the first 24 hours; in smaller children, a small amount of dextrose may be added

**FIGURE 46.21** Calculate total body surface area (TBSA) affected by using the child's age and the area affected, as well as whether the burned area is second degree (partial thickness) or third degree (full thickness).

- Administration of most of the volume during the first 8 hours (amounts and timing of fluid volume resuscitation will vary from child to child)
- Reassessment of the child and adjustment of the fluid rate accordingly; fluid requirements greatly decrease after 24 hours and should be adjusted to reflect this.
- Administration of a colloid fluid later in therapy once capillary permeability is less of a concern
- Monitoring of the child's urine output as part of ongoing assessment of response to therapy, expecting at least 1 mL/kg/hour
- Daily weights obtained at the same time each day (the best indicator of fluid volume status)
- Monitoring of electrolyte levels (particularly sodium and potassium) for their return to normal levels
- Promote good infection control technique among your colleagues.
- Assist with restraining young children, using the positions of comfort previously discussed in relation to atraumatic care.
- Encourage participation by the child's parents.
- Talk soothingly to the child, explain what you are going to do, and provide distraction during the procedure.

### Preventing Hypothermia

Due to the loss of the protective dermis, children who are burned are at high risk for hypothermia and secondary infection. Therefore, take care to keep the child warm. Warm intravenous fluids before administration. Maintain a neutral thermal environment and monitor the child's temperature frequently.

### Cleansing the Burn

Initially, it is very important to stop the burning. Therefore, remove charred clothing. Wash and rinse the burn thoroughly with mild soap and cool water from the tap. Never apply ice. Children who are burned with tar require special care. Remove tar with cool water and mineral oil. Do not routinely remove blisters because they provide a protective barrier; however, débridement is recommended in certain cases where large blisters impede wound care. Wounds that are open require débridement. Débridement involves the removal of loose skin and eschar (dead, charred skin). This procedure is usually performed with sterile scissors and a pair of forceps or with a gauze sponge. Gently cleanse the burned area; there is no advantage to aggressive scrubbing, and this technique only makes the pain more intense for the child. Wear a gown, mask, head covering, and gloves during dressing changes. Débridement is a necessary, but often excruciatingly painful, procedure. Thus, pain management needs of the child are of utmost importance (refer to the pain management section below).

When children return for evaluation of a wound that was previously seen in your facility, remove the dressing. Soak the dressing in lukewarm tap water to ease the removal of gauze, which may be stuck to the wound. The nurse plays an important role in ensuring that the dressing change goes smoothly. Be sure to:

- Have all dressing supplies ready.
- Provide pain medication as ordered.

### Preventing Infection

Prevention of infection is critical to successful outcomes for burned children. If the child's immunization status is unknown or if it has been 5 years or longer since the last tetanus vaccine, administer the tetanus vaccine (Jenkins & Schraga, 2011). If the child has never received tetanus vaccination, also give 250 units tetanus human immunoglobulin intravenously. Apply antibiotic ointment in conjunction with burn dressing changes. Refer to Drug Guide 46.1 for information about topical antibiotics. Membrane dressings such as biosynthetic, hydrocolloid, and antibiotic-impregnated foam dressings are alternatives to topical antibiotics and sterile dressings. Evaluate the child's wound during dressing changes, looking for wound redness, swelling, odor, or drainage. Strictly adhere to infection control procedures and hand hygiene to decrease the risk of burn infection. Maximize the child's nutritional status to decrease his or her susceptibility to a burn infection. Monitor the child's temperature for the development of fever. Upon discharge, instruct the parents about the signs of a wound infection.

### Managing Pain

Pain management is of the utmost importance, and several options are available for the treatment of burn-related pain. Local anesthesia, sedatives, and systemic analgesics are commonly used. Children who have less severe burns that are managed at home can be given oral medications such as acetaminophen with codeine 30 to 45 minutes before dressing changes. In burns that result in more severe pain, the child should be hospitalized and given intravenous pain control with medications such as morphine sulfate. Midazolam (a sedative) may be used in conjunction with pain medication for pain reduction during dressing changes.

Pain may also occur at any time of the day or night, not just in relation to dressing changes. Assess the child's pain status frequently using an age-appropriate pain assessment scale. Administer pain medications as prescribed and/or use nonpharmacologic techniques to alleviate or decrease the child's perception of pain.

## Atraumatic Care

*Immersion in virtual reality computer games before and during burn dressing changes provides an exceptionally powerful form of cognitive distraction. It appears to be most useful if instituted early in the child's course of treatment (Sbarar et al., 2008).*

### Treating Infected Burns

The potential for burn infection increases if the child has a large, open burn wound and if there are other sources of infection, such as multiple intravenous lines. In addition, children who are immunocompromised have an increased risk of burn infection. *S. aureus* is the usual bacterium implicated in burn cellulitis and burn impetigo (Quilty, 2010). In burn wound cellulitis, the area around the burn becomes increasingly red, swollen, and painful early in the course of burn management. With invasive burn cellulitis, the burn develops a dark brown, black, or purplish color, with a discharge and foul odor. Burn impetigo is characterized by multifocal small superficial abscesses. Burn impetigo causes marked destruction of skin-grafted areas. Extensive infected burns may also become infected with a fungus.

When an infection is suspected, antibiotics are usually started, pending wound culture results. Administer antibiotics as prescribed or antifungals if necessary.

### Providing Burn Rehabilitation

Children who have suffered a significant burn injury face myriad physical and psychological challenges that extend well beyond the acute injury phase. Burned children most often exhibit anxiety and attention or behavioral problems (Pardo, Garcia, & Gomez-Cia, 2010). Skin grafting or special burn dressings are required for some children (Box 46.5). Children who have suffered extensive burns often require multiple skin-grafting surgeries. Figures 46.22 and 46.23 show healed skin grafts. Extensive burns may also result in the need for pressure garments to decrease the risk of extensive scarring. Pressure garments are not comfortable and they must be worn continuously for at least 1 year, sometimes 2, but they have been shown to be very effective in reducing hypertrophic scarring resulting from significant burn injury.

Physical therapy will usually be initiated in the critical care setting and will continue long after hospital discharge, sometimes throughout life. Positioning, exercise, and range of motion are necessary to maintain joint flexibility.

Nurses play a key role in smoothing the transition from the acute care phase of life-saving interventions and frequent dressing changes to normal activities such as school and play. Body image considerations may have

## BOX 46.5

### SPECIAL BURN CARE AND SKIN GRAFTING

- To prevent infection and promote healing:
  - Biosynthetic skin coverings such as Biobrane (silicone film bonded to flexible nylon fabric and purified collagen peptides) and Mepilex Ag (soft silicone soaked with silver)
  - Kaltostat (calcium alginate dressing) is a brown seaweed extract that is spun into a fiber that is highly absorbent. It reacts with exudate on the wound to form a protective gel.
- Autograft allows for permanent coverage of a deep partial-thickness or full-thickness burn.
  - Consists of child's own skin
  - Split thickness consists of epidermis and superficial layers of dermis. The donor site heals completely.
  - Full thickness consists of full dermal thickness. Cover the donor site with fine-mesh gauze or synthetic wound coverings to allow the site to heal.

Adapted from Quilty, J. (2010). *Pediatric burn management*. Presented at meeting of the Florida Chapter of the National Association of Pediatric Nurse Practitioners, Orlando, FL.

a significant impact on the child when he or she returns to school and should be addressed. Children with altered body image as a result of a burn might benefit from regular counseling and group therapy. Parents often need assistance with the behavioral challenges of caring for a child who is recovering from a burn injury. Various websites are available for support of persons who are burned. Links to websites are available on [thePoint](#).

Navigating through life after suffering a serious burn injury can be difficult for the child and family, and a skilled nurse can provide valuable assistance to families during the equally important, but less acute, phase of the journey.

FIGURE 46.22 Healed mesh graft.

**FIGURE 46.23** Extensive grafting to the face.

### Preventing Burns and Carbon Monoxide Poisoning

Instruct parents about prevention of burns. Explain that all homes should have working smoke detectors, and batteries should be changed yearly. Instruct families that all homes should be equipped with fire extinguishers, and adults and older teenagers should be taught how to operate them. Explain that children should sleep in fire-retardant sleepwear, parents should not smoke in the house or the car, and parents should keep lighters and matches out of children's reach. Young children are particularly susceptible to burns that occur in the kitchen, such as scalds from hot liquids and foods and burns from contact with hot burners or oven doors. Caution parents about the extreme danger that fireworks present to children. Teaching Guidelines 46.3 gives additional information for parents related to burn prevention. The booklet "Burn Prevention Tips," which includes a coloring book, is available from the Shriners Hospitals for Children. A link to their website is provided on [thePoint](#).

#### Teaching Guidelines 46.3

##### BURN PREVENTION

- Keep hot water heater temperature lower than 120°F.
- Test bath water temperature before bathing children.
- Keep children away from open flames, stoves, and candles.
- Cook with pots on the inside of the stove with the handles turned in.
- Keep children away from the stove while cooking.

- Place hot liquids out of reach of children.
- Avoid drinking hot beverages while holding a child.
- Keep curling irons out of reach of children.
- Teach older children how to safely get out of the house in case of fire.
- Practice fire drills.
- Teach children to "stop, drop, and roll" if their clothes catch on fire.

Children are at significant risk for burns related to hot water. Scald burns can occur when hot water comes into contact with the child's skin, even for a relatively short time. Since hot water presents such a serious risk to children, the temperature on all hot water heaters should be 120°F or lower. Figure 46.24 is a graph that shows how long a child can be exposed to water of various temperatures before a burn occurs. For example:

- If the water is 150°F, a child can receive a third-degree burn within 2 seconds.
- If the water is 140°F, it takes 6 seconds of exposure to cause a significant burn.
- If the water is 130°F, a child can be burned significantly in only 30 seconds.
- At 120°F, the recommended maximal home hot water heater temperature, it takes as long as 5 minutes of exposure to burn a person (plenty of time to get out of the tub!) (Accurate Building Inspectors, 2012).

Instruct parents about prevention of carbon monoxide poisoning. All homes should have working carbon monoxide detectors, and batteries should be changed yearly. Teach parents the signs of carbon monoxide poisoning: headaches, dizziness, disorientation, and nausea. If the carbon monoxide detector sounds, turn off any potential sources of combustion, if possible, and evacuate all occupants immediately. Do not attempt to reenter the home until a qualified professional repairs the source of the carbon monoxide leak.

### Providing Burn Care at Home

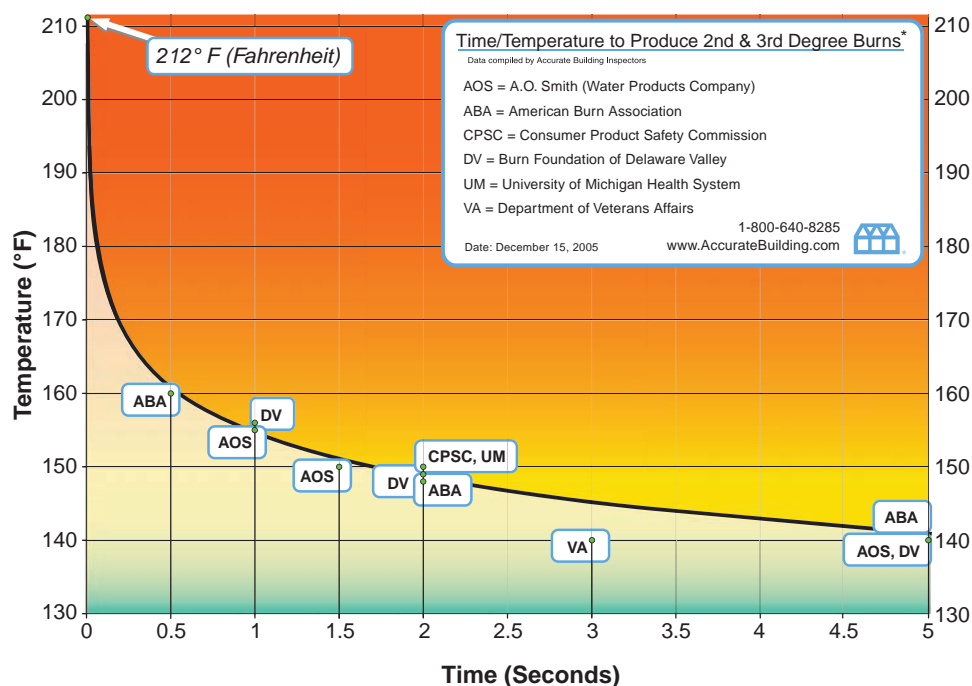

Teach parents about proper burn care in the home. Seek medical attention for burns when:

- The child has a second- or third-degree burn.
- Burns result from a fire, an electrical wire or socket, or chemicals.
- The child has a burn on the face, scalp, hands, feet, or genitals or over the joints.
- The burn appears to be infected.
- The burn is causing prolonged and significant pain.
- Concern exists that the burn was a result of abuse.

If the burn is very extensive, even if it appears to be a first-degree burn, seek medical attention immediately. Teaching Guidelines 46.4 gives specific information about burn care at home.

### Hot Water Burn & Scalding Graph

**FIGURE 46.24** Length of hot water exposure that results in significant burns based on water temperature. (Used with permission of Accurate Building Inspectors. [2012]. *Water temperature thermometry*. Retrieved July 7, 2012, from [http://www.accuratebuilding.com/services/legal/charts/hot\\_water\\_burn\\_scalding\\_graph.html](http://www.accuratebuilding.com/services/legal/charts/hot_water_burn_scalding_graph.html))

#### Teaching Guidelines 46.4

##### PROVIDING BURN CARE AT HOME

###### For First-Degree (Superficial) Burns

- Run cool water over the burned area until the pain lessens.
- Do not apply ice to the skin.
- Do not apply butter, ointment, or cream.
- Cover the burn lightly with a clean, nonadhesive bandage.
- Administer acetaminophen or ibuprofen for pain.
- Have the child seen by the physician or nurse practitioner within 24 hours.
- Ongoing care: clean in tub or shower with fragrance-free mild soap; pat or air dry.
  - Apply a thin layer of antibiotic ointment.
  - Cover with a nonadherent dressing such as Adaptic, and then cover with dry gauze.

###### For More Extensive Burns

- Remove clothing only if it comes off easily or if it is still smoldering.
- Check the child's ABCs (airway, breathing, and circulation) and perform cardiopulmonary resuscitation (CPR) if necessary.
- Do not apply butter, ointment, or any other type of cream.
- Cover the burn with a clean, lint-free bandage or sheet.

- Avoid applying large, wet sheets, as this can cause the child to become too cold.
- Do not attempt to break any blisters.
- If the child appears to be in shock, elevate the legs while protecting the burn and call 911.

### Sunburn

Sunburn occurs as a result of overexposure to the ultraviolet (UV) rays of the sun. The erythema and eventual blisters occur as a result of the skin's blood flow changes as well as alterations in cell kinetics and pigment products in response to UV exposures. Erythema may occur within 4 hours and blisters within 6 hours. Excessive sun exposure has been linked to the development of skin cancer later in life (Burns et al., 2009). See Healthy People 2020.

Sunburn is usually treated with cool compresses, cooling lotions, and oral nonsteroidal anti-inflammatory agents.

### Nursing Assessment

Obtain the health history, noting recent sun exposure. Determine length of exposure and whether any type of sunscreen or sun block product was used. Note redness of the skin on the exposed areas. More severe areas will have a darker red, slightly purple hue. Blisters may be noted with more severe sunburn.

**HEALTHY PEOPLE 2020****Objective**

(Developmental)  
Increase the proportion of adolescents in grades 9 through 12 who follow protective measures that may reduce the risk of skin cancer.

**Nursing Significance**

- Encourage use of sunscreen in all children older than 6 months of age, to form a lifelong habit.
- Discourage sun exposure between 10 a.m. and 2 p.m.
- Inform teens of the hazards of ultraviolet light (even artificial) and discourage the use of tanning beds.

*Healthy People Objectives based on data from <http://www.healthypeople.gov>.*

**Nursing Management**

Cool compresses may help to cool the burn. Aloe vera gel applied topically may provide significant soothing. Rarely are adverse effects reported with the use of aloe vera gel. Administer a nonsteroidal anti-inflammatory such as ibuprofen. Discourage hot showers or baths. Instruct the child to wear loose clothing and to ensure that burned areas are covered when going outside (until they are healed). If skin flaking occurs, discourage the child from “peeling” the flaked skin in order to prevent further injury. Refer to Chapter 31 for further information about safe sun exposure.

**Cold Injury**

The term “frostbite” implies freezing of the tissues. It is described on a continuum from first to fourth degree. When a child is exposed to an extremely cold environment, changes in cutaneous circulation help to maintain the core body temperature. Because circulation is shunted to the core, the most peripheral body parts are those at highest risk for frostbite. Local damage occurs when the tissue temperature drops to 32°F (0°C). Initially skin sensation is lost, the vasculature constricts, and plasma leakage occurs. Ice crystals develop in the extracellular fluid, and eventually vascular stasis leads to endothelial cell damage, necrosis, and sloughing of dead tissue.

**Nursing Assessment**

Note history of cold exposure. Inquire about pain or numbness. Examine the skin for indications of frostbite. First-degree frostbite results in superficial white plaques with surrounding erythema. Second-degree frostbite

demonstrates blistering with erythema and edema. In third-degree frostbite, hemorrhagic blisters occur, progressing to tissue necrosis and sloughing in fourth-degree frostbite.

**Nursing Management**

Remove wet or tight clothing. Avoid vigorous massage to decrease the chance of damaging the skin further. Immerse the affected part in 104°F water for 15 to 30 minutes. Thawing may cause significant pain, so administer analgesics. Keep the thawed part loosely covered, warm, and dry. Splinting may be used to help decrease associated edema. Consult the wound care specialist or plastic surgeon for further management.

Prevent frostbite by:

- Dressing warmly in layers, and keeping warm and dry
- Avoiding exertion
- Not playing outside when wind chill advisories are in effect, and locking doors with high locks to prevent toddlers from going outside

**Human and Animal Bites**

Yearly, significant emergency room visits occur as a result of bites from mammals. Dog bites account for the majority of injuries, but children may be bitten by other children, cats, or rodents (Hansen & Ahmed, 2010). The hand and face are common locations for animal bites. A dog is most often provoked to bite a child when the child is playing with the dog or when the child hits, kicks, hugs, grabs, or chases the dog.

Therapeutic management involves cleansing and irrigating the wound, wound suturing or stapling if necessary, and administering topical and/or systemic antibiotic therapy. Rabies prophylaxis is indicated if the rabies status of the dog is unknown. Secondary bacterial infection of the bite wound with streptococci, staphylococci, or *Pasteurella multocida* may occur. Cat and human bites are the most likely to become infected (Hansen & Ahmed, 2010).

**Nursing Assessment**

Determine the history of the attack and whether it was provoked. Determine the child’s tetanus vaccination status. Inspect the bite to determine the extent of laceration, avulsion, or crushing injury.

**Nursing Management**

Provide rabies immunoprophylaxis and a tetanus booster vaccination if indicated. Thoroughly cleanse the wound with soap and water or a povidone-iodine solution. Irrigate the wound well with normal saline after cleansing. If the animal may be rabid, cleanse the wound for at least

10 minutes with a virucidal agent such as povidone-iodine solution. Administer antibiotics as prescribed.

Prevention of animal bites is important. Teach children the following:

- Never provoke a dog with teasing or roughhousing.
- Get adult permission before interacting with a dog, cat, or other animal that is not your pet.
- Do not bother an eating, sleeping, or nursing dog.
- Avoid high-pitched talking or screaming around dogs.
- Display a closed fist first for the dog to sniff.
- Keep ferrets away from the face.
- If a cat hisses or lashes out with the paw, leave it alone.

Never leave a child younger than 5 years of age alone with a dog (Centers for Disease Control and Prevention, 2009). Contact the local humane society for a dog bite prevention program that is appropriate for school-age children.

Children may suffer significant emotional distress after being bitten. Nightmares and increased anxiety are common (National Health Service, 2010). Help children through this period by talking about the incident or reading books about this type of event.

### Insect Stings and Spider Bites

Members of the Hymenoptera class of insects sting. This class includes bees, wasps, ants, yellow jackets, and hornets. Spiders inject their venom when they bite. Stings and bites usually result in a local reaction. A systemic or anaphylactic reaction to a Hymenoptera sting may also occur, possibly resulting in airway compromise (refer to Chapter 48 for additional information on anaphylaxis). Serious reactions may occur with brown recluse or black widow spider bites. This discussion will focus on local reactions.

Local reactions to insect stings and spider bites include pruritus, pain, and edema. A hypersensitivity reaction thought to be mediated by IgE occurs in response to the venom. This may be a physiologic response to the antigens present in the insect's or spider's saliva and other fluids that are transmitted during stinging or biting. Bacterial superinfection may occur as a complication and as a result of scratching. Therapeutic management includes antihistamines to decrease itching and in some cases corticosteroids to decrease inflammation and swelling.

### Nursing Assessment

Obtain the history of the bite or sting. Children are usually acutely aware when they have been stung by an insect, but spiders are generally not observed before the bite. Inspect the bite or sting, noting an urticarial wheal or papular reaction. A large local reaction may be mistaken for cellulitis. Note whether a stinger remains

present. Assess the child's work of breathing to determine if a systemic reaction or anaphylaxis is occurring (refer to Chapter 48).

### Nursing Management

Remove jewelry or constrictive clothing if the sting is on an extremity. Cleanse the wound with mild soap and water. If the stinger is present, scrape it away with your fingernail or a credit card. Apply ice intermittently to decrease pain and edema. Administer diphenhydramine as soon as possible after the sting in an attempt to minimize the reaction.

Prevent insect stings and spider bites by wearing protective clothing and shoes when outdoors. Use insect repellants (with a maximum concentration of 30% *N,N*-diethyl-meta-toluamide [DEET] in infants and children older than 2 months) (U.S. Food and Drug Administration, 2010a). Teach children never to disturb a bee or wasp nest or an ant hill.

#### KEY CONCEPTS

- The infant's epidermis is thinner, loses heat more readily, absorbs substances more easily, and is more accessible to bacterial invasion than the skin of the adult. The increased water content of the infant's skin compared with the adult's places the infant at increased risk of blister development and other skin alterations.
- The child's skin thickness and characteristics reach adult levels in the late teenage years.
- Children with dark skin tend to have more pronounced cutaneous reactions than children with lighter skin.
- Sebum production increases in the preadolescent and adolescent years, contributing to the development of acne at that time.
- Most bacterial skin infections are caused by *Staphylococcus aureus* and group A  $\beta$ -hemolytic streptococcus.
- Skin scrapings placed on a slide and prepared with potassium chloride may be evaluated microscopically to determine the presence of fungus.
- Fungal skin infections, referred to collectively as tinea, may require up to several weeks of treatment.
- Contact dermatitis and atopic dermatitis both present as pruritic rashes, whereas psoriasis is generally nonpruritic.
- Hypersensitivity responses may result in erythema multiforme or urticaria.

- Scaling may occur with atopic dermatitis and psoriasis, whereas honey-colored crusting is common with impetigo. Erythema is a common finding with many skin disorders in children.
- Burns may result in significant weeping and fluid loss.
- Keeping the skin well moisturized is a key intervention in the management of atopic dermatitis and psoriasis.
- Appropriate hygiene is of particular importance in integumentary disorders.
- Pain management, prevention of infection, and rehabilitation are the focus of nursing management for the burned child.
- The constant itch–rash–itch cycle of atopic dermatitis may have a considerable impact on the child's sleep, school functioning, and self-esteem.
- Acne vulgaris, particularly if moderate or severe, may have a significant negative effect on the teen's self-esteem.
- Teach children with chronic disorders such as atopic dermatitis, psoriasis, and acne (and their parents) to cleanse and moisturize the skin properly, avoid particular skin irritants, and use medications appropriately.
- Many skin disorders are preventable. Teach families how to prevent contact dermatitis, burns, sunburn, frostbite, and bites and stings.
- Educate children and families about the importance of good soap-and-water cleansing of all minor skin injuries.

## MULTIPLE CHOICE QUESTIONS

- The nurse is teaching about skin care for atopic dermatitis. Which statement by the parent indicates that further teaching may be necessary?
  - “I will use Vaseline or Crisco to moisturize my child’s skin.”
  - “A hot bath will soothe my child’s itching when it is severe.”
  - “I will buy cotton rather than wool or synthetic clothing for my child.”
  - “I will apply a small amount of the prescribed cream after the bath.”
- The nurse is caring for a child who has received significant partial-thickness burns to the lower body. What is the priority assessment in the first 24 hours after injury?
  - Fluid balance.
  - Wound infection.
  - Respiratory arrest.
  - Separation anxiety.
- The nurse is caring for a child in the emergency department who was bitten by the family dog, who is fully immunized. What is the priority nursing action?
  - Administer rabies immunoglobulin.
  - Refer the child to a counselor.
  - Assess the depth and extent of the wound.
  - Administer a tetanus booster.
- The nurse is caring for an infant on the pediatric unit who has a very red rash in the diaper area, with red lesions scattered on the abdomen and thighs. What is the priority nursing intervention?
  - Administer griseofulvin with a fatty meal.
  - Institute contact isolation precautions.
  - Apply topical antibiotic cream.
  - Apply topical antifungal cream.
- A varsity high-school wrestler presents with a “rug burn” type of rash on his shoulder that is not healing

as expected, despite use of triple antibiotic cream. Two other wrestlers on his team have a similar abrasion. What infection should the nurse be most concerned about, based on the history?

- Tinea cruris.
- MRSA.
- Impetigo.
- Tinea versicolor.

## CRITICAL THINKING EXERCISES

- A 4-year-old presents with his mother for evaluation of a yellowish, runny sore on his head. What questions would be most appropriate to ask the mother when taking the history? Should this child be placed in isolation? If so, why?
- An 11-month-old comes to the primary care office with his mother for evaluation of a significant flaking red rash on both cheeks. The child is diagnosed with atopic dermatitis. What additional information should be obtained in the health history? What information should be included in the teaching plan for this family?

## STUDY ACTIVITIES

- Plan an educational activity:
  - For parents of babies about the treatment and prevention of diaper dermatitis
  - For parents of school-age children about prevention of contact dermatitis (related to poison ivy)
- During your clinical rotation, spend a day with the wound and ostomy care nurse in a children’s hospital. Report to the clinical group about what you learned that day.
- Talk to teenagers with severe acne, atopic dermatitis, or psoriasis about their feelings about their skin’s appearance. Reflect on this information in your clinical journal.

# Nursing Care of the Child With a Hematologic Disorder

## Learning Objectives

*Upon completion of the chapter, you will be able to:*

1. Define the key terms used in this chapter.
2. Identify major hematologic disorders that affect children.
3. Determine priority assessment information for children with hematologic disorders.
4. Analyze laboratory data in relation to normal findings and report abnormal findings.
5. Provide nursing diagnoses appropriate for the child and family with hematologic disorders.
6. Identify priority interventions for children with hematologic disorders.
7. Develop a teaching plan for the family of children with hematologic disorders.
8. Identify resources for children and families with hematologic disorders or nutrition deficits.

*Shaun O'Malley, 10 months old, is being admitted to the pediatric unit after being brought to the clinic by his father for a small laceration that he thought needed stitches. His father states, "I didn't think the cut was very deep. I was surprised by how long it bled."*

### Words of Wisdom

Blood is just red to the child,  
but to the nurse, blood is life.

The hematologic system consists of the blood and blood-forming tissues of the body. These typically function together in a balance that affects the metabolism of the body. The three categories of cells are erythrocytes, or **red blood cells** (RBCs); thrombocytes, or **platelets**; and leukocytes, or **white blood cells** (WBCs). RBCs are responsible for transporting nutrients and oxygen to the body tissues and waste products from the tissues. The platelets are responsible for clotting. WBCs are responsible for fighting infection. WBCs are further divided into granulocytes (neutrophils, eosinophils, and basophils) and agranulocytes (lymphocytes and monocytes).

All blood cells originate from a single type of cell called a multipotent stem cell, which goes on to differentiate into the various types of blood cells. Thrombopoietin (TPO) and interleukin-7 (IL-7) act on the cell and differentiate the cell into either myeloid or lymphoid progenitor cells. The lymphoid cells either, under the influence of IL-6, become B lymphocytes or change directly into T lymphocytes. The myeloid cells are differentiated in one of two ways, either by the action of erythropoietin (EPO) or granulocyte-monocyte colony-stimulating factor (GM-CSF). When the cell is acted upon by EPO, which is produced by

the kidneys, the cell becomes the megakaryocyte, also known as the erythroid progenitor cell. The megakaryocyte is acted on by either EPO, to become the red blood cell, or TPO and IL-11, to become a megakaryocyte that goes on to form platelets. GM-CSF influences the cell to become the granulocyte, also known as the macrophage progenitor cell. These cells further differentiate under various influences to become the WBCs (Fig. 47.1).

Certain conditions may cause problems to develop within this system. These problems are related to either the production of the blood cells (too much or too little) or loss and destruction of these cells. Many factors are involved in the development of hematologic disorders, ranging from genetic causes to disorders resulting from injury, infection, or nutritional deficit.

Nursing care for the child with a hematologic disorder is often multifaceted. A child who has iron-deficiency anemia requires adequate oxygenation and may require packed red blood cells; a child with hemophilia requires factor replacement and monitoring for safety. Nurses who care for children need to be familiar with common hematologic disorders of infancy, childhood, and adolescence so they can effectively intervene with children and their families.

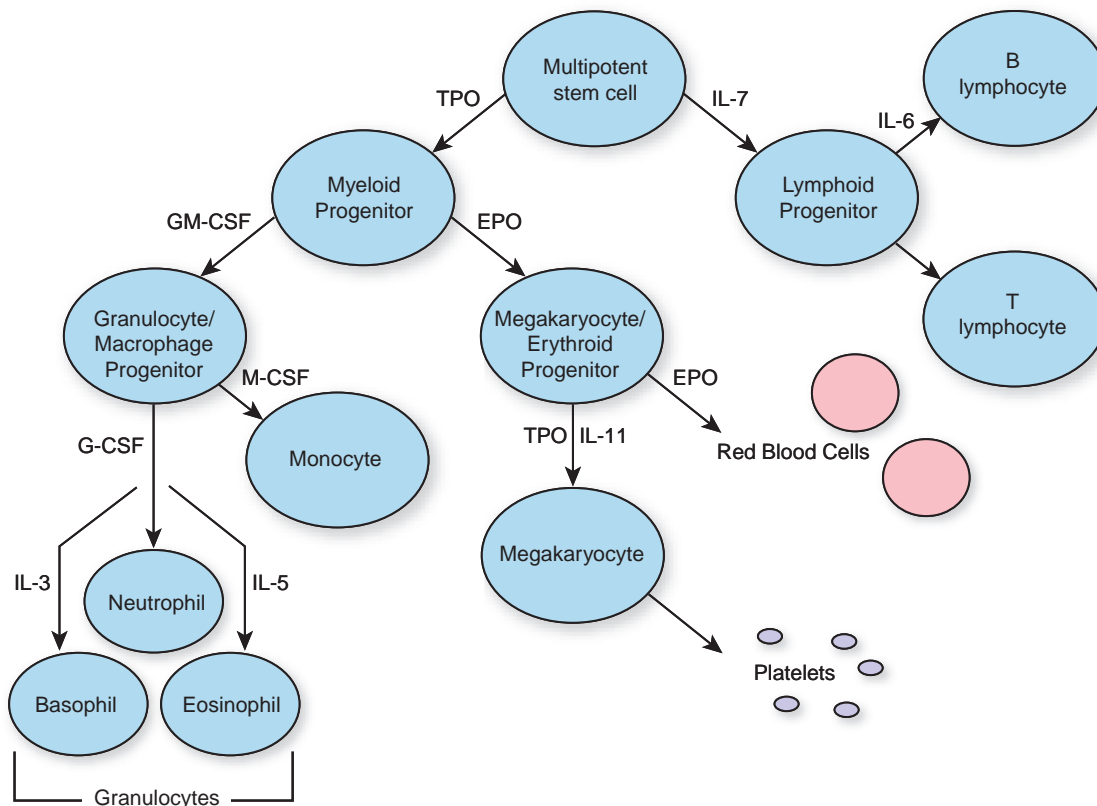

FIGURE 47.1 Process of blood cell formation.

## VARIATIONS IN PEDIATRIC ANATOMY AND PHYSIOLOGY

In the absence of a congenital defect, the hematologic system is intact and functional at birth. RBC and hemoglobin production as well as iron stores undergo changes in the first few months of life; after this time, hematologic function is stable.

### Red Blood Cell Production

The production of blood cells in the embryo begins by 8 weeks' gestation. In the embryo, blood cells primarily form in the liver; this continues until a few weeks before delivery. Some cell production, lymphoid cells in particular, takes place in the spleen of the embryo, and the thymus is a site for some transient lymphocyte production. EPO, the hormone that regulates RBC production, is derived primarily from the liver in the fetus, and after birth the kidneys take over this production.

### Hemoglobin

Three types of normal **hemoglobin** (Hgb) are present at any given time in the blood: Hgb A, Hgb F or fetal, and Hgb A<sub>2</sub>. After 6 months of age, Hgb A is the predominant type. In the neonatal period, the largest difference is with the RBCs. Fetal hemoglobin, which has a much shorter cell life, is present in higher quantities, putting the infant at risk for anemia and leading to problems with the oxygen-carrying capacity of the blood. As the production of the cells transfers from the liver to the bone marrow of the long and flat bones, the balance between oxygenation and production is affected.

### Iron

The fetus receives iron through the placenta from the mother. The preterm infant misses out on the final weeks or months of transplacental iron transfer, putting him or her at increased risk for anemia (Cunningham et al., 2010). In the term infant, a period of physiologic anemia occurs between the age of 2 and 6 months. This is due to the fact that the infant demonstrates rapid growth and an increase in blood volume over the first several months of life, and maternally derived iron stores are depleted by 4 to 6 months of age. Sufficient iron intake is critical for the appropriate development of hemoglobin and RBCs. Therefore, the infant must ingest adequate quantities of iron either from breast milk or from iron-fortified formula in early infancy and other food sources in later infancy (Bryant, 2010). Adolescence is also a time of rapid growth, and intake of iron must increase.

## COMMON MEDICAL TREATMENTS

Various medications as well as other medical treatments are used to treat hematologic disorders in children. Most of these treatments will require a physician's or nurse practitioner's order when the child is in the hospital. The most common treatments and medications are listed in Common Medical Treatments 47.1 and Drug Guide 47.1. The nurse caring for the child with a hematologic disorder should be familiar with the procedures used, how the medications work, and common nursing implications related to their use.

## NURSING PROCESS OVERVIEW FOR THE CHILD WITH A HEMATOLOGIC DISORDER

Care of the child with a hematologic disorder includes assessment, nursing diagnosis, planning, interventions, and evaluation. There are a number of general concepts related to the nursing process that may be applied to hematologic dysfunction in children.

Development of a plan of care will depend on which component of the blood is altered. A decrease in hemoglobin will necessitate evaluation of oxygen-carrying capacity and effects of hypoxia on the tissues. A reduction in platelet production will lead the nurse to evaluate for prolonged bleeding, hemorrhage, and shock. An elevation in WBCs would require an evaluation for infection.

**Remember Shaun, the 10-month-old with the laceration and prolonged bleeding? What additional health history and physical examination assessment information should you obtain?**

### Assessment

Signs of changes in the hematologic system are often insidious and overlooked. Skin color changes such as pallor, bruising, and flushing are often the first signs that a problem is developing. Changes in mental status such as lethargy can indicate a decrease in Hgb and a decreased amount of oxygen being delivered to the brain. Nursing assessment must include a thorough approach.

### Health History

Elicit the birth and maternal history, noting low birthweight or gestational diabetes and ascertaining whether vitamin K was given after birth. The past medical history might be significant for recent illnesses that may contribute to a change in blood cell distribution. Determine the child's sleep/wake

## COMMON MEDICAL TREATMENTS 47.1

Treatment	Explanation	Indications	Nursing Implications
Blood product transfusion	Intravenous administration of whole blood, packed red blood cells (PRBCs), platelets, or plasma	PRBCs: severe anemia, thalassemia, sickle cell disease Whole blood: acute hemorrhage or trauma Fresh-frozen plasma: hemophilia	Follow institution's transfusion protocol. Double-check blood type and product label with a second nurse. Use only leukodepleted, CMV-negative blood products in the child with a hemoglobinopathy. Monitor vital signs and assess child frequently to detect adverse reaction to blood transfusion. If adverse reaction is suspected, immediately discontinue transfusion, run normal saline IV, reassess the child, and notify the physician. Some children require premedication with diphenhydramine and/or acetaminophen before receiving blood products.
Supplemental oxygen	Administration of oxygen via mask, cannula, or blow-by	Hypoxia associated with sickle cell crisis or severe anemia	Frequently monitor work of breathing, oxygen saturation via pulse oximetry, cardiopulmonary status, and level of consciousness.
Splenectomy	Surgical removal of the spleen	Life-threatening or recurrent splenic sequestration of sickle cell disease; thalassemia	Provide immunization against the following organisms, because they place the child at risk for overwhelming infection: <i>Streptococcus pneumoniae</i> , <i>Neisseria meningitidis</i> , and <i>Haemophilus influenzae</i> type B. Monitor carefully for signs of infection. Administer prophylactic antibiotics. Instruct child or teen to wear medical alert bracelet. Teach families to seek medical treatment at first sign of infection or fever.
Hematopoietic stem cell transplantation	Bone marrow transplant: transfer of healthy bone marrow into a child with disease; the transplanted cells can then develop into functional cells.  Stem cell transplant: Peripheral stem cells are removed from the donor via apheresis, or stem cells are retrieved from the umbilical cord and placenta. The stem cells are then transplanted into the recipient.	Sickle cell disease, aplastic anemias, thalassemia	Maintain medical asepsis and protective isolation to prevent infection. Monitor closely for graft-versus-host disease. Provide meticulous oral care. Avoid taking rectal temperatures and inserting suppositories. Encourage appropriate nutrition. Administer immunosuppressive medications as ordered.

CMV, cytomegalovirus.

patterns and bowel elimination patterns, which may be affected by alterations in circulating blood volume or changes in oxygenation. Explore the family history for inherited disorders such as hemophilia, sickle cell disease, and thalassemia. Evaluate the child's typical diet for nutritional deficits. Determine risk for lead exposure based on the use of a standard questionnaire. When eliciting the history of the present illness, inquire about:

- Fatigue or malaise
- Pallor of the skin

- Unusual bruising
- Excessive bleeding or difficulty stopping bleeding
- Pain: location, onset, duration, quality, and relieving factors

### Physical Examination

A child's general appearance gives great insight into his or her health and can indicate problems such as malnutrition or lead poisoning. Physical examination of the

**DRUG GUIDE 47.1 COMMON DRUGS FOR HEMATOLOGIC DISORDERS**

Medication	Actions/Indications	Nursing Implications
Iron supplements (ferrous sulfate, ferrous fumarate)	Supplemental iron in deficient child Iron-deficiency anemia	Dosage is based on milligrams of elemental iron. Give with vitamin C–containing foods to increase absorption Do not administer with milk or milk products. May color stools and urine black. Liquid can stain the teeth; mix with a small amount of juice; drinking with straw decreases tooth staining. May cause constipation; increase fiber and fluid intake.
Deferasirox (Exjade)	Binds with iron, which is removed in the feces Iron toxicity (as in children chronically transfused)	Oral agent, should be taken at the same time daily, on an empty stomach. Monitor hearing and vision.
Deferoxamine (Desferal)	Binds with iron, which is removed via the kidneys Iron toxicity (as in children chronically transfused)	Rotate subcutaneous injection sites to decrease local reactions. Apply corticosteroid cream to irritation.
Factor (VIII or IX) replacement	Replaces deficient clotting factors Hemophilia	Use filter needle to draw up medication. Administer IV when bleeding occurs.
Penicillin VK	Kills susceptible bacteria Prophylaxis of infection in asplenia	Determine whether penicillin allergy is present. Monitor renal and hematologic function during prolonged use.
Folic acid	Replaces the vitamin Folic acid deficiency; questionable use with sickle cell anemia	Administer without regard to meals. Monitor hematologic function.
Hydroxyurea	Stimulates the development of hemoglobin F in sickle cell anemia	<i>Monitor for mild GI discomfort, modest neutropenia, hyperpigmentation of the skin and nails.</i>
Intravenous immune globulin (IVIG) (multiple manufacturers)	Provides exogenous IgG antibodies Idiopathic thrombocytopenic purpura	Do not mix with IV medications or with other IV fluids. Do not give IM or SQ. Monitor vital signs and watch for adverse reactions frequently during infusion. Child may require antipyretic or antihistamine to prevent chills and fever during infusion. Have epinephrine available during infusion.
Chelating agents: dimercaprol (BAL), edentate calcium disodium (CaEDTA), succimer (Chemet)	Remove lead from soft tissues and bone, allowing for its excretion via the renal system Used for blood lead levels >45 mcg/dL	Monitor intake and output closely to ensure adequacy of renal system. Encourage adequate oral hydration or provide IV hydration if required. Follow lead levels as prescribed. Ensure that lead is being removed from the child's home.

GI, gastrointestinal; IM, intramuscularly; SQ, subcutaneously.

Adapted from Taketokmo, C. K., Hodding, J. H., & Kraus, D. M. (2011). *Pediatric and neonatal dosage handbook* (18th ed.). Hudson, OH: Lexi-comp.

child with a hematologic disorder includes inspection and observation, palpation, and auscultation.

### INSPECTION AND OBSERVATION

Note the child's color and general appearance, including thin or emaciated appearance or obesity. Measure weight and height (or length) and plot on standardized growth charts. Observe the nail beds, palms, and soles for pallor. Evaluate the fingertips for clubbing, which occurs with chronic hypoxemia. Document the location and extent of bruises, petechiae, or purpura. Count the respiratory rate and observe for work of breathing. Obtain a pulse oximeter reading to determine oxygen saturation of tissues. Note conjunctival color as well as color and moisture of oral mucosa. Determine urinary output, which may be altered with decreases in circulatory blood volume or inadequate oxygenation. Note the child's responsiveness to stimuli, movement of extremities, and quality of gait.

### AUSCULTATION

Auscultate breath sounds, noting adequacy of air movement and depth of respiration. Note adventitious sounds or absence of breath sounds (which would occur in an area of the lung filled with blood). Auscultate heart sounds, listening closely for murmurs (which can develop with changes in blood viscosity and volume). Note the rate and rhythm of the heart tones. Auscultate bowel sounds, noting presence and normalcy.

### PALPATION

Measure blood pressure, which may change with alterations in blood volume. Palpate the peripheral pulses for strength and equality. Determine capillary refill time, which may be prolonged when the circulating blood volume is decreased. Carefully palpate the abdomen for tenderness, hepatomegaly, or **splenomegaly** (increased spleen size). Note temperature of the skin. Determine elasticity of skin, noting decreased turgor. Palpate the joints for tenderness. Assess range of motion.

## Laboratory and Diagnostic Testing

The nurse must understand the main elements of the complete blood count (CBC; hemogram) to recognize critical values and intervene as appropriate. The components of the CBC are:

- **RBC count:** the actual number of counted RBCs in a certain volume of blood
- **Hemoglobin (Hgb):** measure of the protein made up of heme (iron surrounded by protoporphyrin) and globin,  $\alpha$ - and  $\beta$ -polypeptide chains, primarily responsible for the transport of nutrients and oxygen to the tissues
- **Hematocrit (Hct):** an indirect measure of red blood cells (number and volume)
- **RBC indices**
  - Mean corpuscular volume (MCV): average size of the RBC
  - Mean corpuscular hemoglobin (MCH): a calculated value of the oxygen-carrying capacity of the Hgb in the RBCs
  - Mean corpuscular hemoglobin concentration (MCHC): a calculated value that reflects the concentration of Hgb inside the RBC
  - Red cell distribution width (RDW): a calculated value that is a measure of the width of RBCs
- **WBC count:** actual count of the number of WBCs in a volume of blood
- **Platelet count:** number of platelets per blood volume
- **Mean platelet volume (MPV):** a measurement of the size of the platelets

Tables 47.1 and 47.2 provide age-related values for the CBC and leukocyte count. When evaluating the CBC, the nurse must take into account the presenting clinical picture of the child. For instance, the RBC count may be truly elevated (erythrocytosis or **polycythemia**) in certain diseases or in the case of dehydration from diarrhea or burns. When anemia is present, the RBC count is low. When the MCV is elevated, the RBCs are larger than normal (**macrocytic**). When the MCV is decreased, the RBCs are smaller than normal (**microcytic**). A decrease in the MCHC means that the Hgb is diluted in the cell and less of the red color is present (**hypochromic**). When the Hgb concentration is increased in the RBC, then the pigmentation (red color) is increased (hyperchromic). Alterations in these red blood cell indices assist the physician or nurse practitioner with diagnosis.

WBCs are the body's defense against infection or injury. The specific types of WBCs are discussed in Chapter 37. Platelets are necessary for clot formation, and if changes occur, problems may develop. Elevations in platelet levels can indicate an increase in clotting, while decreases can put the child at risk for increased bleeding. Decreases can result if the platelets are being used up when bleeding is present, if an inherited disorder is present, or if the spleen holds them, as in hypersplenism. Platelets are larger when they are new; thus, an elevation in the mean platelet volume indicates that an increased number of platelets are being produced in the bone marrow.

Common Laboratory and Diagnostic Tests 47.1 explains the most commonly used laboratory and diagnostic tests for children with hematologic disorders. The tests can assist the physician or nurse practitioner in diagnosing the disorder and/or be used as guidelines in determining ongoing treatment. Laboratory or nonnursing personnel obtain some of the tests, while the nurse

might obtain others. In either instance the nurse should be familiar with how the tests are obtained, what they are used for, and normal versus abnormal results. This knowledge will also be necessary when providing child and family education related to the testing.

### Nursing Diagnoses, Goals, Interventions, and Evaluation

Upon completion of a thorough assessment, the nurse might identify several nursing diagnoses, including:

- Fatigue
- Pain
- Impaired physical mobility
- Ineffective health maintenance
- Anxiety
- Ineffective family coping

**You have finished assessing Shaun and your findings include the following. The health history revealed he bled with all four of the teeth he has cut. Upon physical examination numerous bruises are noted. Based on the assessment findings, what would your top three nursing diagnoses be for Shaun?**

Nursing goals, interventions, and evaluation for the child with hematologic dysfunction are based on

the nursing diagnoses. Nursing Care Plan 47.1 may be used as a guide in planning nursing care for the child with a hematologic disorder. Refer to Chapter 36 for additional information related to pain management. Children's responses to hematologic disorders and their treatments will vary, and nursing care should be individualized based on the child's and family's responses to illness. Other conditions may contribute to these nursing diagnoses and must also be considered when prioritizing care. Additional information about nursing management will be included later in the chapter as it relates to specific disorders.

**Based on your top three nursing diagnoses for Shaun, describe appropriate nursing interventions.**

### ANEMIA

**Anemia** is a condition in which levels of RBCs and Hgb are lower than normal. Hgb levels vary throughout childhood. Therefore, it is important to monitor them to ensure that adequate growth and development will be achieved. Anemia may develop as a result of decreased production of RBCs or loss and destruction of RBCs. The loss of production can be related to lack of dietary

**COMMON LABORATORY AND DIAGNOSTIC TESTS 47.1**

Test	Explanation	Indications	Nursing Implications
Blood type and cross-match	Determines ABO blood type as well as presence of antigens. Cross-match is performed on RBC-containing products to avoid transfusion reaction	Trauma victim or any person in whom blood loss is suspected, in preparation for transfusion	Avoid hemolysis of specimen. Appropriately sign and date specimen. Apply “type and cross” or “blood band” to child at the time of blood draw if indicated by the institution. Most type and cross-match specimens expire after 48 to 72 hours.
Clotting studies	Prothrombin time (PT), partial thromboplastin time (PTT), activated partial thromboplastin time (aPTT), international normalized ratio (INR)	Evaluation of common pathway in clotting mechanism PT, INR: evaluation of extrinsic system PTT, aPTT: evaluation of intrinsic system	Apply pressure to venipuncture site. Assess for bleeding (gums, bruising, blood in urine or stool).
Coagulating factor concentration	Measures concentration of specific coagulating factors in the blood	Hemophilia, DIC	Apply pressure to venipuncture site. Assess for bleeding (gums, bruising, blood in urine or stool). Deliver specimen to laboratory as soon as possible (unstable at room temperature).
Complete blood count (CBC) with differential	Evaluates hemoglobin and hematocrit, WBC count (particularly the percentage of individual WBCs), and platelet count	Anemia, infection, bleeding disorder, clotting disorder	Normal values vary according to age and gender. WBC differential is helpful in evaluating source of infection. May be affected by certain medications.
Hemoglobin electrophoresis	Measures percentage of normal and abnormal hemoglobin in the blood	Sickle cell anemia, thalassemia	Blood transfusions within the previous 12 weeks may alter test results.
Iron	Evaluates iron metabolism	Iron-deficiency anemia, hemosiderosis with chronic transfusion or hemoglobinopathies	Recent blood transfusions increase level. Child should fast for 12 hours before the test. Avoid hemolysis (will falsely elevate result).
Lead	Measures level of lead in blood	Lead poisoning	Normal amount in blood is zero.
Reticulocyte count	Measures the amount of reticulocytes (immature RBCs) in the blood	Indicates bone marrow's ability to respond to anemia with production of RBCs	Rises quickly in response to iron supplementation in the iron-deficient child.
Serum ferritin	Measures the level of ferritin (the major iron storage protein) in the blood	Most sensitive test for determining iron-deficiency anemia	Elevated in hemolytic disease and if transfused recently. Iron supplementation increases ferritin levels.

## NURSING CARE PLAN 47.1

## Overview for the Child With a Hematologic Disorder

**NURSING DIAGNOSIS:** Fatigue related to decreased oxygen supply in the body as evidenced by lack of energy, increased sleep requirements, or decreased interest in play

**Outcome Identification and Evaluation**

Child will display increased endurance, desire to play without developing symptoms of exertion.

**Intervention: Decreasing Fatigue**

- Cluster nursing care activities and plan for periods of rest before and after exertion *to decrease oxygen need and consumption.*
- Encourage activity or ambulation per physician's orders: *early mobilization results in better outcomes.*
- Observe child for signs of activity intolerance such as pallor, nausea, lightheadedness, or dizziness or changes in vital signs *to determine level of tolerance.*
- If child is on bed rest, perform range-of-motion exercises and frequent position changes: *negative changes to the musculoskeletal system occur quickly with inactivity and immobility.*
- Refer the child to physical therapy *for exercise prescription to increase skeletal muscle strength.*

**NURSING DIAGNOSIS:** Impaired physical mobility related to pain from sickle cell crisis or acute bleeds or imposed activity restrictions, as evidenced by guarding of painful extremity, resistance to activity

**Outcome Identification and Evaluation**

Child will be able to engage in activities within age parameters and limits of disease: *child is able to move extremities, move about environment, and participate in exercise programs within limits of age and disease.*

**Interventions: Promoting Physical Mobility**

- Encourage gross and fine motor activities as able within constraints of pain/bleed *to facilitate motor development.*
- Collaborate with physical therapy to strengthen muscles and promote mobility *to facilitate motor development.*
- Use passive and active range-of-motion (ROM) exercises and teach the child and family how to perform them *to prevent contractures and facilitate joint mobility and muscle development (active ROM) to help increase mobility.*
- Praise accomplishments and emphasize child's abilities *to improve self-esteem and encourage feelings of confidence and competence.*

**NURSING DIAGNOSIS:** Ineffective health maintenance related to knowledge and skill acquisition regarding nutritional and medical treatment of anemia, prevention of infection, home administration of intravenous clotting factors, or protection from injury as evidenced by new diagnosis and inability to verbalize appropriate treatment regimen or demonstrate medication administration skills

## NURSING CARE PLAN 47.1

**Overview for the Child With a Hematologic Disorder** (continued)**Outcome Identification and Evaluation**

Child's health will be maintained: *child will receive supplements, medications as prescribed and will eat an appropriate diet.*

**Intervention: Educating Parents About Effective Health Maintenance**

- Educate the family about iron-rich foods to be promoted in the child with iron-deficiency anemia and limited in the child with thalassemia.
- Limit cow's milk intake in the child with iron-deficiency anemia *to decrease risk of microscopic gastrointestinal (GI) bleeding and increase appetite for other foods.*
- Provide ongoing evaluation of nutritional intake *to ensure that appropriate dietary restrictions are followed.*
- Ensure that parents can verbalize understanding of home medication regimen: iron or folic acid supplementation for anemia, prophylactic antibiotics for sickle cell anemia, chelation for thalassemia, and factor replacement for hemophilia.
- Have parents provide return demonstration of subcutaneous infusion of deferoxamine or intravenous factor as appropriate *to ensure accuracy and independence in the home environment.*
- Educate families about when to call or visit physician or nurse practitioner *to ensure timely intervention when signs and symptoms develop.*

**NURSING DIAGNOSIS:** Anxiety related to diagnostic testing as evidenced by parent verbalization, child resistance or crying with procedures

**Outcome Identification and Evaluation**

Child's anxiety will be minimized: *child will verbalize less fear, experience less pain with procedures.*

**Intervention: Relieving Anxiety**

- Use topical anesthetic creams or agents for nonemergency laboratory draws to decrease stress related *to needlesticks or venipunctures.*
- Maintain a quiet and calm environment *to reduce the child's stress.*
- Educate the child, as appropriate, and the family regarding the need for laboratory specimens *to alleviate anxiety related to the unknown.*
- Identify the need for the specific test and explain the procedure before obtaining the specimen *to decrease the anxiety and time required for the procedure.*
- Provide developmentally appropriate activities for the child: *activities can reduce stress and also provide stimulus for children; serves as a model for the family.*

(continued)

## NURSING CARE PLAN 47.1

## Overview for the Child With a Hematologic Disorder (continued)

**NURSING DIAGNOSIS:** Ineffective family coping related to hospitalization of child or chronic, possibly life-threatening genetic disorder as evidenced by excessive tearfulness or denial statements, withdrawal, or verbalization of inadequate coping skills

### Outcome Identification and Evaluation

Child and/or family will demonstrate adequate coping skills, *will verbalize feeling supported and demonstrate healthy family interactions.*

### Intervention: Promoting Effective Family Coping

- Provide emotional support to the child and family to improve coping abilities.
- Actively listen to the child's and family's concerns to validate their feelings and establish trust.
- Encourage parents to talk about their child and the illness to bring feelings out in the open.
- Validate feelings of guilt, shock, frustration, resentment, or depression to promote trust and begin appropriate coping.
- Provide open communication with the child and siblings: *children appreciate honesty about their illness, and coping is improved.*
- Refer families to community resources such as parent support groups and grief counseling to improve coping abilities.
- Encourage role-playing and play activities to identify the child's fears and work through feelings.

**NURSING DIAGNOSIS:** Risk for injury related to alteration in peripheral sensory perception, decreased platelet count, deficient coagulation factor, or excessive iron load

### Outcome Identification and Evaluation

Child will not experience hemorrhage: *will experience decreased bruising or episodes of prolonged bleeding.*

### Intervention: Preventing Injury

- Assess for petechiae, purpura, bruising, or bleeding to provide baseline data for comparison; if present, may warrant intervention.
- Encourage quiet activities or play to avoid trauma with active play.
- Avoid rectal temperatures and examinations. Post sign at head of bed "no rectal temperatures or medications" to avoid rectal mucosa damage resulting in bleeding.
- Avoid intramuscular injections and lumbar puncture if possible to decrease risk of bleeding from a puncture site.
- If bone marrow aspiration must be performed, apply pressure dressing to site to prevent bleeding.
- Teach families about preferred physical activities for the child with idiopathic thrombocytopenia purpura (ITP) or hemophilia to provide safe physical activities and decrease risk for injury.

intake of the nutrients needed to produce the cells, alterations in the cell structure, or malfunctioning tissues (e.g., bone marrow). Anemia related to nutritional deficiency includes iron deficiency, folic acid deficiency, and pernicious anemia. Anemia may also result from toxin exposure (lead poisoning) or as an adverse reaction to a medication (aplastic anemia). Blood loss may result from surgery or trauma. Alteration or destruction of cells occurs in certain genetic and cellular development disorders (Bryant, 2010).

Anemia caused by the alteration or destruction of the RBCs is termed hemolytic anemia. There are several types of hemolytic anemia, such as sickle cell disease and thalassemia; these two disorders are discussed under the section on hemoglobinopathies.

Anemia related to insufficient intake of specific nutrients is the most common type of anemia in children. Nutrient intake may be reduced in children due to food dislikes or conditions that produce malabsorption.

## Iron-Deficiency Anemia

Iron-deficiency anemia occurs when the body does not have enough iron to produce Hgb. In the United States, iron-deficiency anemia has a peak prevalence in children between the ages of 6 and 20 months, and again at the age of puberty (Borgna-Pignatti & Marsella, 2008). Cow's milk consumption contributes to iron-deficiency anemia in older infants and young children due to its poor iron availability (Bryant, 2010).

The heme portion of Hgb consists of iron surrounded by protoporphyrin. When not enough iron is available to the bone marrow, Hgb production is reduced. Adequate dietary intake of iron is required for the body to make enough Hgb. As Hgb levels decrease, the oxygen-carrying capacity of the blood is decreased, resulting in weakness and fatigue. In addition to delayed growth, iron-deficiency anemia has been associated with cognitive delays and behavioral changes.

### Take Note!

For appropriate growth to occur in adolescence, increased amounts of iron must be consumed and absorbed.

## Therapeutic Management

Iron supplements are usually provided in the form of ferrous sulfate or ferrous fumarate and are available over the counter. Dosage is based on the amount of elemental iron. The recommended amounts of elemental iron are:

- For prophylaxis: 1 to 2 mg/kg/day, up to a maximum of 15 mg elemental iron per day
- Mild to moderate iron deficiency: 3 mg/kg/day of elemental iron in one or two divided doses
- Severe iron-deficiency anemia: 4 to 6 mg/kg/day of elemental iron in three divided doses (Borgna-Pignatti & Marsella, 2008)

In more severe cases, blood transfusions may be indicated. Transfusion of packed red blood cells (PRBCs) is reserved for the most severe cases (Bryant, 2010). When PRBC administration is warranted, follow specific blood bank guidelines for administration. Monitor subsequent laboratory results for improvement.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1707. Assessment findings pertinent to iron-deficiency anemia are discussed below.

### Health History

Elicit a description of the current illness and chief complaint. Common signs and symptoms reported during the health history may include irritability, headache,

dizziness, weakness, shortness of breath, pallor, and fatigue. Other symptoms may be subtle and difficult for the clinician to identify; these include difficulty feeding, pica, muscle weakness, or unsteady gait.

Explore the health history for risk factors such as:

- Maternal anemia during pregnancy
- Poorly controlled diabetes during pregnancy
- Prematurity, low birthweight, or multiple birth
- Cow's milk consumption before 12 months of age
- Excessive cow's milk consumption (greater than 24 ounces a day)
- Infant consumption of low-iron formula
- Lack of iron supplementation after age 6 months in breastfed infants
- Excessive weight gain
- Chronic infection or inflammation
- Chronic or acute blood loss
- Restricted diets
- Use of medication interfering with iron absorption, such as antacids
- Low socioeconomic status
- Recent immigration from a developing country (Borgna-Pignatti & Marsella, 2008; Bryant, 2010)

Evaluate the child's diet for adequate intake of iron-rich foods. Recommended dietary daily intake for iron in children is:

- 0 to 6 months: 0.27 mg
- 6 to 12 months: 3 mg
- 1 to 3 years: 7 mg
- 4 to 8 years: 11 mg
- 9 to 13 years: 8 mg
- Boys 14 to 18 years: 11 mg
- Girls 14 to 18 years: 15 mg (Krebs, Primark, & Haemer, 2011)

## Physical Examination

Observe the child for fatigue and lethargy. Inspect the skin, conjunctivae, oral mucosa, palms, and soles for pallor. Note spooning of the nails (concave shape) (Fig. 47.2). Obtain a pulse oximeter reading. Evaluate the heart rate for tachycardia. Auscultate the heart for a flow murmur. Palpate the abdomen for splenomegaly.

FIGURE 47.2 Note the concave shape of nails ("spooning") that occurs with iron-deficiency anemia.

## Laboratory and Diagnostic Tests

Laboratory evaluation will reveal decreased Hgb and Hct, decreased reticulocyte count, microcytosis, hypochromia, decreased serum iron and ferritin levels, and an increased free erythrocyte protoporphyrin (FEP) level.

## Nursing Management

Nursing management of the child with iron deficiency focuses on promoting safety, ensuring adequate iron intake, and educating the family.

### Promoting Safety

The child with anemia is at risk for changes in neurologic functioning related to the decreased oxygen supply to the brain. This can lead to fatigue and inability to eat enough. Neurologic effects may be manifested when the child's ability to sit, stand, or walk is impaired. Provide close observation of the anemic child. Assist the older child with ambulation. Educate the parents on how to protect the child from injury due to an unsteady gait or dizziness.

### Providing Dietary Interventions

Ensure that iron-deficient infants are fed only formulas fortified with iron. Interventions for breastfed infants include beginning iron supplementation around the age of 4 or 5 months. Iron supplementation may range from adding iron-fortified cereals to the child's diet to giving iron-containing drops. Encourage breastfeeding mothers to increase their dietary intake of iron or take iron supplements when breastfeeding so that the iron may be passed on to the infant. For children over 1 year of age, limit cow's milk intake to 24 ounces per day. Limit fast-food consumption and encourage intake of iron-rich foods such as red meats (iron from red meat is the easiest for the body to absorb), tuna, salmon, eggs, tofu, enriched grains, dried beans and peas, dried fruits, leafy green vegetables, and iron-fortified breakfast cereals.

Teach the parents about dietary intake of iron. Encourage parents to provide a variety of foods for iron support and vitamins and other minerals necessary for growth. A big problem for toddlers is their picky eating. This often becomes a means of control for the child, and parents should guard against getting involved in a power struggle with their child. Referring parents to a developmental specialist who can assist them in their approach to diet may prove beneficial. Refer families who meet the financial limits and who have children age 5 and younger to the Women, Infants, and Children (WIC) program, which provides for supplementation of infants' and children's diets.

## HEALTHY PEOPLE 2020

Objective	Nursing Significance
Reduce iron deficiency among young children and females of child-bearing age.	<ul style="list-style-type: none"> <li>• Encourage use of iron-fortified formulas and infant cereal.</li> <li>• Encourage iron supplementation in the second half of infancy for the breast-fed infant.</li> <li>• Educate parents about iron-containing foods.</li> <li>• Encourage adolescent females to consume a diet high in iron-rich foods.</li> </ul>

*Healthy People* Objectives based on data from <http://www.healthypeople.gov>.

### Take Note!

Parents are often concerned that a diagnosis of iron-deficiency anemia or referral to the WIC program may lead to interventions from children's services. Assure the family that as long as appropriate measures are taken to address the anemia, referrals of this nature are not generally made.

## Teaching About Iron Supplement Administration

The use of iron supplements in infants begins with the use of formula fortified with iron in the formula-fed infant. Oral supplements may also be necessary if the baby's iron levels are extremely low. Oral supplements or multivitamin formulas that contain iron are often dark in color because the iron is pigmented. Teach parents to precisely measure the amount of iron to be administered. Parents should place the liquid behind the teeth, as iron in liquid form can stain the teeth. Iron supplementation can also cause constipation. In some cases reducing the amount of iron can resolve this problem, but stool softeners may be necessary to control painful or difficult-to-pass stools. Encourage parents to increase their child's fluid intake and include adequate dietary fiber to avoid constipation.

### Take Note!

Teach parents to keep iron-containing supplements out of the reach of young children in order to prevent accidental ingestion leading to overdose or poisoning.

## COMPARISON CHART 47.1

## FOLIC ACID DEFICIENCY VERSUS PERNICIOUS ANEMIA

	Folic Acid Deficiency	Pernicious Anemia
<i>Cause</i>	Low dietary intake of green leafy vegetables, liver, and citrus Malabsorption from medication such as phenytoin (Dilantin) or parasitic infection	Deficiency in vitamin B <sub>12</sub>
<i>Assessment</i>	Determine risk factors such as prematurity, low socioeconomic status, and history of malabsorption disease. Determine dietary history, noting dislike of fresh vegetables or fruit, ingestion of overcooked foods, or lack of family purchase of fruits and vegetables. Note history of fatigue, headache, poor growth, anorexia, or diarrhea. Inspect the skin for pallor or jaundice, and note presence of a sore on the mouth or tongue.	Note history of anorexia, irritability, or chronic diarrhea. Observe the skin or conjunctivae for pallor and the tongue for smooth texture and bright-red color.
<i>Laboratory analysis</i>	RBC, Hgb, Hct	RBC, Hgb, Hct, low vitamin B <sub>12</sub> level
<i>Management</i>	Encourage parents to include green leafy vegetables, liver, and citrus in diet. Ensure that parents comply with dietary changes.	Administer monthly injections of vitamin B <sub>12</sub> . Inform parents injections will be required throughout the child's life. Provide emotional support related to the chronic nature of this disorder.

### Other Nutritional Causes of Anemia

Other forms of anemia related to nutritional deficit include folic acid deficiency and pernicious anemia. Comparison Chart 47.1 discusses the causes, assessment, and management of these disorders.

### Lead Poisoning

Elevated lead levels are found annually in about 250,000 U.S. children between 1 and 5 years of age (Centers for Disease Control and Prevention, 2012). Lead exerts toxic effects on the bone marrow, erythroid cells, nervous system, and kidneys. The presence of lead in the bloodstream interferes with the enzymatic processes of the biosynthesis of heme. The process results in hypochromic, microcytic anemia, and children may exhibit classic signs of anemia. Risk factors for lead poisoning are related to lead exposure in the home, school, or local environment. Sources of lead include:

- Paint in homes built before 1978, at which time lead was banned as an additive to paint used in houses
- Dust from windowsills, walls, and plaster in older homes
- Soil where cars that used leaded gas have been in the past (lead was removed from all gasoline in the United States as of 1996)

- Glazed pottery
- Stained glass products
- Lead pipes supplying water to the home
- On the clothing of parents who work in certain manufacturing jobs (battery makers, cable makers)
- Certain folk remedies, such as *greta* or *arzacón*
- Old painted toys or furniture (American Academy of Pediatrics, 2009)

Complications of lead poisoning include behavioral problems and learning difficulties and, with higher lead levels, encephalopathy, seizures, and brain damage.

Therapeutic management for high blood levels of lead involves **chelation therapy** (removal of heavy metals from the body via chelating agents), either orally or intravenously. Drug Guide 47.1 gives further information on chelating agents.

### Nursing Assessment

Explore the health history for subtle signs such as anorexia, fatigue, or abdominal pain. Determine whether behavioral problems, irritability, hyperactivity, or lack of ability to meet developmental milestones have occurred in recent months. Screen children for risk of exposure to lead in the home. Refer to Chapter 31 for a simple screening questionnaire that can be used to determine the need for lead screening in young children. Blood levels of lead greater than 10 mcg/dL require conscientious follow-up. Note pallor of the skin.

## Nursing Management

Prevention of elevated lead levels is critical. Screen children for lead exposure risk. The American Academy of Pediatrics (AAP) recommends screening in high-risk children at ages 12 and 24 months (AAP, 2009). Table 47.3 gives recommendations for appropriate follow-up depending on lead levels.

Removing old paint is the best way to eliminate the most significant source of lead exposure for a large number of children. If the family rents or lives in public housing, the landlord or owner is responsible for following the guidelines set forth by local and state governmental agencies to correct the problem.

Educate families about how to prevent exposure to lead, particularly in young children. Additional resources for families are located on [thePoint](#).

If the child is undergoing chelation therapy, ensure adequate fluid intake and monitor intake and output

closely. Refer children with elevated lead levels and developmental or cognitive deficits to developmental centers. These children may need an early intervention program for further evaluation and treatment of developmental delays.

### HEALTHY PEOPLE 2020

#### Objective

Eliminate elevated blood lead levels in children.

#### Nursing Significance

- Appropriately screen infants and young children for lead exposure at each health care visit.

*Healthy People Objectives based on data from <http://www.healthypeople.gov>.*

TABLE 47.3

### INTERVENTIONS BASED ON BLOOD LEAD LEVEL

Blood Lead Level (in mcg/dL)	Recommended Action
<10	None required
10–14	Confirm with repeat test in 1 month and educate parents to decrease lead exposure. Repeat test within 3 months.
15–19	Confirm with repeat test in 1 month and educate parents to decrease lead exposure. Repeat test within 2 months.
20–44	Confirm with repeat test within 1 week and educate parents to decrease lead exposure. Refer to local health department for investigation of home for lead reduction, with referrals for support services.
45–69	Confirm with repeat test within 2 days and educate parents to decrease lead levels. Begin chelation therapy and refer to health department as above.
>70	Hospitalize child and begin chelation therapy. Ensure lead is removed from the home.

Adapted from Karr, C. (2008). Reducing childhood lead exposure: Translating new understanding into clinic-based practice. *Pediatric Annals*, 37(11), 748–756.

## Aplastic Anemia

Aplastic anemia (failure of the bone marrow to produce cells) is characterized by bone marrow aplasia and pancytopenia (decreased numbers of all blood cells). Most cases are acquired, but there are a few rare types of inherited aplastic anemias (Bryant, 2010). The inherited types present as congenital bone marrow failure; the best known is Fanconi anemia, an autosomal recessive disorder. Acquired aplastic anemia is thought to be an immune-mediated response. Most cases are idiopathic, meaning the trigger remains unidentified. Other causes include exposure to environmental toxins, viruses, myelosuppressive drugs, or radiation.

Aplastic anemia may be classified as severe or non-severe. In the severe form, the granulocyte count is less than 500, the platelet count is less than 20,000, and the reticulocyte count is less than 1%. In nonsevere aplastic anemia, the granulocyte count is about 500, the platelet count is over 20,000, and the reticulocyte count is over 1% (Ambruso, Hays, & Goldenberg, 2011). Complications of aplastic anemia include severe overwhelming infection, hemorrhage, and death. Therapeutic management of aplastic anemia in children involves hematopoietic stem cell transplantation from a human leukocyte antigen (HLA)-matched sibling donor; if one is not available, immunosuppressive therapy or high-dose cyclophosphamide can be given.

## Nursing Assessment

Determine history of exposure to myelosuppressive medications or radiation therapy. Obtain a detailed family, environmental, and infectious disease history. Note history of epistaxis, gingival oozing, or increased bleeding with

menstruation. Anemia may lead to headache and fatigue. On physical examination, note ecchymoses, petechiae or purpura, oral ulcerations, tachycardia, or tachypnea. In addition to suppression of all blood cells, laboratory and diagnostic testing may reveal:

- Guaiac-positive stool
- Blood in the urine
- Severe decrease in or absence of hematopoietic cells on bone marrow aspiration

## Nursing Management

Safety is of the utmost concern in children with aplastic anemia. It is important to prevent injury in order to avoid hemorrhage. Stool softeners may be used to prevent anal fissures associated with constipation. Administer only irradiated and leukocyte-depleted packed red blood cells or platelet transfusions as necessary. This limits exposure to HLA antigens should the child require bone marrow transplantation in the future. If the child does require hematopoietic stem cell transplantation, refer to Chapter 50 for additional nursing management information.

Refer families whose child has only mild or moderate disease to the Aplastic Anemia and Myelodysplastic Syndrome International Foundation, a link to which can be found on [thePoint](#).

## Hemoglobinopathies

Hemoglobinopathy is a condition in which abnormal hemoglobin is present. A large percentage of the newborn's hemoglobin is fetal hemoglobin (Hgb F). Hgb F can exchange oxygen molecules at lower oxygen tensions compared to adult hemoglobin. Over the first several months of life, Hgb F levels fall as it is replaced with Hgb A (adult hemoglobin). The healthy older infant then displays Hgb AA. In hemoglobinopathies, this normal hemoglobin configuration is disturbed. Causes of hemoglobinopathies are genetic and include sickle cell anemia, hemoglobin SC disease,  $\alpha$ -thalassemia, and  $\beta$ -thalassemia. This discussion will focus on sickle cell disease and  $\beta$ -thalassemia (Cooley anemia).

## Sickle Cell Disease

Sickle cell disease is a group of inherited hemoglobinopathies in which the RBCs do not carry the normal adult hemoglobin, but instead carry a less effective type. In the United States, the most common types of sickle cell disease are hemoglobin SS disease (sickle cell anemia), hemoglobin SC disease, and hemoglobin sickle- $\beta$ -thalassemia. Among the sickle cell diseases, sickle cell anemia is the most common and will be the focus of this discussion (Bryant, 2010).

Sickle cell anemia is a severe chronic blood disorder that affects 2,000 infants born in the United States each

**FIGURE 47.3** This peripheral blood smear demonstrates the elongated sickle-shaped red blood cell seen in sickle cell disease.

year (Ambruso et al., 2011). It is most common in individuals of African, Mediterranean, Middle Eastern, and Indian descent (Ambruso et al., 2011). One in 400 African Americans has sickle cell anemia (Ambruso et al., 2011). Instead of Hgb AA, individuals with sickle cell anemia have Hgb SS. In hemoglobin S, glutamic acid is replaced with valine in the hemoglobin molecule. This results in an elongated RBC with a shortened life span. The elongated cell is more rigid than a normal cell and becomes sickled in shape (Fig. 47.3). Persons with heterozygous representation (Hgb AS) are said to have sickle cell trait and are carriers for the disorder; about 8% of African Americans have sickle cell trait (Ambruso et al., 2011). Generally, persons with sickle cell trait have only minimal health problems.

The recessive genes for sickle cell are passed on from both parents who have the gene or trait. Each parent has the gene Hgb AS. Hgb A refers to normal adult hemoglobin and Hgb S refers to sickle hemoglobin. These recessive genes for sickle cell may be passed on to the child. The risk for developing Hgb SS is one in four, or 25%, in each child from this union. With each pregnancy the risk is 25% that the child will have disease, 25% that the child will have normal hemoglobin, and 50% that the child will have the trait (Hgb AS) and will be a carrier (Pitts & Record, 2010). Figure 47.4 illustrates the inheritance probability. Infants with sickle cell anemia are usually asymptomatic until 3 to 4 months of age because Hgb F protects against sickling.

Complications of sickle cell anemia include recurrent vaso-occlusive pain crises, stroke, sepsis, acute chest syndrome, splenic sequestration, reduced visual acuity related to decreased retinal blood flow, chronic leg ulcers, cholestasis and gallstones, delayed growth and development, delayed puberty, and priapism (the sickled cells prevent blood from flowing out of an erect penis).

**FIGURE 47.4** Simplified genetic scheme for sickle cell disease. A denotes adult hemoglobin; S denotes sickle hemoglobin. Hemoglobin AA, normal hemoglobin; hemoglobin AS, sickle cell trait; hemoglobin SS, sickle cell disease.

Children with sickle cell anemia have an increased incidence of enuresis because the kidneys cannot concentrate urine effectively (Pitts & Record, 2010). As children reach adulthood, multiple organ dysfunction is common.

## Pathophysiology

Significant anemia may occur when the RBCs sickle. Sickling may be triggered by any stress or traumatic event, such as infection, fever, acidosis, dehydration, physical exertion, excessive cold exposure, or hypoxia (Ambruso et al., 2011). As the cells sickle, the blood becomes more viscous because the sickled cells clump together and prevent normal blood flow to the tissues of that area. The sickle-shaped RBCs cannot pass through the smaller capillaries and venules of the circulatory system (Fig. 47.5). This vaso-occlusive process leads to local tissue hypoxia followed by ischemia and may result in infarction. Pain crisis results as circulation is decreased to the area. Pain can occur in any part of the body but is most common in the joints. Pain causes increased metabolic need by resulting in tachycardia and sometimes tachypnea, which leads to further

**FIGURE 47.5** Clumping of sickle-shaped cells.

sickling. Clumping of cells in the lungs (acute chest syndrome) results in decreased gas exchange, producing hypoxia, which leads to further sickling. Sequestration of blood in the spleen leads to splenomegaly and abdominal pain. Hemolysis follows sickling and leads to further anemia. The increased activity of the spleen related to RBC hemolysis leads to splenomegaly, then fibrosis and atrophy. Functional asplenia may develop as early as 6 months of age, and occurs by age 9 years in 90% of children with sickle cell disease (Pitts & Record, 2010).

## Therapeutic Management

The therapeutic management of children with sickle cell anemia focuses on preventing sickling crisis and infection as well as other complications. Prevention of infection is critical because the child with sickle cell anemia is at increased risk for serious infection related to alterations in splenic function. Functional asplenia (decrease in the ability of the spleen to function appropriately) places the child at significant risk for serious infection with *Streptococcus pneumoniae* or other encapsulated organisms. Prophylactic antibiotics in the young child and appropriate immunization in all children with sickle cell anemia can reduce the risk of serious infection (Pitts & Record, 2010).

Treatment of sickle cell crisis focuses on pain control. Oxygen administration is necessary during episodes of crisis to prevent additional cell sickling. Adequate hydration with intravenous fluids is critical. Close monitoring of Hgb, Hct, and reticulocytes determines the point at which transfusion of packed red blood cells becomes necessary. Electrolyte analysis is also necessary to ensure that appropriate amounts of electrolytes are present in the serum. When RBCs are administered, there is the potential for hemolysis of the cells, thus increasing the potassium level in the serum. Antibiotic therapy is necessary when infection is present. Box 47.1 describes additional medical treatments that are needed in some children.

## Nursing Assessment

Children with sickle cell anemia experience a significant number of acute and chronic manifestations of the condition (Comparison Chart 47.2). For a full description of the assessment phase of the nursing process, refer to page 1707. Assessment findings pertinent to sickle cell anemia are discussed below.

### Health History

Elicit the health history, noting growth and development, frequency and extent of vaso-occlusive crises, past hospitalizations, and treatment for pain crises. Note history of immunizations, including pneumococcal, flu,

## COMPARISON CHART 47.2

## ACUTE VERSUS CHRONIC MANIFESTATIONS OF SICKLE CELL ANEMIA

Acute	Chronic
*Acute chest syndrome	Anemia
*Aplastic crisis	Avascular necrosis of the hip
*Bacterial sepsis or meningitis	Cardiomegaly, functional murmur
Bone infarction	Cholelithiasis
Dactylitis	Delayed growth and development
Hematuria	Delayed puberty
Recurrent pain episodes	Functional splenia
Pain crisis	Hyposthenuria (low urine specific gravity) and enuresis
*Splenic sequestration	Jaundice
*Stroke	Leg ulcers
Priapism	Proteinuria
	*Pulmonary hypertension
	*Restrictive lung disease
	Retinopathy
*Often life-threatening.	

and meningococcal vaccinations. Determine history of blood transfusions. Document the current medication regimen. Note history of recurrent infections. Determine history of the present illness that results in a precipitating event, such as hypoxia, infection, or dehydration.

Note onset, character, and quality of pain, as well as relieving factors.

### Physical Examination

Perform a thorough physical examination, because sickling, hypoxia, and tissue ischemia affect most areas of the body (Fig. 47.6). Note the physical findings discussed below that may be detected using inspection, observation, auscultation, and palpation.

#### BOX 47.1

#### ADDITIONAL MEDICAL TREATMENTS FOR SOME CHILDREN WITH SICKLE CELL ANEMIA

- Cholecystectomy may become necessary if gallstones develop.
- Splenectomy may be performed to prevent recurrence of splenic sequestration if it is life-threatening.
- Considered investigational, administration of hydroxyurea may increase the percentage of fetal hemoglobin; a large clinical trial in children is ongoing.
- Blood transfusions, though not routinely given to children with sickle cell disease, are indicated in children with prolonged or widespread pain, aplastic crisis, or splenic sequestration.
- Partial exchange transfusion may be used to rapidly lower the circulating amount of Hgb SS in the event of stroke or acute chest syndrome.
- Hematopoietic stem cell transplantation is usually reserved for children with an identical HLA-matched sibling (risk of death and incidence of graft-versus-host disease is high) (Pitts & Record, 2010).

#### INSPECTION AND OBSERVATION

Inspect the conjunctivae, palms, and soles for pallor and the skin for pallor, lesions, or ulcers. Note jaundice of the skin or scleral icterus. Document color and moisture of oral mucosa. Measure temperature to evaluate for infection (which can precipitate a sickling crisis). Note blood pressure, which may be decreased with severe anemia or increased with sickle cell nephropathy. Determine baseline mental status. Perform a neurologic assessment frequently, as about 30% of children with sickle cell anemia experience a stroke (Inati, Koussa, Taher, & Perrine, 2008).

#### AUSCULTATION

Auscultate heart sounds for a murmur. The heart rate is often elevated with pain, hyperthermia, or dehydration. Listen to breath sounds, noting the rate and depth of respiration as well as the adequacy of aeration. Adventitious breath sounds may be present if a respiratory infection

FIGURE 47.6 Effects of sickle cell anemia on various parts of the body.

has triggered the sickle cell crisis or in the case of acute chest syndrome.

**PALPATION**

Palpate the joints for warmth, tenderness, and range of motion. Palpate the abdomen for areas of tenderness. Note hepatomegaly or splenomegaly.

**Take Note!**

Immediately report symmetric swelling of the hands and feet in the infant or toddler. Termed dactylitis, aseptic infarction occurs in the metacarpals and metatarsals. Occurrence before age 1 year is predictive of severity of illness (Maakaron, Taher, & Woermann, 2012) (Fig. 47.7).

**Laboratory and Diagnostic Testing**

Newborn screening for sickle cell anemia is required by law or rule in all of the 50 United States (March of Dimes, 2011). Screening by Sickledex or sickle cell prep does not distinguish between sickle cell disease and sickle cell trait. If the screening test result indicates the possibility of sickle cell anemia or sickle cell trait, Hgb electrophoresis is performed promptly to confirm the diagnosis. Hgb electrophoresis is the only accurate test for sickle cell disease. Hgb electrophoresis will demonstrate the presence of Hgb S and Hgb F only in the young infant; in the older infant or child, the result will be Hgb SS.

**FIGURE 47.7** Swelling of the hands (dactylitis) in a toddler.

Common laboratory and diagnostic studies ordered for the assessment of sickle cell anemia include:

- Hemoglobin: baseline is usually 7 to 10 mg/dL; will be significantly lower with splenic sequestration, acute chest syndrome, or aplastic crisis
- Reticulocyte count: greatly elevated
- Peripheral blood smear: presence of sickle-shaped cells and target cells
- Platelet count: increased
- Erythrocyte sedimentation rate: elevated
- Abnormal liver function tests with elevated bilirubin

X-ray studies or other scans may be performed to determine the extent of organ or tissue damage resulting from vaso-occlusion.

### HEALTHY PEOPLE 2020

#### Objective

(Developmental)  
Ensure appropriate newborn bloodspot screening, follow-up testing, and referral to services.

#### Nursing Significance

- Follow up with state agencies at first contact with infant to ascertain results of newborn screening.
- If screening was not done at birth, ensure Hgb electrophoresis is obtained.

*Healthy People Objectives based on data from <http://www.healthypeople.gov>.*

## Nursing Management

Nursing care of the child with sickle cell anemia focuses on preventing vaso-occlusive crises, providing education to the family and child, managing pain episodes, and

providing psychosocial support to the child and family. All children with sickle cell anemia need ongoing evaluation of growth and development to maximize their potential in those areas. Monitor school performance to detect neurodevelopmental problems and seek intervention early. The nursing diagnoses and interventions provided in Nursing Care Plan 47.1 should be individualized based on the child's and family's response to the disorder. Specifics related to sickle cell disease are discussed below.

### Educating the Family and Child

Begin child and family education immediately after the diagnosis of sickle cell anemia is confirmed. Initially, teach the family about the genetics of the disease and encourage family members to be tested for carrier status. Educate families about the disease process. Emphasize the importance of regularly scheduled health maintenance visits and immunizations. Teach families how to administer prophylactic penicillin. Encourage families to seek medical evaluation urgently for any febrile illness. Educate families about how to prevent and recognize vaso-occlusive events (Teaching Guidelines 47.1). Discuss complications such as delayed growth and development, delayed puberty,

#### Teaching Guidelines 47.1

##### PREVENTION OR EARLY RECOGNITION OF VASO-OCCLUSIVE EVENTS

- Seek immediate attention for ANY febrile illness.
- Obtain vaccinations and penicillin prophylaxis.
- Encourage adequate fluid intake daily.
- Avoid temperatures that are too hot or too cold.
- Avoid overexertion or stress.
- Have 24-hour access to physician, nurse practitioner, or facility familiar with sickle cell care.
- Contact medical provider promptly if you suspect a pain crisis is developing.
- Seek medical attention immediately if any of the following develop:
  - Child is pale and listless
  - Abdominal pain
  - Limp or swollen joints
  - Cough, shortness of breath, chest pain
  - Increasing fatigue
  - Unusual headache, loss of feeling, or sudden weakness
  - Sudden vision change
  - Painful erection that won't go down (priapism)

## Atraumatic Care

Teach the child with sickle cell anemia age-appropriate distraction and coping skills to assist the child to relieve stress related to his or her disease and/or recurrent crises.

stroke, cholelithiasis, retinopathy, avascular necrosis, priapism, and leg ulcers.

## Managing Pain Crisis

Initiate pain assessment with a standardized pain scale upon admission. Provide frequent evaluations of pain. Always believe the child's report of pain; only the person suffering the pain knows what it feels like. Moderate to severe pain usually requires opioid medication. To bring the pain under control, initially administer analgesics routinely rather than on an "as needed" (PRN) basis. Once the pain is better managed, medications may be moved to PRN status. Monitor patient-controlled analgesia (PCA) in the child or adolescent. Addiction to narcotics is rarely a concern in the child with sickle cell anemia if the narcotic is used to alleviate severe pain (Pitts & Record, 2010). Nonsteroidal anti-inflammatory medications and acetaminophen are often used for less severe pain. Adequate pain management helps to decrease the child's stress level; elevated stress may contribute to further sickling and additional pain. Use nonpharmacologic pain management techniques such as relaxation or hypnosis, music, massage, play, guided imagery, therapeutic touch, or behavior modification to augment the pain medication regimen. Box 47.2 provides a summary of sickle cell pain management.

### BOX 47.2

#### ABCs OF MANAGING SICKLE CELL PAIN

- A: Assess the pain (use a pain assessment tool).
- B: Believe the child's report of pain.
- C: Complications or cause of pain (look for complications)
- D: Drugs and distraction: pain medication (opiates and NSAIDs, if no contraindications); use fixed dosing; give on a timed schedule; no PRN dosing for pain medications; distraction with music, TV, and relaxation techniques
- E: Environment (rest in quiet area with privacy)
- F: Fluids (hypotonic—D<sub>5</sub>W or D<sub>5</sub> with 0.25% normal saline solution)

Adapted from Platt, A., Eckman, J. R., Beasley, J., & Miller, G. (2002). Treating sickle cell pain: An update from the Georgia Comprehensive Sickle Cell Information Center. *Journal of Emergency Nursing*, 28(4), 297–303, with permission.

### Take Note!

Avoid repeated use of meperidine (Demerol) for pain management during sickle cell crises because it has been associated with an increased risk of seizures when used in children with sickle cell anemia (Sickle Cell Information Center [SCIC], 2011).

## Managing Sickle Cell Crisis

Treat any underlying conditions such as infection or injury. Deficient fluid volume occurs as a result of decreased intake, increased fluid requirements during sickle cell crisis, and the kidney's inability to concentrate urine. Increasing fluid intake will dilute the blood and decrease its viscosity. To promote hemodilution, provide 150 mL/kg of fluids per day or as much as double maintenance, either orally or intravenously. Maintain appropriate electrolyte and pH balance.

Risk for ineffective tissue perfusion related to the effects of RBC sickling and infarction of tissues is another concern. Frequently evaluate respiratory and circulatory status. Administer supplemental oxygen if the pulse oximetry reading is 92% or less to promote adequate oxygenation (SCIC, 2011). Supplementation with oxygen in the absence of hypoxia is unnecessary and may inhibit erythropoiesis. Monitor level of consciousness and immediately report changes.

### HEALTHY PEOPLE 2020

#### Objective

Reduce stroke deaths.

#### Nursing Significance

- Educate families appropriately to decrease incidence of vaso-occlusive episodes in children with sickle cell anemia.

*Healthy People* Objectives based on data from <http://www.healthypeople.gov>.

### Take Note!

Maintain the child's temperature as close to normal as possible without the use of cooling mattresses, as sudden temperature change can further precipitate sickling of the red blood cells (Eckman, 2012).

## Preventing Infection

To prevent severe infection in the child with sickle cell anemia, a variety of interventions are necessary. By 2 months of age, begin administration of oral penicillin V potassium as prophylaxis against pneumococcal

**EVIDENCE-BASED PRACTICE 47.1****PROPHYLACTIC ANTIBIOTICS AND PNEUMOCOCCAL INFECTION IN CHILDREN WITH SICKLE CELL DISEASE**

Children with sickle cell disease are prone to infection, particularly respiratory infections and sepsis. *Streptococcus pneumoniae* is one of the most common causes of respiratory infection and sepsis in all young children. Though pneumococcal vaccines are available, they do not prevent infection by all strains of pneumococci. Prophylactic antibiotics are routinely prescribed for infants and young children (younger than 5 years of age) with sickle cell disease in an attempt to prevent overwhelming pneumococcal infection.

**STUDY**

To determine the effect that prophylactic antibiotic treatment has on the prevention of pneumococcal infection in children with sickle cell disease, the authors of this review searched for randomized or quasi-randomized controlled trials comparing prophylactic antibiotics to no treatment or placebo. Three trials were analyzed, consisting of just under 900 young children. Both authors independently reviewed the studies and documented the results.

**Findings**

In all three trials, the incidence of pneumococcal infection was reduced in young children with sickle cell disease who received prophylactic penicillin. Overall pneumococcal infection rates were reduced by 50% to 100% in treated children. Adverse drug reactions were rare and minor.

Adapted from Hirst, C., & Owusu-Ofori, S. (2007). Prophylactic antibiotics for preventing pneumococcal infection in children with sickle cell disease. *Cochrane Database of Systematic Reviews*. Retrieved November 2, 2007, from Ovid-EBM Review Database.

No deaths occurred in any of the trials as a result of pneumococcal infection. The authors concluded that antibiotic prophylaxis for pneumococcal infection in children younger than 5 years of age with sickle cell disease is an appropriate approach to treatment and recommend its continuation as standard of practice.

**Nursing Implications**

Nurses are in an optimal position to educate parents about the importance of daily administration of antibiotic prophylaxis of pneumococcal infection in young children with sickle cell anemia. The occurrence of antibiotic resistance was minimal in the trials but did exist, so providers must weigh the risks and benefits of antibiotic prophylaxis. Review the medication regimen at each clinic visit and with each hospitalization. Ensure that prescriptions are being filled; if insurance or payment is an issue, refer the family for financial assistance. Educate families about the need to continue antibiotic prophylaxis even if the child has been immunized against *S. pneumoniae*. Encourage families to comply with the recommendations for 7-valent conjugate vaccine in children younger than 2 years of age and 23-valent polysaccharide vaccine after 2 years of age. Educate families and provide reassurance about the decreased risk for overwhelming pneumococcal infection after age 5 years, as they may be fearful of discontinuing the antibiotics at that time.

infection. In the penicillin-allergic child, erythromycin may be used. Continue prophylaxis until at least age 5 years. Administer childhood immunizations according to the currently recommended schedule. To prevent overwhelming sepsis or meningitis as a result of infection with *S. pneumoniae*, the child should receive not only the 7-valent pneumococcal vaccine series in infancy but also the 23-valent pneumococcal conjugate vaccine annually after age 2 years. Meningococcal vaccination is also warranted (refer to Chapter 31 for additional information on these vaccines). Provide influenza immunization annually before the onset of flu season (after 6 months of age) (Pitts & Record, 2010). (See Evidence-Based Practice 47.1.)

**Supporting the Family and Child**

As with any chronic illness, families of children with sickle cell anemia need significant support. They often feel guilty or responsible for the disease. Reassure the family and provide education. Refer families to a regional sickle cell disease center for multidisciplinary care. Web links for additional resources for families are included on [thePoint](#).

**Consider This**

A 3-year-old boy with sickle cell disease is being admitted to the pediatric unit. He has had a runny nose, slight fever, and vomiting over the past 2 to 3 days. He has not been eating well and is complaining of pain in the right leg and refusing to walk. On assessment you find his vital signs to be temperature 101.7°F, pulse 132, respirations 32, and blood pressure 88/52. He is coughing, he has slightly dusky mucous membranes, and his capillary refill is 4 seconds.

1. List nursing assessment findings in order of priority.
2. Identify at least three nursing interventions, prioritize them, and list the rationale for the prioritization and the intervention itself.
3. List teaching you will perform with this family.

**Thalassemia**

Thalassemia is a genetic disorder that most often affects those of African descent, but it also affects individuals of Caribbean, Middle Eastern, South Asian, and Mediterranean descent (Bryant, 2010). The genetics of thalassemia are

similar to those of sickle cell disease in that it is inherited via an autosomal recessive process. Children with thalassemia have reduced production of normal hemoglobin.

There are two basic types of thalassemia,  $\alpha$  and  $\beta$ . In  $\alpha$ -thalassemia, synthesis of the  $\alpha$  chain of the hemoglobin protein is affected. Problems with the  $\beta$  chain occur more often, and the condition  $\beta$ -thalassemia can be divided into three subcategories based on severity:

- Thalassemia minor (also called  $\beta$ -thalassemia trait): leads to mild microcytic anemia; often no treatment is required.
- Thalassemia intermedia: child requires blood transfusions to maintain adequate quality of life.
- Thalassemia major: to survive the child requires ongoing medical attention, blood transfusions, and iron removal (chelation therapy).

The focus of this discussion will be on  $\beta$ -thalassemia major (Cooley anemia).

In  $\beta$ -thalassemia major, the  $\beta$ -globulin chain in hemoglobin synthesis is reduced or entirely absent. A large number of unstable globulin chains accumulate, causing the RBCs to be rigid and hemolyzed easily. The result is severe hemolytic anemia and chronic hypoxia. In response to the increased rate of RBC destruction, erythroid activity is increased. The increased activity causes massive bone marrow expansion and thinning of the bony cortex. Growth retardation, pathologic fractures, and skeletal deformities (frontal and maxillary bossing) result.

**Hemosiderosis** (excessive supply of iron) is an additional complication of significant concern. It occurs as a result of rapid hemolysis of RBCs, the decrease in hemoglobin production, and the increased absorption of dietary iron in response to the severely anemic state. The excess iron is deposited in the body's tissues, causing bronze pigmentation of the skin, bony changes, and altered organ function, particularly in the cardiac system. Additional complications include splenomegaly, endocrine abnormalities, osteoporosis, liver and gallbladder disease, and leg ulcers.

Left untreated,  $\beta$ -thalassemia major is fatal, but the use of blood transfusions and chelation therapy has increased the life expectancy of these children to beyond their teen years (Yaish, 2010).

## Therapeutic Management

The therapeutic management for children with  $\beta$ -thalassemia includes monitoring hemoglobin and hematocrit and transfusing packed red blood cells at regular intervals. Blood iron levels are also monitored and iron chelation therapy is provided.

## Nursing Assessment

Infants are usually diagnosed by 1 year of age and have a history of pallor, jaundice, failure to thrive,

**FIGURE 47.8** Iron overload related to thalassemia leads to bony changes such as frontal bossing and maxillary prominence.

and hepatosplenomegaly (Yaish, 2010). Determine the history of the present illness or whether the child is presenting for a routine blood transfusion. Note medications taken at home and any concerns that have arisen since the last visit. Inspect the skin, oral mucosa, conjunctivae, soles, and/or palms for pallor. Note icteric sclerae or jaundice of the skin. Measure weight and height (or length) and plot on an appropriate growth chart. Observe the child for bony deformities and frontal bossing (prominent forehead) (Fig. 47.8). Measure oxygen saturation via pulse oximetry. Evaluate neurologic status, determining level of consciousness and developmental abilities.

Laboratory testing may reveal the following:

- Hemoglobin and hematocrit are significantly decreased.
- Peripheral blood smear shows prominence of target cells, hypochromia, microcytosis, and extensive **anisocytosis** and **poikilocytosis** (variation in the size and shape of the RBCs, respectively).
- Bilirubin levels are elevated.
- Hgb electrophoresis shows presence of Hgb F and Hgb A<sub>2</sub> only.
- Iron level is elevated.

## Nursing Management

The nursing care of the child with thalassemia is primarily aimed at supporting the family and minimizing the effects of the illness. This includes administering blood transfusions and educating the family.

### Administering Packed Red Blood Cell Transfusions

Administer packed red blood cell transfusions as prescribed to maintain an adequate level of hemoglobin for oxygen delivery to the tissues and to suppress erythrocytosis in the bone marrow. Monitor for reactions to the transfusions.

Excess iron (hemosiderosis) is removed by chelation therapy. Administer the chelating agent Desferal (deferoxamine) with the transfusion. Deferoxamine binds to the iron and allows it to be removed through the stool or urine. Oral deferasirox (Exjade) may also be prescribed and is generally well tolerated, with minimal gastrointestinal side effects.

### Educating the Family

Educate the child and family about the recommended regimen. Ensure that families understand that adhering to the prescribed blood transfusion and chelation therapy schedule is essential to the child's survival. Chelation therapy must be maintained at home to continuously decrease the iron levels in the body. Teach family members to administer deferoxamine subcutaneously with a small battery-powered infusion pump over a several-hour period each night (usually while the child is sleeping). If oral deferasirox is prescribed, instruct the family to dissolve the tablet in juice or water and administer it once daily.

Refer the family for genetic counseling and family support as needed. A good resource for families of children with thalassemia is the Cooley's Anemia Foundation, a link to which can be found on [thePoint](#). A group of young adults with Cooley anemia started the Thalassemia Action Group (TAG) (a subgroup of the Cooley's Anemia Foundation) to provide a forum for communication and information, promote a positive outlook on living with the disease, and raise awareness of the importance of continuing therapy for the disease. TAG is part of the Cooley anemia website and more information about the group can be found by calling (510) 409-9664.

### Atraumatic Care

*When a child is receiving blood transfusion every few weeks, he or she must experience at least two venipunctures each time, one for the type and cross-match and other relevant laboratory tests on the day before transfusion, and the intravenous (IV) insertion for the actual transfusion. Minimize trauma by teaching the parent to apply EMLA (eutectic mixture of local anesthetic) cream at home just before leaving for the blood draw or transfusion appointment.*

### Glucose-6-Phosphate Dehydrogenase Deficiency

Glucose-6-phosphate dehydrogenase (G6PD) is an enzyme that is responsible for maintaining the integrity of RBCs by protecting them from oxidative substances. G6PD deficiency is an X-linked recessive disorder that occurs when the RBCs have insufficient G6PD, or the enzyme is abnormal and does not function properly. The RBCs are then affected by oxidative stress more easily. Triggers that may result in oxidative stress and hemolysis include bacterial or viral illness or exposure to certain substances such as medications (e.g., sulfonamides, sulfones, malaria-fighting drugs [such as quinine], or methylene blue [for treating urinary tract infections]), naphthalene (an agent in mothballs), or fava beans.

G6PD deficiency occurs most commonly in children of African, Mediterranean, or Asian descent (Ambruso et al., 2011). Complications include prolonged neonatal jaundice and life-threatening acute episodes of hemolysis. Therapeutic management is primarily aimed at avoiding triggers that cause oxidative stress.

### Nursing Assessment

Note health history, including fatigue. Determine the parents' understanding of the disorder and the medications and foods to avoid. Inspect the skin for pallor or jaundice. Evaluate neurologic status, which may also be affected. Measure heart rate and respiratory rate, noting elevations. Determine oxygen saturation via pulse oximeter or blood gas analysis. Note tea-colored urine. Palpate the abdomen for splenomegaly. Laboratory studies will reveal anemia.

### Nursing Management

Administer oxygen and treat the symptoms. Once the triggering agent is removed or the child recovers from an illness, the child will improve. Provide further education to the child and family about triggers and advise them that the child should avoid contact with these agents.

## CLOTTING DISORDERS

Clotting of blood is a process that occurs after injury. The blood clotting system requires certain factors in the blood and platelets to perform adequately. Individuals with deficiencies of these factors or platelets tend to bleed; they do not bleed more easily than people without these conditions, but it is just more difficult for the clot to form, and bleeding cannot be stopped easily. Factors that are most often involved in problems with clotting include factor VIII, factor IX, and factor XI. Each plays a role in clot formation. Platelets also play a role in the clotting cascade and are necessary for clot formation.

**TABLE 47.4** CLOTTING STUDIES

Test	Measure
Prothrombin time (PT)	11.0–13.0 seconds (may vary by laboratory)
Partial thromboplastin time (PTT), activated partial thromboplastin time (aPTT)	21–35 seconds
International normalized ratio (INR) (used to evaluate coagulation)	2.0–3.0 usual target in thromboembolic conditions

Adapted from Fischbach, F. T. (2008). *A manual of laboratory and diagnostic tests* (8th ed.). Philadelphia: Lippincott Williams & Wilkins.

Some processes can lead to destruction of the platelets and may lead to a reduction in clotting. Bleeding times are prolonged when a clotting disorder is present. Table 47.4 provides usual values for clotting studies.

Conditions affecting clotting include idiopathic thrombocytopenia purpura, Henoch-Schönlein purpura,

disseminated intravascular coagulation, and factor deficiencies such as hemophilia A (factor VIII deficiency), von Willebrand disease, hemophilia B (Christmas disease, factor IX deficiency), and hemophilia C (factor XI deficiency). Table 47.5 reviews the proteins involved in coagulation.

**TABLE 47.5** SELECT PROTEINS INVOLVED IN COAGULATION (FACTORS)

Protein	Synonym	Concentration in Plasma (mg/dL)	Function
Fibrinogen	Factor I	200–400	Converts fibrin along with platelets to form clot
Factor II	Prothrombin	10–15	Is converted to thrombin (Ia), splits fibrinogen into fibrin
Factor V	Proaccelerin; labile factor	0.5–1.0	Supports Xa activation of II to Iia
Factor VII	Stable factor; proconvertin	0.2	Activates X
Factor VIII:C	Antihemophilic factor (AHF); platelet cofactor I	1.0–2.0	Supports IXa activation of X
Factor IX	Christmas factor; plasma thromboplastin component (PTC)	0.3–0.4	Activates X
Factor X	Stewart-Prover factor (AVTD prothrombin III)	0.6–0.8	Activates II
Factor XI	Plasma thromboplastin antecedent (antihemophilic factor C)	0.4	Activates XII and prekallikrein
Factor XII	Hageman factor	2.9	Activates XI and prekallikrein
Factor XIII	Fibrin-stabilizing factor; Laki-Lorand factor	2.5	Cross-links fibrin and other proteins
von Willebrand factor	Factor VIII–related antigen (VIII:VWD)	1.0	Stabilizes VIII, mediates platelet adhesion

Adapted from Fischbach, F. T. (2008). *A manual of laboratory and diagnostic tests* (8th ed.). Philadelphia: Lippincott Williams & Wilkins.

## Idiopathic Thrombocytopenia Purpura

Idiopathic thrombocytopenia purpura (ITP) is thought to be an immune response following a viral infection that produces antiplatelet antibodies. These antibodies destroy platelets, which then leads to the development of petechiae, purpura, and excessive bruising. **Petechiae** are pinpoint hemorrhages that occur anywhere on the body and do not blanch to pressure (Fig. 47.9). **Purpura** are larger areas of hemorrhage in which blood collects under the tissues; they are purplish (see Fig. 47.9). ITP usually develops about 1 to 4 weeks after a viral infection and is most common in young children (Ambruso et al., 2011). Within a few months, most children will recover spontaneously (Ambruso et al., 2011). Complications include severe hemorrhage and bleeding into vital organs and intracranial hemorrhage, although these rarely occur.

For children with platelet counts below 20,000/mm<sup>3</sup>, corticosteroids or intravenous immunoglobulin (IVIG) may be used (Ambruso et al., 2011). Prednisone or prednisolone is administered for 2 to 3 weeks, or until platelet counts increase above 30,000/mm<sup>3</sup>. IVIG will be infused for 1 to 3 days. Platelet transfusions are not indicated unless a life-threatening condition such as intracranial hemorrhage is present. Refer the child for follow-up care with a pediatric hematologist. ITP is usually self-limiting, but if it persists for a year or longer, splenectomy may be indicated.

### Nursing Assessment

Elicit the child's health history (usually a previously healthy child who recently has developed increased bruising, epistaxis, or bleeding of the gums). Note history of blood in the stool. Note risk factors such as recent

**FIGURE 47.9** Pinpoint hemorrhages (petechiae) and large purplish areas of discoloration (purpura) in an infant with idiopathic thrombocytopenia purpura (ITP).

viral illness, recent MMR immunization, or ingestion of medications that can cause thrombocytopenia. Inspect for petechiae, purpura, and bruising, which may progress rapidly within the first 24 to 48 hours of the illness. Document the size and location of each lesion. Inspect the lips and buccal mucosa for petechiae. The remainder of the physical examination is usually within normal limits.

Usual laboratory findings include an extremely low platelet count (less than 50,000), normal WBC count and differential, and normal hemoglobin and hematocrit unless hemorrhage has occurred (this is rare). Bone marrow aspiration may be performed to rule out leukemia.

### Nursing Management

Many children require no medical treatment except observation and reevaluation of laboratory values. Educate the family about avoiding aspirin, nonsteroidal anti-inflammatory drugs (NSAIDs), and antihistamines because these medications may precipitate the development of anemia in these children. The use of acetaminophen for pain control is more appropriate when necessary. Teach the family to prevent trauma by avoiding activities that may cause injury, such as contact sports. Instead, encourage activities, such as swimming, that provide physical activity with less risk of trauma. Explain to parents the signs and symptoms of serious bleeding and whom to call if it is suspected.

## Henoch-Schönlein Purpura

Henoch-Schönlein purpura is a condition that, in children, develops in association with a viral or bacterial infection (Barillas-Arias, Adams, & Lehman, 2008). In adults the condition is usually caused by drugs or toxins. The classic presentation is vasculitis with immunoglobulin A (IgA)-dominant immune deposits affecting small vessels. These small vessels are generally in the skin, gut, and kidney. In most children the course of the disease is benign and the prognosis is good. In a few children, however, ongoing nephrotic syndrome may occur as a result of renal injury, and those children may have hypertension. Pulmonary, cardiac, and neurologic complications can also occur.

No specific treatment exists for Henoch-Schönlein purpura, since most of the cases resolve without treatment. Treatment with corticosteroids, such as prednisone, is reserved for children with persistent symptoms (Barillas-Arias et al., 2008). If renal injury occurs, children may require renal function testing, and evaluation for hypertension and treatment when present.

### Nursing Assessment

Note history of viral or bacterial infection. Determine the onset of the complaint and how it has progressed

**FIGURE 47.10** Palpable purpura on an adolescent's arm.

or changed. Note history of joint or abdominal pain. Measure blood pressure. Inspect the skin for a purpuric palpable rash, and document the size and location of lesions. Palpate the rash to determine its extent (Fig. 47.10). Gently palpate the joints for tenderness. Palpate the abdomen for tenderness. Note visible or occult blood in the stool. Note cherry- or tea-colored urine, indicating the presence of blood in the urine; urinalysis can verify the amount of blood present in the urine. Serum IgA levels may be elevated.

## Nursing Management

Treatment of the symptoms is the focus. In children with severe joint or abdominal pain, administer analgesics as prescribed and note the response to pain medications. If the child has normal renal function, maintaining hydration is the most important intervention. Monitor intake and output. Note the color of urine. Administer corticosteroids and anticoagulants, alone or together, if ordered to reduce renal impairment. Teach the child and family about the therapy, such as management of hypertension with medications, and sodium restriction. Teach them about signs of renal injury, such as blood in the urine and changes in weight, as well as frequency and volume of urine output.

### Disseminated Intravascular Coagulation

Disseminated intravascular coagulation (DIC) is a complex condition that leads to activation of coagulation; it usually occurs in critically ill children. Common triggers

of DIC include septic shock, presence of endotoxins and viruses, tissue necrosis or injury, and cancer treatment (Becker & Wira, 2011). In DIC, thrombin is generated, fibrin is deposited in the circulation, and platelets are consumed. Deficiencies of coagulation and anticoagulation pathways occur. Hemorrhage and organ tissue damage result and can be irreversible if not recognized and treated immediately.

Therapeutic management of children with DIC requires careful consideration of the etiology. Initial treatment focuses on treating the underlying cause. For example, if DIC occurs secondary to an infection, appropriate antibiotics would be used to treat the infection. Heparin is also used at lower doses to counteract the deficiency in the coagulation/anticoagulation pathway. Heparin reduces consumption of the platelets, resulting in improved platelet counts. Since heparin is an anticoagulant, there is an increased risk of bleeding.

## Nursing Assessment

Because DIC occurs as a secondary condition, it may occur in a child hospitalized for any reason. DIC may affect any body system, so a thorough physical examination is warranted. Inspect for signs of bleeding such as petechiae or purpura, blood in the urine or stool, or persistent oozing from venipuncture or from the umbilical cord in the newborn. Evaluate respiratory status and determine the level of tissue oxygenation via pulse oximetry. Perform a complete circulatory assessment and note signs of circulatory collapse such as poor perfusion, tachycardia, prolonged capillary refill, and weak distal pulses. Note altered level of consciousness and decreased urine output. Careful abdominal palpation may reveal hepatomegaly or splenomegaly.

Laboratory testing may reveal prolonged prothrombin time (PT), partial thromboplastin time (PTT), activated partial thromboplastin time (aPTT), bleeding time, and thrombin time and decreased levels of fibrinogen; platelets; clotting factors II, V, VIII, and X; and anti-thrombin III. Increases will be noted in levels of fibrinolysin, fibrinopeptide A, positive fibrin split products, and D-dimers.

## Nursing Management

Continue to provide nursing care related to the triggering event. Assess the child's status frequently. If bleeding is observed, apply pressure to the area along with cold compresses. Elevate the affected body part if this does not affect the child's overall stability. If neurologic deficits are assessed, report the findings immediately so that treatment to prevent permanent damage can be started. Administer anticoagulation therapy (even though hemorrhage is a concern) to interrupt the coagulation process that is present in this condition. Provide ventilatory

support as needed and provide continuous cardiac monitoring. Administer clotting factors, platelets, and cryoprecipitate as prescribed to prevent severe hemorrhage. Report changes in laboratory values to the physician or nurse practitioner. Changes can occur rapidly, and vigilance is necessary to prevent further tissue damage to the affected system.

## Hemophilia

Hemophilia is a group of X-linked recessive disorders that result in deficiency in one of the coagulation factors in the blood. X-linked recessive disorders are transmitted by carrier mothers to their sons, so usually only males are affected by hemophilia. The coagulation factors in the blood are essential for clot formation either spontaneously or from an injury, and when factors are absent bleeding will be difficult to stop. There are several types of hemophilia, including factor VIII deficiency (hemophilia A), factor IX deficiency or Christmas disease (hemophilia B), and factor XI deficiency (hemophilia C). The most common, hemophilia A, will be the focus of this discussion (Karp & Riddell, 2010). Hemophilia A occurs when there is a deficiency of factor VIII in an individual. Factor VIII is essential in the activation of factor X, which is required for the conversion of prothrombin into thrombin, resulting in an inability of the platelets to be used in clot formation.

Hemophilia is classified according to the severity of the disease, ranging from mild to severe. The more severe the disease, the more likely it is that there will be bleeding episodes. When bleeding occurs the vessels constrict and a platelet plug forms, but because of the deficient factor the fibrin will not solidify, and thus bleeding continues.

## Therapeutic Management

The primary goal of managing hemophilia is to prevent bleeding. This is best accomplished by instructing the child to avoid activities with a high potential for injury (e.g., football, riding motorcycles, skateboarding). Instead, encourage the child to participate in activities with the least amount of contact (e.g., swimming, running, tennis). Limiting activities does not mean the child should do nothing; activities that promote health without increased exposure to injury are best.

If bleeding or injury occurs, factor administration is prescribed; this practice has been common in outpatient facilities or the child's home for many years. Once the deficient factor is replaced, clotting factors return to fairly normal levels for a period of time. Factor replacement should be given before any surgeries or other procedures that can lead to bleeding, such as intramuscular injections and dental care.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1707. Assessment findings pertinent to hemophilia in children are discussed below.

### Health History

Elicit the health history, determining the nature of the bleeding episode or bruise. Include in the history any hemorrhagic episodes in other systems, such as the gastrointestinal tract (e.g., black tarry stools, hematemesis) or as a result from injury resulting in joint hemorrhage, or hematuria (Fig. 47.11). Inquire about length of bleeding and amount of blood loss. Because hemophilia A results in difficulty with clotting, the child may bleed for a longer period when injury occurs.

### Physical Examination

Focus the physical examination on identification of any bleeding. This is of particular concern after injury, but a nosebleed or other spontaneous bleed can occur if factor levels are extremely low. Assess circulation by evaluating pulses and heart sounds if severe or prolonged bleeding is identified. Without intervention, hypovolemia could follow, leading to shock. Note chest pain or abdominal pain, which may indicate internal bleeding. Report these findings immediately so that the underlying condition can be diagnosed and treated rapidly.

**FIGURE 47.11** Significant swelling and discoloration associated with a bleeding episode in a hemophiliac's knee.

## Laboratory and Diagnostic Testing

Laboratory findings may include decreased hemoglobin and hematocrit if bleeding is prolonged or severe. Factor levels may be quantified with blood testing.

## Nursing Management

Nursing management includes preventing bleeding episodes, managing bleeding episodes, and providing education and support.

### Preventing Bleeding Episodes

All children with hemophilia should attempt to prevent bleeding episodes. Major bleeds into the joints may limit range of motion and function, eventually decreasing physical abilities and crippling some boys (Karp & Riddell, 2010). Teach children and families that regular physical activity or exercise helps to keep the muscles and joints stronger, and children with stronger joints and muscles have fewer bleeding episodes (see Teaching Guidelines 47.2). Refer the child with moderate to severe hemophilia to a pediatric hematologist and/or a comprehensive hemophilia treatment center.

### Teaching Guidelines 47.2

#### PREVENTING BLEEDING IN THE CHILD WITH HEMOPHILIA

- Protect toddlers with soft helmets, padding on the knees, carpets in the home, and softened or covered corners.
- Children should stay active: swimming, baseball, basketball, and bicycling (wearing a helmet) are good physical activities.
- Avoid intense contact sports such as football, wrestling, soccer, and high diving.
- Avoid trampoline use and riding all-terrain vehicles (ATVs).
- Arrange premedication with Amicar if oral surgery is indicated.

### Managing a Bleeding Episode

Administer factor VIII replacement as prescribed. Factor replacement is pooled from multiple blood donors, so families may be concerned about transmission of viruses via the product (specifically hepatitis and HIV). Several methods of viral inactivation (solvent detergent, dry heat, and monoclonal purification) have been used to treat factors VIII and IX since 1986, so since that time there has been no risk of HIV transmission via factor infusion (National Hemophilia Foundation, 2009).

Administer factor replacement by slow IV push. Document the product name, number of units, lot number, and expiration date. Doses are based on the severity of the bleeding and the weight of the child. Specific dosing guidelines can be obtained from the product insert. In mild cases of hemophilia A, desmopressin may be effective in stopping bleeding (see below in the nursing management section of von Willebrand disease for additional information).

If external bleeding develops, apply pressure to the area until bleeding stops. If it is inside a joint, apply ice or cold compresses to the area and elevate any injured extremities, except when contraindicated by further injury. Make sure that all cases of bleeding are followed up to identify whether factor replacement is necessary.

### Providing Education

Inform the family that the child should wear a medical alert bracelet. Families should notify the school nurse and teachers of the child's diagnosis and share precautions with them. Instruct all school personnel to call the parent immediately if the child sustains a head, abdominal, or orbit injury at school. Teach parents and caregivers how to administer the intravenous infusion of factor VIII. Administration in the home is the preferred method for factor infusion, as the child will be able to receive treatment in the most timely and efficient manner when a bleeding episode occurs. Alternatives to the parent giving the infusion are to arrange for a home care nursing visit or for the family to keep their own supply of factor VIII that they take to the local emergency room for infusion if bleeding occurs.

Involve children as developmentally appropriate in the infusion process. Young children may hold and apply the Band-Aid; older children may assist with dilution and mixing of the factor. Teach teenagers to administer their own factor infusions.

Children with severe hemophilia may need factor infusions so often that implantation of a central venous access port is warranted. Teach the family access, care, and flushing of the implanted port.

### Thinking About Development

Toby Henderson is an 18-month-old male with a history of moderate hemophilia. He is a very active child; his mother calls him a "typical boy."

Considering Toby's developmental stage, how will his diagnosis impact his ability to accomplish toddler developmental milestones?

Develop a teaching plan for Toby's parents related to safety for Toby. Incorporate age-appropriate activities that would be safe for Toby in the plan.

## Providing Support

Children with hemophilia may be able to lead a fairly normal life, with the exception of avoiding a few activities. However, accepting the diagnosis of a bleeding disorder in their child is very difficult for parents. They fear the worst (bleeding that won't stop) as well as complications such as infection with blood-borne viruses. Reassure parents that since 1986, when factor replacement began to be treated with heat, there have been no reports of virus transmission from factor infusion (National Hemophilia Foundation, 2009). Educate and support the parents. Factor replacement is expensive and bleeding episodes often cause parents to miss work, both of which create financial strains. Refer families to the National Hemophilia Foundation and NHF Youthworld, which offer support, education, youth leadership, scholarships, and a directory of camps for children with hemophilia and other bleeding disorders. Links to these and other helpful resources are located on [thePoint](#).

## Von Willebrand disease

Von Willebrand disease (vWD) is a genetically transmitted bleeding disorder that may affect both genders and all races. The disorder is a deficiency in von Willebrand factor (vWF). Under ordinary circumstances vWF serves two functions: to bind with factor VIII, protecting it from breakdown, and to serve as the “glue” that attaches platelets to the site of injury. Deficiency in this factor results in a mild bleeding disorder. Children with vWD bruise easily, have frequent nosebleeds (epistaxis), and tend to bleed after oral surgery. Pubescent girls often have menorrhagia.

Therapeutic management of vWD is similar to that of hemophilia. Prevention of injury is important. When bleeding or injury does occur, vWF is administered. Desmopressin may also be used to release the factors necessary for clotting. Desmopressin (DDAVP) raises the plasma level from stores in the endothelium of blood vessels; this releases factor VIII and vWF from these stores into the bloodstream. These may also be administered before dental work or surgery.

## Nursing Assessment

Nursing assessment of the child with vWD is similar to the assessment of the child with hemophilia, though severe bleeding occurs much less frequently.

## Nursing Management

Nursing management is also similar to the management of the child with hemophilia. The major difference is

the administration of desmopressin. Administer desmopressin nasal spray as prescribed when a bleeding episode occurs. Desmopressin may also be given via an intravenous infusion or subcutaneously (less common). Stimate is the only brand of desmopressin nasal spray that is used for controlling bleeding; the other brands are used for homeostasis and enuresis. Desmopressin is an antidiuretic hormone, so closely monitor fluid balance. Twenty-four hours should lapse between doses, as lessening of the response (tachyphylaxis) occurs with more frequent use (Karp & Riddell, 2010). vWD may also be treated with intravenous infusion of vWF, similar to factor VIII infusion for hemophilia A. Teach children and their families how to avoid or minimize bleeding episodes (see Teaching Guidelines 47.2).

## KEY CONCEPTS

- The major forms of anemia affecting children are iron-deficiency anemia, lead poisoning, folic acid deficiency, pernicious anemia, sickle cell anemia, thalassemia, and G6PD deficiency.
- The major bleeding disorders affecting children are idiopathic thrombocytopenic purpura, Henoch-Schönlein purpura, disseminated intravascular coagulation, and hemophilia and von Willebrand disease.
- Assess for hypoxia, fatigue, and pallor in the child with anemia.
- Nursing assessment for the child with a bleeding disorder focuses on determining its extent and severity.
- Supplementation with iron is the key intervention for the child with iron-deficiency anemia.
- All young children should be screened for lead exposure.
- Prevention of infection and vaso-occlusive episodes takes priority in children with sickle cell anemia.
- Multimodal pain management and astute physical assessment for serious complications are critical in the nursing care of the child having a sickle cell crisis.
- The priority intervention for management of thalassemia is chronic transfusion of packed red blood cells and chelation of iron.
- Idiopathic thrombocytopenic purpura and Henoch-Schönlein purpura are usually self-limiting diseases.
- Administration of factor VII or desmopressin is the key nursing intervention when a bleeding episode occurs in the child with hemophilia or von Willebrand disease.
- Significant anemia may result in hypoxia to the tissues.

- Prolonged bleeding times place the child at risk for hemorrhage.
- Prevention of injury is key for all children with hematologic disorders.
- Child and family teaching for anemias resulting from nutritional deficiencies focuses on promotion of a diet high in the deficient nutrients.
- Child and family teaching for bleeding disorders focuses on the prevention of injury.
- Numerous nationwide and local resources are available to children with hematologic disorders or nutritional deficits. These organizations offer a wide range of services, including education, support, multidisciplinary care (as appropriate), and financial assistance in caring for the disease.

## MULTIPLE CHOICE QUESTIONS

1. A child on the pediatric unit has morning laboratory results of Hgb 10.0, Hct 30.2, WBC 24,000, and platelets 20,000. What is the priority nursing assessment?
  - a. Assess for pallor, fatigue, and tachycardia.
  - b. Monitor for fever.
  - c. Assess for bruising or bleeding.
  - d. Determine intake and output.
2. A child with hemophilia fell while riding his bicycle. He was wearing a helmet and did not lose consciousness. He has a mild abrasion on his knee that is not oozing. He is complaining of abdominal pain. What is the priority nursing assessment?
  - a. Perform neurologic checks.
  - b. Assess ability to void frequently.
  - c. Carefully assess his abdomen.
  - d. Examine his knee frequently.
3. A 14-year-old with thalassemia asks for your assistance in choosing her afternoon snack. Which choice is the most appropriate?
  - a. Peanut butter with rice cake.
  - b. Small spinach salad.
  - c. Apple slices with cheddar cheese.
  - d. Small burger on wheat bun.
4. The nurse is caring for a child who has just been admitted to the pediatric unit with sickle cell crisis. He is complaining that his right arm and leg hurt. What is the priority nursing intervention?
  - a. Administer pain medication every 3 hours intravenously until pain is controlled.
  - b. Perform passive range of motion of the arm and leg to maintain function.
  - c. Try acetaminophen for pain first, moving up to opioids only if needed.
  - d. Use narcotic analgesics and warm compresses as needed to control the pain.

## CRITICAL THINKING EXERCISES

1. Develop a discharge teaching plan for the parent of a toddler who has just been diagnosed with hemophilia and received factor infusion treatment for a bleeding episode.
2. An 8-year-old girl has been diagnosed with iron-deficiency anemia. Formulate a nutrition plan for this child.
3. A 5-year-old with  $\beta$ -thalassemia is resistant to nightly chelation therapy at home. Devise a developmentally appropriate teaching plan for this child.
4. Develop a nursing care plan for a child with sickle cell disease who experiences frequent vaso-occlusive crises.

## STUDY ACTIVITIES

1. Visit your local WIC office. Meet with the staff and learn about the services offered for prevention of and nutritional support for anemia. Provide a written report of your learning experience or provide a presentation to your classmates.
2. In the clinical setting, compare the growth and development of a child with sickle cell disease to that of a similarly aged child who has been healthy.
3. Talk to a teenager with hemophilia about his life experiences and feelings about his disease and his health. Reflect upon this conversation in your clinical journal.
4. Visit a public health clinic that provides primary care to children. Spend time with the registered nurse, the advanced practice nurse, and the unlicensed assistive personnel. Write a summary of the roles of the registered nurse in screening for and managing hematologic disorders in children, noting roles that are reserved for the advanced practice nurse and activities that the RN would delegate to unlicensed assistive personnel.

# Nursing Care of the Child With an Immunologic Disorder

## Learning Objectives

*Upon completion of the chapter, the learner will be able to:*

1. Define the key terms used in this chapter.
2. Explain anatomic and physiologic differences of the immune system in infants and children versus adults.
3. Describe nursing care related to common laboratory and diagnostic testing used in the medical diagnosis of pediatric immune and autoimmune disorders.
4. Distinguish immune, autoimmune, and allergic disorders common in infants, children, and adolescents.
5. Identify appropriate nursing assessments and interventions related to medications and treatments for pediatric immune, autoimmune, and allergic disorders.
6. Develop an individualized nursing care plan for the child with an immune or autoimmune disorder.
7. Describe the psychosocial impact of chronic immune disorders on children.
8. Devise a nutrition plan for the child with immunodeficiency.
9. Develop child/family teaching plans for the child with an immune or autoimmune disorder.

*Lakeisha Harris, 15 years old, is brought to the clinic by her mother. She presents with complaints of pain and swelling in her joints, weight gain, and fatigue. Lakeisha states, "I'm just very tired all the time, and my knees and ankles ache."*

### Words of Wisdom

Resistance to disease can be a child's battle for life.

**Immunodeficiency** (incapacity to mount an appropriate immune response), autoimmune, and allergic disorders have a significant impact on the lives of affected children. Infants and children are exposed to many infectious microorganisms and allergens and thus need a functional immune system to protect themselves. Temporary immune deficiencies may follow a common viral infection, surgery, or blood transfusion, and may also be caused by malnutrition or the use of certain medications (Nield, Troischt, & Kamat, 2009). Temporary immune depression resolves over a period of time. Primary or secondary immune deficiencies are the focus of this discussion, along with allergy and anaphylaxis. These immune disorders are chronic, and affected children have more infections compared with healthy children. Recurrent viral or bacterial infections may cause the child to miss significant amounts of school or playtime with other children. Many immunodeficiencies require chronic and frequent clinic visits as well as daily medications. This can be a stress on the family as well. Autoimmune disorders are also chronic, causing significant disruption to the child's and family's life. Allergic disorders in some children may cause significant stress for the child and family. Nurses who care for children need to be familiar with common immunodeficiencies, autoimmune disorders, and allergies to intervene effectively with children and their families.

## VARIATIONS IN PEDIATRIC ANATOMY AND PHYSIOLOGY

Normal immune function is a complex process involving **phagocytosis** (process by which phagocytes swallow up and break down microorganisms), **humoral immunity** (immunity mediated by antibodies secreted by B cells), **cellular immunity** (cell-mediated immunity controlled by T cells), and activation of the complement system. The lymphatic system and the white blood cells (WBCs) are the primary “players” in the immune response. Though these structures and cells are present at birth, the healthy full-term infant's immune system is still immature. The

newborn exhibits a decreased inflammatory response to invading organisms, and this increases his or her susceptibility to infection. Cellular immunity is generally functional at birth, and as the infant is exposed to various substances over time, humoral immunity develops. Comparison Chart 48.1 provides more information on humoral and cellular immunity.

## Lymph System

Lymph nodes in the newborn are relatively small, soft, and difficult to palpate. As the infant is exposed to various germs or illnesses, the lymph system passively filters plasma for bacteria or other foreign material before returning it to the bloodstream and back to the heart. As WBCs infiltrate the lymph nodes to attack the foreign substance, the nodes enlarge. Young children have frequent episodes of localized enlarged lymph nodes because of their repeated exposure to viral illnesses (Tosi, 2009). The spleen is functional at birth and also filters the blood for foreign cells. The thymus, responsible for the production of lymphocyte T cells as well as for the development and maturation of peripheral lymphoid tissue, is quite enlarged at birth and remains so until about 10 years of age. It then involutes slowly throughout adulthood. The tonsils are also often enlarged throughout early childhood. The bone marrow is functional at birth, producing stem cells capable of differentiating into various blood cells.

## Phagocytosis

Under conditions of stress, the newborn and infant exhibit decreased phagocytic activity. The complement system, which is responsible for **opsonization** (process of making microorganisms more susceptible to phagocytosis) and **chemotaxis** (movement of neutrophils toward microorganisms), is immature in the newborn but reaches adult levels of activity by 3 to 6 months of age. The infant's phagocytic cells (neutrophils and monocytes) demonstrate decreased chemotaxis, reaching adult levels

### COMPARISON CHART 48.1

#### HUMORAL VERSUS CELLULAR IMMUNITY

##### Humoral Immunity (Antibody Protection)

- Lymphocytes: B cells
- Secrete antibodies to viruses and bacteria
- Recognize antigens
- Antibodies mark the antigen cell for destruction
- Do not destroy the foreign cell
- Crosses the placenta in the form of IgG

##### Cellular Immunity (Cell-Mediated Immune Response)

- Lymphocytes: T cells
- Do not recognize antigens
- Direct and regulate immune response (helper T cells)
- Attack infected or foreign cells (killer T cells and natural killer cells)
- Do not cross the placenta

when the child is several years old. With complement levels being only 50% to 75% of adult levels in the full-term infant, decreased opsonization may be responsible for decreased phagocytic activity compared with adults.

## Cellular Immunity

Maternal T cells do not cross the placenta, so the fetal thymus begins production of T cells early in gestation, and the newborn demonstrates a relative lymphocytosis compared with the adult, probably due to increased amounts of T-cell lymphocytes. Though cellular immunity does not cross the placenta, the fetal T cells may become sensitized to antigens that do cross the placenta. Viral infection, hyperbilirubinemia, and drugs taken by the mother late in pregnancy may contribute to depressed T-cell function in the newborn. Since delayed hypersensitivity reactions are mediated by T cells rather than antibodies, skin test responses (such as purified protein derivative [PPD] for tuberculosis detection) are diminished until about 1 year of age, probably due to the infant's decreased ability to mount an inflammatory response.

## Humoral Immunity

The newborn's B cells do not respond as well to infection as do adults. B cells are responsible for the formation of **antibodies** (specific immunity). The antibodies bind to the **antigen** (substance stimulating an immune response), thus disabling the specific toxin. The fetus is normally in an antigen-free environment and so produces only trace amounts of **immunoglobulins** (Ig; gammaglobulin antibody

proteins), specifically IgM. Most of the newborn's IgG is acquired transplacentally from the mother. Hence, the newborn exhibits passive immunity to antigens to which the mother had developed antibodies. These antibodies wane over the first months of life as the transplacental IgG is catabolized, having a half-life of only about 25 days.

The newborn begins to make IgG but ordinarily experiences a physiologic hypogammaglobulinemia between 2 and 6 months of age until self-production of IgG reaches higher levels. The breastfed infant will acquire passive transfer of maternal immunity via the breast milk and will be better protected during the physiologic hypogammaglobulinemia phase. By 1 year of age IgG is 70% of the adult level, and by 8 years of age it should reach the adult level.

IgA, IgD, IgE, and IgM do not cross the placenta; they require an antigenic challenge for production. IgD and IgE constitute a very small percentage of the immunoglobulins in all ages. IgA increases slowly to about 30% of the adult level at 1 year of age, reaching the adult level by age 11 years. IgM is close to the adult level by 1 year of age (Lederman, 2006).

## COMMON MEDICAL TREATMENTS

A variety of medications and other medical treatments are used to treat immune deficiencies and autoimmune problems in children. Most of these treatments will require a physician's or nurse practitioner's order when the child is in the hospital. The most common treatments and medications are listed in Common Medical Treatments 48.1 and Drug Guide 48.1. The nurse caring for

### COMMON MEDICAL TREATMENTS 48.1

Treatment	Explanation	Indications	Nursing Implications
Immunizations	Killed or modified microorganisms, or components of them, cause the immune system to develop antibodies to the microorganism without developing disease.	Prevention of certain viral and bacterial infections	Do not administer live vaccines to immunosuppressed persons. Refer to the individual vaccine for method of administration and contraindications. Report adverse reactions via the Vaccine Adverse Reaction (VAR) reporting system.
Bone marrow or stem cell transplantation	Bone marrow transplant: transfer of healthy bone marrow into the bones of a person with immune malfunction; the transplanted cells can then develop into functional B and T cells. Stem cell transplant: peripheral stem cells are removed from the donor via apheresis or stem cells are retrieved from the umbilical cord and placenta. The stem cells are then transplanted into the recipient.	Wiskott-Aldrich syndrome, SCID	Administer immunosuppressive medications as ordered. Maintain medical asepsis and protective isolation to prevent infection. Monitor closely for graft-versus-host disease. Provide meticulous oral care. Avoid rectal temperatures and suppositories. Encourage appropriate nutrition.

## DRUG GUIDE 48.1 COMMON DRUGS FOR IMMUNOLOGIC DISORDERS

Medication	Actions/Indications	Nursing Implications
Intravenous immune globulin (IVIG); multiple manufacturers	Provides exogenous IgG antibodies Indicated for primary immune deficiencies, HIV infection	Do not mix with IV medications or with other IV fluids. Do not give IM or SQ. Monitor vital signs and watch for adverse reactions frequently during infusion. May require antipyretic or antihistamine to prevent chills and fever during infusion. Have epinephrine available during infusion.
Nucleoside analog reverse transcriptase inhibitors (NRTIs): abacavir, lamivudine, zidovudine	Inhibit reverse transcription of the viral DNA chain For treatment of HIV-1 infection as part of a three-drug regimen. Zidovudine is also used to prevent perinatal transmission of HIV.	Notify physician of muscle weakness, shortness of breath, headache, insomnia, rash, or unusual bleeding. Give IV zidovudine over 1 hour. Fatal hypersensitivity reaction may occur with abacavir.
Nonnucleoside analog reverse transcriptase inhibitors (NNRTIs): efavirenz, nevirapine	Bind to HIV-1 reverse transcriptase, blocking DNA polymerase activity and disrupting the virus life cycle. Used for treatment of HIV-1 infection as part of a three-drug regimen	<i>Nevirapine:</i> Avoid St. John's wort. Shake suspension gently before administration. Observe for symptoms of Stevens-Johnson syndrome. <i>Efavirenz:</i> May cause drowsiness
Protease inhibitors: amprenavir, atazanavir, indinavir, lopinavir, nelfinavir, ritonavir, saquinavir	Inhibit protease activity in the HIV-1 cell, resulting in immature, noninfectious viral particles. Used for treatment of HIV-1 infection as part of a three-drug regimen	Multiple drug interactions. Review specific medication for adverse effects and administration implications.
Nonsteroidal anti-inflammatory drugs (NSAIDs): aspirin, trisalicylate, ibuprofen, naproxen, others	Inhibit prostaglandin synthesis, anti-inflammatory action Indicated for juvenile idiopathic arthritis	Administer with food to decrease GI upset. May cause gastric bleeding, increased liver enzymes, decreased renal function. Monitor liver enzymes. Do not crush or chew extended-release or timed-release preparations. <i>Aspirin and trisalicylate:</i> Follow serum salicylate levels. Observe for signs of toxicity, including hyperventilation with heavy breathing, drowsiness, nausea, vomiting, bruising, tinnitus, and hearing loss.
Corticosteroids	Anti-inflammatory and immunosuppressive action. Used for juvenile idiopathic arthritis, SLE, and immunosuppression in children with bone marrow or stem cell transplants	Administer with food to decrease GI upset. May mask signs of infection. Monitor blood pressure, urine for glucose. Do not stop treatment abruptly or acute adrenal insufficiency may occur. Monitor for Cushing syndrome. Doses may be tapered over time. <i>Intravenous pulse:</i> Monitor for hypertension during infusion.

**DRUG GUIDE 48.1 COMMON DRUGS FOR IMMUNOLOGIC DISORDERS** (continued)

Medication	Actions/Indications	Nursing Implications
Cytotoxic drugs (cyclophosphamide [Cytosan])	Interfere with normal function of DNA by alkylation. For treatment of severe SLE	Cause bone marrow suppression. Monitor for signs of infection. <i>Cyclophosphamide:</i> Administer in the morning. Provide adequate hydration and have child void frequently during and after infusion to decrease risk of hemorrhagic cystitis.
Immunosuppressant drugs (cyclosporine A [CyA], azathioprine)	Inhibition of production and release of interleukin II (CyA) Antagonize purine metabolism (azathioprine). Used for severe steroid-resistant autoimmune disease	Monitor CBC, serum creatinine, potassium, and magnesium. Monitor blood pressure and watch for signs of infection. Draw blood levels before morning dose. CyA: Do not give with grapefruit juice.
Antimalarial drugs: hydroxychloroquine sulfate (Plaquenil)	Impair complement-dependent antigen-antibody reactions to prevent flares in SLE and juvenile arthritis	Fundoscopic eye examination and visual field testing every year.
Disease-modifying antirheumatic drugs (DMARDs): methotrexate, etanercept	Methotrexate: antimetabolite that depletes DNA precursors, inhibits DNA and urine synthesis Etanercept: binds to tumor necrosis factor (TNF), rendering it ineffective. Used for severe polyarticular juvenile arthritis	<i>Methotrexate:</i> Do not give oral form with dairy products. Approximate time to benefit in treatment of arthritis is 3 to 6 weeks. Salicylates may delay clearance. Protect IV preparation from light. Monitor CBC, renal and liver function, and symptoms of infection. <i>Etanercept:</i> Monitor closely for infection. Do not give live vaccines. Give SQ, twice weekly; effect in 1 week to 3 months.

CBC, complete blood count; GI, gastrointestinal; IM, intramuscularly; SQ, subcutaneously.  
Adapted from Taketokmo, C. K., Hodding, J. H., & Kraus, D. M. (2011). *Pediatric and neonatal dosage handbook* (18th ed.). Hudson, OH: Lexi-comp

the child with an immune deficiency or autoimmune disorder should be familiar with what the procedures and medications are, how they work, and common nursing implications related to use of these modalities.

### Atraumatic Care

*When a child requires repeat injections related to an immune or allergic disorder, use a local anesthetic such as EMLA (eutectic mixture of local anesthetic) cream or a numbing spray to reduce the amount of associated pain.*

### NURSING PROCESS OVERVIEW FOR THE CHILD WITH AN IMMUNOLOGIC DISORDER

Care of the child with an immunologic or allergic disorder includes assessment, nursing diagnosis, planning, interventions, and evaluation. There are a number of general concepts related to the nursing process that may be applied to immunodeficiencies and autoimmune disorders. From a general understanding of the care involved for a child with immune dysfunction, the nurse can then individualize the care based on the particular child's specifics.

## Assessment

Assessment of children with immunodeficiency, autoimmune disorders, or allergy includes health history, physical examination, and laboratory and diagnostic testing.

**Remember Lakeisha, the 15-year-old with joint pain and swelling, fatigue, and weight gain? What additional health history and physical examination assessment information should you obtain?**

### Health History

The health history consists of past medical history, including the mother's pregnancy history; family history; and history of present illness (when the symptoms started and how they have progressed), as well as medications and treatments used at home. The past medical history may be significant for:

- Maternal HIV infection
- Frequent, recurrent infections such as otitis media, sinusitis, or pneumonia
- Chronic cough
- Recurrent low-grade fever
- Two or more serious infections in early childhood
- Recurrent deep skin or organ abscesses
- Persistent thrush in the mouth
- Extensive eczema
- Growth failure

Family history may be positive for primary immune deficiency or autoimmune disorder. Document history of known allergy. Note the response that occurs when the child encounters the allergen.

### Physical Examination

Physical examination of the child with immunodeficiency or autoimmune disorder includes inspection and observation, auscultation, percussion, and palpation.

#### INSPECTION AND OBSERVATION

Plot weight and length or height on appropriate growth charts. Inspect the oropharynx for tonsillar size. Note eczematous or other skin lesions, which may occur with allergic diseases or Wiskott-Aldrich syndrome. Document the presence of thrush, which occurs frequently in children with immunodeficiency. Observe gait for unexplained ataxia (neurologic alterations occur with HIV infection).

#### AUSCULTATION, PERCUSSION, AND PALPATION

Auscultate the lungs for adventitious sounds, which may be present with a concurrent respiratory infection. Note any wheezing that may occur with an allergic reaction.

Percuss the abdomen and determine liver span. Palpate for unusually enlarged lymph nodes, particularly in nonadjacent locations. Palpate the abdomen for an enlarged spleen or liver.

### Laboratory and Diagnostic Testing

Common Laboratory and Diagnostic Tests 48.1 explains the laboratory and diagnostic tests most commonly used when considering immune disorders. Results of these tests may assist the physician or nurse practitioner in diagnosing the disorder and/or be used as guidelines in determining ongoing treatment. Laboratory or nonnursing personnel obtain some of the tests, while the nurse might obtain others. In either instance it is important for the nurse to be familiar with how the tests are obtained, what they are used for, and normal versus abnormal results. This knowledge will also be necessary when providing child and family education related to the testing.

### Nursing Diagnoses and Related Interventions

Upon completion of a thorough assessment, the nurse might identify several nursing diagnoses. These may include:

- Ineffective protection
- Imbalanced nutrition, less than body requirements
- Pain
- Impaired skin integrity
- Activity intolerance
- Delayed growth and development

**After completing an assessment of Lakeisha, you note the following: alopecia, abdominal tenderness, and oral ulcers. Based on these assessment findings, what would your top three nursing diagnoses be for Lakeisha?**

Nursing goals, interventions, and evaluation for the child with an immunologic disorder are based on the nursing diagnoses. Nursing Care Plan 48.1 can be used as a guide in planning nursing care for the child with an immunologic disorder, autoimmune disorder, or allergic response. It should be individualized based on the child's symptoms and needs. Refer to Chapter 36 for thorough information related to pain management. Additional information will be included later in the chapter as it relates to specific disorders.

**Based on your top three nursing diagnoses for Lakeisha, describe appropriate nursing interventions.**

## COMMON LABORATORY AND DIAGNOSTIC TESTS 48.1

Test	Explanation	Indications	Nursing Implications
Complete blood count (CBC) with differential	Evaluates hemoglobin and hematocrit, WBC count (particularly the percentage of individual WBCs), and platelet count	Infection, inflammatory process, immunosuppression	Normal values vary according to age and gender. WBC count differential is helpful in evaluating source of infection. May be affected by myelosuppressive drugs.
Immunoglobulin electrophoresis	Determines level of individual immunoglobulins (IgA, IgD, IgE, IgG, IgM) in the blood	Immune deficiency, autoimmune disorders	Normal levels vary with age. IVIg administration and steroids alter levels.
IgG subclasses	Measure the levels of the four subclasses of IgG (1, 2, 3, and 4)	Determine immune deficiency	Normal levels vary with age. IVIg administration and steroids alter levels.
Lymphocyte immunophenotyping T-cell quantification	Measures level of T cells (T helper [CD4], T suppressor [CD8]), B cells, and natural killer cells in the blood	Ongoing monitoring of progressive depletion of CD4 T lymphocytes in HIV disease	Do not refrigerate specimen. Steroids may elevate and immunosuppressive drugs may depress lymphocyte levels.
Delayed hypersensitivity skin test	Measures the presence of activated T cells that recognize certain substances	Immune disorders	Administered intradermally. Read and document size of reaction at 48 to 72 hours (tuberculosis, mumps, Candida, tetanus).
HIV antibodies	Used to detect antibodies to HIV	Determining HIV infection when suspected	ELISA method detects only antibodies, so may remain negative for several weeks up to 6 months (false-negative). False-positive may result with autoimmune disease. Requires serial testing. HIV test results are confidential.
Polymerase chain reaction (PCR)	Used to detect HIV DNA and RNA	Diagnosis of HIV infection in children older than 1 month old	Sensitive and specific for presence of HIV in blood. Poor accuracy on samples obtained at birth. Sequential testing needed to determine perinatal transmission.
Complement assay (C3 and C4)	Measures the level of total complement in the blood, as well as levels of C3 and C4	Monitor SLE. Determine complement deficiency	Send to laboratory immediately (unstable at room temperature). Usually sent out to a reference laboratory.
Erythrocyte sedimentation rate (ESR)	Nonspecific test used to determine presence of infection or inflammation	Immune disorder initial workup, ongoing monitoring of autoimmune disease	Send to laboratory immediately; if allowed to stand >3 hours, falsely low result may occur.
Rheumatoid factor (RF)	Determines the presence of RF in the blood	Juvenile idiopathic arthritis, SLE	Positive RF is also sometimes seen in chronic infectious disorders.

**COMMON LABORATORY AND DIAGNOSTIC TESTS 48.1** (continued)

Test	Explanation	Indications	Nursing Implications
Antinuclear antibody (ANA)	Tests for presence of autoantibodies that react against cellular nuclear material	SLE	Check for signs of infection at venipuncture site. Steroid use can cause false-negative result. May be weakly positive in about 20% of healthy individuals
RAST (radioallergen sorbent test)	Measures minute quantities of IgE in the blood Carries no risk of anaphylaxis but is not as sensitive as skin testing	Asthma (food allergies)	Blood test that is usually sent out to a reference laboratory.
Allergy skin testing	Suggested allergen is applied to skin via scratch, pin, or prick. A wheal response indicates allergy to the substance. Carries risk of anaphylaxis. (Nursing note: Antihistamines must be discontinued before testing, as they inhibit the test.)	Allergic rhinitis, asthma	Close observation for anaphylaxis is necessary. Epinephrine and emergency equipment should be readily available. Some children react to the skin test almost immediately; others take several minutes.
Food-specific IgE antibody testing	Measures IgE antibody to specific food allergens	Accurately determine specific food allergy	IVIG administration and steroids alter levels.

Adapted from Pagana, K. D., & Pagana, T. J. (2010). *Mosby's manual of diagnostic and laboratory tests* (4th ed.). St. Louis, MO: Mosby.

## PRIMARY IMMUNODEFICIENCIES

Many primary immunodeficiencies have been identified. They are mostly hereditary or congenital. Primary immunodeficiencies may be related to humoral deficiencies, cellular immunity deficiencies, or a combination of the two; phagocytic system defects; or complement deficiencies. This discussion will focus on a few of the more common and/or severe primary immunodeficiencies in children. Box 48.1 lists 10 warning signs that a child may need further evaluation for the possibility of primary immunodeficiency.

### Hypogammaglobulinemia

Hypogammaglobulinemia refers to a variety of conditions in which the child does not form antibodies appropriately. It results in low or absent levels of one or more of the immunoglobulin classes or subclasses.

#### BOX 48.1

### TEN WARNING SIGNS OF PRIMARY IMMUNODEFICIENCY

- Four or more new episodes of acute otitis media in 1 year
- Two or more episodes of severe sinusitis in 1 year
- Treatment with antibiotics for 2 months or longer with little effect
- Two or more episodes of pneumonia in 1 year
- Failure to thrive in the infant
- Recurrent deep skin or organ abscesses
- Persistent oral thrush or skin candidiasis after 1 year of age
- History of infections requiring IV antibiotics to clear
- Two or more serious infections such as sepsis
- Family history of primary immunodeficiency

Adapted from Jeffrey Modell Foundation. (2012). *10 warning signs of primary immunodeficiency*. Retrieved July 11, 2012, from <http://www.info4pi.org/aboutPI/index.cfm?section=aboutPI&content=warningsigns&TrkId=24&CFID=826462&CFTOKEN=12451348>

## NURSING CARE PLAN 48.1

## Overview for the Child With an Immunologic Disorder

**NURSING DIAGNOSIS:** Ineffective protection related to inadequate body defenses, inability to fight infection as evidenced by deficient immunity

**Outcome Identification and Evaluation**

Child will not experience overwhelming infection: *will be infection-free or able to recover if he or she becomes infected.*

**Intervention: Preventing Infection**

- Maintain meticulous hand-washing procedures (include family, visitors, staff) *to minimize spread of infectious organisms.*
- Maintain isolation as prescribed *to minimize exposure to infectious organisms.*
- Clean frequently touched surfaces with an appropriate cleanser *to minimize spread of infectious organisms.*
- Educate family and visitors that child should be restricted from contact with known infectious exposures (in hospital and at home) *to encourage cooperation with infection control.*
- Strictly observe medical asepsis *to avoid unintentional introduction of microorganisms.*
- Promote nutrition and appropriate rest *to maximize body's potential to heal.*
- Educate family to contact physician or nurse practitioner if child has known exposure to chickenpox or measles *so that preventive measures (e.g., varicella zoster immunoglobulin [VZIG]) can be taken.*
- Administer vaccines (not live) as prescribed *to prevent common childhood communicable diseases.*
- Administer prophylactic antibiotics as prescribed *to prevent infection with opportunistic organisms.*

**NURSING DIAGNOSIS:** Imbalanced nutrition, less than body requirements, related to poor appetite, chronic illness, debilitated state, concurrent illness as evidenced by poor growth, weight gain and stature increases less than expected, poor head growth

**Outcome Identification and Evaluation**

Child will consume adequate intake: *will demonstrate appropriate weight gain and growth of length/height and/or head circumference.*

**Intervention: Promoting Adequate Nutritional Intake**

- Monitor growth (weight and height/length weekly) *to determine progress toward goal.*
- Determine realistic goal for weight gain for age (consulting dietitian if necessary) *to have a specific outcome to work toward.*
- Observe child's physical ability to eat *(if pain from candidiasis or motor impairment is present, will need additional interventions).*
- Provide nutrient-rich meals and snacks *to maximize caloric intake.*
- Supplement milkshakes with protein powder or other additives *to maximize caloric intake.*
- Provide child's favorite foods *to encourage increased intake.*
- Provide smaller, more frequent meals *to reduce sensation of fullness and increase overall intake.*
- If vomiting is an issue, administer antiemetics as ordered prior to meals *to provide optimal state for success at mealtime.*

## NURSING CARE PLAN 48.1

**Overview for the Child With an Immunologic Disorder** (continued)

**NURSING DIAGNOSIS:** Impaired skin integrity related to disease process or photosensitivity as evidenced by skin rash or alopecia

**Outcome Identification and Evaluation**

Skin integrity will be maintained: *secondary infection will not occur, rash will not increase.*

**Intervention: Preventing Skin Impairment**

- Assess and monitor extent and location of rash *to provide baseline information and evaluate success of interventions.*
- Keep skin clean and dry *to prevent secondary infection.*
- For the child with eczema, apply topical medications as ordered *to decrease inflammatory response.*
- For the child with limited mobility, turn frequently and use specialty mattress or bed *to prevent pressure ulcers.*
- Implement a written plan of care directed toward topical treatment of skin integrity impairment *to provide consistency of care and documentation.*
- Educate child and family to limit direct sun exposure and use sunscreen *to prevent sun damage.*

**NURSING DIAGNOSIS:** Activity intolerance related to joint pain, fatigue or weakness, concurrent illness as evidenced by dyspnea, lack of desire to participate in play, inability to maintain usual routine

**Outcome Identification and Evaluation**

Child will participate in activities: *will demonstrate easy work of breathing and participate in daily routine and play.*

**Intervention: Promoting Activity**

- Cluster care *to decrease disturbances and allow for longer uninterrupted rest periods.*
- Pace activities and encourage regular rest periods *to conserve energy.*
- Administer early morning warm bath *to ease a.m. stiffness (juvenile arthritis).*
- Use assistive devices such as splints and orthotics *to improve physical function.*
- Plan developmentally appropriate activities that the child can participate in while in bed *to encourage play and continued development.*
- Schedule activities for the time of day the child usually has the most energy *to encourage successful participation.*

**NURSING DIAGNOSIS:** Delayed growth and development related to physical effects of chronic illness, or physical disability (juvenile arthritis) as evidenced by delay in meeting expected milestones

**Outcome Identification and Evaluation**

Development will be enhanced: *child will make continued progress toward expected developmental milestones.*

(continued)

NURSING CARE PLAN 48.1

Overview for the Child With an Immunologic Disorder (continued)

**Intervention: Enhancing Growth and Development**

- Screen for developmental capabilities to determine child's current level of functioning.
- Offer age-appropriate toys, play, and activities (including gross motor) to encourage further development.
- Encourage peer contact through telephone, e-mail, or letters to promote/continue socialization.
- Perform interventions as prescribed by physical or occupational therapist: repeat participation in those activities helps child improve function and acquire developmental skills.
- Provide support to families of children with developmental delay: progress in achieving developmental milestones can be slow, and ongoing motivation is needed.
- Encourage child to continue schoolwork so that child will not fall behind.
- Reinforce positive attributes in the child to maintain motivation.

Table 48.1 provides an overview of several types of hypogammaglobulinemia. Therapeutic management of most types of hypogammaglobulinemia is periodic administration of intravenous immunoglobulin (IVIG).

**Nursing Assessment**

Note history of recurrent respiratory, gastrointestinal, or genitourinary infections. Palpate for enlarged lymph nodes and spleen in the child with X-linked hyper-IgM

TABLE 48.1 TYPES OF HYPOGAMMAGLOBULINEMIA

Type	Definition	Characteristics	Treatment
Selective IgA deficiency	Serum IgA <7 mg/dL, normal IgG and IgM	May be asymptomatic Child is more prone to allergies due to lack of the mucosal protection that IgA offers. Recurrent infections of respiratory, gastrointestinal, and genitourinary tracts, development of autoimmune disorders	No specific gammaglobulin treatment available. Treat infections or autoimmune disorders. Severe anaphylactic reaction can occur if child receives transfusion of blood containing IgA and IgA antibodies.
X-linked agammaglobulinemia	Markedly reduced or absent IgG, IgM, and IgA. Absence of B cells	Males only Recurrent respiratory and gastrointestinal infections	Routine IVIG infusions. Treat infections.
X-linked hyper-IgM syndrome	Defect in protein found on T-cell surface, resulting in decreased IgG and IgA levels with significant increase in IgM levels	Males only Recurrent respiratory infections, diarrhea, malabsorption. Neutropenia, autoimmune disorders	Routine administration of IVIG. Subcutaneous granulocyte colony-stimulating factor (G-CSF) when neutropenic. Bone marrow transplantation. Treatment of autoimmune disorders.
IgG subclass deficiency	Low levels of one or more of the subclasses of IgG	Recurrent respiratory infections. Some children outgrow this condition	Treatment of respiratory infections. Administration of IVIG is helpful in some children.

syndrome. In children presenting for routine administration of IVIG, determine whether any infections have occurred since the previous infusion.

## Nursing Management

Nursing management of hypogammaglobulinemia involves IVIG administration and the provision of education and support to the child and family.

### Administering Intravenous Immunoglobulin

Determine the amount of IVIG to be given and reconstitute the product according to the manufacturer's

directions (available on the package insert). Some IVIG preparations are provided as a solution, requiring no reconstitution (Fig. 48.1). Others are packaged as two vials, one of IVIG powder and one of sterile diluent. After the diluent is added to the powder, gently roll the vial between your hands to mix. Reconstituted IVIG may be refrigerated overnight but should be brought to room temperature prior to infusion. Assess baseline serum blood urea nitrogen (BUN) and creatinine, as acute renal insufficiency may occur as a serious adverse reaction. Though less common in children than adults, assess for risk factors associated with an increased risk for a thromboembolic event, such as history of stroke, hypertension, diabetes, hypercholesterolemia, impaired cardiac output, monoclonal gammopathy, clotting disorder, obesity, or immobility (Kirmse, 2009).

**FIGURE 48.1** Intravenous administration of exogenous immunoglobulin every several weeks can decrease the frequency and severity of infections in children with various forms of hypogammaglobulinemia.

**Take Note!**

Do not shake the IVIG, as this may lead to foaming and may cause the immunoglobulin protein to degrade (Kirmse, 2009).

Ensure that the child is well hydrated before the infusion to decrease the risk for rate-related reactions and aseptic meningitis after the infusion. Premedication with diphenhydramine or acetaminophen may be indicated in children who have never received IVIG, have not had an infusion in more than 8 weeks, have had a recent bacterial infection, have a history of serious infusion-related adverse reactions, or are diagnosed with agammaglobulinemia or hypogammaglobulinemia (Taketokmo, Hodding, & Kraus, 2011).

The rate for infusion of IVIG is generally prescribed as milligrams of IVIG per kilogram of body weight per minute. Carefully calculate the infusion rate. Obtain a baseline physical assessment and set of vital signs. Begin the infusion slowly, increasing to the prescribed rate as tolerated (see Fig. 48.1). Assess vital signs and check for adverse reactions every 15 minutes for the first hour, then every 30 minutes throughout the remainder of the infusion (the frequency of assessments may vary according to institutional protocol). IVIG is a plasma product, so observe closely for signs of anaphylaxis such as headache, facial flushing, urticaria, dyspnea, shortness of breath, wheezing, chest pain, fever, chills, nausea, vomiting, increased anxiety, or hypotension. If these symptoms occur, discontinue the infusion and notify the physician or nurse practitioner. The infusion may be restarted after the symptoms have subsided. Have oxygen and emergency medications such as epinephrine, diphenhydramine, and intravenous corticosteroids available in case of anaphylactic reaction. If the child complains of discomfort at the intravenous site, a cold compress may be helpful.

**Take Note!**

Many children who have had previous reactions to IVIG can tolerate the infusion without reaction if they are premedicated and if the infusion is given at a slower rate (Taketokmo et al., 2011).

### Providing Education and Support

Provide education and support to the child and family. An excellent book for children with an immune deficiency is *Our Immune System* (1993) by Sara le Bien (available from the Immune Deficiency Foundation, a link to which can be found on [thePoint](#)).

## Wiskott-Aldrich Syndrome

Wiskott-Aldrich syndrome is an X-linked genetic disorder that results in immunodeficiency, eczema, and thrombocytopenia. It affects males only. The defective gene responsible for this disorder has been identified recently and is called the Wiskott-Aldrich syndrome protein (WASp). Complications include autoimmune hemolytic anemia, neutropenia, skin or cerebral vasculitis, arthritis, inflammatory bowel disease, and renal disease (Dibbern & Routes, 2012).

Autoimmune disease may require high-dose steroids, azathioprine, or cyclophosphamide. Splenectomy may be performed to correct thrombocytopenia. The only cure is bone marrow or cord blood stem cell transplantation.

### Nursing Assessment

Note history of petechiae, bloody diarrhea, or bleeding episode in the first 6 months of life. Note any history of hematemesis or intracranial or conjunctival hemorrhages. Observe the skin for eczema, which usually worsens with time and tends to become secondarily infected (Fig. 48.2). Laboratory findings include low IgM concentration, elevated IgA and IgE concentrations, and normal IgG concentrations.

**Take Note!**

An episode of prolonged bleeding, such as after circumcision, may be the first sign of Wiskott-Aldrich syndrome in the male infant (Dibbern & Routes, 2012).

**FIGURE 48.2** Boys with Wiskott-Aldrich syndrome often have worsening of eczema over time.

## Nursing Management

Administer IVIG as ordered to help decrease the frequency of bacterial infections. Perform good skin care and frequently assess eczematous areas to detect secondary infection (refer to Chapter 46 for care of eczema). If the child undergoes splenectomy, in addition to providing routine postoperative care, be aware of the additional risk for development of infection in the asplenic child. Explain to the child and family that severe cutaneous human papillomavirus infection may occur after stem cell transplantation (even years later) (Neven et al., 2009).

### Severe Combined Immune Deficiency

Severe combined immune deficiency (SCID) is a rare X-linked or autosomal recessive disorder; it can occur in girls or boys. SCID is characterized by absent T-cell and B-cell function. There are at least 12 types of SCID, classified according to the exact genetic defect. Infants with SCID normally demonstrate symptoms in the first few months of age (Schwartz & Sinha, 2011). SCID is a potentially fatal disorder requiring emergency intervention at the time of diagnosis (Schwartz & Sinha, 2011). Gene therapy provides some promise for the future treatment of SCID, but until then bone marrow or stem cell transplantation is necessary (Schwartz & Sinha, 2011).

#### Take Note!

Use only cytomegalovirus (CMV)-negative, irradiated blood or platelets if transfusion is necessary in the infant with SCID. CMV-positive blood could cause an infection in the infant, and T lymphocytes in blood products may cause fatal graft-versus-host disease to occur (Norville & Tomlinson, 2010).

IVIG infusions may help decrease the number of infections until bone marrow or stem cell transplantation can be done (Schwartz & Sinha, 2011). Certain children with SCID (adenosine deaminase enzyme deficiency) may benefit from lifelong subcutaneous adenosine deaminase enzyme replacement. In addition, long-term antibiotic therapy helps to contain chronic infections in some children with SCID.

## Nursing Assessment

Note history of chronic diarrhea and failure to thrive. Note history of severe infections beginning early in infancy. Inspect the mouth for persistent thrush. Auscultate the lungs, noting adventitious sounds related to pneumonia. Laboratory findings include very low levels of all of the immunoglobulins.

## Nursing Management

Preventing infection is critical. Teach the family to practice good hand washing. The child must not be exposed to persons outside the family, particularly young children. Instruct families to administer prophylactic antibiotics if prescribed. Educate families that the child should not receive live vaccines. Encourage adequate nutrition; supplemental enteral feedings may be necessary in the child with poor appetite. Administer IVIG infusions as prescribed and monitor for adverse reactions (refer to the nursing management section for hypogammaglobulinemia for further information related to IVIG administration). If the child receives a bone marrow transplant (human leukocyte antigen [HLA]-matched sibling is preferred), provide posttransplant care as outlined in Chapter 50. Teach the family that severe cutaneous human papillomavirus infection may occur after stem cell transplantation (even years later). Refer the family for genetic counseling. Provide ongoing support; this is a difficult disease for families to cope with and the therapy required is lifelong.

#### Take Note!

Monitor the child who had a bone marrow or stem cell transplant closely for a maculopapular rash that usually starts on the palms and soles; this is an indication that **graft-versus-host disease** (GVHD) is developing. GVHD is a life-threatening condition in which donor cells attack host cells (Norville & Tomlinson, 2010).

## SECONDARY IMMUNODEFICIENCIES

Secondary immunodeficiency may occur as a result of chronic illness, malignancy, use of **immunosuppressive** (lowering the immune response) medication, malnutrition or protein-losing state, prematurity, or HIV infection. This discussion will focus on HIV infection.

### HIV Infection

Worldwide, 2.1 million children younger than 18 years old are living with HIV infection and about 1,200 become infected with HIV each day (UNAIDS, 2009). Children acquire HIV either vertically or horizontally. Vertical transmission refers to perinatal (in utero or during birth) transmission or via breast milk. Horizontal transmission refers to transmission via nonsterile needles (as in intravenous drug use or tattooing) or via intimate sexual contact. With nationwide screening of blood products, HIV transmission via transfused blood products has become rare (Fahrner & Romano, 2010). HIV infection in children may be further classified depending on severity of immune suppression. This classification may serve to guide health care planning.

Infants primarily become infected through their mothers, whereas adolescents primarily contract HIV infection through sexual activity or intravenous drug use (Fahrner & Romano, 2010). In the United States, perinatal transmission of HIV infection has declined dramatically due to improved maternal detection and treatment, as well as newborn treatment (Fahrner & Romano, 2010). Data available from 46 states indicate that current incidence is 7.1 per 100,000 children under 13 years of age. (Centers for Disease Control and Prevention [CDC], 2010). Over 2200 new cases of HIV infection were reported in 2010 among adolescents 13 to 19 years of age (CDC, 2010). Currently, there is no cure for HIV infection, though survival has improved since the advent of highly active antiretroviral therapy (HAART) (see Evidence-Based Practice 48.1). In addition to improved survival, improved growth, neurodevelopment, and immune function occur with HAART (Fahrner & Romano, 2010). See EBP 48.1

## Pathophysiology

HIV affects immune function via alterations mainly in T-cell function, but it also affects B cells, natural killer cells, and monocyte/macrophage function. HIV infects the CD4 (T-helper) cells. The virus replicates itself via the CD4 cell and renders the cell dysfunctional. Immune deficiency results as the number of normal, functioning CD4 cells drops. Initially, as CD4 counts decrease, the T-suppressor (CD8) counts increase, but as the disease progresses, CD8 counts also fall. The helper T-cell function declines even in asymptomatic infants and children who have not experienced significant decreases in the

CD4 cell count. The T cells lose response to recall antigens, and this loss is associated with an increased risk of serious bacterial infection (Farland, 2011).

B-cell defects also occur in HIV-infected children, contributing to high rates of serious bacterial infections. The B cells demonstrate impaired response to mitogens and antigens. They also exhibit defective antibody production in response to antigen exposure or vaccination. Also, infants lack a pool of memory B cells for recall antigens (simply from lack of exposure). Natural killer cells also are affected by HIV infection, as they are dependent on cytokines secreted by the CD4 cells for development of functionality. Functional killer cells play a role in fighting viruses and are critical to immunity in the newborn while the T-cell line develops. Decreased function of the natural killer cells then contributes to increased severity of viral infection in the HIV-infected child or infant. Though the virus does not destroy monocytes and macrophages, their function is affected. Macrophages in the HIV-infected child exhibit decreased chemotaxis and the antigen-presenting capability of the monocytes is defective.

Without appropriate T-cell, B-cell, natural killer cell, monocyte, and macrophage function, the infant's or child's immune system cannot fight infections it ordinarily could. Recurrent infection with ordinary organisms occurs more frequently in children with HIV infection, and the infections are more severe than in noninfected children. Opportunistic infections also occur in HIV-infected children, similar to those in adults with HIV infection.

HIV rapidly invades the central nervous system in infants and children and is responsible for progressive

### EVIDENCE-BASED PRACTICE 48.1

#### DOES PATIENT EDUCATION AND SUPPORT PROMOTE ADHERENCE TO HIGHLY ACTIVE ANTIRETROVIRAL THERAPY (HAART) FOR HIV/AIDS?

##### STUDY

The key determinant of degree and length of viral suppression in HIV infection is high adherence to HAART. Conversely, poor adherence leads to treatment failure. Children potentially have a significant number of years of life for which they will need to remain compliant with HAART. Each period of noncompliance further contributes to cross-resistance, limiting future treatment options. The authors evaluated a large number of randomized controlled trials that examined the effectiveness of patient education and support in improving HAART adherence.

##### Findings

Education and support interventions are effective in improving HAART adherence. The most effective interventions are those delivered over a 12-week period or longer,

targeting individuals rather than groups, and that provide practical medication management skills.

##### Nursing Implications

HAART adherence is critical to the potential life of an HIV-infected child. Despite numerous medication side effects and the stigma associated with HIV infection, nurses can make a difference in these children's lives. Educate parents at every opportunity about the importance of HAART adherence. Provide families with ideas for managing unpleasant side effects of antiretroviral drugs. Involve children in medication administration. Provide developmentally appropriate education to children and adolescents. Praise families' and children's efforts at HAART adherence.

Adapted from Reuda, S., Park-Wyllie, L. Y., Bayoumi, A. M., Tynan, A. M., Antoniou, T. A., Rourke, S. B., et al. (2007). Patient support and education for promoting adherence to highly active antiretroviral therapy for HIV/AIDS. *The Cochrane Library* 2007, 4. Indianapolis, IN: John Wiley & Sons.

HIV encephalopathy. As a result of encephalopathy, acquired microcephaly, motor deficits, or loss of previously achieved developmental milestones may occur. In children with progressive HIV encephalopathy, neurologic symptoms may present before immune suppression.

## Therapeutic Management

Current recommendations for treatment of HIV infection in children include the use of a combination of antiretroviral drugs (Fahrner & Romano, 2010). Medication therapy ranges from single-drug therapy in the asymptomatic HIV-exposed newborn to highly active antiretroviral therapy, consisting of a combination of antiretroviral drugs. Medications are prescribed based on the severity of the child's illness. One of the goals of HAART is to prevent or arrest progressive HIV encephalopathy (Fahrner & Romano, 2010).

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1743. Assessment findings pertinent to HIV infection in children are discussed below.

### Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Failure to thrive
- Recurrent bacterial infections
- Opportunistic infections
- Chronic or recurrent diarrhea
- Recurrent or persistent fever
- Developmental delay
- Prolonged candidiasis

These signs and symptoms may be present in either the child who is undergoing initial diagnosis or the child with known HIV infection. Explore the child's current and past medical history for risk factors such as maternal HIV infection or AIDS, receipt of blood transfusions in a developing country (without adequate screening measures), adolescent or childhood sexual abuse, substance use or abuse (including intravenous drug use), or participation in vaginal or anal sex without the use of a condom. Document who the primary caregiver is, as many children with HIV have lost their parents to the disease. In addition, for the child with known HIV infection, determine the child's medications and dosages as well as the outcome of any recent health care visits or hospitalizations.

### Physical Examination

Perform a thorough and complete physical examination on the child with suspected or known HIV infection.

### BOX 48.2

#### VIROLOGIC TESTING FOR HIV-EXPOSED INFANTS (WITH POLYMERASE CHAIN REACTION)

- At birth
- 4 to 7 weeks of age
- 8 to 16 weeks of age
- Serologic testing at 12 months of age or older to document disappearance of the HIV-1 antibody

### INSPECTION AND OBSERVATION

Note presence of fever. Measure weight, height or length, and head circumference (in children younger than 3 years old) and plot this information on standard growth charts, noting whether the measurements fall within the average or below the lower percentiles. Perform a developmental screening test to detect developmental delay. Inspect the oral cavity for candidiasis. Observe work of breathing (may be increased if pneumonitis or pneumonia is present). Determine level of consciousness (may be depressed if HIV encephalopathy is present).

### AUSCULTATION AND PALPATION

Auscultate the lungs, noting adventitious breath sounds associated with pneumonia or pneumonitis. Palpate for the presence of enlarged lymph nodes (lymphadenopathy) or swollen parotid glands. Palpate the abdomen, noting hepatosplenomegaly.

### Laboratory and Diagnostic Tests

Common laboratory and diagnostic studies ordered for the assessment of HIV infection include:

- Polymerase chain reaction (PCR) test: positive in infected infants older than 1 month of age. PCR is the preferred test to determine HIV infection in infants and to exclude HIV infection as early as possible. Box 48.2 gives recommendations for testing.
- Enzyme-linked immunosorbent assay (ELISA) test: positive in infants of HIV-infected mothers because of transplacentally received antibodies. These antibodies may persist and remain detectable up to 24 months of age, making the ELISA test less accurate at detecting HIV infection in infants and toddlers than the PCR.
- Platelet count: above 500,000 (in severe HIV infection)
- CD4 counts (low in HIV infection)

## Nursing Management

Nursing care of the child with HIV infection is directed at avoiding infection, promoting compliance with the medication regimen, promoting nutrition, providing

pain management and comfort measures, educating the child and caregivers, and providing ongoing psychosocial support. Children with HIV infection may access health services through funding provided by the Ryan White Comprehensive AIDS Resources Emergency Act (Health Resources and Services Administration, the HIV/AIDS Program, 2011). This federal funding provides for primary health care and other services to persons with HIV infection. Nursing Care Plan 48.1 lists appropriate nursing diagnoses and interventions. In addition, nursing management specific to HIV infection is covered below.

### Preventing HIV Infection in Children

It is important to offer all pregnant women routine HIV counseling and voluntary testing. Depending on the stage of pregnancy, the mother should be treated with an anti-retroviral drug if she is HIV positive. Children born to HIV-positive mothers should receive a 6-week course of zidovudine (ZDV) therapy (Fahrner & Romano, 2010). Discourage breastfeeding in the HIV-infected mother and instruct her about safe alternatives to breastfeeding. Early recognition of infection is crucial so that treatment can begin, HIV encephalopathy may be prevented, and progression to acquired immune deficiency syndrome can be prevented. Educate sexually active adolescents about HIV transmission and urge them to use condoms. Counsel teens about the increased risk of HIV transmission with all forms of sexual activity, explaining that vaginal and anal sex are even riskier than oral sex. Urge teens to limit the number of sexual partners. Discourage substance use, as the effects of drugs and alcohol often impair the teen's ability to make wise choices about sexual conduct. Warn teens of the risk of contracting HIV infection via shared needles (as with intravenous drug use or via unclean needles used in tattooing). See Healthy People 2020.

#### HEALTHY PEOPLE 2020

Objective	Nursing Significance
Reduce the number of perinatally acquired HIV and AIDS cases. (Developmental)	<ul style="list-style-type: none"> <li>Encourage sexually active adolescents to seek appropriate reproductive health care and screening.</li> </ul>
Increase the proportion of pregnant females screened for sexually transmitted diseases (including HIV infection and bacterial vaginosis) during prenatal health care visits, according to recognized standards.	<ul style="list-style-type: none"> <li>For the pregnant adolescent, encourage HIV testing to determine status.</li> <li>Encourage the HIV-positive pregnant adolescent to comply with HIV treatment as prescribed.</li> </ul>

*Healthy People* Objectives based on data from <http://www.healthypeople.gov>.

#### HEALTHY PEOPLE 2020

Objective	Nursing Significance
Reduce the number of new cases of HIV infection and diagnoses among adolescents and adults.	<ul style="list-style-type: none"> <li>Discourage intravenous illicit drug use. Educate teens about the risk of contaminated tattoo needles.</li> </ul>
Reduce the number of new AIDS cases among adolescent and adult heterosexuals, males who have sex with males, and those who inject drugs.	<ul style="list-style-type: none"> <li>Encourage abstinence in adolescents.</li> <li>If adolescents are sexually active, educate about the risks of HIV transmission; encourage condom use with all sexual activity.</li> </ul>

*Healthy People* Objectives based on data from <http://www.healthypeople.gov>.

### Promoting Compliance With Antiretroviral Therapy

Before HAART was available as a treatment option, progressive HIV encephalopathy was inevitably fatal, usually within 2 years of diagnosis (Fahrner & Romano, 2010). To prevent progression of HIV disease and prevent encephalopathy, compliance with the HAART regimen is required. Educate the family about the importance of complying with the medication regimen. Help the caregivers develop a schedule for medication administration that is compatible with the family's home routine. See Healthy People 2010.

#### HEALTHY PEOPLE 2020

Objective	Nursing Significance
Reduce deaths from HIV infection.	<ul style="list-style-type: none"> <li>Educate families about the importance of complying with medication therapy (highly active antiretroviral therapy [HAART]) and receiving regularly scheduled medical evaluations.</li> </ul>
Increase the proportion of HIV-infected adolescents and adults who receive HIV care and treatment consistent with current standards.	

*Healthy People* Objectives based on data from <http://www.healthypeople.gov>.

### Reducing Risk for Infection

In the newborn whose mother is infected with tuberculosis, syphilis, toxoplasmosis, cytomegalovirus, hepatitis B or C, or herpes simplex virus, provide testing and treatment. To prevent infection with *Pneumocystis jiroveci*, administer prophylactic antibiotics as prescribed in

### Thinking About Development

Jasmine Smith is a 5-year-old female with HIV infection. She fights taking her antiretroviral medications because of the nausea and vomiting associated with them. Lucy Panco is a 15-year-old female also with HIV infection. She is noncompliant with her antiretroviral medications, also because of the associated nausea and vomiting.

How will the nurse teach Jasmine about the medications? How will she foster compliance in Jasmine?

What is the most appropriate approach for the nurse to take to educate Lucy about compliance with medications?

How will the approaches to education and encouragement of compliance be different for these two children? How will they be similar?

any HIV-exposed infant in whom HIV infection has not yet been excluded. Provide tuberculosis screening and childhood immunization in accordance with national guidelines.

#### Take Note!

Do not administer live vaccines to the immunocompromised child without the express consent of the infectious disease or immunology specialist. Immunosuppression is a contraindication to vaccination with live vaccines (Nield et al., 2009).

### Promoting Nutrition

For the infant, provide increased-calorie formula as tolerated. For the child, provide high-calorie, high-protein meals and snacks. Supplements may be added to milkshakes to increase the protein intake. Ensure that the child is able to choose foods that he or she prefers from the hospital menu. Document growth through weekly measurements of weight and height/length.

### Promoting Comfort

Children with HIV infection experience pain from infections, encephalopathy, adverse effects of medications, and the numerous procedures and treatments that are required, such as venipuncture, biopsy, or lumbar puncture. Refer to Chapter 36 for detailed information about pain assessment and management.

#### Take Note!

Family-centered care of the HIV-exposed child and HIV-infected mother may involve a multidisciplinary approach and can result in improved outcomes for both the mother and the child (Fahrner & Romano, 2010).

### Providing Family Education and Support

Educate caregivers about the medication regimen, the ongoing follow-up that is needed, and when to call the infectious disease provider. Families of HIV-infected children experience a significant amount of stress from many sources: the diagnosis of an incurable disease, financial difficulties, multiple family members with HIV, HIV-associated stigmas, desire to keep HIV infection confidential, and multiple medical appointments and hospitalizations. Parents of HIV-infected children often die of AIDS themselves, leaving care of the child to another relative or foster parent. The day care center or school that the child attends will need education about HIV, which can be provided only if the parent or caretaker consents to divulging the child's diagnosis to that agency. Provide education to the school or day care center about how the infection is transmitted (i.e., not through casual contact).

Disclosure of the diagnosis of HIV to the child is another source of stress for the family. The timing of this disclosure will vary considerably depending on the child's and family's situation. Generally, children older than 6 years of age will eventually need to have their diagnosis disclosed to them in an age-appropriate manner. They begin to ask questions and often seem to sense that something is going on other than what they've been told so far. When made aware of the diagnosis and educated about the disease, the child may exhibit a variety of reactions. Anger, depression, or school problems may occur. The child may experience a spiritual dilemma. The nurse should continue to provide emotional support to the child and family. If the disclosure results in significant emotional turmoil, refer the child and caregivers to a counselor, social worker, or psychologist.

Anticipatory grieving also may occur. Parents or caregivers may express guilt or anger over the diagnosis of HIV infection. At the other end of the spectrum, families may use denial as their method for coping. Use therapeutic communication with open-ended questions to discover the family's thoughts and fears. Provide emotional support and allow for crying and verbalization. If needed, refer the caregivers to the appropriate professional for additional psychological and emotional intervention.

Many children with HIV have psychosocial, emotional, and cognitive problems. These contribute to a lower quality of life. They are affected by the stigma of their diagnosis and often by the social isolation associated with it. They may suffer multiple losses within the family related to deaths caused by HIV infection. Children with HIV infection need significant psychosocial support and intervention. Resources for families of HIV-infected children are listed in Box 48.3.

## BOX 48.3

**RESOURCES FOR HIV-INFECTED CHILDREN AND THEIR FAMILIES**

- [www.pedaids.org](http://www.pedaids.org): Elizabeth Glaser Pediatric AIDS Foundation—resources for HIV-infected children and their families
- [www.vachss.com/help\\_text/hiv\\_aids\\_ped.html](http://www.vachss.com/help_text/hiv_aids_ped.html): Pediatric HIV infection and AIDS resources
- [www.womenchildrenhiv.org/](http://www.womenchildrenhiv.org/): Women, Children, and HIV—resources for prevention and treatment

**Consider This**

Jake Reddington, a 2-year-old diagnosed with HIV infection, is brought to the clinic by his aunt for his regular check-up. His aunt has recently taken over the care of Jake since his mother is too ill with HIV infection to care for him.

What education will be important for Jake's aunt and her family?

Discuss some of the psychosocial issues and concerns that face a child with HIV and his or her family.

**AUTOIMMUNE DISORDERS**

Autoimmune disorders result from the immune system's malfunction. The body manufactures T cells and antibodies against its own cells and organs (**autoantibodies**). The development of an autoimmune disorder is thought to be multifactorial. Potential influencing factors include heredity, hormones, self-marker molecules, and environmental influences such as viruses and certain drugs.

**Systemic Lupus Erythematosus**

Systemic lupus erythematosus (SLE) is a multisystem autoimmune disorder that affects both humoral and cellular immunity. SLE can affect any organ system, so the onset and course of the disease are quite variable. SLE is usually diagnosed after age 5 years (usually between 15 and 45 years of age), but onset can occur at any age (Mina & Brunner, 2010). The female-to-male ratio for persons affected by SLE is 4:1 in childhood and 9:1 in adolescence (Mina & Brunner, 2010). SLE is more common in non-Caucasians, and typically African American and Hispanic children and adolescents experience more severe effects from SLE than other racial or ethnic groups (Mina & Brunner, 2010).

**Pathophysiology**

In SLE, autoantibodies react with the child's self-antigens to form immune complexes. The immune complexes accumulate in the tissues and organs, causing an inflammatory response resulting in vasculitis. Injury to the tissues and pain occur. Since SLE may affect any organ system, the potential for alterations or damage to tissues anywhere in the body is significant. In some cases, the autoimmune response may be preceded by a drug reaction, an infection, or excessive sun exposure. In children, the most common initial symptoms are hematologic, cutaneous, and musculoskeletal in origin. The disease is chronic, with periods of remission and exacerbation (flares). Common complications of SLE include ocular or visual changes, cerebrovascular accident (CVA), transverse myelitis, immune complex-mediated glomerulonephritis, pericarditis, valvular heart disease, coronary artery disease, seizures, and psychosis.

**Therapeutic Management**

Therapeutic management focuses on treating the inflammatory response. Nonsteroidal anti-inflammatory drugs (NSAIDs), corticosteroids, and antimalarial agents are often prescribed for the child with mild to moderate SLE. The child with severe SLE or frequent flare-ups of symptoms may require high-dose (pulse) corticosteroid therapy or immunosuppressive drugs. When end-stage renal failure develops as a result of glomerulonephritis, dialysis becomes necessary.

**Nursing Assessment**

For a full description of the assessment phase of the nursing process, refer to page 1743. Assessment findings pertinent to SLE in children are discussed below.

**Health History**

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history are history of fatigue, fever, weight changes, pain or swelling in the joints, numbness, tingling or coolness of extremities, or prolonged bleeding. Assess for risk factors, which include female sex; family history; African, Native American, or Asian descent; recent infection; drug reaction; or excessive sun exposure.

**Physical Examination**

Measure temperature and document the presence of fever. Observe the skin for malar rash (a butterfly-shaped rash over the cheeks); discoid lesions on the face, scalp, or neck; changes in skin pigmentation; or scarring (Fig. 48.3). Document alopecia. Inspect the oral cavity for painless ulcerations and the joints for edema.

**FIGURE 48.3** The malar or butterfly rash (erythema over the cheeks in the shape of a butterfly) is typical in systemic lupus erythematosus (SLE).

Measure blood pressure, as hypertension may occur with renal involvement. Auscultate the lungs; adventitious breath sounds may be present if the pulmonary system is involved. Palpate the joints, noting tenderness. Palpate the abdomen and note areas of tenderness (abdominal involvement is more common in children with SLE than in adults). Box 48.4 lists common clinical findings in SLE.

### Laboratory and Diagnostic Findings

Laboratory findings may include decreased hemoglobin and hematocrit, decreased platelet count, and low WBC count. Complement levels, C3 and C4, will

#### BOX 48.4

##### **MOST COMMON CLINICAL MANIFESTATIONS OF SYSTEMIC LUPUS ERYTHEMATOSUS**

- Alopecia
- Anemia
- Arthralgia
- Arthritis
- Fatigue
- Lupus nephritis
- Photosensitivity
- Pleurisy
- Raynaud phenomenon
- Seizures
- Skin rashes, including malar rash
- Stomatitis
- Thrombocytopenia

also be decreased. Though not specific to SLE, the antinuclear antibody (ANA) is usually positive in children with SLE.

### Nursing Management

Nursing management of the child or adolescent with SLE is long term and supportive. Management focuses on preventing and monitoring for complications. Educate the child and family about the importance of a healthy diet, regular exercise, and adequate sleep and rest. Administer NSAIDs, corticosteroids, and antimalarial agents as ordered for the child with mild to moderate SLE and pulse corticosteroid therapy or immunomodulators to the child with severe SLE or frequent flare-ups. Refer families to support services such as the Lupus Alliance of America and the Lupus Foundation of America, links to which can be found on [thePoint](#).

### Preventing and Monitoring for Complications

Teach families to apply sunscreen (minimum SPF 15) to their child's skin daily to prevent rashes resulting from photosensitivity. Instruct the child and family to protect against cold weather by layering warm socks and wearing gloves when outdoors in the winter. If the child is outside for extended periods during the winter months, inspect the fingers and toes for discoloration. Watch for the development of nephritis by evaluating blood pressure, serum BUN and creatinine levels, and urine output and monitoring for hematuria or proteinuria. Ensure that yearly vision screening and ophthalmic examinations are performed to preserve visual function should changes occur.

#### **Take Note!**

Avascular necrosis (lack of blood supply to a joint, resulting in tissue damage) may occur as an adverse effect of long-term or high-dose corticosteroid use. Teach families to report new onset of joint pain, particularly with weight bearing, or limited range of motion to their physician or nurse practitioner (Tofferi & Gilliland, 2012).

### Juvenile Idiopathic Arthritis

Juvenile idiopathic arthritis is an autoimmune disorder in which the autoantibodies mainly target the joints. Inflammatory changes in the joints cause pain, redness, warmth, stiffness, and swelling. Stiffness usually occurs after inactivity (as in the morning, after sleep). Some forms also affect the eyes or other organs. Table 48.2 explains the three most common types. Juvenile idiopathic arthritis is a chronic disease; the child may experience healthy

TABLE 48.2

## TYPES OF JUVENILE IDIOPATHIC ARTHRITIS

Type	Definition	Nonjoint Manifestations	Complications
<b>Pauciarticular</b>	Involvement of four or fewer joints; quite often the knee is involved. Most common type	Eye inflammation, malaise, poor appetite, poor weight gain	Iritis, uveitis, uneven leg bone growth
<b>Polyarticular</b>	Involvement of five or more joints; frequently involves small joints and often affects the body symmetrically	Malaise, lymphadenopathy, organomegaly, poor growth	Often a severe form of arthritis; rapidly progressing joint damage, rheumatoid nodules
<b>Systemic</b>	In addition to joint involvement, fever and rash may be present at diagnosis.	Enlarged spleen, liver, and lymph nodes; myalgia; severe anemia	Pericarditis, pericardial effusion, pleuritis, pulmonary fibrosis

Adapted from Jones, K. B., & Higgins, G. C. (2010). Juvenile rheumatoid arthritis. In P. J. Allen, J. A. Vessey, and N. A. Schapiro (Eds.), *Primary care of the child with a chronic condition* (5th ed.). St. Louis, MO: Mosby.

periods alternating with flare-ups. In some children the disease resolves as they approach adolescence or adulthood, while others will have more severe disease that continues throughout the adult years (Jones & Higgins, 2010). Juvenile idiopathic arthritis was formerly termed “juvenile rheumatoid arthritis,” but unlike adult rheumatoid arthritis, few types of juvenile arthritis actually demonstrate a positive rheumatoid factor.

Therapeutic management focuses on inflammation control, pain relief, promotion of remission, and maintenance of mobility. NSAIDs, corticosteroids, and anti-rheumatic drugs such as methotrexate and etanercept are prescribed, depending on the type and severity of the disease. NSAIDs are helpful with pain relief, but disease-modifying (antirheumatic) drugs are necessary to prevent disease progression.

## Nursing Assessment

Note history of irritability or fussiness, which may be the first sign of this disease in the infant or very young child. Note complaints of pain, though children do not always communicate this. Document history of withdrawal from play or difficulty getting the child out of bed in the morning (joint stiffness after inactivity). Inquire about history of fever (above 39.5°C for 2 weeks or more in systemic disease).

Measure temperature (fever is present with systemic disease). Inspect skin for evanescent, pale red, nonpruritic macular rash, which may be present at diagnosis of systemic disease. Observe the gait, noting limping or guarding of a joint or extremity. Document growth,

which may be delayed. Inspect and palpate each joint for edema, redness, warmth, and tenderness (Fig. 48.4). Note positioning of joints (usually flexed in position of comfort). Mild to moderate anemia and an elevated erythrocyte sedimentation rate are common. Young children with the pauciarticular form may demonstrate a positive antinuclear antibody, and adolescents with polyarticular disease may have a positive rheumatoid factor.

## Nursing Management

Nursing management focuses on managing pain, maintaining mobility, and promoting a normal life. Refer the child to a pediatric rheumatologist to ensure that he or

FIGURE 48.4 Note the swollen, reddened joints of this child with juvenile arthritis.

she receives the most up-to-date treatment. Disease-modifying medications approved for use in children may produce better long-term outcomes than were possible in the past. Clinical research trial information is available through the Childhood Arthritis & Rheumatology Research Alliance. Encourage regular eye examinations and vision screening to allow for early treatment of visual changes and to prevent blindness.

### **Managing Pain and Maintaining Mobility**

Administer medications as prescribed to control inflammation and prevent disease progression. Refer to Drug Guide 48.1 for information related to NSAIDs, corticosteroids, and disease-modifying antirheumatic drugs. Maintain joint range of motion and muscle strength via exercise (physical or occupational therapy). Swimming is a particularly useful exercise to maintain joint mobility without placing pressure on the joints. Teach families appropriate use of splints prescribed to prevent joint contractures. Monitor for pressure areas or skin breakdown with splint or orthotic use.

### **Promoting Normal Life**

Chronic pain and decreased mobility may impact the child's psychological and emotional status significantly, during both childhood and adulthood. Providing adequate pain relief and promoting compliance with the disease-modifying medication regimen may allow the child to have a more normal life in the present as well as in the future. In addition to measures described in the previous section, encourage adequate sleep to allow the child to cope better with symptoms and to function better in school. Sleep may be promoted by a warm bath at bedtime and warm compresses to affected joints or massage. To prevent social isolation, encourage the child to attend school and ensure that teachers, the school nurse, and classmates are educated about the child's disease and any limitations on activity. Having two sets of books (one at school and one at home) allows the child to do homework without having to carry heavy books home. Modifications such as allowing the child to leave the classroom early in order to get to the next class on time may seem small but can have a significant impact on the child's life.

Encourage children and families to become involved with local support groups so they can see that they are not alone. Assist children to set and achieve goals to increase their sense of hopefulness. Special summer camps for children with juvenile arthritis allow the child to socialize and belong to a group and have been shown to promote self-esteem in the child with chronic illness. Encourage appropriate family functioning and refer the family to support groups such

as those sponsored by the American Juvenile Arthritis Organization.

## **ALLERGY AND ANAPHYLAXIS**

Allergy is an immune-mediated response resulting in an adverse physiologic event or reaction. Allergy affects up to 25% of the pediatric population (Sloand & Caschera, 2010). The extent of the allergic response is determined by the duration, rate, and amount of exposure to the allergen as well as environmental and host factors. IgE-mediated allergy will be the focus of this discussion. This type of allergic response is mediated by antigen-specific IgE antibodies. When the antibody is exposed to the antigen (allergen), rapid cell activation occurs and potent mediators and cytokines are released, resulting in changes in the blood vessels, bronchi, and mucus-secreting glands. In addition to the atopic diseases (asthma, allergic rhinitis, and atopic dermatitis), urticaria, digestive allergy, and systemic anaphylaxis are also IgE mediated. Though any allergen has the potential to trigger an anaphylactic response, food and insect sting allergies are most common (Sloand & Caschera, 2010).

### **Food Allergies**

A true food hypersensitivity or allergy is defined as an immunologic reaction resulting from the ingestion of a food or food additive. This type of reaction is an IgE-mediated response to a particular food. Food allergy affects approximately 2% to 8% of children and can lead to significant medical complications (Sloand & Caschera, 2010). During the first few years of life, the most common food allergens are milk, eggs, peanuts, tree nuts, fish and shellfish, wheat, and soy. Typically, allergies to these foods are acquired in childhood. For most children only allergies to peanuts, tree nuts, and fish and shellfish persist into adulthood (Sloand & Caschera, 2010). Most reactions occur within minutes of exposure, but they may occur up to 2 hours after ingestion. Signs and symptoms of a food allergy reaction include hives, flushing, facial swelling, mouth and throat itching, and runny nose. Many children also have a gastrointestinal reaction, including vomiting, abdominal pain, and diarrhea. In extreme cases, swelling of the tongue, uvula, pharynx, or upper airway may occur. Wheezing can be an ominous sign that the airway is edematous. Rarely, cardiovascular collapse occurs. Though the risk for anaphylaxis is small, parents, caregivers, and physicians and nurse practitioners should be vigilant when caring for children with food allergies.

## Therapeutic Management

Therapeutic management involves verifying the food allergy, avoiding the allergen, and treating the reaction with medications, including antihistamines and epinephrine (in the case of an anaphylactic reaction).

Discerning a true food allergy from intolerance to certain foods is an important part of therapeutic management. “Food intolerance” is a general term that describes an abnormal physiologic response to an ingested food or food additive that has not been proven to be immunologic. Often a milk allergy is confused with lactose intolerance. Therefore, a detailed dietary history is important when distinguishing a true allergy versus intolerance.

Preventing the development of food allergies is also a key intervention. To prevent the development of food allergies, infants should be breastfed for at least the first 6 months of life and the following common food allergens should be avoided in children younger than 1 year of age:

- Cow’s milk
- Eggs
- Peanuts
- Tree nuts
- Citrus
- Fish and shellfish (Burns, Dunn, Brady, Starr, & Blosser, 2009)

## Nursing Assessment

It is important to accurately assess children with food allergy reactions. In the initial nursing assessment, immediately assess the child for airway, breathing, or circulation problems (see Chapter 53). If the child’s condition is stable, finish the assessment. Make sure that the health history includes a detailed food history and documentation of the reaction, including the food suspected of causing the reaction, the quantity of food ingested, the length of time between ingestion and development of symptoms, the symptoms, what treatment has been administered, and the subsequent response. Note gastrointestinal symptoms such as:

- Burning in the mouth or throat
- Bloating
- Nausea
- Diarrhea

Assess for risk factors such as previous exposure to the food, history of poorly controlled asthma, or an increase in atopic dermatitis flare-ups in relation to food intake.

Inspect the skin for color, rash, hives, or edema. Auscultate the heart and lungs to determine heart rate and to assess for wheezing.

Allergy skin-prick tests and radioallergosorbent blood tests (RASTs) are used widely by physicians and

nurse practitioners to look for allergic reactions. However, these tests may have false-positive results, and children may need to avoid many foods unnecessarily (Sloand & Caschera, 2010). Food-specific IgE testing is recommended if the child has a history of food allergy. If the child has episodic symptoms, an oral challenge in a controlled setting may be appropriate. For an oral challenge, the child slowly eats a serving of the offending food over the period of 1 hour. Record vital signs and note the presence or absence of allergic symptoms.

If symptoms are chronic, a trial elimination diet may be indicated. If symptoms resolve without the food, true allergy may be present. On an elimination diet, the child should stop eating all suspicious foods for 1 to 2 weeks and then retry the foods one at a time, over a period of several days, to see whether a similar reaction occurs. Oral challenge testing and retrying of foods after an elimination diet are often done in the physician’s or nurse practitioner’s office or hospital setting if severe reactions have occurred in the past. If a similar reaction to a previous reaction to a certain food or foods occurs with the oral challenge or elimination diet testing, it is very suggestive of a food allergy. Food avoidance is recommended for those who have a highly predictive reaction to testing or a history of anaphylactic response.

## Nursing Management

Initial nursing management is aimed at stabilizing the child’s condition if an acute reaction to a food allergen is present (see Chapter 53). As stated above, medications used in the treatment of a food allergy reaction include histamine blockers and, in anaphylactic reactions, epinephrine. Teach the child (if appropriate) and the parents how and when to use these medications during an allergic reaction. The child who has been prescribed an EpiPen should carry the pen with him or her at all times. Since these reactions can be so sudden (unknown ingestion of allergen) and severe, it is helpful for the family to have a written emergency plan in case of a reaction.

### *Managing the Child’s Diet*

Aim dietary teaching at educating the child and family on how to avoid the offending foods. Families should be extremely careful when reading food labels. A dietitian may be helpful in this teaching process. Teaching Guidelines 48.1 gives information about hidden allergens in food. Teach the parents what “safe” foods can be substituted for offensive ones (Box 48.5). Children with peanut allergy should also avoid tree nuts.

Having a child with a food allergy can be very anxiety producing for parents; they often live in fear that the

## Teaching Guidelines 48.1

**ALLERGENS HIDDEN IN FOOD**

If Child is Allergic to	Teach Families to Avoid	Unexpected Locations of Common Ingredients
Milk	Artificial butter flavor, casein, lactalbumin, nougat, pudding, whey, yogurt, ghee	Some deli meats and hot dogs, nondairy products, coffee whiteners
Wheat	Cereal extract, couscous, durum, semolina, spelt	Some imitation crab meat and wheat flour shaped to look like shrimp, beef, or pork especially in Asian dishes
Eggs	Albumin, globulin, ovalbumin	Some egg substitutes and foam toppings for drinks, commercially cooked pastas
Peanuts	Fast food cooked in peanut oil, many Asian foods, baked goods with nuts or processed on equipment that also processes peanuts	Brown gravy, barbeque sauce, meat sauce, egg rolls, enchilada sauce, hot chocolate

Adapted from The Food Allergen and Anaphylaxis Network. (2012). *Allergens*. Retrieved July 3, 2011, from <http://www.foodallergy.org/section/allergens>

child may accidentally ingest an allergen. Educate the child and family about allergic reactions to help decrease their anxiety. Teach the child and family how to recognize the signs and symptoms of an allergic reaction. It may be necessary to provide information to day care providers as well as schoolteachers, staff, and camp counselors. Refer families to the Food Allergy & Anaphylaxis Network. A link to this website can be found on [thePoint](#).

## Anaphylaxis

Anaphylaxis is an acute IgE-mediated response to an allergen that involves many organ systems and may be life-threatening. In addition to nuts, shellfish, eggs, and bee or wasp stings, drugs such as penicillin and NSAIDs, radiopaque dyes, and latex are the leading causes of

anaphylaxis (Linzer, 2011). The reaction is severe and usually starts within 5 to 10 minutes of exposure, though delayed reactions are possible. Histamines and secondary mediators are released from the mast cells and eosinophils in response to contact with an allergen. Cutaneous, cardiopulmonary, gastrointestinal, and neurologic symptoms occur. Vasodilation results in a rapid decrease in plasma volume, leading to the risk of circulatory collapse. Prolonged resuscitation may be needed, and death may occur.

Therapeutic management focuses on assessment and support of the airway, breathing, and circulation. Epinephrine is usually required, and intramuscular or intravenous diphenhydramine is used secondarily. Late-onset reactions can be prevented with corticosteroids.

## Nursing Assessment

Assess patency of the airway and adequacy of breathing. Determine if circulation is sufficient. Note level of consciousness. Obtain a brief history, inquiring specifically about allergen exposure. Determine whether the child has received any medication (e.g., epinephrine or diphenhydramine) since the onset of the reaction and what effect the medication had on the symptoms. Table 48.3 gives additional signs and symptoms of anaphylaxis.

## Nursing Management

Nursing management initially focuses on supporting the airway, breathing, and circulation. Provide supplemental oxygen by mask or bag-valve-mask ventilation. Ensure that bronchodilator inhalation treatment (albuterol) is given if bronchospasm is present. Administer intravenous fluids to provide volume expansion. Administer

### BOX 48.5

#### FOOD SUBSTITUTIONS

- Replace milk with water, fruit juice, rice milk, or soy milk.
- Replace each egg with 1.5 tablespoons each of water and oil and 1 teaspoon baking powder; OR 1 packet plain gelatin with 2 tablespoons warm water added at time of use; OR 1 teaspoon yeast and a quarter-cup warm water.
- Replace peanuts or tree nuts with raisins, dates, or crispy cereal.

Adapted from Järvinen, K. M. (2009). Allergic reactions to stinging and biting insects and arachnids. *Pediatric Annals*, 34(4), 199–209; and Linzer, J. F. (2011). *Pediatric anaphylaxis*. Retrieved July 3, 2011, from <http://emedicine.medscape.com/article/799744-overview#a1>

epinephrine, diphenhydramine, and/or corticosteroids as ordered to reverse the allergic process.

### Preventing and Managing Future Episodes

It is critical to educate the family about preventing and managing future episodes. Teach the family how to use injectable epinephrine in case of subsequent allergen exposure. Intramuscular epinephrine may be given via the EpiPen® or EpiPen Jr®. Dosage is based on the child's weight. The child should carry the pen with him or her at all times. Explain to the child and family that the gray safety release on the EpiPen® should never be removed until just before use. In addition, teach the child and family that the thumb, fingers, or hand should not be placed over the black tip. Nursing Procedure 48.1 gives further instructions related to EpiPen® use. Instruct the child and family to call 911 and seek immediate medical attention after using the EpiPen®. Warn the child that the epinephrine may make him or her feel as if the heart is racing.

Day care providers, school nurses, teachers, and staff who interact with the child must know how to recognize an anaphylactic event. In 2004, Public Law No. 108-377, Asthmatic Schoolchildren's Treatment and Health Management Act, was passed by the U.S. Congress. This law is intended to ensure that students with severe allergies can carry prescribed medications (i.e., EpiPen®) with them. All children with allergies should have an action plan in place at the school or day care center. Advise the child to wear a medical ID alert bracelet or necklace at all times.

Teach children and families to avoid known food allergens. Avoid stings from bees and wasps (Hymenoptera) by being alert when eating outdoors, wearing long

sleeves and pants when in fields, and having bee and wasp hives or nests removed from areas near the family's home. Avoid use of cephalosporins in children with severe penicillin allergy. Desensitization is available for children with severe penicillin allergy. Desensitization involves administration of increasingly larger doses of penicillin over a period of hours to days in an intensive care setting.

### Latex Allergy

Latex allergy is an IgE-mediated response to exposure to latex, a natural rubber product used in many common items (especially gloves in the health care setting). The pathophysiology of latex allergy is similar to that of food allergy. Avoidance of latex products is recommended for those who are allergic to it. An immediate allergic reaction may occur if a latex-allergic child comes into contact with latex. Latex allergy can also result in anaphylaxis (refer to section above on anaphylaxis).

### Nursing Assessment

Screen all children who visit a health care facility of any kind for latex allergy. Ask if the child is allergic to rubber gloves or has ever developed hives after exposure to them. Ask the parent if the child has symptoms such as coughing, wheezing, or shortness of breath after glove exposure. Has the child ever had swelling in the mouth or complained that the mouth itched after a dental examination? Determine whether the child has ever had allergic symptoms after eating foods with a known cross-reactivity to latex, such as pear, peach, passion fruit, plum, pineapple, kiwi, fig, grape, cherry,

## NURSING PROCEDURE 48.1

## Using the EpiPen® or EpiPen Jr.®

1. Grasp the EpiPen® or EpiPen Jr.® with the black tip pointing downward, forming a fist (Fig. 1).

2. With the other hand, pull off the gray safety release.

3. Swing and jab the EpiPen® firmly into the outer thigh at a 90-degree angle and hold firmly there for 10 seconds (Figs. 2 and 3).

4. Remove the EpiPen® and massage the thigh for 10 seconds.

Adapted from Dey Pharma. (2011). *How to use EpiPen autoinjector*. Retrieved July 11, 2012, from [http://www.cdc.gov/hiv/surveillance/resources/reports/2010report/pdf/2010\\_HIV\\_Surveillance\\_Report\\_vol\\_22.pdf#Page=5](http://www.cdc.gov/hiv/surveillance/resources/reports/2010report/pdf/2010_HIV_Surveillance_Report_vol_22.pdf#Page=5)

melon, nectarine, papaya, apple, apricot, banana, chestnut, carrot, celery, avocado, tomato, or potato. For the child who has come into contact with latex, assess for symptoms of a reaction such as hives; wheeze; cough; shortness of breath; nasal congestion and rhinorrhea; sneezing; nose, palate, or eye pruritus; or hypotension.

latex allergy on the chart, the child's identification band, the medication administration record, and the physician's order sheet. Refer families to resources for persons with latex allergy. Some helpful links are provided on [thePoint](#).

## Nursing Management

Nursing management of latex allergy focuses on preventing exposure to latex products. Instruct children and their families to avoid foods with a known cross-reactivity to latex such as those listed above. If the child is exposed to latex, remove the irritating substance and cleanse the area with soap and water. Assess for the need for resuscitation and perform it if needed. Become familiar with your institution's latex allergy policy. Know which products contain latex and which do not. Document

### KEY CONCEPTS

- Waning of maternal antibodies in early infancy while humoral immunity is developing leads to physiologic hypogammaglobulinemia, placing the young infant at risk for overwhelming infection.
- Infants and young children have large lymph nodes, tonsils, and thymus compared with adults.
- Infants have decreased phagocytic activity, placing them at higher risk for serious infection.

- Children with immune disorders often show a decreased or absent response to delayed hypersensitivity skin testing (e.g., the tuberculosis test).
- The ELISA test for HIV detects only antibodies to HIV (which in the infant may be maternal in origin), whereas the PCR test for HIV tests for HIV genetic material, making it the more accurate test for HIV infection in infants and young children.
- Primary immune deficiencies such as SCID and Wiskott-Aldrich syndrome are congenital and serious; they can be cured only by bone marrow or stem cell transplantation.
- Systemic lupus erythematosus is a chronic autoimmune disorder that can affect any organ system, primarily causing vasculitis.
- Juvenile idiopathic arthritis results in chronic pain and affects growth and development as well as school performance.
- Nasal, palatal, or throat pruritus and difficulty breathing may indicate an anaphylactic reaction.
- Various forms of hypogammaglobulinemia may be treated with exogenous immunoglobulin administered intravenously every several weeks, allowing children to lead a healthier life with fewer infections.
- Children with severe allergy or previous anaphylactic episodes must avoid contact with allergens.
- Nursing management of lupus focuses on preventing flare-ups and complications.
- Managing pain, maintaining mobility, and administering disease-modifying medications are key nursing interventions in the management of juvenile idiopathic arthritis.
- HIV infection may be prevented in infants by prenatal screening and maternal treatment, as well as postnatal treatment with zidovudine.
- HIV infection in children often results in encephalopathy and developmental delay.
- Spread of HIV infection can be prevented in adolescence by avoiding high-risk behaviors.
- For children with immune deficiency or autoimmune disease, prevention of infection is a primary nursing concern.
- A chronic illness such as immune deficiency, SLE, or juvenile arthritis has a significant impact on the family as well as the child.
- When planning care for the child with an immune deficiency or autoimmune disorder, the nurse should include the child and the family.

- To promote proper growth, encourage the child with an immune or autoimmune disorder to eat a balanced diet.
- Teach families of children with immune deficiencies about infection prevention.
- Teach the family of the child with juvenile arthritis about ways to decrease pain while increasing or maintaining the child's mobility.
- Teach families of children with severe allergy how to avoid allergens and how to use the EpiPen. Make sure that staff at the child's school or day care center are aware of the allergy.
- Explain to the child with severe allergy the importance of wearing a medical ID alert bracelet or necklace.

## MULTIPLE CHOICE QUESTIONS

- The nurse is caring for a 6-year-old with juvenile idiopathic arthritis. The mother states that she has trouble getting her daughter out of bed in the morning and believes the girl's behavior is due to a desire to avoid going to school. What is the best advice by the nurse?
  - Refer the girl to a psychologist for evaluation of school phobia related to chronic illness.
  - Administer a warm bath every morning before school.
  - Give the child her prescribed NSAIDs 30 minutes before getting out of bed.
  - Allow her to stay in bed some mornings if she wants.
- A 14-year-old with systemic lupus erythematosus wants to know how to care for her skin. What should the nurse teach this adolescent?
  - Careful sun tanning will give her skin an attractive color.
  - No special skin care is needed.
  - Use sunscreen daily to avoid rashes.
  - Use makeup to camouflage the butterfly rash on her face.
- The mother of a child with hypogammaglobulinemia reports that her child had a fever and slight chills with an intravenous gammaglobulin infusion last month. She wants to know what other course of treatment might be available. What is the best response by the nurse?
  - Administration of acetaminophen or diphenhydramine prior to the next infusion may decrease the incidence of fever or chills.
  - Giving the gammaglobulin intramuscularly is recommended to prevent a reaction.
  - Talk to her physician or nurse practitioner about alternative medications that may be used to boost the gammaglobulin level in the blood.
  - If the child is no longer experiencing frequent infections, then the IV infusions may not be necessary.
- A 4-month-old infant born to an HIV-infected mother is going into foster care because the mother is too ill to care for the child. The foster mother wants to know if the infant is also infected. What is the best response by the nurse?
  - "It's too early to know; we have to wait until the infant has symptoms."
  - "Since the mother is so ill, it's likely the child is also infected with HIV."
  - "The ELISA test is positive, so the child is definitely infected."
  - "The PCR test is positive; this indicates HIV infection, which may or may not progress to AIDS."
- A mother has received instructions about avoiding wheat and soy allergens. Which response by the mother would indicate that further education is needed?
  - "I will not feed my child any breads made with wheat flour."
  - "I will allow my child to eat semolina pasta, the kind he loves."
  - "I will not feed my child shakes made with soy protein."
  - "I will read labels to be sure I am avoiding wheat and soy."

## CRITICAL THINKING EXERCISES

- Develop a discharge teaching plan for a 14-year-old with systemic lupus erythematosus who will be taking corticosteroids long term.
- Devise a developmental stimulation plan for a 22-month-old with HIV infection and encephalopathy with developmental delay (to the level of a 9-month-old).
- Determine an appropriate nursing plan of care for an infant who has undergone bone marrow transplantation for severe combined immune deficiency.
- Develop a prioritized list of nursing diagnoses for a child with HIV infection, candidiasis, poor growth, and pneumonia requiring oxygen.
- A child with recurrent infections is being evaluated. Other than information about onset of symptoms and events leading up to this present episode, what other types of information would the nurse ask while obtaining the history?

## STUDY ACTIVITIES

- In the clinical setting, compare the growth and development of two children the same age, one with HIV infection and one who has been healthy.

2. Attend an outpatient clinic that provides care to children with HIV infection. Observe the physician or nurse practitioner during office visits and attend a multidisciplinary planning meeting. Identify the role of the registered nurse in providing family education, coordination of care, and referrals.
3. Conduct an Internet search to determine the educational material available to children and their families related to immune deficiencies, autoimmune disorders, or allergies.
4. Research your clinical institution's policies related to latex allergy, alternative products available at the institution, and how to obtain them for a child with latex allergy. Provide a presentation to your clinical group about your findings.

## Nursing Care of the Child With an Endocrine Disorder

### Learning Objectives

*Upon completion of the chapter, the learner will be able to:*

1. Define the key terms used in this chapter.
2. Describe the major components and functions of a child's endocrine system.
3. Differentiate between the anatomic and physiologic differences of the endocrine system in children versus adults.
4. Identify the essential assessment elements, common diagnostic procedures, and laboratory tests associated with the diagnosis of endocrine disorders in children.
5. Identify the common medications and treatment modalities used for palliation of endocrine disorders in children.
6. Distinguish specific disorders of the endocrine system affecting children.
7. Link the clinical manifestations of specific disorders in the endocrine system of a child with the appropriate nursing diagnoses.
8. Establish the nursing outcomes, evaluative criteria, and interventions for a child with specific disorders in the endocrine system.
9. Develop child/family teaching plans for the child with an endocrine disorder.

*Carlos Rodriguez, 12 years old, is seen in the clinic today with complaints of weakness, fatigue, blurred vision, and headaches. His mother states, "Carlos' teacher has noticed mood changes and is concerned about his behavior at school. He's always been a good boy. I'm not sure what's going on."*

### Words of Wisdom

Words of Wisdom  
 Endocrine disorders in children often elude the medical radar screen.

**The** endocrine system consists of various glands, tissues, or clusters of cells that produce and release hormones. **Hormones** are chemical messengers that stimulate and/or regulate the actions of other tissues, organs, or other endocrine glands that have specific receptors to a hormone. Along with the nervous system, the endocrine milieu influences all physiologic effects such as growth and development, metabolic processes related to fluid and electrolyte balance and energy production, sexual maturation and reproduction, and the body's response to stress. The release patterns of the hormones vary, but the level in the body is maintained within specified limits to preserve health.

Problems develop in the endocrine system when there is a deficiency (**hypofunction**) or excess (**hyperfunction**) of a specific hormone. In children, endocrine conditions often develop insidiously and result from an insufficient production of hormones. If the problem is not diagnosed and treated early, delayed growth and development, cognitive impairments, or death may result. Generally, the treatment plan involves correction of the underlying reason for the dysfunction, such as surgical removal of a tumor, and supplementation of missing hormones or adjustment of specific hormone levels. This allows most children to live normal lives.

## VARIATIONS IN ANATOMY AND PHYSIOLOGY

The organs or tissues of the endocrine system include the hypothalamus, pituitary gland, thyroid gland, parathyroid glands, adrenal glands, gonads, and islets of Langerhans located in the pancreas. Figure 49.1 shows the location of the organs or tissues involved in the endocrine system. Typically, most endocrine glands begin to develop during the first trimester of gestation, but their development is incomplete at birth. Thus, complete hormonal control is lacking during the early years of life, and the infant cannot appropriately balance fluid concentration, electrolytes, amino acids, glucose, and trace substances.

### Hormone Production and Secretion

The hypothalamic-pituitary axis produces a number of releasing and inhibiting hormones that regulate the function of many of the other endocrine glands, including the thyroid gland, the adrenal glands, and the male and female gonads. Some glands regulate their function in connection with the nervous system, such as the islets of Langerhans in the pancreas and the parathyroid glands. Many other cells in the body secrete hormones such as the pineal gland, the scattered epithelial cells in the gastrointestinal tract, and the thymus. Disorders related to these other cells are discussed in other chapters in this textbook.

Figure 49.1 shows the major glands, the hormones produced by the glands, and the effect each hormone has on the target cell, tissue, or organ. The process of hormone production and secretion involves the principle of feedback control. One gland produces a hormone that affects another endocrine gland. Once the physiologic effect is achieved, this gland, known as the target organ, inhibits the further release of the original hormone. The reverse occurs when the first gland detects low levels of the target gland hormone. If the original gland does not release enough of the hormone, the inhibition process stops so that the gland increases the production of the hormone. The endocrine system and the nervous system work closely together to maintain an optimal internal environment for the body, known as homeostasis.

## COMMON MEDICAL TREATMENTS

Primarily, the treatment of endocrine disorders involves decreasing hormone production (in cases of hypersecretion) or replacing the hormones (in cases of hypofunction). The first step in treating many of these disorders is to screen for potential problems, especially when familial patterns are present. Since the proper functioning of the endocrine system is critical to growth and development, the child's growth is affected by endocrine dysfunction and lack of treatment may lead to serious problems, such as intellectual disability or even death. Early treatment is often associated with better prognosis and prevention of long-term problems. The next step in treatment involves identifying underlying causes for the dysfunction (e.g., a tumor or growth that requires surgical removal or irradiation). The use of supplemental hormone in cases of hypofunction is generally successful in children, as is the use of inhibiting substances in cases of hyperfunction.

Common Medical Treatments 49.1 describes the common treatments used in children with endocrine disorders. The table explains and gives indications for each treatment as well as relevant nursing implications. Advances in technology and our understanding of molecular biology continue to increase our knowledge of these disorders and the modalities needed to prevent them or improve quality of life for affected children. These advances are vital, since the whole body is influenced by the endocrine milieu.

Drug Guide 49.1 lists the medications most commonly used to treat endocrine disorders. The table gives the actions and indications of each drug, as well as pertinent nursing implications. Many of the medications are synthetic preparations of the actual hormones. It is important to maintain specific blood levels of the drugs to mimic the actual hormone in the body. Nurses must monitor for side effects of too little or too much of the hormone in the child's system. Most endocrine disorders in children require treatment and follow-up with a pediatric endocrinologist as well as a multidisciplinary team that includes a registered nurse who specializes in this area.

FIGURE 49.1 Location of the endocrine glands in the body, with the major effects of the glands listed.

## NURSING PROCESS OVERVIEW FOR THE CHILD WITH AN ENDOCRINE DISORDER

The nursing care of the child with an endocrine disorder requires astute assessment skills, accurate nursing diagnoses and expected outcomes, skilled interventions, and evaluation of the entire process. Children, especially very young ones, easily develop imbalances such as fluid and electrolyte disturbances that can cause further problems. Most of the endocrine disorders are chronic conditions that require ongoing care related to health maintenance, education, developmental issues, and psychosocial needs. These conditions are sometimes complex and range from mild to profound. Early

diagnosis and treatment can improve the long-term outcomes for these children.

**Remember Carlos, the 12-year-old with weakness, fatigue, blurred vision, headaches, and mood changes? What additional health history and physical examination assessment information should the nurse obtain?**

### Assessment

Nursing assessment of a child with endocrine dysfunction includes obtaining a thorough health history, performing

## COMMON MEDICAL TREATMENTS 49.1

Treatment	Explanation	Indications	Nursing Implications
Surgery	Surgical removal of tumors or cysts	Any endocrine malfunction caused by the presence of a mass	<ul style="list-style-type: none"> <li>• Provide routine preoperative and postoperative care, depending on location and extent of surgery.</li> <li>• Keep family informed of choices.</li> </ul>
Irradiation/ radioactive iodine	Radiation is used to influence the hormone secretion of a gland; it is less invasive than surgery.	Hyperfunction of an endocrine gland; may be used when surgery is not possible	<ul style="list-style-type: none"> <li>• Prepare child for specific procedures following protocols.</li> <li>• Explain the procedure.</li> <li>• Check to ensure child has no sensitivity to iodine preparations.</li> </ul>
Glucose monitoring	Fingerstick blood sample several times per day	Monitoring of glucose control	<ul style="list-style-type: none"> <li>• Teach family appropriate procedure.</li> <li>• Refer family to sources for equipment and supplies.</li> <li>• Assist family to develop a system of record keeping that works for them.</li> </ul>
Dietary interventions (medical nutrition therapy)	Restriction or manipulation of dietary intake	Diabetes mellitus	<ul style="list-style-type: none"> <li>• Refer family to a dietitian specializing in pediatric diabetes mellitus.</li> <li>• Reinforce teaching related to special diets.</li> </ul>

## DRUG GUIDE 49.1 COMMON DRUGS FOR ENDOCRINE DISORDERS

Medication	Actions/Indications	Nursing Implications
Insulin	Used for DM to replace body's natural insulin, which is necessary for proper glucose use. Indicated for DM type 1 and, sometimes, DM type 2	<ul style="list-style-type: none"> <li>• Monitor vital signs and blood glucose levels.</li> <li>• Educate child and family on proper techniques, actions, and adverse effects.</li> <li>• Rotate site of injections to prevent adipose hypertrophy.</li> </ul>
Oral hypoglycemic drugs (glipizide, glyburide, metformin)	Assist body's production of insulin by stimulating $\beta$ cells to secrete more insulin Indicated for DM type 2	<ul style="list-style-type: none"> <li>• Monitor vital signs and glucose levels.</li> <li>• Administer with food to minimize gastric upset.</li> <li>• Instruct child and family on use of drug and adverse effects.</li> <li>• Warn family that some over-the-counter or other drugs may increase hypoglycemic effect.</li> </ul>
Growth hormone (GH)/somatotropin (Humatrope)	Stimulates linear bone, skeletal muscle, and organ growth Used for GH deficiency, growth failure related to inadequate pituitary hormone	<ul style="list-style-type: none"> <li>• Monitor blood sugar and electrolyte levels.</li> <li>• Administer before epiphyses are fused.</li> <li>• Monitor growth with accurate measurements.</li> <li>• Instruct child and family on appropriate route and method of administration.</li> <li>• Periodic thyroid function tests will be needed.</li> <li>• May interact with glucocorticoid therapy</li> <li>• Monitor for limping or complaints in knee or hip related to slipped epiphysis.</li> </ul>
Ocreotide acetate (Sandostatin)	Suppresses GH release Indicated for acromegaly	<ul style="list-style-type: none"> <li>• Monitor for biliary tract abnormalities, glucose tolerance, and hypothyroidism.</li> <li>• Give subcutaneous injections between meals to decrease gastric effects.</li> </ul>

**DRUG GUIDE 49.1 COMMON DRUGS FOR ENDOCRINE DISORDERS** (continued)

Medication	Actions/Indications	Nursing Implications
Corticosteroids (dexamethasone or hydrocortisone)	Cortisol replacement in congenital adrenal hyperplasia, absence of adrenal glands. Also used to close epiphyseal plates in hyperpituitarism	<ul style="list-style-type: none"> <li>• Give with milk or food.</li> <li>• May need to increase dose if child is ill or runs fever</li> <li>• Monitor for edema, weight gain, glycosuria, signs of infection, and symptoms of peptic ulcer development.</li> <li>• Do not decrease dose or abruptly stop drug to avoid adrenal crisis.</li> </ul>
Desmopressin acetate (DDAVP)	Synthetic antidiuretic hormone that promotes reabsorption of water by action on renal tubules Used to control diabetes insipidus	<ul style="list-style-type: none"> <li>• Contraindicated in nephrogenic diabetes insipidus</li> <li>• Monitor for water intoxication, signs and symptoms of hyponatremia, and adverse effects such as nasal irritation, headache, nausea, and increased blood pressure.</li> <li>• Record fluid intake and output and weigh child daily.</li> <li>• Titrate dose until appropriate fluid output is obtained.</li> <li>• Instruct child and family in proper intranasal administration.</li> <li>• Avoid over-the-counter cough/hay fever preparations, as they may decrease the drug response.</li> <li>• Store in refrigerator.</li> </ul>
Levothyroxine (Synthroid)	Thyroid hormone replacement for hypothyroidism	<ul style="list-style-type: none"> <li>• Check blood pressure and pulse before each dose.</li> <li>• Monitor fluid intake and output, daily weights, and thyroid function tests.</li> <li>• Watch for thyroid storm.</li> <li>• Report irritability or anxiety.</li> <li>• Instruct child and family to avoid over-the-counter preparations with iodine or foods such as soybeans, iodized salt, tofu, and turnips.</li> <li>• Administer at same time each day.</li> </ul>
Methimazole, propylthiouracil	Antithyroid drug; blocks synthesis of $T_3$ and $T_4$ Indicated for hyperthyroidism	<ul style="list-style-type: none"> <li>• Check pulse and blood pressure before each dose.</li> <li>• Monitor input and output, daily weights, serum <math>T_3</math> and <math>T_4</math> levels; watch for edema, leukopenia, thrombocytopenia, or agranulocytosis.</li> <li>• Administer with meals to decrease gastric upset.</li> <li>• Give at the same time each day.</li> <li>• Store in light-resistant container.</li> <li>• Instruct child and family to report sore throat, mouth lesions, unusual bleeding, or bruising.</li> <li>• Signs of overdose: periorbital edema, cold intolerance, mental depression</li> <li>• Signs of inadequate dose: tachycardia, diarrhea, fever, or irritability</li> </ul>
Mineralocorticoid (Florinef)	Promotes reabsorption of Na and K, water from distal renal tubules Used in adrenal insufficiency	<ul style="list-style-type: none"> <li>• Monitor daily weights, blood pressure, and intake and output.</li> <li>• Observe for potassium depletion.</li> <li>• Titrate dose to lowest effective dose.</li> <li>• Adverse effects include flushing, sweating, headache, and increased blood pressure.</li> </ul>

Adapted from Karch, A. (2010). *2010 Lippincott's nursing drug guide*. Philadelphia: Wolters Kluwer Health/Lippincott Williams & Wilkins; and Taketomo, C. K., Hodding, J. H., & Kraus, D. M. (2010). *Lexi-comp's Drug Reference Handbook: Pediatric & Neonatal Dosage Handbook* (18th ed.). Hudson, OH: Lexi-comp, Inc.

a physical assessment, and assisting with or obtaining laboratory and diagnostic tests. The clinical manifestations of endocrine disorders occur as a result of the altered control of the bodily processes normally regulated by the gland or hormone. These manifestations present in many areas of the body because of the diverse functions associated with the endocrine system.

### Health History

The health history should include questions regarding any family history of an endocrine disorder or growth and development difficulties. Use a genogram or family tree to detail the information about the family history in a clear and concise manner.

Discuss prenatal history, including any maternal factors that may affect growth and development such as substance abuse, use of tobacco or alcohol, and Graves disease; birth history, such as trauma during delivery, birth size, feeding difficulties, and neonatal screening and results; past medical history, such as any chronic childhood disease, treatment for any endocrine problems, recent gastroenteritis or viral syndrome, or exposures to exogenous steroids or gonadotropins; and growth and development patterns, including presence of any delays, learning disabilities, and early or late development of secondary sexual characteristics.

Discuss present complaints or illness. Note onset of symptoms, whether gradual or sudden. Endocrine disorders often cause problems in normal growth and development as well as behavioral changes. Question the parent or caregiver about prior growth patterns, achievement of developmental milestones, and the child's behavior. Inquire about recent increases or decreases in weight and height, changes in physical appearance, sleep patterns, muscle weakness, cramps, twitching, or headaches. Have the child and family describe the child's activities on a typical day, including school performance, to identify subtle variations in the child's behavior or moods. For example, a child who is typically quiet might ordinarily be less active than average children of that age, and the child with decreased endocrine function also often displays inactivity and fatigue. By having the family and child describe a typical day, the nurse can distinguish between what is appropriate for that child and what may be a change related to endocrine dysfunction.

In addition, obtain a history of dietary and elimination habits. Note extreme thirst, excessive appetite, vomiting, or frequent voiding. Children with endocrine disorders may have some of these symptoms.

### Physical Examination

Physical examination of the child with an endocrine disorder includes inspection and observation, auscultation,

percussion, and palpation. Table 49.1 lists key physical examination findings that may be present in the child with endocrine dysfunction.

### INSPECTION AND OBSERVATION

Note a fatigued appearance, poor muscle tone, sweating, faintness, nervousness, or confusion. Inspect the head and face, and note hair texture and growth, a protruberant tongue, drooping eyelids, or **exophthalmos** (protrusion of the eyeballs). Plot the child's height and weight on growth charts to determine abnormal growth velocity, which occurs in many of these disorders.

### AUSCULTATION

Auscultate the heart and lungs. Note heart rate and rhythm. During auscultation of the lungs, note labored respiratory effort, such as Kussmaul breathing, which occurs in diabetic ketoacidosis. Document blood pressure.

### PERCUSSION AND PALPATION

Percuss and then palpate the abdomen. Dull (nontympanic) sounds or the presence of masses may indicate constipation or a tumor of the ovaries.

### Laboratory and Diagnostic Testing

Common Laboratory and Diagnostic Tests 49.1 describes the diagnostic tests and procedures frequently used in identifying and monitoring endocrine disorders in children. Serum and urine hormone and other levels are used to determine whether amounts are adequate, deficient, or excessive. Radiographic studies are used to evaluate bone maturation and growth potential as well as density or tissue calcification. Genetic studies may be used to determine enzyme deficiencies or chromosome defects. Stimulation studies provide a more accurate or definitive test for identifying the disorder after preliminary serum levels are abnormal. Serial blood sampling identifies peak or trough levels of hormones. Computed tomography (CT) scans, magnetic resonance imaging (MRI), nuclear medicine studies, and ultrasonography are used to look for tumors, cysts, or structural defects.

### Nursing Diagnoses, Goals, Interventions, and Evaluation

After completing the assessment, the nurse identifies nursing diagnoses with related goals/outcomes, interventions, and evaluations. The nursing diagnoses for a child with endocrine dysfunction may include:

- Delayed growth and development
- Disturbed body image

TABLE 49.1

## KEY PHYSICAL EXAMINATION FINDINGS RELATED TO ENDOCRINE PROBLEMS

Height and weight	Below 3rd percentile or above 90th percentile (pituitary, thyroid, adrenal, or diabetes mellitus)
Hair	Coarse, brittle, excessive (hypothyroidism) Abnormal distribution (adrenal disorders)
Face	Round with hair growth (Cushing syndrome) Deformities or abnormal features (hypoparathyroidism)
Eyes	Blurred or changes in vision (diabetes mellitus, pituitary tumors, precocious puberty)
Mouth	Delayed dentition (hypocalcemia, hypopituitarism) Fruity breath (ketoacidosis)
Neck	Goiter (hyperthyroidism)
Skin	Cool to touch, dry (hypothyroidism) Changes in color or texture (pituitary disorders) Easy bruising, striae (Cushing syndrome)
Chest	Tachycardia (hyperthyroidism) Palpitations, sweating (thyroid disorders) Deep, labored breathing (ketoacidosis) Hypertension (Cushing syndrome)
Abdomen	Extreme weight loss (diabetes mellitus) Extreme fat (Cushing syndrome) Changes in bowel habits (SIADH, diabetes insipidus, diabetes mellitus)
Fingers	Trembling (hyperthyroidism, parathyroid disorders)
Genitals	Excessive growth (adrenogenital syndrome) Early growth (precocious puberty) Delayed growth (hypopituitarism)

## COMMON LABORATORY AND DIAGNOSTIC TESTS 49.1

Diagnostic Test or Procedure	Explanation	Indications	Nursing Implications
Newborn metabolic screening programs (refer to Chapter 31 for further information)	Newborn blood testing to identify certain harmful or potentially fatal disorders that are otherwise not apparent at birth. Disorders tested vary by state.	Identify newborns so that treatment can begin early to prevent impact of disorder, such as severe cognitive impairment or death	<ul style="list-style-type: none"> <li>Refer to each state's protocol for fetal/newborn screening for endocrine disorders.</li> <li>Explain to family the rationale and procedure.</li> <li>Collect blood sample accurately.</li> <li>Collect prior to blood transfusion if possible.</li> <li>Ensure screening is done for early discharges.</li> <li>Screening between 24 and 48 hours is satisfactory but optimal screening is performed between the third and fifth day of life.<sup>a</sup></li> <li>If collected before 24 hours of age, a repeat test is needed within 14 days.</li> </ul>

**COMMON LABORATORY AND DIAGNOSTIC TESTS 49.1** (continued)

Diagnostic Test or Procedure	Explanation	Indications	Nursing Implications
Random serum hormone levels	Serum levels of various hormones; immunoassay measures levels with very small amounts of blood.	High or low levels are used to evaluate the function of the specific gland.	<ul style="list-style-type: none"> <li>• May need to draw specimens at specific times</li> <li>• Keep child NPO after midnight before test if ordered.</li> <li>• Diurnal variations and episodic secretion of many hormones may require special directions or further testing.</li> </ul>
Self-monitoring blood glucose (SMBG)	Fingerstick (monitors that utilize alternative sites, such as the forearm, are available) blood sample several times per day Noninvasive methods are being developed. <sup>b</sup>	Monitor glucose level and effectiveness of treatment	<ul style="list-style-type: none"> <li>• Teach family appropriate procedure.</li> <li>• Refer family to sources for equipment and supplies.</li> <li>• Assist family to develop a system of record keeping that works for them.</li> <li>• Refer to Teaching Guideline 49.2.</li> </ul>
Fasting plasma glucose (FPG)	Fasting forces the body to produce glucagon, which causes the release of glucose. In a healthy child the body will respond by releasing insulin, therefore lowering blood glucose and preventing hyperglycemia	Detect hyperglycemia related to diabetes or other conditions such as Cushing syndrome or liver or kidney disease Can detect prediabetes	<ul style="list-style-type: none"> <li>• Child may not have had any caloric intake for at least 8 hours.</li> <li>• Draw sample prior to insulin or oral diabetic medications.</li> <li>• Normal value is less than 100 mg/dL; impaired fasting glucose or prediabetes is between 100 and 125 mg/dL; diabetes is considered with a result greater than or equal to 126 mg/dL on two separate occasions.</li> </ul>
2-hour plasma glucose test (2-h PG)	Oral glucose tolerance test Oral glucose is ingested and in a healthy child insulin will respond and return blood glucose to normal levels.	Usually performed to detect diabetes, often gestational diabetes Can also detect prediabetes	<ul style="list-style-type: none"> <li>• Child should not have taken any insulin or oral diabetic medication before the test.</li> <li>• Time of oral glucose ingestion needs to be noted.</li> <li>• Specimen to be drawn at specified time interval from ingestion</li> <li>• May have limited value in diagnosing children<sup>b</sup></li> </ul>
Urine or serum ketone testing	Ketones are the result of the metabolism of fat and in a healthy child are present in insignificant amounts	Screening for ketones in urine is regularly performed in children, people with diabetes, hospitalized patients, preoperatively, and in pregnant women. In children, ketones found in urine during routine urinalysis can detect undiagnosed diabetes. In children with diabetes, the presence of ketones in serum or urine is a sign that their diabetes is not well controlled and can be an early sign of diabetic ketoacidosis (DKA).	<ul style="list-style-type: none"> <li>• Urine ketone testing can be performed using dipsticks at the bedside and at home (follow manufacturer's directions; time reaction accurately and compare the strip to the control chart on the bottle).</li> <li>• Encourage testing for ketones when blood glucose is elevated, when therapy regimen is changing, or during times of stress or illness.</li> </ul>

(continued)

## COMMON LABORATORY AND DIAGNOSTIC TESTS 49.1 (continued)

Diagnostic Test or Procedure	Explanation	Indications	Nursing Implications
Hemoglobin A1C (glycated hemoglobin)	Glycated hemoglobin reflects the percentage of hemoglobin to which glucose is attached. In the case of hyperglycemia an increase in glycohemoglobin leads to an increase in hemoglobin A1C. This test shows the average blood glucose level for the past 2 to 3 months.	Diagnose diabetes Indicated for children with diabetes. Provides information regarding long-term glycemic control and effectiveness of therapy	<ul style="list-style-type: none"> <li>Elevated levels seen in newly diagnosed diabetes or poorly controlled diabetes</li> <li>Levels can be elevated in nondiabetic children with certain conditions such as blood loss, hemolysis, iron-deficiency anemia, sickle cell disease, and lead toxicity.</li> </ul>
Genetic testing	Tests for the presence of the gene for disease or carrier status	Determine genetic involvement of any disorder	<ul style="list-style-type: none"> <li>Explain procedure and the expense involved.</li> <li>Refer for genetic counseling if needed.</li> </ul>
Serum chemistry levels	Serum blood urea nitrogen (BUN), creatinine, sodium, potassium, glucose, calcium, phosphorus, alkaline phosphatase, etc.	Rule out chronic renal failure or other chronic illnesses; monitor effects of treatment	<ul style="list-style-type: none"> <li>BUN levels may be elevated with high-protein diet or dehydration, and may be decreased with overhydration or malnutrition.</li> <li>A diet high in meat may cause a transient but not pronounced increase in creatinine. There are also slight diurnal variations in levels.</li> <li>Avoid hemolysis of specimen, as this may cause elevation in potassium levels.</li> <li>Calcium and phosphorus: avoid prolonged tourniquet use during blood draw, as this may falsely increase levels. Child should be NPO past midnight prior to the morning of the blood draw.</li> </ul>
Growth hormone stimulation	Stimulate release of GH in response to administration of insulin, arginine, clonidine, or glucagon	Evaluate and diagnose GH deficiency	<ul style="list-style-type: none"> <li>Keep child NPO for specified time.</li> <li>Limit stress and physical activity at least 30 minutes before test.</li> <li>Obtain serial blood samples at specific times.</li> <li>Monitor blood glucose levels during study.</li> <li>Observe for signs of hypoglycemia, diaphoresis, and somnolence.</li> <li>Provide cookies and punch at end of test.</li> </ul>
Water deprivation study	Child is deprived of fluids for several hours, and serum sodium and urine osmolality are monitored.	Diagnose diabetes insipidus and distinguish between types of DI	<ul style="list-style-type: none"> <li>Stop test if child exhibits extreme weight loss or changes in vital signs or neurologic status.</li> <li>Weigh child before, during, and after test.</li> <li>Rehydrate child after test.</li> <li>Monitor for orthostatic hypotension.</li> </ul>

**COMMON LABORATORY AND DIAGNOSTIC TESTS 49.1** (continued)

Diagnostic Test or Procedure	Explanation	Indications	Nursing Implications
Bone age radiograph	Radiographic study of wrist or hand to determine bone maturation compared to national standards	Determine if bone age is consistent with chronological age to rule out GH deficiency or excess or hypothyroidism	<ul style="list-style-type: none"> <li>• Explain procedure to child because child must hold still for the radiograph.</li> <li>• Allow family to accompany child. Enlist the family's help if needed to calm child during radiography.</li> </ul>
Other nuclear medicine studies	Contrast media uptake is assessed with serial radiographs.	Visualize an ectopic, enlarged, absent, or nodular gland	<ul style="list-style-type: none"> <li>• Assess child for allergy to iodine or shellfish.</li> <li>• Explain procedure to child.</li> </ul>
Computed tomography (CT)	Noninvasive x-ray study that looks at tissue density and structures. Images a "slice" of tissue	Evaluate presence of tumors, cysts, or structural abnormalities that may affect specific gland or structure	<ul style="list-style-type: none"> <li>• Machine is large and can be frightening to children.</li> <li>• Scan may be lengthy and the child must remain still, so sedation may be necessary.</li> <li>• If contrast medium is to be used, assess for allergy.</li> <li>• Encourage fluids after procedure if not contraindicated.</li> </ul>
Magnetic resonance imaging (MRI)	Based on how hydrogen atoms behave in a magnetic field when disturbed by radiofrequency signals. Does not require ionizing radiation. Provides a 3D view of the body part being scanned	Evaluate presence of tumors, cysts, or structural abnormalities that may affect specific gland or structure	<ul style="list-style-type: none"> <li>• Remove all metal objects from the child.</li> <li>• Child must remain motionless for entire scan; parent can stay in room with child. Younger children will require sedation in order to be still.</li> <li>• A loud thumping sound occurs inside the machine during the procedure, which can be frightening to children.</li> </ul>
Ultrasonography	Noninvasive sound waves are used to visualize structures such as thyroid or pelvic region.	Evaluate presence of tumors or cysts in specific gland, such as the adrenal glands or ovaries, to rule out disorders	<ul style="list-style-type: none"> <li>• Requires full bladder if in pelvic region</li> <li>• Better tolerated by nonsedated children than CT or MRI</li> <li>• Can be performed with a portable unit at bedside</li> </ul>

- Deficient knowledge (specify)
- Interrupted family processes
- Imbalanced nutrition: less than or more than body requirements
- Deficient or excess fluid volume
- Noncompliance

**After completing an assessment of Carlos, the nurse noted the following: history reveals Carlos has had episodes of bedwetting over the past month and has had polydipsia and polyphagia. His weight continues to be greater than the 95th percentile on the growth chart. Based on these assessment findings, what would your top three nursing diagnoses be for Carlos?**

Because of the gradual, insidious onset of many of these disorders, the child may first be seen in an acute situation. It may be easier for the child and family to work with short-term goals until they accept the chronic situation. A major goal will be to achieve compliance with medical management. The goals for the child with a disorder of the endocrine system generally include reestablishing homeostasis, promoting adequate growth and development, establishing appropriate body image, promoting health-seeking behaviors, and providing education so the family can manage the condition.

Nursing Care Plan 49.1 can be used as a guide in planning care for the child with a disorder of the endocrine system. Of course, this plan will need to be individualized based on the child's symptoms, needs, and disorder as well as the family's requirements. A key element to include in any care plan for the child with an endocrine disorder involves preparing the child, based on his or her developmental needs, for invasive procedures and tests. Provide an opportunity for the family and child to express their concerns and fears during diagnosis and treatment. Reinforce realistic expectations for treatment and prospects for improvement with the family and child. The care plan also needs to address developmental, acute, chronic, and home care issues as well as child and family education. Families will need assistance with managing the condition from a multidisciplinary team.

**Based on your top three nursing diagnoses for Carlos, describe appropriate nursing interventions.**

## PITUITARY DISORDERS

Because of the close anatomic and functional relationships between the hypothalamus and pituitary gland, we will discuss them together. The hypothalamus affects the pituitary by releasing and inhibiting hormones and may be the cause of pituitary disorders. In general, disorders of the pituitary fall into two major groups: the anterior pituitary hormones and the posterior pituitary hormones. Anterior pituitary primary disorders in children include growth hormone deficiency, hyperpituitarism, and precocious puberty. Posterior pituitary disorders include diabetes insipidus and syndrome of inappropriate antidiuretic hormone secretion.

### Take Note!

Infants with congenital defects of the pituitary gland or hypothalamus may present as a neonatal emergency. The symptoms include apnea, cyanosis, severe hypoglycemia with possible seizures, and prolonged jaundice (Parks & Felner, 2011).

## Growth Hormone Deficiency

Growth hormone (GH) deficiency, also known as hypopituitarism or dwarfism, is characterized by poor growth and short stature. GH is vital for postnatal growth. It is released throughout the day, with most secreted during sleep. GH stimulates linear growth, bone mineral density, and growth in all body tissues.

GH deficiency occurs in approximately 1 in 3,500 children (Hatcher, 2010). Often this condition is first identified when the physician or nurse practitioner assesses growth patterns. Children may start with a normal birth weight and length, but within a few years the child is less than the third percentile on the growth chart.

Possible complications related to GH deficiency and its treatment include altered carbohydrate, protein, and fat metabolism; hypoglycemia; glucose intolerance/diabetes; slipped capital femoral epiphysis; pseudotumor cerebri; leukemia; recurrence of central nervous system (CNS) tumors; infection at the injection site; edema; and sodium retention.

## Pathophysiology

GH deficiency is generally a result of the failure of the anterior pituitary or hypothalamic stimulation on the pituitary to produce sufficient GH. This lack of GH impairs the body's ability to metabolize protein, fat, and carbohydrates.

Primary causes of GH deficiency include injury to, or destruction of, the anterior pituitary gland or hypothalamus. Causes include a tumor (e.g., craniopharyngioma), infection, infarction, irradiation, abnormal formation of these organs in utero, or damage or trauma during birth or after. It may also be part of a genetic syndrome, such as Prader-Willi syndrome or Turner syndrome, or the result of a genetic mutation or deletion.

In some cases the cause may be idiopathic, such as nutritional deprivation or psychosocial issues, and reversible. Psychosocial dwarfism results from emotional deprivation that causes suppression of production of the pituitary hormones, resulting in decreased growth hormone. The child is withdrawn, has bizarre eating and drinking habits such as drinking from toilets, and has primitive speech. The treatment involves removing the child from the dysfunctional environment and providing normal dietary intake. With normalized eating and behavioral habits, pituitary secretion is restored and the child dramatically catches up in growth parameters.

## Therapeutic Management

Treatment of primary GH deficiency involves the use of supplemental GH. Secondary GH deficiency requires

## NURSING CARE PLAN 49.1

## Overview for the Child With an Endocrine Disorder

**NURSING DIAGNOSIS:** Delayed growth and development related to hypo- or hyperfunction of gland/hormone as evidenced by weight and/or height less than expected for age, failure to meet expected age-appropriate developmental milestones

**Outcome Identification and Evaluation**

Nutritional status will be maximized and development will be enhanced: *child will maintain or gain weight appropriately and will make continued progress toward expected developmental milestones.*

**Interventions: Enhancing Growth and Development**

- Monitor growth parameters using standard growth charts: *provides a baseline and allows for tracking growth trends.*
- Encourage favorite foods (within prescribed diet restrictions if present) *to maximize oral intake.*
- Consult dietitian *for appropriate diet supplementation recommendations.*
- Encourage compliance with hormone supplementation *to enhance ability to achieve appropriate growth.*
- Provide care related to any complications of dysfunction *such as correcting fluid and electrolyte imbalances or diarrhea.*
- Screen for developmental capabilities *to determine child's current level of functioning.*
- Offer age-appropriate toys, play, and activities (including gross motor) *to encourage further development.*
- Provide support to families of children with developmental delay: *progress in achieving developmental milestones can be slow and ongoing motivation is needed.*
- Reinforce positive attributes in the child *to maintain motivation.*

For the child with diabetes mellitus:

- Provide a calorie-appropriate, nonrestricted, well-balanced diet *to maintain appropriate growth.*
- Encourage three meals with two or three snacks with consistent carbohydrates *to maintain appropriate blood glucose levels and promote growth.*

**NURSING DIAGNOSIS:** Disturbed body image related to abnormal growth and development/changes in physical appearance due to hormone dysfunction as evidenced by verbalization of dissatisfaction with the child's or adolescent's looks

**Outcome Identification and Evaluation**

Child demonstrates appropriate self-esteem in relation to body image: *expresses positive feelings about self and participates in social activities.*

**Interventions: Promoting Healthy Body Image**

- Provide opportunities for child to explore feelings related to appearance: *venting feelings is associated with less body image disturbance.*
- Relate to child on age level, not appearance level: *"babying" a child who looks younger due to his or her small size reduces self-image.*
- Involve the child and especially the teen in the decision-making process: *a sense of control will improve body image.*
- Encourage the child to spend time with peers who have similar endocrine disorders: *peers' opinions are often better accepted than those of persons in authority, such as parents or health care professionals.*
- Refer to counseling or support groups *to further support the child.*

(continued)

## NURSING CARE PLAN 49.1

## Overview for the Child With an Endocrine Disorder (continued)

**NURSING DIAGNOSIS:** Deficient knowledge related to therapeutic regimen as evidenced by questions about endocrine disorder and self-management

### Outcome Identification and Evaluation

Child and family will demonstrate sufficient understanding and skills for self-management: *verbalize information about disorder, complications/adverse effects, home care regimen, and long-term needs, and provide return demonstrations of medication administration or other procedures.*

### Interventions: Promoting Knowledge Required for Self-Management

- Assess child's developmental level and family's ability to absorb instruction *to determine how to approach teaching sessions.*
  - Establish teaching plan with child and family *to gain cooperation and involvement.*
  - Teach and give printed instructions on disorder, complications, home care, and follow-up requirements *so family has a source to refer to at home.*
  - Evaluate teaching with return demonstrations *to determine whether child/family is skilled enough for home management of the disorder.*
- For the child with diabetes mellitus:
- First teach "survival skills" (e.g., glucose and urine testing, administering insulin, record keeping, food guidelines, when to call physician) *to provide initial base of knowledge for self-management.*
  - Implement second-phase home management program with more extensive instruction: *providing additional teaching over time is necessary for management of a significant chronic illness.*
  - Monitor outcomes of teaching with every contact *to ensure progress with child/family education.*

**NURSING DIAGNOSIS:** Interrupted family processes or adjustment issues related to lifestyle changes required to manage chronic illness and possible lifestyle changes as evidenced by family's presence in the hospital, missed work, demonstration of inadequate coping

### Outcome Identification and Evaluation

Family will maintain functional system of support; demonstrate adequate coping, adaptation of roles and functions, and decreased anxiety: *parents are involved in child's care, ask appropriate questions, express fears and concerns, identify needs, seek appropriate resources and support, can discuss child's care and condition calmly.*

### Interventions: Encouraging Healthy Family Processes

- Encourage parents and family members to verbalize concerns related to child's illness, diagnosis, and prognosis: *allows the nurse to identify concerns and areas where further education may be needed.*
- Explain treatments, medications, procedures, child's behaviors, and plan of care to parents: *understanding of the child's current status and plan of care helps decrease anxiety.*
- Identify support system for family and child: *helps nurse identify needs and resources available for coping.*
- Provide family with information about support groups, financial resources, and special clinics in the area for the particular type of disorder *to provide family with a wide base of support.*
- Encourage parents to become involved in care: *allows parents to feel needed and valued and gives them a sense of control over their child's health.*
- Evaluate coping processes on follow-up visits *to determine restoration of family processes.*

## NURSING CARE PLAN 49.1

**Overview for the Child With an Endocrine Disorder** (continued)

**NURSING DIAGNOSIS:** Imbalanced nutrition: less than or more than body requirements related to pathophysiology of dysfunction as evidenced by growth parameters significantly less or more than expected for age

**Outcome Identification and Evaluation**

Child's nutritional status is balanced: *child adheres to nutritional guidelines, demonstrates adequate growth (weight and height) pattern within normal range for age and gender or, in the child who has difficulty growing, a progressive increase over time.*

**Interventions: Maintaining Adequate Nutrition**

- Determine body weight and length/height norm for age or what the child's pretreatment measurements were *to determine goal to work toward.*
  - Weigh daily or weekly (according to physician order or institutional standard) and measure length/height weekly *to monitor for appropriate growth.*
  - Determine child's food preferences and provide favorite foods as able *to increase the likelihood that the child will consume appropriate amounts of foods.*
  - Instruct child and family about nutritional requirements *so that they are involved and are prepared for home care.*
  - Refer to dietitian *for more detailed information and assistance.*
- For the child who needs to gain weight:
- Offer highest-calorie meals at the time of day when the child's appetite is the greatest *to increase likelihood of increased caloric intake.*
  - Provide increased-calorie shakes or puddings within dietary restrictions: *high-calorie foods increase weight gain.*
  - Administer vitamin and mineral supplements as prescribed *to attain/maintain vitamin and mineral balance in the body.*

**NURSING DIAGNOSIS:** Deficient or excess fluid volume related to pathophysiology of endocrine dysfunction as evidenced by signs and symptoms of dehydration (deficient fluid volume) or edema and excessive urine output (excess fluid volume)

**Outcome Identification and Evaluation**

Child will maintain adequate fluid volume *as evidenced by elastic skin turgor; absence of edema; moist, pink oral mucosa; presence of tears; urine output 1 mL/kg/hour or more; vital signs within normal range for age; and normal electrolyte/hormone serum levels.*

**Interventions: Maintaining Adequate Fluid Volume**

- Assess hydration status (skin turgor, oral mucosa, presence of tears) every 4 to 8 hours *to evaluate maintenance of adequate fluid volume.*
- Assess adequacy of urine output *to evaluate end-organ perfusion.*
- Maintain strict intake and output record *to evaluate effectiveness of rehydration.*
- Weigh child daily: *accurate weight is one of the best indicators of fluid volume status in children.*
- Administer specific hormone, fluid, and electrolyte requirements as ordered *to aid in fluid balance.*

Fluid volume deficit:

- Maintain IV line and administer IV fluid as ordered *to maintain fluid volume.*

Fluid volume excess:

- Maintain fluid restriction as ordered *to restore homeostasis.*

(continued)

## NURSING CARE PLAN 49.1

## Overview for the Child With an Endocrine Disorder (continued)

**NURSING DIAGNOSIS:** Noncompliance related to long-term/complex management of some disorders as evidenced by failure to keep appointments, development of complications or exacerbation of symptoms, or child/family verbalization of inability to maintain treatment plan

### Outcome Identification and Evaluation

Child and family will comply with treatment regimen: *child and family will list treatment expectations and agree to follow through.*

### Interventions: Encouraging Compliance

- Listen nonjudgmentally while the child and family describe reasons for noncompliance: *assessment of problem should begin with nonthreatening discussion.*
- Help the child and family develop a schedule for medication administration and other home regimens that works best for them: *involving child and family in planning care will increase compliance by making them feel respected and valued.*
- Work with the child and family to develop a written treatment plan or schedule that best suits their needs *to provide support for maintenance of treatment plan.*
- Establish follow-up visits to fit family's situation *to promote compliance.*
- Encourage monitoring with pediatric endocrinologist and specialists: *multidisciplinary involvement has been shown to increase compliance.*
- Recognize that behavioral change comes slowly: *allows time for child and family to adjust to chronic nature of illness.*

removal of any tumors that might be the underlying problem, followed by GH therapy. Biosynthetic GH, derived from recombinant DNA, is given by subcutaneous injection. The weekly dosage is 0.2 to 0.3 mg/kg, divided into equal doses given daily for best growth (Hatcher, 2010). Treatment continues until near final height is achieved. This can be determined by the child deciding he or she is tall enough, a growth rate of less than 1 inch/year, or bone age greater than 16 years in boys and greater than 14 years in girls (Parks & Felner, 2011).

### Take Note!

Reports have found no evidence linking GH therapy to higher risk of leukemias (Bell et al., 2010; Parks & Felner, 2011).

## Nursing Assessment

The focus of the evaluation for GH deficiency is to rule out chronic illnesses such as renal failure, liver disorders, and thyroid dysfunction. For a full description of the assessment phase of the nursing process, refer to page 1770. Assessment findings pertinent to GH deficiency are discussed below.

## Health History

The health history may reveal a familial pattern of short stature or a prenatal history of maternal disorders such as malnutrition. The past history may be significant for birth history of intrauterine growth retardation or past history of severe head trauma or a brain tumor such as craniopharyngioma. Evaluate previous and current growth patterns. Note history of chronic illness such as cardiac, kidney, or intestinal disorders that may contribute to a decreased growth pattern. Assess the child's feelings about being short.

## Physical Examination

In addition to the linear height being at or below the third percentile on standard growth charts, the physical assessment findings may show that the child has a higher weight-to-height ratio (Fig. 49.2). Other physical findings may include prominent subcutaneous deposits of abdominal fat; a child-like face with a large, prominent forehead; a high-pitched voice; delayed sexual maturation (e.g., micropenis and undescended testes in boys); delayed dentition; delayed skeletal maturation; and decreased muscle mass.

**FIGURE 49.2** The child with growth hormone deficiency displays short stature.

### Take Note!

Growth measurements are often inaccurate and unreliable in children. Improved accuracy, especially in performing linear measurements, could yield earlier detection and diagnosis of growth disorders (Mohr et al., 2010). Evidence-based clinical practice guidelines on linear growth measurement of children have been developed. A link to these and other helpful resources are provided on [thePoint](#).

### Laboratory and Diagnostic Testing

The child will undergo laboratory tests to rule out chronic illnesses such as renal failure or liver and thyroid dysfunction. Laboratory and diagnostic tests used in children with suspected GH deficiency include:

- Bone age (as shown by radiographs) will be two or more deviations below normal.
- CT or MRI scans rule out tumors or structural abnormalities.
- Pituitary function testing confirms the diagnosis. This test consists of providing a GH stimulant such as glucagon, clonidine, insulin, arginine, or L-dopa to stimulate the pituitary to release a burst of GH. Peak GH levels below 7 to 10 ng/mL in at least two tests confirm the diagnosis.

### Nursing Management

Nursing management for the child with GH deficiency focuses on promoting growth, enhancing the child's

self-esteem related to short stature, and providing appropriate education about the disorder.

### Promoting Growth

The goal of growth promotion is for the child to demonstrate an improved growth rate, as evidenced by at least 3 to 5 inches in linear growth in the first year of treatment without complications. With early diagnosis and treatment, the child has a better prognosis for reaching a normal adult height. Growth is usually excellent in the first year of therapy compared to later years (Parks & Felner, 2011). Treatment stops when the epiphyseal growth plates fuse.

At the beginning of treatment, monitor for height increase and possible side effects related to the medications. Measure the child's height at least every 3 to 6 months and plot growth over time on standardized growth charts. Provide information to the child and family about normal development and growth rates, bone age, and growth potential. Explore with the family and child the expectations and their understanding of what is normal so they will have realistic expectations of treatment. Consult a dietitian if the child and family need assistance in providing adequate nutrition for growth and development.

### Enhancing the Child's Self-Esteem

The child with GH deficiency often has younger-looking features and is shorter than his or her peers. Encourage the child to express positive feelings about his or her self-image, as shown by comments during health care visits as well as involvement with peers. Encourage the child to voice concerns. Emphasize the child's strengths and assets. Provide information about community support groups or websites related to GH deficiency. Evaluate for long-term learning problems that may develop if the child had a tumor and surgery or irradiation to remove it. Unidentified learning problems can have a negative impact on the child's self-esteem. Treat and communicate with the child in an age-appropriate manner even though he or she may appear younger.

### Educating the Family

GH is a powder that is mixed with packaged diluents. Explain how to prepare it and give the correct dosage. Encourage rotation of sites in the subcutaneous tissue to prevent skin irritation. Have the family provide a return demonstration to make sure they understand correct dilution and administration of GH. Continue to provide periodic evaluation and ongoing support. Instruct the family to report headaches, rapid weight gain, increased thirst or urination, or painful hip or knee joints as possible adverse

reactions. Explain to the family that the child will need to visit the pediatric endocrinologist every 3 to 6 months to monitor for growth, for potential adverse effects, and for compliance with therapy. Stress the importance of complying with the GH replacement therapy and frequent supervision by a pediatric endocrinologist. Educate the family about the financial costs of therapy, which may be high; the family may need help in obtaining assistance and require referral to social services.

Guide the family and child in setting realistic goals and expectations based on age, personal abilities and strengths, and the effectiveness of the GH replacement therapy. For example, the family may want to encourage the child to choose sports that are not dependent on height. Encourage the family to dress the child according to age, not size. Refer the child and family to counseling if indicated. Inform families about support groups such as the Short Stature Foundation, the Human Growth Foundation, and the Magic Foundation. Links and additional information about these groups are provided on [thePoint](#).

### Hyperpituitarism (Pituitary Gigantism)

Hyperpituitarism, an extremely rare disorder in children, results from an excessive secretion of GH that leads to an increased growth rate greater than the 97th percentile (Lifshitz, 2007; Hosono & Cohen, 2011). The cause of this overproduction of GH is most often a tumor of the anterior pituitary, a pituitary adenoma, or, if combined with precocious puberty, a tumor of the hypothalamus. If this overproduction occurs before the epiphyseal plates close, the child may grow to 7 to 8 feet in height. If the overproduction occurs after they close, acromegaly occurs. Acromegaly is an enlargement of the bones of the head and soft parts of the feet and hands. Being tall is valued in today's society, so assessment for accelerated growth is often delayed, especially in boys (Hosono & Cohen, 2011).

Therapeutic management includes removing the tumor, restoring the GH patterns to normal, and preventing recurrence. Treatment depends on the cause and may involve surgery, radiation therapy, radioactive implants, or pituitary hormone replacement after surgery. Alternatively, treatment may involve administration of somatostatin analogs to suppress GH production.

Complications of hyperpituitarism include hypogonadism, visual loss, and heart failure.

### Nursing Assessment

In addition to excessive height, physical findings include coarse facial features and enlarged hands and feet. Some children display behavioral and visual problems. Typically, the condition presents at puberty, but it has been found

as early as the newborn period. Increased levels of insulin-like growth factor 1 (IGF-1) establish the diagnosis of hyperpituitarism. The gold standard for making the diagnosis of GH excess is failure to suppress serum GH levels after an oral glucose challenge test (Hosono & Cohen, 2011). A bone scan determines whether the epiphyseal plates are closed. Radiologic studies, including MRI, are used to detect any tumors.

### Nursing Management

Nursing management depends on which treatment the child undergoes. If surgical removal of a tumor is required, provide routine pre- and postoperative care. Administer somatostatin analog (e.g., octreotide acetate) if ordered. It is usually given as a subcutaneous injection every 12 hours; refer to Drug Guide 49.1 for further information. Treat the child according to chronologic age rather than according to height. Assess the child's self-image, teach the child and family about the disorder and the treatment plan, and provide emotional support. Monitor for and report signs of potential complications such as hypogonadism, visual loss, or heart failure.

### Precocious Puberty

In precocious puberty, the child develops sexual characteristics before the usual age of pubertal onset. Puberty, also known as sexual maturation, occurs when the gonads produce increased amounts of sex hormones. Typically, this occurs around 10 to 12 years of age for girls and 11 to 14 years of age for boys. In precocious puberty, breasts develop before age 7 years in white girls or before age 6 years in African American girls, or secondary sex characteristics develop in boys younger than 9 years (Matfin, 2009). The disorder is more common in females and most of the time the cause is unknown (Garibaldi & Chemaitilly, 2011, 2011). Other causes include benign hypothalamic tumor, brain injury or radiation, a history of infectious encephalitis, meningitis, congenital adrenal hyperplasia, and tumors of the ovary, adrenal gland, pituitary gland, or testes.

### Pathophysiology

Central precocious puberty, the most common form, develops as a result of premature activation of the hypothalamic-pituitary-gonadal axis that results in the production of gonadotropin-releasing hormone (GnRH), which stimulates the pituitary to produce luteinizing hormone (LH) and follicle-stimulating hormone (FSH). These hormones in turn stimulate the gonads to secrete the sex hormones (estrogen or testosterone). The child develops sexual characteristics, shows increased growth and skeletal maturation, and has reproductive capability.

Peripheral precocious puberty presents with no early secretion of gonadotropin or maturation of gonads but rather early overproduction of sex hormones. The condition results in increased end-organ sensitivity to low levels of circulating sex hormones and leads to premature pubic hair and breast development.

If left untreated, the child may become fertile. In addition, the hormones stimulate rapid growth. Therefore, the child may appear taller than peers but will reach skeletal maturity and closure of the epiphyseal plates early, which results in overall short stature.

## Therapeutic Management

The clinical treatment for precocious puberty first involves determining the cause. For example, if the etiology is a tumor of the central nervous system, the child undergoes surgery, radiation, or chemotherapy. The treatment for central precocious puberty involves administering a GnRH analog. This is available as a depot injection given every 3 to 4 weeks, a subcutaneous injection given daily, or an intranasal compound given two or three times each day. This analog stimulates gonadotropin release initially but when given on a long-term basis will suppress gonadotropin release. With this treatment, the growth rate slows and secondary sexual development stabilizes or regresses. Medroxyprogesterone injections (Depo-Provera) or tablets (Cycrin) reduce secretion of gonadotropins and prevent menstruation. When treatment is discontinued, puberty resumes according to appropriate developmental stages. The overall aim of treatment is to halt or even reverse sexual development and rapid growth as well as promote psychosocial well-being.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1770. Pertinent assessment findings related to precocious puberty are discussed below.

### Health History

The health history may reveal complaints of headaches, nausea, vomiting, and visual difficulties due to the circulating hormones. The psychosocial development is typical for the child's age, but the child may show emotional lability, aggressive behavior, and mood swings. Information from the child and family may also reveal risk factors such as exposure to exogenous hormones, history of central nervous system trauma or infection, or a family history of early puberty.

### Physical Examination

Physical examination may reveal acne and an adult-like body odor. The child will present with an accelerated

rate of growth. The Tanner staging of breasts, pubic hair, and genitalia reveals advanced maturation for the child's age, but the child does not typically display sexual behavior.

## Laboratory and Diagnostic Testing

Radiologic examinations and pelvic ultrasound identify advanced bone age, increased uterus size, and development of ovaries consistent with the diagnosis of precocious puberty. Laboratory studies include screening radioimmunoassays for LH, FSH, estradiol, or testosterone. The child's response to GnRH stimulation confirms the diagnosis of central precocious puberty versus gonadotropin-independent puberty. This test involves administering synthetic GnRH intravenously and drawing serial blood levels, about every 2 hours, of LH, FSH, and estrogen or testosterone. A positive result is defined as pubertal or adult levels of these hormones in response to the GnRH administration. CT, MRI, or skull radiography reveals any lesions in the central nervous system or tumors or cysts present in the abdomen, pelvic area, or testes.

## Nursing Management

In general, nursing management of the child with precocious puberty focuses on educating the child and family about the physical changes the child is experiencing and how to correctly use the prescribed medications and helping the child to deal with self-esteem issues related to the accelerated growth and development of secondary sexual characteristics. Goals of nursing management include appropriate physical development and pubertal progression appropriate for age. Refer to Nursing Care Plan 49.1, and individualize care based on the child's and family's response to this disorder.

### Providing Education

Nursing care involves assessing and documenting the physical changes the child is experiencing and administering medications. Demonstrate correct administration of medication and observe for potential adverse effects (teach this information to the family as well). Encourage the family to comply with follow-up appointments, which typically occur every 6 months and include scheduled stimulation tests. Inform families that pharmacologic intervention stops when the child reaches the age appropriate for pubertal development. Provide appropriate sex education. Reassure parents that precocious puberty does not always involve precocious sexual behavior, but that it may be seen, especially in boys (Dowshen, 2011a).

### Dealing With Self-Esteem Issues

Often these children develop self-esteem issues and anxiety related to body image disturbances and impaired

social interactions (Dowshen, 2011a). The goal is for the child to exhibit normal psychosocial development and understand the physical and emotional changes that occur with early onset of puberty. Communicate with the child on an age-appropriate level, even when physical characteristics make the child appear older. Maintain a calm, supportive atmosphere and provide for privacy during examinations. Refer the child and family for counseling as needed. Since the child may have issues with self-image and may be self-conscious, encourage him or her to express his or her feelings about the changes, and use role-playing to show the child how to handle teasing from other children. Let the child know that everyone develops sexual characteristics in time.

### Delayed Puberty

Delayed puberty is a condition of delayed secondary sexual development. In girls, it exists if the breasts have not developed by age 13, pubic hair has not appeared by age 14, or **menarche** has not occurred by age 16 (Children's Hospital of Pittsburgh, 2008; Hatcher, 2010). In boys, it exists when no testicular enlargement or scrotal changes have occurred by age 14 or pubic hair has not appeared by age 15 followed by testicular enlargement (Children's Hospital of Pittsburgh, 2008; Hatcher, 2010).

The most common cause for delayed puberty is a hereditary pattern of growth and development known as **constitutional delay** (or a "late bloomer") (Dowshen, 2011b). In these cases there is a family pattern of late-onset puberty. These teens will usually develop normally, just at a later time than their peers. Hypogonadism also may result when there is decreased stimulation of the gonads due to dysfunction or tumors in the hypothalamus or pituitary gland. Other causes include irradiation, infection, trauma, or genetic syndromes such as Turner or Klinefelter syndrome. Another common cause is a chronic condition such as anorexia or cystic fibrosis.

Therapeutic management involves administering testosterone (males) or estradiol conjugated estrogen (females) in low dosages if there is no underlying situation to address. This is usually necessary for only a short time to get puberty started.

### Nursing Assessment

Assessment involves obtaining a health history to identify the indications for this condition. Assessment of the growth pattern using correct techniques and standards for comparison is essential. On physical assessment, note absence of secondary sex characteristics as noted above. Laboratory and diagnostic testing rules out other causes for delayed puberty. Blood levels of reproductive hormones may also be evaluated.

## Nursing Management

In addition to the general interventions presented in Nursing Care Plan 49.1, instruct the child and family about the medication therapy. Educate the child and family about the different stages of puberty. Help the family develop a home management schedule for the administration of medication. Answer the family's questions about the condition or potential complications (e.g., infertility), depending on the cause of the condition.

### Diabetes Insipidus

Diabetes insipidus (DI) can be classified into two types—nephrogenic DI and central DI. Nephrogenic DI can be transmitted genetically (e.g., sex-linked, autosomal dominant, or autosomal recessive forms) or be acquired due to chronic renal disease, hypercalcemia, hypokalemia, or use of certain drugs such as lithium, amphotericin, methicillin, and rifampin (Breault & Majzoub, 2011a). This variant of DI is not associated with the pituitary gland and is related to decreased renal sensitivity to antidiuretic hormone (ADH). Therapeutic management for nephrogenic DI involves diuretics, high fluid intake, restricted sodium intake, and a high-protein diet. Desmopressin acetate (DDAVP) is ineffective in the treatment of nephrogenic DI.

Central DI is a disorder of the posterior pituitary gland and is the most common form of DI (Children's Hospital of Boston, 2011; Cooperman, 2011). Therefore, central DI will be the focus of the remainder of this discussion. Central DI is characterized by excessive thirst (**polydipsia**) and excessive urination (**polyuria**) that is not affected by decreasing fluid intake. Typically, this disorder occurs in children as a result of complications from head trauma or after cranial surgery to remove hypothalamic-pituitary tumors such as craniopharyngioma. Other causes include genetic mutations, granulomatous disease, infections such as meningitis or encephalitis, vascular anomalies, congenital malformations, infiltrative disease such as leukemia, or administration of certain drugs that are associated with inhibition of vasopressin release, such as phenytoin (Breault & Majzoub, 2011a). However, 10% of central DI cases in children are idiopathic (Breault & Majzoub, 2011a). Some cases can be hereditary.

DI is usually permanent and requires treatment throughout life.

### Pathophysiology

Central DI results from a deficiency in the secretion of ADH. This hormone, also known as vasopressin, is produced in the hypothalamus and stored in the pituitary gland. ADH is involved in concentrating the urine from the kidneys by stimulating reabsorption of water in the renal collecting tubules through increased

membrane permeability. This conserves water and maintains normal osmolality. With a deficiency in ADH, the kidney loses massive amounts of water and retains sodium in the serum.

## Therapeutic Management

Unless a tumor is present (in which case it is removed by surgery), the usual treatment of central DI involves daily replacement of ADH in older children. The drug of choice for home treatment is DDAVP, a long-acting vasopressin analog (Breault & Majzoub, 2011a; Hatcher, 2010). In children, it is typically given intranasally. However, it can also be administered subcutaneously or orally. The drug is given every 8 to 12 hours. The dose depends on the child's age, urine output, and urine specific gravity. The use of DDAVP in infants is controversial and complicated (Rivkees, Dunbar, & Wilson, 2007). In fact, in neonates and young infants, the treatment is often solely fluid therapy due to their large volume requirements of nutritive fluid (i.e., the drive behind an infant's fluid intake is hunger rather than thirst) (Breault & Majzoub, 2011a). However, research has shown that subcutaneously administered DDAVP may be more effective than oral or intranasal therapy in infants (Rivkees et al., 2007).

In the hospital, the child may receive aqueous vasopressin, 8-arginine vasopressin (Pitressin), intravenously (Breault & Majzoub, 2011a). This is a short-acting drug, so the dosage can be adjusted quickly.

Both the long-acting and short-acting forms of the medication decrease urinary output and thirst, and the dosages of both forms of these drugs need to be titrated to achieve the desired effect.

### Take Note!

A metered nasal spray form of DDAVP is available, but the prescribed dose must be greater than 10 mcg/0.1 mL in order for the child to use the spray (Taketomo, Hodding, & Kraus, 2010).

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1770. Assessment findings pertinent to DI are discussed below.

### Health History

Nursing assessment involves obtaining a history of any conditions that led to the development of the disorder. This review includes information about the neonatal period as well as a current history of infections such as meningitis, diseases such as leukemia, or familial patterns. Although most symptoms of endocrine disorders develop slowly, the onset of this disorder is abrupt. The health

history usually elicits the cardinal symptoms as well as complaints representing the early signs of dehydration.

The most common initial symptoms reported are polyuria and polydipsia (Breault & Majzoub, 2011a). Except for unconscious children, the child typically maintains adequate perfusion by drinking water. The parent or child may report frequent trips to the bathroom, nocturia, or enuresis. When the child cannot compensate for the excessive loss of water by increasing fluid intake, other symptoms will be reported, such as weight loss or signs of dehydration. For example, irritability may be due to the early signs of dehydration or the frustration the child feels at being unable to quench his or her thirst. Other signs may be intermittent fever, vomiting, and constipation.

### Physical Examination

Observation and inspection may reveal weight loss or failure to thrive in the young infant. Inspection may also reveal signs of dehydration, such as dry mucous membranes or decreased tears. The child may excrete greater than 3 L/m<sup>2</sup> of urine per day. On auscultation, tachycardia or increased respiratory rate may be signs of compensation for the decrease in fluid volume. Palpation reveals slightly depressed fontanels or decreased skin turgor.

### Laboratory and Diagnostic Testing

Diagnostic tests used to evaluate DI include:

- Radiographic studies such as CT scan, MRI, or ultrasound of the skull and kidneys can determine whether a lesion or tumor is present.
- Urinalysis: urine is dilute, osmolality is less than 3,000 mOsm/L, specific gravity is less than 1.005, and sodium is decreased.
- Serum osmolality is greater than 300 mOsm/L.
- Serum sodium is elevated.
- Fluid deprivation test measures vasopressin release from the pituitary in response to water deprivation. Normal results will show decreased urine output, increased urine specific gravity, and no change in serum sodium.

### Take Note!

During a fluid deprivation test, the child may be irritable and frustrated because fluid is being withheld. Don't drink in front of the child.

## Nursing Management

Refer to Nursing Care Plan 49.1 and individualize the plan of care based on the child's and family's response to the illness. Specific interventions related to nursing care of the child with DI are discussed below.

## Promoting Hydration

The goal of treatment is to achieve hourly urine output of 1 to 2 mL/kg and urine specific gravity of at least 1.010.

### Take Note!

Notify the physician or nurse practitioner if the urine output is greater than 1,000 mL per hour for two consecutive voids.

Maintain fluid intake regimens as ordered. Monitor fluid status by measuring vital signs, fluid intake and output, and daily weights (using the same scale at the same time of day). If fluids are stopped too soon, the child may become hypernatremic, which can lead to seizures. Feed infants more frequently, since they excrete more dilute urine, consume larger volumes of free water, and secrete lower amounts of vasopressin than older children. Monitor for signs and symptoms of dehydration during the fluid deprivation test as well as when starting the treatment regimen.

### Take Note!

Monitor blood pressure closely when initiating vasopressin.

If the child is unconscious or has brain injury, maintain hydration and nutrition with nasogastric or gastrostomy feedings.

## Promoting Activity

Establish appropriate activity for the child, and allow time for him or her to regain strength and the desire to increase level of activity. Assess the child's abilities daily, schedule frequent bathroom breaks, keep fluids the child likes available at all times, and fit the treatment plan to the child's daily activities.

## Educating the Family

Involve the family in development of the fluid intake regimens. A journal or daily log is essential in maintaining the fluid regimen and identifying problems. Children with intact thirst centers can self-regulate their need for fluids, but if this is not the situation, help the family develop a plan for 24-hour fluid replacement. This may require instruction on nasogastric or gastrostomy feedings. Infants will need fluid intake at night. Educate the family about the symptoms of water intoxication (drowsiness, listlessness, headache, confusion, sudden weight gain, and anuria) and dehydration. Help the family develop a plan to inform the school and other individuals in the child's life about the need for liberal bathroom privileges and extra fluids to prevent accidents

or dehydration. Teaching Guidelines 49.1 gives tips on educating the family about the medication regimen. Recommend that the family obtain a medical ID alert bracelet or necklace for the child. Encourage compliance with follow-up appointments, which will probably be every 6 months.

## Teaching Guidelines 49.1

### DDAVP INTRANASAL ADMINISTRATION

- Keep DDAVP in the refrigerator at all times.
- Clear the nostrils (the medication may be poorly absorbed if the child has nasal congestion).
- Insert the measuring tube into the bottle.
- Fill to proper dosage and hold the top of the tube closed while inserting the medication-filled end into the nostril.
- Blow the liquid out of the tubing into the nostril.
- If the child sneezes, repeat the dosage.
- Measure urine specific gravity to monitor effectiveness of the drug.
- Monitor for signs and symptoms of overdose such as confusion, headache, drowsiness, and rapid weight gain due to fluid retention.

## Syndrome of Inappropriate Antidiuretic Hormone

Syndrome of inappropriate antidiuretic hormone (SIADH) occurs when ADH (vasopressin) is secreted in the presence of low serum osmolality because the feedback mechanism that regulates ADH does not function properly. ADH continues to be released, and this leads to water retention, decreased serum sodium due to hemodilution, and extracellular fluid volume expansion. SIADH can be caused by central nervous system infections such as meningitis, head trauma, brain tumors, intracranial surgery, and certain medications such as analgesics, barbiturates, or chemotherapy. SIADH is rare in children (Breault & Majzoub, 2011b). However, when seen, it is often related to excessive administration of vasopressin during the treatment of DI (Breault & Majzoub, 2011b).

Therapeutic management of SIADH includes correcting the underlying disorder in addition to fluid restriction and intravenous sodium chloride administration to correct hyponatremia and increase serum osmolality.

## Nursing Assessment

Obtain a health history, noting history of a central nervous system infection or tumor, intracranial surgery, head trauma, use of the above-mentioned medications, or a

## COMPARISON CHART 49.1

## DIABETES INSIPIDUS VERSUS SIADH

Diabetes Insipidus	Syndrome of Inappropriate Antidiuretic Hormone
<ul style="list-style-type: none"> <li>• “High and dry”</li> <li>• Increased urination</li> <li>• Hypernatremia</li> <li>• Serum osmolality &gt;300 mOsm/kg</li> <li>• Urine specific gravity &lt;1.005</li> <li>• Decreased urine osmolality</li> <li>• Dehydration, thirst</li> </ul>	<ul style="list-style-type: none"> <li>• “Low and wet”</li> <li>• Decreased urination</li> <li>• Hyponatremia</li> <li>• Serum osmolality &lt;280 mOsm/kg</li> <li>• Urine specific gravity &gt;1.030</li> <li>• Increased urine osmolality</li> <li>• Fluid retention, weight gain, and hypertension</li> </ul>

history of DI. Note symptoms such as decreased urine output and weight gain, or gastrointestinal symptoms such as anorexia, nausea, and vomiting. Assess neurologic status, noting lethargy, behavioral changes, headache, altered level of consciousness, seizure, or coma. Neurologic signs develop as the sodium level decreases. Diagnostic tests reveal low serum sodium and osmolality, as well as decreased urea, creatinine, uric acid, and albumin levels. Urine samples demonstrate elevated osmolality, high sodium concentrations, and specific gravity greater than 1.030. Adrenal, thyroid, and renal function studies may be used to rule out other causes of hyponatremia.

### Nursing Management

Nursing goals focus on restoring fluid balance and preventing injury. Institute safety precautions if altered level of consciousness, confusion, or seizures are present. Notify the physician or nurse practitioner if headache or irritability is present. Monitor fluid intake and output and weigh the child daily. An indwelling urinary catheter may be needed to allow for hourly monitoring of urine volume and specific gravity. Help the child cope with fluid restriction by offering sugarless candy, a wet washcloth, or, perhaps, ice chips. Administer electrolyte replacement as necessary to correct imbalances.

Comparison Chart 49.1 compares DI with SIADH.

## DISORDERS OF THYROID FUNCTION

Disorders of the thyroid gland are relatively common in infancy and childhood (Hatcher, 2010). These disorders can be serious because thyroid hormones are important for growth and development; they regulate metabolism of nutrients and energy production.

### Congenital Hypothyroidism

Congenital hypothyroidism, also known as cretinism, usually results from failure of the thyroid gland to migrate during fetal development (Lafranchi, 2011a). This results in malformation or malfunction of the thyroid gland, which leads to insufficient production of the thyroid hormones that are required to meet the body’s metabolic and growth and development needs. Congenital hypothyroidism leads to low concentrations of circulating thyroid hormones (triiodothyronine [ $T_3$ ] and thyroxine [ $T_4$ ]).

Congenital hypothyroidism occurs in 1 in 4,000 live births (Hatcher, 2010). It occurs over a wide range of ethnic groups, though less among African Americans, and is more common in girls than boys (Lafranchi, 2011a). Complications include intellectual disability if untreated, short stature, growth failure, and delayed physical maturation and development (Hatcher, 2010).

### Pathophysiology

Congenital hypothyroidism is due to a defect in the development of the thyroid gland in the fetus due to a spontaneous gene mutation, an inborn error of thyroid hormone synthesis resulting from an autosomal recessive trait, pituitary dysfunction, or failure of the central nervous system–thyroid feedback mechanism to develop. Transient primary hypothyroidism may also occur; it results from transplacental transfer of maternal medications, maternal thyroid-blocking antibodies, and fetal or neonatal exposure to excessive iodines (such as use of iodine antiseptics during delivery or procedures, or excess ingestion of iodine by the mother) (Lafranchi, 2011a).

### Therapeutic Management

To prevent intellectual disability and restore normal growth and motor development, thyroid hormone

replacement with sodium l-thyroxine (Synthroid, synthetic thyroxine, or Levothroid) is given. The recommended starting dosage is 10 to 15 mcg/kg per day; infants and younger children typically require a higher dosage per unit of body weight (American Academy of Pediatrics, 2011). There are no adverse effects with physiologic doses, but thyroid function tests are performed initially every 2 weeks to closely monitor for effects and to ensure proper dosing. Since thyroid hormone is vital to the infant's developing central nervous system, the goal is to normalize thyroid function as quickly as possible. This treatment will be needed lifelong to maintain normal metabolism and promote normal physical and mental growth and development.

## Nursing Assessment

Nursing assessment of the child with congenital hypothyroidism includes health history, physical examination, and laboratory testing.

### Health History

Inquire whether the neonatal metabolic screening test was performed and results obtained. Determine if the test was done less than 24 to 48 hours after birth. If so a repeat test may be warranted (see Laboratory and Diagnostic Testing below). Inquire about maternal history that may indicate a connection to hypothyroidism, such as maternal exposure to iodine. Additional history findings may include sensitivity to cold, constipation, feeding problems, or lethargy. Since parents like babies to sleep well, the parents may not complain that the baby is sleeping too much; rather, they may remark that it is difficult to keep the baby awake.

### Physical Examination

Most infants are asymptomatic until the first month, when they begin to develop clinical signs. Inspection and observation reveal a lethargic baby or a child with hypotonia, hypoactivity, and a dull expression. A combination of lethargy and irritability may exist, with an overall delayed mental responsiveness. Measurements of weight and height may reveal delayed growth. Other findings may include a persistent open posterior fontanel, coarse facies with short neck and limbs, periorbital puffiness, enlarged tongue, and poor sucking response (Fig. 49.3). The skin may appear pale with mottling or yellow from prolonged jaundice, or it may be cool, dry, and scaly to the touch, with sparse hair development on the older child. Auscultation of the chest might reveal bradycardia. Signs of respiratory distress and decreased pulse pressure may also be present. On palpation of the abdomen, there may be evidence of an umbilical hernia or a mass due to constipation.

FIGURE 49.3 Newborn with congenital hypothyroidism.

### Laboratory and Diagnostic Testing

States mandate newborn screening for thyroid hormone levels before discharge from the hospital or 2 to 6 days after birth (March of Dimes, 2011). When the test is performed within the first 24 to 48 hours along with other metabolic screenings, the result may be inaccurate because of the immediate increase in thyroid-stimulating hormone (TSH) shortly after birth (Hatcher, 2010). Radioimmunoassay is used to measure levels of  $T_4$ , which accurately reflects the child's thyroid status. If the  $T_4$  level is low then a second confirming laboratory test is performed, as well as determining whether the TSH is elevated. A thyroid scan may also be used to check for the absence or ectopic placement of the gland. In addition to serum measurement of  $T_4$ , other diagnostic tests include serum  $T_3$ , radioiodine uptake, thyroid-bound globulin, and ultrasonography.

## Nursing Management

The overall goal of nursing management of the infant or child with congenital hypothyroidism is to establish a normal growth pattern without complications such as intellectual disability or failure to thrive. Individualize the nursing care plan based on the infant's responses to the illness.

### Promoting Appropriate Growth

Measure and record growth at regular intervals. Thyroid levels are measured at recommended intervals, such as every 2 to 4 weeks until the target range is reached on a stabilized dose of medication, then every 2 to 3 months for the first several years of life, and becoming less frequent as the child gets older (Lafranchi, 2011a). A trial off the medication may be performed around the age of 3, under physician or nurse practitioner supervision, to confirm the diagnosis (Hatcher, 2010; Lafranchi, 2011a). Monitor for signs of hypo- or hyperfunction, including changes in vital signs, thermoregulation, and activity level.

Provide adequate rest periods and meet thermoregulation needs. If the infant's tongue is unusually large, observe feeding ability, prevent airway obstruction, and position the infant on the side. Fluid restrictions or a low-salt diet may be ordered.

### Take Note!

Observe for signs of thyroid hormone overdose (irritability, rapid pulse, dyspnea, sweating, and fever) or ineffective treatment (fatigue, constipation, and decreased appetite).

## Educating the Family

Since many infants are asymptomatic, the diagnosis may be unexpected, so reassure and convey realistic expectations to the family. Developmental screening may be required if the child showed any symptoms initially or as the child gets older to ensure that drug therapy is appropriate. Educate the family about the disorder, the medication and method of administration, and adverse effects such as increased pulse rate (which may indicate an overdose of thyroid hormone).

L-Thyroxine is an oral medication that is available only as a pill. It must be crushed for infants and young children. It can be mixed with a small amount of formula and placed in the nipple, but it should not be placed in a full bottle of formula because the infant will not ingest all the medication if he or she does not finish the bottle. The medication can also be mixed with a small amount of liquid and given with a dropper. Medication absorption is affected by soy-based formulas, fiber, and iron preparations (American Academy of Pediatrics, 2011). Therefore, carefully evaluate the formula the infant is on before administering L-thyroxine.

Inform the family that this medication will be needed throughout the child's life. Explain that missed doses may lead to developmental delays and poor growth. Tell them that frequent blood tests will be needed to evaluate thyroid function and the child's growth rate; genetic counseling may be needed. Clinical examination, including growth and development assessment, should occur every few months until the child is 3 years old. Serum  $T_4$  and TSH should be evaluated 2 to 4 weeks after initiation of treatment, every 1 to 2 months up to 6 months of age, every 3 to 4 months from 6 months to 36 months of age, and then every 6 to 12 months until growth is complete (American Academy of Pediatrics, 2011). More frequent monitoring may be needed if noncompliance occurs, if abnormal values occur, or with any changes in medication dosage or treatment regimen. The nurse may need to help the family to find a laboratory nearby or to handle financial issues related to the therapy. Educate the family about infant stimulation programs if the child shows cognitive problems, retarded physical growth, or

slow intellectual development. Some information may need to be reinforced during school-age or adolescent stages of development. Finally, encourage the family to obtain a medical ID bracelet or necklace for the child.

### Consider This

Asha Virani, 1 week old, is brought to the clinic. Her newborn screening test was positive for hypothyroidism. Her parents are shocked and upset by the news. Her mother states, "My daughter's been doing so well since she came home from the hospital. She seems to be doing everything she should be. She's a great sleeper. I just can't believe anything's wrong with her."

1. How would you address the parents' concerns?
2. What teaching will be appropriate for this family?

## Acquired Hypothyroidism

Hypothyroidism also occurs as an acquired condition. This disorder most commonly results from an autoimmune chronic lymphocytic thyroiditis (Lafranchi, 2011a; 2011b). As a genetic condition, antibodies develop against the thyroid gland, causing the gland to become inflamed, infiltrated, and progressively destroyed. It occurs more often in girls during childhood and adolescence (Lafranchi, 2011b). Less common etiologies include hypothyroidism associated with pituitary or hypothalamic dysfunction or exposure to drugs or substances such as lithium that interfere with thyroid hormone synthesis, radiation, thyroidectomy, and iodine deficiency.

Therapeutic management is the same as for congenital hypothyroidism. Management involves oral sodium L-thyroxine, which is given at 2 to 5 mcg/kg per day to maintain  $T_4$  in the upper half of the normal range and to suppress TSH.

## Nursing Assessment

Interview the family and child to determine activity tolerance and behavior changes. The symptoms may develop over a period of time and may be subtle. Note vague complaints of fatigue, weakness, weight gain, cold intolerance, constipation, and dry skin. The severity of symptoms depends on the length of time that the hormone deficiency has existed and its extent. Reviewing the growth pattern may reveal a slowed or arrested growth rate (height) and increased weight.

Physical examination may reveal a **goiter** (enlargement of the thyroid gland). Deep tendon reflexes may be sluggish and the face, eyes, and hands may be edematous. Note thinning or coarse hair, muscle hypertrophy

with muscle weakness, and signs of delayed or precocious puberty. The diagnostic evaluation involves serum thyroid function studies (TSH,  $T_3$ , and  $T_4$ ) as well as serum thyroid antibodies to confirm autoimmune thyroiditis. MRI and a thyroid uptake test and scan may also be necessary.

## Nursing Management

Work with the family to establish a daily schedule for administering L-thyroxine, which should be taken 30 to 60 minutes before a meal for optimal absorption. Explain to the family that growth is related to the child's response to the treatment, and there are no specific strategies to aid in this growth. The family should understand the diagnosis, should be able to recognize signs and symptoms of thyroid hypo- and hyperfunction, and should know when to notify the physician or nurse practitioner. The family and child may need assistance in accepting the therapy as well as the experience of catch-up growth that may occur at the beginning of therapy. The child with chronic or severe hypothyroidism may be at risk for adverse effects such as restlessness, insomnia, or irritability. The child's thyroid levels should be evaluated at recommended intervals such as every 3 to 6 months by a pediatric endocrinologist.

### Hyperthyroidism

Hyperthyroidism is the result of hyperfunction of the thyroid gland. This leads to excessive levels of circulating thyroid hormones. This condition is uncommon in children. The peak incidence in children occurs in adolescence as a result of Graves disease (Lifshitz, 2007; Lafranchi, 2011c). Graves disease is an autoimmune disorder that causes excessive amounts of thyroid hormone to be released in response to human thyroid stimulator immunoglobulin (TSI). It occurs five times more often in girls than in boys (Lafranchi, 2011c). A goiter usually develops in this condition. There is a genetic marker in individuals affected by Graves disease, with 60% of affected people having a family history of autoimmune thyroid problems (Lafranchi, 2011c). A congenital form of hyperthyroidism, neonatal thyrotoxicosis, occurs in infants of mothers with Graves disease. This neonatal condition, which can be life-threatening, is a self-limiting disorder lasting 2 to 4 months. Less common causes of hyperthyroidism are thyroiditis, thyroid hormone-producing tumors, and pituitary adenomas.

Therapeutic management is aimed at decreasing thyroid hormone levels. Current treatment involves antithyroid medication, radioactive iodine therapy, and subtotal thyroidectomy. First-line treatment involves propylthiouracil (PTU) or methimazole (MTZ, Tapazole), which blocks the production of  $T_3$  and  $T_4$ . Adjunct therapy with  $\beta$ -adrenergic blockers (Inderal) may also be used if the

child has marked symptoms. Radioactive iodine therapy is becoming acceptable for children greater than 10 years of age as a long-term therapy (Lafranchi, 2011c). This therapy is administered orally and results in tissue damage and destruction of the thyroid gland within 6 to 18 weeks, but it can result in hypothyroidism. Subtotal thyroidectomy is used when drug therapy is not possible or other treatments have failed. Risks include hypothyroidism, hypoparathyroidism, or laryngeal nerve damage.

## Nursing Assessment

Initially, symptoms of hyperthyroidism are mild and often overlooked. Many children with hyperthyroidism are first seen in the outpatient setting with a history of a problem with sleep, school performance, and distractibility. They become easily frustrated, overheated, and fatigued during physical education class. The child may complain of diarrhea, excessive perspiration, and muscle weakness. The history may also reveal hyperactivity, heat intolerance, emotional lability, and insomnia.

Physical examination of the older child may reveal an increased rate of growth; weight loss despite an excellent appetite; hyperactivity; warm, moist skin; tachycardia; fine tremors; an enlarged thyroid gland or goiter; and ophthalmic changes (exophthalmos, which is less pronounced in children; proptosis; lid lag and retraction; staring expression; periorbital edema; and diplopia) (Fig. 49.4). Elevated pulse and blood pressure may also be noted. Laboratory and diagnostic tests reveal that serum  $T_4$  and  $T_3$  levels are markedly elevated while TSH levels are suppressed.

FIGURE 49.4 Adolescent with Graves disease.

## COMPARISON CHART 49.2

## HYPOTHYROIDISM VERSUS HYPERTHYROIDISM

Hyperthyroidism	Hypothyroidism
<ul style="list-style-type: none"> <li>• Nervousness/anxiety</li> <li>• Diarrhea</li> <li>• Heat intolerance</li> <li>• Weight loss</li> <li>• Smooth, velvety skin</li> </ul>	<ul style="list-style-type: none"> <li>• Tiredness/fatigue</li> <li>• Constipation</li> <li>• Cold intolerance</li> <li>• Weight gain</li> <li>• Dry, thick skin; edema of face, eyes, and hands</li> <li>• Decreased growth</li> </ul>

**Take Note!**

The sudden release of high levels of thyroid hormones results in thyroid storm, which progresses to heart failure and shock. Immediately report the signs of thyroid storm, which include sudden onset of severe restlessness and irritability, fever, diaphoresis, and severe tachycardia (Lafranchi, 2011c).

## Nursing Management

Once the treatment plan is initiated, educate the family and child about the medication and potential adverse effects, the goals of treatment, and possible complications. Monitor for adverse drug effects such as rash, mild leukopenia, loss of taste, sore throat, gastrointestinal disturbances, and arthralgia. If the medication is given two or three times a day, teach the family to use a pill dispenser and alarm clock. Inform the family of the need for routine blood tests and follow-up visits with the pediatric endocrinologist every 2 to 4 months until normal levels are reached; then visits may be decreased to once or twice a year. Instruct the parents to contact the physician or nurse practitioner if the child has tachycardia or extreme fatigue.

Help the child and family to cope with symptoms such as heat intolerance, emotional lability, or eye problems. Explain these symptoms to the school or day care personnel and make sure that they understand that the child should take more frequent rest breaks in a cool environment, and should avoid physical education classes until normal hormone levels are attained. Encourage the family to have the child consume a healthy diet with an appropriate level of calories; the child may need to eat five or six meals a day. Provide community referrals such as to the National Graves' Disease Foundation, a link to which can be found on [thePoint](#). Encourage the family to obtain a medical ID bracelet or necklace.

If surgical intervention is chosen, provide appropriate preoperative teaching and postoperative care. Provide supportive measures such as fluid maintenance,

nutritional support, and electrolyte correction. Monitor red blood cell count and liver function tests. Close monitoring for signs and symptoms of hypothyroidism is important.

Comparison Chart 49.2 compares hypothyroidism and hyperthyroidism.

## DISORDERS RELATED TO PARATHYROID GLAND FUNCTION

The parathyroid glands secrete parathyroid hormone (PTH). This hormone, along with vitamin D and calcitonin, regulates calcium/phosphate homeostasis by increasing osteoclastic activity, absorption of calcium and excretion of phosphate by the kidneys, and absorption of calcium in the gastrointestinal tract. The two disorders associated with parathyroid gland dysfunction are hypoparathyroidism and hyperparathyroidism. Both of these disorders are rare in children. Refer to Table 49.2.

## DISORDERS RELATED TO ADRENAL GLAND FUNCTION

Disorders of the adrenal gland include acute and chronic adrenal insufficiency (hypofunction) and disorders of hyperfunction, such as Cushing syndrome. The adrenal cortex is the site of production of glucocorticoids (for blood glucose regulation), mineralocorticoids (for sodium retention), and androgenic and estrogenic steroid compounds (for phallic and secondary sex development). The adrenal medulla is the site of production of the catecholamines (dopamine, norepinephrine, and epinephrine) and is under neuroendocrine control. When production of these compounds is altered, disease results. Pediatric adrenocortical insufficiency is similar to adults with the exception of congenital adrenal hyperplasia, which will be discussed below. Refer to Table 49.3 for an overview of other disorders of the adrenal gland.

TABLE 49.2

## PARATHYROID DISORDERS

Parathyroid Disorder	Cause	Nursing Assessment	Nursing Management
Hypoparathyroidism (deficiency of PTH)	Most common is accidental removal or destruction of the parathyroid gland during thyroidectomy or radial neck dissection; may also be congenital (result of aplasia or hypoplasia of the parathyroid gland)	Hypocalcemia Hyperphosphatemia Hyperexcitability of neuromuscular function, uncontrolled spasms, and hypocalcemic tetany (general muscular hypertonia); positive Chvostek sign (facial muscle spasm elicited by tapping the facial nerve); positive Trousseau sign (carpopedal spasm that results from oxygen deficiency) Laryngeal spasm, stridor Poor eating Lethargy	<ul style="list-style-type: none"> <li>Administer intravenous calcium gluconate for acute or severe tetany, then intramuscular or oral calcium as prescribed.</li> <li>Monitor the child for the development of cardiac arrhythmias. Ensure that the intravenous site is patent; if extravasation occurs, tissue damage or cardiac arrhythmias may result.</li> <li>Monitor fluid and electrolyte status, weigh the child daily, and measure urinary calcium excretion to prevent nephrocalcinosis.</li> <li>Institute seizure precautions and reduce environmental stimuli (e.g., loud or sudden noises, bright lights, or stimulating activities).</li> <li>Observe for signs and symptoms of laryngospasm (e.g., stridor, hoarseness, or a feeling of tightness in the throat). Teach the child and family about the need for continuous daily administration of calcium salts and vitamin D. Have the family observe for signs such as weakness, fatigue, lassitude, headache, nausea and vomiting, and diarrhea.</li> </ul>
Hyperparathyroidism (hypersecretion of PTH)	Parathyroid adenoma is the most common cause; secondary hyperparathyroidism is primarily due to renal failure.	Hypercalcemia Hypophosphatemia Depression of neuromuscular function, child may trip and drop objects, general fatigue, failure to thrive, headaches, poor school performance, and irritability, somnolence, stupor, or difficulty concentrating. Irregular heart rate, possibly related to cardiac dysrhythmias. Skeletal pain, fractures, formation of bone tumors, or flank pain related to renal calculi	<ul style="list-style-type: none"> <li>Administer IV fluids and diuretics as prescribed to increase urinary excretion of calcium in children not in renal failure.</li> <li>Administer prescribed medication to treat hypercalcemia, such as oral phosphate (antihypercalcemic agent), pamidronate, calcitonin, or etidronate disodium (by inhibiting bone resorption of calcium).</li> <li>Increase the child's fluid intake to minimize renal calculi formation. Provide fruit juices to maintain low urinary pH, acidity of body fluids, and calcium absorption. Strain the urine for renal casts.</li> <li>Dietary calcium is restricted.</li> <li>Monitor for safety by assessing the child's level of muscular weakness, preventing falls or injury, and checking for fractures.</li> <li>If the child develops renal rickets (osteodystrophy), long-term braces may be required, so provide family education and encourage compliance.</li> <li>Surgery may be performed to remove abnormal parathyroid tumor.</li> <li>Keep the diet low in phosphorus and watch for hypocalcemia and onset of tetany after surgery.</li> </ul>

**TABLE 49.3** OTHER DISORDERS OF THE ADRENAL GLAND

Disorder	Cause	Nursing Assessment	Nursing Management
Addison disease (deficiency in the adrenal steroids, glucocorticoids [cortisol], and mineralocorticoids [aldosterone])	It results from damage or destruction of the adrenal glands caused by infections such as tuberculosis, fungal infections, or HIV-related infections; hemorrhage or surgical removal of both glands; or dysfunction of the hypothalamus or pituitary gland. Generally, the etiology in children is an autoimmune process that is familial or sporadic. <sup>a</sup>	Hyponatremia Hyperkalemia Water loss, dehydration, muscular weakness, fatigue, weight loss, anorexia, syncope, nausea, vomiting, and diarrhea Hypoglycemia Hypotension Hyperpigmentation of skin Adrenal crisis, also referred to as Addisonian crisis, can occur (refer to section on CAH for more information).	<ul style="list-style-type: none"> <li>Similar to that of congenital adrenal insufficiency</li> </ul>
Cushing syndrome (excess levels of one or all the hormones [glucocorticoids, mineralocorticoids, and adrenal androgens] but most commonly glucocorticoid excess)	Usually this condition is due to a small ACTH-producing pituitary adenoma. The most common cause in older children is prolonged or excessive use of corticosteroid therapy. <sup>a</sup>	Note history of rapid weight gain, decreased velocity of linear growth, muscle weakness, fatigue, irritability, sleep disturbance, and hypertension. History of long-term corticosteroid use, water retention, poor wound healing, frequent infections, and in teenage girls, missed menstrual periods Refer to Figure 49.6. Skin may be thin and fragile; acne may be present.	<ul style="list-style-type: none"> <li>Management varies depending on the cause.</li> <li>The goal is to restore hormone balance and reverse Cushing syndrome.</li> <li>If the cause is an adrenal or pituitary tumor, then surgical removal of the tumor alone or the entire adrenal gland is performed.</li> <li>If the cause is long-term steroid therapy, then the corticosteroid dose is reduced to the lowest dose that is effective in treating the underlying disorder.</li> <li>Cortisol synthesis-inhibiting medications may be used.</li> <li>Counsel the family that the cushingoid appearance is reversible with appropriate treatment.</li> <li>Be alert for signs of adrenal insufficiency if the child has surgery or if corticosteroid withdrawal occurs quickly.</li> </ul>

<sup>a</sup>White, P. C. (2011). Section 4: Disorders of the adrenal glands. In R. M. Kliegman, B. F. Stanton, J. W. St. Geme, N. F. Schor, & R. E. Behrman, (Eds.), *Nelson's textbook of pediatrics* (19th ed., p. 1923–43). Philadelphia: Saunders.

## Congenital Adrenal Hyperplasia

Congenital adrenal hyperplasia (CAH) is a group of autosomal recessive inherited disorders in which there is an insufficient supply of the enzymes required for the synthesis of cortisol and aldosterone. It is the most common type of adrenocortical insufficiency seen in children with

an incidence of about 1 in 15,000 to 20,000 live births (Hatcher, 2010; White, 2011). More than 90% of the cases of CAH are caused by a deficiency of 21-hydroxylase (21-OH) enzyme (Hatcher, 2010; White, 2011). Therefore, our discussion will focus on this type. This condition can be life-threatening and requires prompt diagnosis and treatment after birth (Hatcher, 2010). Complications of CAH include hyponatremia (low blood sodium levels),

hyperkalemia (high blood potassium levels), hypotension (abnormally low blood pressure), shock, hypoglycemia (low blood glucose levels), short adult stature, and adult testicular tumor in males.

## Pathophysiology

21-OH enzyme deficiency results in blocking the production of adrenal mineralocorticoids and glucocorticoids. A reduction of cortisol occurs, which leads to increased adrenocorticotropic hormone (ACTH) production by the anterior pituitary to stimulate adrenal gland production. Prolonged oversecretion of ACTH causes enlargement or hyperplasia of the adrenal glands and excess production of androgens, leading to male characteristics appearing early or inappropriately.

In males, the enzyme deficiency of 21-OH with excessive androgen secretion leads to a slightly enlarged penis, which may become adult-sized by school age, and a hyperpigmented scrotum. Males do not have obvious signs at birth but may enter puberty by 2 to 3 years of age. The female fetus develops male secondary sexual characteristics; thus, CAH causes ambiguous genitalia in girls (Hatcher, 2010). The clitoris is enlarged and may resemble the penis, the labia have a rugated appearance, and the labial folds are fused, but the internal reproductive organs, including the ovaries, fallopian tubes, and uterus, are normal.

A milder form of 21-OH deficiency becomes evident later (genitals are normal at birth), in the toddler or preschool years, with premature **adrenarche** (early sexual maturation), pubic hair development, accelerated growth velocity, advanced bone age, early closure of the epiphyseal plates resulting in short stature as an adult, acne, and **hirsutism** (excessive body hair growth). Males usually have normal fertility while females may have lower fertility.

Aldosterone insufficiency also leads to fluid and electrolyte imbalances, such as hyponatremia, hyperkalemia, and hypotension due to depletion of extracellular fluid. Cortisol insufficiency leads to hypoglycemia.

## Therapeutic Management

The goal of treatment is to stop excessive adrenal secretion of androgens while maintaining normal growth and development. Most children with 21-OH deficiency will take a glucocorticoid such as hydrocortisone and the mineralocorticoid fludrocortisone (Florinef) for life. Infants may also require sodium supplementation. When the medications are taken at physiologic doses there are no adverse effects, but if the drug levels become elevated, hypertension, growth impairment, and acne become a problem. Regular follow-up care and appropriate titration maintain the dose at appropriate levels to allow normal growth and development.

Usually when girls are born with ambiguous genitalia, standard medical treatment is to correct the external genitalia and establish adequate sexual functioning. Gender can be determined by karyotyping chromosomes. Typically, a reduction of the clitoris and opening of the labial folds is done within 2 to 6 months of life, with further surgeries at puberty (White, 2011). Some argue that surgery should be delayed until the child is old enough to decide what kind of correction (if any) should be performed (White, 2011). The decision to intervene immediately or to delay treatment is a complex one that raises many concerns for the family. Further long-term follow-up research is needed to determine risks and benefits of early versus delayed treatment (White, 2011).

## Nursing Assessment

Nursing assessment of the child with CAH includes health history, physical examination, and laboratory and diagnostic testing. Specific findings related to CAH are presented below.

### Health History and Physical Examination

Obtain the health history, noting history of abnormal genitalia at birth in the infant. In the toddler or preschooler, note history of accelerated growth velocity and signs of premature adrenarche. Upon inspection of the infant's genitalia, note a large penis in the boy and ambiguous genitalia in the girl (Fig. 49.5). When observing the toddler or preschooler, note pubic hair development, acne, and hirsutism.

### Laboratory and Diagnostic Testing

The most common type of CAH, 21-OH enzyme deficiency, is detected by newborn metabolic screening. See

FIGURE 49.5 Newborn with ambiguous genitalia.

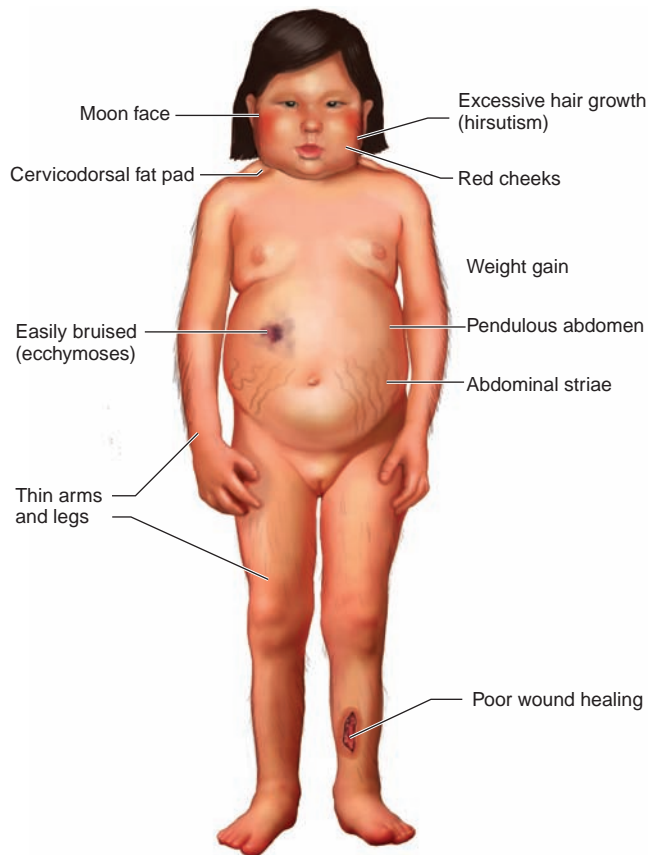

FIGURE 49.6 Cushing syndrome.

Healthy People 2020. If this test has not been done or the results are unavailable, obtain random hormone levels or levels associated with ACTH stimulation. Radiographs reveal advanced bone age and premature closure of epiphyseal plates of the long bones.

### HEALTHY PEOPLE 2020

#### Objective

Increase appropriate newborn blood-spot screening and follow-up testing.

*Healthy People Objectives based on data from <http://www.healthypeople.gov>.*

#### Nursing Significance

- Follow up with state agencies at first contact with infant to ascertain results of newborn screening.

## Nursing Management

In addition to the common interventions associated with endocrine disorders in childhood (see Nursing Care Plan 49.1), nursing management of the infant or child with CAH focuses on preventing and monitoring for acute

adrenal crisis, helping the family to understand the disease, providing education to the child and family about the importance of maintaining hormone supplementation, and providing emotional support to the family.

### Preventing and Monitoring for Acute Adrenal Crisis

Providing ongoing assessment of the ill or hospitalized child with a history of CAH is crucial in order to recognize the development of life-threatening acute adrenal crisis. Signs and symptoms of acute adrenal crisis include persistent vomiting, dehydration, hyponatremia, hyperkalemia, hypotension, tachycardia, and shock. Monitor children with CAH closely and notify the physician or nurse practitioner if adrenal crisis is suspected. If signs and symptoms of adrenal crisis develop, the child will receive intravenous steroids, such as hydrocortisone, and aggressive fluid resuscitation, often using 5% dextrose in normal saline (D5NS), to correct electrolyte imbalances.

#### Take Note!

Adrenal crisis in the newborn is often unrecognized. It presents within the first few days to weeks of life with vomiting, lethargy, and feeding difficulties.

### Educating the Family About the Medication Regimen

Medication will be required throughout the child's life because cortisone is necessary to sustain life. Teach the family the appropriate oral dosages of hydrocortisone and fludrocortisone. It is critical to maintain tight control over the levels of these medications in the bloodstream. Either underdosing or overdosing may lead to short adult stature. Low levels of the hormones may also result in adrenal crisis (as discussed above). These drugs are usually given orally but in some instances will need to be given via intramuscular injections. Teach families how to give hydrocortisone intramuscularly if the child is vomiting and cannot keep down oral medication. If the child becomes ill, is under stress, or needs surgery, additional doses of medications may be required. Encourage the family to obtain a medical ID bracelet or necklace for the child.

#### Take Note!

Families must keep extra steroids in an injectable form, such as Solu-Cortef or Decadron, at home to give during an emergency.

### Providing Family Support

Make sure the family of a newborn with ambiguous genitalia feels comfortable asking questions and exploring their feelings. There are many issues to consider, such as

whether the family will reassign the child's sex or raise the child with the original assignment at birth. The birth certificate may pose a problem if the state requires identification of sex. Cultural attitudes, the parents' expectations, and the extent of family support influence the family's response to the child and the decision-making process related to sex assignment and surgical correction. If corrective surgery is immediately decided upon, then typical surgical concerns for newborns will need to be addressed.

In general, laypeople do not understand adrenal function and what this diagnosis may mean to the family. Provide families with privacy to discuss these issues, and offer emotional support. When referring to the infant, use terms such as "your baby" instead of the pronouns "he," "she," or "it" and describe the genitals as "sex organs" instead of "penis" or "clitoris." Refer families to the CARES (Congenital Adrenal Hyperplasia Research, Education, and Support) Foundation and the Magic Foundation for additional support and resources. Links to these resources are provided on [thePoint](#). Local parent-to-parent support groups are also helpful.

## POLYCYSTIC OVARY SYNDROME

Polycystic ovary syndrome (PCOS), also referred to as functional ovarian hyperandrogenism or ovarian androgen excess, is an endocrine disorder that produces a variety of symptoms in adolescent girls and women. The exact cause is unknown. Testosterone production by the ovaries and adrenal cells is excessive, causing hirsutism, balding, acne, increased muscle mass, and decreased breast size. Polycystic ovaries may or may not be present. There is a genetic predisposition for PCOS, and many women with PCOS are also obese (Shayya & Chang, 2009).

Complications of excess androgen production in women include infertility, insulin resistance, and hyperinsulinemia, leading to diabetes mellitus, increased risk for endometrial carcinoma, and cardiovascular disease. Therapeutic management involves the administration of oral contraceptives for their hormonal effects, as well as insulin-sensitizing medications such as metformin (Glucophage).

## Nursing Assessment

Explore the health history for oligomenorrhea (irregular, infrequent periods) or amenorrhea. Symptoms typically emerge at or soon after puberty but often go undiagnosed. Note weight in relation to standardized growth charts and calculate body mass index (BMI) to determine whether the girl is overweight or obese. Inspect the skin for acne, acanthosis nigricans (darkened, thickened pigmentation, particularly around the

neck or in the axillary region), and hirsutism (excess body hair growth). Assist with collection of timed blood specimens for glucose and insulin levels (which will often show unexpectedly elevated insulin levels in relation to the glucose level). Laboratory tests may show elevated levels of free testosterone and other androgenic hormones.

## Nursing Management

One of the most important functions of the nurse in relation to PCOS is to assist with early recognition and treatment. Educate the adolescent girl about the use of oral contraceptives to normalize hormone levels, which will decrease androgenic effects. Support the teen in her efforts to diet and exercise to lose weight. Oral insulin-sensitizing drugs such as metformin (Glucophage) may be prescribed. Encourage the teen to comply with the medication regimen. Routinely measure weight to determine progress with weight loss. Measure blood pressure to screen for hypertension, which may develop as a complication of PCOS. Online support groups and education are available. Links to several resources are provided on [thePoint](#).

## DIABETES MELLITUS

Diabetes mellitus (DM) is a common chronic disease seen in children and adolescents. In DM, carbohydrate, protein, and lipid metabolism is impaired. The cardinal feature of DM is hyperglycemia. The major forms of diabetes are classified as:

- Type 1, which is caused by a deficiency of insulin secretion due to pancreatic  $\beta$ -cell damage
- Type 2, which is a result of insulin resistance that occurs at the level of skeletal muscle, liver, and adipose tissue with different degrees of  $\beta$ -cell impairment (Alemzadeh & Ali, 2011)
- Other types of diabetes secondary to certain conditions such as cystic fibrosis, glucocorticoid use (as in Cushing syndrome), and certain genetic syndromes such as Down syndrome, Klinefelter syndrome, and Turner syndrome (Alemzadeh & Ali, 2011; National Diabetes Education Program, 2008)
- Gestational diabetes (diabetes during pregnancy)

The discussion for this chapter will focus on type 1 and type 2 diabetes as these are the most common types seen in children. However, clinical presentation and disease progression of DM can vary considerably. Therefore, in some cases children cannot be clearly defined as having type 1 or type 2 (American Diabetes Association, 2011).

In the past childhood DM was assumed to be type 1. Every year approximately 13,000 children and adolescents are diagnosed with type 1 DM (Center for Disease

Control and Prevention, 2012). Historically, type 2 DM occurred mostly in adults. However, in recent years, type 2 DM has been reported in U.S. children and adolescents at an increasing and alarming rate (Centers for Disease Control and Prevention, 2012). Some studies report that between 8% and 45% of children with newly diagnosed diabetes have type 2 (Dowshen, 2009). In the next 10 years, the prevalence of type 2 DM is expected to exceed type 1 in U.S. children (American Academy of Pediatrics Policy, 2009). This increase in incidence of type 2 DM among children and adolescents may be attributed to the rise in obesity and decreased physical activity in young people along with exposure to diabetes in utero (Centers for Disease Control and Prevention, 2012). Many children with type 2 DM have a relative with type 2 DM and/or are overweight. Children of American Indian/Alaska Native descent have a higher rate of type 2 DM, and Mexican American, Asian American, and African American children are at a higher risk for developing the disease (American Academy of Pediatrics Policy, 2009). See Healthy People 2020.

### HEALTHY PEOPLE 2020

#### Objective

Reduce the annual number of new cases of diagnosed diabetes in the population.

#### Nursing Significance

- Screen all children periodically for the development of overweight and obesity using body mass index on the Centers for Disease Control and Prevention growth charts.
- Educate families about appropriate diet and exercise beginning in toddlerhood in order to prevent the development of obesity.

*Healthy People Objectives based on data from <http://www.healthypeople.gov>.*

Care of children with diabetes differs from that of adults due to physiologic and developmental differences. In children insulin sensitivity varies as the child grows and goes through sexual maturation. Children are dependent on others for their care, and self-management ability varies among children based on age, developmental level, and individual differences. Care will be needed in a variety of settings such as school, day care, and extracurricular activities. Therefore, teaching and education will need to involve parents and other caregivers throughout childhood and adolescence. Refer to Table 49.4, which discusses developmental issues related to diabetes mellitus.

## Pathophysiology

Type 1 DM is an autoimmune disorder that occurs in genetically susceptible individuals who may also be exposed to one of several environmental or acquired factors, such as chemicals, viruses, or other toxic agents implicated in the development process. As the genetically susceptible individual is exposed to environmental factors, the immune system begins a T-lymphocyte-mediated process that damages and destroys the  $\beta$  cells of the pancreas, resulting in inadequate insulin secretion. This deficiency of insulin leads to an inability of cells to take up glucose. The end result is hyperglycemia, glucose accumulation in the blood, and the body's inability to use its main source of fuel efficiently. The kidneys try to lower blood glucose, resulting in glycosuria and polyuria, and protein and fat are broken down for energy. The metabolism of fat leads to a build-up of ketones and acidosis (see discussion of diabetic ketoacidosis below).

In type 2 DM the pancreas usually produces insulin but the body is resistant to the insulin or there is an inadequate insulin secretion response (the body can produce insulin but not enough to meet the body's needs). Eventually, insulin production decreases (resulting from the pancreas working overtime to produce insulin), with a result similar to type 1 DM.

If DM goes unrecognized or is inadequately treated (especially type 1 DM), **diabetic ketoacidosis (DKA)** or fat catabolism develops (a deficiency or ineffectiveness of insulin results in the body using fat instead of glucose for energy), resulting in anorexia, nausea and vomiting, lethargy, stupor, altered level of consciousness, confusion, decreased skin turgor, abdominal pain, Kussmaul respirations and air hunger, fruity (sweet-smelling) or acetone breath odor, presence of ketones in urine and blood, tachycardia, and, if left untreated, coma and death.

#### Take Note!

DKA is a medical emergency. It requires early recognition and prompt intervention. Be alert to the increased chance of DKA during times of stress such as illness, infection, and surgery, as hormones produced by the body in times of stress result in decreased insulin sensitivity and increased glucose production.

Prolonged exposure to high blood glucose levels results in damage to blood vessels and nerves. Long-term complications of DM include failure to grow, delayed sexual maturation, poor wound healing, recurrent infections (especially of the skin), retinopathy, neuropathy, vascular complications, nephropathy, cerebrovascular disease, peripheral vascular disease, and cardiovascular disease. Consistent, well-controlled blood glucose levels can prevent these complications from developing for many years. On the other hand, poorly controlled DM can lead to complications much earlier.

TABLE 49.4

## DEVELOPMENTAL ISSUES RELATED TO DIABETES MELLITUS

Age Group	Child and Family Implications	Nursing Implications
Infants	Management falls on parents/caretakers. Infant is unable to communicate hypo-/hyperglycemic symptoms; signs and symptoms are sometimes difficult to assess. Increased risk of hypoglycemia due to inconsistent feeding times and amounts. Developing brain may experience adverse consequences to severe hypo-/hyperglycemia.	Prevent extreme fluctuations in blood glucose. Prevent hypoglycemia and, if present, treat promptly. Attempt to achieve consistent dietary intake. Establish rituals/routines with home management. Provide support for parents and caregivers.
Toddlers	Management falls on parents/caretakers. Increased risk of hypoglycemia due to inconsistent food intake (picky eaters). Developing brain may experience adverse consequences to severe hypo-/hyperglycemia. Discipline and temper tantrums common in this age group; may be hard to distinguish between normal toddler behavior and hypoglycemia symptoms. Parents may be overcautious and hinder child's ability to explore and develop normally.	Prevent hypoglycemia and if present treat promptly. Assist parents in managing a picky eater. Let toddler choose foods. Get toddler to find a word or phrase to use to describe feelings when hypoglycemic. Help parents to provide appropriate discipline and protection while continuing to promote normal development. Establish rituals/routines with home management.
Preschoolers	Increased motor maturity. Widening social circle, so the child will notice that he or she is "different." Magical thinking presents some issues. Developing brain may experience more adverse consequences to severe hypo-/hyperglycemia than older children. Preschooler wants to be an active participant in diabetes care but may lack some of the developmental skills (such as fine motor and cognitive skills). Some children can begin to perform blood glucose testing with the newer devices. Increased risk of hypoglycemia due to varied food intake and activity.	Prevent hypoglycemia and if present treat promptly. Use simple explanations and play therapy when instructing or preparing for a procedure. Encourage child's participation as appropriate.
School-age children	Can begin to participate in more of the daily diabetes care; may be able to perform self-monitoring blood glucose testing, record glucose levels, choose injection sites and give injections, perform ketone testing, count carbohydrates, recognize need to eat, and treat for hypoglycemia. Beginning to rely on others (such as school nurse, child care provider, preschool teacher) to provide diabetes care. Children may feel different from their peers and struggle socially. Must incorporate management into school day, and plan for field trips.	Use concise and concrete terms when instructing. Allow child to proceed at his or her own rate. Assist family to incorporate the testing and injections into school day and plan for field trips. Involve the school nurse in helping with the school plan. Encourage the child's participation but emphasize importance of continued adult supervision. Encourage regular attendance at school and participation in extracurricular activities. Assist in the development of a care schedule that is flexible enough to allow for participation in school activities. Assist with education of other care providers as needed.
Adolescents	Undergoing rapid physical, emotional and cognitive growth. Working toward separate identity from parents and the demands of diabetic care can hinder this. This struggle for independence can lead to nonadherence of diabetic care regimen. Conflicts develop with self-management, body image, and peer group acceptance. They acquire the skills to perform tasks related to diabetic care but may lack decision-making skills needed to adjust treatment plan. Teens do not always foresee the consequences of their activity.	Slowly care is turned over to the adolescent with minor supervision from the family. Encourage parents and teen to find the right balance of shared management. Encourage parents to continue to provide guidance and supervision and be actively involved in the plan of care. Assess adherence to diabetic care regimen. Assess for signs/symptoms of depression, eating disorders, or evidence of risky behaviors. In later adolescence assist teen in transitioning to independent self-management and adult diabetes physician or nurse practitioner.

## Therapeutic Management

Treatment for DM must occur as part of a multidisciplinary health care team, with the family and child as a central part of that team. In the past the child would be admitted to the hospital for 3 to 5 days for stabilization and education, but today the trend is toward treating children on an outpatient basis. Established glucose control is essential in reducing the risk of long-term complications associated with DM. Therefore, general goals for therapeutic management include:

- Achieving normal growth and development
- Promoting optimal serum glucose control, including fluid and electrolyte levels and near-normal **hemoglobin A1C** or glycosylated hemoglobin (which is hemoglobin that glucose is bound to and it monitors long-term control of blood sugars and diabetes) levels
- Preventing complications
- Promoting positive adjustment to the disease, with ability to self-manage in the home

The key to success is to educate the child and family so they can self-manage this chronic condition. Therapeutic management involves blood glucose monitoring; daily injections of insulin and/or administration of oral hypoglycemic medications; a realistic and well-balanced diet; an exercise program; and self-management and decision-making skills.

Research is ongoing to develop alternative medications, including alternative routes for insulin administration (such as inhaled) and therapies to monitor and treat diabetes (such as continuous glucose sensing systems [National Diabetes Education Program, 2008]).

### Monitoring Glycemic Control

Consistent glycemic control leads to fewer long-term diabetes-related complications. Two important methods for monitoring glycemic control include blood glucose monitoring and monitoring hemoglobin A1C levels.

#### BLOOD GLUCOSE MONITORING

Blood glucose monitoring evaluates short-term glycemic control. It allows for tight glucose control because supplemental insulin can be used to correct or prevent hyperglycemia; it also enables children and their parents and their physicians or nurse practitioners to provide better management of the disease. (Refer to Common Laboratory and Diagnostic Tests 49.1). The frequency of blood glucose monitoring is based on the goals for each particular child. Children who are in the hospital for management of their DM or are on insulin therapy require blood glucose monitoring before meals and at bedtime if not more frequently. Additional glucose checks may be necessary if glycemic control has not occurred, during times of illness, during episodes of hypoglycemic

or hyperglycemic symptoms, or when there are changes in therapy. Children receiving noninsulin therapy may check their blood glucose less frequently but it can remain a useful guide to their therapy and its effectiveness. The procedure for glucose monitoring will vary based on equipment used but often involves a fingerstick, a reagent strip, and a glucometer.

Self-monitoring of blood glucose (SMBG) at home is essential to improve glycemic control, to provide self-management of this disease, and to help to prevent complications such as severe hypo-/hyperglycemia. The child and caregiver need to be aware of the importance of checking blood glucose regularly and more frequently when needed. Documenting blood glucose values is necessary to provide information on glucose control. This allows their physician or nurse practitioner to evaluate the effectiveness of their treatment regimen. Accuracy of SMBG is dependent on proper user technique; therefore, assessment of technique and education reinforcement are important at each visit (see Teaching Guidelines 49.2).

#### MONITORING HEMOGLOBIN A1C LEVELS

Hemoglobin A1C (HbA1C) provides the physician or nurse practitioner with information regarding the long-term control of glucose levels (refer to Common Laboratory and Diagnostic Tests 49.1). In adults the goal is to achieve a near-normal HbA1C. However, in children, especially infants and children younger than 3 years, hypoglycemia poses some unique risks and can be hard to recognize (American Diabetes Association, 2011) (refer to Table 49.4). Glycemic control goals need to be individualized, but the American Association of Diabetes (2011) has developed standards related to HbA1C goals in children with type 1 diabetes. These include:

- Infants and young children 0 to 6 years: HbA1C less than 8.5% but greater than 7.5%
- Children 6 to 12 years: less than 8%
- Children and adolescents 13 to 19 years: less than 7.5%

### Insulin Replacement Therapy

Insulin replacement therapy is the cornerstone of management of type 1 DM. Insulin is administered daily by subcutaneous injections into adipose tissue over large muscle masses using a traditional insulin syringe or a subcutaneous injector (Fig. 49.7). U-100 insulin may also be administered using a portable insulin pump (see discussion below). The frequency, dose, and type of insulin are based on how much the child needs to achieve a normal, average blood glucose concentration and to prevent hypoglycemia. Typically, two to four daily injections are commonly used, with dosage depending on the needs of the child. The dose may need to be increased during the pubertal growth spurt as well as during times of illness or stress. See Evidence-Based Practice 49.1.

## EVIDENCE-BASED PRACTICE 49.1

## IDEAL INJECTION TECHNIQUES WHEN USING 5-MM NEEDLES IN CHILDREN

## STUDY

One hundred and twenty-two otherwise healthy children/adolescents (5 to 19 years of age) with type 1 DM and 137 adults (22 to 85 years of age) with type 1 and type 2 DM were injected with sterile air (corresponding to 20 IU insulin) with 32-gauge 5-mm needles at 90 and 45 degrees with or without pinched skin in the abdomen and thigh. Via ultrasound injection depth was measured (assessed as either intradermal, intramuscular, or subcutaneous placement) and subjects rated pain on a facial or visual analog scale. To assess injection leakage, test medium injections, at 45 or 90 degrees with pinched skin, into the abdomen and thigh were also performed.

## Findings

No adverse effects, such as bleeding and bruising, were associated with the injections. In children few injections were located outside of the subcutaneous tissue, but there was a significant association between age and likelihood of intramuscular (IM) injection, with the incidence of IM injection even lower in adults. The analysis also showed

clear sex differences in the number of IM injections in children and adolescents, with higher frequency of IM injection in boys. In boys angled and pinched skin resulted in less IM incidence. In girls no IM injections were noted when the skin was pinched or injection administered in the thigh. Children experienced more pain with injection than adults but about one third of children reported no pain. Angle or site of injection did not affect experience of pain. Injections in adults more likely lead to leakage than in children. Leakage was not affected by the volume of the medium but was more likely to occur with vertical injections and with thigh injections (but even then leakage was minimal).

## Nursing Implications

The use of 32-gauge 5-mm needles is associated with minimal leakage and pain, and these can be reliably inserted into subcutaneous tissue. In children, nurses should use a 32-gauge 5-mm needle utilizing an angled technique with pinched skin fold to reduce the chance of IM injection and decrease pain and leakage.

Adapted from Hofman, P. L., Derraik, J. G. B., Pinto T. E., Tregurtha, S., Faherty, A., Peart, J. M., et al. (2010). Defining the ideal injection techniques when using 5-mm needles in children and adults. *Diabetes Care*, 33(9), 1940–1944.

An insulin pump is a device that administers a continuous infusion of rapid-acting insulin. These devices have been increasing in usage and studies have found them to be a safe and effective way to improve glycemic control in young people (Nelson, Genthe, Gall, & Edwards, 2009). It consists of a computer, a reservoir of rapid-acting insulin, thin tubing through which the insulin is delivered, and a small needle inserted into the abdomen. Insulin pumps attempt to mimic the physiologic insulin release by delivering small continuous infusions of insulin with additional bolus units administered at mealtimes, for planned carbohydrate intake, and

if glucose testing results show it is needed. Advantages of this kind of therapy include:

- There are fewer injections and less trauma.
- Children's food intake can be unpredictable, so insulin delivery can occur after a meal and be adjusted based on actual intake.
- Children can be sensitive to insulin and require only minute doses, which the pump can deliver with precision.
- The pumps can store different basal rates for different times during the day and days of the week. For example, a higher basal rate may be needed in the morning when the child is sitting at his or her desk and a lower rate may be necessary during the afternoon when the child is more active with recess and physical education classes. In addition, rates can be programmed differently for school days versus weekend days, when the child may sleep later and have differing activity levels.

The use of an insulin pump does require a commitment from the child and caregiver in order to achieve success and improved glycemic control. The child and caregiver must be able to count carbohydrates, monitor glucose levels frequently, and work closely with the physician or nurse practitioner.

**FIGURE 49.7** The subcutaneous injector uses pressure jets to deliver insulin safely and accurately.

**Take Note!**

Some insulin pumps have a built-in sensor to monitor blood glucose continuously.

**TABLE 49.5** INSULIN TYPE, ACTION, AND DURATION

Type	Generic (Brand) Name	Onset	Peak	Duration
Rapid acting	Aspart/(NovoLog) Lispro/(Humalog) Glulisine/(Apidra)	Within 15 minutes	30–90 minutes	3–5 hours
Short acting	Regular (Humulin R, Novolin R)	30–60 minutes	2–4 hours	5–8 hours
Intermediate acting	NPH (Humulin N, Novolin N)	1–3 hours	2–4 hours	10–16 hours
Long acting	Glargine (Lantus) Detemir (Levemir)	1–2 hours	No clear peak, offer continuously steady coverage	6–24 hours

Adapted from National Diabetes Information Clearinghouse (NDIC). (2012). *What I need to know about diabetes medicines*. Retrieved July 13, 2012, from [http://diabetes.niddk.nih.gov/dm/pubs/medicines\\_ez/index.htm](http://diabetes.niddk.nih.gov/dm/pubs/medicines_ez/index.htm); and Guven, S., Matfin, G., & Kuenzi, J. A. (2009). Diabetes mellitus and the metabolic syndrome. In C. M. Porth & G. Matfin (Eds.), *Pathophysiology: Concepts of altered health states* (8th ed., pp. 1047–1077). Philadelphia: Wolters Kluwer Health/Lippincott Williams & Wilkins.

Types of insulin include rapid acting, short acting, intermediate acting, and long acting (Table 49.5). Each type works at a different pace and most children will use more than one type. In some cases premixed combinations of intermediate and short or rapid acting, such as 70% NPH and 30% regular, may be used. Again, this depends on the needs of the child. Insulin can be kept at room temperature (insulin that is administered cold may increase discomfort with injection) but should be discarded 1 month after opening even if refrigerated. Any extra, unopened vials should be stored in the refrigerator.

### Take Note!

Lantus is usually given in a single dose at bedtime. Do not mix Lantus with other insulins.

## Oral Diabetic Medications

Oral diabetic medications, also referred to as hypoglycemic, antidiabetic, or antihyperglycemic medications, are used in DM type 2 if glycemic control cannot be achieved by diet and exercise. Oral diabetic medications work in a variety of ways. Sulfonylureas [such as glipizide (Glucotrol) and glyburide (DiaBeta)], meglitinides [such as repaglinide (Prandin)], and nateglinide (Starlix) stimulate insulin secretion by increasing the response of  $\beta$  cells to glucose. Another group, the biguanides, reduces glucose production from the liver. Metformin is an example of a biguanide and is an effective initial therapy unless significant liver or kidney impairment is present. Insulin sensitizers are used to help decrease insulin resistance and improve the body's ability to use insulin in the

liver and skeletal tissues.  $\alpha$ -Glucosidase inhibitors are used to slow digestion of starch in the small intestines so that glucose from the starch enters the bloodstream more slowly and can be matched more effectively with the impaired insulin response of the body. Combination agents are also available.

Common adverse effects of these oral diabetic medications include headache, dizziness, flatulence and gastrointestinal (GI) distress, edema, and liver enzyme elevation. If the oral hypoglycemics fail to maintain a normal glucose level, then insulin injections will be required to manage type 2 DM.

## Diet and Exercise

Other therapies involve diet and exercise protocols. Medical nutrition therapy (MNT) can be initiated to prevent type 2 diabetes in children showing signs of prediabetes, to help glycemic control in existing diabetes, and to help slow the development of complications associated with diabetes (American Diabetes Association, 2011). MNT can be complex and must be individualized to each child incorporating the child's food preferences, activity level, cultural preferences, and family habits and schedule. Enlisting the help of a registered dietician who has expertise in diabetic management is recommended (American Diabetes Association, 2011).

The appropriate diet for a child or adolescent with diabetes is a balanced, healthy diet that meets the child's growth and development needs. The child and family need to understand the effect that food has on the child's glucose levels. Monitoring carbohydrate intake is an important component of diet management and assists

with glycemic control. Nutritional recommendations for a child with diabetes or prediabetes include the following: limit sweets, ensure consistent food intake (eat often and try to avoid skipping meals), monitor carbohydrate intake, eat whole grains and plenty of fruits and vegetables, and limit fat.

It has been shown that regular exercise can improve glycemic control and can prevent the development of type 2 diabetes (American Diabetes Association, 2011). Also, exercise has an important influence on the hypoglycemic effects of insulin (by causing the release of glucagon, which will result in increased blood glucose). Therefore, it is important for the child to maintain or increase his or her activity levels. If the child is taking insulin, the family must know how to change the medication dosage or add food to maintain blood glucose control. Children with type 2 DM are often overweight, so the exercise plan is very important in helping the child to lose weight as well as assisting with the hypoglycemic effects of the medications.

### Management of Complications

Another important aspect of therapeutic management includes monitoring and managing complications. The American Diabetes Association (2011) has developed recommendations for standards of medical care to help monitor complications and reduce risk (American Diabetes Association, 2011; National Diabetes Education Program, 2008). These include:

- Retinopathy:
  - Type 1 diabetes: eye examination by ophthalmologist (with expertise in diabetes) once child is 10 and has had diabetes for 3 to 5 years; annual examinations unless different recommendation by professional
  - Type 2 diabetes: eye examination by ophthalmologist (with expertise in diabetes) shortly after diagnosis; annual examinations unless different recommendation by professional
- Nephropathy:
  - Type 1 diabetes: annual screening for microalbuminuria (which occurs when the kidneys leak small amounts of albumin into the urine) once child is 10 and has had diabetes for 5 years
  - Type 2 diabetes: annual screening for microalbuminuria shortly after diagnosis
- Dyslipidemia: in children older than 2 years with a family history of high cholesterol or cardiovascular disease or unknown family history, obtain a lipid profile at time of diagnosis (once glucose level has been stabilized); otherwise, obtain lipid panel at puberty.
- In addition, children with type 1 diabetes should be screened for celiac disease and hypothyroidism every 1 to 2 years (once glucose levels are stabilized) since both are commonly associated with diabetes.

## Nursing Assessment

Assessment involves understanding the ever-changing needs of children as they grow and develop. The first phase of assessment involves identifying the child who may have DM. The second phase involves identifying problems that might develop in the child with DM. It is important to always be aware of this when observing the child for possible complications or management problems. In addition, always be alert for opportunities to provide education that will expand the understanding and skills related to management of DM of the child and family.

### Health History and Physical Examination

During the initial diagnosis of DM, obtain a detailed history of family patterns and problems in school related to some of the mental and behavior changes that may occur in a hyperglycemic state (e.g., weakness, fatigue, and mood changes). The child or parent may report unusual or excessive thirst (polydipsia) coupled with frequent urination (polyuria). The child may also complain of blurred vision, headaches, or bedwetting. The child with type 1 DM may have a history of poor growth. Comparison Chart 49.3 gives information about common history and physical examination findings in children with type 1 DM versus type 2 DM. Type 1 DM typically presents with acute symptoms and hyperglycemia, while type 2 DM can frequently go undiagnosed until complications appear (American Diabetes Association, 2011).

In the child who is known to have DM, the health history includes any problems with hyperglycemia or hypoglycemia, diet, activity and exercise patterns, types of medications (insulin or oral diabetic medications) and dose and times of administration, ability to monitor blood glucose levels, and ability to administer insulin. Perform a thorough physical examination, noting any abnormal findings.

### Laboratory and Diagnostic Testing

The American Diabetes Association (2011) currently recommends the use of hemoglobin A1C to diagnose diabetes (refer to Common Laboratory and Diagnostic Tests 49.1). The American Diabetes Association (2011) still recognizes fasting plasma glucose levels and 2-hour postprandial glucose levels as reliable sources to diagnose diabetes (refer to Common Laboratory and Diagnostic Tests 49.1). A hemoglobin A1C greater than 6.5%, a random glucose level above 200 mg/dL (accompanied by typical symptoms of diabetes), a fasting glucose level greater than or equal to 126 mg/dL, and a 2-hour plasma glucose level above 200 mg/dL during an oral glucose tolerance test are laboratory criteria for the diagnosis of DM (American Diabetes Association, 2011). With each of these tests, if hyperglycemia is not explicit, the results

## COMPARISON CHART 49.3

## TYPE 1 VERSUS TYPE 2 DIABETES MELLITUS

## History and Physical Findings Usually Present at Diagnosis

	Type 1	Type 2
<i>Family history</i>	Less tendency than type 2	Yes
<i>Prone ethnic groups</i>	All	Native American, African American, Hispanic/Latino, Asian/Pacific Island descent
<i>Polydipsia, polyuria, polyphagia</i>	Yes	Yes, may be mild or absent
<i>Weight</i>	Possibly weight loss	Usually obese
<i>Age of onset</i>	Usually younger children	Usually pubertal children
<i>Incidental finding on screening urinalysis</i>	Rare	Common
<i>Antecedent flu-like illness/symptoms</i>	Common	Possible
<i>Autoimmune antibodies</i>	Yes	No
<i>Diabetic ketoacidosis</i>	Common	Possible
<i>Hypertension</i>	No	Common
<i>Acanthosis nigricans</i>	No	Common
<i>Vaginal infections, skin infections, frequent urinary tract infections</i>	No	Common
<i>Dyslipidemia</i>	No	Common

Adapted from Alemzadeh, R., & Ali, O. (2011). Section 6: Diabetes mellitus in children. In R. M. Kliegman, B. F. Stanton, J. W. St. Geme, N. F. Schor, & R. E. Behrman, (Eds.), *Nelson's textbook of pediatrics* (19th ed., p. 1968–97). Philadelphia: Saunders.

should be confirmed with a repeat test on a different day (American Diabetes Association, 2011). Other laboratory and diagnostic tests include serum measurements of islet cell antibodies. Serum levels of urea nitrogen, creatinine, calcium, magnesium, phosphate, and electrolytes such as potassium and sodium may be drawn. Additional tests include a complete blood count, urinalysis, and immunoassay to measure levels of C peptides after a glucose challenge to verify endogenous insulin secretion.

The American Diabetes Association (2011) recommends screening for type 2 DM if a child presents with being overweight or obese and also has any two of the following risk factors:

- Family history: a parent or relative with type 2 DM
- Ethnic background: Native American, African American, Latino, or Asian American/Pacific Islander
- Conditions associated with insulin resistance such as acanthosis nigricans, hypertension, dyslipidemia, or PCOS
- History of maternal diabetes or mother with gestational diabetes when child was in utero
- Age older than 10 years or onset of puberty before age 10 (American Diabetes Association, 2011; Cox & Polvado, 2008)

## Nursing Management

Individualize the general nursing care discussed in Nursing Care Plan 49.1 based on the child's and family's response to illness. Additional nursing care topics related to DM are discussed below, including regulating glucose control, monitoring for complications, providing education to the child and family, and supporting the child and family.

### Regulating Glucose Control

Consistent and established glucose control can reduce the risk of long-term complications associated with diabetes. Therefore, regulating glucose is a very important nursing function.

Typically, in children with type 1 DM and sometimes in cases of type 2 DM, glucose is regulated by subcutaneous injections of insulin. Often, the regimen consists of three injections of intermediate-acting insulin, with the addition of rapid-acting insulin before breakfast and dinner. Insulin doses are typically ordered on a sliding scale related to the serum glucose level and how the insulin works. Insulin doses and frequency are based on the needs of the child utilizing information gained

FIGURE 49.8 Insulin injection sites.

from blood glucose testing. Regulating glucose can be challenging in children due to continual growth, onset of puberty, varying activity levels with unpredictable schedules, unpredictable eating habits, and the inability to always verbalize the way they are feeling. Thus, close monitoring of changing glucose levels through SMBG is essential in determining adjustments needed in insulin therapy, food intake, and activity level.

Teach the child and family to use proper subcutaneous injection techniques to avoid injecting into muscle or vascular spaces. Figure 49.8 shows appropriate sites for subcutaneous injection of insulin. Teach the child and family to rotate sites to avoid adipose hypertrophy (fatty lumps that absorb insulin poorly). If the child is using an insulin pump, additional education will be needed.

### Atraumatic Care

*Children with diabetes experience numerous finger-pricks and injections. Providing atraumatic care remains important. Allow the child to choose the prick or injection site when possible. Use positioning that is comforting to the child. Encourage participation in care as developmentally appropriate.*

#### Take Note!

When giving a combination of short- and long-acting insulin, draw up the clear (short-acting) insulin first to prevent contamination with the long-acting insulin.

In children with type 2 diabetes, glucose levels can be controlled by the use of oral diabetic medications, diet, and exercise or a combination of all three.

### Monitoring for, and Managing, Complications

While the child is in the hospital, monitor for signs of complications such as acidosis, coma, hyperkalemia or hypokalemia, hypocalcemia, cerebral edema, or hyponatremia. Assess for the development of hypoglycemia or hyperglycemia every 2 hours (Comparison Chart 49.4). Monitor the child's status closely during peak times of insulin action. Perform blood glucose testing as ordered or as needed if the child develops symptoms.

If the child has a severe hypoglycemic reaction, administer glucagon (a hormone produced by the pancreas and stored in the liver) either subcutaneously or intramuscularly. Children under 20 kilograms receive 0.5 mg; children over 20 kilograms receive 1 mg (Alemzadeh & Ali, 2011). Dextrose (50%) may be given intravenously if needed. If the child is not having a severe reaction and is coherent, glucose paste or tablets may be used. Offer 10 to 15 g of a simple carbohydrate such as orange juice if the child feels some symptoms of low blood glucose and glucose monitoring indicates a drop in blood glucose level. Follow this with a more complex carbohydrate such as peanut butter and crackers to maintain the glucose level.

The child with severe hyperglycemia resulting in DKA is usually treated in the pediatric intensive care

## COMPARISON CHART 49.4

## HYPOGLYCEMIA VERSUS HYPERGLYCEMIA

Hypoglycemia	Hyperglycemia
Behavioral changes, confusion, slurred speech, belligerence	Mental status changes, fatigue, weakness
Diaphoresis	Dry, flushed skin
Tremors	Blurred vision
Palpitations, tachycardia	Abdominal cramping, nausea, vomiting, fruity breath odor

unit. In the case of a child presenting with DKA to the hospital, monitor the glucose level hourly to prevent it from falling more than 100 mg/dL per hour. A too-rapid decline in blood glucose predisposes the child to cerebral edema. Administration of regular insulin, given intravenously, is preferred during DKA (only regular insulin may be given intravenously [IV]). A bolus dose of 0.1 unit/kg is given, followed by a continuous infusion of 0.1 unit/kg per hour (Hatcher, 2010). Fluid therapy is given to treat dehydration, correct electrolyte imbalances (sodium and potassium due to osmotic diuresis), and improve peripheral perfusion.

Any child exhibiting signs and symptoms of hyperglycemia requires insulin. The dosage is usually based on a sliding scale or determined after consultation with the physician or nurse practitioner.

**Take Note!**

Double-check all insulin doses against the order sheet and with another nurse to ensure accuracy.

Child and family education that focuses on managing and monitoring for complications at home or in other settings such as school or day care is essential (see Educating the Family below).

**Educating the Family**

Education is the priority intervention for DM because it will enable the child and family to self-manage this chronic condition. Allow the child and family time to adjust to the diagnosis of a chronic illness that will require self-management. DM is a lifelong condition that requires regular follow-up visits (three or four times a year) to a diabetes specialty clinic. Because approximately 215,000 children and adolescents younger than the age of 20 have diabetes, this becomes a health issue for the community, especially for the schools (Centers for Disease Control and Prevention, 2011). Daily management of the child with DM is complex and dynamic. It will require frequent monitoring of blood glucose levels, medications (including oral diabetic medications and

insulin injections), and individual meal plans, including snacks, while the child is at school. The school nurse will be a principal contact person for both staff and family. With appropriate management, involvement of the community, and confidence and compliance by the family, the child can maintain a happy, productive life. See Healthy People 2020.

**HEALTHY PEOPLE 2020****Objective****Nursing Significance**

Increase the proportion of persons with diabetes who receive formal diabetes education.

Increase the proportion of persons with diagnosed diabetes who receive formal diabetes education

- Begin diabetes education with child and family upon knowledge of diagnosis.
- Use developmentally appropriate education with children.
- Increase the self-management skills taught as the child progresses in age and cognitive development.

*Healthy People* Objectives based on data from <http://www.healthypeople.gov>.

Challenges related to educating children with DM include:

- Children lack the maturity to understand the long-term consequences of this serious chronic illness.
- Children do not want to be different from their peers; having to make lifestyle changes may result in anger or depression.
- Poor families may not be able to afford appropriate food, medication, transportation, and telephone service.
- Families may demonstrate unhealthy behaviors, making it difficult for the child to initiate change because of the lack of supervision or role modeling.
- Family dynamics are affected because management of diabetes must occur all day, every day.

**Take Note!**

Children with DM have higher rates of depression and may have other comorbid conditions, such as eating disorders, adjustment disorders, or anxiety disorders (Alemzadeh & Ali, 2011).

The initial goal of education is for the family to develop basic management and decision-making skills. Assess the family's ability to learn the basic concepts and offer psychological support. Teach about specific topics in sessions lasting 15 to 20 minutes for the children and 45 to 60 minutes for the caregivers. Teaching must be geared toward the child's level of development and understanding (refer to Table 49.4).

Among the topics to include when teaching children and their families about diabetes management are:

- Self-measurement of blood glucose (Fig. 49.9)
- Urine ketone testing
- Medication use (Fig. 49.10)
  - Oral diabetic agents
  - Subcutaneous insulin injection or insulin pump use
  - Subcutaneous site selection and rotation
  - When to alter insulin dosages
  - Use of glucagon to treat severe hypoglycemia
- Signs and symptoms of hypoglycemia and hyperglycemia (refer to Comparison Chart 49.4)
- Treatment for hypoglycemia and hyperglycemia at home or other setting such as school
- Monitoring for and managing complications (see above)
- Sick-day instructions
- Laboratory testing and follow-up care
- Diet and exercise as part of DM management (see above)

Teaching Guidelines 49.2 presents information to cover when teaching the family about self-monitoring of blood glucose. Teach families how to give insulin, how

**FIGURE 49.9** The school-age child has developed the psychomotor skills needed for blood glucose monitoring and insulin injection.

**FIGURE 49.10** The school-age child may first practice insulin injections on a doll.

to use the insulin pump, and how to rotate injection sites (see above).

**Teaching Guidelines 49.2****BLOOD GLUCOSE MONITORING**

- Obtain glucose levels before meals and bedtime snacks.
- Perform monitoring more often during prolonged exercise, if you are ill, if you have eaten more food than usual, or if you suspect nighttime hypoglycemia.
- Use the manufacturer's recommendations and perform quality control measures as directed.
- Look for patterns. For example, 3 to 4 days of a consistent pattern of glucose values above 200 mg/dL before dinner indicates a need to adjust the insulin dose.
- Blood glucose measurements are the best way to determine daily insulin dosages.
- Normal levels are as follows: nondiabetics: 70 to 110 mg/dL; toddlers and children with type 1 DM younger than 6 years old: before meals 100 to 180 mg/dL, at bedtime 110 to 200 mg/dL; children with type 1 DM ages 6 to 12: before meals 90 to 180 mg/dL, at bedtime 100 to 180 mg/dL; adolescents 13 to 19 years of age, before meals 90 to 130 mg/dL, at bedtime 90 to 150 mg/dL (American Diabetes Association, 2011).

Good glucose control is dependent on accurate monitoring and medication administration by the child or caregiver. Assessment of the child's or parent's technique and review of procedure and instructions should occur with each visit. Treatment of hypoglycemia and hyperglycemia may have to occur at home or in another setting such as school. In either case, someone that is trained and able to check the child's blood glucose level needs to be available. In the case of hypoglycemia, early recognition is key. Therefore, all caregivers need

to be educated on the causes of hypoglycemia (such as increased physical activity, delayed meals or snacks, insulin, oral diabetic medication, illness, stress, and hormonal fluctuations) along with the signs and symptoms. The child also needs access to glucose tablets or a rapidly absorbing carbohydrate such as orange juice as well as a snack with complex carbohydrates and protein within 30 to 60 minutes of the hypoglycemic episode. Injectable glucagon needs to be available in the case that the hypoglycemia is severe and the child is unconscious. In the event of hyperglycemia, the child needs immediate access to rapid-acting insulin injection.

Sick-day instructions may include the following:

- Contact the physician or nurse practitioner.
- Perform SMBG more often.
- Check for ketones in the urine, especially if blood glucose is elevated.
- Use a sliding scale to calculate the insulin dosage.

A dietitian can help the family with detailed meal planning and dietary guidelines. Review basic nutritional information with the child and family and provide sample meals. Encourage the child and family to keep a food diary. For the child who needs to lose weight, suggest low-carbohydrate snacks. Encourage all children with DM to incorporate physical activity daily (Teaching Guidelines 49.3).

### Teaching Guidelines 49.3

#### DIET AND EXERCISE FOR CHILDREN WITH DIABETES MELLITUS

- Provide sufficient calories and good nutrition for normal growth and development. The diet should be low in saturated fats and concentrated carbohydrates.
- Learn to identify carbohydrate, protein, and fat foods.
- Make adjustments during periods of rapid growth and for issues such as travel, school parties, and holidays.
- Consult a dietitian with expertise in diabetes education as needed.
- Provide three meals per day and midafternoon and bedtime snacks. Consistency of intake can help prevent complications and maintain near-normal blood glucose levels.
- Encourage the child to exercise routinely to help the body use insulin efficiently, thus reducing the insulin requirement.
- Encourage the child to participate in age-appropriate sports.
- When exercising, monitor insulin dose and nutritional and fluid intake, and observe for hypoglycemic reactions. Add an extra snack containing 15 to 30 g carbohydrate for each 45 to 60 minutes of exercise. Avoid exercising excessively when insulin is peaking.

## Supporting the Child and Family

Children with DM and their families may have difficulty coping if they lack confidence in their self-management skills. Assess the ability of the child and family to handle situations. Role-play specific situations related to symptoms or complications to help them see different ways to solve problems. Work with the child and family to enhance their conflict resolution skills. Provide opportunities for them to express their feelings. Observe for signs of depression, especially in adolescents.

To enhance the child's confidence and promote feelings of mastery and inclusion, refer him or her to a special camp for children with DM. Also refer families to local support groups, parent-to-parent networks, or one of many national support resources and foundations. Links to camps for children as well as support groups, parent-to-parent networks, and national foundations are provided on [thePoint](#).

### KEY CONCEPTS

- The endocrine system consists of cells, tissues, and glands that produce and/or secrete hormones (chemical messengers) in response to a negative feedback system involving the hypothalamus and nervous system.
- Hormones (chemical messengers), along with the nervous system, play an intricate role in reproduction, growth and development, energy production and use, and maintenance of the internal homeostasis.
- The pituitary, along with the hypothalamus connection, is considered the “control center,” producing hormones that stimulate many glands to produce other hormones or to inhibit the process.
- Hormonal control is immature at birth; this is partly why the infant has trouble maintaining an appropriate balance of fluid concentration, electrolytes, amino acids, glucose, and trace substances.
- Linear growth and cognitive development may be impaired by untreated endocrine dysfunction in the infant or child.
- A thorough health history of the child with a known or potential endocrine disorder often reveals poor growth, school or learning problems, and inactivity or fatigue.
- Serial measurement of growth parameters is a key part of the physical assessment for children with endocrine dysfunction.
- Close monitoring of the child's status is critical during a hormone stimulation test or water deprivation study.

- Hormone supplementation is required lifelong for many of the endocrine disorders.
- The key nursing functions related to hormone supplementation are educating the child and family about medication use and monitoring for therapeutic results and adverse effects.
- Children with adrenocortical dysfunction will require additional hormone supplementation during times of stress such as fever, infection, or surgery.
- Growth hormone deficiency is characterized by poor growth and short stature as a result of failure of the anterior pituitary to produce sufficient growth hormone. Early treatment enables the child to reach normal growth.
- Precocious puberty involves early development of secondary sex characteristics as a result of premature activation of the hypothalamic-pituitary-gonadal axis.
- Diabetes insipidus is characterized by water intoxication as a result of a deficiency in the antidiuretic hormone that leads to the cardinal signs of polyuria and polydipsia, resulting in hypernatremic dehydration.
- Key findings in congenital hypothyroidism are a thickened protuberant tongue, an enlarged posterior fontanel, feeding difficulties, hypotonia, and lethargy.
- Early diagnosis and treatment of hypothyroidism can prevent impaired growth and severe cognitive impairment.
- Congenital adrenal hyperplasia results from a genetic defect that causes a breakdown in steroid synthesis and an overproduction of androgens that can lead to ambiguous genitalia in females.
- Diabetes mellitus is the most common endocrine disorder now seen in children.
- Type 1 DM is an autoimmune disorder resulting from damage and destruction of the  $\beta$  cells in the islets of Langerhans in the pancreas; the end result is insulin insufficiency. Peak onset occurs in childhood.
- Type 2 DM results in an insensitivity or resistance to insulin. The incidence of type 2 DM has risen dramatically. It is occurring at an alarming rate in children, especially in those who are obese and from certain ethnic groups.
- DKA is a medical emergency. The child will usually be admitted to a pediatric intensive care unit.
- Critical areas in the nursing management of children with endocrine dysfunction include maintaining appropriate nutrition and fluid balance and promoting growth and development.
- The nurse provides ongoing assessment and education of the child and family, imparting to them the knowledge and skills required for self-management.
- Encouraging the child to have a healthy body image and working with the family in establishing healthy family processes are also key nursing functions.
- The focus of DM management is regulation of glucose control, which is accomplished by medications, diet, and exercise.
- DM education involves instruction in glucose monitoring, administration of insulin or oral hypoglycemics, meal planning, and promotion of a healthy lifestyle.

## MULTIPLE CHOICE QUESTIONS

1. A young mother brings her new baby, diagnosed with congenital hypothyroidism, to the clinic so she can learn how to administer levothyroxine. The nurse should include which of the following instructions?
  - a. Crush the medication and place it in a full bottle of formula to disguise the taste.
  - b. Administer the medication every other day.
  - c. Use an oral dispenser syringe or nipple to give the crushed medication mixed with a small amount of formula.
  - d. Tell the mother that the medication will not be needed after the age of 7.
2. During a well-child examination which of the following comments made by the parent would indicate the possibility of a growth hormone deficiency?
  - a. "I have to buy my child new clothes every 2 to 3 months."
  - b. "I have to buy my child larger shirts than pants; otherwise, the sleeves are too short."
  - c. "My child wears out his clothes before he outgrows them."
  - d. "I can hand down my child's clothes to his younger brother."
3. The nurse is caring for a 14-year-old boy with type 1 DM. He takes NPH insulin every morning at 7:30 a.m. Which assessment data will the nurse use to evaluate the therapeutic effectiveness of the medication?
  - a. Presence of signs and symptoms of hypoglycemia or hyperglycemia during the morning physical assessment
  - b. Blood glucose level at 1630
  - c. Appetite and food intake at lunch
  - d. Blood glucose level before breakfast
4. When monitoring the blood glucose level of a 12-year-old child with type 2 DM, your reading is 50 mg/dL. Which is the most appropriate action?
  - a. Encourage the child to get out of bed and increase activity.
  - b. Take the child's vital signs.
  - c. Ask the child about frequent urine output.
  - d. Give the child 4 oz of orange juice.

## CRITICAL THINKING EXERCISES

1. A 12-year-old boy with type 1 DM has the flu. His mother calls the diabetes clinic to report that he stayed home from school and does not have an appetite, so he is not eating. The mother asks the nurse how much insulin the boy should take. He is currently taking three injections daily with regular and NPH in the morning before breakfast, regular and NPH in the evening after

dinner, and regular before bedtime. What questions should the nurse ask before answering the mother's question? Based on the answers to these questions, how would you instruct the mother?

2. The mother of Robin, a 5-year-old girl, reports that Robin has a body odor. She is developing breasts and some pubic hair and was teased when she had a sleepover with friends. The review of her growth charts reveals that Robin went from the 50th percentile to the 93rd percentile in the past 6 months. Based on this information, what are the three major nursing diagnoses to begin establishing a plan of care for the child and family? What are the expected outcomes and major interventions associated with the nursing diagnosis of knowledge deficit?
3. A mother brings her baby to the clinic after receiving a phone message from the clinic saying there was a problem with the baby's thyroid test. She says the trip on the bus took a long time, but the infant slept the entire way. She says that the baby is sleeping much of the time and does not want to eat very much. The baby was discharged from the hospital 2 weeks ago. The birth was without difficulty and there were no problems during labor. Why is this visit urgent? What would the test show if the disorder was due to a pituitary gland problem and not the thyroid gland?

## STUDY ACTIVITIES

1. During your clinical experiences, ask to be on an inpatient unit that provides care for children with alterations in endocrine function. Compare and contrast the health histories, assessments, laboratory tests, diagnostic procedures, and plans of care for these children with those for the care of children on other units. Participate in the teaching plan for these children and their families.
2. Attend an outpatient clinic that provides care to children with endocrine disorders. Identify the role of the registered nurse in providing coordination of care, health teaching, and referrals for these children and their families.
3. Shadow a diabetes nurse educator to observe the teaching methods and strategies he or she uses to provide an education plan for a child with DM. Observe how the nurse educator includes the family in the plan. Are there any differences between the teaching plans for type 1 DM and type 2 DM?
4. Conduct a literature review for one of the common endocrine disorders to research current management practices. Are there evidence-based practice guidelines for nursing interventions?
5. Conduct an Internet search to research the information that is available to children and their families related to DM.

# Nursing Care of the Child With a Neoplastic Disorder

## Learning Objectives

*Upon completion of the chapter, the learner will be able to:*

1. Define the key terms used in this chapter.
2. Compare childhood and adult cancers.
3. Describe nursing care related to common laboratory and diagnostic testing used in the medical diagnosis of pediatric cancer.
4. Identify types of cancer common in infants, children, and adolescents.
5. Identify appropriate nursing assessments and interventions related to medications and treatments for pediatric cancer.
6. Develop an individualized nursing care plan for the child with cancer.
7. Describe the psychosocial impact of cancer on children and their families.
8. Devise a nutrition plan for the child with cancer.
9. Develop child/family teaching plans for the child with cancer.

*John Shaw, 4 years old, is brought to the clinic by his parents with a fever. His father states, "John seems to get fevers and colds more often than our other children. He's also very tired these days. He hardly ever wants to go out and play with his friends. He complains of headaches frequently and just doesn't really seem like himself."*

### Words of Wisdom

Be inspired by the courage of a child with cancer and reflect it in the care you provide.

**Cancer** accounts for the most deaths from disease in children older than 1 year of age. Cure has been achieved in some children with childhood leukemia and other cancers, but there is no universal long-term cure available for any of the childhood cancers. However, the 5-year survival rate for all cancers in children is 80% (Baggott, 2010).

Cancer is a life-threatening illness that involves emotional distress, fear of the unknown, and changes in life priorities for the child and family. Initial and ongoing diagnostic testing and the adverse effects of treatment for cancer, including chemotherapy, radiation, surgery, or other treatments, are often painful as well. Management of cancer also has a significant psychosocial impact on the child or adolescent. Children with cancer are at significant risk for depression because they have a life-threatening illness and must undergo frequent and stressful tests and treatments (National Cancer Institute, 2010a). In addition, the child often feels isolated from his or her peers, and the adolescent may have difficulty achieving independence, which is the core developmental task of the teenage years. Children and teens with cancer often demonstrate poorer school performance compared to healthy peers.

Nurses caring for children with cancer need to be knowledgeable about the medical treatment of the disease (including adverse effects) and must also be particularly aware of the psychosocial and emotional impact of cancer on the child and family.

## CHILDHOOD CANCER VERSUS ADULT CANCER

Cancers in children differ greatly from cancers in adults. Pediatric cancers most often arise from primitive embryonal (mesodermal) and neuroectodermal tissues, resulting in leukemias, lymphomas, sarcomas, or central nervous system (CNS) tumors (American Cancer Society, 2012; Larsen, 2012). This is in direct contrast to adult cancers, which mostly arise from epithelial cells, resulting in carcinomas. The most common childhood cancers, in order of frequency, are leukemia, CNS tumors, lymphoma, neuroblastoma, rhabdomyosarcoma, Wilms tumor, bone tumors, and retinoblastoma. Comparison Chart 50.1 explains how cancer is different in children versus adults.

In children, warning signs of cancer are most often related to changes in blood cell production or as a result of compression, infiltration, or obstruction caused by the tumor. Changes in blood cell production may result in fatigue, pallor, frequent or severe infection, or easy bruising. Infiltration, obstruction, or compression by a tumor may result in bone or abdominal pain, pain in other parts of the body, swelling, or unusual discharge.

## COMMON MEDICAL TREATMENTS

Deciding on a course of medical treatment for cancer in a developing child is complicated. Some of the treatments can impair the child's growth and development. Many

### COMPARISON CHART 50.1

### CHILDHOOD CANCER VERSUS ADULT CANCER

	Childhood Cancer	Adult Cancer
<i>Cancer usually affects</i>	Tissues	Organs
<i>Histologic type</i>	Embryonal, leukemia, lymphoma	Epithelial in origin
<i>Most common sites</i>	Blood, lymph, brain, bone, kidney, muscle	Breast, lung, prostate, bowel, bladder
<i>Environmental and lifestyle factors</i>	Only a small amount of environmental influence proven	Strong influence on cancer development
<i>Cancer prevention</i>	Little known	80% preventable
<i>Detection</i>	Usually incidental or accidental	Very early detection possible if screening recommendations followed
<i>Latent period</i>	Relatively short	Can be very long (20 years or greater)
<i>Extent of disease</i>	Metastasis often present at diagnosis	Metastasis less often present at diagnosis
<i>Response to treatment</i>	Very responsive	Less responsive

(2012). *Childhood cancer*. Retrieved July 11, 2012, from [http://www.cancerstory.org/2/html\\_backup/c\\_trans.shtml](http://www.cancerstory.org/2/html_backup/c_trans.shtml)

**HEALTHY PEOPLE 2020****Objective**

Increase the proportion of persons who participate in behaviors that reduce their exposure to harmful ultraviolet (UV) irradiation and avoid sunburn.

**Nursing Significance**

- Educate families to start skin protection from the sun in childhood to reduce the risk of skin cancer as an adult.
- Teach parents to use PABA-free sunscreen (formulated specifically for children) after age 6 months with an SPF of 15 or greater and to reapply sunscreen frequently while the child is out of doors.
- Advocate for schools to encourage a sun-safe environment.

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

pediatric oncologists and cancer treatment centers are active members of the Children's Oncology Group (COG), a National Cancer Institute–supported group that approves and administers clinical trials devoted exclusively to childhood and adolescent cancer research. A **clinical trial** is a carefully designed research study that assesses the effectiveness of a treatment as well as its acute and long-term effects on the child. Current cancer care in children is a result of the knowledge gained through clinical trials. A clinical trial may include existing medications or treatments in combination with new drugs or may involve a different approach to sequencing or dosing of medications and treatment (Dzolganovski, 2010).

To provide optimal outcomes, the child with cancer should be treated at an institution with multidisciplinary cancer care specialists that can provide the most advanced care available. Each case of pediatric cancer should be considered individually, with the oncology health care team and the family reaching treatment decisions together, whether the treatment plan is standard or involves enrollment in a clinical trial.

In the child with cancer, particularly advanced disease, the decision to provide treatment (“let’s do everything we can”) or to withhold treatment in the event of an extremely poor prognosis is extraordinarily challenging in an ethical sense. A mature older child or adolescent may have a strong desire to continue or discontinue treatment, and sometimes this desire conflicts with the parents’ desires or choices. The American Academy of Pediatrics Committee on Bioethics (2007) recommends

**BOX 50.1**
**AMERICAN ACADEMY OF PEDIATRICS  
COMMITTEE ON BIOETHICS  
RECOMMENDATIONS REGARDING  
PEDIATRIC ASSENT**

- Give consideration to each child’s developmental capacity, rationality, and autonomy.
- Help each child to achieve a developmentally appropriate understanding of the illness.
- Tell the child what he or she can expect regarding testing procedures and treatments.
- Assess the child’s understanding of the situation and how he or she is responding.
- Note if there is inappropriate pressure to assent to testing or treatment.
- Seriously solicit the child’s expression of willingness to accept the proposed plan of care.

Adapted from American Academy of Pediatrics. (2011). *Session 4. Informed consent and assent in pediatrics*. Retrieved July 11, 2012, from [http://www2.aap.org/sections/bioethics/PDFs/Curriculum\\_Session4.pdf](http://www2.aap.org/sections/bioethics/PDFs/Curriculum_Session4.pdf).

that decision making for older children and adolescents should include the assent of the older child or adolescent (Box 50.1).

Hospice or palliative care may be needed for the child with cancer. Children facing the end of life experience the same symptoms that adults do, including pain, fatigue, nausea, and dyspnea. Standards for end-of-life care are still in development, but all dying children have the right to die comfortably and with palliation of symptoms, as has been well established in adult hospice programs. Children’s Hospice International (CHI) has demonstration models in several U.S. states that focus on enhancing the quality of life of children with life-threatening conditions. Formerly, only children with a life expectancy of less than 6 months had access to hospice care, and they were required to forego curative care to enroll in hospice. CHI’s goal is to provide a comprehensive, interdisciplinary continuum of care to the child and family from the time of diagnosis with a life-threatening condition through the time of death, if cure is not achieved (CHI, 2012). For further information related to nursing care of the dying child, refer to Chapter 34.

A variety of medications and treatments are used to treat **neoplastic** (referring to cells that abnormally proliferate) disorders in children. Most of these treatments will require a physician’s or nurse practitioner’s order when the child is in the hospital. The most common treatments and medications are listed in Common Medical Treatments 50.1 and Drug Guide 50.1. Commonly, chemotherapy and radiation therapy are used to treat childhood cancers. In some instances, hematopoietic

stem cell transplantation is used. The nurse caring for the child with cancer should be familiar with the procedures, how the treatments and medications work, and common nursing implications related to use of these modalities.

## Chemotherapy

To understand how **chemotherapy** works to destroy cancer cells, it is necessary to review the normal cell cycle, through which all cells progress (Fig. 50.1). The cell cycle consists of five phases:

- G0 phase: the resting phase; lasts from a few hours to a few years; cells have not started to divide

- G1 phase: cell makes more protein in preparation for dividing; lasts 18 to 30 hours
- S phase: chromosomes are copied so that newly formed cells have the appropriate DNA; lasts 18 to 20 hours
- G2 phase: just before the cell splits into two cells; lasts 2 to 10 hours
- M phase: mitosis, the actual splitting of the cell into two new cells; lasts 30 minutes to 1 hour

Chemotherapy drugs work in two different ways in relation to the cell cycle. Cell cycle-specific agents exert their actions during a specific phase of the cell cycle. Cell cycle-nonspecific drugs exert their effect on the cells regardless of which phase the cell is in. Chemotherapy

### COMMON MEDICAL TREATMENTS 50.1

Treatment	Explanation	Indications	Nursing Implications
Biopsy	A small piece of the tumor is removed with a needle or via an open incision	Solid tumors	Monitor for bleeding at the needle biopsy site. Provide routine incision care for open biopsy site.
Surgical removal of tumor	The tumor is completely or partially resected surgically	Solid tumors	Provide routine postoperative nursing care based on the location of the tumor excision.
Leukapheresis	Whole blood is removed from the body, the WBCs are extracted, and then the blood is retransfused into the child	Hyperviscosity with leukemia (WBC >100,000)	Performed by specially trained personnel Monitor blood pressure and other vital signs.
Blood product transfusion	Administration of whole blood, packed red blood cells, platelets, or plasma intravenously	Anemia, thrombocytopenia, bleeding	Follow institution's transfusion protocol. Double-check blood type and product label with a second nurse. Use only irradiated, leukodepleted, CMV-negative blood products in the child with cancer. Monitor vital signs and assess child frequently to detect adverse reaction to blood transfusion. If adverse reaction is suspected, immediately discontinue transfusion, run normal saline IV, reassess child, and notify physician. Some children require premedication with diphenhydramine and/or acetaminophen before receiving blood products.

## COMMON MEDICAL TREATMENTS 50.1 (continued)

Treatment	Explanation	Indications	Nursing Implications
Radiation therapy	Ionizing radiation (high-energy x-ray) is delivered to the cancerous area. The radiation damages all cells in the locally treated area (normal and cancerous), but the normal cells are able to repair themselves. Usually administered several times a week for several weeks (a short rest between treatments allows the normal cells time to regenerate). The lowest possible dose of radiation is used and it is directed to a specific area	Solid tumors, before or after surgical resection, leukemia, lymphoma	<p>Do not wash off radiation marking.</p> <p>Keep skin clean and dry.</p> <p>Fatigue is a common side effect.</p> <p>Skin at the site of radiation may become red, dry, or pruritic or may peel; eventually may become moist and red.</p> <p>Mucositis, dry mouth, and loss of taste may occur if head or neck radiated.</p> <p>Radiation may also have adverse effects on the organ irradiated, such as the brain; monitor for changes.</p>
Hematopoietic stem cell transplantation	<p><i>Bone marrow transplant:</i> transfer of healthy bone marrow into a child with cancer. The transplanted cells can then develop into functional cells</p> <p><i>Stem cell transplant:</i> peripheral stem cells are removed from the donor via apheresis, or stem cells are retrieved from the umbilical cord and placenta. The stem cells are then transplanted into the recipient</p>	Leukemia, lymphoma, other cancers	<p>Maintain medical asepsis and protective isolation to prevent infection.</p> <p>Monitor closely for GVHD.</p> <p>Provide meticulous oral care.</p> <p>Avoid rectal temperatures and suppositories. Encourage appropriate nutrition.</p> <p>Administer immunosuppressive medications as ordered.</p>
Central venous catheter (see image A)	IV catheters are inserted into the central circulation for the purpose of administering medications, total parenteral medication, or blood products	Any child with cancer who will require long-term IV medications or parenteral nutrition	<p>Complaints of shortness of breath or chest pain may indicate air entry into the central venous catheter. Have child lie on left side, and notify physician immediately.</p> <p>Keep dressing clean and dry.</p> <p>Perform sterile dressing change per institution policy or physician order.</p> <p>Monitor for fever.</p> <p>Monitor insertion site for erythema or drainage.</p> <p>Maintain sterile technique when accessing line, performing dressing change, or administering any fluid through catheter.</p>

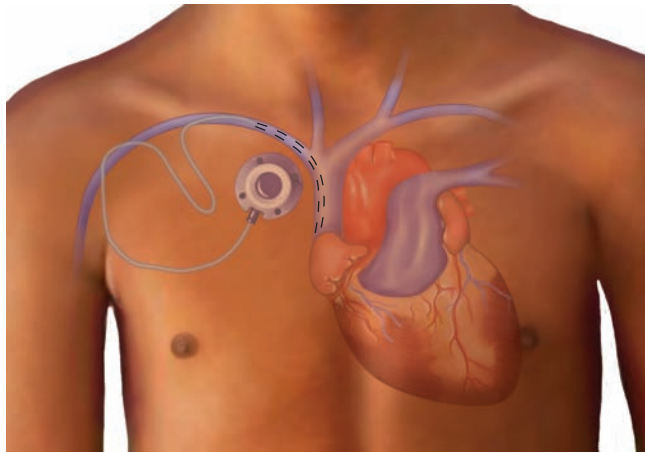

A

**Image A:** The central venous access catheter is tunneled under the skin and secured with a cuff.

(continued)

COMMON MEDICAL TREATMENTS 50.1 (continued)

Treatment	Explanation	Indications	Nursing Implications
Implanted port (see image B)	A needle-accessible port is implanted under the skin, usually on the chest. The port has a thin catheter exiting it that is tunneled under the skin into the superior vena cava or subclavian vein	Any child with cancer who will require long-term IV medications or parenteral nutrition	Flush nonaccessed port with prescribed heparin dose per institution policy. Use sterile technique to access port with Huber needle. Monitor port site for erythema or warmth.

**Image 2:** The implanted port consists of a reservoir under the skin for ready access. The catheter exiting the port is threaded into the subclavian vein or right atrium. **Image 3:** A 90-degree Huber needle is used to access the port.

Adapted from Baggott, C. (2010). Cancer. In P. J. Allen, J. A. Vessey, and N. A. Schapiro (Eds.), *Primary care of the child with a chronic condition* (5th ed.). St. Louis, MO: Mosby; and Tomlinson, D., & Kline, N. E. (Eds.). (2010). *Pediatric oncology nursing*. New York, NY: Springer.

DRUG GUIDE 50.1 COMMON DRUGS FOR NEOPLASTIC DISORDERS

Medication	Actions/Indications	Nursing Implications
<b>Chemotherapy</b>		
Alkylating agents: busulfan, carboplatin, cisplatin, ifosfamide, temozolomide, thiotepa	Interfere with DNA replication and RNA transcription by alkylation (replacing the hydrogen ion with an alkyl group), cross-link DNA	Causes myelosuppression, nausea, vomiting, alopecia, mucositis. Monitor for signs of infection. Provide adequate hydration.
Nitrosoureas: carmustine, lomustine	Cell cycle nonspecific	Cyclophosphamide, ifosfamide: administer in the morning, provide adequate hydration, and have child void frequently during and after infusion to decrease risk of hemorrhagic cystitis.
Nitrogen mustard: chlorambucil, cyclophosphamide, mechlorethamine, melphalan	The nitrosoureas are highly lipid soluble and easily cross the blood-brain barrier Used in a variety of cancer protocols	Cisplatin, mechlorethamine, melphalan: avoid <b>extravasation</b> (leakage into surrounding tissues, potentially damaging them). Temozolomide: avoid opening capsules. Thiotepa: if contact with skin occurs, wash thoroughly with soap and water.

**DRUG GUIDE 50.1 COMMON DRUGS FOR NEOPLASTIC DISORDERS** (continued)

Medication	Actions/Indications	Nursing Implications
Antitumor antibiotics: bleomycin, dactinomycin, daunorubicin, doxorubicin, idarubicin, mitomycin, mitoxantrone	Interfere with cellular metabolism, causing disruptions in DNA and/or RNA synthesis Cell cycle nonspecific. Indicated in a variety of cancer pro- tocols	May cause alopecia, nausea, vomiting, myelosuppression. Bleomycin: fever and chills may occur 20 hours after infusion. Dactinomycin, mitomycin: avoid extravasation. Daunorubicin, doxorubicin, idarubicin: may turn urine red-orange, monitor for arrhythmias, congestive heart failure; avoid extravasation. Mitoxantrone: may color urine, sweat, tears, skin, sclera blue-green; monitor for arrhythmias, congestive heart failure.
Antimetabolites: cladribine, cytarabine, fludarabine, fluorouracil, mercapto- purine, methotrexate, thioguanine	Substitute for a natural metabolite in the molecule, altering the cell's function and ability to replicate Cell cycle specific (S phase); cladribine is cell cycle nonspecific Used in a variety of cancer protocols	May cause alopecia, nausea, vomiting, mucositis, and myelosuppression. Cladribine: monitor for fever. Cytarabine: use corticosteroid eye drops to prevent conjunctivitis with high doses. Fludarabine: monitor for visual changes and neurotoxicity; maintain adequate hydration. Fluorouracil: maintain adequate hydration; may cause photosensitivity. Mercaptopurine: do not give oral doses with meals; may cause drug fever; avoid extravasation. Methotrexate: intensive hydration with high doses; may cause photosensitivity. Thioguanine: maintain hydration; administer on empty stomach.
Antimicrotubulars: paclitaxel	Inhibit mitotic cellular function in late G2 and M phases of cell cycle Indicated for refractory leukemia, recurrent Wilms tumor	May cause alopecia, nausea, vomiting, mucositis, myelosuppression. May cause drowsiness. Avoid extravasation.
Miscellaneous: asparagi- nase, pegaspargase	Inhibit protein synthesis by depriving tumor cells of the essential amino acid asparagine Used in acute lymphocytic leukemia, lymphomas	May cause alopecia, nausea, vomiting, and myelosuppression. Monitor for vital signs during infusion and for signs of anaphylaxis. Have emergency equipment, oxygen, epinephrine, antihistamines, and steroids available at bedside.
Miscellaneous: dacarbazine, procarbazine	Inhibit DNA and RNA synthesis via cross-linking or suppression of mitosis Indicated in a variety of cancer protocols	May cause alopecia, nausea, vomiting, myelosuppression. Monitor for flu-like symptoms. Dacarbazine: photosensitivity may occur; avoid extravasation.
Mitotic inhibitors: etoposide, vinblastine, vincristine	Inhibit mitotic activity by inhibiting DNA topoisomerase (etoposide) Cause metaphase arrest by binding to the mitotic spindle (vinblastine, vincristine) Used in a variety of cancer protocols	May cause alopecia, nausea, vomiting, myelo- suppression (only minimal with vincristine). Etoposide: monitor for anaphylaxis; have emer- gency equipment, oxygen, epinephrine, anti- histamines, and steroids available at bedside. Vinblastine, vincristine: maintain hydration; administer allopurinol; avoid extravasation.

(continued)

**DRUG GUIDE 50.1 COMMON DRUGS FOR NEOPLASTIC DISORDERS** (continued)

Medication	Actions/Indications	Nursing Implications
Topoisomerase inhibitors: irinotecan, topotecan	Bind to DNA complex, preventing religation of single-strand DNA breaks Indicated for refractory solid tumors	May cause alopecia, nausea, vomiting, myelosuppression, severe diarrhea (irinotecan), hypotension (topotecan). Maintain hydration. Avoid extravasation. Monitor blood pressure during topotecan infusion.
Corticosteroids: prednisone, dexamethasone	Suppress immune system by decreasing lymphatic activity and volume. Also decrease edema caused by tumor or tumor necrosis Indicated for leukemia and some other cancers	Administer with food to decrease GI upset. May mask signs of infection. Monitor blood pressure; monitor urine for glucose. Do not stop treatment abruptly or acute adrenal insufficiency may occur. Monitor for Cushing syndrome. Doses may be tapered over time.
<b>Biotherapy</b>		
Colony-stimulating factors: darbepoetin alfa, epoetin alfa, filgrastim, sargramostim	Stimulate production of red blood cells (epoetin) or granulocytes (filgrastim, sargramostim) Used to counteract myelosuppressive effects of chemotherapy	Administer SQ or IV. Filgrastim, sargramostim: may cause bone pain. Sargramostim may cause hypotension and a first-dose reaction.
Interleukins: aldesleukin	Recombinant DNA interleukin-2 product that recruits T, B, and natural killer cells Indicated for non-Hodgkin lymphoma	Adverse effects are dose dependent. May cause capillary leak syndrome within 2 to 12 hours of start of treatment: hypotension and decreased organ perfusion result.
Tumor necrosis factor (protein cytokine)	Increases effectiveness of immune cells, stops cancer cells from dividing, damages tumor blood vessels Used in a variety of cancer protocols	May cause fever, chills, rigors, nausea, vomiting.
Monoclonal anti-bodies: rituximab, gemtuzumab	Bind to CD20 antigen on B lymphocytes Indicated in CD20-positive non-Hodgkin lymphoma, posttransplant lymphoproliferative disorder	Monitor blood pressure for hypotension. Monitor for anaphylaxis and infusion-related reaction. Have epinephrine, antihistamines, and steroids available at bedside for treatment of reaction.
Interferons: $\alpha$ , $\gamma$	Alter cancer cell proliferation ( $\alpha$ ), stimulate macrophage production to fight bacteria and fungus ( $\gamma$ ) Indicated in a variety of cancer protocols	May cause flu-like symptoms. Maintain adequate hydration.
Allopurinol	Decreases production of uric acid Use to treat secondary hyperuricemia occurring during leukemia or tumor treatment	Give PO after meals with plenty of food. Cardiovascular adverse effects may occur with IV administration. Maintain adequate hydration.

**DRUG GUIDE 50.1 COMMON DRUGS FOR NEOPLASTIC DISORDERS** (continued)

Medication	Actions/Indications	Nursing Implications
Antibiotics (oral, parenteral)	Treatment of documented bacterial infections Also used as prophylaxis of <i>Pneumocystis jiroveci</i> and in the neutropenic child	Check for antibiotic allergies. Should be given as prescribed for the length of time prescribed. Start IV antibiotics as soon as possible in the neutropenic child admitted with fever.
Antiemetics: promethazine, metoclopramide, ondansetron	Act on the CNS transmitters to prevent vomiting	May cause CNS side effects, such as drowsiness or irritability. Ondansetron: may cause dry mouth.
Antifungal agents: nystatin, amphotericin B (conventional and lipid complex)	Invade fungal cell wall, enabling its destruction Indicated for mucositis, or systemic fungal infection	Nystatin: administer after meals. Amphotericin B: may cause fever, chills, rigors, cardiovascular adverse effects; monitor child closely throughout infusion; note dose differences between conventional and lipid complex.
Immunosuppressant drugs: cyclosporine A (CyA), mycophenolate, tacrolimus	Inhibition of production and release of interleukin II (CyA) Inhibition of T- and B-cell proliferation (mycophenolate). Inhibition of T-cell activation (tacrolimus) Used for treatment of GVHD after HSCT	Monitor CBC, serum creatinine, potassium, and magnesium. Monitor blood pressure and for signs of infection. Draw blood levels prior to morning dose. CyA: do not give with grapefruit juice. Mycophenolate: give on empty stomach; do not open capsule or crush tablet. Tacrolimus: give on empty stomach; monitor for anaphylaxis with first IV dose.
Mesna	Binds with and detoxifies cyclophosphamide and ifosfamide metabolites in the urinary bladder to prevent hemorrhagic cystitis	Maintain adequate hydration. Administer concurrently and after cyclophosphamide or ifosfamide. May cause hypotension.
Methotrexate antidote: leucovorin	Reduces toxic effects of methotrexate	May cause skin disturbances, wheezing, thrombocytosis. Dose depends on methotrexate level. Dose increased with increased creatinine levels

GI, gastrointestinal; PO, by mouth; SQ, subcutaneously.

Adapted from Baggott, C. (2010). Cancer. In P. J. Allen, J. A. Vessey, and N. A. Schapiro (Eds.), *Primary care of the child with a chronic condition* (5th ed.). St. Louis, MO: Mosby; Taketokmo, C. K., Hodding, J. H., & Kraus, D. M. (2011). *Pediatric and neonatal dosage handbook* (18th ed.). Hudson, OH: Lexi-comp; and Tomlinson, D., & Kline, N. E. (Eds.). (2010). *Pediatric oncology nursing*. New York, NY: Springer.

protocols often call for a combination of drugs that act on different phases of the cell cycle, thus maximizing the destruction of cancer cells.

Chemotherapy drugs are divided into classes that exert slightly different actions and have an effect on different portions of the cell cycle. Drug Guide 50.1 gives

further explanation about the different classes of chemotherapy drugs.

Unfortunately, chemotherapeutic medications disrupt the cell cycle of not only cancer cells but also normal rapidly dividing cells. This results in a significant number of adverse effects. The cells most likely to be

FIGURE 50.1 Phases of the cell cycle.

affected by chemotherapy are those in the bone marrow, the digestive tract (especially the mouth), the reproductive system, and hair follicles.

Adverse effects common to chemotherapeutic drugs include immunosuppression, infection, myelosuppression, nausea, vomiting, constipation, oral mucositis, alopecia, and pain. Long-term complications include microdontia and missing teeth as a result of damage to developing permanent teeth; hearing and vision changes; hematopoietic, immunologic, or gonadal dysfunction; endocrine dysfunction, including altered growth and precocious or delayed puberty; various alterations of the cardiorespiratory, gastrointestinal, and genitourinary systems; and development of a second cancer as an adolescent or adult (Chordas & Graham, 2010).

### Take Note!

Acupuncture as an adjuvant therapy has been demonstrated to significantly decrease nausea, vomiting, and aversion to chemotherapy (Rheingans, 2007).

## Radiation Therapy

Radiation therapy uses high-energy radiation to damage or kill cancer cells. Radiant energy in either a gamma or particle form is emitted during the treatment. Radiation affects not only cancer cells but also any rapidly growing cells with which they are in contact. It may be used as a curative, adjuvant, or palliative treatment, either alone or in combination with chemotherapy. Radiation therapy is also used to shrink a tumor prior to surgical resection. The area to be treated is marked carefully to minimize damage to normal cells.

Adverse effects of radiation therapy include fatigue, nausea, vomiting, oral mucositis, myelosuppression, and alterations in skin integrity at the site of irradiation. Long-term complications are related to the area of the body that was irradiated and include alterations in growth; hormone dysfunction; hearing and vision alterations; learning problems; cardiac dysfunction; pulmonary fibrosis; hepatic, sexual, or renal dysfunction; osteoporosis; and development of secondary cancer (particularly at the site of irradiation) (Loch & Khorrami, 2010).

## Hematopoietic Stem Cell Transplantation

Hematopoietic stem cell transplantation (HSCT), also called bone marrow transplantation, is a procedure in which hematopoietic stem cells are infused intravenously into the child. This follows a period of purging of abnormal cells in the child that is accomplished through high-dose chemotherapy or irradiation. The use of high-dose chemotherapy and total body irradiation kills the tumor cells but also destroys the child's bone marrow. The transplanted cells migrate to the empty spaces in the child's bone marrow and reestablish normal hematopoiesis in the child.

HSCT is used for a variety of childhood cancers, including leukemia, lymphoma, brain tumors, neuroblastoma, and other solid tumors. For most pediatric cancers, it is not the first line of treatment but is used for refractory or advanced disease.

Autologous HSCT is achieved through harvest and treatment of the child's own bone marrow, followed by infusion of the treated stem cells. Risk for relapse of the original disease is highest in autologous HSCT. Allogenic HSCT refers to transplantation using stem cells from another individual that are harvested from the bone marrow, peripheral blood, or umbilical cord blood. Allogenic HSCT requires human leukocyte antibody (HLA) matching for antigen-specific sites on the leukocytes. Closely matched HLA donors may be difficult to find from a donor listing, and sibling donors are often the closest match. The degree of match is inversely related to the risk for graft rejection and the development of graft-versus-host disease (GVHD). In other words, the lesser the degree of HLA matching in the donor, the higher the risk for graft rejection and GVHD. GVHD occurs to at least some extent in 11% to 85% of all allogenic HSCT recipients (Kristovich & Callard, 2010).

In addition to graft rejection and GVHD, additional initial complications of HSCT are infection, electrolyte imbalance, bleeding, and organ, skin, and mucous membrane toxicities. Long-term complications include impaired growth and fertility related to endocrine

dysfunction, developmental delay, cataracts, pulmonary and cardiac disease, avascular necrosis of the bone, and development of secondary cancers.

## NURSING PROCESS OVERVIEW FOR THE CHILD WITH A NEOPLASTIC DISORDER

Care of the child with a neoplastic disorder includes assessment, nursing diagnosis, planning, interventions, and evaluation. There are a number of general concepts related to the nursing process that may be applied to cancers in children. From a general understanding of the care involved for a child with cancer, the nurse can then individualize the care based on specifics for the particular child. Children with cancer often suffer many physical effects as a result of the disease and its treatment. The nurse must be diligent when assessing for these effects and should involve the parents as a reliable source for reporting the child's physical symptoms.

### Assessment

Assessment of children with neoplastic disorders includes health history, physical examination, and laboratory and diagnostic testing.

**Remember John, the 4-year-old with fever, fatigue, and headaches? What additional health history and physical examination assessment information should you obtain?**

### Health History

Determine current medical history. Note history of recurrent fever or frequent infections. Inquire about bleeding tendencies, such as unusual bruising or petechiae. Note early-morning headache with nausea or vomiting, gait or behavior changes, or visual disturbances. Inquire about changes in bowel or bladder habits or decrease in appetite. Note history of bone fractures unrelated to trauma. Explore the health history for the presence of risk factors such as previous malignancy and treatment; synthetic chemical exposures; parental exposure to radiation, chemicals, or chemotherapeutic agents; and a family history of malignancy (especially childhood), immune disorders, or genetic disorders such as neurofibromatosis or Down syndrome.

### Physical Examination

A complete physical examination should be performed on any child with, or suspected of having, cancer. Note particular findings as discussed below.

#### INSPECTION AND OBSERVATION

Observe the child's overall appearance and energy level. Note a thin or frail appearance, fatigue, or altered level of consciousness. Document visible masses or asymmetry of the face, thorax, abdomen, or extremities. Note difficulty breathing. Inspect the skin for pallor, bruising, or petechiae. Examine the oral cavity for bleeding gums or pale mucous membranes. Observe the child's gait, noting ataxia or limp. Note rectal bleeding or vaginal discharge.

#### AUSCULTATION, PERCUSSION, AND PALPATION

Auscultate the heart, lungs, and abdomen, noting any abnormalities. Percuss the abdomen, noting dullness over a mass if present. Palpate for lymphadenopathy; in particular, note nontender or firm lymph nodes. Palpate any unusual area of swelling anywhere on the body, noting size and absence of tenderness. Palpate the abdomen, noting organomegaly or presence of a mass. Note limited range of motion or pain upon palpation of extremities.

### Psychosocial Assessment

Assess the child's and family's psychosocial status, using open-ended questions. It is particularly important to determine the child's self-esteem, level of anxiety or stress, and coping mechanisms. Determine the spiritual status of the child and family. Ongoing medical procedures and the fear of dying take a toll on the child and family. Ask the child how things are going at home; how does he or she get along with brothers, sisters, and parents? If the child is school age, ask how school is going. Does the child have friends with whom he or she gets to spend time? Ask the child what he or she does in his spare time; are there any hobbies? These types of queries will provide the nurse with information about how well the child is coping.

Assess the parents' status as well. Ask about the marital relationship and how other children in the family are doing. Determine whether certain stressors may need to be addressed.

### Laboratory and Diagnostic Testing

Common Laboratory and Diagnostic Tests 50.1 explains the laboratory and diagnostic tests most commonly used for neoplastic disorders. The tests can assist the

## COMMON LABORATORY AND DIAGNOSTIC TESTS 50.1

Test	Explanation	Indications	Nursing Implications
Complete blood count (CBC) with differential	Evaluate hemoglobin and hematocrit, WBC count (particularly the percentage of individual WBCs), and platelet count	Infection, immunosuppression, to determine neutropenia in myelosuppression	Normal values vary according to age and gender. WBC count differential is helpful in evaluating source of infection. May be affected by myelosuppressive drugs.
$\alpha$ -Fetoprotein (AFP)	Produced by the fetal liver and yolk sac; normally decreases to very low levels by 1 year of age	May be elevated in Hodgkin disease and other cancers. Used to determine tumor burden	No food or fluid restriction required.
Urine catecholamines (VMA, HVA)	Catabolism of catecholamines causes elevated levels in urine	Diagnosis of neuroblastoma (produces catecholamines)	24-hour urine collection. Levels may be altered with certain foods and drugs or vigorous exercise.
Chest radiography	Radiograph of the chest	Identify tumor or metastasis in the thorax	Chest must be held stationary for a brief time.
Computed tomography (CT) scan	Multiple films taken in successive layers to provide a 3D view of the body part being scanned	Identify tumor location or metastasis	Some CT scans are done with oral or IV contrast (notify physician if child has iodine or shellfish allergy). May require a several-hour period of NPO if contrast is used (contrast may cause nausea). Encourage fluid intake after scan to facilitate excretion of contrast dye.
Magnetic resonance imaging (MRI)	Based on how hydrogen atoms behave in a magnetic field when disturbed by radiofrequency signals. Does not require ionizing radiation. Provides a 3D view of the body part being scanned	Identify extent of tumor or metastatic spread	Remove all metal objects from the child. Child must remain motionless for entire scan; parent can stay in room with child. Younger children will require sedation to keep still. A loud thumping sound occurs inside the machine during the scan procedure; this can be frightening to children.
Bone scan	Administration of IV radionuclide material, which is taken up by the bone and is visible on the scans	Identify metastasis to bone	Requires patent IV for injection. Encourage fluid intake after injection to increase uptake of injected radionuclide. Scan will be performed 1 to 3 hours after injection.
Ultrasound	High-frequency sound waves are directed at internal organs and structures, and an image is made of the waves as they are reflected back through the tissues.	Identify tumor presence, especially in abdomen or on kidney	Fasting for a few hours may be required when certain organs are to be visualized.

**COMMON LABORATORY AND DIAGNOSTIC TESTS 50.1** (continued)

Test	Explanation	Indications	Nursing Implications
Bone marrow aspiration and biopsy	A needle is inserted through the cortex of the bone into the bone marrow (most often the iliac spine), bone marrow is aspirated, and the cells are evaluated.	Evaluation for leukemia or metastasis of other cancers to bone marrow	Use EMLA or lidocaine to decrease pain with procedure. Often performed under conscious sedation. Apply a pressure dressing to arrest bleeding. Assess for tenderness or erythema. May require mild analgesia for post-procedure pain.
Lumbar puncture (LP)	A needle is placed in the subarachnoid space of the spinal column, below the base of the cord, and cerebrospinal fluid is withdrawn for analysis.	Evaluation of tumor or metastasis to brain or spinal cord. Also used to administer intrathecal medications	Use EMLA before the procedure to decrease pain. May be performed under conscious sedation. Position child appropriately. Use distraction techniques in the older child or teen. Encourage child to recline for up to 12 hours after LP.

Adapted from Pagana, K. D., & Pagana, T. J. (2010). *Mosby's manual of diagnostic and laboratory tests* (4th ed.). St. Louis, MO: Mosby.

physician or nurse practitioner in diagnosing the disorder, or can be used as guidelines in determining treatment. Laboratory or nonnursing personnel obtain some of the tests, while the nurse might obtain others. In either instance the nurse should be familiar with how the tests are obtained, what they are used for, and normal versus abnormal results. This knowledge will also be necessary when providing child and family education about the testing.

### **Nursing Diagnosis, Goals, Interventions, and Evaluation**

Upon completion of a thorough assessment, the nurse might identify several nursing diagnoses, including:

- Risk for infection
- Pain
- Impaired oral mucous membranes
- Nausea
- Imbalanced nutrition
- Constipation
- Diarrhea
- Risk for impaired skin integrity
- Activity intolerance
- Disturbed body image
- Situational low self-esteem
- Compromised family coping
- Anticipatory grieving

**After completing a nursing assessment of John, you note the following: history of recurrent infections, unusual bruising, and enlarged lymph nodes. Based on the assessment findings, what would your top three prioritized nursing diagnoses be for John?**

Nursing goals, interventions, and evaluation for the child with cancer are based on the nursing diagnoses. Nursing Care Plan 50.1 may be used as a guide in planning nursing care for the child with a neoplastic disorder. The care plan includes many nursing diagnoses that are applicable to the child or adolescent, but not all children will have the same effects from cancer and its treatment. Nursing care should be individualized based on the child's and family's responses to illness. Additional information about nursing management related to specific types of cancer will be included later in the chapter as it relates to specific disorders.

**Based on your top three nursing diagnoses for John, describe appropriate nursing interventions.**

### **PROVIDING EDUCATION**

Provide education to families of all children with cancer as outlined in Teaching Guidelines 50.1.

## NURSING CARE PLAN 50.1

## Overview for the Child With a Neoplastic Disorder

**NURSING DIAGNOSIS:** Risk for infection related to neutropenia and immunosuppression

**Outcome Identification and Evaluation**

Child will not experience overwhelming infection: *will be free from infection or able to recover if he or she becomes infected.*

**Interventions: Preventing Infection**

- Assess for fever, pain, cough, tachypnea, adventitious breath sounds, skin ulceration, stomatitis, and perirectal fissures *to identify potential infection.*
- Administer antibiotics for temperature greater than 38.4°C *to decrease likelihood of overwhelming sepsis.*
- Maintain meticulous hand-washing procedures (including family, visitors, staff) *to minimize spread of infectious organisms.*
- Maintain isolation as prescribed *to minimize exposure to infectious organisms.*
- Avoid rectal temperatures and examinations, intramuscular injections, and urinary catheterization when child is neutropenic *to decrease possibility of introducing microorganisms.*
- Educate family and visitors that child should be restricted from contact with known infectious exposures (in hospital and at home) *to encourage cooperation with infection control.*
- Strictly observe medical asepsis *to avoid unintentional introduction of microorganisms.*
- Promote nutrition and appropriate rest *to maximize body's potential to heal.*
- Inform family to contact the physician or nurse practitioner if child has known exposure to chickenpox or measles *so that preventive measures (e.g., varicella zoster immunoglobulin [VZIG],) can be taken.*
- Administer vaccines (not live) as prescribed (after clearance with oncologist) *to prevent common childhood communicable diseases.*
- Teach family to monitor for fever at home and report temperature elevations to oncologist immediately *so that antibiotic therapy may be instituted as soon as possible.*

**NURSING DIAGNOSIS:** Pain related to invasive diagnostic testing, surgical procedure, neuropathy, disease progression, or adverse effects of treatment as evidenced by verbalization of pain, elevated pain scale ratings, guarding, withdrawal from play or refusal to participate in activities of daily living, or physiologic indicators such as elevated heart rate, diaphoresis, muscle tension or rigidity

**Outcome Identification and Evaluation**

Child will demonstrate pain relief *in amount sufficient to allow participation in play, activities of daily living, or therapeutic interventions. Use the age-appropriate pain scale to set the goal and set a time frame for achievement of the goal.*

**Interventions: Promoting Comfort**

- Determine level of pain using child interview, pain scale, and assessment of physiologic variables *to determine baseline.*
- Document location, intensity, and description of pain *to determine baseline.*
- Discuss with the child and parent techniques that have helped alleviate pain in the past *to incorporate successful interventions into the plan of care.*
- Administer acetaminophen for mild pain: *avoid salicylate and nonsteroidal anti-inflammatory drugs due to increased risk for bleeding.*
- Administer medications as ordered using the least invasive method possible *to avoid pain (intramuscular, subcutaneous, and rectal route should be avoided in the child with thrombocytopenia).*

## NURSING CARE PLAN 50.1

**Overview for the Child With a Neoplastic Disorder** (continued)

- Monitor frequently for adverse effects (particularly respiratory effects) of opioid analgesics, *as opioids reduce responsiveness of carbon dioxide receptors in the brain's respiratory center.*
- Use nonpharmacologic measures such as play therapy, games, TV, guided breathing, imagery, hypnosis, or meditation as appropriate: *distracts child's attention from the pain.*
- Use massage, positioning, or heat *to relieve pain in a particular area.*
- Use EMLA before needlesticks and conscious sedation with lumbar puncture and bone marrow aspiration *to reduce recurrent acute painful episodes associated with frequent blood draws and diagnostic/treatment procedures.*
- Have the child lie flat for 30 minutes after a lumbar puncture and increase fluid intake for 24 hours after the procedure *to decrease incidence of headache.*

**NURSING DIAGNOSIS:** Impaired oral mucous membranes related to chemotherapy, radiation therapy, immunocompromise, decreased platelet count, malnutrition, or dehydration as evidenced by oral lesions, ulcers, plaques, hyperemia or bleeding, difficulty eating or swallowing, or complaint of oral discomfort

**Outcome Identification and Evaluation**

Child will maintain intact, moist mucosa *free from redness, ulceration, or debris.*

**Interventions: Restoring Healthy Oral Mucosa**

- Frequently assess oral cavity for redness, lesions, ulcers, plaques, or bleeding *to provide baseline for comparison and identify alterations early.*
- Offer ice chips frequently while child is NPO *to maintain hydration of mucosa.*
- Use only a soft toothbrush or toothette for dental care, avoiding excessive pressure with brushing, *to decrease incidence of bleeding with mouth care.*
- Keep lips lubricated with petroleum jelly or fragrance-free lip balm *to maintain moist, hydrated lips.*
- Rinse with salt solution or mouthwash every 1 to 2 hours *to keep oral cavity clean and moist.*
- Administer glutamine and/or  $\beta$ -carotene supplements, *which have been shown to decrease the incidence and severity of mucositis.*
- Have child swish and spit 1:1 Benadryl/Maalox solution *to decrease pain.*
- Administer antifungal solution *to prevent or treat oral candidiasis.*
- Avoid spicy, acidic, or very hot or very cold foods *to decrease pain.*
- Administer pain medication (usually acetaminophen or codeine) as ordered *to decrease pain.*

**NURSING DIAGNOSIS:** Nausea related to adverse effects of chemotherapy or radiation therapy as evidenced by verbalization of nausea, increased salivation, swallowing movements, or vomiting

**Outcome Identification and Evaluation**

Child will experience decreased nausea: *will verbalize symptom relief and will be free from vomiting.*

(continued)

## NURSING CARE PLAN 50.1

**Overview for the Child With a Neoplastic Disorder** (continued)**Interventions: Alleviating Nausea and Vomiting**

- Administer antiemetics prior to chemotherapy and as needed thereafter *to decrease frequency of nausea.*
- Assess frequency of vomiting and level of hydration *to provide baseline data and recognize alterations early.*
- Offer frequent, smaller meals or snacks: *smaller amounts are less likely to be vomited.*
- Avoid spicy foods *to avoid stomach upset.*
- Allow bubbles to dissipate from carbonated beverages before they are ingested: *carbonation may contribute to nausea.*
- Remove cover from meal tray before entering child's room: *this will allow the food odor to dissipate outside of the room; food odors may trigger nausea and vomiting.*

**NURSING DIAGNOSIS:** Imbalanced nutrition: less than body requirements related to anorexia, nausea, vomiting, or mucosal irritation associated with chemotherapy or radiation as evidenced by decreased oral intake and weight, length/height, and/or body mass index (BMI) below average for age or individual child's usual measures

**Outcome Identification and Evaluation**

Child will improve nutritional intake, resulting in *steady increase in weight and length/height.*

**Interventions: Promoting Adequate Nutrition**

- Determine body weight and length/height norm for age or find out what the child's pretreatment measurements were *to determine goal to work toward.*
- Determine child's food preferences and provide favorite foods as able *to increase the likelihood that the child will consume adequate amounts of foods.*
- Administer antiemetics as ordered *to increase the likelihood that the child will retain the food he or she ingests.*
- Weigh child daily or weekly (according to physician order or institutional standard) and measure length/height weekly *to monitor for growth.*
- Offer highest-calorie meals at the time of day when the child's appetite is the greatest *to increase likelihood of increased caloric intake.*
- Provide increased-calorie shakes or puddings within diet restriction: *high-calorie foods increase weight gain.*
- Administer vitamin and mineral supplements as prescribed *to attain/maintain vitamin and mineral balance in the body.*
- Administer total parenteral nutrition and intravenous lipids as ordered *to provide adequate nutrition for healing.*

**NURSING DIAGNOSIS:** Constipation related to effects of vinca alkaloids, opioid use, decreased activity, and dietary changes as evidenced by hard stool or stool that is difficult to pass

**Outcome Identification and Evaluation**

Child's bowel function will return to usual pattern: *child will pass a formed, soft stool every day (or modify this criterion according to child's usual pattern).*

## NURSING CARE PLAN 50.1

**Overview for the Child With a Neoplastic Disorder** (continued)**Interventions: Preventing or Managing Constipation**

- Ensure that child increases fluid intake *to provide enough water in the intestines for soft stool formation.*
- Increase fiber in the diet *to provide bulk for stool formation.*
- Administer stool softeners such as mineral oil or docusate sodium: *these help soften the stool, aiding in passage.*
- Provide motivator laxatives such as magnesium hydroxide, lactulose, or sorbitol *to stimulate stool passage.*
- Use stimulant laxatives such as senna or bisacodyl only intermittently rather than on a daily basis *to avoid dependency and diarrhea.*

**NURSING DIAGNOSIS:** Diarrhea related to effects of radiation therapy as evidenced by loose or watery stools, possibly frequent

**Outcome Identification and Evaluation**

Child's bowel function will return to usual pattern: *child will pass a formed, soft stool daily (or modify this criterion according to child's usual pattern).*

**Interventions: Managing Diarrhea**

- Assess frequency of diarrhea and level of hydration *to provide data about severity.*
- Obtain weight daily on same scale *to determine extent of fluid loss.*
- Maintain accurate intake and output records *to determine extent of fluid loss.*
- Administer oral rehydration solutions or intravenous fluids as ordered *to maintain or restore adequate hydration.*
- Restrict roughage and residue in diet *to decrease likelihood of diarrhea.*
- Avoid milk products during acute diarrheal phase: *lactose often worsens diarrhea.*
- Provide an elemental diet to relieve symptoms: *absorbed in the upper small bowel.*
- Provide meticulous perineal care *to avoid skin breakdown related to frequent or loose stools.*
- Administer antidiarrheal medications if ordered *to decrease frequency of stools.*
- If severe and related to radiation therapy, a 3- to 4-day rest period from radiation may be required *to begin recovery of normal absorptive capabilities of bowel.*

**NURSING DIAGNOSIS:** Risk for impaired skin integrity related to radiation therapy

**Outcome Identification and Evaluation**

Child's skin will remain intact: *areas of redness in radiation field will not progress to desquamation.*

**Interventions: Promoting Skin Integrity**

- Assess skin frequently for erythema, erosions, ulcers, or blisters *to provide baseline data and intervene early if skin is impaired.*
- Use a mild soap for cleansing and pat dry rather than rubbing *to avoid skin irritation.*
- Use aloe vera lotion *to moisturize the skin.*
- Avoid perfumed lotions, soaps, heat, cold, or sun, *as these will further irritate the skin in the irradiated area.*
- Do not scrub ink from marked radiation field, and avoid adhesive tape in that area, *to avoid further skin irritation.*
- Administer diphenhydramine or apply hydrocortisone 1% cream *to reduce itching and urge to scratch.*
- For areas of desquamation related to radiation, apply Silvadene cream once or twice a day *to hasten skin repair.*

(continued)

## NURSING CARE PLAN 50.1

**Overview for the Child With a Neoplastic Disorder** (continued)

**NURSING DIAGNOSIS:** Activity intolerance related to treatment adverse effects, anemia, or generalized weakness as evidenced by verbalization of weakness or fatigue; elevation of heart rate, respiratory rate, or blood pressure with activity; complaint of shortness of breath with play or activity

**Outcome Identification and Evaluation**

Child will display increased activity tolerance: *desire to play without developing symptoms of exertion.*

**Interventions: Promoting Activity**

- Encourage activity or ambulation per physician's orders: *early mobilization results in better outcomes.*
- Observe child for symptoms of activity intolerance such as pallor, nausea, lightheadedness or dizziness, or changes in vital signs *to determine level of tolerance.*
- If child is on bed rest, perform range-of-motion exercises and frequent position changes: *negative changes to the musculoskeletal system occur quickly with inactivity and immobility.*
- Cluster nursing care activities and plan for periods of rest before and after exertion *to decrease oxygen need and consumption.*
- Refer the child to physical therapy *for exercise prescription to increase skeletal muscle strength.*

**NURSING DIAGNOSIS:** Disturbed body image related to hair loss as evidenced by verbalization of dissatisfaction with appearance

**Outcome Identification and Evaluation**

Child or adolescent will display appropriate body image: *will look at self in mirror and participate in social activities.*

**Interventions: Promoting Body Image**

- Acknowledge the child's feelings of anger over body changes and illness: *venting feelings is associated with less body image disturbance.*
- Encourage the child or teen to choose a wig or hats and scarves *to involve the child in making decisions about appearance.*
- Support the child's or teen's choices of comfortable, fashionable clothing *to disguise weight loss or scarring while promoting self-esteem.*
- Involve the child in the decision-making process, *as a sense of control will improve body image.*
- Encourage the child to spend time with peers who have experienced hair, limb, or weight loss, *as peers' opinions are often better accepted than those of persons in authority, such as parents or health care professionals.*

**NURSING DIAGNOSIS:** Risk for situational low self-esteem related to loss of control and inability to progress with quest for independence (adolescents)

**Outcome Identification and Evaluation**

Adolescent will maintain or increase self-esteem: *will display increased coping responses and verbalize control as appropriate as well as discuss plans for future.*

## NURSING CARE PLAN 50.1

**Overview for the Child With a Neoplastic Disorder** (continued)**Interventions: Promoting Self-Esteem**

- Identify the adolescent's positive abilities *to promote self-esteem.*
- Give genuine and honest positive feedback, *as the child or adolescent desires honesty.*
- Explore strengths and weaknesses with the adolescent: *helps the teen to see similarities and differences with healthy peers of the same age.*
- Encourage the teen to perform self-care as possible *to promote independence.*
- Offer emotional support: *reduces psychological distress and increases coping abilities.*
- Encourage participation in a support group *to allow teens to discuss body changes and the reactions they perceive in others.*
- When the adolescent is physically able, encourage attendance at camp or an adventure/wilderness event: *these programs have been shown to improve mental health and coping skills.*

**NURSING DIAGNOSIS:** Compromised family coping related to potentially life-threatening illness and stressors involved with cancer treatment

**Outcome Identification and Evaluation**

Child and/or family will demonstrate adequate coping skills: *will verbalize feeling supported and demonstrate healthy family interactions.*

**Interventions: Promoting Child and Family Coping**

- Provide emotional support to the child and family: *improves coping abilities.*
- Actively listen to the child's and family's concerns: *validates their feelings and establishes trust.*
- Provide open communication with the child and siblings: *children appreciate honesty about their illness, and coping is improved.*
- Refer families to community resources such as parent support groups and grief counseling: *such support improves coping abilities.*
- Give terminally ill children permission to discuss their feelings about their illness, *allowing them to conquer fears and express love for their family and friends.*
- Encourage families to be honest with siblings about the treatment and prognosis of the child with cancer: *children often sense what is going on and cope better when they are prepared and are given an honest explanation of events.*
- Prepare siblings for the death of the child with cancer, using the child life specialist and chaplain as necessary: *the bereavement period is eased when siblings are prepared.*

**NURSING DIAGNOSIS:** Anticipatory grieving (family) related to diagnosis of cancer in a child and impending loss of child as evidenced by crying, disbelief of diagnosis, and expressions of grief

**Outcome Identification and Evaluation**

Family will express feelings of grief: *seek help in dealing with feelings, plan for future one day at the time.*

(continued)

## NURSING CARE PLAN 50.1

## Overview for the Child With a Neoplastic Disorder (continued)

**Intervention: Supporting the Grieving Family**

- Use therapeutic communication with open-ended questions *to encourage an open and trusting relationship for better communication.*
- Actively listen to the family's expression of grief: *just being present and listening conveys support.*
- Encourage the family to cry and express feelings away from the child *to work through feelings while not upsetting the child.*
- Assess for spiritual distress *and refer the family to the hospital chaplain or clergy of choice for support.*
- Educate the family about the child's condition honestly: *knowing what is going on, what is to be expected, and what the treatment plan is gives the family a sense of control.*
- Support the family through discussions with the child about anticipated death *when the illness is deemed terminal.*

## Teaching Guidelines 50.1

**EDUCATION FOR FAMILIES OF CHILDREN WITH CANCER**

- Obtain a printed or written copy of the child's treatment plan.
- Keep a calendar of all appointment times, blood count lab draw days, and phone numbers of all physicians and nurse practitioners, home care companies, the laboratory, and the hospital.
- Seek medical care IMMEDIATELY if the child's temperature is 38.3°C (101°F) or higher.
- Call the oncologist or seek medical care if any of the following occur:
  - Cough or rapid breathing
  - Increased bruising, bleeding or petechiae, pallor, or increased levels of fatigue
  - Earache, sore throat, nuchal rigidity
  - Blisters, rashes, ulcers
  - Red, irritated skin on the child's buttocks
  - Abdominal pain, difficulty or pain with eating, drinking, or swallowing
  - Constipation or diarrhea
  - For children with central venous catheters:
    - Pus, redness, or swelling at the site
    - Breakage of the catheter
- Do not give the child aspirin.

Adapted from Kline, N. E. (2008). *Essentials of pediatric oncology nursing: A core curriculum* (3rd ed.). Glenview, IL: Association of Pediatric Hematology/Oncology Nurses.

**ADMINISTERING CHEMOTHERAPY**

All chemotherapy medications have the potential to cause toxicities in the child as well as the persons handling or preparing the medication. General guidelines related to the preparation and administration of chemotherapy include:

- Chemotherapy should be prepared and administered only by specially trained personnel.
- Personal protective equipment (PPE) in the form of double gloves and nonpermeable gowns should be worn when preparing or administering chemotherapy. If splashing is possible or a spill occurs, then a face shield and/or mask may also be necessary.
- Dispose of all equipment used in chemotherapy preparation and administration in a puncture-resistant container (Chordas & Graham, 2010).

It is critical to calculate the chemotherapy dose correctly. Chemotherapy medication doses in children are based on body surface area (BSA). A nomogram is a commonly used device for determining BSA. To use the nomogram, draw a straight line between the child's height on the left and the child's weight on the right. The point at which the straight line crosses the center is the child's BSA expressed in meters squared (Fig. 50.2).

An alternative to using the nomogram is to use the following formula:  $BSA (m^2) = \frac{\text{height [in centimeters]} \times \text{weight [in kilograms]}}{3,600}$  (Chordas & Graham, 2010). For example, for a child 140 cm tall and weighing 30 kg:  $140 \times 30 = 4,200$ ;  $4,200/3,600 = 1.167$ ; and the square root of 1.167 is 1.08. The BSA would be 1.08.

**MANAGING ADVERSE EFFECTS OF CHEMOTHERAPY**

Chemotherapy can result in multiple adverse effects. Myelosuppression leads to low blood counts in all cell lines, placing the child at risk for infection, hemorrhage, and anemia. Nausea, vomiting, and anorexia may hinder the child's growth. Alopecia and facial changes may affect the child's self-esteem (Fig. 50.3). Nursing interventions related to the effects of myelosuppression, nausea, vomiting, and anorexia are discussed below. Refer to

**FIGURE 50.2** A child who weighs 13.2 kg and is 140 cm tall has a body surface area (BSA) of 0.80 m<sup>2</sup>.

Nursing Care Plan 50.1 for nursing interventions related to altered body image.

### Take Note!

Cooling the scalp during chemotherapy administration with the use of a cooling cap may decrease hair loss (Tomlinson & Kline, 2010).

**Preventing Infection.** Many chemotherapeutic drugs cause significant bone marrow suppression and decreased amounts of circulating mature neutrophils (“segs,” or segmented neutrophils). Administer granulocyte colony-stimulating factor (GCSF) as ordered to promote neutrophil growth and maturation (Brundige, 2010). Administer varicella zoster immunoglobulin (VZIG) within 72 hours of exposure to active chickenpox. If the child is actively infected with chickenpox, administer intravenous acyclovir as ordered. Children receiving treatment for acute lymphoblastic leukemia are at risk for opportunistic infection with *Pneumocystis jiroveci*, as most children are colonized with this fungus. Administer prophylactic antibiotics as ordered and teach the parents to administer them at home (Tomlinson & Kline, 2010). Teaching Guidelines 50.2 gives further information about infection prevention at home.

**FIGURE 50.3** Chemotherapy often causes alopecia.

### Teaching Guidelines 50.2

#### PREVENTING INFECTION IN CHILDREN RECEIVING CHEMOTHERAPY FOR CANCER

- Practice meticulous hygiene (oral, body, perianal).
- Avoid known ill contacts, especially persons with chickenpox.
- Immediately notify the physician or nurse practitioner if exposed to chickenpox.
- Avoid crowded areas.
- Do not let the child receive live vaccines.
- Do not take the child’s temperature rectally or give medications by the rectal route.
- Administer twice-daily trimethoprim–sulfamethoxazole for 3 consecutive days each week as ordered for prevention of *Pneumocystis pneumonia*.

Adapted from Baggott, C. (2010). Cancer. In P. J. Allen, J. A. Vessey, and N. A. Schapiro (Eds.), *Primary care of the child with a chronic condition* (5th ed.). St. Louis, MO: Mosby; and Tomlinson, D., & Kline, N. E. (Eds.). (2010). *Pediatric oncology nursing*. New York, NY: Springer.

As neutrophils are the primary means of fighting bacterial infection, when the neutrophil count is low, the chance for developing an overwhelming bacterial infection is high. Each drug that causes bone marrow suppression has a point of nadir. *Nadir* is the time after administration of the drug when bone marrow suppression is expected to be at its greatest and the neutrophil count is expected to be at its lowest (neutropenia). Nadir is individual for each drug and ranges from 7 to 28 days after dosing. An absolute neutrophil count (ANC) below 500 places the child at greatest risk, although an ANC below 1,500 usually warrants evaluation (Brundige, 2010). Refer to Box 50.2 for information related to calculating the absolute neutrophil count.

## BOX 50.2

**CALCULATING THE ABSOLUTE NEUTROPHIL COUNT (ANC)**

1. Add together the percentage of banded and segmented neutrophils reported on the complete blood count with differential (CBC with diff).
2. Multiply the total number of white blood cells reported on the CBC by the sum above. This yields the ANC (total number of neutrophils present).

Example: Bands 5%, Segs 15%, WBCs 2,500

$5\% + 15\% = 20\% (0.20)$

$2,500 \times 0.20 = 500$

ANC = 500

Adapted from Brundige, K. (2010). Neutropenia. In D. Tomlinson & N. E. Kline (Eds.), *Pediatric oncology nursing*. New York, NY: Springer.

Depending on institutional policy, precautions for neutropenia will be followed if the ANC is depressed. Precautions related to neutropenia generally include:

- Place the child in a private room.
- Perform hand hygiene before and after contact with each child.
- Monitor vital signs every 4 hours.
- Assess for signs and symptoms of infection at least every 8 hours.
- Avoid rectal suppositories, enemas, or examinations; urinary catheterization; and invasive procedures.
- Restrict visitors with fever, cough, or other signs/symptoms of infection.

- Do not permit raw fruits or vegetables or fresh flowers or live plants in the room.
- Place a mask on the child when he or she is being transported outside of the room.
- Perform dental care with a soft toothbrush if the platelet count is adequate.

Children with neutropenia and fever must be started on intravenous broad-spectrum antibiotics without delay to avoid overwhelming sepsis (Brundige, 2010).

**Preventing Hemorrhage.** Assess for petechiae, purpura, bruising, or bleeding. Determine changes from baseline that warrant intervention. Encourage quiet activities or play to avoid trauma. Avoid rectal temperatures and examinations to avoid rectal mucosal damage that results in bleeding. Post a sign at the head of the bed stating “no rectal temperatures or medications.” Avoid intramuscular injections and lumbar puncture if possible to decrease the risk of bleeding from a puncture site. If bone marrow aspiration must be performed, apply a pressure dressing to the site to prevent bleeding. For active or uncontrolled bleeding, transfuse platelets as ordered to control bleeding.

**Preventing Anemia.** To maintain blood volume, limit blood draws to the minimum volume required. Encourage the child to eat an appropriate diet that includes adequate iron. Administer erythropoietin injections as ordered. Teach families to give the injections at home if prescribed.

**EVIDENCE-BASED PRACTICE 50.1****NONPHARMACOLOGIC THERAPIES FOR SYMPTOM MANAGEMENT IN CHILDHOOD CANCER****STUDY**

Even with significant advances in childhood cancer surgery and treatment, troublesome symptoms remain a large problem. Children report that the most upsetting aspect of cancer treatment is the numerous side effects they suffer. The author performed a systematic review of research studies that evaluated the use of complementary and alternative therapies for cancer treatment side effect management. Forty-one studies were reviewed that addressed such topics as procedural pain, distress, fear and anxiety, nausea/vomiting, anxiety, distress, and depression. Nonpharmacologic adjunctive therapies evaluated in the studies included hypnosis, distraction, cognitive behavioral therapies, relaxation, imagery, breathing, music therapy, play, self-hypnosis, acupuncture, art therapy, coping skills training, hand holding, humor, and nonessential touch.

**Findings**

Many of the nonpharmacologic adjuvant therapies studies were found to be effective for symptom relief. Cognitive behavioral therapy, distraction, and hypnosis were particularly helpful. Although safety concerns for various therapies were not reported, the author proposed that further rigorous research on these modalities is necessary.

**Nursing Implications**

Many families will be seeking nonpharmacologic or complementary/alternative therapies for relieving the distressing symptoms associated with cancer treatment. Nurses must keep an open mind about these therapies. When families have questions about using these treatments, they should be directed to authorities in the area. Nurses are in a perfect position to initiate additional rigorous research to determine the effectiveness and long-term safety of these therapies.

Adapted from Rheingans, J. I. (2007). A systematic review of nonpharmacologic adjunctive therapies for symptom management in children with cancer. *Journal of Pediatric Oncology Nursing*, 24(2), 81–94.

**Managing Nausea, Vomiting, and Anorexia.** Many chemotherapeutic drugs produce the adverse effect of nausea and vomiting, which often leads to anorexia. The cycle of nausea, vomiting, and anorexia is difficult to break once it begins. In addition, taste alterations are common in children who have received chemotherapy. During or after chemotherapy, children may develop an aversion to a food that was previously their favorite (Tomlinson & Kline, 2010). Provide foods the child desires or asks for in order to increase the likelihood of eating.

Prevent nausea by administering antiemetic medications prior to the administration of chemotherapy and on a routine schedule around the clock for the first 1 to 2 days rather than on an as-needed (PRN) basis. Herbal or complementary therapies may provide another option for management of nausea.

#### Take Note!

Ginger capsules, ginger tea, and candied ginger have been used as a nausea remedy for centuries (ginger ale is usually artificially flavored, so it would not have the same effect). Though ginger is considered safe, instruct families to check with the oncologist before using this remedy.

Bright lights and noise may worsen nausea. Therefore, keep the child's environment dimly lit and calm. Relaxation therapy and guided imagery may also be helpful in preventing or treating nausea and vomiting. Refer to Nursing Care Plan 50.1 for additional interventions.

#### Take Note!

Foot massage may decrease the nausea and pain associated with chemotherapy (Post-White & Ladas, 2010).

### MONITORING THE CHILD RECEIVING RADIATION THERAPY

Radiation causes damage to the cells in a localized area, which may include normal cells in addition to the cancerous ones. Assess the child's skin daily, particularly at the treatment site. Provide good hygiene, but perform this care gently. Encourage moisture retention in the skin by applying aqueous creams or moisturizers. Do not apply deodorants or perfumed lotions on the radiation treatment site. Avoid the use of heat or ice packs at the site. Instruct the child and family that clothing should fit loosely so as not to irritate the site (Loch & Khorrami, 2010). During, and for 8 weeks after, the radiation treatment, the skin will be more photosensitive. Explain the importance of protecting the skin with a high-SPF (30 or above) sunscreen.

### PROVIDING CARE TO THE CHILD UNDERGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION

Stem cell transplantation is performed at limited specialty medical centers in the United States. In addition, special training is required for all personnel caring for the child who undergoes a stem cell transplant. The intent of this discussion is to provide only a brief introduction to, and overview of, nursing management related to HSCT.

Care for the child undergoing HSCT may be divided into three phases—the pretransplant phase, the posttransplant phase, and the lengthy supportive care phase. Nursing management of each phase is briefly discussed below.

**Pretransplant Phase.** In the pretransplant phase, the child is being prepared to receive the transplant. The child's own bone marrow cells are eradicated through high-dose chemotherapy and total body irradiation. This phase usually occurs over 7 to 10 days. The child will be hospitalized because he or she is at extreme risk for serious infection. Maintain protective isolation in a positive-pressure room and limit visitors. Administer gammaglobulin, acyclovir, or antibiotics as ordered to prevent or treat infection. Lymphohematopoietic rescue occurs with infusion of the donor or autologous cells (Norville & Tomlinson, 2010).

**Posttransplant Phase.** The posttransplant phase is also a time of high risk for the child. Monitor closely for symptoms of GVHD such as severe diarrhea and maculopapular rash progressing to redness or desquamation of the skin (especially palms or soles) (Fig. 50.4). If GVHD occurs, administer immunosuppressive drugs such as cyclosporine, tacrolimus, or mycophenolate (which place the child at further risk for infection) (Norville & Tomlinson, 2010).

**FIGURE 50.4** The first sign of graft-versus-host disease (GVHD) may be a maculopapular rash. (Courtesy of Mary L. Brandt, MD)

**Supportive Care.** During the supportive care phase, which lasts several months after the transplant, continue to monitor for and prevent infection. Administer packed red blood cells or platelets and granulocyte colony-stimulating factor as needed.

Families and children who undergo HSCT need prolonged and extensive emotional and psychosocial support. A medical social worker and psychologist or counselor are usually members of the transplant team and are excellent resources for these families' needs (Norville & Tomlinson, 2010).

### PROMOTING A NORMAL LIFE

Children and teens want to be normal and to experience the things that other children their age do. The child should attend school when he or she is well enough and the white blood cell counts are not dangerously low. Children, their families, and their teachers should be aware that cancer and its treatment can affect scholastic abilities. Learning disabilities, difficulty with memory, attention disorders, and cognitive deficits can occur (Tomlinson & Kline, 2010).

Maintain other activities if the child is able and if platelet counts are within normal limits. Special camps are available for children with cancer. These camps offer an opportunity for children and adolescents to experience a variety of activities safely and to network with other children who are experiencing similar physical and emotional challenges (Conrad & Altmaier, 2009). The Children's Oncology Camping Association and the American Childhood Cancer Foundation provide lists of camps throughout the United States and Canada and internationally for children and teens with cancer. Links to these resources are provided on [thePoint](#).

### PROMOTING GROWTH

Promote growth in children with cancer by encouraging an appropriate diet and preventing nausea and vomiting and also by addressing concerns such as diarrhea and constipation. Chronic diarrhea related to radiation therapy may prevent the child from gaining weight and growing properly (see Nursing Care Plan 50.1). The use of vinca alkaloids and opioids, as well as the decreased activity level of the child with cancer, may contribute to constipation. Constipation increases the pain experience, contributes to the child's malaise, and decreases quality of life. It directly affects the child's ability to grow by increasing anorexia, nausea, and vomiting (Tomlinson & Kline, 2010). Nursing Care Plan 50.1 details interventions related to preventing and managing constipation.

### PREVENTING AND TREATING ONCOLOGIC EMERGENCIES

Oncologic emergencies may occur as an effect of the disease process itself or from cancer treatment. As

progress is made in chemotherapy and radiation treatment, children with cancer have an increased survival rate, but they still face the risk of developing an oncologic emergency. Nurses caring for children with cancer need to be familiar with signs and symptoms of oncologic emergencies as well as with their treatment. All of these problems warrant careful, frequent monitoring of respiratory, cardiovascular, neurologic, and renal status. Table 50.1 provides information about oncologic emergencies.

### CARING FOR THE DYING CHILD

Among children in the United States diagnosed with cancer, over 2,200 will die from the disease each year (Centers for Disease Control and Prevention, 2007). A "do not resuscitate" (DNR) order for the child with progressive cancer is obtained in many situations. This order helps to optimize care in the terminal phase of cancer. Nurses serve as child and family advocates, clarifying terminology and providing support as needed during the discussion of DNR orders and throughout the rest of the terminal phase.

Children with terminal cancer often experience a great deal of pain, particularly when death is imminent. Pain is often accompanied by agitation and dyspnea, which further contribute to the child's discomfort. Whether the child has a DNR order or his or her status remains that of "full code," pain management is central to the nursing care of the child who is dying from cancer. The Association of Pediatric Oncology Nurses' position paper entitled "Pain Management for the Child With Cancer in End-of-Life Care" outlines the following recommendations for managing children's pain at the end of life:

- Prevention and alleviation of pain is a primary goal of care in the child dying of cancer.
- Children and parents are equal partners with members of the health care team in managing the child's pain.
- Children dying of cancer may require aggressive dosing of analgesics. Medications that do not have a dose maximum should be escalated, sometimes rapidly, to achieve adequate pain control or to maintain pain control when tolerance has occurred.
- The nurse's role in caring for children who are in pain at the end of life includes assessment, identifying expected outcomes, and planning, performing, and evaluating interventions (Hooke, Hellsten, Stutzer, & Forte, 2002).

Interventions related to pain management may be found in Nursing Care Plan 50.1. Further discussion related to care of the dying child is found in Chapter 34.

TABLE 50.1

## ONCOLOGIC EMERGENCIES

Emergency	Associated With	Signs and Symptoms	Laboratory or Diagnostic Test Findings	Management
Sepsis	Neutropenia resulting from bone marrow suppression due to chemotherapy	<ul style="list-style-type: none"> <li>Fever or low temperature</li> <li>Respiratory distress</li> <li>Poor perfusion</li> <li>Altered level of consciousness</li> </ul>	<ul style="list-style-type: none"> <li>ANC &lt;500</li> <li>Positive blood culture</li> <li>Increased BUN, creatinine, potassium, clotting times</li> <li>Decreased platelet count</li> <li>Metabolic acidosis</li> </ul>	<ul style="list-style-type: none"> <li>Airway and ventilation maintenance</li> <li>Fluid volume resuscitation</li> <li>Inotropic support</li> <li>Broad-spectrum antibiotics and antifungals</li> <li>Dialysis if needed</li> </ul>
Tumor lysis syndrome	ALL, lymphoma, neuroblastoma	<ul style="list-style-type: none"> <li>Nausea, vomiting, diarrhea, anorexia</li> <li>Lethargy</li> <li>Increased heart rate and blood pressure</li> <li>Decreased or absent urine output</li> <li>Altered level of consciousness</li> </ul>	<ul style="list-style-type: none"> <li>Hyperuricemia</li> <li>Hyperkalemia</li> <li>Hyperphosphatemia</li> <li>Hypocalcemia</li> <li>Hypoxia</li> </ul>	<ul style="list-style-type: none"> <li>Prevent by giving allopurinol for several days prior to chemotherapy (also treat with allopurinol)</li> <li>Double IV fluid maintenance</li> <li>Sodium bicarbonate</li> </ul>
Hyperleukocytosis	Leukemia with high WBC count	<ul style="list-style-type: none"> <li>Respiratory distress</li> <li>Murmur, increased heart rate</li> </ul>	<ul style="list-style-type: none"> <li>WBC count &gt;100,000</li> <li>Hyperkalemia, hyperphosphatemia</li> <li>Hyperuricemia</li> <li>Decreased pH and bicarbonate</li> </ul>	<ul style="list-style-type: none"> <li>Leukapheresis</li> <li>Respiratory support</li> <li>Double IV fluid maintenance with sodium bicarbonate added</li> <li>Diuretics</li> </ul>
Typhlitis (neutropenic enterocolitis)	Inflammatory process of GI tract occurring with induction phase of leukemia chemotherapy	<ul style="list-style-type: none"> <li>Acute abdominal pain</li> <li>Nausea, vomiting</li> <li>Bloody diarrhea and emesis</li> <li>Fever</li> <li>Anorexia</li> </ul>	<ul style="list-style-type: none"> <li>KUB: scarcity of bowel gas, possibly ileus</li> <li>CT (abdominal): inflammation, bowel wall thickening, peritoneal fluid</li> </ul>	<ul style="list-style-type: none"> <li>Bowel rest (NPO status)</li> <li>IV nutrition</li> <li>Assess for bowel perforation/shock.</li> <li>Broad-spectrum antibiotics and antifungals</li> <li>Comfort measures</li> </ul>
Superior vena cava (SVC) syndrome	Compression on the SVC by NHL or other mediastinal mass, such as neuroblastoma	<ul style="list-style-type: none"> <li>Dyspnea and cyanosis</li> <li>Large cervical lymph nodes</li> <li>Wheezing, diminished breath sounds</li> </ul>	<ul style="list-style-type: none"> <li>Chest radiograph or CT shows mediastinal mass.</li> <li>Pleural effusion</li> </ul>	<ul style="list-style-type: none"> <li>Intubation and ventilation</li> <li>Comfort measures</li> <li>Treat cause (usually surgical removal of mass).</li> </ul>
Spinal cord compression	Tumor or metastasis compresses spinal cord.	<ul style="list-style-type: none"> <li>Back, neck, or leg pain</li> <li>Sensory or autonomic dysfunction</li> <li>Extremity weakness or paralysis</li> </ul>	<ul style="list-style-type: none"> <li>MRI reveals location of tumor or metastasis to epidural space.</li> </ul>	<ul style="list-style-type: none"> <li>Dexamethasone</li> <li>Careful assessment</li> <li>Radiation therapy</li> <li>Comfort measures</li> </ul>

(continued)

TABLE 50.1

## ONCOLOGIC EMERGENCIES (continued)

Emergency	Associated With	Signs and Symptoms	Laboratory or Diagnostic Test Findings	Management
Increased intracranial pressure	Brain tumor or metastasis to brain causing compression of brain; may result in herniation	<ul style="list-style-type: none"> <li>• Headache, visual disturbances</li> <li>• Morning vomiting</li> <li>• Infants: increased head circumference</li> <li>• Altered level of consciousness</li> <li>• Cushing triad</li> <li>• Seizure activity</li> </ul>	<ul style="list-style-type: none"> <li>• Head CT or MRI reveals extent of mass.</li> </ul>	<ul style="list-style-type: none"> <li>• Frequent, careful neurologic assessment</li> <li>• Limit fluids.</li> <li>• Dexamethasone</li> <li>• Anticonvulsants</li> <li>• Tumor resection, radiation, or chemotherapy</li> <li>• Comfort measures</li> </ul>
Massive hepatomegaly	Obstruction caused by neuroblastoma filling a large portion of the abdominal cavity	<ul style="list-style-type: none"> <li>• Distended, enlarged abdomen</li> <li>• Respiratory distress, hypoxia</li> <li>• Poor perfusion</li> <li>• Tachycardia, hypotension</li> </ul>	<ul style="list-style-type: none"> <li>• Abdominal CT reveals extent of tumor</li> <li>• Coagulopathy</li> </ul>	<ul style="list-style-type: none"> <li>• Tumor resection or debulking</li> <li>• Mechanical ventilation, inotropic support</li> <li>• Nasogastric decompression</li> <li>• Position to minimize abdominal pressure.</li> <li>• Blood transfusions</li> <li>• Comfort measures</li> </ul>

GI, gastrointestinal; KUB, kidney, ureters, and bladder scan; NPO, nothing by mouth.

Adapted from Maloney, K., Foreman, N. K., Giller, R. H., Greffe, B. S., Graham, D. K., Quinones, R. R., et al. (2011). Neoplastic disease. In W. W. Hay, M. J. Levin, J. M. Sondheimer, & R. R. Deterding (Eds.), *Current pediatric diagnosis and treatment* (20th ed.). New York, NY: McGraw-Hill; and Tomlinson, D., & Kline, N. E. (Eds.). (2010). *Pediatric oncology nursing*. New York, NY: Springer.

## LEUKEMIA

Leukemia accounts for about one third of all childhood cancers (Zupanec & Tomlinson, 2010). It is a primary disorder of the bone marrow in which the normal elements are replaced with abnormal white blood cells. Normally, lymphoid cells grow and develop into lymphocytes, and myeloid cells grow and develop into red blood cells, granulocytes, monocytes, and platelets. Leukemia may develop at any time during the usual stages of normal lymphoid or myeloid development.

Leukemia may be classified as acute or chronic, lymphocytic or myelogenous. Acute leukemias are rapidly progressive diseases affecting the undifferentiated or immature cells; the result is cells without normal function. Chronic leukemias progress more slowly, permitting maturation and differentiation of cells so that they retain some of their normal function. Acute leukemias, including acute lymphoblastic leukemia (ALL) and acute myelogenous leukemia (AML), make up a significant majority of all cases of leukemia in children and adolescents (Zupanec & Tomlinson, 2010). Therefore, they will be the focus of the discussion below.

Complications of leukemia include **metastasis** (spread of cancer to other sites) to the blood, bone, CNS, spleen, liver, or other organs and alterations in growth. Late effects include problems with neurocognitive function and ocular, cardiovascular, or thyroid dysfunction. With advances in treatment over the past 50 years, most cases of childhood leukemia are curable. However, children who experience relapse or present with advanced disease have a poorer prognosis (Zupanec & Tomlinson, 2010).

### Acute Lymphoblastic Leukemia

ALL is the most common form of cancer in children. Eighty-five percent of cases of ALL occur in children between 2 and 10 years of age (Maloney et al., 2011). It is more common in white children than in other races. ALL is classified according to the type of cells involved—T cell, B cell, early pre-B cell, or pre-B cell. Most children will achieve initial remission if appropriate treatment is given. The overall cure rate of ALL is over 70% (Maloney et al., 2011).

Prognosis is based on the white blood cell (WBC) count at diagnosis, the type of cytogenetic factors and immunophenotype, the age at diagnosis, and the extent of extramedullary involvement. Generally, the higher the WBC count at diagnosis, the worse the prognosis. Children between 1 and 9 years of age and with a white blood cell count less than 50,000 at diagnosis have the best prognosis. When a child experiences a relapse, the prognosis becomes poorer. Complications include infection, hemorrhage, poor growth, and CNS, bone, or testicular involvement.

### Take Note!

Growth hormone replacement therapy using recombinant human growth hormone may improve the long-term growth of children with leukemia (Zupanec & Tomlinson, 2010).

muscle wasting. The bone marrow becomes unable to maintain normal levels of red blood cells, WBCs, and platelets, so anemia, neutropenia, and thrombocytopenia result. As the bone marrow expands or the leukemic cells infiltrate the bone, joint and bone pain may occur. The leukemic cells may permeate the lymph nodes, causing diffuse lymphadenopathy, or the liver and spleen, resulting in hepatosplenomegaly. With spread to the CNS, vomiting, headache, seizures, coma, vision alterations, or cranial nerve palsies may occur (Zupanec & Tomlinson, 2010).

### Take Note!

Changes in behavior or personality, headache, irritability, dizziness, persistent nausea or vomiting, seizures, gait changes, lethargy, or altered level of consciousness may indicate CNS infiltration with leukemic cells. Immediately report these findings to the pediatric oncologist.

## Pathophysiology

The exact cause of ALL remains unknown. Genetic factors and chromosome abnormalities may play a role in its development. In ALL, abnormal lymphoblasts abound in the blood-forming tissues. The lymphoblasts are fragile and immature, lacking the infection-fighting capabilities of the normal WBC. The growth of lymphoblasts is excessive and the abnormal cells replace the normal cells in the bone marrow. The proliferating leukemic cells demonstrate massive metabolic needs, depriving normal body cells of needed nutrients and resulting in fatigue, weight loss or growth arrest, and

## Therapeutic Management

Therapeutic management of the child with ALL focuses on giving chemotherapy to eradicate the leukemic cells and restore normal bone marrow function. Treatment is divided into three stages. CNS prophylaxis is provided at each stage; without CNS prophylaxis, leukemia would spread to the CNS in up to 50% of children with ALL (Zupanec & Tomlinson, 2010). The length of treatment and choice of medications are based on the child's age, risk category, and subtype determined by bone marrow analysis. Table 50.2 discusses the stages of leukemia

**TABLE 50.2** STAGES OF LEUKEMIA TREATMENT

Stage	Purpose	Length	Usual Medications
Induction	Rapid induction of complete remission	3 to 4 weeks	Oral steroids, IV vincristine, IM L-asparaginase, daunomycin (high risk)
Consolidation (intensification)	Strengthen remission, reduce leukemic cell burden	Varies	High-dose methotrexate, 6-mercaptopurine; possibly cyclophosphamide, cytarabine, asparaginase, thioguanine, epipodophyllotoxins
Maintenance	Eliminate all residual leukemic cells	2 to 3 years	Low dose: daily 6-mercaptopurine, weekly methotrexate, intermittent IV vincristine and oral steroids
CNS prophylaxis	Reduce risk of development of CNS disease	Given periodically in all stages	Intrathecal chemotherapy; cranial radiation is used infrequently

Adapted from Maloney, K., Foreman, N. K., Giller, R. H., Greffe, B. S., Graham, D. K., Quinones, R. R., et al. (2011). Neoplastic disease. In W. W. Hay, M. J. Levin, J. M. Sondheimer, & R. R. Deterding (Eds.), *Current pediatric diagnosis and treatment* (20th ed.). New York, NY: McGraw-Hill; and Zupanec, S., & Tomlinson, D. (2010). Leukemia. In D. Tomlinson & N. E. Kline (Eds.), *Pediatric oncology nursing*. New York, NY: Springer.

treatment. For relapsed or less responsive leukemia, HSCT may be necessary.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1823. Assessment findings pertinent to ALL are discussed below.

### Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Fever (may be persistent or recurrent, with unknown cause)
- Recurrent infection
- Fatigue, malaise, or listlessness
- Pallor
- Unusual bleeding or bruising
- Abdominal pain
- Nausea or vomiting
- Bone pain
- Headache (Zupanic & Tomlinson, 2010)

Explore the child's current and past medical history for risk factors such as:

- Male gender
- Age 2 to 5 years
- Caucasian race
- Down syndrome, Shwachman syndrome, or ataxia-telangiectasia
- X-ray exposure in utero
- Previous radiation-treated cancer (Zupanic & Tomlinson, 2010)

Determine the child's history of varicella zoster immunization or disease. Chickenpox infection in the leukemic child may lead to disseminated, overwhelming infection.

### Physical Examination

Take the child's temperature (fever may be present), and look for petechiae, purpura, or unusual bruising (due to decreased platelet levels). Inspect the skin for signs of infection. Auscultate the lungs, noting adventitious breath sounds, which may indicate pneumonia (present at diagnosis or due to immunosuppression during treatment). Note location and size of enlarged lymph nodes. Palpate the liver and spleen for enlargement. Document tenderness on abdominal palpation.

### Laboratory and Diagnostic Tests

Common laboratory and diagnostic studies ordered for the assessment of ALL include:

- Complete blood counts: abnormal findings include low hemoglobin and hematocrit, decreased red blood cell count, decreased platelet count, and elevated, normal, or decreased WBC count
- Peripheral blood smear may reveal blasts.
- Bone marrow aspiration: stained smear from bone marrow aspiration will show greater than 25% lymphoblasts. Bone marrow aspirate is also examined for immunophenotyping (lymphoid vs. myeloid, and level of cancer cell maturity) and cytogenetic analysis (determines abnormalities in chromosome number and structure). Immunophenotyping and cytogenetic analysis are used in the classification of the leukemia, which helps guide treatment.
- Lumbar puncture will reveal whether leukemic cells have infiltrated the CNS.
- Liver function tests and blood urea nitrogen (BUN) and creatinine levels determine liver and renal function, which, if abnormal, may preclude treatment with certain chemotherapeutic agents.
- Chest radiography may reveal pneumonia or a mediastinal mass.

## Atraumatic Care

*The child with leukemia undergoes frequent implantable port accesses for blood draws and chemotherapy, bone marrow aspirations for assessment of blood cell status, and lumbar punctures for laboratory studies and intrathecal medication administration. To decrease trauma produced by these repetitive painful procedures, utilize EMLA (eutectic mixture of local anesthetics) cream appropriately. Teach the child's primary caregiver to apply the cream to the implantable port site 30 minutes to 1 hour prior to the child's clinic appointment time. Apply EMLA cream to the posterior hip or lumbar spine, 1 to 3 hours prior to bone marrow aspiration or lumbar puncture.*

## Nursing Management

Nursing care of children with ALL focuses on managing disease complications such as infection, pain, anemia, bleeding, and hyperuricemia and the many adverse effects related to treatment. Many children require blood product transfusion for the treatment of severe anemia or low platelet levels with active bleeding.

Individualize nursing care based on the diagnoses, interventions, and outcomes presented in Nursing Care Plan 50.1, depending on the child's response to the disease and chemotherapy. Refer to the nursing process

overview section for further information related to managing the adverse effects of chemotherapy.

### Take Note!

Blood products administered to children with any type of leukemia should be irradiated, cytomegalovirus (CMV) negative, and leukodepleted. This treatment of blood products before transfusion will decrease the amount of antibodies in the blood, an important factor in preventing GVHD should HSCT become necessary at a later date (Nixon, 2010).

## Reducing Pain

Children and teens with leukemia suffer pain related to the disease as well as the treatment. Chemotherapy drugs commonly used in leukemia may cause peripheral neuropathy and headache. Lumbar puncture and bone marrow aspiration, which are periodically performed throughout the course of treatment, also cause pain. The most common areas of pain are the head and neck, legs, and abdomen (probably from protracted vomiting with chemotherapy). Use distraction techniques, such as listening to music, watching TV, or playing games, to help take the child's mind off the pain. Administer mild analgesics such as acetaminophen for acute episodes of pain. Using EMLA cream prior to venipuncture, port access, lumbar puncture, and bone marrow aspiration may decrease procedure-related pain events. In addition, applying heat or cold to the painful area is usually acceptable. Administer narcotic analgesics, as prescribed, for episodes of acute severe pain or for palliation of chronic pain (Simon, 2010).

## Acute Myelogenous Leukemia

AML is the second most common type of leukemia in children (Zupanec & Tomlinson, 2010). Its incidence peaks during the adolescent years (Zupanec & Tomlinson, 2010). AML affects the myeloid cell progenitors or precursors in the bone marrow, resulting in **malignant** (invasive and fast-growing) cells. The French-American-British (FAB) classification system identifies eight subtypes of AML (M0 to M7), depending on myeloid lineage involved and the degree of cell differentiation. These subtypes are useful for determining treatment. The overall survival rate for childhood AML is 50% to 70% (Maloney et al., 2011). Complications include treatment resistance, infection, hemorrhage, and metastasis. The induction phase of AML requires intense bone marrow suppression and prolonged hospitalization because AML is less responsive to treatment than ALL. Toxicity from treatment is more common in AML and is

likely to be more serious than with ALL. Empiric broad-spectrum antibiotics and prophylactic platelet transfusions may be prescribed. After remission is achieved, children require intensive chemotherapy to prolong the duration of remission. HSCT is often required in children with AML, depending on the subtype (Zupanec & Tomlinson, 2010).

### Take Note!

At the time of diagnosis, some children with AML present with a WBC count above 100,000 (hyperleukocytosis); this results in venous stasis and backup of blast cells in small vessels, causing hypoxia, hemorrhage, and lung or brain infarction. Hyperleukocytosis is a medical emergency. These children require leukapheresis to decrease hyperviscosity by quickly decreasing the number of circulating blasts (Maloney et al., 2011).

## Nursing Assessment

Explore the health history for common signs and symptoms, including recurrent infections, fever, or fatigue. Explore the medical history for risk factors, such as Hispanic race, previous chemotherapy, and genetic abnormalities such as Down syndrome, Fanconi anemia, neurofibromatosis type I, Shwachman syndrome, Bloom syndrome, and familial monosomy 7.

Perform a thorough physical examination. Note skin pallor and salmon-colored or blue-gray papular lesions. Palpate the skin for subcutaneous rubbery nodules. Palpate for lymphadenopathy. Note headache, visual disturbance, or signs of increased intracranial pressure, such as vomiting, which may indicate CNS involvement. Upon diagnosis of AML, the child's WBC count is typically extremely elevated. Bone marrow aspiration will reveal greater than 20% blast cells (Zupanec & Tomlinson, 2010).

## Nursing Management

Nursing management of the child with AML is similar to that of the child with ALL. Nursing interventions focus on managing the adverse effects of treatment and preventing infection. Refer to the nursing process overview section and to Nursing Care Plan 50.1 for appropriate interventions.

## LYMPHOMAS

Lymphomas, or tumors of the lymph tissue (lymph nodes, thymus, spleen), account for about 10% to 15% of cases of childhood cancer (Maloney et al., 2011). Lymphomas may be divided into two categories—Hodgkin disease (or Hodgkin lymphoma) and non-Hodgkin lymphoma (NHL), which includes more than a dozen types. Hodgkin

disease tends to affect lymph nodes located closer to the body's surface, such as those in the cervical, axillary, and inguinal areas, whereas NHL tends to affect lymph nodes located more deeply inside the body.

## Hodgkin Disease

In Hodgkin disease, malignant B lymphocytes grow in the lymph tissue, usually starting in one general area of lymph nodes. The presence of Reed-Sternberg cells (giant transformed B lymphocytes with one or two nuclei) differentiates Hodgkin disease from other lymphomas. As the cells multiply, the lymph nodes enlarge, compressing nearby structures, destroying normal cells, and invading other tissues. The cause of Hodgkin disease is still being researched, but there appears to be a link to Epstein-Barr virus infection (Zupanec, 2010). Hodgkin disease is rare in children younger than 5 years of age and is most common in adolescents and young adults; in children 14 years and younger, it is more common in boys than girls (Zupanec, 2010).

In addition to the traditional **staging** (I through IV, depending on the amount of spread; Table 50.3), Hodgkin is also classified as A (asymptomatic) or B (presence of symptoms of fever, night sweats, or weight loss of 10% or more). Prognosis depends on the stage of the disease, tumor bulk, and A or B classification (disease classified as A generally carries a better prognosis). Overall, children with Hodgkin disease have a 75% 20-year survival rate (Maloney et al., 2011). Complications of Hodgkin disease include liver failure and

secondary cancer such as acute nonlymphocytic leukemia and NHL.

Chemotherapy, usually with a combination of drugs, is the treatment of choice for children with Hodgkin disease. Radiation therapy may also be necessary. In the child with disease that does not go into remission or in the child who experiences relapse, HSCT may be an option.

## Nursing Assessment

Explore the health history for common signs and symptoms, which may include recent weight loss, fever, drenching night sweats, anorexia, malaise, fatigue, or pruritus. Elicit the health history, determining risk factors such as prior Epstein-Barr virus infection, family history of Hodgkin disease, genetic immune disorder, or HIV infection.

Evaluate respiratory status, as the presence of a mediastinal mass may compromise respiration. Palpate for enlarged lymph nodes; they may feel rubbery and tend to occur in clusters (most common sites are cervical and supraclavicular) (Fig. 50.5). Palpate the abdomen for hepatomegaly or splenomegaly, which may be present with advanced disease. The chest radiograph may reveal a mediastinal mass. The complete blood count may be normal or reflect anemia. Tissue sampling will reveal Reed-Sternberg cells.

### Take Note!

Significant pain in the affected lymph nodes has sometimes been noted after alcohol ingestion (Zupanec, 2010).

**TABLE 50.3 STAGING OF HODGKIN DISEASE**

Stage	Clinical Findings
I	One group of lymph nodes is affected.
II	Two or more groups on the same side of the diaphragm are affected.
III	Groups of lymph nodes above and below the diaphragm are affected.
IV	Metastasis to organs such as the liver, bone, or lungs
A or B suffix	A—Absence of systemic symptoms at diagnosis B—Systemic symptoms present at diagnosis (fever, night sweats, weight loss)

Adapted from Zupanec, S. (2010). Lymphoma. In D. Tomlinson & N. E. Kline (Eds.), *Pediatric oncology nursing*. New York: Springer.

**FIGURE 50.5** Hodgkin lymphoma. Large, fixed cervical masses in a 14-year-old with weight loss. (Used with permission from Chung, E. K., Atkinson-McEvoy, L. R., Boom, J. A. & Matz, P. S. (2010). *Visual diagnosis and treatment in pediatrics* (2nd ed.). Philadelphia, PA: Lippincott Williams & Wilkins.)

## Nursing Management

Nursing management of the child with Hodgkin lymphoma focuses on addressing the adverse effects of chemotherapy or radiation. Refer to the nursing process overview section and Nursing Care Plan 50.1 to develop an individualized nursing care plan based on the child's response to treatment.

### Non-Hodgkin Lymphoma

NHL results from mutations in the B and T lymphocytes that lead to uncontrolled growth. NHL tends to affect lymph nodes located more deeply within the body. NHL spreads by the bloodstream and in children is a rapidly proliferating, aggressive malignancy that is very responsive to treatment. Prognosis depends on the cell type involved and the extent of the disease at diagnosis. Ninety percent of children with localized NHL have disease-free long-term survival after treatment (Maloney et al., 2011). Complications include metastasis and the development of a secondary malignancy later in life.

Remission is induced with chemotherapy and followed with a maintenance phase of chemotherapy lasting about 2 years. NHL tends to spread easily to the CNS, so CNS prophylaxis similar to that used in leukemia is warranted (Zupanec, 2010). Autologous bone marrow transplantation may be used in some children.

## Nursing Assessment

Children with NHL are usually symptomatic for only a few days or a few weeks before diagnosis because the disease progresses so quickly. Note onset and location of pain or lymph node swelling. Document history of abdominal pain, diarrhea, or constipation. Explore the health history for risk factors such as congenital or acquired immune deficiency.

Observe for increased work of breathing, facial edema, or venous engorgement (mediastinal mass). Palpate for the presence of lymphadenopathy and palpate the abdomen for the presence of a mass. Lymph node biopsy and bone marrow aspiration determine the diagnosis. Computed tomography (CT) scan, chest radiography, and bone marrow results may be used to determine the extent of metastasis.

#### Take Note!

Cough, dyspnea, orthopnea, facial edema, or venous engorgement may indicate mediastinal disease in the child with NHL. This is an emergency requiring rapid treatment (Maloney et al., 2011).

## Nursing Management

As with Hodgkin lymphoma, nursing management of NHL is directed toward managing the adverse effects of chemotherapy. Refer to the nursing process overview section and Nursing Care Plan 50.1 to plan nursing care for the child and family based on the responses they exhibit.

### BRAIN TUMORS

Brain tumors are the most common form of solid tumor and the second most common type of cancer in children (Maloney et al., 2011). Slightly more than half of brain tumors arise in the posterior fossa (infratentorial); the rest are supratentorial in origin. The cause of brain tumors in children is unknown. Some tumors are localized (low grade), while others are of higher grade and more invasive. The prognosis depends on the location of the tumor and extent of tumor. Low-grade tumors and those that are fully resectable have a better prognosis than tumors that are located deeper within the brain or are more invasive, making them difficult to resect (Kline & O'Hanlon-Curry, 2010). There are many different types of childhood brain tumors; Table 50.4 explains the most common ones.

Complications of brain tumors include hydrocephalus, increased intracranial pressure, brain stem herniation, and negative effects of radiation such as neuropsychological, intellectual, and endocrinologic sequelae (Kline & O'Hanlon-Curry, 2010; Maloney et al., 2011).

## Pathophysiology

Though the cause of brain tumors is generally not known, the effects of brain tumors are predictable. As the tumor grows within the cranium, it exerts pressure on the brain tissues surrounding it. The tumor mass may compress vital structures in the brain, block cerebrospinal fluid flow, or cause edema in the brain. The result is an increase in intracranial pressure. Presenting symptoms vary according to location and type of tumor.

## Therapeutic Management

The type of tumor may be identified at the time of surgery. The location of the tumor within the brain will determine the extent to which it can safely be resected. Children with hydrocephalus may require a ventriculoperitoneal shunt (see Chapter 38 for further information on hydrocephalus). Radiation is reserved for children older than age 2 years because it can have long-term

**TABLE 50.4** CHILDHOOD BRAIN TUMORS

Tumor	Location	Characteristics
Medulloblastoma (most common)	Cerebellum	Invasive, highly malignant, grows rapidly. Less favorable outcome with disseminated disease. Progresses quickly to increased intracranial pressure, seeds on CNS pathways. Half occur in children younger than 6 years old.
Brain stem glioma	Brain stem	Aggressive, difficult to resect, resistant to chemotherapy. Spreads widely within the brain stem but rarely extends outside of brain stem area. Affects cranial nerve function.
Ependymoma	Frequently arises from floor of fourth ventricle	Varying speed of growth. Often causes hydrocephalus. Usually diagnosed before it spreads to other parts of the brain or spinal cord.
Astrocytoma	Cerebellum, cerebral hemispheres, thalamus, hypothalamus	Slow course with insidious onset. Responsive to chemotherapy, often resectable. Causes slowly increasing intracranial pressure. Low-grade tumor may be removed completely. High-grade tumors have poor prognosis.

Adapted from Kline, N. E. (2008). *Essentials of pediatric oncology nursing: A core curriculum* (3rd ed.). Glenview, IL: Association of Pediatric Hematology/Oncology Nurses; and Maloney, K., Foreman, N. K., Giller, R. H., Greffe, B. S., Graham, D. K., Quinones, R. R., et al. (2011). Neoplastic disease. In W. W. Hay, M. J. Levin, J. M. Sondheimer, & R. R. Deterding (Eds.), *Current pediatric diagnosis and treatment* (20th ed.). New York, NY: McGraw-Hill.

neurocognitive effects (Maloney et al., 2011). Chemotherapy is being used increasingly in the treatment of pediatric brain tumors in an attempt to avoid the use of radiation therapy.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1823. Assessment findings pertinent to CNS tumors are discussed below.

### Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Nausea or vomiting
- Headache
- Unsteady gait
- Blurred or double vision
- Seizures
- Motor abnormality or hemiparesis
- Weakness, atrophy
- Swallowing difficulties
- Behavior or personality changes
- Irritability, failure to thrive, or developmental delay (in very young children)

Explore the child's current and past medical history for risk factors such as history of neurofibromatosis, tuberous sclerosis, or prior treatment for CNS leukemia.

## Physical Examination

### INSPECTION AND OBSERVATION

Observe for strabismus or nystagmus, "sunsetting" eyes, head tilt, alterations in coordination, gait disturbance, or alterations in sensation. Note alteration in gag reflex, cranial nerve palsy, lethargy, or irritability. Note the child's posture. Check pupillary reaction, noting size, equality, reaction to light, and accommodation.

### PALPATION

Measure blood pressure, which may decrease with increasing intracranial pressure. In the infant, palpate the anterior fontanel for bulging. Assess deep tendon reflexes, noting hyperreflexia.

#### Take Note!

A fixed and dilated pupil is a neurosurgical emergency.

## Laboratory and Diagnostic Tests

Common laboratory and diagnostic studies ordered for the assessment of CNS tumors include:

- CT, magnetic resonance imaging (MRI), or positron emission tomography (PET) will demonstrate evidence of the tumor and its location within the intracranial cavity.

- Lumbar puncture with cerebrospinal fluid cell evaluation may show tumor markers or the presence of  $\alpha$ -fetoprotein or human chorionic gonadotropin, which may assist in the diagnosis.

## Nursing Management

Nursing management of the child with a brain tumor includes preoperative and postoperative care, as well as interventions to manage adverse effects related to chemotherapy and radiation. Refer to the nursing process overview section for a discussion of nursing interventions related to chemotherapy adverse effects. Nursing Care Plan 50.1 provides additional interventions that may be individualized depending on the child's response to the brain tumor and its treatment.

### Providing Preoperative Care

Preoperatively, care focuses on monitoring for additional increases in intracranial pressure and avoiding activities that cause transient increases in intracranial pressure. Administer dexamethasone as prescribed to decrease intracranial inflammation. Prevent straining with bowel movements by use of a stool softener. Assess the child's pain level as well as level of consciousness, vital signs, and pupillary reaction to determine subtle changes as soon as possible. Provide a tour of the intensive care unit, which is where the child will wake up after the surgery. Instruct the child and family about the possibility of intubation and ventilation in the postoperative period. If a ventriculoperitoneal shunt will be placed for the treatment of hydrocephalus caused by the tumor, provide education about shunts to the child and family (see Chapter 38).

Shave the portion of the head as determined by the neurosurgeon. Some children may choose to have the entire head shaved. Sometimes children with long hair may feel better about losing it if they donate it to Locks of Love, an organization that provides hairpieces for financially disadvantaged children who have long-term medical hair loss. A link to this resource is provided on [thePoint](#).

### Providing Postoperative Care

Regulate fluid administration, as excess fluid intake may cause or worsen cerebral edema. Administer mannitol or hypertonic dextrose to decrease cerebral edema. Assess vital signs frequently, along with checking pupillary reactions and determining level of consciousness. Extreme lethargy or coma may be present for several days postoperatively. Increases in temperature may indicate infection or may be caused by cerebral edema or disturbance of the hypothalamus. Treat hyperthermia with antipyretics such as acetaminophen and with

sponge baths, as increases in temperature increase metabolic need. Reduce the temperature slowly.

Monitor for signs of increased intracranial pressure. Headache is common in the postoperative period. Assess pain level and provide analgesics as prescribed. Minimize environmental stimuli, providing a calm and quiet atmosphere. Check the head dressing for cerebrospinal fluid drainage or bleeding. Assess for and document the extent of head, face, or neck edema. Administer eye lubricant if edema prevents complete closure of the eyelids. Apply cool compresses to the eyes to decrease swelling.

As the child begins to regain consciousness, he or she may be confused or combative. Restrain the child if needed to keep him or her in bed and prevent dislodging of tubes and lines.

### Positioning the Child in the Postoperative Period

Position the child on the unaffected side with the head of the bed flat or at the level prescribed by the neurosurgeon. Side positioning is usually preferred, as the child may have difficulty handling oral secretions if the level of consciousness is decreased. Do not elevate the foot of the bed, as this may increase intracranial pressure and contribute to bleeding. When changing the child's position, maintain the head in alignment with the remainder of the body. Children with paralyzed or spastic extremities will need additional positioning support.

#### Take Note!

Observe preoperatively and postoperatively for signs of brain stem herniation such as opisthotonos (see Fig. 38.13 in Chapter 38), nuchal rigidity, head tilt, sluggish pupils, increased blood pressure with widening pulse pressure, change in respirations, bradycardia, irregular pulse, and changes in body temperature.

#### Consider This

Alice Tice, 6 years old, is scheduled to receive chemotherapy for a brain tumor. As the nurse caring for her, how can you prepare Alice for this? What nursing interventions are important when caring for a child receiving chemotherapy? (Discuss reducing pain, reducing risk of infection, promoting adequate nutrition, and managing nausea and vomiting.)

## NEUROBLASTOMA

Neuroblastoma, a tumor that arises from embryonic neural crest cells, is the most common extracranial solid tumor in children (Hendershot, 2010). It most frequently occurs

**TABLE 50.5** STAGING OF NEUROBLASTOMA

Stage	Clinical Findings
I	Tumor confined to organ or structure of origin
II	Tumor extends beyond organ or structure, not beyond midline (“A” negative lymph nodes, “B” regional nodes on same side involved).
III	Tumor invasively extends beyond the midline with bilateral lymph node involvement.
IV	Metastasis to bone, bone marrow, other organs, distant lymph nodes
IV-S	Tumor would have been considered a stage I or II, but remote metastasis to one or more sites (liver, skin, or bone marrow) has occurred without metastasis to the bone.

Adapted from Hendershot, E. (2010). Solid tumors. In D. Tomlinson & N. E. Kline (Eds.), *Pediatric oncology nursing*. New York: Springer; and Maloney, K., Foreman, N. K., Giller, R. H., Greffe, B. S., Graham, D. K., Quinones, R. R., et al. (2011). Neoplastic disease. In W. W. Hay, M. J. Levin, J. M. Sondheimer, & R. R. Deterding (Eds.), *Current pediatric diagnosis and treatment* (20th ed.). New York: McGraw-Hill.

in the abdomen, mainly in the adrenal gland, but it may occur anywhere along the paravertebral sympathetic chain in the chest or retroperitoneum (Hendershot, 2010). By the time of diagnosis, the neuroblastoma has usually already metastasized. Neuroblastoma is the second most frequently occurring solid tumor in children; 90% of cases are diagnosed before the age of 5 years (Maloney et al., 2011).

Staging of the tumor at diagnosis determines the course of treatment and prognosis. Table 50.5 discusses the staging of neuroblastomas. Survival rates range from about 40% to 90%, depending on the staging of the tumor (Hendershot, 2010). Prognosis depends on the tumor stage, age at diagnosis, location of tumor, and location of metastasis. Infants younger than 12 months of age and children with stage I disease have the best survival rates (Maloney et al., 2011). Children with tumors above the diaphragm tend to have a better prognosis than those with abdominal tumors. Metastasis to the bone is a worse prognostic factor than metastasis to the skin, liver, or bone marrow. Children who relapse after initial treatment also tend to have a dismal prognosis. In addition to metastasis, complications may include nerve compression, resulting in neurologic deficits.

The neuroblastoma must be removed surgically. Radiation and chemotherapy are administered to all children with neuroblastoma except those with stage I disease, in whom the tumor is completely resected.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1823. Assessment findings pertinent to neuroblastoma are discussed below.

### Health History

Presenting signs and symptoms of neuroblastoma depend on the location of the primary tumor and the extent of metastasis. Often parents are the first to notice a swollen or asymmetric abdomen. Elicit the health history, documenting bowel or bladder dysfunction, especially watery diarrhea, neurologic symptoms (brain metastasis), bone pain (bone metastasis), anorexia, vomiting, or weight loss.

### Physical Examination

Note neck or facial swelling, bruising above the eyes, or edema around the eyes (metastasis to skull bones). Inspect the skin for pallor or bruising (bone marrow metastasis) and document cough or difficulty breathing. Auscultate the lungs for wheezing. Palpate for lymphadenopathy, especially cervical. Palpate the abdomen, noting a firm, nontender mass. Palpate for and note hepatomegaly or splenomegaly if present.

### Laboratory and Diagnostic Testing

Laboratory and diagnostic testing may reveal the following:

- CT scan or MRI to determine site of tumor and evidence of metastasis
- Chest radiograph, bone scan, and skeletal survey to identify metastasis
- Bone marrow aspiration and biopsy to determine metastasis to the bone marrow
- 24-hour urine collection for homovanillic acid (HVA) and vanillylmandelic acid (VMA); levels will be elevated.

## Nursing Management

Postoperative nursing care depends on the site of tumor removal, which is most often the abdomen. Provide routine care after abdominal surgery. Refer to the nursing process overview section and Nursing Care Plan 50.1 for nursing care related to the effects of chemotherapy and radiation. Provide emotional support and possible referrals to help children and families cope with a potentially poor prognosis (due to the fact that the disease has often metastasized significantly by the time of diagnosis).

## Atraumatic Care

*The child with cancer often undergoes a large number of painful procedures related to laboratory specimens and treatment protocols. To assist the child to cope with these procedures, provide distraction in the form of reading a favorite book or playing a favorite movie or musical selection.*

## BONE AND SOFT TISSUE TUMORS

Bone and soft tissue tumors are common solid tumors in children. Bone tumors are most often diagnosed in adolescence, whereas soft tissue tumors tend to occur in younger children (Hendershot, 2010). This discussion will focus on the most common bone and soft tissue tumors occurring in childhood. The most common bone tumors in children are osteosarcoma and Ewing sarcoma (Hendershot, 2010). These bone tumors often initially go undiagnosed, as adolescents frequently seek care for traumatic events and the pain suffered with a bone tumor may initially be attributed to trauma. Rhabdomyosarcoma is the most common soft tissue tumor in childhood (Hendershot, 2010).

### Osteosarcoma

Osteosarcoma is the most common malignant bone cancer in children, occurring most frequently in adolescents at the peak of the growth spurt (Maloney et al., 2011). Osteosarcoma occurs slightly more often in males and Caucasians (Hendershot, 2010). It presumably arises from the embryonic mesenchymal tissue that forms the bones. The most common sites are in the long bones, particularly the proximal humerus, proximal tibia, and distal femur. Complications include metastasis, particularly to the lungs and other bones, and recurrence of disease within 3 years, primarily affecting the lungs.

Surgical removal of the tumor is necessary. Chemotherapy is often administered before surgery to decrease the size of the tumor; it is usually administered after surgery to treat or prevent metastasis. The type of surgery performed depends on the tumor size, extent of disease outside of the bone, distant metastasis, and skeletal maturity. Radical amputation may be performed, but often teens undergo a limb salvage procedure. Radical amputation may include the entire extremity or the entire affected bone. Limb-sparing surgery entails removing only the affected portion of the bone, replacing it with either an endoprosthesis or cadaver bone (Abed & Grimer, 2010).

### Nursing Assessment

Obtain the health history, ascertaining when pain, limp, or limitation of motion was first noticed. Dull bone pain

may be present for several months, eventually progressing to limp or gait changes.

Inspect the affected limb for erythema and swelling. Palpate the affected area for warmth and tenderness and to determine the size of the soft tissue mass, if also present. As with other pediatric cancers, a thorough physical examination is warranted to detect other abnormalities that may indicate metastasis.

Laboratory and diagnostic testing may include:

- CT scan or MRI to determine the extent of the lesion and to identify metastasis
- Bone scan to determine the extent of malignancy

## Nursing Management

The adolescent will generally be quite anxious about the possibility of amputation and even about the limb salvage procedure. Present preoperative teaching at the adolescent's developmental level and ensure that he or she is included in planning treatment. Regardless of the type of surgery performed, provide routine orthopedic postoperative care. Educate the adolescent and parents on the care of the stump, if amputation is necessary, and ensure that the teen becomes competent in crutch walking. A prosthesis may be ordered. The adolescent will need time to adjust to these significant body image changes and may benefit from talking with another teen who has undergone a similar procedure. Support the teen in choosing clothing that may camouflage the prosthesis while still allowing the teen to appear fashionable. Provide emotional support, as the teen's maturity level allows him or her to understand the severity of the disease. Peer support groups are often helpful, as teens value their peers' opinions and enjoy being part of a group. Examples of comprehensive online support groups are Melissa's Living Legacy Foundation/Helping Teens Live with Cancer and The Wellness Community. Links to these resources are provided on [thePoint](#).

### Ewing Sarcoma

Ewing sarcoma is a highly malignant bone tumor. It is rarer than osteosarcoma, accounting for only about 10% of childhood bone tumors (Maloney et al., 2011). It occurs most frequently in the pelvis, chest wall, vertebrae, and long bone diaphyses (midshaft). About 25% of children demonstrate metastasis; the lungs, bone, and bone marrow are the most common sites (Maloney et al., 2011). The prognosis for Ewing sarcoma depends on the extent of metastasis.

Radiation, chemotherapy, and surgical excision are usually used in combination. Treatment varies depending on the site of the primary tumor and the extent of metastasis at diagnosis. Myeloablative chemotherapy (which destroys the child's marrow) may be used for metastatic disease, followed by a stem cell rescue transplant.

## Nursing Assessment

Explore the history for intermittent pain that progressively worsens. Note a possible history of fever. Eventually the pain becomes constant and severe, sometimes interrupting sleep.

Note the presence of swelling or erythema at the tumor site. CT scan or MRI of the affected area will reveal the extent of the tumor. Biopsy is necessary to establish the diagnosis. CT scan of the chest, bone scan, and bilateral bone marrow aspiration with biopsy determine the extent of metastasis.

## Nursing Management

Before treatment begins, discourage active play or weight bearing on the affected extremity to avoid pathologic fracture at the tumor site. Nursing management focuses on addressing the adverse effects of treatment (refer to the nursing process overview section). Give honest and direct answers to teens with Ewing sarcoma who ask questions about their disease. These children will undergo intensive therapy and spend a great deal of time in the hospital. Depending on the age of the child, fantasy play, art or pet therapy, drama, writing, humor, and/or music may help the child to work through the psychological impact of this disease. Refer to Nursing Care Plan 50.1 for additional interventions, which should be individualized depending on the child's and family's response to the disease process and treatment.

### Thinking About Development

Serena Jameson is a 14-year-old cheerleader with newly diagnosed Ewing sarcoma. Her prescribed treatment protocol involves several medications known to cause severe alopecia. Considering Serena's developmental stage, how will this impact her ability and/or willingness to participate in future cheerleading exhibitions? Develop a list of ideas for assisting Serena to cope with the anticipated changes to her body image.

## Rhabdomyosarcoma

Rhabdomyosarcoma is a soft tissue tumor that usually arises from the embryonic mesenchymal cells that would ordinarily form striated muscle. The most common locations for the tumor are the head and neck, genitourinary tract, and extremities (Fig. 50.6). The tumor is highly malignant and spreads via local extension or through the venous or lymphatic system, with the lung being the most common site for metastasis. Diagnosis is usually made between 2 and 5 years of age, with 70% of all

FIGURE 50.6 The most common sites of rhabdomyosarcoma.

rhabdomyosarcomas diagnosed by age 10 years (Maloney et al., 2011). The prognosis is based on the stage of the disease at diagnosis. Box 50.3 explains the staging of rhabdomyosarcoma. Prognosis is generally favorable for stage I disease, but 3-year survival occurs in only 39% of children with metastatic disease (Maloney et al., 2011). Complications of rhabdomyosarcoma include metastasis to lung, bone, or bone marrow and direct extension into the CNS, resulting in brain stem compromise or cranial nerve palsy.

Surgical removal of the primary tumor is generally performed. At the time of the surgery, the lesion is biopsied and the stage of disease determined. Depending on the site (especially head, neck, and pelvis) and size of the tumor, radiation and chemotherapy may be used to shrink the tumor to avoid disability.

## Nursing Assessment

The child or parent will often discover an asymptomatic mass and seek medical attention at that time. Obtain a

## BOX 50.3

**STAGING OF RHABDOMYOSARCOMA**

- Stage I: completely resectable localized tumor
- Stage II: after local tumor resection, microscopic residual disease remains
- Stage III: after local tumor resection, gross residual disease remains
- Stage IV: metastasis present at diagnosis

Adapted from Hendershot, E. (2010). Solid tumors. In D. Tomlinson & N. E. Kline (Eds.), *Pediatric oncology nursing*. New York, NY: Springer.

**Take Note!**

Primary tumors arising in the neck region may compress the child's airway. Assess work of breathing and lung sounds.

**Nursing Management**

Provide routine postoperative care, depending on the site of surgery. Assess for adverse effects of high-dose radiation, which is generally used to treat the primary tumor as well as metastatic sites. Administer chemotherapy as ordered and assess for adverse effects. Refer to the nursing process overview section and Nursing Care Plan 50.1 to determine an individualized plan of care based on the child's response to the treatment.

health history, noting recent illness, when the mass was discovered, and whether it has changed since first noted. Examine the history for risk factors such as parental smoking, exposure to environmental chemicals, family history of cancer, or neurofibromatosis. Note respiratory effort and cough, and auscultate the lungs for adventitious sounds. Palpate for lymphadenopathy. Palpate the abdomen for a mass or hepatosplenomegaly. Abnormalities found on physical examination depend on the location of the rhabdomyosarcoma (Table 50.6).

Laboratory and diagnostic testing may include:

- CT scan or MRI of primary lesion and the chest for metastasis
- Open biopsy of the primary tumor for definitive diagnosis
- Bone marrow aspiration and biopsy, bone scan, and skeletal survey to determine metastasis

**WILMS TUMOR**

Wilms tumor is the most common renal tumor and the fourth most common solid tumor in children (Hendershot, 2010). Peak incidence occurs between the ages of 2 and 3 years (Hendershot, 2010). It usually affects only one kidney (Fig. 50.7). The etiology is unknown, but some cases occur via genetic inheritance. Associated anomalies may occur with Wilms tumor. Wilms tumor demonstrates rapid growth and is usually large at diagnosis. Metastasis occurs via direct extension or through the bloodstream. Wilms tumor most commonly metastasizes to the perirenal tissues, liver, diaphragm, lungs, abdominal muscles, and lymph nodes. The prognosis depends on staging at diagnosis and the extent of metastasis (Box 50.4).

TABLE 50.6

**PRESENTING SIGNS AND SYMPTOMS RELATED TO LOCATION OF RHABDOMYOSARCOMA**

Location of Tumor	Presenting Signs and Symptoms
Orbit	Proptosis
Middle ear	Drainage, pain, facial nerve palsy
Sinuses	Discharge, pain, sinusitis, facial swelling
Nasopharynx	Pain, epistaxis, dysphagia, nasal quality to speech, airway obstruction
Neck	Dysphagia, hoarseness
Thorax, testicle, extremities	Enlarging mass, painless
Retroperitoneum	Gastrointestinal and urinary tract obstruction, pain, weakness, paresthesia
Bladder, prostate	Hematuria, urinary obstruction
Vagina	Mass, vaginal bleeding or chronic discharge

Adapted from Hendershot, E. (2010). Solid tumors. In D. Tomlinson & N. E. Kline (Eds.), *Pediatric oncology nursing*. New York, NY: Springer; and Maloney, K., Foreman, N. K., Giller, R. H., Greffe, B. S., Graham, D. K., Quinones, R. R., et al. (2011). Neoplastic disease. In W. W. Hay, M. J. Levin, J. M. Sondheimer, & R. R. Deterding (Eds.), *Current pediatric diagnosis and treatment* (20th ed.). New York, NY: McGraw-Hill.

FIGURE 50.7 Wilms tumor is usually unilateral.

The overall survival rate is about 90% (Hendershot, 2010). Complications include metastasis or complications from radiation therapy such as liver or renal damage, female sterility, bowel obstruction, pneumonia, or scoliosis.

## Therapeutic Management

Surgical removal of the tumor and affected kidney (nephrectomy) is the treatment of choice and also allows for accurate staging and assessment of tumor spread. Radiation or chemotherapy may be administered either before or after surgery.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1823. Assessment findings pertinent to Wilms tumor are discussed below.

### Health History

Parents typically initially observe the abdominal mass associated with Wilms tumor and then seek medical

### BOX 50.4

#### STAGING OF WILMS TUMOR

- Stage I: unilateral, limited to kidney, completely resectable
- Stage II: unilateral, tumor extends beyond kidney but is completely resectable
- Stage III: unilateral, tumor has spread outside of kidney, located in abdominal cavity only, not fully removed
- Stage IV: unilateral with metastasis in liver, lung, bone, or brain
- Stage V: bilateral kidney involvement

Adapted from Hendershot, E. (2010). Solid tumors. In D. Tomlinson & N. E. Kline (Eds.), *Pediatric oncology nursing*. New York, NY: Springer.

attention. Elicit the health history, noting when the mass was discovered. Note abdominal pain, which may be related to rapid tumor growth. Document history of constipation, vomiting, anorexia, weight loss, or difficulty breathing. Determine risk factors such as hemihypertrophy of the spine, Beckwith-Wiedemann syndrome, genitourinary anomalies, absence of the iris, or family history of cancer.

### Physical Examination

Measure blood pressure; hypertension occurs in 25% of children with Wilms tumor (Maloney et al., 2011). Inspect the abdomen for asymmetry or a visible mass. Observe for associated anomalies as noted above. Auscultate the lungs for adventitious breath sounds associated with tumor metastasis. Palpate for lymphadenopathy.

#### Take Note!

Avoid palpating the abdomen after the initial assessment preoperatively. Wilms tumor is highly vascular and soft, so excessive handling of the tumor may result in tumor seeding and metastasis.

### Laboratory and Diagnostic Testing

Laboratory and diagnostic testing may include:

- Renal or abdominal ultrasound to assess the tumor and the contralateral kidney
- CT scan or MRI of the abdomen and chest to determine local spread to lymph nodes or adjacent organs, as well as any distant metastasis
- Complete blood count, BUN, and creatinine: usually within normal limits
- Urinalysis: may reveal hematuria or leukocytes
- 24-hour urine collection for HVA and VMA to distinguish the tumor from neuroblastoma (levels will not be elevated with Wilms tumor)

## Nursing Management

Postoperative care of the child with Wilms tumor resection is similar to that of children undergoing other abdominal surgery. Assessment of remaining kidney function is critical. The child may have adverse effects related to chemotherapy or radiation. Refer to the nursing process overview section and Nursing Care Plan 50.1 to individualize care for the child based on the child's response to therapy.

### Take Note!

To avoid injuring the remaining kidney, children with a single kidney should not play contact sports.

## RETINOBLASTOMA

Retinoblastoma is a congenital, highly malignant tumor that arises from embryonic retinal cells. It accounts for 5% of cases of blindness in children (Maloney et al., 2011). Most children are diagnosed by age 3, and the overall survival rate is 90% (Maloney et al., 2011). Retinoblastoma may be hereditary or nonhereditary. Nonhereditary retinoblastoma may be associated with advanced paternal age and always presents with unilateral involvement. Hereditary retinoblastoma is inherited via the autosomal dominant mode. These cases may be unilateral or bilateral. The tumor may grow forward into the vitreous cavity of the eye or extend into the subretinal space, causing retinal detachment. The tumor may extend into the choroid, the sclera, and the optic nerve.

Complications include spread to the brain and the opposite eye, as well as metastasis to lymph nodes, bone, bone marrow, and liver. Secondary tumors, most often sarcomas, may also occur in children who have been treated for retinoblastoma. Table 50.7 explains the staging of retinoblastoma.

The goals of treatment are to eradicate the tumor, preserve vision, and provide a good cosmetic outcome. Retinoblastoma may be treated with radiation, chemotherapy, laser surgery, cryotherapy, or a combination of these treatments. Moderate vision may be preserved for most children without advanced disease. In advanced disease or in the case of a massive tumor with retinal detachment, enucleation (removal of the eye) is necessary.

## Nursing Assessment

Parents are often the first to notice the “cat’s eye reflex” or “whitewash glow” to the child’s affected pupil. Obtain the health history, determining when other associated symptoms such as strabismus, orbital inflammation, vomiting, or headache began. Inquire about risk factors

**TABLE 50.7** STAGING OF RETINOBLASTOMA

Stage	Clinical Findings
A	Small tumors (<3 mm; about 0.1 inch) confined to the retina
B	Larger tumors confined to the retina
C	Localized seeding of the vitreous or under the retina <6 mm (0.2 inches) from the original tumor
D	Widespread vitreous or subretinal seeding, may have total retinal detachment
E	No visual potential, eye cannot recover

Adapted from Shields, C. L. (2008). Forget-me-nots in the care of children with retinoblastoma. *Seminars in Ophthalmology*, 23(5), 324–334.

such as a family history of retinoblastoma or other cancer, or the presence of chromosomal anomalies. Assess pupils for size and reactivity to light. Note presence of leukocoria (“cat’s eye reflex,” a whitish appearance of the pupil) in the affected eye (Fig. 50.8). Assess the eyes for associated signs, which may include erythema, orbital inflammation, or hyphema.

Diagnostic evaluation includes an ophthalmologic examination under anesthesia. CT, MRI, or ultrasound of the head and eyes will help to visualize the tumor. The infant or toddler may also undergo lumbar puncture and bone marrow aspiration to determine the presence and extent of metastasis.

**FIGURE 50.8** Note the whitish appearance of this child’s pupil (leukocoria). (Used with permission from Rubin, E. & Farber, J. L. (1999) *Pathology* (3rd ed.). Philadelphia, PA: Lippincott Williams & Wilkins.)

## Nursing Management

Provide routine postoperative care to the infant or toddler. If the eye is enucleated, observe the large pressure dressing on the eye socket for bleeding. Dressing changes to the socket may include sterile saline rinses and/or antibiotic ointment application. If disease occurs outside of the eye or if metastasis is present, inform the parents that chemotherapy will be necessary. Monitor for side effects of chemotherapy (see the nursing process overview section). Follow-up will include eye examinations every 3 to 6 months until age 6 and then annually to check for further tumor development. If the eye is enucleated, a prosthetic eye will be fitted several weeks after removal. Teach families use of the prosthetic eye; it does not require daily removal.

Provide parents with support and encouragement. Refer the family for genetic counseling. Any subsequent children will require ophthalmologic examination every 1 to 3 weeks until 1 year of age, with close follow-up until age 3 years (Canty, 2009). Children treated for retinoblastoma will also need genetic counseling as they reach puberty because of the risk of bilateral disease in their offspring (Canty, 2009).

### Take Note!

Educate parents about protecting vision in the remaining eye: routine eye check-ups, protection from accidental injury, use of safety goggles during sports, and prompt treatment of eye infections. Generally, children with one eye should not participate in contact sports.

## SCREENING FOR REPRODUCTIVE CANCERS IN ADOLESCENTS

Increasingly, reproductive cancers are being diagnosed in adolescents. Cervical cancer and testicular cancer may be discovered early with appropriate screening, and earlier discovery leads to better outcomes. Starting screening in the teenage years may also instill a lifelong healthy habit in the adolescent.

### Cervical Cancer

Risk factors for cervical cancer include young age at first intercourse, infection with a sexually transmitted disease, and a history of multiple sex partners. More and more teenagers are presenting with these risk factors. Cervical cancer is most commonly attributed to human papillomavirus (HPV) (American Academy of Pediatrics [AAP], 2012). HPV vaccine (Gardasil) is recommended to be given as a three-vaccine series to all girls beginning at age 11 to 12 years (AAP, 2012). Despite the availability of the vaccine, not all girls will receive it. Counsel all sexually

active adolescents to seek reproductive care, which is available without parental consent in most states. The screening Papanicolaou (Pap) smear is efficient and reliable at determining abnormal cervical cells and is a key part of screening for cervical cancer (if cancer is present, the parent will have to be notified). Cervical cancer has a very high response to therapy and rate of cure if treated in its early stages. Therefore, encourage teenage girls to be responsible for their sexual health by seeking appropriate examination and screening.

### HEALTHY PEOPLE 2020

#### Objective

Increase the proportion of women who receive a cervical cancer screening based on the most recent guidelines.

#### Nursing Significance

- When an adolescent girl makes the decision to become sexually active, counsel her about the importance of getting annual Pap smears, which should begin within 3 years of becoming sexually active.

*Healthy People* Objectives based on data from <http://www.healthypeople.gov>.

### Testicular Cancer

Although uncommon in teens, testicular cancer is the most frequently diagnosed cancer in males between 15 and 34 years of age (National Cancer Institute, 2012). It is one of the most curable cancers if diagnosed early. To get into the habit of screening for testicular lumps, encourage adolescent boys to begin performing testicular self-examinations monthly (Teaching Guidelines 50.3).

### HEALTHY PEOPLE 2020

#### Objective

Reduce the overall cancer death rate. Increase the proportion of cancer survivors who are living 5 years or longer after diagnosis.

#### Nursing Significance

- Teach adolescent boys testicular self-examination.
- Reinforce the importance of this self-screening measure at subsequent visits.

*Healthy People* Objectives based on data from <http://www.healthypeople.gov>.

### Teaching Guidelines 50.3

#### TESTICULAR SELF-EXAMINATION

- Perform the examination once a month, after a shower.
- Be familiar with the size and weight of your testicles.
- Roll the testicle between your fingers. The small rope-like structure is the epididymis; this is normal.
- Report any lump, swelling, or heaviness of one testicle to your physician or nurse practitioner.

Adapted from Figueroa, T. E. (2012). How to perform a testicular self-examination. Retrieved [http://kidshealth.org/teen/sexual\\_health/guys/tse.html](http://kidshealth.org/teen/sexual_health/guys/tse.html)

#### KEY CONCEPTS

- Childhood cancer tends to develop from embryonal tissue; in general, it is more responsive to therapy than adult cancers, which tend to be derived from epithelial tissue.
- In adults, cancer is influenced to a large extent by environmental factors. Cancer in children is most often not attributed to environmental factors, so generally there are no routine screening measures or prevention strategies for childhood cancer.
- The pain associated with lumbar puncture or bone marrow aspiration may be minimized with the use of topical anesthetics or conscious sedation.
- CT scans and MRI are used extensively in the diagnosis and follow-up of childhood cancer. The young child may have difficulty holding still for these scans and may need short-term sedation.
- Leukemia often presents in children with a history of fever, infection, and fatigue. Bone pain or CNS symptoms may be present if metastasis to the bone or brain has occurred.
- Lymphomas in children present similarly to those in adults, often with an enlarged, nontender lymph node.
- Symptoms of brain tumors depend on the location of the tumor; commonly they present with signs and symptoms of increased intracranial pressure, such as headache, nausea, and vomiting.
- Neuroblastoma has often significantly metastasized at diagnosis. It most commonly presents as a mass in the abdomen.
- Shortness of breath or chest pain in the child with cancer is a medical emergency; it may indicate superior vena cava syndrome or a tumor in the mediastinal region.
- Retinoblastoma may be identified by the presence of leukocoria in one or both eyes. Retinoblastoma occurs in early infancy up until early childhood.
- Bone cancer does not necessarily require amputation; it may be treated with a combination of limb salvage procedure, radiation, and chemotherapy.
- The symptoms of rhabdomyosarcoma depend on the location of the tumor.
- Avoid abdominal palpation preoperatively in the child with Wilms tumor; palpation may cause seeding of the tumor and metastasis.
- Radiation therapy may result in fatigue, nausea and vomiting, and long-term cognitive sequelae (if directed to the cranium).
- Nursing care of the child receiving treatment for cancer focuses on preventing or treating adverse effects such as fatigue, nausea, vomiting, alopecia, mucositis, and infection.
- The neutropenic child with fever should receive medical attention as soon as possible so that intravenous antibiotics may be started immediately.
- Cancer is a significant stressor for children and families. Families need support and education throughout the diagnostic process, treatment and cure, or palliative care.
- The child with cancer should lead as near normal a life as possible. When physically able and cleared by the oncologist, the child should resume usual activities such as school. Camps for children with cancer provide an excellent opportunity for children to enjoy everyday activities and meet children experiencing similar alterations in their lives.
- Nutrition may be optimized for children with cancer by managing nausea and vomiting with antiemetics, providing favorite foods, and possibly using total parenteral nutrition.
- Teach adolescents appropriate screening techniques for reproductive cancers.

- Educate the child and family about the adverse effects of cancer treatments.
- Teach parents how to avoid infection in the child receiving chemotherapy, the signs and symptoms of infection, and when to seek medical treatment.

## MULTIPLE CHOICE QUESTIONS

- A 5-year-old has been diagnosed with Wilms tumor. What is the priority nursing intervention for this child?
  - Educate the parents about dialysis, as the kidney will be removed.
  - Measure abdominal girth every shift.
  - Avoid palpating the child's abdomen.
  - Monitor BUN and creatinine every 4 hours.
- A child with leukemia has the following a.m. laboratory results: Hgb 8.0, Hct 24.2, WBC 8,000, platelets 150,000. What is the priority nursing assessment?
  - Monitor for fever.
  - Assess for bruising or bleeding.
  - Determine intake and output.
  - Assess for pallor, fatigue, and tachycardia.
- A child with leukemia received chemotherapy about 10 days ago. She presents today with a temperature of 100.4°F, an absolute neutrophil count of 500, and mild bleeding of the gums. What is the priority nursing intervention?
  - Administer IV antibiotics as ordered.
  - Provide vigorous oral care frequently with a firm toothbrush.
  - Monitor pulse and blood pressure for changes.
  - Administer packed red blood cell transfusion.
- A child with cancer is receiving chemotherapy, and his mother is concerned that the nausea and vomiting associated with chemotherapy are reducing his ability to eat and gain weight appropriately. What is the most appropriate nursing action?
  - Administer an antiemetic at the first hint of nausea.
  - Offer the child's favorite foods to encourage him to eat.
  - Start antiemetic drugs prior to the chemotherapy infusion.
  - Maintain IV fluid infusion to avoid dehydration.
- A 17-year-old girl has recently been diagnosed with osteosarcoma. She is worried about how treatment will affect her plans for college, marriage, and children. How will you respond to her concerns?
- A 3-year-old is going to be starting chemotherapy for rhabdomyosarcoma. Develop an age-appropriate teaching plan for this child.
- Develop a nursing care plan for an adolescent with cancer who is undergoing radiation and chemotherapy and experiencing a significant number of adverse effects from his treatment.

## STUDY ACTIVITIES

- While in the clinical area, care for a young child who has undergone therapy for a brain tumor. Compare this child's growth and development to those of a healthy similar-age child who you know or have cared for.
- During your clinical rotation, care for a child who has received several chemotherapy treatments. After establishing a therapeutic relationship, talk with the child about his or her understanding of the disease and the experience the child has had with diagnosis and treatment thus far. If time allows, ask the child to draw a picture describing this experience. Record your observations in your clinical journal and reflect on the emotions you feel about this experience.
- Attend the pediatric oncology clinic. Determine the role of the advanced practice nurse (nurse practitioner or clinical nurse specialist) compared to the role of the registered nurse in the outpatient care of children with cancer. Determine which activities the nurse appropriately delegates to unlicensed assistive personnel in that setting.
- Talk to the hospital chaplain about his or her experiences with dying children. Reflect on this conversation in your clinical journal.

## CRITICAL THINKING EXERCISES

- Develop a discharge teaching plan for a child who has just completed the induction phase of chemotherapy for acute lymphocytic leukemia.

# Nursing Care of the Child With a Genetic Disorder

## Learning Objectives

*Upon completion of the chapter, the learner will be able to:*

1. Define the key terms used in this chapter.
2. Discuss the nurse's role and responsibilities when caring for a child diagnosed with a genetic disorder and his or her family.
3. Identify nursing interventions related to common laboratory and diagnostic tests used in the diagnosis and management of genetic conditions.
4. Distinguish various genetic disorders occurring in childhood.
5. Devise an individualized nursing care plan for the child with a genetic disorder.
6. Develop child/family teaching plans for the child with a genetic disorder.

*Julie Woods, a 5-year-old, is brought to the clinic for her annual examination. Her mother states, "She's so much smaller than all of the other kindergartners."*

### **Words of Wisdom**

Nursing includes care for the helpless and brave child victim of heredity.

**Genetics** is the study of heredity—its transmission and its variation. A genetic disorder is a disease caused by an abnormality in an individual's genetic material or genome. Some genetic disorders occur in multiple family members (via inheritance of abnormal genes). Other disorders may occur in only a single family member (via spontaneous mutation).

A genetic disorder is caused by completely or partially altered genetic material. In contrast, a familial disorder is more common in relatives of the affected individual but may be caused by environmental influences, not genetic alterations.

Many chronic disorders of childhood have a genetic or inherited cause. Common disorders suspected to be caused or influenced by genetic factors include birth defects, chromosomal abnormalities, neurocutaneous disorders, intellectual disability, many types of short stature disorders, connective tissue disorders, and inborn errors of metabolism. Genetic disorders can present at any age but the most serious disorders are present in childhood (Scott & Lee, 2011).

Our ability to diagnose genetic conditions is far superior to our ability to cure or treat them. However, accurate diagnosis does lead to improved treatment and outcomes. Nurses should have a basic knowledge of genetics, common genetic disorders in children, genetic testing, and genetic counseling so that they can provide support and information to families and can promote an improved quality of life.

Refer to chapter 10 for information on advances in genetics, inheritance, and genetic counseling and evaluation.

## NURSE'S ROLE AND RESPONSIBILITIES

Pediatric nurses will encounter children with genetic disorders in every clinical specialty area. This includes clinics, hospitals, schools, and community-based centers. Talking with families who have recently been diagnosed with a genetic disorder or who have had a child born with congenital anomalies is very difficult. Many times the nurse is the one who has first contact with these parents and will be the one to provide follow-up care. Genetic disorders are significant, life-changing, and possibly life-threatening situations. The information is highly technical and the field is still evolving. Therefore, it is important to refer the family to a physician or nurse practitioner who specializes in genetics. The nurse should understand who will benefit from genetic counseling and should be able to discuss the role of the genetic counselor with families. Inform families at risk that genetic counseling is available before they attempt to have another baby.

The nurse is in an ideal position to help families review what has been discussed during the genetic

counseling sessions and to answer any additional questions they might have. Nurses play an essential role in providing emotional support to the family throughout this challenging time. Nurses should also refer the family to appropriate agencies, support groups, and resources, such as a social worker, a chaplain, or an ethicist.

## COMMON MEDICAL TREATMENTS

A variety of medications and other medical treatments are used to treat the symptoms of genetic disorders in children. Genetic disorders do not have specific treatments and there is no cure, so treatment focuses on the specific symptoms of each disorder. Genetic disorders often involve multiple organ systems and children with these disorders have complex medical needs. Thus, a multidisciplinary approach and good communication are imperative. See below for a discussion on common genetic disorders and their management.

## NURSING PROCESS OVERVIEW FOR THE CHILD WITH A GENETIC DISORDER

Care of the child with a genetic disorder includes assessment, nursing diagnosis, planning, interventions, and evaluation. There are a number of general concepts related to the nursing process that may be applied to the care of children with genetic disorders. From a general understanding of the care involved for a child with a genetic disorder, the nurse can then individualize the care based on specifics for the particular child.

### Assessment

Assessment of the child with a genetic disorder includes health history, physical examination, and laboratory and diagnostic testing.

**Remember Julie, the 5-year-old brought in for her annual examination? What additional health history and physical examination information should you obtain?**

### Health History

The health history consists of past medical history, including the mother's pregnancy history; family history; neonatal history; and history of present illness (when the symptoms started and how they have progressed), as well as treatments used at home. Explore the child's current and past medical history for risk factors such as:

- Family history of genetic disorders
- Any complications during the prenatal, perinatal, or postnatal periods
- Changes in developmental status or delays in developmental milestones

The pregnancy history can be extremely relevant when identifying a genetic disorder. The pregnancy history may be significant for maternal age older than 35 years or paternal age older than 50 years, repeated premature births, breech delivery, congenital hip dysplasia, abnormalities found on ultrasound, abnormalities in prenatal blood screening tests (e.g., triple/quadruple screen,  $\alpha$ -fetoprotein), amniotic fluid abnormalities (polyhydramnios, oligohydramnios), multiple births, exposure to medications and known teratogens, and decreased fetal movement.

A focused neonatal history can also help identify a genetic problem. The neonatal history may be significant for symmetric intrauterine growth restriction, large for gestational age without a reason, hearing impaired, persistent hyperbilirubinemia, poor adaptation to the extrauterine environment (demonstrated by temperature and heart rate instability and poor feeding), hypotonia or hypertonia, seizures, and abnormal newborn screening results.

The family history plays a critical role in identifying genetic disorders. Gather data for three generations. If there is a positive family history, the likelihood of a genetic disorder in the child is increased. It is helpful to create a family pedigree (refer to the genetic counseling section in Chapter 10). The family history may be significant for major congenital anomalies, intellectual disability, genetic diseases, metabolic disorders, multiple miscarriages or stillbirths, developmental delays, significant learning disabilities, psychiatric problems, consanguinity, and chronic serious illness (e.g., diabetes, hypertension, renal disease, hearing impairment, blindness, asthma, seizures, and unexplained death).

When eliciting the history of the present illness, inquire about:

- Developmental delay
- Seizures
- Hypotonia or hypertonia
- Feeding problems
- Lethargy
- Failure to thrive
- Septic appearance
- Vomiting

Children known to have a genetic disorder are often admitted to the hospital for other health-related issues or complications and management of the genetic disorder. The health history should include questions related to:

- Age when the disorder was diagnosed
- Developmental delay

- Complications of the disorder (e.g., thyroid problems, cardiac problems, respiratory problems, leukemia, seizures, cognitive impairment)
- Medications the child takes for complications associated with the disorder
- Dietary restrictions
- Compliance with management regimen

Once complications have been identified, further investigation into their severity, frequency, and management is essential to the care of this child while in the hospital.

## Physical Examination

Physical examination of the child with a genetic disorder includes inspection and observation, palpation, and auscultation.

### INSPECTION AND OBSERVATION

Inspect and observe for congenital anomalies, either major or minor. A major anomaly is an anomaly or malformation that creates significant medical problems and requires surgical or medical management (Stevenson, 2006; Wynshaw-Boris & Biesecker, 2011) (Box 51.1). Minor anomalies are features that vary from those seen in the general population but do not cause an increase in morbidity in and of themselves (Stevenson, 2006; Wynshaw-Boris & Biesecker, 2011) (Box 51.2).

#### Take Note!

Low-set ears are a minor anomaly that is associated with numerous genetic dysmorphisms. If noted, assess thoroughly for other abnormalities.

### BOX 51.1

#### EXAMPLES OF MAJOR CONGENITAL ANOMALIES

- Cleft lip
- Cleft palate
- Congenital heart disease, structural and conduction disorders
- Neural tube defects, such as myelomeningocele
- Chromosomal abnormalities
- Omphalocele
- Renal agenesis/hypoplasia
- Limb reduction defects
- Generalized dysmorphism
- Specific skin lesions, such as café-au-lait macules, hypopigmented macules, or cutaneous hemangiomas

Adapted from Stevenson, R. E. (2006). Human malformations and related anomalies. In R. E. Stevenson & J. G. Hall (Eds.), *Human malformations and related anomalies* (2nd ed., pp. 4–5). New York: Oxford University Press, Inc.

## BOX 51.2

**EXAMPLES OF MINOR CONGENITAL ANOMALIES**

- Flat occiput
- Prominent occiput
- Triple hair whorl
- Flat-bridged nose
- Nostrils anteverted
- Ear lobe crease
- Ear lobe notched
- Cup-shaped ears
- Cleft uvula
- Webbed neck
- Extra nipples
- Single umbilical artery
- Umbilical hernia
- Tapered fingers
- Overlapping digits
- Broad thumb or great toe
- Increased space between toes
- Syndactyly

Adapted from Stevenson, R. E. (2006). Human malformations and related anomalies. In R. E. Stevenson & J. G. Hall (Eds.), *Human malformations and related anomalies* (2nd ed., p. 8). New York: Oxford University Press, Inc.

As the number of minor anomalies present increases, the probability of the presence of a major anomaly increases. In fact, when three or more minor anomalies are present, the risk for a major anomaly or intellectual disability is approximately 20% (Marino & Claybon, 2008). Assess for a recognized pattern of anomalies that may be associated with certain syndromes.

**Take Note!**

Cleft lip and cleft palate are associated with many syndromes. If noted, assess for other anomalies.

Inspect and observe for an abnormal or foul odor of the child's excretions. Certain metabolic disorders or inborn errors of metabolism are associated with specific odors (Table 51.1).

**AUSCULTATION**

Physical examination includes auscultation of the heart. Murmurs or dysrhythmias may have a genetic cause. In a child with a congenital heart problem (e.g., ventricular septal defect) and a strong family history of cardiac structural problems, a genetic cause needs to be considered.

TABLE 51.1

**INBORN ERRORS OF METABOLISM AND ASSOCIATED ODOR**

Inborn Error of Metabolism	Associated Odor
Phenylketonuria	Mousy or musty
Maple syrup urine disease	Maple syrup, burnt sugar, or curry
Tyrosinemia	Cabbage-like, rancid butter
Trimethylaminuria	Rotting fish

Adapted from Rezvani, I. & Rezvani, G. (2011). Chapter 78: An Approach to Inborn Errors of Metabolism. In R. M. Kliegman, B. F. Stanton, J. W. St. Geme, N. F. Schor, & R. E. Behrman, (Eds.), *Nelson's textbook of pediatrics* (19th ed., p. 416–18). Philadelphia: Saunders; and Kaye, C. I., & the Committee on Genetics. (2011). Newborn screening fact sheets. *Pediatrics*, 118(3), e934–e963. doi:10.1542/peds.2006-1783.

**PALPATION**

Palpation can be used to detect hepatosplenomegaly (an enlarged spleen and liver). However, physicians or nurse practitioners usually perform this assessment because it requires skill and experience. Hepatosplenomegaly may indicate a metabolic disorder.

**Laboratory and Diagnostic Testing**

Common Laboratory and Diagnostic Tests 51.1 explains the laboratory and diagnostic tests used most commonly to detect genetic disorders. The tests can assist the physician or nurse practitioner in diagnosing the disorder or can be used as guidelines in determining treatment. Laboratory or nonnursing personnel obtain some of the tests, while the nurse might obtain others. In either instance the nurse should be familiar with how the tests are obtained, what they are used for, and normal versus abnormal results. This knowledge will also be necessary when providing child and family education related to the testing. Due to the nature of the information, a referral to genetic counseling before testing may be appropriate. Advances in genetic technology, including information obtained from the Human Genome Project, have led to dramatic increases in the number of diagnostic and screening tests (GeneTests, 2011).

**Nursing Diagnoses, Goals, Interventions, and Evaluation**

Upon completion of an assessment, the nurse might identify several nursing diagnoses, including:

- Deficient knowledge (specify)
- Decisional conflict

## COMMON LABORATORY AND DIAGNOSTIC TESTS 51.1

Test	Explanation	Indications	Nursing Implications
Amniocentesis	Ultrasound-guided (to determine placental location) insertion of a needle through the abdomen and into the uterine cavity of a pregnant woman to obtain a sample of amniotic fluid. The fluid contains skin cells that have been shed by the fetus and can be isolated and grown in the laboratory to provide enough genetic material for testing.	Test for chromosomal abnormality, neural tube defects, or specific genetic conditions of the fetus. Performed if considered high risk for a genetic disorder or abnormal ultrasound. Most common prenatal test used to diagnose chromosomal and congenital anomalies	Usually not performed until after 15 weeks' gestation. Some clinicians offer early amniocentesis (between 11 and 14 weeks), but this is still considered experimental and may be riskier than second-trimester amniocentesis. Complications include miscarriage, fetal injury, amniotic fluid leakage, infection, spontaneous abortion, premature labor, maternal hemorrhage, amniotic fluid embolism, abruptio placentae, and damage to the bladder or intestines. Results are usually not available for 2 weeks, but this varies by laboratory. Monitor fetus before and after procedure.
Chorionic villi sampling (CVS)	Involves the removal of a small amount of tissue directly from the chorionic villi (minute vascular projections of the fetal chorion that combine with maternal uterine tissue to form the placenta). In the laboratory, the chromosomes of the fetal cells are analyzed for number and type. Extra chromosomes, such as are present in Down syndrome, can be identified. Additional laboratory tests can be performed to look for specific disorders.	Test for chromosomal abnormality, fetal metabolic or blood disorders, or specific genetic conditions of the fetus. Performed if considered high risk for a genetic disorder or abnormal ultrasound. CVS cannot detect $\alpha$ -fetoprotein levels; therefore, does not detect neural tube defects	Performed at 7 to 11 weeks of gestation, so provides early detection of genetic abnormalities Complications include accidental abortion, infection, bleeding, amniotic fluid leakage, fetal limb deformities. Results are usually available within a week, but this varies depending on the laboratory and location of procedure (results are usually available sooner than with an amniocentesis). Monitor fetus before and after procedure.
Triple/quadruple screen	A maternal serum laboratory screening test that measures the level of three substances made by the developing baby and placenta: $\alpha$ -fetoprotein (AFP), human chorionic gonadotropin (hCG), and unconjugated estriol (uE3). Dimeric inhibin A has been added to make the "quadruple test." The addition of dimeric inhibin A increases the detection rate of Down syndrome and trisomy 18 in the quadruple screen.	A screening test for low-risk pregnant women to determine pregnancies at an increased risk for open neural tube defects, Down syndrome, and trisomy 18	Performed between 16 and 19 weeks of gestation Educate mothers that a normal test does not guarantee a healthy baby. Conversely, an abnormal result does not guarantee the baby has a problem. Additional testing will be necessary to confirm or rule out a specific genetic condition.

**COMMON LABORATORY AND DIAGNOSTIC TESTS 51.1** (continued)

Test	Explanation	Indications	Nursing Implications
Fetal nuchal translucency (FNT); may be combined with pregnancy-associated plasma protein (PAPP-A) and $\beta$ -hCG to increase detection rate	Ultrasound prenatal screening to help identify higher risks of Down syndrome, trisomy 13, trisomy 18, and Turner syndrome. The ultrasound assesses the amount of fluid behind the neck of a fetus (known as the nuchal fold). Increased fluid increases the risk of a chromosomal abnormality. During this early ultrasound other markers may be looked at such as presence of nasal bones (in Down syndrome hypoplasia or absence of the nasal bones may be noted); short femur or humerus increases the risk of trisomy, echogenic foci (bright spots) in the heart can increase the risk of Down syndrome, and echogenic bowel (bowel looks bright and white) can be associated with chromosomal abnormalities. A serum blood test is performed to determine the level of two hormones, PAPP-A and $\beta$ -hCG. Using a combination of the results of the ultrasound and the blood test, the risk of having a baby with Down syndrome is predicted.	Any pregnant woman presenting by 11 to 14 weeks' gestation can be screened. Particularly for women with increased risk or desired screening for Down syndrome, trisomy 13, trisomy 18, or Turner syndrome	Must be performed between 11 and 14 weeks Genetic counseling before testing may be warranted. Positive tests require follow-up tests and genetic counseling.
Ultrasound	Safe, noninvasive, accurate investigation of the fetus. A transducer is placed in contact with the mother's abdomen and high-frequency sound waves are directed at the fetus. The sound waves are reflected back through the tissues and recorded and displayed in real time on a screen.	Screen for structural malformations	Usually performed at 18 to 20 weeks of gestation; routinely done Early ultrasound can be performed at 11 to 14 weeks to evaluate for Down syndrome and other chromosomal abnormalities.
Percutaneous umbilical blood sampling	An ultrasound-guided needle is inserted through the abdominal and uterine wall to the umbilical cord and a sample of blood is retrieved and sent to the laboratory for analysis. Procedure is similar to amniocentesis but requires a higher level of expertise and experience. Less risk than fetoscopy	Detect chromosome abnormalities. Usually done when diagnostic information cannot be obtained through amniocentesis, CVS, or ultrasound or the results of these tests were inconclusive	Performed at or after 18 weeks. Complications include miscarriage, blood loss, infection, premature rupture of membranes. The risk to the pregnancy is greater than with other prenatal procedures such as amniocentesis and CVS. Not performed as often due to risks and since discovery of fluorescent in situ hybridization (FISH)

(continued)

**COMMON LABORATORY AND DIAGNOSTIC TESTS 51.1** (continued)

Test	Explanation	Indications	Nursing Implications
Fetoscopy	<p>Endoscopic procedure that allows direct visualization of the fetus through the insertion of a tiny flexible instrument called a fetoscope. It is inserted through the abdominal wall and into the uterine cavity. Ultrasound is used to guide the placement of the scope. Direct visualization can evaluate the fetus for severe congenital anomalies such as neural tube defects. Fetal blood samples from the umbilical cord can be obtained and tested for congenital blood disorders such as hemophilia and sickle cell anemia. Fetal tissue samples (usually skin) can be collected and tested for genetic diseases.</p>	<p>Indicated for any woman at risk for delivering a baby with significant congenital anomalies; can be used to perform corrective surgery (e.g., shunt placement) on the fetus</p>	<p>Performed during or after the 18th week of pregnancy</p> <p>Complications include spontaneous abortion, premature delivery, premature rupture of membranes, amniotic fluid leak, intrauterine fetal death, infection.</p> <p>Monitor fetus before and after procedure.</p>
Gene testing	<p>Gene testing is currently available for many inherited diseases. It involves analysis of DNA, RNA, chromosomes, proteins, metabolites, and biochemical agents.</p> <p>Specimens for gene testing can be obtained from numerous sources; leukocytes from blood are the most common and easily obtained site; during pregnancy, amniocentesis and chorionic villus sampling; and fetal tissue or products of conception after a miscarriage</p> <p>Most common use is DNA or chromosomes isolated from blood</p> <p>Direct detection of abnormalities in genes and chromosomes is performed using DNA-based test or cytogenetic tests (which look at chromosome) and other methods. Cytogenetic tests also include FISH to assist in detecting chromosomal abnormalities such as duplication, deletion, rearrangements, and translocations; newer testing, known as array comparative genomic hybridization (aCGH), or microarray, analyzes small duplications or deletions across all of the chromosomes.</p>	<p>To detect abnormalities that may indicate actual disease or predict future disease. Indicated in the evaluation of congenital anomalies, intellectual disability, growth retardation, recurrent miscarriage to determine reason for the loss of a fetus, prenatal diagnosis of genetic disease.</p>	<p>Provide support, information, and resources to family.</p> <p>Refer to genetic counseling before and after test.</p>

**COMMON LABORATORY AND DIAGNOSTIC TESTS 51.1** (continued)

Test	Explanation	Indications	Nursing Implications
Newborn screening (refer to Chapter 31 for further information)	<p>Blood screening performed shortly after birth, used to identify many life-threatening genetic illnesses that have no immediate visible effects but can lead to physical problems, intellectual disability, and even death</p> <p>Every U.S. state routinely screens all newborns, but each state dictates which disorders to screen for, so components of the screening vary from state to state.</p>	Identification of newborns so that treatment can begin early to prevent impact of disorder, such as severe cognitive impairment or death	<p>Refer to each state's protocol for fetal/newborn screening for endocrine disorders.</p> <p>Explain to family the rationale and procedure.</p> <p>Collect blood sample accurately.</p> <p>Collect prior to blood transfusion if possible.</p> <p>Ideally performed after 24 hours of age; obtain specimen as close to time of discharge from newborn or labor and delivery unit as possible and no later than 7 days of age</p> <p>The test is less accurate if done before 24 hours of age and should be repeated by 2 weeks of age if the newborn is younger than 24 hours old.</p> <p>Screening between 24 and 48 hours is satisfactory, but optimal screening is performed between the third and fifth days of life.<sup>a</sup></p> <p>Ensure appropriate follow-up with newborn screening results; results are available in 2 to 3 weeks.</p>

<sup>a</sup>March of Dimes. (2012b). *Clinical issues and considerations: Newborn screening: Frequently asked questions*. Retrieved July 14, 2012, from [http://www.milesforbabies.org/professionals/24279\\_9612.asp](http://www.milesforbabies.org/professionals/24279_9612.asp)

- Risk for delayed growth and development
- Fear
- Interrupted family processes

**After completing an assessment of Julie, the nurse noted the following: short stature for age and a low posterior hairline. Based on these assessment findings, what would your top three nursing diagnoses be for Julie?**

Nursing goals, interventions, and evaluation for the child with a genetic disorder are based on the nursing diagnoses. Nursing Care Plan 51.1 provides a general guide for planning care for a child with a genetic disorder. Additional information about nursing management will be included later in the chapter as it relates to specific disorders.

No matter what the genetic abnormality is, the news may be shattering to the family. It is difficult for nurses to even begin to understand what the family is going through. When providing support and education to families of children with serious genetic abnormalities, use these guiding principles:

- Build a trusting relationship.
- Stress the authenticity of the parents' feelings.
- Reject your own personal biases.
- Recognize that individuals cope in various ways; the family's behavior may not be what you would expect.
- Help the family to identify their own strengths and supports, building on those as able.
- Know that the family's emotions may exhaust and disorganize them.
- Assist the family members to maintain open communication among themselves.
- Provide referrals to local parent groups or other families with a child with a similar disorder.

## NURSING CARE PLAN 51.1

**Overview for the Child With a Genetic Disorder**

**NURSING DIAGNOSIS:** Deficient knowledge related to lack of information regarding complex, technical medical condition; prognosis; and medical needs as evidenced by verbalization, questions, or actions demonstrating lack of understanding about child's condition or care

**Outcome Identification and Evaluation**

Child and family will verbalize accurate information and understanding about condition, prognosis, and medical needs: *child and family demonstrate knowledge of condition, prognosis, and medical needs, including possible causes, contributing factors, and treatment measures.*

**Intervention: Providing Child and Family Teaching**

- Assess child's and family's willingness to learn: *child and family must be willing to learn for teaching to be effective.*
- Provide family with time to adjust to diagnosis: *will facilitate adjustment and ability to learn and participate in child's care.*
- Repeat information: *allows family and child time to learn and understand.*
- Teach in short sessions: *many short sessions are more helpful than one long session.*
- Gear teaching to the child and family's level of understanding (depends on age of child, physical condition, memory) *to ensure understanding.*
- Provide reinforcement and rewards: *facilitates the teaching/learning process.*
- Use multiple modes of learning involving many senses (written, verbal, demonstration, and videos) when possible: *child and family are more likely to retain information when it is presented in different ways using many senses.*
- Refer child and family to a genetics specialist: *genetic information is highly technical; the field is advancing at a rapid pace, and information needs to be the most current and accurate. A genetic specialist can provide this along with expertise, support, and resources.*

**NURSING DIAGNOSIS:** Decisional conflict related to treatment options, conflicting values, and ethical, legal, and social issues surrounding genetic testing as evidenced by verbalization of uncertainty about choices, verbalization of undesired consequences of alternative actions being considered, delayed decision making, physical signs of stress

**Outcome Identification and Evaluation**

Family will state they are able to make an informed decision: *family will state advantages and disadvantages of choices and share fears and concerns regarding choices.*

**Intervention: Providing Decision-Making Support**

- Give family time and encourage them to express their feelings associated with decision making: *the decision-making process becomes more difficult if feelings are not expressed.*
- Encourage family to list advantages and disadvantages of each alternative: *aids in problem solving and helps family recognize all alternatives.*
- Initiate health teaching and referral to genetic specialist when needed: *genetic testing information is often technical and complex. Families need accurate and up-to-date information to aid in decision making.*
- Maintain a nondirective manner: *this is a difficult decision that the family must make for themselves; the nurse should provide all the necessary information while maintaining an unobtrusive role.*
- Validate the family's feelings regarding the decisional conflict: *validation is a therapeutic communication technique that promotes the nurse-family relationship.*

## NURSING CARE PLAN 51.1

**Overview for the Child With a Genetic Disorder** (continued)

**NURSING DIAGNOSIS:** Risk for delayed growth and development related to physical disability, cognitive deficits, activity restrictions secondary to genetic disorder

**Outcome Identification and Evaluation**

Child's growth and development will be enhanced: *child will demonstrate adequate growth patterns within parameters of disease. Child will make continued progress toward attainment of developmental milestones and will not suffer regression in abilities.*

*Child will demonstrate developmental milestones within age parameters and limits of disease.*

*Child will make steady gains in growth patterns (e.g., height and weight) within disease parameters. Child expresses interest in the environment and people around him or her and interacts with environment appropriately for developmental level.*

**Intervention: Promoting Growth and Development**

- Screen for developmental capabilities to determine child's current level of functioning.
- Offer age-appropriate toys, play, and activities (including gross motor) to encourage further development.
- Perform exercises or interventions as prescribed by physical or occupational therapist: *these activities promote function and developmental skills.*
- Provide support to families: *due to immobility and extremity deficits, the child's progress toward developmental milestones may be slow.*
- Use therapeutic play and adaptive toys to facilitate developmental functioning.
- Provide stimulating environment when possible to maximize potential for growth and development.
- Praise accomplishments and emphasize child's abilities to improve self-esteem and encourage feeling of confidence and competence.
- Monitor height and weight and plot on growth chart to identify growth patterns and deviations in these patterns.

**NURSING DIAGNOSIS:** Fear related to outcome of genetic testing as evidenced by reports of apprehension and increased tension

**Outcome Identification and Evaluation**

Family will state they can cope with the results of the genetic testing or demonstrate reduced fear: *family accurately discusses chances of offspring having genetic disease, demonstrates positive coping, and asks questions about genetic testing and meaning of results.*

**Intervention: Managing Fear**

- Empathize with the family and avoid false reassurances; be truthful: *allows family to recognize that fear is a reasonable response. Giving false information or reassurance will actually increase fear.*
- Explore coping skills used previously by the family to cope with fear. Reinforce these skills and explore other outlets, such as relaxation, breathing, and physical activity: *encourages use of coping mechanisms that help control fear.*
- Encourage verbalization of feelings and concerns about genetic testing. Allow time for questions: *provides a safe outlet to express feelings and encourages open communication between the family members.*
- Explain all procedures and review results as available: *knowledge deficit contributes to fear.*
- Refer to appropriate support groups and genetic counseling: *talking with families who have gone through similar situations can help decrease fear and provide methods of coping. Genetic counseling provides information along with support and additional resources.*

(continued)

## NURSING CARE PLAN 51.1

## Overview for the Child With a Genetic Disorder (continued)

**NURSING DIAGNOSIS:** Family processes, interrupted, related to child's illness, hospitalization, diagnosis of genetic illness in child, and potential long-term effects of illness as evidenced by family's presence in hospital and clinic, missed work, demonstration of inadequate coping

**Outcome Identification and Evaluation**

Family will maintain functional system of support and demonstrate adequate coping, adaptation of roles and functions, and decreased anxiety: *parents are involved in child's care, ask appropriate questions, express fears and concerns, and can discuss child's care and condition calmly.*

**Intervention: Promoting Family Coping**

- Encourage family to verbalize concerns about child's illness, diagnosis, and prognosis: *allows the nurse to identify concerns and areas where further education may be needed and demonstrates family-centered care.*
- Explain therapies, procedures, child's behaviors, and plan of care to parents: *understanding the child's current status and plan of care helps decrease anxiety.*
- Encourage parental involvement in care: *allows parents to feel needed and valued and gives them a sense of control over their child's health.*
- Identify support system for family and child: *helps nurse identify needs and resources available for coping.*
- Educate family about resources available to help them develop a wide base of support.

- Allow the family to verbalize their emotions and ask questions.
- Always ask the parents how *they* are doing (Lashley, 2005).

**Based on your top three nursing diagnoses for Julie, describe appropriate nursing interventions.**

## COMMON CHROMOSOMAL ABNORMALITIES

Chromosomal abnormalities are seen in about 1 in 150 babies (March of Dimes, 2009a). Many children with chromosomal abnormalities have associated intellectual disabilities, learning disabilities, behavioral problems, and distinct features, including physical birth defects. The risk for autosomal trisomies increases with advanced maternal age (March of Dimes, 2009a). The most common chromosomal abnormalities will be discussed below. New techniques in chromosome analysis allow for the identification of tiny abnormalities that could not be seen before (March of Dimes, 2009a). Therefore, more chromosomal abnormalities are being identified in children (Table 51.2).

### Trisomy 21 (Down Syndrome)

Trisomy 21 (Down syndrome) is a genetic disorder caused by the presence of all or part of an extra 21st chromosome. It is the most common chromosomal abnormality associated with intellectual disability (March of Dimes, 2009a). One in 800 live births results in trisomy 21 (March of Dimes, 2009a). Approximately 75% of trisomy 21 conceptions result in spontaneous abortion (Chen, 2010). Trisomy 21 is seen in all ages, races, and socioeconomic levels, but a higher incidence is found with a maternal age older than 35 years (March of Dimes, 2009a). The likelihood of having a baby with Down syndrome is 1 in 1,000 in women younger than age 30, 1 in 400 at age 35, 1 in 100 at age 40, 1 in 35 at age 45, and 1 in 12 by age 49 (March of Dimes, 2009a; National Institutes of Health, National Institute of Child Health and Human Development, 2012).

Trisomy 21 is associated with some degree of intellectual disability, characteristic facial features (e.g., slanted eyes and depressed nasal bridge), and other health problems (e.g., cardiac defects, visual and hearing impairment, intestinal malformations, and an increased susceptibility to infections). The severity of these problems varies.

The prognosis has been improving over the past few decades. Fundamental changes in the care of these

**TABLE 51.2** LESS COMMON CHROMOSOMAL ABNORMALITIES

Chromosomal Abnormality	Features
Prader-Willi syndrome (abnormality on chromosome 15)	Affects 1 in 10,000 to 25,000 babies <sup>a</sup> Severe hypotonia, obesity, short stature, small hands and feet, hypogonadism, hyperphagia, and intellectual disability (varies from mild to severe)
Angelman syndrome (abnormality on chromosome 15)	Affects 1 in 12,000 to 20,000 babies <sup>b</sup> Hypotonia, microbrachycephaly, fair hair, midface hypoplasia, deep-set eyes, large mouth with tongue protrusion, seizures, jerky ataxic movements (resembling a puppet gait), uncontrolled bouts of laughter/smiling, happy demeanor, easily excitable personality, developmental delay and speech impairment, and severe intellectual disability
Cri-du-chat syndrome (abnormality on chromosome 5)	Affects 1 in 20,000 to 25,000 babies <sup>a</sup> Hypotonia; short stature; slow growth; low birthweight; characteristic weak, cat-like cry during infancy; microcephaly with protruding metopic suture; moon-like round face; bilateral epicanthal folds (folds of skin over the eyelids); high-arched palate; wide and flat nasal bridge; micrognathia (small receding chin); simian crease; and intellectual disability
Wolf-Hirschhorn syndrome (abnormality on chromosome 4)	Affects 1 in 50,000 babies <sup>a</sup> Hypotonia, intellectual disability, delayed growth and development, poor muscle tone, cardiac defects, seizures, and characteristic facial features (broad, flat nose bridge; high forehead; widely spaced, protruding eyes; microcephaly)
Williams syndrome (abnormality on chromosome 4)	Affects 1 in 10,000 children <sup>c</sup> Cardiovascular disease (supravalvular aortic stenosis most common, hypertension also seen); distinct facial features such as broad forehead, short nose with broad tip, full cheeks, and a wide mouth with full lips; small, wide-spaced teeth with occlusal abnormalities; hypercalcemia; early puberty for both males and females; structural abnormalities of the kidneys, delayed bladder training and urinary frequency, hypotonia, and joint laxity; learning disabilities and intellectual disability, attention deficit disorder, problems with anxiety and phobias such as fears of sounds and tactile issues; unique personality characteristics, such as outgoing and engaging personality; other medical problems involving eyes and vision and digestive tract
Beckwith-Wiedemann syndrome (abnormality on chromosome 11)	Affects 1 in 12,000 babies <sup>d</sup> Infants considerably larger than normal and grow at an unusual rate in childhood, growth slows in later childhood with adults not unusually tall, specific parts of the body may grow larger leading to asymmetric appearance; abdominal wall defects such as omphalocele, umbilical hernia; infants present with abnormally large tongue that may interfere with breathing, swallowing, and speaking; abnormally large abdominal organs; crease or pits in skin near ears, hypoglycemia, and kidney abnormalities; increased risk of developing cancerous and noncancerous tumors, such as Wilms tumor, neuroblastoma
22q11 deletion syndrome (Velocardiofacial/DiGeorge syndrome) (abnormality of chromosome 22)	Affects 1 in 4,000 babies <sup>a</sup> Hypoplasia or agenesis of the thymus and parathyroid glands, hypoplasia of auricle and external auditory canal, cardiac anomalies, immune system abnormalities, cleft palate, short stature, distinctive facial appearance (elongated face, almond-shaped eyes, wide nose, small ears), and learning, speech, feeding, and behavioral problems <a href="http://www.vcfsef.org/">www.vcfsef.org/</a> : Velo-Cardio-Facial Syndrome Educational Foundation, Inc.

Helpful links related to the chromosomal abnormalities and features outlined here are provided on [thePoint](#).

children have resulted in longer life expectancy (around 60 years of age) and an improved quality of life (Buckley & Buckley, 2008).

## Pathophysiology

Trisomy 21 is a disorder caused by nondisjunction or translocation before, at, or after conception.

Each egg and sperm cell normally contain 23 chromosomes. When they join, this results in 23 pairs or 46 chromosomes. Sometimes an extra chromosome originates in the development of either the egg or the sperm, resulting in an embryo with three chromosome 21's in *all* cells (Fig. 51.1). This results in the characteristic features and birth defects of Down syndrome. This type and timing of nondisjunction, resulting in the presence of three chromosome 21's in all cells, is responsible for 95% of cases of Down syndrome (American Academy of Pediatrics, 2011; Bacino & Lee, 2011).

In approximately 1 to 2% of cases of Down syndrome, the nondisjunction occurs *after* fertilization and a mixture of two cell types is seen (American Academy of Pediatrics, 2011; Bacino & Lee, 2011). In these cases some cells have 47 chromosomes (due to three chromosome 21s), while others have the normal 46 chromosomes (with the normal two chromosome 21s present). This is referred to as the mosaic form of Down syndrome. Children with mosaic Down syndrome may have a milder form of the disorder, but this is not a general finding.

About 3 to 4% of Down syndrome cases involve a translocation, in which part of the number 21 chromosome breaks off during cell division *before or at* conception and attaches (or translocates) to another chromosome (American Academy of Pediatrics, 2011; Bacino & Lee, 2011). The cells will remain with 46 chromosomes, but this extra portion of the number 21 chromosome results in the clinical findings of Down syndrome. Cases of translocation are not associated with advanced maternal age, as is the situation with nondisjunction errors.

In fact, 25% of cases are the result of a hereditary translocation (Chen, 2012).

## Therapeutic Management

Management of Down syndrome will involve multiple disciplines, including a primary physician; specialty physicians such as a cardiologist, ophthalmologist, and gastroenterologist; nurses; physical therapists; occupational therapists; speech therapists; dietitians; psychologists; counselors; teachers; and, of course, the parents. There is no standard treatment for all children, and there is no prevention or cure. Treatment is mainly symptomatic and supportive. The overall focus of therapeutic management will be to promote the child's optimal growth and development and function within the limits of the disease.

## Managing Complications

Children with Down syndrome need the usual immunizations, well-child care, and screening recommended by the American Academy of Pediatrics. In addition, medical management will focus on complications associated with Down syndrome.

Congenital heart disease occurs in 40% to 50% of children with Down syndrome (American Academy of Pediatrics, 2011; Chen, 2012). Cardiac problems vary from minor defects that respond to medication therapy to major defects that require surgical intervention. Children with Down syndrome also have an increased incidence of gastrointestinal disorders (American Academy of Pediatrics, 2011; Chen, 2012). These disorders vary from those that can be managed by dietary manipulation, such as celiac disease and constipation, to intestinal malformations such as Hirschsprung disease and imperforate anus, which require surgical intervention.

Hearing and vision impairments also are common. Approximately 75% of children with Down syndrome have a hearing loss (American Academy of Pediatrics, 2011). Therefore, regular evaluation of vision and hearing is essential.

Obstructive sleep apnea is present in 50% to 75% of children with Down syndrome (American Academy of Pediatrics, 2011). Often parents are unaware their child is having sleep disturbances, so baseline testing in young children may be warranted.

Children with Down syndrome have a higher incidence of thyroid disease, which can affect growth and cognitive function (American Academy of Pediatrics, 2011; Chen, 2012). Most of these children have hypothyroidism (an underactive thyroid), but sometimes hyperthyroidism (an overactive thyroid) occurs. Periodic thyroid testing may be warranted. Children with Down syndrome are also at a higher risk for obesity and malocclusions (American Academy of Pediatrics, 2011; Chen, 2012).

Atlantoaxial instability (increased mobility of the cervical spine at the first and second vertebrae) is seen

**FIGURE 51.1** Down syndrome karyotype. Note the third chromosome located at chromosome 21.

in of children with Down syndrome (American Academy). In most cases these children are asymptomatic, but symptoms may appear if spinal cord compression occurs. Screening for atlantoaxial instability may be appropriate, especially if the child is involved in sports.

### Take Note!

If neck pain, unusual posturing of the head and neck (torticollis), change in gait, loss of upper body strength, abnormal reflexes, or change in bowel or bladder functioning is noted in the child with Down syndrome, immediate attention is required.

The risk of acute lymphocytic leukemia (ALL) and acute myelogenous leukemia (AML) is higher than that of children without Down syndrome, (Chen, 2012). Children with Down syndrome also have a higher susceptibility to infection and a higher mortality rate from infectious diseases (Chen, 2012; Schoenstadt, 2008). Precautions to prevent and monitor for infection are needed. Other potential complications include alopecia, communication disorders, and seizures.

Due to their increased risk for certain congenital anomalies and diseases, children with Down syndrome

will need to be monitored closely, and regular medical care is essential.

### Early Intervention Therapy

Early intervention refers to a variety of specialized programs and resources available to young children with developmental delay or other impairment. These programs may involve an array of health care professionals such as physical, occupational, and speech therapists; special educators; and social workers. The programs focus on providing stimulation and encouragement to children with Down syndrome. They help encourage and accelerate development and may help to prevent some developmental delays. The earlier the intervention can begin, the more beneficial it will be. The programs are individualized to meet the specific needs of each child.

Children with Down syndrome progress through the same developmental stages as typical children, but they do so on their own timetable (refer to Table 51.3 for the average age of skill acquisition in children with Down syndrome). For example, children with Down syndrome will learn to walk, but the average child with Down syndrome walks at 24 months (versus

**TABLE 51.3** AVERAGE AGE OF SKILL ACQUISITION IN CHILDREN WITH DOWN SYNDROME

Developmental Milestone	Average Age of Acquisition, Children With Down Syndrome	Average Age of Acquisition, Typical Children
Smile	2 months	1 month
Roll over	6 months	4 months
Sit alone	9 months	7 months
Crawl	11 months	9 months
Walk	21 months	13 months
Speak words	14 months	10 months
Speak in sentences	24 months	21 months
Feed self with fingers	12 months	8 months
Use spoon	20 months	13 months
Bladder training	48 months	32 months
Bowel training	42 months	29 months
Undress	40 months	32 months
Put on clothes	58 months	47 months

Adapted from Pueschel, S. M. (2011). *A parent's guide to Down syndrome: Toward a brighter future* (rev. ed.). Baltimore: Paul H. Brookes Publishing Company, Inc.

12 months for a child without Down syndrome). Conditions such as hypotonia, ligament laxity, decreased strength, enlarged tongue, and short arms and legs are common in children with Down syndrome, and early intervention can help in the development of gross and fine motor skills, language, and social and self-care skills.

Parents also benefit from early intervention programs in terms of support, encouragement, and information. Early intervention programs teach parents how to interact with their child while meeting the child's specific needs and encouraging development.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1857. Assessment findings pertinent to Down syndrome are discussed below.

### Health History

Down syndrome is often diagnosed prenatally using perinatal screening and diagnostic tests. If not diagnosed prenatally, most cases are diagnosed in the first few days of life based on the physical characteristics associated with Down syndrome. Identify high-risk deliveries. Explore the pregnancy history and past medical history for risk factors such as:

- Lack of prenatal care or screening
- Abnormal prenatal screening or diagnostic tests for Down syndrome (e.g., triple/quadruple screen, ultrasound, amniocentesis)
- Maternal age older than 35 years

The older infant or child known to have Down syndrome is often admitted to the hospital for corrective surgeries or other complications of the disease, such as infections. Elicit a description of the present illness and chief complaint. In an infant or child returning for a clinic visit or hospitalization, the health history should include questions related to:

- Cardiac defects or disease (treatment regimen, surgical repair)
- Hearing or vision impairment (last hearing and vision evaluation, any corrective measures)
- Developmental delays (speech, gross and fine motor skills)
- Sucking or feeding problems
- Cognitive abilities (degree of intellectual disability)
- Gastrointestinal disorders such as vomiting or absence of stools (special dietary management, surgical interventions)
- Thyroid disease
- Leukemia
- Atlantoaxial instability
- Seizures

- Infections such as recurrent or chronic respiratory infections, otitis media
- Growth (height and weight changes, feeding problems, unexplained weight gain)
- Signs and symptoms of sleep apnea, such as snoring, restlessness during sleep, daytime sleepiness
- Any other changes in physical state or medication regimen

### Physical Examination

The initial assessment after birth may reveal certain physical features characteristic of Down syndrome (Box 51.3 and Fig. 51.2).

#### BOX 51.3

#### COMMON CLINICAL MANIFESTATIONS OF DOWN SYNDROME

- Hypotonia
- Short stature
- Flattened occiput
- Small (brachycephalic) head
- Flat facial profile
- Depressed nasal bridge and small nose
- Oblique palpebral fissures (an upward slant to the eyes)
- Brushfield spots (white spots on the iris of the eye)
- Low-set ears
- Abnormally shaped ears
- Small mouth
- Protrusion of tongue; tongue is large compared to mouth size
- Arched palate
- Hands with broad, short fingers
- A single deep transverse crease on the palm of the hand (simian crease)
- Congenital heart defect
- Short neck, with excessive skin at the nape
- Hyperflexibility and looseness of joints (excessive ability to extend the joints)
- Dysplastic middle phalanx of fifth finger (one flexion furrow instead of two)
- Epicanthal folds (small skin folds on the inner corner of the eyes)
- Excessive space between large and second toe

Adapted from Bacino, C. A. & Lee, B. (2011). Chapter 76: Cytogenetics. In R. M. Kliegman, B. F. Stanton, J. W. St. Geme, N. F. Schor, & R. E. Behrman, (Eds.), *Nelson's textbook of pediatrics* (19th ed., p. 394–414). Philadelphia: Saunders; and American Academy of Pediatrics, Committee on Genetics. (2011). Health supervision for children with Down syndrome. *Pediatrics*, 128(2), 393–406. doi: 10.1542/peds.2011–1605

FIGURE 51.2 Child with Down syndrome.

Observe the child's general appearance. Note lack of muscle tone and loose joints; this is usually more pronounced in infancy, and the infant has a floppy appearance. Observe growth and development. Plot growth on appropriate growth charts. Because children with Down syndrome grow at a slower rate, special growth charts have been developed (see [thePoint](#) for an example).

When assessing achievement of developmental milestones in children with Down syndrome, it may be more useful to look at the sequence of milestones rather than the age at which they were achieved. Each milestone represents a skill that is needed for the next stage of development.

Perform a subjective assessment of hearing and refer the child for further evaluation if indicated. Assess vision, especially for cataracts. Assess respiratory status and cardiac status. Auscultate for murmurs and pulmonary changes, which can indicate congenital heart disease. Chronic or recurrent respiratory infections, such as pneumonia and otitis media, may be found.

### Laboratory and Diagnostic Tests

Down syndrome risk screening can be calculated prenatally between 11 and 14 weeks using ultrasound and blood tests (nuchal translucency and pregnancy-associated plasma protein A [PAPP-A] and human chorionic gonadotropin [hCG]), and around 16 and 18 weeks using triple/quadruple blood tests to detect  $\alpha$ -fetoprotein (AFP), hCG, *estriol*, and/or *inhibin A levels* (Anderson & Brown, 2009). Ultrasound and amniocentesis or chorionic villi sampling (CVS) to detect chromosomal abnormalities can also occur prenatally. Down syndrome can

be confirmed after birth using chromosome analysis (see Common Laboratory and Diagnostic Tests 51.1).

Common laboratory and diagnostic studies ordered for the diagnosis and assessment of complications associated with Down syndrome include:

- Echocardiogram: to detect cardiac defects
- Vision and hearing screening: to detect vision and hearing impairments
- Thyroid hormone level: to detect thyroid disease
- Cervical radiographs: to assess for atlantoaxial instability
- Ultrasound: to assess for gastrointestinal malformations

These tests will be important in evaluating the severity of the child's physical disabilities.

## Nursing Management

Due to the high incidence of Down syndrome and the complex medical needs of these children, most pediatric nurses are likely to care for these children in their practice. Nursing management focuses on providing supportive measures such as promoting growth and development, preventing complications, promoting nutrition, and providing support and education to the child and family. In addition to the nursing diagnoses and related interventions discussed in Nursing Care Plan 51.1, additional considerations are reviewed below.

### Promoting Growth and Development

Children with Down syndrome tend to grow more slowly, learn more slowly, have shorter attention spans, and have trouble with reasoning and judgment. Their personality tends to be one of genuine warmth and cheerfulness along with patience, gentleness, and a natural spontaneity. Growth and developmental milestones for children with Down syndrome have been developed as a guide for physicians and nurse practitioners. Table 51.3 gives examples of the average age at which these children reach selected milestones versus typical children.

### Thinking About Development

As a nurse in a physician's office, how will your education on safety differ when caring for an infant with Down syndrome compared to a toddler or adolescent?

Nurses play a key role in connecting families with appropriate resources that can facilitate the child's growth and development. The sooner early intervention programs can begin, the better for the child (see the above discussion on early intervention). Speech and language therapy, occupational therapy, and

physical therapy will be important in promoting the child's growth and development. Special education should fit the child's individual needs, and the child should be integrated into mainstream education whenever possible.

### Preventing Complications

Children with Down syndrome are at risk for certain health problems (see above). Even though most nurses will encounter a child with Down syndrome in their practice, only a few nurses will become experts in their care. The needs of these children are complex, and guidelines have been established that can help the nurse care for these children and their families (these guidelines are available on the National Down Syndrome Society webpage, a link to which is provided on [thePoint](#)). See also Appendix I at the back of this book. Nurses play a key role in educating parents and caregivers about how to prevent the complications of Down syndrome (see Teaching Guidelines 51.1 and Fig. 51.3).

#### Teaching Guidelines 51.1

##### HEALTH GUIDELINES FOR CHILDREN WITH DOWN SYNDROME

- Have your child evaluated by a pediatric cardiologist before 3 months of age, including an echocardiogram.
- Take your child for routine vision and hearing tests. By 6 months have your child seen by a pediatric ophthalmologist.
- Make sure your child gets regular medical care, including recommended immunizations and a thyroid test at 6 and 12 months and then yearly.
- Have your child follow a regular diet and exercise routine.
- Make sure all family members perform proper hand hygiene to prevent infection.
- Monitor for signs and symptoms of respiratory infections, such as pneumonia and otitis media.
- Discuss with your physician the use of pneumococcal, respiratory syncytial virus, and influenza vaccines.
- Begin early interventions, therapy, and education as soon as possible.
- Make sure your child brushes his or her teeth regularly. He or she should visit the dentist every 6 months.
- Make sure the child gets a cervical radiograph between 3 and 5 years of age to screen for atlantoaxial instability.

Adapted from American Academy of Pediatrics, Committee on Genetics. (2011). Health supervision for children with Down syndrome. *Pediatrics*, 128(2), 393–406. doi: 10.1542/peds.2011-1605

### Promoting Nutrition

Children with Down syndrome may have difficulty sucking and feeding due to lack of muscle tone. They tend to have small mouths; a smooth, flat, large tongue; and due to the underdeveloped nasal bone, chronically stuffy noses. This may lead to poor nutritional intake and problems with growth. These problems usually improve as the child gains tongue control. Use of a bulb syringe, humidification, and changing the infant's position can lessen the problem. Breastfeeding a baby with Down syndrome is usually possible, and the antibodies in breast milk can help the infant fight infections. The caregiver's hand can be used to provide additional support of the chin and throat. Speech or occupational therapists can work on strengthening muscles and assisting in feeding accommodations. Other feeding problems and failure to thrive can be related to cardiac defects and usually improve after medical management is initiated or corrective surgery performed.

Children with Down syndrome do not need a special diet unless underlying gastrointestinal disease is present, such as celiac disease. A balanced, high-fiber diet and regular exercise are important. Research has suggested that children with Down syndrome have lower basal metabolic rates, which can lead to problems with obesity, so it is important in the early years to develop appropriate eating habits and a regular exercise routine. High fiber intake is important for children with Down syndrome because their lack of muscle tone may decrease gastric motility, leading to constipation.

### Providing Support and Education for the Child and Family

Down syndrome is a lifelong disorder that can result in health problems and cognitive disability. The diagnosis is usually made prenatally or shortly after birth. Parents and caregivers will need support and education during this difficult time. The range of mental impairment varies from mild to moderate; severe deficits occur occasionally. Some families may see having a child with Down syndrome as a lifelong tragedy; others may view it as a positive growing experience. Evaluate how the family defines and manages this experience. Base the plan of care on each individual family's values, beliefs, strengths, and resources.

Family members may have trouble meeting the demands of caring for a child with Down syndrome. These children have complex medical needs, which place strain on the family and its finances. From the time of diagnosis, the family should be involved in the child's care. Include parents in planning interventions and care for the child. In most cases they are the primary caregivers and will provide daily care as well as assisting the

child in the development of functioning and skills. They can provide essential information to the health care team and will be advocates for their child throughout his or her life.

As the child grows, the needs of the family and child will change. Recognize and respect these needs and provide ongoing education and support for the child and family. Children with Down syndrome will need meaningful education programs. Many children with Down syndrome begin formal education in infancy and continue through high school. Full integration has become more common (Schoenstadt, 2008).

The outlook is brighter than it once was for children with Down syndrome. Many go on in adulthood to obtain jobs, to receive secondary education, and to live on their own or in semi-independent housing. Be familiar with local and national resources for families of children with Down syndrome so that you can help these children fulfill their potential. An extensive list of helpful resources is provided on [thePoint](#).

### Consider This

Charles Faust, a 10-month-old with Down syndrome, is seen in the clinic for a well-child examination. The parents have questions about his growth and development. They are concerned because Charles can't pick up finger foods such as Cheerios and put them in his mouth.

How would you address their concerns?

Discuss ways the family can encourage Charles's growth and development.

In addition to usual well-child care, what other medical management will you want to discuss with the family to prevent complications associated with Down syndrome?

## Trisomy 18 and Trisomy 13

Trisomy 18 (also known as Edwards syndrome) and trisomy 13 (also known as Patau syndrome) are two other common trisomies. These trisomies are much more severe and debilitating than trisomy 21. The incidence of trisomy 18 (the presence of three number 18 chromosomes) is 1 in 6,000 births; the incidence of trisomy 13 (the presence of three number 13 chromosomes) is 1 in 10,000 births (Bacino & Lee, 2011). Like Down syndrome, trisomy 13 and trisomy 18 usually result from nondisjunction during cell division. Trisomy 18 and trisomy 13 can be present in all cells or may occur in mosaic forms. Both are associated with a characteristic set of anomalies and severe intellectual disability (Bacino & Lee, 2011).

The prognosis for trisomy 18 and trisomy 13 is usually poor; these children usually do not survive beyond the first year of life. There is no cure for trisomy 18 or trisomy 13. Therapeutic management will focus on managing the various congenital anomalies and health issues associated with the disorders.

### Nursing Assessment

Nursing assessment will include a general observation for characteristic anomalies (Table 51.4 and Figs. 51.3 and 51.4).

Prenatal screening and diagnostic tests for trisomy 18 and trisomy 13 exist. If not diagnosed during the prenatal period, most cases are diagnosed in the first few days of life based on the physical characteristics associated with the disorders.

### Nursing Management

Nursing management will be mainly supportive. This will be a difficult time for the family, so providing support and resources for the family will be an important nursing function. SOFT is a support organization for families who have had a child with a chromosome abnormality (visit [thePoint](#) for a link to this resource).

**TABLE 51.4** CLINICAL MANIFESTATIONS OF TRISOMY 18 AND TRISOMY 13

Chromosomal Abnormality	Clinical Manifestations
Trisomy 18	Prominent occiput, low-set ears, short eyelid fissures, severe intellectual disability, severe hypotonia, webbing, clenched fist with index finger over third digit and fifth digit overlapping the fourth, hypoplasia of fingernails, narrow hips with limited abduction, short sternum, congenital cardiac defects
Trisomy 13	Microcephalic head, wide sagittal suture and fontanel, malformed ears, small eyes, extra digits, severe hypotonia, severe intellectual disability, congenital heart defects, cleft lip, cleft palate

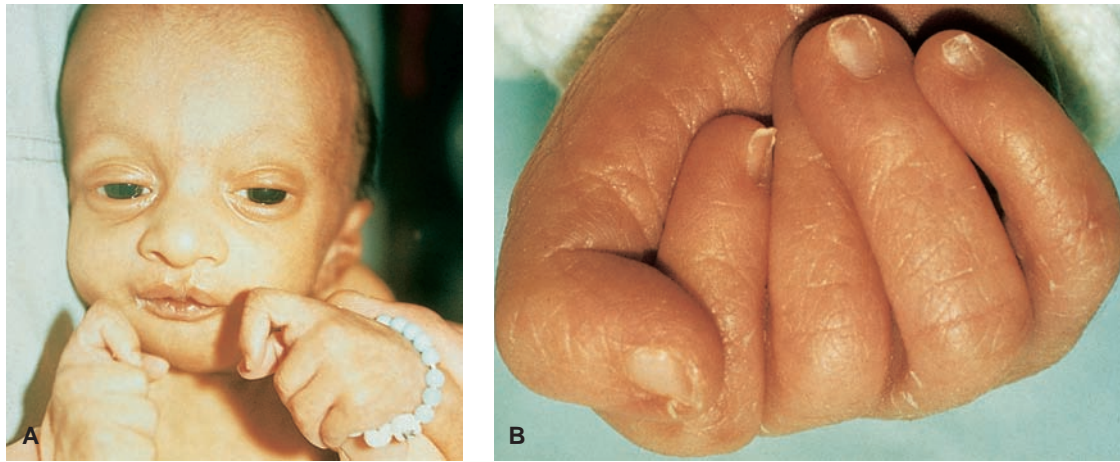

FIGURE 51.3 Trisomy 18.

FIGURE 51.4 Trisomy 13.

## Turner Syndrome

Turner syndrome is a common abnormality of the sex chromosome. The phenotype is female. It occurs in about 1 in 2,500 to 5,000 live female births (Conley, 2010; Bacino & Lee, 2011). The abnormality is due to a loss of all or part of one of the sex chromosomes. About half of the affected individuals have only one X chromosome; the other half have a variety of abnormalities of one of their sex chromosomes and may present with the mosaic form.

There is no cure for Turner syndrome. Therapeutic management will focus on managing the health issues

associated with the syndrome. Children with Turner syndrome are more prone to cardiovascular problems, kidney and thyroid problems, skeletal disorders such as scoliosis and osteoporosis, hearing and eye disturbances, learning disabilities, and obesity (Kansra & Donohue, 2011). Infertility is usually present, but a few spontaneous pregnancies have been reported (Kansra & Donohue, 2011). Growth hormone administration is a standard of care and usually begins when the child's height falls below the fifth percentile for healthy girls. Hormone replacement therapy may also be given to initiate puberty and complete growth.

## Nursing Assessment

On assessment, note patterns of growth; short stature and slow growth will be a characteristic finding and often the first indication. Other physical characteristics include a webbed neck, low posterior hairline, wide-spaced nipples, edema of the hands and feet, amenorrhea, no development of secondary sex characteristics, sterility, and perceptual and social skill difficulties (Fig. 51.5).

Turner syndrome can be suspected prenatally by ultrasound findings such as fetal edema or redundant nuchal skin or by abnormal results of the triple or quadruple screen (Bondy, 2007). It can be diagnosed by chromosomal analysis, either prenatally or after birth. Most children are diagnosed at birth or in early childhood when slow growth or growth failure is noted. Some cases will not be diagnosed until the pubertal growth spurt does not occur.

## Nursing Management

Nursing management is mainly supportive. Provide education and support to the family; they need to understand that short stature and infertility are likely. Explain that intellectual disability is unlikely, but some learning disabilities may be present. Emphasize that with medical supervision and support, girls with Turner syndrome may

**FIGURE 51.5** Note the webbed neck of the child with Turner syndrome.

lead healthy, satisfying lives. Counseling about infertility is important. Parents may be upset that their daughter will not be able to reproduce, so explain that many alternatives for reproduction, such as in vitro fertilization and adoption, are available.

Providing support and resources for the family is an important nursing function. The Turner Syndrome Society of the United States provides assistance, support, and education to individuals with Turner syndrome and their families. A link to resources is provided on [thePoint](#).

### Klinefelter Syndrome

Klinefelter syndrome is the most common sex chromosomal abnormality (Bacino & Lee, 2011). The karyotype and phenotype are male, but one or more extra X chromosomes is present. The abnormality is usually caused by nondisjunction during meiosis, but mosaic forms do present. The incidence of Klinefelter syndrome is 1 in 500 to 700 males (Conley, 2010; Bacino & Lee, 2011). Males present with some female-like physical features that are caused by testosterone deficiency. The risk of recurrence in future pregnancies is not increased.

There is no cure for Klinefelter syndrome. Therapeutic management will focus on interventions to enhance masculine characteristics, such as testosterone replacement. Early recognition and hormonal treatment

are important to improve quality of life and prevent serious consequences. Cosmetic surgery may be performed to minimize female characteristics such as gynecomastia (increased breast size).

### Nursing Assessment

Due to nonspecific findings during childhood, the diagnosis is not usually made until adolescence or adulthood. Prenatal diagnosis is rare unless amniocentesis was performed for genetic testing. Many males with Klinefelter syndrome go through life without being diagnosed (Descartes & Carroll, 2007). The diagnosis is confirmed by chromosomal analysis.

On assessment, lack of development of secondary sex characteristics may be found. The individual may have decreased facial hair, gynecomastia, decreased pubic hair, and hypogonadism or underdeveloped testes, which leads to infertility. The individual may be taller than average by 5 years of age, with long legs and a short torso (Fig. 51.6). Intellectual disability is not present, but cognitive impairments of varying degree, such as motor delay, speech or language difficulties, attention deficits, and learning disabilities, may be found.

### Nursing Management

Nursing management will be mainly supportive. Provide education and support to the family. Links to The American

FIGURE 51.6 Klinefelter syndrome.

Association for Klinefelter Syndrome, The Klinefelter Syndrome Support Group, and Klinefelter Syndrome and Associates are provided on [thePoint](#).

Counseling about infertility is important. Educate children and families that marriage and sexual relations are possible. Parents may be upset that their son will not be able to reproduce, so explain that many alternatives for reproduction are available and technology is advancing in the field of infertility.

### Fragile X Syndrome

Fragile X syndrome is the most common inherited cause of intellectual disability (National Institute of Child Health and Human Development, 2010). It is the outcome of a mutation of a gene (FMR1 [fragile X mental retardation]) on the X chromosome. This mutation essentially “turns off” the gene, triggering fragile X syndrome. Males and females are both affected, but it is more commonly seen in males, and affected females usually have milder symptoms (Watson, 2010). The incidence is approximately 1 in 8,000 females and 1 in 4,000 males (Genetics Home Reference, 2012). The inheritance of fragile X is complex and is less straightforward than single-gene or mendelian inheritance. Some carrier females are affected, and not all males with the gene abnormality show symptoms. Males and females are both fertile and can transmit the disorder

to their offspring, so genetic counseling is appropriate. The prognosis for individuals with fragile X is good, and they tend to live a normal life span.

There is no cure for fragile X syndrome. Therapeutic management will be multidisciplinary and aimed at interventions to improve cognitive, emotional, and behavioral impairments.

### Nursing Assessment

During childhood, clinical manifestations are subtle, with minor dysmorphic features and developmental delay. Problems with sensation, emotion, and behavior often are the first signs. A delay in attaining developmental milestones will most likely be the first clue found on assessment. Intellectual impairment can range from subtle learning disabilities to severe intellectual disability and autistic-like behaviors. In adolescence, boys tend to present with characteristic features such as an elongated face; prominent jaw; large, protruding ears; large size; macroorchidism (large testes); and a range of behavioral abnormalities and cognitive deficits (Fig. 51.7). There is a characteristic pattern to the cognitive deficits, with problems in abstract reasoning, sequential processing, and mathematics. Typical behavior problems include attention deficits, hand flapping and biting, hyperactivity, shyness, social isolation, low self-esteem, and gaze aversion. In females the clinical manifestations are similar but are more varied and often present in a milder form.

Diagnosis is confirmed by molecular genetic testing. Fragile X can be diagnosed prenatally if inheritance is suspected.

### Nursing Management

Nursing management will be mainly supportive. Early diagnosis and intervention with developmental therapies and an individualized education plan are ideal. Care of these children will be the same as care of other children with intellectual disability (see Chapter 52 for further information on intellectual disability).

Provide education and support to the family. The National Fragile X Foundation provides education and emotional support and works to increase awareness and advance research for fragile X. Links to resources are provided on [thePoint](#).

## NEUROCUTANEOUS DISORDERS

Neurocutaneous disorders, also referred to as hamartoses, are a group of disorders characterized by abnormalities of both the skin and the central nervous system. Many neurologic conditions are associated with cutaneous manifestations, since the skin and the nervous system share a common embryologic origin. They are complex conditions and most also affect other organ

FIGURE 51.7 Fragile X syndrome.

systems such as eyes, bones, heart, and kidneys. Most are hereditary and follow an autosomal dominant inheritance pattern or sporadic occurrence. Neurofibromatosis is a common neurocutaneous syndrome and will be discussed in detail below. Table 51.5 provides information on other neurocutaneous syndromes.

## Neurofibromatosis

Neurofibromatoses are neurocutaneous genetic disorders of the nervous system that primarily affect the development and growth of neural cell tissues. There are distinct types: neurofibromatosis 1, neurofibromatosis 2, and schwannomatosis (which used to be considered a variation of neurofibromatosis 2) (National Institute of Neurological Disorders and Stroke, 2010).

Neurofibromatosis 1 (von Recklinghausen disease) is the more common type and is discussed here (Sahin, 2011; National Institute of Neurological Disorders and Stroke, 2010). This disorder causes tumors to grow on nerves and produce other abnormalities such as skin changes and bone deformities. Although many affected persons inherit the disorder, nearly half of the cases are due to a new mutation (National Institute of Neurological Disorders and Stroke, 2010). The inheritance pattern is autosomal dominant; therefore, offspring of affected individuals have a 50% chance of inheriting the altered gene and presenting with symptoms. Neurofibromatoses are due to a mutation of the neurofibromin gene on

chromosome 17. The estimated prevalence is 1 in 2,500 to 3,000 live births (Tuli, Tuli, Kelly, & Ryan, 2010; Sahin, 2011).

Complications associated with neurofibromatosis include headaches; hydrocephalus; scoliosis; cardiac defects; hypertension; seizures; vision and hearing loss; neurocognitive deficits, including learning disabilities, attention deficit disorder, fine and gross motor delays, autism spectrum disorder, and behavior and psychosocial issues; abnormalities of speech; and a higher risk for neoplasms.

There is no cure for neurofibromatosis. Therapeutic management is aimed at controlling symptoms and managing complications. Surgical intervention can help reduce some of the bone malformations and remove painful or disfiguring tumors. These children should have a yearly physical, including blood pressure and cardiovascular examination, scoliosis screening, ophthalmology examination, developmental screening, and a neurologic examination.

The disease is progressive and symptoms usually worsen over time, but it is difficult to predict the course. Most affected individuals develop mild to moderate symptoms, with non-life-threatening complications, and live a normal, productive life.

## Nursing Assessment

On assessment the nurse may find café-au-lait spots (light-brown macules), which are the hallmark of neurofibromatosis (Sahin, 2011) (Fig. 51.8). These are usually

**TABLE 51.5** OTHER NEUROCUTANEOUS SYNDROMES

Disorder	Incidence	Clinical Manifestations	Nursing Considerations
Tuberous sclerosis	1 in 6,000 <sup>a</sup>	Benign tumors present in the brain and skin. Presents most often as a generalized seizure disorder. Tumors can also involve heart, kidney, eyes, lung, and bones. Developmental delay and behavioral problems may be noted. Usually evident in early childhood. Wide clinical spectrum from severe intellectual disability with incapacitating seizures to normal intelligence and no seizures	Treatment will be mainly symptomatic with goal to prevent and treat associated complications. Seizure control will be a primary concern. Provide support and education to the family. Referral for genetic counseling (it follows an autosomal dominant inheritance pattern and half the cases are due to a new mutation) and appropriate resources www.tsalliance.org: Tuberous Sclerosis Alliance
Sturge-Weber syndrome	1 in 50,000 <sup>a</sup>	Facial nevus (port wine stain) most often seen on the forehead and on one side of the face, seizures, hemiparesis, intracranial calcifications. In many cases intellectual disability, behavioral and emotional problems, and learning disabilities are present. Seizures usually begin in infancy and may worsen with age. Convulsions are usually noted on the side of the body opposite the facial nevus. Muscle weakness may be present on the same side. Most affected individuals have glaucoma at birth or will develop it later in life.	Treatment will be mainly symptomatic. Seizure control will be a primary concern (use of anticonvulsants or surgery). Seizures due to Sturge-Weber are often difficult to control. Laser treatment may be used to lighten or remove the facial nevus. Surgery may be performed on more serious cases of glaucoma. Physical therapy should be considered for infants and children with muscle weakness. Educational therapy is often prescribed for those with intellectual disability or developmental delays. Provide support and education to the family. Refer to appropriate resources. Genetic counseling may be appropriate (inheritance is unclear and sporadic). www.sturge-weber.org: Sturge-Weber Foundation

<sup>a</sup>Sahin, M (2011).Chapter 589: Neurocutaneous syndromes In R. M. Kliegman, B. F. Stanton, J. W. St. Geme, N. F. Schor, & R. E. Behrman, (Eds.), *Nelson's textbook of pediatrics* (19th ed., p. 2046–53). Philadelphia: Saunders.

present at birth but can appear during the first year of life and usually increase in size, number, and pigmentation. They are present all over the body, particularly the

**FIGURE 51.8** Café-au-lait spots associated with neurofibromatosis.

trunk and extremities, while usually sparing the face. Pigmented nevi, axillary freckling, and slow-growing cutaneous, subcutaneous, or dermal neurofibromas, which are benign tumors, are other signs of neurofibromatosis. Many children with neurofibromatosis have larger than normal head circumference and are shorter than average. Enough features are usually present by 10 years of age to make a diagnosis (National Institute of Neurological Disorders and Stroke, 2010). The severity of symptoms varies greatly, but the diagnosis is made if two or more of the clinical signs in Box 51.4 are present.

**Take Note!**

If more than six café-au-lait spots are present, neurofibromatosis should be suspected.

## BOX 51.4

**CLINICAL SIGNS OF NEUROFIBROMATOSIS**

Diagnosis is made if two or more of the following are present:

- Six or more café-au-lait macules (light brown spots) >5 mm in diameter in children and >15 mm in diameter in adolescents and adults
- Two or more neurofibromas (benign tumors) or one plexiform neurofibroma (tumor that involves many nerves)
- Freckling in the armpit or groin
- Presence of an optic glioma (a tumor on the optic nerve)
- Two or more growths on the iris of the eye (Lisch nodules or iris hamartomas)
- Abnormal development of the spine (scoliosis), the temple bone of the skull, or the tibia
- A first-degree relative (parent, sibling, or child) with neurofibromatosis

Adapted from National Institute of Neurological Disorders and Stroke. (2010). *Neurofibromatosis fact sheet*. Retrieved July 14, 2012, from [http://www.ninds.nih.gov/disorders/neurofibromatosis/detail\\_neurofibromatosis.htm](http://www.ninds.nih.gov/disorders/neurofibromatosis/detail_neurofibromatosis.htm); and Sahin, M (2011). Chapter 589: Neurocutaneous syndromes In R. M. Kliegman, B. F. Stanton, J. W. St. Geme, N. F. Schor, & R. E. Behrman, (Eds.), *Nelson's textbook of pediatrics* (19th ed., p. 2046–53). Philadelphia: Saunders.

**Nursing Management**

Nursing management will be mainly supportive. Early detection of treatable conditions and complications is a priority. Provide support and education to the child and family. Discuss genetic counseling with the family. Referral to appropriate resources is essential. Links to resources for The Children's Tumor Foundation are provided on [thePoint](#).

**OTHER GENETIC DISORDERS**

Thousands of genetic disorders are known, and new ones are being discovered, but most of them are rare. Table 51.6 lists other genetic disorders that the pediatric nurse may encounter. Nursing management of these disorders will be mainly supportive and will focus on providing support and education to the family and child, with an emphasis on developmental and educational needs. Referral to genetic counseling and appropriate resources is an important nursing function.

**INBORN ERRORS OF METABOLISM**

Inborn errors of metabolism are a group of hereditary disorders. They are collectively common, but individually rare (Weiner, 2009). Most follow an autosomal recessive inheritance pattern. They are caused by gene mutations

that result in abnormalities in the synthesis or catabolism of proteins, carbohydrates, or fats. The body cannot convert food into energy as it normally would. Most inborn errors are due to a defect in an enzyme or transport protein that results in a block in the metabolic pathway. The blocked metabolic pathway allows for accumulation of the damaging byproduct of the impaired metabolic process or may be responsible for a deficiency or absence of a necessary product. Presentation can occur at any time, even in adulthood, but many affected individuals exhibit signs in the newborn period or shortly after. Most inborn errors of metabolism presenting in the neonatal period are lethal if specific treatment is not initiated immediately.

Newborn screening is used to detect these disorders before symptoms develop. Recent developments in screening techniques (tandem mass spectrometry) allow dozens of metabolic disorders to be detected from a single drop of blood (Newborn Screening Authoring Committee, 2008). A child who tests positive will require additional testing to confirm the diagnosis (see Chapter 31 for more information on newborn screening for inborn errors of metabolism).

Therapeutic management of these disorders varies depending on the cause of the error of metabolism, but dietary management is often a key component.

**Nursing Assessment**

Clinical signs and symptoms vary with each disorder. Table 51.7 gives information on some common inborn errors of metabolism seen in children. See Evidence-Based Practice 51.1.

**Take Note!**

If the blood sample for the newborn screening was obtained within the first 24 hours after birth, the American Academy of Pediatrics recommends that a repeat sample be obtained within 1 to 2 weeks (Bartoszesky, 2009).

Because of newborn screening and early identification and management, it is rare to see an untreated newborn with clinical signs and symptoms of disease caused by one of the inborn error of metabolism disorders. If seen, a newborn who was healthy at birth will often present with lethargy, poor feeding, apnea or tachypnea, recurrent vomiting, altered consciousness, failure to thrive, seizures, septic appearance, or developmental delay. Physical changes that may be seen include dysmorphism, cardiomegaly, rashes, cataracts, retinitis, optic atrophy, corneal opacity, deafness, skeletal dysplasia, macrocephaly, hepatomegaly, jaundice, or cirrhosis.

**Take Note!**

When a previously healthy newborn presents with a history of deterioration, suspect an inborn error of metabolism.

The diagnostic workup usually requires a variety of specific laboratory studies and may include:

- Glucose: may be elevated
- Ammonia: may be elevated
- Blood gases: may have low bicarbonate and low pH, metabolic acidosis (respiratory alkalosis may also be seen, especially when high ammonia levels are present)

Early diagnosis is the key to saving and improving the lives of these children.

**Take Note!**

If an inborn error of metabolism is suspected, feedings will usually be stopped until the test results are received.

**TABLE 51.6 OTHER GENETIC DISORDERS, SYNDROMES, AND ASSOCIATIONS**

Disorder	Inheritance/Cause	Signs and Symptoms	Management
<p>CHARGE syndrome (a recognizable pattern of congenital anomalies seen)</p> <p><b>C:</b> Coloboma  <b>H:</b> Heart disease  <b>A:</b> Atresia (choanal)  <b>R:</b> Retarded growth and development and/or CNS anomalies  <b>G:</b> Genital anomalies, hypogonadism  <b>E:</b> Ear anomalies and deafness</p> <p>Incidence is 1 in 9,000 to 10,000.<sup>a</sup></p>	<p>Autosomal dominant inheritance possible, but most cases are due to new mutation of the gene. Mutations in the gene CDH7 have been indicated in some cases.</p>	<p>Coloboma is a lesion or defect of the eye, usually a fissure or cleft in the iris, ciliary, or choroid; can also see microphthalmos (small eyes) and cryptophthalmos (absent eye). Can lead to vision impairments</p> <p>Heart anomaly can include any type but most common are aortic arch anomalies and tetralogy of Fallot.</p> <p>Atresia (choanal) is blocked or narrowed passages from the nose to the throat, which can lead to aspiration.</p> <p>Retarded growth or cognitive development can range from mild to severe.</p> <p>Genital anomaly may include micropenis, undescended testes, and hypoplastic labia.</p> <p>Ear anomalies include short, wide ears with little or no lobe, prominent inner fold, floppy appearance, asymmetry; can have hearing impairment</p> <p>Each feature occurs in a spectrum from absent to severe; no single feature is present in all individuals.</p>	<p>Focus is on identifying and treating all defects; early diagnosis is important.</p> <p><a href="http://www.chargesyndrome.org">www.chargesyndrome.org</a>; CHARGE Syndrome Foundation</p>
<p>Marfan syndrome: disorder of connective tissue</p> <p>Incidence is 1 in 5,000 to 10,000.<sup>b</sup></p>	<p>Autosomal dominant inheritance; caused by a mutation in the gene fibrillin-1, which results in changes in connective tissue</p>	<p>Tall stature with long slim limbs, minimal subcutaneous fat, muscle hypotonia, loose joints, long and narrow face, abnormalities of skeletal system (e.g., pectus excavatum [funnel chest] or pectus carinatum [pigeon breast]), ocular system (e.g., enlarged cornea or lens subluxation), and cardiovascular system (e.g., dilation of the aorta or mitral valve prolapse)</p> <p>Delayed achievement of gross and fine motor milestones may occur.</p>	<p>Focus is on preventing complications.</p> <p><a href="http://www.marfan.org">www.marfan.org</a>: National Marfan Foundation  <a href="http://www.marfan.ca">www.marfan.ca</a>: Canadian Marfan Association</p>

<p>VATER association (not a diagnosis, but refers to a nonrandom association of defects found to occur together)</p> <p><b>V:</b> Vertebral defects  <b>A:</b> Anal atresia  <b>TE:</b> TracheoEsophageal fistula with esophageal atresia  <b>R</b>adial and <b>R</b>enal dysplasia</p> <p>May also occur as VACTERL association, with <b>C:</b> Cardiac anomalies  <b>L:</b> Limb abnormalities added</p>	<p>Sporadic inheritance. Cause is unknown. Can occur with other chromosomal abnormalities such as trisomy 18</p> <p>Frequently seen in the offspring of diabetic mothers</p>	<p>Three or more anomalies are present. Anomalies seen include hypoplastic (small) vertebrae or hemivertebra (only half the bones are formed). These anomalies lead to an increased risk of scoliosis.</p> <p>With imperforate anus or anal atresia, the anus does not open to the outside of the body.</p> <p>Incomplete formation of one or more kidneys, obstruction of urine flow out of kidneys, or severe reflux back into kidneys can all lead to kidney failure later in life.</p> <p>Cardiac anomalies: most common are ventricular septal defects, atrial septal defects, and tetralogy of Fallot.</p> <p>Absent or displaced thumb, polydactyly (extra digits), syndactyly (fusion of digits)</p> <p>A single umbilical artery at birth is often present.</p> <p>Failure to thrive and slow development in early infancy due to anomalies</p> <p>Usually normal intelligence</p>	<p>Focus is on identifying and treating all defects.</p> <p><a href="http://www.tefvater.org">www.tefvater.org</a>: TEF VATER National Support Network</p> <div style="display: flex; align-items: center;">  <div> <p><b>Take Note!</b></p> <p>Children with VATER syndrome who have only one kidney should not play contact sports.</p> </div> </div>
<p>Apert syndrome (named for the French physician who described the syndrome)</p> <p>Incidence is 1 in 65,000 to 88,000 live births.<sup>c,d</sup></p>	<p>Autosomal dominant inheritance. Cases are sporadic and have been associated with older paternal age.</p>	<p>Craniosynostosis, bilateral symmetric syndactyly, and craniofacial anomalies such as prominent forehead, midface hypoplasia resulting in sunken appearance, short anteroposterior diameter, down-slanting eyelids. Small nasopharynx can lead to upper airway obstruction and sleep apnea.</p> <p>Learning disabilities and mental deficiency</p>	<p>Early surgery for craniosynostosis when increased intracranial pressure is noted. Vigorous early management should occur with a multidisciplinary approach to address multiple anomalies.</p> <p><a href="http://www.aboutfaceusa.org">www.aboutfaceusa.org</a>: About Face USA  <a href="http://www.ccakids.com">www.ccakids.com</a>: Children's Craniofacial Association  <a href="http://www.faces-cranio.org">www.faces-cranio.org</a>: National Craniofacial Association  <a href="http://www.nffr.org">www.nffr.org</a>: National Foundation for Facial Reconstruction</p>

(continued)

TABLE 51.6

## OTHER GENETIC DISORDERS, SYNDROMES, AND ASSOCIATIONS (continued)

Disorder	Inheritance/Cause	Signs and Symptoms	Management
Achondroplasia (most common chondrodysplasia [diseases resulting in disordered growth]) Incidence is 1 in 15,000 to 40,000. <sup>d,e</sup>	Autosomal dominant inheritance pattern. Caused by mutations in fibroblast growth factor receptor 3 (FGFR3). 90% new gene mutation. Older paternal age may be a contributing factor.	Characterized by abnormal body proportion Small stature (average adult height is 4 feet for both men and women), short limbs with normal-size torso, low nasal bridge with prominent forehead. Midface hypoplasia, caudal narrowing of spinal canal, megaloccephaly, small foramen magnum; hands are short and stubby with separation between middle and ring fingers (“trident hand”). Delayed motor skills, problems with persistent middle ear dysfunction and infections, and bowing of lower legs. Less common complications include hydrocephalus, craniocervical junction compression, upper airway obstruction, and thoracolumbar kyphosis. Usually present with normal intelligence and lead independent, productive lives	Medical management of symptoms Monitor height, weight, and head circumference. Manage and prevent complications (careful and thorough neurologic examination, assessment for sleep apnea). Growth hormone therapy is controversial and still experimental. Limb-lengthening surgeries may be performed. www.shortsupport.org; Short Persons Support

When a child who has previously been diagnosed with an inborn error of metabolism is hospitalized, the nurse must determine the prescribed diet and medications so these may be continued while in the hospital setting.

## Nursing Management

Ensure that the diet prescribed for the infant or child is followed. For amino acid disorders (e.g., phenylketonuria [PKU]), urea cycle defects (e.g., tyrosinemia type I), and organic acidemia (e.g., maple syrup urine disease), nutritional therapy is the major intervention. Dietary intake of specific amino acids is restricted according to the disorder. Ensure that overall protein and calorie needs are still met, as children need sufficient calories for proper growth. In children with urea cycle defects and organic acidemia, anorexia is common and severe,

and the child may need gastrostomy tube feeding supplementation. In fatty acid oxidation disorders (e.g., medium-chain acyl-coenzyme A [CoA] dehydrogenase deficiency), the goal is to avoid prolonged periods of fasting and to provide frequent feeds when the child is sick. Supplementation with specific vitamins may also be important in the treatment of these disorders. Strict adherence to the diet is necessary and will require close supervision by registered dietitians, physicians, and nurses and the cooperation of both the parent and child.

Nursing management will focus on education and support for the family, who will need thorough knowledge about the child's disease and management. Refer the child and family to a dietitian and appropriate resources, including support groups. In addition, monitor the child's developmental progress and begin therapies as soon as a concern arises.

TABLE 51.7

## INBORN ERRORS OF METABOLISM

Disorder/Explanation	Incidence <sup>a</sup>	Clinical Manifestations	Management
Phenylketonuria (PKU): deficiency in a liver enzyme leading to inability to process the essential amino acid phenylalanine properly. Phenylalanine accumulation can lead to brain damage unless PKU is detected soon after birth and treated.	>1 in 25,000	No symptoms at birth. Most cases are identified before symptoms are present due to newborn screening (PKU is screened for in all states). If undiagnosed, newborn may present with vomiting, irritability, eczema-like rash, and mousy odor to urine.	Low-phenylalanine diet Phenylalanine is found mostly in protein-containing foods such as meat and milk (including breast milk and formula). <a href="http://www.pkunetwork.org">www.pkunetwork.org</a> : Children's PKU Network <a href="http://www.pkunews.org">www.pkunews.org</a> : National PKU News
Galactosemia: deficiency in the liver enzyme needed to convert galactose, the breakdown product of lactose, which is commonly found in dairy products, into glucose. Galactose accumulation leads to damage to vital organs.	>1 in 50,000	No symptoms at birth. If undiagnosed, newborn will have jaundice, diarrhea, and vomiting and will not gain weight. If untreated, can lead to liver disease, blindness, severe intellectual disability, and death.	Ingestion of galactose can produce sepsis in an affected child; therefore, septic workup and antibiotics may be necessary in a child if galactose ingestion has occurred. Elimination of galactose and lactose from the diet is the only treatment. Therefore, milk and dairy products will be eliminated for life. <a href="http://www.galactosemia.org">www.galactosemia.org</a> : Parents of Galactosemic Children
Maple sugar urine disease: affects the metabolism of amino acids. A deficiency in the enzyme that metabolizes leucine, isoleucine, and valine, which are components of protein often referred to as the branch chain amino acids. These amino acids then accumulate in the blood and cause damage to the brain.	<1 in 100,000	No symptoms at birth, but if untreated newborns soon begin to show neurologic signs, vomiting, poor feeding, increased reflex action, and seizures. If untreated, can lead to life-threatening neurologic damage	Special low-protein diet, will vary based on severity of symptoms Thiamine supplements may be given. Diet must be continued throughout life. <a href="http://www.msud-support.org">www.msud-support.org</a> : Maple Syrup Urine Disease Family Support Group
Biotinidase deficiency: lack of the enzyme biotinidase results in biotin deficiency	>1 in 75,000	No symptoms at birth; in first weeks or months of life, symptoms such as hypotonia, uncoordinated movement, seizures, developmental delay, alopecia, seborrheic dermatitis, hearing loss, optic nerve atrophy, and intellectual disability develop. Metabolic acidosis can lead to death.	Daily oral free biotin <a href="http://biotinidasedeficiency.20m.com/">http://biotinidasedeficiency.20m.com/</a> : Biotinidase Deficiency Family Support Group

(continued)

TABLE 51.7

## INBORN ERRORS OF METABOLISM (continued)

Disorder/Explanation	Incidence <sup>a</sup>	Clinical Manifestations	Management
Medium-chain acyl-CoA dehydrogenase deficiency (MCAD): lack of an enzyme required to metabolize fatty acids	>1 in 25,000	Recurrent episodes of metabolic acidosis and hypoglycemia, lethargy, seizures, liver failure, brain damage, coma, and cardiac arrest. Can lead to serious and fatal illness in children not eating well	Avoid fasting; have frequent meals. Special considerations during illness. If unable to tolerate food, IV dextrose is required. www.fodsupport.org: Fatty Oxidation Disorders (FOD) Family Support Group
Homocystinuria: deficiency in the enzyme needed to digest a component of food called methionine (an amino acid)	<1 in 100,000	If undetected and untreated can lead to intellectual disability, psychiatric disturbances, developmental delays, displacement of the lens of the eye, abnormal thinning and weakness of bones, and formation of thrombi in veins and arteries that can lead to life-threatening complications such as stroke	Methionine-restricted diet and cystine supplements; vitamin B <sub>6</sub> and B <sub>12</sub> supplements and possibly other supplements, such as betaine and folic acid www.rarediseases.org: National Organization for Rare Disorders
Tyrosinemia: deficiency in an enzyme essential in the metabolism of tyrosine; accumulation of the byproducts results in liver and kidney damage	<1 in 100,000	Symptoms usually appear in the first months of life: poor weight gain, enlarged liver and spleen, increased bleeding tendency, distended abdomen, jaundice, cirrhosis, and liver failure.	Diet low in phenylalanine, methionine, and tyrosine www.liverfoundation.org: American Liver Foundation
Tay-Sachs: caused by insufficient activity of an enzyme called hexosaminidase A, which is necessary for the breakdown of certain fatty substances in brain and nerve cells	Occurs more frequently among persons of Central and Eastern European and Ashkenazi Jewish descent. ~1 in every 27 Jews is a carrier, whereas in the general population 1 in 250 people is a carrier. <sup>b</sup> Non-Jewish French Canadians from the East St. Lawrence River Valley of Quebec and members of the Cajun population in Louisiana are also at an increased risk. These groups have about a 100 times higher incidence than other ethnic groups. <sup>c</sup>	Infants appear normal and healthy for the first few months of life. Then, as harmful quantities of the fatty substances (called gangliosides) build up in tissues and nerve cells and cause damage, mental and physical deterioration occur. The child becomes blind, deaf, and unable to swallow; muscles begin to atrophy; and paralysis sets in. Dementia, seizures, and an increased startle reflex may be seen. There is a late-onset type of Tay-Sachs seen in persons in their 20s and early 30s, but this is much rarer.	No treatment or cure. Medical management will focus on managing symptoms and maintaining comfort. Anticonvulsants may be given to control seizures. Death usually occurs in early childhood, by age 4 or 5. Carriers can be identified by a blood test and prenatal testing is available. www.ntsad.org: National Tay-Sachs & Allied Diseases Association

**EVIDENCE-BASED PRACTICE 51.1****EFFECTS OF GESTATIONAL AGE AND BIRTHWEIGHT ON FALSE-POSITIVE NEWBORN SCREENING RATES**

Newborn screening tests have improved outcomes and the health of infants and children. However, the rates of false-positive results are a concern. False-positive newborn screening results have been found to be higher among premature infants. What are the effects of gestational age and birthweight on false-positive newborn screening rates?

**STUDY**

A retrospective cohort study was conducted utilizing the Ohio State Newborn Screening Program Database; 455,125 newborn screens were reviewed. Gestational age, birthweight, and age in hours at time of collection were extracted.

**Findings**

False-positive rates were found to increase as gestational age and birthweight decreased with the exceptions of

increased false-positive rates for infants older than 42 weeks' gestational age. Very low-birthweight (VLBW) infants had a 13-fold higher false-positive rate compared with average-weight infants. One in 10 VLBW infants had a false-positive result. The study also found an increase in false-positive results among VLBW infants where specimen collection occurred before 48 hours.

**Nursing Implications**

Waiting to collect newborn screen specimens, in infants born at less than 32 weeks' gestation and nontransfused, until 24 to 48 hours postnatal age will potentially reduce false-positive results. Reducing false-positive rates in neonates would lead to decreased parental anxiety, improved cost effectiveness, and enhanced screening efficiency. Further studies are needed to investigate results of newborn screens collected at 48 hours postnatal age in infants born at less than 32 weeks' gestation.

Adapted from Slaughter, J. L., Meizen-Derr, J., Rose, S. R., Leslie, N. D., Chandrasekar, R., Linard, S. M., et al. (2010). The effects of gestational age and birth weight on false-positive newborn-screening rates. *Pediatrics*, 126(5), 910–916.

**KEY CONCEPTS**

- Nurses play an important role in the counseling process. Many times the nurse is the one who has first contact with these parents and is the one to provide follow-up care.
- The nurse must be able to identify those who could benefit from genetic counseling and must be able to discuss the role of the genetic counselor with families. Families at risk must be aware that genetic counseling is available before they attempt to have another baby.
- Nurses play an essential role in providing emotional support and referrals to appropriate agencies, support groups, and resources when caring for families with suspected or diagnosed genetic disorders.
- Referral for genetic counseling prior to genetic testing may be appropriate.
- Many children with chromosomal abnormalities have intellectual disability, learning disabilities, behavioral problems, and distinct features, including birth defects.
- Trisomy 21 (Down syndrome) is associated with some degree of intellectual disability, characteristic facial features (e.g., slanted eyes and depressed nasal bridge), and other health problems, such as cardiac defects, visual and hearing impairments, intestinal malformations, and an increased susceptibility to infections.
- In Turner syndrome, short stature and slow growth are characteristic findings.
- Klinefelter syndrome is usually diagnosed in adolescence or adulthood due to a lack of development of secondary sex characteristics.
- Fragile X syndrome's clinical manifestations are subtle during childhood, with minor dysmorphic features and developmental delay. Problems with sensation, emotion, and behavior often are the first signs.
- Café-au-lait spots (light-brown macules) are the hallmark of neurofibromatosis (Sahin, 2011).
- Inborn errors of metabolism are caused by gene mutations that result in abnormalities in the synthesis or catabolism of proteins, carbohydrates, or fats. Most inborn errors of metabolism presenting in the neonatal period are lethal if specific treatment is not initiated immediately.
- Nurses should have a basic knowledge of genetics, common genetic disorders in children, genetic testing, and genetic counseling so they can provide support and information to families and can help improve their quality of life.
- Genetic disorders usually result in a lifelong complex medical condition. Nurses must provide ongoing education and support for the child and family about the disorder, treatment, and management as well as available resources.

## MULTIPLE CHOICE QUESTIONS

1. You are counseling a couple, one of whom is affected by neurofibromatosis, an autosomal dominant disorder. They want to know the risk of transmitting the disorder. The nurse should tell them that each offspring has a:
  - a. One in four (25%) chance of getting the disease
  - b. One in eight (12.5%) chance of getting the disease
  - c. One in one (100%) chance of getting the disease
  - d. One in two (50%) chance of getting the disease
2. A child born with a single transverse palmar crease, a short neck with excessive skin at the nape, a depressed nasal bridge, and cardiac defects is most likely to have which autosomal abnormality?
  - a. Trisomy 21
  - b. Trisomy 18
  - c. Trisomy 14
  - d. Trisomy 13
3. A mother brings her 4-day-old infant to the clinic with vomiting and poor feeding. The newborn was healthy at birth. The nurse should suspect:
  - a. Sturge-Weber syndrome
  - b. An inborn error of metabolism
  - c. Trisomy 18
  - d. Turner syndrome
4. The nurse is caring for a child with Down syndrome. What should the nurse's focus be?
  - a. Teaching hygiene skills to the child in order to increase self-esteem
  - b. Screening for anomalies and teaching about prevention of respiratory infection
  - c. Finding opportunities to increase socialization for the child and family
  - d. Expecting walking at age 1 year and toilet training completion at age 2 years
5. The nurse is caring for a child with Turner syndrome admitted to the unit for treatment of a kidney infection. What characteristics associated with this syndrome may the nurse expect to find upon assessment?
  - a. Microcephaly, polydactyly
  - b. Low-set ears, cleft lip
  - c. Short stature, webbed neck
  - d. Gynecomastia, taller than average

## CRITICAL THINKING EXERCISES

1. An 8-month-old is seen in the clinic. On assessment the nurse finds eight café-au-lait spots on the child's trunk and extremities. What other assessment findings may be pertinent?
2. A child's newborn screen came back positive for phenylketonuria. After further testing, the diagnosis is confirmed. What instructions would you give the parents regarding care of their child?
3. A 6-year-old boy with Down syndrome is admitted to the hospital with pneumonia. Choose three pieces of information that the nurse should seek when obtaining the health history:
  - a. Presence of cardiac defects or disease
  - b. Last hearing and vision evaluation
  - c. Mother's pregnancy history
  - d. Presence of thyroid disease
  - e. Mother's immunization history

## STUDY ACTIVITIES

1. Develop a nursing care plan for a child with Down syndrome.
2. Shadow a genetic counselor. Identify ways he or she helps families understand and cope with genetic disorders.
3. Attend a meeting of an ethics committee at a local hospital. Identify some of the ethical, legal, and social issues in health care that they discuss, particularly related to genetic testing and genetic disorders.

# Nursing Care of the Child With a Cognitive or Mental Health Disorder

## Learning Objectives

Upon completion of the chapter, the learner will be able to:

1. Define the key terms used in this chapter.
2. Discuss the impact of alterations in mental health on the growth and development of infants, children, and adolescents.
3. Describe techniques used to evaluate the status of mental health in children.
4. Identify appropriate nursing assessments and interventions related to therapy and medications for the treatment of childhood and adolescent mental health disorders.
5. Distinguish mental health disorders common in infants, children, and adolescents.
6. Develop an individualized nursing care plan for the child with a mental health disorder.
7. Develop child/family teaching plans for the child with a mental health disorder.

*John Howard, age 6 years, is brought to the clinic for his annual examination. His father states, "John has frequent emotional outbursts and his mood seems to switch from happy to sad rather quickly. His teachers have said his performance at school has been poor."*

### **Words of Wisdom**

A child's sense often exceeds all human intellect.

**Mental** health issues make up the bulk of the “new morbidity” of children. Such issues include developmental and behavioral disorders, eating disorders, mood disorders, anxiety disorders, and abuse and **violence** (acts of aggression) directed toward children. As many as one in five children may be suffering from mental health–related problems, yet up to 80% of those children fail to receive the services they need, leading to further academic and social difficulties (American Academy of Pediatrics [AAP], 2012). Mental illness manifested in the early years increases the risk of adolescent emotional issues, use of firearms, reckless driving, substance abuse, and promiscuous sexual activity. Some cognitive or neurobehavioral disorders may have a genetic or physiologic cause, whereas others result from family or environmental stressors.

Usually children with cognitive or mental health disorders are treated in the community or on an outpatient basis, but sometimes the disorder has such a significant impact on the child and family that hospitalization is required. Many hospitalized children also suffer from cognitive or mental health disorders. When a child is diagnosed with a cognitive or mental health disorder, the family may become overwhelmed by the multifaceted services that he or she requires.

The scope of mental health issues among children, adolescents, and their families has become so extensive that the U.S. Surgeon General has published a “National Agenda for Action.” The Surgeon General’s Conference on Children’s Mental Health has set the following goals:

1. Promote public awareness of children’s mental health issues and reduce the stigma associated with mental illness.
2. Continue to develop, disseminate, and implement scientifically proven prevention and treatment services in the field of children’s mental health.
3. Improve the assessment of and recognition of mental health needs in children.
4. Eliminate racial/ethnic and socioeconomic disparities in access to mental health care services.
5. Improve the infrastructure for children’s mental health services, including support for scientifically proven interventions across professions.
6. Increase access to, and coordination of, quality mental health care services.
7. Train front-line providers to recognize and manage mental health issues, and educate mental health care providers about scientifically proven prevention and treatment services.
8. Monitor the access to and coordination of quality mental health care services (U.S. Public Health Service, 2000).

Mental health problems in children are real and painful and can be severe. For affected children to have a chance at a healthy future, nurses must participate in the early identification and referral of children with potential cognitive deficits or other mental health issues.

## EFFECTS OF MENTAL HEALTH ISSUES ON HEALTH AND DEVELOPMENT

Children’s behavior is influenced by biologic or genetic characteristics, nutrition, physical health, developmental ability, environmental and family interactions, the child’s individual temperament, and the parents’ or caregivers’ responses to the child’s behavior. The changes that occur with normal growth and development are often a source of stress for children, and in some children they may lead to dysfunction. Children progress at very different rates, so it is often difficult to identify subtle abnormalities. When stress, fatigue, or pain occurs in children, they may quickly regress to earlier patterns of behavior. These regressive behaviors may continue if a mental health concern is present. It is possible that stress placed on developing neurons leads to decreased coping abilities later in life. Children learn through their experiences. Therefore, they may develop maladaptive behaviors through life interactions (Stafford, 2011).

## COMMON MEDICAL TREATMENTS

A variety of medications and other medical and psychological treatments are used to treat mental health disorders in children. Most of these treatments will require a physician’s or nurse practitioner’s order when the child is in the hospital. The most common medications are listed in Drug Guide 52.1. The nurse caring for the child with a mental health disorder should become familiar with how the treatments and medications work, as well as medication adverse effects to monitor for. Many mental health disorders are treated with some type of therapy, including behavioral, play, family, and cognitive therapy. Table 52.1 reviews the types of therapies commonly used. These therapies are generally carried out only by specially trained personnel.

Behavior management techniques are also used to help children alter negative behavior patterns (Nurcombe, 2008). The methods may be used outside of therapy sessions, in the hospital, clinic, classroom, or home. Behavior management techniques include the following:

- Set limits with the child, holding him or her responsible for his or her behavior.
- Do not argue, bargain, or negotiate about the limits once established.
- Provide consistent caregivers (unlicensed assistive personnel and nurses for the hospitalized child) and establish the child’s daily routine.
- Use a low-pitched voice and remain calm.
- Redirect the child’s attention when needed.
- Ignore inappropriate behaviors.
- Praise the child’s self-control efforts and other accomplishments.
- Use restraints only when necessary.

**DRUG GUIDE 52.1 DRUGS USED FOR PEDIATRIC MENTAL HEALTH DISORDERS**

Medication	Actions/Indications	Nursing Implications
Psychostimulants: methylphenidate (Ritalin), dextroamphetamine (Adderall), lisdexamfetamine (Vyvanse), pemoline (Cylert), long-acting methylphenidate (Concerta, Focalin XR, Metadate CD, Ritalin LA), long-acting dextroamphetamine (Dexedrine Spansules, Adderall XR)	Increase synaptic levels of dopamine and norepinephrine ADHD	<ul style="list-style-type: none"> <li>• Methylphenidate has a short half-life; give TID (a.m., midday at school, at home after school).</li> <li>• Long-acting preparations are given once daily in the a.m.</li> <li>• Adverse effects: decreased appetite, headache, abdominal pain, difficulty sleeping, irritability, social withdrawal, motor tics. If dose is too high, child may have flat affect.</li> <li>• Vyvanse—if chest pain and fainting occur notify physician at once.</li> <li>• Pemoline is only rarely used because of hepatotoxicity.</li> </ul>
Antianxiety agent: buspirone (BuSpar)	Highly blocks reuptake of dopamine Anxiety, rage, mania, psychosis, depression, Tourette syndrome	<ul style="list-style-type: none"> <li>• Administer in consistent relation to food (either with or without).</li> <li>• May cause drowsiness.</li> <li>• Monitor for disinhibition, agitation, confusion, depression.</li> </ul>
Antimanic agent: lithium (Eskalith, Lithobid)	Influences reuptake of serotonin and/or norepinephrine Bipolar disorder, depression, hyperaggression	<ul style="list-style-type: none"> <li>• Monitor closely.</li> <li>• May cause polyuria, polydipsia, tremor, nausea, weight gain, diarrhea</li> </ul>
Selective serotonin reuptake inhibitors: fluoxetine (Prozac), paroxetine (Paxil), sertraline (Zoloft)	Potentiate serotonin activity in the brain Depression, obsessive-compulsive disorder, anxiety	<ul style="list-style-type: none"> <li>• Observe for irritability, insomnia, GI distress, nausea, headache.</li> <li>• Monitor BP for increase.</li> </ul>
Atypical antidepressants: trazodone (Desyrel)	Inhibit reuptake of serotonin Depression	<ul style="list-style-type: none"> <li>• Monitor BP for postural hypotension.</li> <li>• Observe for sedation and drowsiness; avoid alcohol use.</li> <li>• Administer after meals or with a snack.</li> </ul>
Nonstimulant norepinephrine reuptake inhibitors: atomoxetine (Strattera)	Enhance norepinephrine activity ADHD	<ul style="list-style-type: none"> <li>• Administer without regard to food once or twice daily.</li> <li>• Monitor weight, height, BP, heart rate.</li> <li>• May cause dizziness, dry mouth.</li> </ul>
$\alpha$ -Agonist antihypertensive agents: clonidine (Catapres), guanfacine (Tenex)	Activate inhibitory neurons in the brain stem ADHD, Tourette syndrome, self-abuse, aggression	<ul style="list-style-type: none"> <li>• Clonidine is strongly sedating.</li> <li>• Monitor BP and pulse.</li> <li>• Observe for dry mouth, confusion, depression, urinary retention, constipation.</li> </ul>
Antipsychotic agents: thioridazine (Mellaril), chlorpromazine (Thorazine), haloperidol (Haldol)	Reversibly block type 2 dopamine receptors in the central nervous system Psychosis, mania, self-harm, violent or destructive behavior	<ul style="list-style-type: none"> <li>• May cause drowsiness</li> <li>• Monitor for anticholinergic effects, drowsiness and dystonia (extrapyramidal effects), dizziness.</li> <li>• Evaluate for the development of orthostatic hypotension, tachycardia.</li> <li>• Observe closely for the development of tardive dyskinesia, particularly early in treatment.</li> </ul>

(continued)

**DRUG GUIDE 52.1 DRUGS USED FOR PEDIATRIC MENTAL HEALTH DISORDERS** (continued)

Medication	Actions/Indications	Nursing Implications
Atypical antipsychotics: risperidone (Risperdal), clozapine (Clozaril), olanzapine (Zyprexa)	Reversibly block type 2 dopamine receptors in the central nervous system Psychosis, bipolar disorder, autism spectrum disorder, Tourette syndrome	<ul style="list-style-type: none"> <li>• Monitor for seizures, agitation, headache, nausea, sedation.</li> <li>• Olanzapine may cause weight gain.</li> <li>• Note WBC count.</li> </ul>
Tricyclic antidepressants: amitriptyline (Elavil), desipramine (Norpramin), imipramine (Tofranil), nortriptyline (Pamelor)	Enhance synaptic concentration of serotonin and/or norepinephrine Depression, ADHD, tics, anxiety	<ul style="list-style-type: none"> <li>• Monitor for anticholinergic effects, weight loss.</li> <li>• Check blood levels.</li> <li>• Monitor ECG for arrhythmias.</li> </ul>

BP, blood pressure; ECG, electrocardiogram; GI, gastrointestinal; WBC, white blood cell.

Leckman (Eds.), *Current diagnosis & treatment: Psychiatry* (2nd ed.). New York, NY: McGraw-Hill; and Varcarolis, E. M. (2011). *Manual of psychiatric nursing care planning: Assessment guides, diagnoses, and psychopharmacology* (4th ed.). St. Louis, MO: Saunders.

TABLE 52.1

TYPES OF THERAPY

Treatment	Explanation
Behavioral therapy	Uses stimulus and response conditioning to manage or alter behavior. Reinforces desired behaviors, replacing the inappropriate ones. Consistency is of utmost importance.
Play therapy	Designed to change emotional status. Encourages the child to act out feelings of sadness, fear, hostility, or anger.
Cognitive therapy	Teaches children to change reactions so that automatic negative thought patterns are replaced with alternative ones.
Family therapy	Exploration of the child's emotional issue and its effect on family members.
Group therapy	May be conducted in a school, hospital, treatment facility, or neighborhood center. Feelings are expressed and participants gain hope, feel a part of something, and benefit from role modeling. Takes advantage of peer relationships as developmental focus in preteen and teen groups.
Milieu therapy	A specially structured setting designed to promote the child's adaptive and social skills. A safe and supportive environment for those at risk for self-harm or those who are very ill or very aggressive.
Individual therapy	The child and therapist work together to resolve the conflicts, emotions, or behavior problems. Trust is central. Structured based on the child's developmental level (e.g., may use play therapy for a younger child).
Hypnosis	Deep relaxation with suggestibility remarks.

Adapted from Nurcombe, B. (2008). Diagnostic formulation, treatment planning, and modes of treatment in children and adolescents. In M. H. Ebert, P. T. Loosen, B. Nurcombe, & J. F. Leckman (Eds.), *Current diagnosis & treatment: Psychiatry* (2nd ed.). New York, NY: McGraw-Hill; and Varcarolis, E. M. (2011). *Manual of psychiatric nursing care planning: Assessment guides, diagnoses, and psychopharmacology* (4th ed.). St. Louis, MO: Saunders.

## NURSING PROCESS OVERVIEW FOR THE CHILD WITH A MENTAL HEALTH DISORDER

Care of the child with a mental health disorder includes assessment, nursing diagnosis, planning, interventions, and evaluation. There are a number of general concepts related to the nursing process that may be applied to mental health concerns in children. From a general understanding of the care involved for a child with a mental health disorder, the nurse can then individualize the care based on specifics for each child.

### Assessment

A careful and thorough health history forms the basis of the nursing assessment of a child with a mental health or cognitive disorder. The physical examination may yield clues to the type of disorder, but the physical examination is often completely normal (except in cases of physical or sexual abuse).

#### Take Note!

Observe a child's play or drawings; if the manner or theme of play or nature of the drawings leads you to suspect cognitive or psychological issues, refer the child for further mental health evaluation.

### Health History

Elicit the health history, noting the child's prenatal and birth history, past medical history (including previously diagnosed cognitive or mental health disorders), history of neurologic injury or disease, and family history of mental health disorder. Perform a developmental history, noting age of attainment (or loss) of milestones. Question the child and/or parent about behavior changes such as:

- Altered sleep
- Difference in eating patterns, weight loss or gain, change in appetite
- Problems at school
- Participation in risk-taking behaviors
- Alterations in friendships
- Changes in extracurricular activity participation

Note results of any developmental testing performed. Ask the family about progression of the child's skills. Note any unusual deficits or capabilities. Question the family about recent stress, trauma, or change in family structure. Ask if any family members are chronically ill. Note medications the child takes routinely, and ask about any allergies to food, drugs, medications, or environmental agents.

Interview the child at an age-appropriate level to determine his or her self-perception, future plans, and stressors and how he or she copes with them. Determine

the child's perception of his or her relationship with parents, siblings, friends, peers, pets, inanimate objects, and transitional or security objects. What is the child's predominant mood? Determine whether the child likes himself or herself, asking such questions as "What do you like most about yourself?" and "What would you like to change about yourself?" Determine whether the child has a sense of pride in his or her accomplishments. Has the child developed an appropriate conscience (with understanding of right and wrong)? Determine the child's gender identity status.

Document if the child displays any of the following during the health interview:

- Hallucinations
- Aggression
- Impulsivity
- Distractibility
- Intolerance to frustration
- Lack of sense of humor or fun
- Inhibition
- Poor attention span
- Potential cognitive or learning disabilities
- Unusual motor activities

Note history of physical complaints that may be associated with physical abuse such as burns or other injuries or with sexual abuse situations, such as sore throat, difficulty swallowing, or genital burning or itching.

**Remember John, the 6-year-old brought in for his annual examination? What additional health history and physical examination assessment information should the nurse obtain?**

### Physical Examination

Observe the child's clothing, noting whether it is appropriate for age, developmental level, and setting. Note the child's facial expression and response to the parent or caretaker and the nurse. Does the child make appropriate eye contact? Determine the child's level of consciousness and extent of interest in and interaction with surroundings. Note the child's posture, **affect** (facial emotional display), and mood. How appropriate to the situation are the child's emotional reactions? Does the child communicate well?

Measure the child's weight and height/length, as well as head circumference if he or she is younger than 3 years old. Perform a thorough physical examination, noting any physical abnormalities or signs of other physical health disorders. Note abnormal findings that may be associated with particular mental health disorders, such as bruising, burns, contusions, cuts, abrasions, unusual skin marks, soft/sparse body hair, split fingernails, inflamed

oropharynx, eroded tooth enamel, reddened gums, or genitourinary discharge or bleeding.

### Laboratory and Diagnostic Testing

Mental health disorders are generally diagnosed based on clinical features. However, brain imaging such as computed tomography or magnetic resonance imaging may be used to evaluate for a congenital abnormality or alterations in the brain tissue that may lead to developmental delay. A blood or urine toxicology panel is useful in the diagnosis of drug abuse or overdose, or instances of bizarre behavior.

## Nursing Diagnoses and Related Interventions

The overall goal of nursing management of cognitive and mental health disorders in children is to help the child and family to reach an optimal level of functioning. This may be achieved through interventions designed to decrease the impact of stressors on the child's life. Upon completion of a thorough assessment of the child and family, the nurse might identify several nursing diagnoses, including:

- Impaired social interaction
- Delayed growth and development
- Ineffective individual coping
- Hopelessness
- Imbalanced nutrition, less than body requirements
- Disturbed thought processes
- Caregiver role strain

**After completing an assessment of John, the nurse noted the following: difficulty sitting still for the examination, easily distracted and frustrated, labile mood. Based on the assessment findings, what would your top three nursing diagnoses be for John?**

Nursing goals, interventions, and evaluation for the child with a mental health disorder are based on the nursing diagnoses. Nursing Care Plan 52.1 provides a general guide for planning care for a child with a mental health disorder. Children's responses to a mental health issue and its treatment will vary, and nursing care should be individualized based on the child's and family's responses to illness. Additional information about nursing management will be included later in the chapter as it relates to specific disorders. See Healthy People 2020.

**Based on your top three nursing diagnoses for John, describe appropriate nursing interventions.**

## HEALTHY PEOPLE 2020

### Objective

Increase the proportion of children with mental health problems who receive treatment.

### Nursing Significance

- Screen all children and adolescents for mental health problems.
- Encourage children and adolescents to participate in treatment planning as is developmentally appropriate, allowing them to make choices about intervention as possible.

*Healthy People Objectives based on data from <http://www.healthypeople.gov>.*

## DEVELOPMENTAL AND BEHAVIORAL DISORDERS

Developmental and behavioral disorders make up a large proportion of mental health disorders in children. They include learning disabilities, intellectual disability, autism spectrum disorder, and attention deficit/hyperactivity disorder.

## Learning Disabilities

About 8% of children age 3 or older have learning disabilities (Kelly & Natale, 2011). About half of the children with a learning disability have at least one other comorbid condition (usually a mental health or behavioral disorder). The National Center for Learning Disabilities (2012) defines a learning disability as “a neurological disorder that affects the brain's ability to receive, process, store and respond to information.” Learning disabilities become evident when a child of average intelligence has difficulty mastering basic academic skills. Learning disabilities can affect the child's ability to listen, speak, read, write, and perform mathematics. For example:

- Children with dyslexia have difficulty with reading, writing, and spelling.
- Children with dyscalculia have problems with mathematics and computation.
- Children with dyspraxia have problems with manual dexterity and coordination.
- Children with dysgraphia have difficulty producing the written word (composition, spelling, and writing).

### Take Note!

Sensory processing disorder may be mistaken for a learning disability, but it is not and should be treated differently (see Box 52.1).

## NURSING CARE PLAN 52.1

## Overview for the Child With a Mental Health Disorder

**NURSING DIAGNOSIS:** Impaired social interaction related to altered social skills as evidenced by impulsivity, intrusive behavior, inability to follow through, anxiety, depressed mood, feelings of unattractiveness or unworthiness

**Outcome Identification and Evaluation**

The child will demonstrate socially acceptable skills, *interacting successfully with peers and in the educational setting, completing tasks as required.*

**Interventions: Promoting Appropriate Social Interaction**

- Identify factors that may aggravate the child's performance *to minimize stimuli that exacerbate the child's undesired behaviors.*
- Modify the environment to decrease distracting stimuli *as the child's ability to deal with external stimuli may be impaired.*
- Ensure that the child hears his or her name and makes eye contact prior to conversing or instructions *so that the child is engaged and has increased ability to follow through.*
- State expectations for tasks or behaviors clearly *as understanding is necessary to ensure completion.*
- Provide positive feedback for appropriate behaviors or task completion, *encouraging the child to adopt expectations into his behaviors and routine.*

**NURSING DIAGNOSIS:** Ineffective individual coping related to inability to deal with life stressors as evidenced by few or no meaningful friendships, inability to empathize or give/receive affection, low self-esteem, or maladaptive coping behaviors such as substance abuse

**Outcome Identification and Evaluation**

The child will demonstrate improved coping, *verbalize feelings, socially engage, demonstrate problem-solving skills.*

**Interventions: Promoting Coping Skills**

- Encourage discussion of thoughts and feelings, *as this is an initial step toward learning to deal with them appropriately.*
- Provide positive feedback for appropriate discussion, *as this increases the likelihood of continuing performance.*
- Demonstrate unconditional acceptance of the child as a person *to increase self-esteem in the child who has been feeling rejection.*
- Set clear limits on behavior as needed *so the child has a structure to adhere to.*
- Teach the child problem-solving skills *as an alternative to acting-out behaviors.*
- Role model appropriate social and conversation skills *so the child can see what is expected in a nonthreatening manner.*

(continued)

## NURSING CARE PLAN 52.1

**Overview for the Child With a Mental Health Disorder** (continued)

**NURSING DIAGNOSIS:** Imbalanced nutrition, less than body requirements, related to intake insufficient to meet metabolic needs as evidenced by weight loss, failure to gain weight, less-than-expected increases in stature and weight, loss of appetite, or refusal to eat

**Outcome Identification and Evaluation**

The child or adolescent will demonstrate appropriate growth, *making gains in weight and stature as appropriate.*

**Interventions: Improving Nutritional Intake**

- Provide favorite foods to *encourage the child with poor appetite to eat more.*
  - Assist families to choose nutrient-rich foods so that *the food the child does eat is most beneficial.*
- For the child with an eating disorder:
- Mutually establish a contract related to treatment to *promote the child's sense of control.*
  - Provide mealtime structure, *as clear limits let the child know what the expectations are.*
  - Encourage the child to choose foods and timing of meals *to develop independence in eating habits.*
  - Ensure the eating environment is pleasant and relaxed, with minimal distractions, *to minimize the child's anxiety and guilt about not eating.*
  - Withdraw attention if the child refuses to eat: *secondary gain is minimized if refusal to eat is ignored.*
  - Provide continuous supervision during the meal and for 30 minutes following it so that the child cannot conceal or dispose of food or induce vomiting.

**NURSING DIAGNOSIS:** Delayed growth and development related to disability, behavioral disorder, or altered nutrition as evidenced by lack of attainment of age-appropriate skills, regression in skills, or altered intellectual functioning

**Outcome Identification and Evaluation**

Child will demonstrate progress toward developmental milestones: *child expresses interest in the environment and people around him or her, interacts with environment in an age-appropriate way.*

**Interventions: Promoting Development**

- Use therapeutic play and adaptive toys *to facilitate developmental functioning.*
- Provide stimulating environment when possible *to maximize potential for growth and development.*
- Praise accomplishments and emphasize the child's abilities *to improve self-esteem and encourage feelings of confidence and competence.*
- Follow through with physical, occupational, and speech therapists' recommendations *to maximize exposure to exercises designed to increase the child's skills.*
- Determine parents' expectations of the child's future achievement *to help them work toward these goals.*

## NURSING CARE PLAN 52.1

**Overview for the Child With a Mental Health Disorder** (continued)

**NURSING DIAGNOSIS:** Disturbed thought processes related to behavioral disorder, depression, anxiety, abusive situation, or substance abuse as evidenced by distractibility, non–reality-based thinking, hypervigilance, or inaccurate interpretation of interactions of others

**Outcome Identification and Evaluation**

Child's thought processes will improve: *child will demonstrate appropriate orientation, remain free from physical harm, and perform activities of daily living as able.*

**Interventions: Improving Thought Processes**

- Observe for causes of altered thought processes *to provide a baseline for assessment and intervention.*
- Perform an age-appropriate mental status examination *to determine extent of altered thinking.*
- Adjust communication style based on the child's cues *to improve communication.*
- Listen carefully and seek clarification *to determine basis for the child's agitation or other behaviors.*
- Provide validation of the child's thoughts and feelings *to improve trust in the relationship.*
- Establish a daily routine *to provide the child with a sense of security.*

**NURSING DIAGNOSIS:** Hopelessness related to child's perception of his or her life situation, negative life view, or alteration in mental well-being as evidenced by passivity, verbalization, alterations in sleep, or lack of initiative

**Outcome Identification and Evaluation**

Child will display a sense of hope: *will verbalize feelings, participate in care, make positive statements.*

**Interventions: Promoting Hope**

- Monitor and document potential for suicide, *as hopelessness often leads to suicidal ideation.*
- Assist the child to identify reasons for hope and for living, *so the nurse is aware of the child's values.*
- Help the child to set goals that are important to him or her *to allow the child to see possibilities.*
- Encourage simple decision making on a daily basis, *as hopelessness often occurs as a response to loss of control.*
- Assist the child to identify positive qualities in himself or herself and his or her life *to facilitate the development of hope.*
- Involve parents or others the child loves in the child's care *as social support is critical to the development of hope.*

(continued)

## NURSING CARE PLAN 52.1

## Overview for the Child With a Mental Health Disorder (continued)

**NURSING DIAGNOSIS:** Caregiver role strain related to long-term care of the child with a chronic mental health disorder as evidenced by fatigue, inattention to own needs, conflict, or ambivalence

### Outcome Identification and Evaluation

The child's caregiver will participate in the child's care, *verbalizing the child's needs and treatment plan and demonstrating skills necessary for care.*

### Interventions: Decreasing Role Strain

- Teach the parent or caregiver about the child's illness, treatments, and medications *to clarify expectations for the child and parent.*
- Role model appropriate interaction behaviors with the child *so the parent can learn these techniques by watching.*
- Encourage structure in daily routines *to allow the parent to meet his or her own needs and allow for adequate rest.*
- Gradually increase the parent's responsibility related to care of the child *to help the parent feel less overwhelmed.*
- Allow the parent to move at his or her own pace in assuming care *to enhance the chances for success.*
- Help the parent to identify a back-up caregiver *so the parent has times of respite from constant involvement with the child.*

## Therapeutic Management

Therapeutic management may involve remedial or compensatory approaches or may use interventions directed toward social-emotional problems. The focus of the remedial approach is to improve specific skills. The compensatory approach helps the child to compensate for the disability, rather than attempting to directly correct it. Social-emotional problems may result from frustration or low self-esteem related to capabilities. These may respond to supportive interventions and improvement in

coping. Occasionally they may be as severe as to warrant pharmacotherapy (Tramontana, 2008).

## Nursing Assessment

Elicit the health history, noting risk factors such as a family history of learning disability, problems during pregnancy or birth, prenatal alcohol or drug use, low birthweight, premature or prolonged labor, head injury, poor nutritional status or failure to thrive, or lead poisoning. Obtain detailed information about the educational difficulties the child is experiencing (e.g., he or she seems to do fine in math but always reverses letters when reading). A thorough physical examination may reveal clues to comorbid conditions. Ensure that the child has undergone a comprehensive education evaluation with assessment testing to diagnose the specific learning disability. Testing may be performed by a school, educational, developmental, or clinical psychologist; occupational therapist; speech and language therapist; or other developmental specialist, depending on the areas of learning with which the child is experiencing difficulty.

### BOX 52.1

#### SENSORY PROCESSING DISORDER (ALSO CALLED SENSORY INTEGRATION DYSFUNCTION)

- A neurologic disorder in which the child cannot organize sensory input used in daily living
- Hyposensitivity or hypersensitivity to sensory input
- Results in overreaction to different textures, decreasing the child's ability to participate in the world
- Preterm and low-birthweight infants are at increased risk compared with typical infants.
- Occupational and other therapies may increase the child's ability to function.

Adapted from Sensory Processing Disorder Foundation. (2012). *About SPD*. Retrieved July 6, 2012, from <http://www.spdfoundation.net/about-sensory-processing-disorder.html>

#### Take Note!

If a child cannot speak in sentences by 30 months of age, does not have understandable speech 50% of the time by age 3 years, cannot sit still for a short story by 3 to 5 years of age, or cannot tie shoes, cut, button, or hop by 5 to 6 years of age, refer the child to be evaluated for a learning disability.

## Nursing Management

Ensure that families are aware of their child's rights under the Individuals with Disabilities Act (IDEA), which was reapproved in 2004 (108th Congress, 2004). IDEA offers protection from discrimination and the right to assistance in the school or workplace. Each child will need an individualized education plan (IEP) that reflects his or her particular needs, which then must be provided for through the school system. Offer encouragement and support to families as they advocate for their child. Follow up at subsequent health care visits to determine that the child is receiving the services he or she needs to optimize his or her potential for success. Refer families for additional resources through the National Center for Learning Disabilities, Learning Disabilities Online, or the Center for Learning Differences (links to these resources are provided on [thePoint](#)).

### Intellectual Disability

Intellectual disability refers to a functional state in which significant limitations in intellectual status and adaptive behavior (functioning in daily life) develop before the age of 18 years. About 2% of the population may be designated as intellectually disabled (NICHCY National Dissemination Center for Children with Disabilities, 2011).

As defined by the American Association on Intellectual and Developmental Disability (AAIDD) (2012), intellectual disability includes:

- Deviations in IQ of two or more standard deviations (IQ of less than 70 to 75)
- Coexisting deficits in at least two adaptive skills: communication, community use, functional academics, health and safety, home living, leisure, self-care, self-direction, social skills, and work
- Disability occurring before the age of 18 years

Long ago persons with intellectual disability (formerly termed mentally retarded) were confined to institutions and were thought to be harmful to society. In the early 21st century, most children with intellectual disability are receiving their education in public schools with their peers and living at home with their families or elsewhere in the community. Only the most severely affected individuals require separate classrooms or schools.

## Pathophysiology

In many instances of intellectual disability the exact cause remains unknown. Prenatal errors in central nervous system development may be responsible. Other potential causes include an insult or damage to the brain during the prenatal, perinatal, or postnatal period. Prenatal exposure to alcohol or other drugs may impact cognitive development as well. Motor problems such as hyper- or

hypotonia, tremor, ataxia, or clumsiness, or visual motor problems may occur concomitantly with intellectual disability. In addition, functioning at a higher level may be prevented when a learning disability or sensory processing impairment is also present. Intellectual disability is generally categorized according to severity:

- Mild: IQ 50 to 70
- Moderate: IQ 35 to 50
- Severe: IQ 20 to 35
- Profound: IQ less than 20 (Council for Exceptional Children, 2011)

## Therapeutic Management

The primary goal of therapeutic management of children with intellectual disability is to provide appropriate educational experiences that allow the child to achieve a level of functioning and self-sufficiency needed for existence in the home, community, work, and leisure settings. A multidisciplinary approach may be used and the child's conceptual, social, practical, and intellectual abilities will drive school placement and the focus of the educational experience. The majority of individuals with intellectual disability require only minimal support in the school or home setting, and these individuals are able to achieve some level of self-sufficiency. Only a few children and adults with intellectual disability require extensive support and require long-term caretaking.

## Nursing Assessment

Perform developmental screening at each health care visit to identify developmental delays early. Elicit the health history, determining the mental and adaptive capacities of the child's parents and other family members. Obtain a detailed pregnancy and birth history. Document sequence and age of attainment of developmental milestones. Note history of motor, visual, or language difficulties. Assess the child's health history for risk factors such as preterm or postterm birth, low birthweight, birth injury, prenatal or neonatal infection, prenatal alcohol or drug exposure, genetic syndrome, chromosomal alteration, metabolic disease, exposure to toxins (e.g., lead), head injury or other trauma, nutritional deficiency, cerebral malformation, and other brain disease or mental health disorder. Note history of or concomitant seizure disorder, orthopedic problems, speech problems, or vision or hearing deficit.

For the child with known intellectual disability, assess language, sensory, and psychomotor functioning. Determine the child's ability to toilet, dress, and feed himself or herself. Ask the parents about involvement with school and community services and support.

On physical examination note dysmorphic features (possibly very mild) consistent with certain syndromes (e.g., fetal alcohol syndrome; see Box 52.2). Evaluate

## BOX 52.2

**FETAL ALCOHOL SYNDROME**

- Results from in utero alcohol exposure
- Typical facial features include low nasal bridge with short upturned nose, flattened midface, long philtrum with narrow upper lip
- Poor coordination, skeletal abnormalities
- Microcephaly
- Failure to thrive
- Hearing loss

Adapted from Goldson, E., & Reynolds, A. (2011). Child development and behavior. In W. W. Hay, M. J. Levin, J. M. Sondheimer, & R. R. Detering (Eds.), *Current pediatric diagnosis and treatment* (20th ed.). New York, NY: McGraw-Hill.

the newborn or metabolic screening results. Computed tomography or magnetic resonance imaging of the head may be performed to evaluate the brain structure. Thyroid function tests may be ordered to rule out thyroid problems leading to developmental delay.

**Take Note!**

Due to the extent of cognition required to understand and produce speech, the most sensitive early indicator of intellectual disability is delayed language development.

**Nursing Management**

When children with intellectual disability are admitted to the hospital (usually for some other physical or medical condition), it is important for the nurse to continue the child's usual home routine. Follow through with feeding and motor supports that the child uses. Ensure that the child is closely supervised and remains free from harm. Allow parents time to verbalize frustrations or fears. For some families the caretaking burden is extensive and lifelong; arrange for respite care as available. Support the child's strengths, and assist the child and family to follow through with therapy or treatment designed to enhance the child's functioning. Assist with the development of the child's IEP as appropriate.

**Autism Spectrum Disorder**

Autism spectrum disorder (ASD), also termed pervasive developmental disorder, has its onset in infancy or early childhood. One child in 150 is affected by autism spectrum disorder (Inglese, 2009). The spectrum of autism disorder ranges from mild (e.g., Asperger syndrome) to severe. Autistic behaviors may be first noticed in infancy as developmental delays or between the age of 12 and 36 months when the child regresses or loses previously

acquired skills. Parental concerns about development may be sensitive indicators of the development of autism.

**Pathophysiology**

The exact etiology of autism continues to elude scientists, but it may be due to genetic makeup, brain abnormalities, altered chemistry, a virus, or toxic chemicals. Children with ASD display impaired social interactions and communication as well as perseverative or stereotypic behaviors. They may fail to develop interpersonal relationships and experience social isolation. Many children with autism are intellectually disabled, requiring lifelong supervision, though some are gifted (Rizzolo & Cerciello, 2009).

**Therapeutic Management**

There are no medications or treatments available to cure autism. The goal of therapeutic management is for the child to reach optimal functioning within the limitations of the disorder. Each child's treatment is individualized; behavioral and communication therapies are very important. Children with ASD respond very well to highly structured educational environments. Stimulants may be used to control hyperactivity, and antipsychotic medications are sometimes helpful in children with repetitive and aggressive behaviors.

Many families are drawn to the use of complementary and alternative medical therapies in attempts to treat their autistic child. They may use vitamins and nutritional supplements, herbs or restrictive diets, music therapy, art therapy, and sensory integration techniques. To date, these therapies have not been scientifically proven to improve autism (Inglese, 2009).

**Nursing Assessment**

Elicit the health history, noting delay or regression in developmental skills, particularly speech and language abilities. The child may be mute, utter only sounds (not words), or repeat words or phrases over and over. The parent may report that the infant or toddler spends hours in repetitive activity and demonstrates bizarre motor and stereotypic behaviors. The infant may resist cuddling, lack eye contact, be indifferent to touch or affection, and have little change in facial expression. Toddlers may display hyperactivity, aggression, temper tantrums, or self-injury behaviors, such as head banging or hand biting. The history may also reveal hypersensitivity to touch or hyposensitivity to pain. Assess the child's functional status, including behavior, nutrition, sleep, speech and language, education needs, and developmental or neurologic limitations (Inglese, 2009). Assist with screening, using an approved autism screening tool such as:

- Checklist for Autism in Toddlers (CHAT)
- Modified Checklist for Autism in Toddlers (M-CHAT)

- Social Communication Questionnaire (SCQ)
- Pervasive Developmental Disorders Screening Test-II (PDDST-II)

Perform a thorough physical examination. Observe the infant or toddler for lack of eye contact, failure to look at objects pointed to by the examiner, failure to point to himself or herself, failure to let his or her needs be known, perseverative play activities, and unusual behavior such as hand flapping or spinning. Measure growth parameters, in particular noting head circumference (macrocephaly or microcephaly may be associated with ASD). Note the presence of large, prominent, or posteriorly rotated ears. Examine the skin for hypo- or hyperpigmented lesions. Note asymmetry of nerve function or palsy, hypertonia, hypotonia, alterations in deep tendon reflexes, toe-walking, loose gait, or poor coordination. Obtain hearing screening results and ascertain that lead screening has been performed.

### Take Note!

Screen all infants and toddlers for warning signs of autism:

- Not babbling by 12 months
- Not pointing or using gestures by 12 months
- No single words by 16 months
- No two-word utterances by 24 months
- Losing language or social skills at any age (Smith, Segal, & Hutman, 2012)

## Nursing Management

When children are initially diagnosed with autism, provide parents with an extensive amount of emotional support, professional guidance, and education about the disorder while they are attempting to adjust to the diagnosis. Assess the fit between the child's developmental needs and the treatment plan. Help parents overcome barriers to obtain appropriate education, developmental, and behavioral treatment programs. Ensure that the child younger than 36 months of age receives services via the local early intervention program and children 3 years and older have an IEP in place if enrolled in the public school system. Stress the importance of rigid, unchanging routines, as children with ASD often act out when their routine changes (which is likely to occur if the child must be hospitalized for another condition). Many special schools exist for children with significant developmental disorders, though some are extremely expensive. Assess the parents' need for respite care and make referrals accordingly. Provide positive feedback to parents for their perseverance in working with their child.

## Attention Deficit/Hyperactivity Disorder

Attention deficit/hyperactivity disorder (ADHD) is one of the most common mental health disorders diagnosed in childhood: it affects 7% to 10% of all children, and up to 5% of adults (Vessey & Wilkinson, 2008). ADHD is characterized by inattention, impulsivity, distractibility, and hyperactivity. Three subtypes of ADHD exist: hyperactive-impulsive, inattentive, and combined. The child with ADHD has a disruption in learning ability, socialization, and compliance, placing significant demands on the child, parents, teachers, and community. About 50% to 60% of children with ADHD also have a **comorbidity** (disorder accompanying the primary illness) such as oppositional defiant disorder, conduct disorder, an anxiety disorder, depression, a less severe developmental disorder, an auditory processing disorder, or learning or reading disabilities (Ryan-Krause, 2010a). Comparison Chart 52.1 gives information about oppositional defiant disorder and conduct disorder to distinguish them from ADHD.

## Pathophysiology

Though the exact cause of ADHD remains unidentified, current thought includes as its etiology an alteration in the dopamine and norepinephrine neurotransmitter system. The symptoms of impulsivity, hyperactivity, and inattention begin before 7 years of age and persist longer than 6 months. Symptoms exist in the school and home settings, impairing family and social interactions. Children and teens with ADHD experience frustration, labile moods, emotional outbursts, peer rejection, poor school performance, and low self-esteem. They may also have poor metacognitive abilities such as organization, time management, and the ability to break a project down into a series of smaller tasks. They are not lazy or unmotivated, but simply have poor skills in these areas. Box 52.3 provides criteria for the diagnosis of ADHD (Ryan-Krause, 2010a).

## Therapeutic Management

Medication management of ADHD includes the use of psychostimulants, nonstimulant norepinephrine reuptake inhibitors, and/or  $\alpha$ -agonist antihypertensive agents. These medications are not a cure for ADHD, but help to increase the child's ability to pay attention and decrease the level of impulsive behavior. The child's activity level is not usually affected. Behavior therapy and classroom restructuring may be useful as part of the therapeutic management plan. Since ADHD manifests into young adulthood, management should continue throughout adolescence (Vessey & Wilkinson, 2008). Concomitant disorders, such as anxiety, should also be treated (see discussion of anxiety disorders below).

## COMPARISON CHART 52.1

## OPPOSITIONAL DEFIANT DISORDER VERSUS CONDUCT DISORDER

## Oppositional Defiant Disorder

- Excessive arguing with adults
- Frequent temper tantrums
- Active defiance
- Revenge-seeking behaviors
- Frequent resentment or anger
- Touchiness; easily annoyed
- Noncompliance with adult requests or limits
- Blaming of others for misbehavior or mistakes

## Conduct Disorder

- Bullying and threatening of others
- Initiation of physical fights
- Weapon use to cause others harm
- Physical cruelty to animals or people
- Destruction of property or arson
- Lying and stealing
- Serious violation of rules: staying out past curfew, truancy, running away
- Use of force in sexual activity

Adapted from Stafford, B. (2011). Child & adolescent psychiatric disorders & psychosocial aspects of pediatrics. In W. W. Hay, M. J. Levin, J. M. Sondheimer, & R. R. Deterding (Eds.), *Current pediatric diagnosis and treatment* (20th ed.). New York, NY: McGraw-Hill.

## BOX 52.3

## DIAGNOSIS OF ATTENTION DEFICIT/HYPERACTIVITY DISORDER

Presence of six or more of the following:

- Failure to pay close attention
- Careless mistakes on schoolwork
- Difficulty paying attention to tasks or play
- Doesn't listen
- Doesn't follow through
- Doesn't complete tasks
- Doesn't understand instructions
- Poorly organized
- Avoids, dislikes, or fails to engage in activities requiring mental effort
- Loses things needed for task completion
- Easily distracted
- Forgetful

Presence of six or more of the symptoms of hyperactivity or impulsivity:

- Fidgety or squirmy
- Often out of seat
- Activity inappropriate to the situation
- Cannot engage in quiet play
- Always on the go
- Talks excessively
- Blurts out answers
- Has difficulty waiting his or her turn
- Often interrupts or intrudes on others<sup>a</sup>

Adapted from Ryan-Krause, P. (2010). Attention deficit hyperactivity disorder: Part I. *Journal of Pediatric Health Care*, 24, 194–198.

## Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1893. Assessment findings pertinent to ADHD are discussed below.

## Health History

Elicit a description of the behavioral issue or school performance problem. Explore the child's history for risk factors such as head trauma, lead exposure, cigarette smoke exposure, prematurity, or low birthweight. The past history may also reveal a larger than usual number of accidents. Determine if there is a family history of ADHD. Question the parent about school behavior. The school-age child may be unable to stay on task, talks out of turn, leaves his or her desk frequently, and either neglects to complete in-class and homework assignments or forgets to turn them in. The adolescent may be inattentive in school, poorly organized, and forgetful.

Several behavioral checklists are available that may assist in the diagnosis of ADHD. They may be completed by the child's teacher and/or parent and focus on behavior patterns related to conduct or learning problems, social competence, anxiety, activity level, and attention. Obtain the completed behavioral checklists (usually one from the parent and one from the teacher) as well as any school records or testing performed.

## Physical Examination

Perform vision and hearing screening to rule out vision or hearing impairment as the cause of poor school performance. Observe the preschool child's behavior, noting

quickness, agility, fearlessness, and the desire to touch or explore everything in the room. The older child or adolescent may have difficulty staying on task during the exam or change the subject frequently while conversing.

### Laboratory and Diagnostic Tests

No definitive laboratory or diagnostic test is available for the identification of ADHD. A complete blood count may be performed to rule out anemia, and thyroid hormone levels may be drawn to determine whether they are normal.

## Nursing Management

Having a child with ADHD can be frustrating as the child's inattention, high activity level, impulsivity, and distractibility are often very difficult to deal with. Parents may doubt their ability to be effective parents or may view their child as somehow defective. Children with ADHD may also feel they are bad, faulty, stupid, or intellectually challenged. Provide emotional support, allowing enough time for the family to air their concerns. Work with the child and family to develop goals such as completion of homework, improved communication, or increasing independence in self-care.

Assist the family to advocate for their child's needs through the public school system. The child is entitled to a developmentally appropriate education via an IEP as necessary (refer to Chapter 33 for additional information about special education). The IEP should be updated as needed. Ensure coordination of health and school services. Flag the child's chart and set up a schedule for systematic communication with the family and school. Teach families and school personnel to use behavioral techniques such as time-out, positive reinforcement, reward or privilege withdrawal, or a token system. The token system rewards appropriate behavior with a token and results in a token being taken away if inappropriate behavior occurs. At the end of a specified period of time, the tokens may be exchanged for a prize or privilege. Refer families to local support groups and the national ADHD support group, links to which are provided on [thePoint](#).

Explain that stimulant medications should be taken in the morning to decrease the adverse effect of insomnia. Some children may experience decreased appetite, so giving the medication with or after the meal may be beneficial. The child may feel "different" from his or her peers if he or she has to visit the school nurse for a lunchtime dose of ADHD medication; this may lead to noncompliance and a subsequent increase in ADHD symptoms, with deterioration in schoolwork. In this situation, encourage the family to explore with their physician or nurse practitioner the option of one of the newer extended-release or once-daily ADHD medications.

## TOURETTE SYNDROME

Tourette syndrome consists of multiple motor tics and one or more vocal tics occurring either simultaneously or at different times. Children are not tic-free for longer than 3 months. Tics are defined as sudden rapid recurrent stereotypical movements and/or sounds over which the child appears to have no control. Tourette syndrome is estimated to affect up to 1% of children (Bloch & Leckman, 2008). Its onset is before 18 years of age.

Comorbid conditions such as ADHD and obsessive-compulsive disorder occur in 50% of children with Tourette syndrome (Bloch & Leckman, 2008). The exact pathophysiologic mechanism of Tourette syndrome has yet to be identified, though genetics does seem to play a part. Therapeutic management is highly individualized and involves psychopharmacology and behavioral therapies. Habit reversal training may help in some children.

## Nursing Assessment

Evaluate the health history for the occurrence of tics. The child may be embarrassed or ashamed about the tics and the parents may feel fearful, angry, or guilty. Determine the presence of symptoms of comorbid conditions. Elicit the child's past health history, noting a family history of tics. Assess the child's psychosocial history to determine the extent to which the tics interfere with friendship, school performance, and self-esteem. Observe the child for simple or complex motor tics. Vocal tics such as sniffing, grunting, clicking, or word utterance may occur. Perform a thorough physical examination, which is usually normal.

## Nursing Management

Inform families that the tics become more noticeable or severe during times of stress and less pronounced when the child is focused on an activity such as watching TV, reading, or playing a video game. Help the family to build on the child's functional behaviors and adaptive skills to improve the child's self-esteem. Encourage the family to pursue classroom accommodations such as allowing for "tic breaks," taking untimed tests or tests in another room, or using note takers or tape recording. Support the family's decisions related to medication use and therapy and provide appropriate education about the particular drugs and therapies. "Teaching the Tiger" by M. P. Dornbush and S. K. Pruitt (Hope Press) is useful for teachers of the child with Tourette syndrome. For additional support, refer families to Tourette Syndrome Association, Tourette Syndrome Foundation of Canada, or Tourette Syndrome Plus (links to these resources are provided on [thePoint](#)).

## EATING DISORDERS

Eating disorders include pica, rumination, anorexia nervosa, and bulimia. They affect a significant number of children, especially adolescents. Pica, which occurs most frequently in 2- to 3-year-olds, is an eating disorder in which the child ingests (over at least a 1-month period) a nonnutritive material such as paint, clay, or sand. Rumination is an eating disorder occurring in infants in which the baby regurgitates partially digested food or formula and expels or swallows it. The numbers of children affected by pica and rumination is not known. This discussion will focus on anorexia nervosa and bulimia, as they are more commonly encountered.

Anorexia nervosa and bulimia are common eating disorders affecting primarily adolescents, though younger children may also be affected. In American society being thin is highly valued, which compounds the problem. Anorexia nervosa occurs in about 1% to 2% of adolescents; bulimia affects about 2% to 4% (Sigel, 2011). Anorexia nervosa is characterized by dramatic weight loss as a result of decreased food intake and sharply increased physical exercise. Bulimia refers to a cycle of normal food intake, followed by binge-eating and then purging. Typically, the adolescent with bulimia remains at a near-normal weight. Complications of anorexia and bulimia include fluid and electrolyte imbalance, decreased blood volume, cardiac arrhythmias, esophagitis, rupture of the esophagus or stomach, tooth loss, and menstrual problems. The mortality rate for anorexia may be as high as 18% (Sigel, 2011).

Therapeutic management may occur in either the inpatient or outpatient setting. In either case, a multidisciplinary approach including individual and family therapy as well as nutritional therapy is needed for the best chance at successful treatment. Atypical antipsychotics may be helpful with body image delusions, and later in therapy antidepressants may be useful (Sigel, 2011).

### Nursing Assessment

Determine the health history, noting risk factors such as family history, female gender, Caucasian race, preoccupation with appearance, obsessive traits, or low self-esteem. Adolescents with anorexia may have a history of constipation, syncope, secondary amenorrhea, abdominal pain, and periodic episodes of cold hands and feet. Parents usually note the chief complaint as weight loss. Note history of depression in the child with bulimia. Evaluate the child's self-concept, noting multiple fears, high need for acceptance, disordered body image, and perfectionism.

Perform a thorough physical examination. The anorexic is usually severely underweight, with a body mass index (BMI) of less than 17. Note cachectic appearance, dry sallow skin, thinning scalp hair, soft sparse

body hair, and nail pitting. Measure vital signs, noting low temperature, bradycardia, or hypotension. Auscultate the heart, noting murmur as a result of mitral valve prolapse (occurs in about one third of adolescents with anorexia).

The adolescent with bulimia will be of normal weight or slightly overweight. Inspect the hands for calluses on the backs of the knuckles and split fingernails. Inspect the mouth and oropharynx for eroded dental enamel, red gums, and inflamed throat from self-induced vomiting.

Careful laboratory and diagnostic evaluation of serum electrolytes and an electrocardiogram are needed in adolescents with anorexia because severe electrolyte disturbances and cardiac arrhythmias often occur.

### Nursing Management

Most children with eating disorders can be treated successfully on an outpatient basis, though this treatment may require many months. Those with anorexia who display severe weight loss, unstable vital signs, food refusal, or arrested pubertal development or who require enteral nutrition will need to be hospitalized. Refeeding syndrome (cardiovascular, hematologic, and neurologic complications) may occur in the severely malnourished adolescent with anorexia if rapid nutritional replacement is given. Therefore, slow refeeding is essential to avoid complications. Give phosphorus supplements as ordered. Assess vital signs frequently for orthostatic hypotension, irregular and decreased pulse, or hypothermia.

Consult the nutritionist for assistance with calculating caloric needs and determining an appropriate diet. Aim for a weight gain goal of 0.5 to 2 lbs per week. Instruct the child and family to keep a daily journal of intake, **bingeing** (excessive consumption) and **purging** (forced vomiting) behaviors, mood, and exercise. The journal may be used as an assessment tool as well as to document progress toward recovery. Assist the child and family to plan a suitably structured routine for the child that includes meals, snacks, and appropriate physical activity.

Use the physical findings associated with anorexia to educate the child about the consequences of malnutrition and how they can be remedied with adequate nutrient intake. Refer the adolescent, as appropriate, to behavior or group therapy. Assess the child's need for medical intervention for concomitant depression or anxiety (some anorexics also require psychotropic medications). Provide emotional support and positive reinforcement to the child and family. Refer the family to local support groups or online resources such as the Academy for Eating Disorders or the National Eating Disorders Association (links to these resources are provided on [thePoint](#)). See Healthy People 2020.

**HEALTHY PEOPLE 2020****Objective**

Reduce the proportion of adolescents who engage in disordered eating behaviors in an attempt to control their weight.

**Nursing Significance**

- Ensure that psychotherapy is available to children with eating disorders.
- Provide appropriate follow-up for all children recovering from anorexia or bulimia.

*Healthy People Objectives based on data from <http://www.healthypeople.gov>.*

**Consider This**

Nicole Ashton, 16 years old, is seen in your clinic due to weight loss. Her mother states that she has lost noticeable weight over the past few months and has stopped menstruating. What additional assessment information would be necessary?

After further examination it is determined that Nicole has anorexia nervosa. Her treatment is to take place on an outpatient basis beginning immediately. Discuss ways the family can encourage and assist in Nicole's recovery.

**MOOD DISORDERS**

Mood disorders in children include depressive disorders and bipolar disorder. Up to 3% of children and 6% of adolescents may suffer from depression at any one time (Lack & Green, 2009). Children may experience major depressive disorder or dysthymic disorder. Girls are twice as likely to be affected as boys, particularly during the teenage years. Bipolar disorder refers to a condition of alternating manic and depressive episodes and affects about 1% of children (Lack & Green, 2009). During the manic episode, mood is significantly elevated and the child displays excess energy.

Depression may cause significant alterations in school performance and social relationships. Anxiety disorders and disruptive behavior may occur together with depression. Substance abuse may also occur concurrently with depression. Divorce and serious family issues may contribute to the development of depression because of the ongoing stress they place on the child and their strong psychological impact.

Children and adolescents experiencing depressive episodes may harm themselves purposefully (without intent to kill themselves). They may hit, cut, or burn themselves (Swannell, Martin, Scott, Gibbons, & Gifford 2008).

Additionally, depressed children are at risk for suicide. The Centers for Disease Control and Prevention (CDC) Youth Risk Behavior Surveillance 2011 Report revealed that 15.8% of teens had seriously considered suicide, 12.8% had a plan, and 7.8% had attempted suicide (Eaton et al., 2012).

**Pathophysiology**

Both norepinephrine and dopamine play a role in mood. Norepinephrine is considered to be important in the areas of energy and alertness, while dopamine is important in the areas of pleasure and motivation. When alterations in the neurotransmission of norepinephrine and dopamine occur, the symptoms of depression (apathy, loss of interest, and pleasure) result. Decreased levels of serotonin have also been implicated in depressive symptoms. Development of a depressive disorder may also be related to genetics, behavior, or cognitive function. Children of parents with a depressive disorder are at an increased risk for developing one themselves. Maladaptive cognitive functions or lack of social skills resulting in negative feelings may also play a role (Lack & Green, 2009).

**Therapeutic Management**

Children with mood disorders usually benefit from psychotherapy. This helps the child to deal with the psychosocial consequences of his or her behavior on his or her interpersonal relationships with others. Crisis management, parental counseling, and individual, group, or family therapy may be useful. Major depressive disorder warrants the use of pharmacologic antidepressants. Bipolar disorder may be treated with neuroleptic agents or mood stabilizers (Nurcombe, 2008).

**Nursing Assessment**

Children with untreated depression are at high risk for suicide as well as the development of comorbid disorders such as anxiety disorders, substance abuse, eating disorders, self-harm, and disruptive behavioral disorders (such as conduct disorder or ADHD) (Stafford, 2011). The nurse must screen all children for the development of depression.

**Health History**

Obtain a health history from the child and separately from the parent. Evaluate the child for history of recent changes in behavior, changes in peer relationships, alterations in school performance, withdrawal from previously enjoyed activities, sleep disturbances, changes in eating behaviors, increase in accidents, or sexual promiscuity. If possible, use a standardized depression screening questionnaire; there are many available.

Ask about potential stressors such as school concerns, conflicts with parents, dating issues, and **abuse** (physical or sexual). When bipolar disorder is suspected, the history may reveal rapid, pressured speech; increased energy; decreased sleep; flamboyant behavior; or irritability during manic episodes.

Note history of weight loss, failure to thrive, or increased incidence of infections in the infant. For the toddler, note delay or regression in developmental skills, increase in nightmares, or parental reports of clinginess. The preschooler may have a history of loss of interest in newly acquired skills; manifest encopresis, enuresis, anorexia, or binge-eating; or make frequent negative self-statements. The parents of a school-age child may report that he or she has a depressed, irritable, or aggressive mood.

Assess for risk factors for suicide, which include:

- Previous suicide attempt
- Change in school performance, sleep, or appetite
- Loss of interest in formerly favorite school or other activities
- Feelings of hopelessness or depression
- Statements about thoughts of suicide

### Physical Examination

Observe the infant for weepiness, withdrawn behaviors, or a frozen facial expression. Note a sad or expressionless face in the toddler or preschooler. In any age child, observe for apathy. Inspect the entire body surface for self-inflicted injuries (such as cuts or burns), which may or may not be present. The remainder of the physical examination is generally normal unless the depressed child also has a chronic medical condition.

### Nursing Management

Nursing management of children and adolescents with mood disorders focuses on education and support, and prevention of depression and suicide.

### Educating and Supporting the Child and Family

Teach families that mood disorders are biologic conditions, not personality flaws. Teach families how to administer antidepressant medication and to monitor for adverse effects. Encourage and praise the child's and family's efforts at following through with cognitive and behavioral therapies. Support the family throughout the process, as sometimes treatment may be lengthy. Refer parents to local support resources or to the Depression and Bipolar Support Alliance or the Child and Adolescent Bipolar Foundation. Links to these resources are provided on [thePoint](#).

### Preventing Depression and Suicide

Establish a trusting relationship with the children and adolescents with whom you interact, particularly in the primary care setting, school, or chronic illness clinic. This trusting relationship may encourage children or adolescents to confide feelings or problems earlier than they may do with their parents. Screen all healthy and chronically ill preteens and teens for the development of depression (Stafford, 2011). Use standardized screening tools such as those listed in Box 52.4. When a potential problem is identified, immediately refer the child for mental health assessment and intervention. It is important to identify depression early so that treatment can start. When a grief-inducing event is impending (such as the death of a family member), begin preventive intervention to help the child to deal with it. Provide appropriate observation for any child exhibiting suicidal ideation. See Healthy People 2020.

#### HEALTHY PEOPLE 2020

Objective	Nursing Significance
Reduce suicide attempts by adolescents.	<ul style="list-style-type: none"> <li>• Screen all children and adolescents for the development of depression.</li> <li>• When depression or excess stress is present, refer the child to the appropriate support.</li> </ul>

*Healthy People Objectives based on data from <http://www.healthypeople.gov>.*

#### Take Note!

Closely observe children taking antidepressants for the development of presuicidal behavior.

#### BOX 52.4

#### SCREENING TOOLS FOR DEPRESSION

The following tools are used to screen for depression. Links to each of these screening tools are provided on [thePoint](#).

- Children's Depression Rating Scale-Revised (CDRS-R)
- Center for Epidemiological Studies Depression Scale Modified for Children (CES-DC)
- Weinberg Depression Scale for Children and Adolescents (WDSCA)
- Children's Depression Inventory (CDI)
- Beck Depression Inventory for Youth (BDI-Y)

## ANXIETY DISORDERS

Anxiety disorders are the most commonly diagnosed psychiatric conditions among children and adolescents. In fact, as many as 4% to 20% of children experience at least one anxiety disorder (Connolly & Nanayakkara, 2010). Anxiety often occurs together with other mental health disorders, especially depression. Normal children experience fear, worry, and shyness. Infants fear loud noises, being startled, and strangers. Toddlers are afraid of the dark and of separation. Preschoolers fear imaginary creatures and body mutilation. School-age children worry about injury and natural events, whereas adolescents are anxious about school and social performance. These normal fears produce a certain level of anxiety that is tolerated by most children, but it is important to distinguish normal developmentally appropriate anxiety from an anxiety disorder.

Anxiety is considered to be a reaction to a perceived or actual threat. The threat may or may not be distorted by the child, and the emotional distress leads to behavioral responses. The “fight-or-flight” response results in tachycardia, increased blood pressure, sweating, enhanced arousal and reactivity, tremors, and increased blood flow to the muscles (Keeley & Storch, 2009).

### Types of Anxiety Disorders

Generalized anxiety disorder (GAD) is characterized by unrealistic concerns over past behavior, future events, and personal competence. Social phobia is a disorder characterized by the child or teen demonstrating a persistent fear of speaking or eating in front of others, using public restrooms, or speaking to authorities. Selective mutism refers to a persistent failure to speak. Separation anxiety is more common in children than adolescents. In this disorder, the child may need to remain close to the

parents, and the child’s worries focus on separation themes. Obsessive-compulsive disorder (OCD) is characterized by compulsions (repetitive behaviors such as cleaning, washing, or checking something), which the child performs to reduce anxiety about obsessions (unwanted and intrusive thoughts). Posttraumatic stress disorder (PTSD) is an anxiety disorder that occurs after a child experiences a traumatic event, later experiencing physiologic arousal when a stimulus triggers memories of the event (Keeley & Storch, 2009).

### Pathophysiology

Anxiety disorders are thought to occur as a result of disrupted modulation within the central nervous system. Underactivation of the serotonergic system and overactivation of the noradrenergic system are thought to be responsible for dysregulation of physiologic arousal and the resulting emotional experience. Disruption of the  $\gamma$ -aminobutyric acid (GABA) system may also play a role. Genetic factors may also play a role in the development of anxiety disorders, as may family and environmental influences. Additionally, abnormal thoughts or behaviors may have been learned through observation or conditioning (Keeley & Storch, 2009).

### Therapeutic Management

Therapeutic management of anxiety disorders generally involves the use of pharmacologic agents and psychological therapies. Anxiolytics or antidepressants are the most common pharmacologic approaches. Cognitive-behavioral therapy; individual, family, or group psychotherapy; and other behavioral interventions such as relaxation techniques may also be useful (Keeley & Storch, 2009). See Evidence-Based Practice 52.1.

#### EVIDENCE-BASED PRACTICE 52.1

#### BEHAVIORAL AND COGNITIVE BEHAVIORAL THERAPY FOR CHILDREN AND ADOLESCENTS WITH OBSESSIVE COMPULSIVE DISORDER

##### STUDY

Behavioral or cognitive-behavioral therapy (BT/CBT) is often recommended for children and adolescents with obsessive-compulsive disorder (OCD). The authors reviewed studies comparing BT/CBT with no treatment or in combination with pharmacotherapeutics for OCD. Four studies with 222 total participants were included in the review.

##### Findings

Participants who underwent BT/CBT demonstrated better posttreatment functioning and reduced risk of continuing with OCD as compared with those receiving no BT/CBT.

Evidence surfaced that BT/CBT combined with medication was superior to treatment with medication alone. The dropout rate during therapy was low, indicating acceptance by participants and their families.

##### Nursing Implications

Encourage families to explore the possibility of adding BT/CBT to the treatment plan. Assist families with finding an appropriate provider of BT/CBT in their local area. Praise children and families for ongoing dedication to BT/CBT. Continue to offer emotional support to all members of the family throughout the treatment process.

Adapted from O’Kearne, R. T., Ansley, K. J., & von Sanden, C. (2006). Behavioural and cognitive behavioural therapy for obsessive compulsive disorder in children and adolescents. *The Cochrane Library 2006*, 4. Indianapolis, NY: John Wiley & Sons.

## Nursing Assessment

Children and adolescents do not usually express anxiety directly. Therefore, it is very important for the nurse to evaluate somatic complaints and perform a careful health history.

### Health History

Explore the child's current and past medical history for risk factors such as depression, anxious temperament, family history of anxiety disorders, certain environmental or life experiences (such as parental dysfunction or significant stressful event or trauma), or unstable parental attachment. Elicit the health history, noting history of social inhibition, panic, or "heart racing." Young children may display overactivity, acting out, sleep difficulties, or separation issues. Older children may describe feelings of nervousness, anger, fear, or tension and may display disruptive behavior. Ask the child to choose a number on a scale from 0 to 10 to describe how much he or she worries about things. Have the parent rank the child's worry in the same fashion, and ask the parent what the child worries about most. Determine frequency of headaches and stomachaches. Use a standardized screening tool such as the Multidimensional Anxiety Scale for Children (MASC), Spence Children's Anxiety Scale (SACS), Preschool Anxiety Scale, and Beck Anxiety Inventory for Youth. Links to each of these screening tools are available on [thePoint](#).

### Physical Examination

Perform a complete physical examination to rule out physiologic causes of the child's symptoms. Note patches of hair loss that occur with repetitive hair twisting or pulling associated with anxiety. Evaluate for evidence of nail biting, sucking blisters, or skin erosion from finger rubbing. Inspect the entire body for signs of self-injury, which may or may not be present.

## Nursing Management

Screen children at well-child or other health care visits, as well as upon admission to the hospital, for anxiety symptoms. If an anxiety disorder is suspected, refer the child to the appropriate mental health provider for further evaluation. When the child is diagnosed with an anxiety disorder and medication is prescribed, teach families about medication administration and adverse effects. Encourage and praise them for follow-through related to cognitive and behavioral therapy or psychotherapy. Provide emotional support to the child and family. Assess the family for the presence of parental anxiety or insecure attachment. Note parenting style and parent-child interactions. Not only the child but also the family will benefit from interventions that improve parent-child relationships,

decrease parental anxiety, and foster parenting skills that promote autonomy in the child. Thus, refer the child and family to concurrent family therapy if needed.

## ABUSE AND VIOLENCE

Abuse and violence contribute significantly to mental illness in children. Children may suffer from child maltreatment, Münchausen syndrome, or substance abuse.

### Child Maltreatment

Child maltreatment includes physical abuse, sexual abuse, emotional abuse, and neglect. Physical abuse refers to injuries that are intentionally inflicted on a child and result in morbidity or mortality. Sexual abuse refers to involvement of the child in any activity meant to provide sexual gratification to an adult. Emotional abuse may be verbal denigration of the child or occur as a result of the child witnessing domestic violence. **Neglect** is defined as failure to provide a child with appropriate food, clothing, shelter, medical care, and schooling (Antonia & Sirotnak, 2011).

Statistics related to family violence as well as child physical and sexual abuse are difficult to determine, as the perpetrator usually forces the victim into silence. Children usually do not want to admit that their parent or relative has hurt them, partly from feelings of guilt and partly because they do not want to lose that parent. In 2008, 44.1 referrals to child protective services were made per 100 children, yet this may be an underestimate of the prevalence of child abuse (Antonia & Sirotnak, 2011). Abuse and violence occur across all socioeconomic levels but are more prevalent among the poor (Antonia & Sirotnak, 2011). Despite the lack of adequate statistics, it is well known that the problem of abuse and violence is widespread. Parents or caregivers are the most frequent perpetrators of abuse against children (Antonia & Sirotnak, 2011).

A history of childhood abuse is associated with the development of depressive disorders, suicidal ideation and attempts, anxiety disorders, and alcohol and drug use. Abuse may result in significant physical injury, poor physical health, and, in some cases, impaired brain development. Being a victim of abuse places children at risk for low self-esteem, poor academic achievement, poor emotional health, and social difficulties. Additional long-term consequences include juvenile delinquency and perpetuation of the violence cycle (Child Welfare Information Gateway, 2008).

Therapeutic management of victims of abuse and violence involves physical treatment of the injury, palliative care in some cases, and intervention to preserve or restore the child's mental well-being as well as family functioning. To protect children, all states require by law that health

care professionals report suspected cases of child abuse or neglect (Child Welfare Information Gateway, 2010).

## Nursing Assessment

Elicit the health history, noting the chief complaint and timing of onset. Assess for appropriateness of the parent–child attachment (often altered in the case of neglect). Pay particular attention to statements made by the child’s parent or caretaker. Is the history given consistent with the child’s injury? Identify abuse and violence by screening all children and families using these questions:

- Questions for children:
  - Are you afraid of anyone at home?
  - Who could you tell if someone hurt you or touched you in a way that made you uncomfortable?
  - Has anyone hurt you or touched you in that way?
- Questions for parents:
  - Are you afraid of anyone at home?
  - Do you ever feel like you may hit or hurt your child when frustrated?

Assess for risk factors in children and parents or caretakers. Risk factors for abuse in children include poverty, prematurity, cerebral palsy, chronic illness, or intellectual disability. Risk factors for being abusers in parents or caretakers include a history of being abused themselves, alcohol or substance abuse, or extreme stress.

Determine if the child has a history of hurting self or others (e.g., cutting), running away, attempting **suicide** (taking one’s own life), or being involved in high-risk behaviors. Note inappropriate sexual behavior for developmental age, such as seductiveness, as this may indicate sexual abuse. Note history of chronic sore throat or difficulty swallowing, which may occur with forced oral sex or sexually transmitted infections. Document history of genital burning or itching (associated with sexual abuse). Note nonspecific symptoms of emotional abuse such as low self-confidence, sleep disturbance, hypervigilance, headaches, or stomachaches.

### Take Note!

A delay in seeking medical treatment, a history that changes over time, or a history of trauma that is inconsistent with the observed injury all suggest child abuse.

## Physical Examination

Perform a gentle but thorough physical examination, using a soft touch and calm voice. Observe the parent–child interaction, noting fear or an excessive desire to please. Note the infant’s level of consciousness. Vigorous shaking in the infant leads to intracranial hemorrhage and shaken baby syndrome. Inspect the skin for bruises, burns, cuts, abrasions, contusions, scars, and any other unusual or suspicious marks. Current or healed scratches

Common nonaccidental injury sites

FIGURE 52.1 Injury sites that are suspicious for abuse.

or cuts may be found on parts of the body ordinarily covered by clothing in the child who self-mutilates. Burns that occur in a stocking or glove pattern, or only to the soles or palms, are highly suspicious for inflicted burns. Injuries in various stages of healing are also indicative of abuse. Bruises on the chest, head, neck, or abdomen are suspicious for abuse. Nonambulatory children infrequently experience bruises or fractures. Figure 52.1 shows injury sites usually indicative of abuse; Figure 52.2

FIGURE 52.2 Note the mark left from a looped electric cord.

is a photograph of a child who was beaten with an electric cord. Observe for inflammation of the oropharynx (may occur with forced oral sex). Inspect the anus and penis or vaginal area for bleeding or discharge (which may indicate sexual abuse).

### Laboratory and Diagnostic Tests

Common laboratory and diagnostic studies ordered for the assessment of abuse include:

- Radiographic skeletal survey or bone scan may reveal current or past fractures.
- Computed tomography scan of the head may reveal intracranial hemorrhage.
- Rectal, oral, vaginal, or urethral specimens may reveal sexually transmitted infections such as gonorrhea or chlamydia.

### Nursing Management

Refer suspected cases of neglect or abuse to the local child protection agency. When abusive activity is identified in the hospital, notify the social services and risk management departments. In addition to physical or palliative care needed for the injuries, abused children need to redevelop a sense of trust in adults. Provide consistent care to the abused child by assigning a core group of nurses. Child abuse requires a multidisciplinary approach that may include psychological therapy for the child and family.

Role model appropriate caretaking activities to the parent or caregiver. Call attention to normal growth and development activities noted in the infant or child, as sometimes parents have expectations of child behavior that may be unrealistic based on the child's age, leading to the abuse. Praise parents and caretakers for taking appropriate steps toward getting help and for providing appropriate care to the child. Refer parents to Parents Anonymous, an organization dedicated to the prevention of child abuse through strengthening of the family (see [thePoint](#) for a link to this website).

When it is determined by the child protective team that the child would be in danger to continue living in the current situation, the child may be removed from the home. If the child is removed from the family temporarily or permanently, provide the foster or adoptive family with education necessary to assume the child's care.

### Münchhausen Syndrome by Proxy

Münchhausen syndrome by proxy (MSBP) is a type of child abuse in which the parent creates physical and/or psychological symptoms of illness or impairment in the child. The adult meets his or her own psychological needs by having an ill child. MSBP is difficult to detect

and may remain hidden for years. In most cases, the biologic mother is the perpetrator (Mason & Poirier, 2010). Therapeutic management focuses on ensuring the safety and well-being of the child, as well providing psychotherapy for the perpetrator.

### Nursing Assessment

Take a thorough and detailed health history of the child's illness or illnesses. Use quotations to document the parent's responses. Warning signs of MSBP include:

- Child with one or more illnesses that do not respond to treatment or that follow a puzzling course; a similar history in siblings
- Symptoms that do not make sense or that disappear when the perpetrator is removed or not present; the symptoms are witnessed only by the caregiver (e.g., cyanosis, apnea, seizure)
- Physical and laboratory findings that do not fit with the reported history
- Repeated hospitalizations failing to produce a medical diagnosis, transfers to other hospitals, discharges against medical advice
- Parent who refuses to accept that the diagnosis is not medical (Antonia & Sirotnak, 2011; Mason & Poirier, 2010)

Observe the mother's behavior with the child, spouse or partner, and staff. Use of covert video surveillance may reveal maternal actions causing illness in the child when the nurse, physician, or nurse practitioner is not in the room. Perform a thorough physical examination, noting where the physical examination findings differ from the reported health history.

### Nursing Management

Management of MSBP is complex. When abusive activity is identified, notify the social services and risk management departments of the hospital. Ensure that the local child protection team and the caregiver's family or support system is present when the caregiver is confronted. Inform the caregiver of the plan of care for the child and of the availability of psychiatric assistance for the caregiver.

### Substance Abuse

Substance use most often begins before age 20. Among eighth graders, 18% report having been drunk at least once prior to high school, and over 75% of teenagers report alcohol use before high school graduation (Kaul, 2011). In addition to alcohol, youths also use marijuana, cocaine, injectable illegal drugs such as heroin, hallucinogenic drugs, methamphetamines, inhalants, and Ecstasy (Kaul, 2011).

## Nursing Assessment

Note risk factors for substance abuse, such as family history of substance abuse, current parental substance use, dysfunctional family relationships, concurrent mental health disorder, aggressive behaviors, low self-esteem or poor academic performance, negative life events, poor social skills, or peers who use substances. Determine the child's history, noting altered school performance or attendance, changes in peer group participation, frequent mood swings, changes in physical appearance, or an altered relationship with or perception of parents. Document history of insomnia, appetite loss, excessive itching, sleepiness or extreme fatigue, dry mouth, or shakiness. Note violent behavior, drunkenness, stupor, blank expression, drowsiness, lack of coordination, confusion, incoherent speech, extremes in emotions, aggressive behavior, silly behavior, or rapid speech.

Perform a complete physical examination. Observe for an odor of alcohol or marijuana smoke. Assess the eyes, noting wateriness or dilated pupils. Inspect the nares, noting rhinorrhea or absence of nasal hair. Inspect the fingers for glue smears or discoloration and the skin for needle marks or tracks. Palpate the hands and feet for coolness.

Laboratory and diagnostic tests include toxicology studies, such as urine screening, to determine the presence of stimulants, sedative-hypnotics, barbiturates, Quaaludes, opiates, cocaine, and marijuana.

## Nursing Management

Help the adolescent to acknowledge that he or she has a problem. Explain the negative consequences of substance use and raise the teen's awareness of risks. Remain empathetic, yet leave responsibility with the adolescent. Key nursing interventions include promoting participation in treatment programs and preventing substance abuse.

### Promoting Participation in Treatment Programs

Refer the adolescent to a substance abuse program. Outpatient or day treatment programs are useful in most situations. Family-based programs produce the highest level of recovery. Self-help or 12-step groups are an important element in the recovery process. Serious addiction, the presence of one or more comorbid psychiatric conditions, or suicidal ideation requires residential treatment or hospitalization. See Healthy People 2020.

### Preventing Substance Abuse

Establish a trusting relationship with children and adolescents in order to improve acceptance of education about substance use and to provide a safe environment

## HEALTHY PEOPLE 2020

### Objective Nursing Significance

- | Objective                                                                                                                           | Nursing Significance                                                                                                                                                                                                                                                   |
|-------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Increase the proportion of persons with co-occurring substance abuse and mental disorders who receive treatment for both disorders. | <ul style="list-style-type: none"> <li>• Screen all children and adolescents with mental health disorders for the coexistence of substance abuse (and vice versa).</li> <li>• Refer children and adolescents to appropriate treatment programs and therapy.</li> </ul> |

*Healthy People Objectives based on data from <http://www.healthypeople.gov>.*

for confiding about their problems. Screen all children and adolescents for risk factors. During routine psychosocial screening, be alert to alterations as noted earlier. Teach all children, beginning at the elementary school level (or earlier in some high-risk communities), that all chemicals have the potential to be harmful to the body, including tobacco, alcohol, and illicit drugs. Educate children and adolescents that no matter which administration route is used, the drug still enters the body and affects it (negatively). Help children to learn problem-solving skills that they can call upon in the future rather than relying on drugs or other substances to avoid their problems. Teach children to “just say no.” Reinforce that they are the ones who have control over their body and what they expose it to. Encourage children to participate in the local community DARE program (Drug Abuse Resistance Education) and praise them for completing it. Teach parents that being involved in their child's social life and knowing where they are and with whom when they are outside of the home is an important step toward limiting substance exposure.

## KEY CONCEPTS

- Mental health and behavioral disorders account for the bulk of the “new morbidity” among children and adolescents.
- The child with behavioral problems or mental health issues often has difficulty in the areas of school, peer relationships, and the family, all of which may worsen the child's self-concept, further hindering his or her emotional health.
- Developmental screening is a key component in the evaluation of a child's mental health.
- Various screening tools are available for depression, ADHD, and anxiety.

- Children with autism spectrum disorder often have impaired social interactions as well as altered communication.
- Learning disabilities and ADHD have a significant negative impact on the child's potential for appropriate education.
- Individualized education plans help children with learning disabilities, intellectual disability, and ADHD receive the educational support they require to optimize their educational capacity.
- Provide support and education to children with mood or anxiety disorders and their families.
- Educating parents about medication administration and its adverse effects is a critical aspect of nursing management of the child with a mental health disorder.
- Provide nutritional replacement at the appropriate pace in the child with anorexia nervosa. Monitor the child closely for the development of refeeding syndrome.
- A key nursing function is screening all children and their families for abuse and violence.
- Report suspected cases of child abuse to the appropriate authorities.
- Educate children about the dangers associated with substance abuse. Reward and praise children and adolescents who do not experiment with or use alcohol or illicit drugs.

## MULTIPLE CHOICE QUESTIONS

1. The nurse is caring for a child with ADHD. Which behavior would the nurse *not* expect the child to display?
  - a. Moody, morose behavior with pouting
  - b. Interruption and inability to take turns
  - c. Forgetfulness and easy distractibility
  - d. Excessive motor activities and fidgeting
2. An adolescent girl who has been receiving treatment for anorexia nervosa has failed to gain weight over the past week despite eating all of her meals and snacks. What is the priority nursing intervention?
  - a. Increase the teen's daily caloric intake by at least 500 calories.
  - b. Ensure that the teen's entire fluid intake includes calories.
  - c. Supervise the teen for 2 hours after all meals and snacks.
  - d. Assess the teen's anxiety level to determine need for medication.
3. A 15-year-old girl has been making demands all day, exaggerating her every need. She is now crying, saying she has nothing to live for and threatening to kill herself. What is the priority nursing action?
  - a. Ignore her continued exaggerated and melodramatic behavior.
  - b. Consult with the physician or nurse practitioner to increase her antidepressant dose.
  - c. Leave the girl alone for a little while until she composes herself.
  - d. Take the girl's suicidal threat seriously and provide close supervision.
4. When trying to manage aggressive or impulsive behaviors in children or adolescents, what is the best nursing intervention?
  - a. Train the child to be assertive.
  - b. Provide consistency and limit setting.
  - c. Allow the child to negotiate the rules.
  - d. Encourage the child to express feelings.

5. The nurse is caring for an adolescent who says, "I'm sick of this. I wish I weren't alive anymore." What is the best response by the nurse?
  - a. "I often feel sad and sick of things."
  - b. "Have you thought about hurting yourself?"
  - c. "Are you trying to escape your problems?"
  - d. "Do your parents know about this feeling?"

## CRITICAL THINKING EXERCISES

1. A mother tells you that her son's behavior is unmanageable, and she is having difficulty coping with it. The boy is argumentative and is bullying others. He is struggling with his schoolwork because he has difficulty staying on task, gets out of his chair often, and frequently distracts others. What additional assessments should you obtain? What interventions would be helpful in managing the boy's behavior?
2. A 14-year-old boy with moderate intellectual disability is able to feed himself but is incontinent. Discuss the issues with which his family must deal.

## STUDY ACTIVITIES

1. Explore several of the websites related to child abuse prevention listed on thePoint. Develop a list of resources for families in your local area.
2. Attend a group therapy session during your pediatric clinical rotation. Observe the children's verbal and nonverbal communication, noting inconsistencies or other interesting observations.
3. Visit a school for autistic children. Spend time with the various specialists who work with children with ASD, determining their roles and the effect the treatment they are providing has on the children. Report your findings to your classmates.
4. Attend a local CHADD meeting. Talk to parents about having a child with ADHD.

## Nursing Care During a Pediatric Emergency

### Learning Objectives

*Upon completion of the chapter, the learner will be able to:*

1. Define the key terms used in this chapter.
2. Identify various factors contributing to emergency situations among infants and children.
3. Discuss common treatments and medications used during pediatric emergencies.
4. Conduct a health history of a child in an emergency situation, specific to the emergency.
5. Perform a rapid cardiopulmonary assessment.
6. Discuss common laboratory and other diagnostic tests used during pediatric emergencies.
7. Integrate the principles of the American Heart Association and Pediatric Advanced Life Support in the comprehensive management of pediatric emergencies, such as respiratory arrest, shock, cardiac arrest, near drowning, poisoning, and trauma.

*Alma Anderson, age 8 years, has been admitted to the pediatric unit. Her mother calls the nurse into the room, stating, “Alma’s having trouble breathing!”*

### Words of Wisdom

A nurse must possess the knowledge and skills to aid an acutely ill child.

**Children** are uniquely vulnerable to a range of emergency situations. These situations are often life-threatening if not treated quickly and effectively. Because of their developmental level, children are at a greater risk for near drowning, poisoning, and traumatic injury compared to adults. Most pediatric cardiopulmonary arrests result from respiratory failure or shock. Data suggest that children who have a cardiopulmonary arrest requiring resuscitative measures rarely fare well. For these reasons, the American Heart Association (AHA) has delineated two distinct chains of survival, one for adults and one for children, which should be followed during a life-threatening situation.

The adult chain of survival is:

1. Early emergency medical system (EMS) activation
2. Early cardiopulmonary resuscitation (CPR)
3. Early defibrillation
4. Early access to advanced care
5. Integrated post–cardiac arrest care

In contrast, the pediatric chain of survival is:

1. Prevention of cardiac arrest and injuries
2. Early CPR
3. Early access to emergency response system
4. Early advanced care (Pediatric Advanced Life Support)
5. Integrated post–cardiac arrest care (Berg et al., 2010)

Considering the special risks that threaten children, the AHA has also developed specific guidelines for Pediatric Advanced Life Support (PALS). Courses in PALS are offered for health care professionals so that they can provide expert care for children in emergencies. This chapter emphasizes the principles of PALS in its discussion of the nurse's role in the management of pediatric emergencies.

### Take Note!

The current pediatric basic life support guidelines define an infant as between 0 and 12 months of age, and a child as age 1 year up until puberty. Children in this range should be managed using the PALS guidelines rather than those for adults (Berg et al., 2010).

## COMMON MEDICAL TREATMENTS

A variety of medications and other medical treatments are used in pediatric emergencies. Most of these treatments will require a physician's order when the child is in the hospital, though some emergency departments and pediatric units may have standing orders for pediatric emergencies. The most common medical treatments and medications used in pediatric emergencies are listed in Common Medical Treatments 53.1 and Drug Guide 53.1. The nurse should be familiar with these procedures and medications, how they work, and nursing implications.

## HEALTHY PEOPLE 2020

### Objective

Increase the number of states and the District of Columbia that have implemented guidelines for prehospital and hospital pediatric care.

### Nursing Significance

- Become politically active in your local area and at the national level.
- Advocate for optimal care for infants, children, and adolescents.

*Healthy People* Objectives based on data from <http://www.healthypeople.gov>.

### Take Note!

Certain emergency drugs for children may be given via a **tracheal tube** (a tube inserted into the trachea that serves to maintain the airway and facilitate artificial respiration). Use the mnemonic LEAN (lidocaine, epinephrine, atropine, and naloxone) to remember which drugs may be given via the tracheal route. In certain cases, when an emergency drug is given via a tracheal tube, the dosage must be increased. In addition, drugs given via this route should be followed by 5 mL of sterile saline and five consecutive multiple positive-pressure ventilations to ensure that the drugs are delivered (Kleinman et al., 2010a).

## NURSING PROCESS OVERVIEW FOR THE CHILD IN AN EMERGENCY SITUATION

The nurse may encounter a pediatric emergency in a variety of settings. As a member of a trauma team at a pediatric hospital, the nurse may participate in the stabilization of a child who has suffered a near drowning or trauma. The emergency department nurse may encounter a child who has just been injured, such as from a fall, an accident, or sports. On the hospital unit, a child with asthma may suffer respiratory distress or stop breathing. Regardless of the setting or how the emergency developed, the principles for managing pediatric emergencies are the same.

Care of the child in an emergency includes all components of the nursing process: assessment, nursing diagnosis, planning, interventions, and evaluation. In an emergency, the nurse must act quickly. It is important to intervene immediately when an abnormality is determined upon assessment. When evaluating a child who presents emergently, always follow the AHA's guidelines for basic life support (Berg et al., 2010), which includes evaluating the child's:

- **A**irway
- **B**reathing
- **C**irculation

After you have evaluated the child's airway, breathing, and circulation, provide care as necessary, including

## COMMON MEDICAL TREATMENTS 53.1

Treatment	Explanation	Indications	Nursing Implications
Suctioning (oropharyngeal, nasopharyngeal, tracheal, or tracheostomy)	Removal of secretions via bulb syringe or suction catheter	Excessive airway secretions affecting airway patency	Use caution and suction only as far as recommended for age, tracheal tube size, or tracheostomy tube size or until coughing or gagging occurs.
Oxygen	Supplementation via mask, nasal cannula, hood, or tent or via tracheal/nasotracheal tube	Hypoxemia, respiratory distress, shock, trauma	Monitor response via color, work of breathing, respiratory rate, oxygen saturation levels via pulse oximetry, and level of consciousness.
Bag-valve-mask ventilation	Provision of ventilation via a bag-valve-mask device, manual ventilation	Apnea, ineffective ventilation and oxygenation with spontaneous breaths, extremely slow respiratory rate	Ensure adequate chest rise with ventilation. Do not overventilate or bag aggressively to avoid barotrauma. Maintain a seal on the child's face with the appropriate-sized mask. Ensure the oxygen supply tubing is connected to 100% oxygen.
Intubation	Insertion of a tube into the trachea to provide artificial ventilation	Apnea, airway that is not maintainable, need for prolonged assisted ventilation	Determine adequacy of breath sounds with bagging immediately upon insertion of the tracheal tube. Assess for symmetric chest rise. Tape tube securely in place and note number marking on the tube. Connect to ventilator when available.
Needle thoracotomy	Insertion of a needle between the ribs into the pleural space to remove air	Tension pneumothorax	There should be a rush of air as the needle reaches the air space. Monitor breath sounds, work of breathing, pulse oximetry. Ensure patency of IV catheter.
IV fluid therapy	Administration of crystalloid or colloid solutions to provide hydration or improve perfusion	Altered perfusion states such as respiratory distress, shock, trauma, cardiac disturbances	Use intraosseous route if a peripheral IV cannot be obtained quickly in the young child in shock. Reassess respiratory and circulatory status frequently after each IV fluid bolus and during continuous infusion.
Blood product transfusion	Administration of whole blood, packed red blood cells, platelets, or plasma intravenously	Trauma, hemorrhage	Follow institution's transfusion protocol. Double-check blood type and product label with a second nurse. Monitor vital signs and assess child frequently to identify adverse reaction to blood transfusion. If adverse reaction is suspected, immediately discontinue transfusion, infuse normal saline solution IV, reassess the child, and notify the physician.
Cervical stabilization	Maintenance of the cervical spine in an immobile position	Trauma, near drowning	Use the jaw-thrust maneuver without head tilt to open the airway. Maintain cervical stabilization until the cervical spine radiographs are cleared by the physician or radiologist.
Defibrillation and synchronized cardioversion	Provision of electrical current to alter the heart's electrical rhythm	Defibrillation: ventricular fibrillation and pulseless ventricular tachycardia Synchronized cardioversion: supraventricular tachycardia and ventricular tachycardia with a pulse	In the pulseless child, always ensure CPR is ongoing while the defibrillator is being readied. Ensure adequate oxygenation. Provide lidocaine or epinephrine if indicated before defibrillation. Sedate the child if time allows.

### DRUG GUIDE 53.1 COMMON MEDICATIONS USED IN PEDIATRIC EMERGENCIES

Medication	Actions/Indications	Nursing Implications
Adenosine (antiarrhythmic)	Slows conduction through AV node, restoring normal sinus rhythm Supraventricular tachycardia (SVT)	<ul style="list-style-type: none"> <li>Administer IV at a dose ranging from 0.05 to 0.1 mg/kg.</li> <li>Administer very rapidly (1 to 2 seconds) followed by a rapid, generous saline flush.</li> <li>Repeat every 1 to 2 minutes, increasing by 0.05 to 0.1 mg/kg with each dose (maximum dose 0.3 mg/kg).</li> <li>Monitor for shortness of breath, dyspnea, worsening of asthma.</li> </ul>
Amiodarone (antiarrhythmics)	Prolongs repolarization of action potential, thus slowing the heart rate Ventricular tachycardia, ventricular fibrillation	<ul style="list-style-type: none"> <li>Administer IV or IO at a dose of 5 mg/kg over 20 to 60 minutes.</li> <li>Avoid use with procainamide.</li> </ul>
Atropine (anticholinergic)	Increases cardiac output, dries secretions, inhibits serotonin and histamine Sinus bradycardia, asystole, pulseless electrical activity	<ul style="list-style-type: none"> <li>Administer via IV, IO, or ET route at a dose of 0.02 mg/kg (maximum dose 0.5 mg child, 1 mg adolescent).</li> <li>Repeat every 5 minutes PRN.</li> <li>Give undiluted over 30 seconds for IV or IO route.</li> <li>Dilute with 3 to 5 mL normal saline for ET route; follow with five positive-pressure ventilations.</li> <li>Do not mix with sodium bicarbonate (incompatible).</li> </ul>
Dobutamine (synthetic catecholamine)	$\beta$ -Adrenergic agent primarily affecting $\beta$ -1 receptors; increases myocardial contractility and heart rate Ongoing short-term management of shock (hypovolemic and cardiogenic)	<ul style="list-style-type: none"> <li>Administer via IV or IO route at 2 to 20 mcg/kg/minute via a continuous infusion. Monitor for development of ventricular arrhythmias.</li> <li>Expect to titrate infusion rate based on cardiac output and BP.</li> <li>Administer via central line if possible due to risk of extravasation.</li> <li>Monitor child closely, preferably in an ICU setting.</li> </ul>
Dopamine (inotropic)	Increases cardiac output, BP, and renal perfusion ( $\beta$ -adrenergic agonist) Bradycardia, hypotension, and poor cardiac output	<ul style="list-style-type: none"> <li>Administer via IV or IO route at a dose of 2 to 20 mcg/kg/minute via continuous infusion.</li> <li>Ensure that child has received adequate fluid resuscitation prior to administration.</li> <li>Due to risk of extravasation, give via central line if possible.</li> <li>Monitor child closely, preferably in an ICU setting.</li> <li>Assess for ventricular arrhythmias.</li> </ul>
Epinephrine (adrenergic)	Stimulates $\alpha$ - and $\beta$ -adrenergic receptors, increasing heart rate and systemic vascular resistance Bradycardia, anaphylaxis	<ul style="list-style-type: none"> <li>Administer via IV or IO route at a dose of 0.01 mg/kg (0.1 mL/kg of 1:10,000 solution) or via ET route at 0.1 mg/kg (0.1 mL/kg of 1:1,000 solution).</li> <li>During CPR, repeat every 3 to 5 minutes.</li> <li>Monitor for ventricular arrhythmias.</li> <li>High doses may cause tachycardia in newborns.</li> <li>Due to risk of extravasation and subsequent tissue necrosis, give through a central line if possible.</li> <li>May also be used as a bronchodilator IV or via inhalation (racemic epinephrine).</li> </ul>

**DRUG GUIDE 53.1 COMMON MEDICATIONS USED IN PEDIATRIC EMERGENCIES** (continued)

Medication	Actions/Indications	Nursing Implications
Glucose	Increases blood glucose level Hypoglycemia	<ul style="list-style-type: none"> <li>Administer via IV or IO route at a dose of 1 to 2 mL/kg (D50%); maximum dose 2 to 4 mL/kg.</li> <li>When administering via a peripheral IV line, dilute 1:1 with sterile water to make D25%. Monitor IV site for infiltration and tissue extravasation.</li> <li>Monitor blood glucose levels closely.</li> </ul>
Lidocaine (antidysrhythmic)	Decreases automaticity of conduction tissues of the heart Ventricular arrhythmias	<ul style="list-style-type: none"> <li>Administer via IV or IO route at a dose of 1 mg/kg; administer via ET route at dose 2 times IV dose diluted with 3 to 5 mL normal saline, followed by positive-pressure ventilation. Maximum dose 5 mg/kg or 100 mg/dose.</li> <li>Monitor ECG continuously.</li> <li>Contraindicated in complete heart block.</li> <li>With larger than normal doses, monitor for hypotension or seizures.</li> </ul>
Naloxone (Narcan)	Antagonizes action of narcotic agents Reversal of respiratory depression related to narcotic effects	<ul style="list-style-type: none"> <li>Administer via IV, IO, SQ, or ET route at a dose of 0.01 to 0.1 mg/kg in children younger than 5 years old or &lt;20 kg or at a dose of 2 mg in children older than 5 years old or &gt;20 kg. Onset of action is within 2 to 5 minutes.</li> <li>May repeat dose as necessary; narcotic effects outlast therapeutic effects of naloxone.</li> </ul>

AV, atrioventricular; ET, endotracheal; IO, intraosseous; SQ, subcutaneous.

Adapted from Kleinman, M. E., Chameides, L., Schexnayder, S. M., Samson, R. A., Hazinski, M. F., Atkins, D. L., et al. (2010). Part 14: Pediatric advanced life support – 2010 American Heart Association guidelines for cardiopulmonary resuscitation and emergency cardiovascular care. *Circulation*, 122, S876–S908; and Taketokmo, C. K., Hodding, J. H., & Kraus, D. M. (2011). *Pediatric and neonatal dosage handbook* (18th ed.). Hudson, OH: Lexi-comp.

rescue breathing or CPR. Once the child's cardiopulmonary status is stabilized or the child is resuscitated, assessment and management will vary depending on the cause of the emergency.

## Assessment

Nursing assessment of the child who presents emergently includes health history, physical examination, and laboratory and diagnostic testing. However, the initial history may be focused and very brief if the child is critically ill; the nurse may need to proceed immediately to rapid cardiopulmonary assessment. Once a child is stabilized, a more comprehensive history is obtained. Laboratory tests, while often important, should never take priority over cardiopulmonary and hemodynamic stabilization.

**Remember Alma, the 8-year-old with breathing trouble? What additional health history and physical examination assessment information should the nurse obtain?**

## Health History

Obtain the health history rapidly while simultaneously evaluating the child and providing life-saving interventions. A brief history is needed initially, followed by a more thorough history after the child is stabilized. The parents or caregiver will provide information about the child's chief complaint. Record the information using the caregiver's own words. For example, the caregiver might say, "He's been having trouble breathing" if the child is presenting in respiratory distress. If the child was injured in a bicycle accident, the caregiver might say, "She was riding her bike down the hill and lost control." This brief statement provides guidance for obtaining more in-depth information about the emergency.

Ask about any significant past history that may affect the care of the child. For example, children who are medically fragile, who were born prematurely, or who have a significant genetically linked disease (e.g., sickle cell anemia) may require special consideration when planning and implementing care.

## Physical Examination

In an emergency, the nurse must perform a rapid cardiopulmonary assessment and intervene immediately if alterations are noted. The remainder of the physical examination then follows.

### RAPID CARDIOPULMONARY ASSESSMENT

As the brief history is being obtained, begin the rapid cardiopulmonary assessment. Most pediatric arrests are related primarily to airway and breathing, and usually only secondarily to the heart. Supported breathing may be all that is needed if the child has a strong, adequate pulse. Always perform the assessment and interventions in that order. In most circumstances, if a child's airway is properly managed and breathing is assisted, the child may not experience a full arrest requiring chest compressions.

#### Take Note!

Assessment and management of the airway of a prearresting or arresting child is ALWAYS the first intervention in a pediatric emergency. Intervene if there is an airway problem before moving on to assessment of breathing. If an intervention for breathing is required, start it before proceeding to assessment of circulation.

**Airway Evaluation and Management.** First evaluate the airway. Assess its patency. Position the airway in a manner that promotes good air flow. If secretions are obstructing the airway, suction the airway to remove them. If the child is unconscious or has just been injured, open the airway using the head tilt–chin lift maneuver. Place the fingertips on the bony prominence of the child's chin and lift the chin to open the airway. Simultaneously, place one hand on the forehead and tilt the child's head back (Fig. 53.1). If the airway is not maintainable,

FIGURE 53.1 Head tilt–chin lift maneuver in a child.

reposition the airway for appropriate airflow. Place the child immediately on oxygen at 100% and apply a pulse oximeter to monitor oxygen saturation levels.

#### Take Note!

If cervical spine injury is a possibility, do not use the head tilt–chin lift maneuver; use only the jaw-thrust technique for opening the airway (see trauma section for explanation and illustration).

**Breathing Evaluation and Management.** After establishing an open airway, look for signs of respiration. Turn your head and place your ear over the child's mouth to “look, listen, and feel” for spontaneous respirations. Look to see if the child's chest is rising, listen for air escaping, and note if you feel any air coming out of the child's nose or mouth. If the child is breathing, evaluate the quality of the respirations: Is ventilation effective, or is the child simply gasping ineffectively for air? Count the respiratory rate. Observe the child's color. Note depth of respiration, chest rise, adequacy of air flow in all lung fields, and presence of adventitious sounds. Evaluate for increased work of breathing and the use of accessory muscles.

When signs of respiratory distress are noted, immediately place the child on oxygen at 100% and apply a pulse oximeter to monitor oxygen saturation levels. If the child is breathing shallowly and has poor respiratory effort, attempt to reposition the airway to promote better airflow.

For the child receiving 100% oxygen who does not improve with repositioning, begin assisted ventilation with a bag-valve-mask (BVM) device. A need for ongoing BVM ventilation may require airway **intubation** (process by which a breathing tube, such as a tracheal tube, is inserted into a child's airway to assist with breathing). See the section on respiratory arrest for information on assisting with ventilation using the BVM device and airway intubation.

**Circulation Evaluation and Management.** Next, evaluate circulation. During this phase, evaluate the heart rate, pulses, perfusion, skin color and temperature, blood pressure, cardiac rhythm, and level of consciousness. Determine the heart rate via direct auscultation or palpation of central pulses. Radial and brachial pulses are more difficult to palpate, especially in infants and young children. If perfusion is poor, such as with shock or cardiac arrest, the child may have a weak pulse or no pulse. In the young infant, check the brachial artery for a pulse. In the child and adolescent, evaluate the carotid pulse.

#### Take Note!

ALWAYS evaluate the presence of a heart rate by auscultation of the heart or by palpation of central pulses. NEVER use the cardiac monitor to determine if the child has a heart rate. The presence of a cardiac rhythm is not a reliable method for evaluation of the ability to perfuse the body. In certain circumstances a rhythm continues but there is no pulse (pulseless electrical activity).

If the child has no heart rate (pulse), begin cardiac compressions. See below for information on performing CPR. High-quality chest compressions of adequate rate and depth are essential (Kleinman et al., 2010a).

If there is a pulse, note its quality: Is it barely palpable or weak? Is it strong or bounding? Compare the strength and quality of central and peripheral pulses. Assess capillary refill time.

Evaluate the child's perfusion by noting skin temperature and color. Is the skin pink? Is it warm to the touch? The child's skin may be cool to the touch and may appear pale, mottled, or cyanotic. As the child's condition worsens with developing shock and cardiovascular compromise, note a line of demarcation of skin temperature. In this situation, the distal extremities will feel cooler than the proximal regions of the body. Measure the blood pressure (BP) and place the child on a cardiac monitor to evaluate the cardiac rhythm. Note the child's sensorium or level of consciousness; if circulation is poor, the child will demonstrate an altered level of consciousness as perfusion to the brain becomes diminished.

### Take Note!

According to PALS, the minimum acceptable systolic BP is 60 for the neonate, 70 for the infant aged 1 to 12 months, and 70 + twice the age in years for children aged 1 to 10 years [e.g., a 4-year-old should have a minimal systolic BP of 78:  $70 = (2 \times 4) = 79$ ]. For children older than age 10, the minimum acceptable systolic BP is 90 (Kleinman et al., 2010a).

If the circulation or perfusion is compromised, then fluid resuscitation is necessary. Establish large-bore intravenous (IV) access immediately and administer isotonic fluid rapidly. Provide 20 mL/kg of normal saline (NS) or lactated Ringer's (LR) as an IV bolus (if the infant is younger than 1 month old, administer 10 mL/kg). If peripheral IV access cannot be obtained in the child with altered perfusion within three attempts or 90 seconds, assist with insertion of an intraosseous needle for fluid administration (refer to shock section for further information about intraosseous access). Central venous lines or cutdown access may also be used, but these measures take longer to accomplish.

## ADDITIONAL PHYSICAL EXAMINATION COMPONENTS

In addition to assessing and stabilizing the child's airway, breathing, and circulation, perform a thorough physical examination and assess pain.

**Neurologic Evaluation.** Quickly evaluate the sensorium in an older child. Ask the child to state his or her name. Ask what happened to the child. Does the child know what day it is? Is the child aware of where he or she is?

If the child is an infant, evaluate his or her interest in the environment and response to parents. An infant who is not interested in the environment or seems unable to recognize his or her parents is a cause for concern. In contrast, an infant who enjoys sucking on a finger and making eye contact with the nurse during the assessment is reassuring.

Evaluate the child's head. In the infant or young toddler, palpate the anterior fontanel to determine if it is normal (soft and flat), depressed, or full. A sunken fontanel is associated with volume depletion from dehydration or blood loss. If the fontanel is full, note if it is bulging or tense, which may indicate increased intracranial pressure. Next assess the eyes. Are they open or closed? If closed, do they open spontaneously, to voice, to pain? Does the child focus on and follow the nurse's movements? Evaluate the pupils for equality and reactivity. Sluggish pupillary reaction may occur with increased intracranial pressure.

### Take Note!

A nonreactive pupil is an ominous sign indicating a need for immediate relief of increased intracranial pressure.

Evaluate the child's face. Does the child smile or cry? Does the child react to playfulness with a laugh? Does the young infant cry vigorously? Are facial movements equal? In a child, a normal or near-normal neurologic examination can be a reassuring sign. Conversely, obtunded or muted responses to environmental stimuli are a cause for concern.

Next evaluate for spontaneous movement of the extremities. Young infants cannot walk, so assess their ability to move their arms and legs and grossly evaluate the tone of their extremities. Does the infant vigorously and equally move the arms and legs? Is the muscle tone normal, or does the infant appear floppy or flaccid? When evaluating the older child, note whether he or she is ambulatory alone, ambulatory with assistance, or unable to walk. Note whether the child has use of the upper extremities. In the case of trauma, the child may arrive immobilized on a backboard. In this scenario, evaluate the child's motor responsiveness and sensation in each extremity, comparing findings bilaterally while the child is in the supine position. Ask the child if he or she feels you touching each extremity. Ask the child to squeeze your fingers and to wiggle the toes. This will provide information about cerebral integrity and perfusion, cerebellar health, and spinal cord integrity.

The Pediatric Glasgow Coma Scale may also be used to evaluate the neurologic status in children (Hartman & Chiefetz, 2011). Chapter 38 provides a more in-depth discussion of this scale.

**Skin and Extremity Evaluation.** Remove the child's clothing and thoroughly examine the skin for bruising, lesions, or rashes. If the child has a rash, note the size, shape, color, configuration, and location. Apply pressure to the rash with the fingertips to see whether it blanches. Inspect the trunk, abdomen, and extremities for abrasions or deformities.

**Take Note!**

Rashes that do not blanch may be classified as petechiae or purpura. This type of rash may be associated with certain serious conditions, such as meningococemia. Report this finding to the physician or nurse practitioner immediately.

**Pain Assessment.** In emergencies, children may experience pain as a direct result of the injury or disease, and life-saving interventions such as resuscitation, insertion of IV lines, and administration of medications may cause further pain. The child's pain may also be exaggerated by light, noise, movement of the stretcher or bed, and the sensations of cold or heat. Nurses play a key role in minimizing the child's pain, and this may decrease the child's future distress (Rzucidio & Campbell, 2009). If the child is awake and verbal, use an age-appropriate pain assessment scale to determine the child's pain level. If the child is sedated or unconscious, assess pain with a standardized scale that relies on physiologic measurements as well as behavioral parameters. Refer to Chapter 36 for additional information on pain assessment in children.

### Laboratory and Diagnostic Testing

A number of laboratory and diagnostic tests may be ordered in a pediatric emergency. Laboratory tests can help to distinguish the cause of the emergency or additional problems that need to be treated. Standard laboratory tests obtained in most emergency departments include:

- Arterial blood gases (ABGs), obtained initially and then serially to assess for changes
- Electrolytes and glucose levels
- Complete blood count (CBC)
- Blood cultures
- Urinalysis

If ingestion is suspected, then a toxicology panel will be obtained. In suspected sepsis, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), and urine and spinal fluid cultures may also be obtained. The pediatric trauma victim may have additional laboratory tests performed, including amylase, liver enzymes, and blood type and cross-match.

Diagnostic tests may include radiologic tests, computed tomography (CT) scanning, and magnetic

resonance imaging (MRI). One advantage of radiologic diagnostic testing is that the tests are relatively noninvasive. A disadvantage of CT and MRI scans is that before they can be performed, the child must be stabilized. Common Laboratory and Diagnostic Tests 53.1 discusses the tests most commonly used in pediatric emergencies.

**After completing an assessment of Alma, the nurse noted the following: a patent airway, anxious but able to speak in short sentences, and skin temperature cool on the extremities. Based on these assessment findings, what would your top three nursing diagnoses be for Alma? Describe appropriate nursing interventions.**

### Nursing Diagnoses and Related Interventions

After completing a thorough assessment and initial stabilization of the child, the nurse might identify several nursing diagnoses, including:

- Ineffective airway clearance
- Ineffective breathing pattern
- Impaired gas exchange
- Deficient fluid volume
- Decreased cardiac output
- Ineffective tissue perfusion (cardiopulmonary, peripheral cerebral, or renal)
- Deficient knowledge
- Fear
- Interrupted family processes

Specific nursing goals, interventions, and evaluation for the child in an emergency are based on the nursing diagnoses. Additional information about nursing management will be included later in the chapter as it relates to specific disorders.

### Providing Cardiopulmonary Resuscitation

Always evaluate and manage the airway first. Call for help and assign someone to obtain the automatic external defibrillator (AED). Open the airway and assess for adequate breathing. If the child is not breathing, begin rescue breathing.

Check for a pulse. In the child, the carotid or femoral pulses are easiest to assess. In the past, it was recommended that the brachial pulse be checked in the infant, but this is often difficult, so an alternative is to check the femoral pulse. Carefully assess for signs of a pulse, but do not spend more than 10 seconds checking the pulse.

If there is not a pulse or if the heart rate is less than 60 beats per minute (bpm), begin chest compressions.

## COMMON LABORATORY AND DIAGNOSTIC TESTS 53.1 PEDIATRIC EMERGENCIES

Test	Explanation	Indications	Nursing Implications
Chest radiograph	Radiograph used to evaluate heart and lung structures	To identify: <ul style="list-style-type: none"> <li>• Infections (e.g., pneumonia)</li> <li>• Foreign body</li> <li>• Injury</li> <li>• Tracheal tube placement</li> <li>• Central line placement</li> <li>• Pneumothorax</li> </ul> Reevaluation of lungs after chest tube placement	<ul style="list-style-type: none"> <li>• Radiographs can be obtained quickly during resuscitation; usually available in emergency department.</li> <li>• Assist the child to lie still if necessary.</li> </ul>
Computed tomography (CT)	Use of high radiation (equivalent to about 100 to 150 chest x-rays) with computer processing targeting specific body areas	Rapid evaluation of tissues and skeletal areas Superior test for the evaluation of internal bleeding	<ul style="list-style-type: none"> <li>• Expect the child to be transported out of the area for the study.</li> <li>• Accompany the child to provide continued observation and management, especially if child's condition is unstable.</li> </ul>
Magnetic resonance imaging (MRI)	Incorporation of responses of hydrogen protons to a dynamic magnetic field	Superior test for the evaluation of the spinal cord and the cerebrospinal fluid spaces; less useful in emergency situations	<ul style="list-style-type: none"> <li>• Administer sedation as ordered.</li> <li>• Assist child in remaining still; MRI requires child to remain still for a longer period than for a CT.</li> <li>• Assist the conscious child to deal with fear related to loud banging noise of the machine.</li> </ul>
Arterial blood gases (ABGs)	Evaluation of blood pH and arterial blood levels of oxygen and carbon dioxide	Evaluation of quality of respiration and evaluation of acid–base balance	<ul style="list-style-type: none"> <li>• Anticipate serial ABGs to assess for status changes.</li> <li>• Never delay resuscitation efforts pending blood gas results.</li> </ul>
Serum electrolytes	Evaluation of electrolyte levels, such as sodium, potassium, and chloride, in the blood	Useful for determining baseline and if dehydration is hypertonic or isotonic	<ul style="list-style-type: none"> <li>• Hemolysis of specimen may lead to falsely elevated potassium levels.</li> </ul>
Glucose	Evaluation of glucose level in the blood	Valuable for determining need for supplementation, as in the case of hypoglycemia	<ul style="list-style-type: none"> <li>• Use ACCU-CHEK® or other rapid glucose test at the bedside or obtain serum blood specimen.</li> <li>• Elevated glucose levels can be associated with stress or with use of corticosteroids.</li> </ul>
Toxicology panel (blood and/or urine)	Determination of most commonly abused mood-altering medications, as well as commonly ingested drugs	Drug abuse, overdose, or poisoning	<ul style="list-style-type: none"> <li>• Standard toxicology panel varies with the agency.</li> <li>• Follow agency protocol; may require special handling or labeling of specimen.</li> <li>• Use a blood specimen that is best for determining overdose or poisoning.</li> </ul>

(continued)

## COMMON LABORATORY AND DIAGNOSTIC TESTS 53.1 PEDIATRIC EMERGENCIES (continued)

Test	Explanation	Indications	Nursing Implications
Complete blood count (CBC)	Evaluation of hemoglobin and hematocrit, white blood cell count, and platelet count	Any condition in which anemia, infection, or thrombocytopenia is suspected Trauma if blood loss is suspected	<ul style="list-style-type: none"> <li>• Be aware of normal values and how they vary with age and gender.</li> <li>• Hemoglobin and hematocrit may be elevated secondary to hemoconcentration in the case of hypovolemia.</li> </ul>
Blood type and cross-match	Determination of ABO blood typing as well as presence of antigens  Cross-match is performed on RBC-containing products to avoid transfusion reaction.	Trauma victim or any person with suspected blood loss as preparation for transfusion	<ul style="list-style-type: none"> <li>• Handle specimen gently to avoid hemolysis.</li> <li>• Ensure that specimen request and label are appropriately signed and dated.</li> <li>• Apply “type and cross” or “blood band” to child at time of specimen collection if required by agency.</li> <li>• Most type and cross-match specimens expire after 48 to 72 hours.</li> </ul>
Urinalysis	Evaluation of color, pH, specific gravity, and odor of urine  Assessment for protein, glucose, ketones, blood, leukocyte esterase, RBCs, WBCs, bacteria, crystals, and casts	Children with fever, dysuria, flank pain, urgency, or hematuria or those who have experienced trauma to provide information about the urinary tract	<ul style="list-style-type: none"> <li>• Many drugs can affect urine color; notify the laboratory if the child is taking one.</li> <li>• Notify the laboratory and document on the laboratory form if the child or adolescent is menstruating.</li> <li>• Refrigerate the specimen if it is not processed promptly.</li> <li>• Specimen may be obtained by catheterization, clean-catch voiding sample, or a U-bag.</li> </ul>

RBCs, red blood cells; WBCs, white blood cells.

**Take Note!**

When a cardiac arrest occurs in a child out of the hospital and is a witnessed, sudden collapse, initial management is slightly different than that for other arrests. In these sudden, witnessed events, call 9-1-1 or the local emergency number for help first, get the AED, and return to start CPR (Berg et al., 2010).

Table 53.1 presents the AHA's most recent recommendations for ratios of breaths and compressions. These recommendations stress the importance of properly performed chest compressions. Therefore, several changes have been made to the guidelines:

- Rescuers must provide compressions of adequate rate and depth.
- Chest recoil should be allowed.
- Minimal interruption of chest compressions should be the goal.
- For infant CPR, two-person infant CPR can be performed by encircling the chest with two thumbs and simultaneously using the hands to provide a thoracic squeeze.
- For two-person CPR, no pauses should occur for ventilation, with the compressing health care provider giving continuous compressions (Berg et al., 2010).

**TABLE 53.1** RATIOS OF BREATHS TO COMPRESSIONS

Age	One-Person CPR	Two-Person CPR
Infant	<ul style="list-style-type: none"> <li>• 30 compressions to 2 breaths</li> <li>• Hand placement: two fingers, placed one fingerbreadth below the nipple line</li> </ul>	<ul style="list-style-type: none"> <li>• 15 compressions to 2 breaths</li> <li>• Hand placement: two thumbs encircling the chest at the nipple line</li> </ul>
Child	<ul style="list-style-type: none"> <li>• 30 compressions to 2 breaths</li> <li>• Hand placement: heel of hand or two hands (adult position in larger child), pressing on the sternum at the nipple line</li> </ul>	<ul style="list-style-type: none"> <li>• 15 compressions to 2 breaths</li> <li>• Hand placement: heel of one hand or two hands (adult position in larger child), pressing on the sternum at the nipple line</li> </ul>

Adapted from Berg, M. D., Schexnayder, S. M., Chameides, L., Terry, M., Donoghue, A., Hickey, R. W., et al. (2010). Part 13: Pediatric basic life support – 2010 American Heart Association guidelines for cardiopulmonary resuscitation and emergency cardiovascular care. *Circulation*, 122, S862–S875.

### Providing Defibrillation or Synchronized Cardioversion

In some cases, the child has an abnormal life-threatening cardiac rhythm or an arrhythmia that does not respond to pharmacologic therapy or leads to hemodynamic instability. In these cases, electrical therapy, in the form of defibrillation or synchronized cardioversion, may be needed.

**Defibrillation** is the use of electrical energy to depolarize the cells of the myocardium to terminate an abnormal life-threatening cardiac rhythm, such as ventricular fibrillation. Defibrillation is used in conjunction with oxygen, CPR, and medications. The effects of defibrillation are enhanced in an oxygen-rich environment coupled with good artificial circulation (CPR).

**Cardioversion**, another means of applying electrical current to the heart, is used when the child has supraventricular tachycardia (SVT) or ventricular tachycardia with a pulse. Cardioversion may also be enhanced with medications. Cardioversion is delivered synchronized—that is, the electrical current is applied on the R wave of the electrocardiogram (ECG).

The basic defibrillator is equipped with adult- and pediatric-sized paddles. A switch turns the machine on and controls are used to select the amount of energy (joules). Typically, the initial energy amount is 2 joules/kg; it can be increased up to 4 joules/kg for defibrillation. Energy for cardioversion is delivered at 0.5 to 1 joule/kg.

When the defibrillator is being used in an acute care setting, the leader of the code team will take charge of defibrillator use. He or she is responsible for ensuring that only the child receives the energy from the defibrillator. The code team leader will count to 4 before delivering a shock to the child to ensure that all personnel and other equipment are clear of the bed to avoid accidental shock.

### Using Automated External Defibrillation

In cases of sudden, witnessed, out-of-hospital collapse, an arrhythmia is often the cause. Therefore, the AHA has revised its recommendations about the use of an AED in children (Berg et al., 2010). An AED is an alternative to manually defibrillating an individual. The AED device consists of electrodes that are applied to the chest. These electrodes are used to monitor the heart rhythm and deliver the electrical current. AED devices are readily available in a variety of locations, such as airports, sports facilities, and businesses. Traditionally, the AED was designed for use in adults, but newer AEDs with smaller pads and the ability to alter energy delivery are now more readily available. Therefore, the AHA has recommended that an AED be used for children who are older than age 1 year who have no pulse and have suffered a sudden, witnessed collapse (Berg et al., 2010).

The AED is designed for persons to use it in the prehospital setting. Once the AED is turned on, the machine uses auditory commands to guide laypersons and health care professionals alike through the correct placement of the electrodes and the administration of energy. The AED periodically evaluates the victim's cardiac rhythm and instructs the user about checking the pulse, continuing CPR, and delivering shocks. Nurses who care for children should be able to operate an AED and be prepared to use it in nontraditional settings. See Evidence-Based Practice 53.1.

### Determining Medication Doses and Equipment Sizes

Many pediatric acute care facilities prepare code reference sheets when a child is admitted. This sheet uses the child's actual weight to determine medication doses and equipment sizes. The reference sheet is kept on a clipboard at the child's bedside or taped on the wall at

**EVIDENCE-BASED PRACTICE 53.1****THE ROLE OF AUTOMATED EXTERNAL DEFIBRILLATORS (AEDs) IN CARDIAC RESUSCITATION OF CHILDREN**

Primary cardiac arrest resulting from arrhythmia or commotio cordis is rare in children and adolescents but often has a very poor outcome. Also, sudden death during sporting events has occurred in children and adolescents. Traditionally, manual defibrillation has been the only form of defibrillation used in children. With the newer technology available in AEDs, the question arose as to whether they could be used effectively to treat arrhythmia in children.

**STUDY**

Cecchin et al. (2001) performed a study of over 600 children to determine the specificity and sensitivity of automated external defibrillation in children.

**Findings**

The researchers found that AEDs can be sensitive and specific for detecting and treating arrhythmia by

Adapted from Cecchin, F., Jorgenson, D. B., Berul, C. I., et al. (2001). Is arrhythmia detection by automatic external defibrillator accurate for children? Sensitivity and specificity of an automatic external defibrillator algorithm in 696 pediatric arrhythmias. *Circulation*, 103, 2438–2483; and Salib, E. A., Cyran, S. E., Cilley, R. E., Maron, B. J., & Thomas, N. J. (2005). Efficacy of bystander cardiopulmonary resuscitation and out-of-hospital automated external defibrillation as life-saving therapy in commotio cordis. *Journal of Pediatrics*, 147, 863–869.

defibrillation in children older than 1 year of age. Salib et al. (2005) report a positive and healthy outcome after an AED was used at the scene on a 13-year-old who suffered a baseball blow to the chest resulting in commotio cordis. As a result of these and many other studies, in 2005 the American Heart Association recommended changes in the pediatric basic life support guidelines to include the use of AEDs in sudden witnessed collapse in children.

**Nursing Implications**

For nurses working in hospitals, ensure that witnessed collapse in children includes assessing for the need for defibrillation. Outside the hospital, nurses should advocate for AEDs to be placed in all high school gymnasiums and at all parks and ball fields.

the head of the bed. An additional copy is placed in the child's chart.

Ambulatory care providers often use the Broselow tape to estimate the child's weight based on the child's length (Fig. 53.2). The tape is color coded and emergency equipment for a child of that size is stored in corresponding color-coded packages or in color-coded drawers on the pediatric emergency cart. Medication doses and equipment sizes are also located on the tape. The most accurate calculation for code medications is based on the child's weight, but use of the Broselow tape for estimating the weight has been shown to be successful in children weighing less than 25 kg (So, Farrington, & Absher, 2009).

**Managing Pain**

Depending on the child's status and pain level, individualize pain management interventions. For the alert child, nonpharmacologic measures may be used in addition to medications. Provide atraumatic care for procedures and use aggressive pharmacologic treatments to manage pain as the child's condition allows. Refer to Chapter 36 for additional information on pain management strategies.

**Ensuring Stabilization**

After a child has been resuscitated, the nurse plays a key role in stabilization and transport. Thoroughly

document the interventions that were performed as well as the ongoing assessment of the child's response to the interventions. Provide continued monitoring of the child while awaiting transport. Copy and assemble any pertinent documentation, such as the resuscitation record, nurse's notes, and laboratory test results, which will be given to the receiving institution. Ensure that all lines are taped securely and that vascular access sites are dressed and labeled with the date and time of insertion. As soon as possible, bring the child's family in to visit with the child. Provide explanations about the IV lines, monitoring equipment, and other medical equipment and devices. Encourage the family to talk to and touch the child.

**Providing Support and Education to the Child and Family**

The experience of respiratory distress, oxygen deprivation, and an emergency situation is a frightening one for persons of all ages. The life-saving interventions that take place during an emergency can be especially intimidating and upsetting to children. Infants and young children cannot understand explanations about these interventions, and older children and adolescents may feel frightened and angry about the loss of control. The caregivers may feel fear, anger, guilt, and sadness. They may be concerned about the very real possibility that their child might die.

A

B

**FIGURE 53.2 (A)** Broselow tape. **(B)** Measure the child's length with the Broselow tape to determine medication doses and tracheal tube size.

Resuscitation of a child is often a perplexing and frightening event for laypersons to observe. Therefore, traditionally family members have been excluded during the resuscitation of children. Recently, however, there has been a trend to allow family members to be present during pediatric resuscitation. Current evidence-based practice guidelines recommend individual evaluation of each family to determine whether allowing their presence during the resuscitation will be beneficial (Meeks, Ahmann, & Dokken, 2009).

Considering the highly technical nature of resuscitation, the rapidity with which interventions occur, and the fear associated with a life-threatening event, nurses can play a crucial role in providing understandable explanations to families, coupled with empathic support. During the acute phase, the nurse should give brief explanations as life-saving interventions are being provided. Examples of these types of explanations include:

- When applying the pulse oximeter sensor: "I need to put this light on your child to check his oxygen level; it won't hurt."
- When connecting the child to the cardiac monitor: "We're going to put these sticky patches on your child and connect them so we can monitor his heart rate on this screen."
- When preparing for intubation and ventilation: "Your child can't breathe on his own right now, so we're going to give him some extra help with this tube."

This tube will go through his breathing passage and this machine will help him to breathe."

The nurse plays a key role in providing empathy and support. Do not provide false reassurance and say, for example, "He's going to be all right." The outcome is never certain. Rather, communicate empathically. For example, say, "This must be very difficult for you. We're doing everything we can to help your child." Provide honest answers in a reassuring manner. Respect each family's diversity and observe their strengths and weaknesses. Be nonjudgmental in all interactions with families, even when the child's emergency situation may have resulted from family neglect.

Parents often feel helpless when their child is in a high-tech environment. Suddenly overwhelmed with the equipment and monitoring devices, they no longer are the persons who are the most skilled in caring for their child. Integrate the child's parents into the health care team. Suggest ways the parents can make the hospital experience more normal for their child. For example, simply allowing a father to read a story to his daughter or encouraging a mother to hold her child's hand is therapeutic both for the child and the parents. Be aware of this dramatic change and how it affects the parents. Always ensure that they feel like they are a welcome part of their child's care.

Providing the child with familiar comfort objects helps to decrease stress. Once the intubated child is alert and stabilized, assist him or her with communication. Some children can lift one finger for yes and two fingers for no. If the child is old enough to write, provide paper and pencil. Play is essential to the work of the child, and even if he or she is immobile, play is still possible. Puppets at the bedside and books help give the child a more normal experience in a scary situation that is far from the norm. Teenagers may enjoy listening to music through headphones. Even children who are comatose should be talked to and allowed to listen to familiar music.

Even if the outcomes are serious, the nurse can provide critical support to children and families. Whether hugging a crying mother or playing "peek-a-boo" with an intubated child, the nurse will be the one who can make a difference during a frightening experience.

## NURSING MANAGEMENT OF CHILDREN IN EMERGENCIES

Nurses must be adept at identifying the beginning stages of an emergency so they can quickly and appropriately intervene to prevent deterioration to cardiopulmonary arrest. Assessment and management of the most common types of emergencies in children are discussed below. The topics covered include respiratory arrest,

shock, cardiac arrhythmias and arrest, near drowning, poisoning, and traumatic injury.

## Respiratory Arrest

Respiratory emergencies may lead to respiratory failure and eventual cardiopulmonary arrest in children. Infants and young children are at greater risk for respiratory emergencies than adolescents and adults because they have smaller airways and underdeveloped immune systems, resulting in a diminished ability to combat serious respiratory illnesses. Young children often lack coordination, making them susceptible to choking on foods and small objects, which may also lead to cardiopulmonary arrest. In addition, sudden infant death syndrome (SIDS) is a leading cause of cardiopulmonary arrest in young infants and thus is one of the leading causes of postneonatal mortality in the United States (Marino & Fine, 2009). For these reasons, nurses must be skilled at recognizing the signs of pediatric respiratory distress so they can prevent progression to cardiopulmonary arrest. Table 53.2 lists some of the more common causes of pediatric respiratory arrest.

### Nursing Assessment

If the child has severe respiratory compromise, obtain a brief history while simultaneously providing respiratory interventions. To obtain the history, use the following questions as a guide:

- When did the symptoms begin and when do they occur?
- Did the symptoms have a sudden onset (as with a foreign body aspiration)?
- How have the symptoms progressed?
- Is the cough continual, intermittent, or worse at night or with exercise?
- Has there been any stridor? (Stridor is heard upon inhalation and may be associated with swelling of the trachea [as with croup] or with a foreign body in the upper airway.)
- Is there wheezing? If so, is the wheezing on inspiration or on expiration, or both?
- What makes the symptoms better and what makes them worse?
- Does drinking from a bottle induce the symptoms (as with gastroesophageal reflux–induced aspiration)?
- Is the child taking any medication for the symptoms? Does the child or do any members of the immediate family have a history of chronic respiratory disease, such as asthma?
- Are the child's immunizations up to date?
- Was the child born prematurely? If so, did the child require mechanical ventilation? For how long?
- Were there any respiratory problems during the first few days of life?
- When did the child last eat? (This question is important because a recent meal will increase the child's risk of aspiration in the event of a respiratory arrest. In addition,

the presence of food in the stomach will increase the risk of aspiration during tracheal intubation.)

If the child can communicate, ask how he or she is feeling. Is he or she short of breath? Does his or her chest hurt? Observe the child while speaking. Children who are in respiratory distress may speak in short sentences with gasping between words.

### PHYSICAL EXAMINATION

In an emergency, physical examination is often limited to inspection, observation, and auscultation. First, quickly survey the respiratory status. Determine if the child is breathing.

**Inspection and Observation.** Establish if the airway is patent, maintainable, or unable to be maintained. The child with a patent airway is breathing without signs of obstruction. The maintainable airway remains patent independently by the child or with interventions such as a towel roll under an infant's neck or the insertion of a nasal trumpet. The airway that cannot be maintained does not remain patent unless a more aggressive intervention, such as the insertion of a tracheal tube, is performed.

Look at the child's posture. Is the child sitting up, leaning forward, and drooling, as with epiglottitis? Observe the child's face: does he or she appear anxious or relaxed? Children in respiratory distress often appear anxious. Look at the nose and mouth. Are the nares patent? Is there noticeable nasal congestion or mucus coming from the nose? Note nasal flaring or mouth breathing. Observe for head bobbing. Listen for audible expiratory grunting or inspiratory stridor. Note the child's color. Does the child appear pale, mottled, dusky, or cyanotic? Children may appear mottled in response to poor oxygenation, hypothermia, or stress. Children with severe respiratory compromise may appear dusky. Look for cyanosis around the mouth or on the trunk. Cyanosis is a late and often ominous sign of respiratory distress. Central cyanosis is more likely to be associated with respiratory or cardiac compromise. In contrast, peripheral cyanosis is more likely to be associated with circulatory alteration.

#### Take Note!

Closely inspect the color of the area around the mouth. Circumoral pallor is a sign of poor oxygenation.

Evaluate the pattern and quality of respiration, noting the respiratory rate. **Tachypnea** (increased respiratory rate) is often noted in children in respiratory distress. However, seriously ill children grunt and may have normal or subnormal respiratory rates. **Hypoventilation**, a decrease in the depth and rate of respirations, is noted in very ill children or children who have central respiratory depression secondary to narcotics. If the child is a young infant (younger than 2 months) or premature, periodic breathing may occur. **Periodic**

TABLE 53.2

## CAUSES OF RESPIRATORY ARREST IN CHILDREN

Condition	Cause
Upper airway	Burns Croup Epiglottitis Foreign body aspiration Reflux Strangulation or near strangulation Tracheomalacia Vascular ring
Lower airway	Asthma Bronchiolitis Burns Foreign body aspiration Pertussis infection Pneumonia Pneumothorax Reflux
Nonrespiratory origins	Septic shock HIV
Neurologic	CNS infection Guillain-Barré syndrome Poliomyelitis Seizures Sleep apnea Spinal cord trauma Sudden infant death
Chronic illness	Complications of severe prematurity Cystic fibrosis Bone marrow transplant Neutropenia
Metabolic/endocrine disorders	Diabetic ketoacidosis Mitochondrial disorders
Cardiac conditions	Arrhythmia Congenital cardiac problems Acquired cardiac problems
Traumatic/unintentional/intentional injury	Asphyxia Child abuse/“shaken baby syndrome” Drowning Electrocution Gunshot wound Toxic ingestion Vehicular-related trauma
<p>CNS, central nervous system. Adapted from Fleisher, G. R., &amp; Ludwig, S. (2010). <i>Textbook of pediatric emergency medicine</i> (6th ed.). Philadelphia, PA: Lippincott Williams &amp; Wilkins.</p>	

**breathing** is regular breathing with occasional short pauses (brief periods of apnea). After the apneic pause, the infant will breathe rapidly (up to 60 breaths per minute) for a short period and then will resume a normal respiratory rate. In general, the infant who has periodic breathing looks pink and has a normal heart rate. Observe for the use of accessory muscles in the neck

or retractions in the chest, determining the extent and severity of the retractions.

**Auscultation.** Auscultate the lungs with the diaphragm of the stethoscope. Breath sounds over the tracheal region are higher pitched and are described as vesicular, while breath sounds over the peripheral lung fields tend to be

lower pitched, known as bronchial. Instruct the child to take deep breaths with the mouth open. To encourage the young child to exhale strongly, instruct him or her to “blow out” the penlight (as with a candle) or to blow on a tissue. Encourage the child not to breathe more rapidly than normal (to prevent hyperventilation [increased depth and rate of respirations]) and to avoid making any noises with the mouth.

### Take Note!

Significant upper respiratory congestion often interferes with assessment of the lower airways because the sound is easily transmitted throughout the chest. Differentiate between the upper and lower airway noises by listening with the stethoscope over the nose. The nurse may be able to determine whether the noise is nasal or bronchial by using this technique.

Auscultate the child’s chest systematically. Listen in all anterior, axillary, and posterior regions, comparing the left to the right sides. Note any decreased or absent breath sounds, which may be the result of bronchial obstruction (as with mucous infection) or air trapping (as in children with asthma). Unilateral absent breath sounds are associated with foreign body aspiration and pneumothorax.

### Take Note!

Sometimes a child’s respiratory status is so severely compromised that little or no air movement is noted. This commonly occurs during a severe asthma exacerbation. Minimal or no air movement requires immediate intervention.

Note the presence and location of adventitious breath sounds such as crackles, wheezes, or rhonchi. Document the presence of a pleural friction rub (a low-pitched, grating sound), a sound resulting from inflammation of the pleura.

**Palpation.** Palpate the chest for any abnormalities. In the older, less severely ill, and cooperative child, assess for tactile fremitus. Using the palm of the hand, palpate over the lung regions in the same manner as for auscultation and percussion while the child says “ninety-nine.” Increased vibrations elicited during this maneuver are associated with consolidating conditions, such as pneumonia.

**Percussion.** Percuss the interspaces of the chest between the ribs in the same systematic fashion as with auscultation. Normally, percussion over an air-filled lung reveals resonant sounds. Note the presence of hyperresonance, which may indicate an acute problem such as a pneumothorax or a chronic disease such as asthma. In contrast, percussion sounds will be dull over a lobe of the lung that is consolidated with fluid, infectious organisms, and blood cells, as in the case of pneumonia.

## Laboratory and Diagnostic Testing

Use continuous pulse oximetry if respiratory status is a concern. Note and report oxygen saturation levels below 95%. (See Chapter 40 for additional information about use of the pulse oximeter.)

Additional tests may reveal:

- Arterial or capillary blood gases: hypoxemia, hypercarbia, altered pH
- Chest radiograph: alterations in normal anatomy or lung expansion, or evidence of pneumonia, tumor, or foreign body
- Metal detector: evidence of metallic foreign body. Novel as it may sound, metal detectors have been found to be highly accurate (99%) in detecting the presence of ingested coins in children (Ramlakhan, Burke, & Gilchrist, 2006).

### Take Note!

Children with cardiac conditions resulting in cyanosis often have baseline oxygen saturations that are relatively low because of the mixing of oxygenated with deoxygenated blood.

## Nursing Management

The basic principle of pediatric emergency care and PALS is prevention of cardiopulmonary arrest (Kleinman et al., 2010a). Therefore, the nurse must rapidly assess and appropriately manage children who have signs of respiratory distress. Nursing management of the child in respiratory distress involves maintaining a patent airway, providing supplemental oxygen, monitoring for changes in status, and in some cases assisting ventilation. In addition to providing these life-saving measures and monitoring the child’s progress, offer support and education to the child and family.

### MAINTAINING A PATENT AIRWAY

When a child exhibits signs of respiratory distress, make a quick decision about whether it will be safe to allow the child to stay with the parent or whether the child must be placed on the examination table or bed. For example, in the case of croup, the child will often breathe more comfortably and experience less stridor while in the comfort of the parent’s lap. Many children in respiratory distress often are most comfortable sitting upright, as this position helps to decrease the work of breathing by allowing appropriate diaphragmatic movement. In contrast, a child with a decreasing level of consciousness may need to be placed in the supine position to facilitate positioning of the airway.

The infant may benefit from a small towel folded under the shoulders or neck (Fig. 53.3). Avoid neck flexion or hyperextension, which may completely occlude the infant’s airway. In children older than age 1 year, the

**FIGURE 53.3** (A) The infant and young child's prominent occiput encourages flexion of the neck and may result in airway occlusion. (B) Putting a towel roll under the shoulders or neck helps to open the infant's or young child's airway by placing it in the neutral or "sniff" position.

**FIGURE 53.4** Jaw-thrust technique for opening the airway.

optimal method for opening the airway is to hyperextend the neck, as recommended by the AHA (Berg et al., 2010). If a cervical spine injury is not suspected, use the head tilt–chin lift technique to open the airway. If the child has suffered head or neck trauma and cervical spine instability is a concern, use the jaw-thrust maneuver by placing three fingers under the child's lower jaw and lifting the jaw upward and outward (Fig. 53.4). In either case, never place the hand under the neck to open the airway.

Often the nurse encounters an acutely ill child who cannot maintain an airway independently but may be able to do so with some assistance. For example, sometimes simply opening the airway and moving the tongue away from the tracheal opening is all that is required to regain airway patency. In certain conditions, a nasopharyngeal or oropharyngeal airway may be necessary for airway maintenance. Comparison Chart 53.1 provides additional information about these types of airways.

### COMPARISON CHART 53.1

#### OROPHARYNGEAL VERSUS NASOPHARYNGEAL AIRWAYS

Oropharyngeal airway  
(used only in  
unconscious children)

- Consists of a simple plastic curved body that has a central air channel to allow for aeration
- Is used when an unconscious child has difficulty maintaining airway patency due to upper airway obstruction, such as from the tongue
- Allows for oral suction
- Determine the correct size of the airway by placing it next to the child's cheek with the tip pointing down. An airway that is too large will extend past the angle of the child's mandible and can obstruct the glottic opening when inserted
- Choose the airway that best fits the child to decrease the risk of injury to the structures of the mouth

Nasopharyngeal airway  
(may be used in  
conscious children and  
children who have an  
intact gag reflex)

- Consists of a flexible curved tube that is inserted nasally
- Is used when the child has difficulty maintaining airway patency due to tongue obstruction or palate problems, when neurologic impairment causes poor pharyngeal tone, or in the child with impaired consciousness
- Allows for nasopharyngeal suction
- When selecting this airway, keep in mind that the diameter of the airway should not be so large that it puts too much pressure on the internal nasal tissue. There are two common methods for measuring this airway: (a) measure the distance from the end of the child's nose to the tragus of the ear; (b) look at the child's fifth digit, which is usually the approximate diameter of the nasopharyngeal airway
- Monitor for mucosal irritation, nasal septum swelling, and laceration of the adenoids.
- Do not use this type of airway in children with a history of bleeding disorders and basilar skull fractures
- This airway's small diameter can easily become obstructed with secretions and blood.

**ASSISTING VENTILATION USING A BAG-VALVE-MASK**

The child in respiratory distress may ventilate poorly, hypoventilate, or tire and become apneic. In this case, the child may require assistance with ventilation through BVM ventilation (see Table 53.3). (Table 53.3 also lists and discusses assisting with ventilation using tracheal intubation [discussed in detail below], an anesthesia bag or flow-inflating ventilation system, and a laryngeal mask airway.)

BVM ventilation is used in the management of children who cannot ventilate or oxygenate effectively on their own. This technique is a more efficient way of ensuring ventilation than using only supplemental oxygen. In addition, resuscitating a child in this manner is

superior to mouth-to-mouth resuscitation as it provides higher oxygen concentrations and protects the nurse from exposure to oral secretions (Berg et al., 2010). However, this technique requires proper training and practice. The proper procedure involves appropriate opening of the airway followed by providing breaths with the BVM.

Ventilation with the BVM may be performed with either one or two rescuers. First, choose an appropriately sized bag and a corresponding face mask that fits the infant or child. Self-inflating bags are usually available in neonatal, infant, child, and adult sizes. Corresponding masks are available. Choose a face mask that properly fits the child’s face and that provides a seal over the nose

**TABLE 53.3 AIRWAY AND VENTILATION METHODS**

Method	Description	Comments
Anesthesia bag or flow-inflating ventilation systems	A small, collapsible bag that consists of a reservoir bag, an overflow port, and a fresh gas inflow port	<ul style="list-style-type: none"> <li>• Adjustment of the oxygen flow and of the outlet control valve is necessary.</li> <li>• Useful in providing positive end-expiratory pressure (PEEP) or continuous positive airway pressure (CPAP)</li> <li>• Adequate training and significant skill are needed to properly operate this device.</li> <li>• Hypercapnia and barotrauma may result with improper use.</li> <li>• Used more commonly in the postanesthesia care unit (PACU) and in the neonatal intensive care unit</li> </ul>
Bag-valve-mask device or manual resuscitator	A self-inflating oxygen delivery bag that does not require an oxygen source for resuscitation and ventilation. The bag can be connected to oxygen to provide higher oxygen levels than room air. When the child exhales, the nonbreathing valve closes, allowing exhaled, deoxygenated air to escape.	<ul style="list-style-type: none"> <li>• Effective in providing oxygen to a child who is in severe respiratory distress or who has suffered a respiratory arrest</li> <li>• A more efficient method of respiratory resuscitation than mouth-to-mouth resuscitation; decreased rescuer exposure to communicable disease</li> <li>• Most medical personnel can be trained to perform resuscitation with this method.</li> <li>• Possibly tiring for the rescuer when used to ventilate a child for long periods of time (see discussion on bag-mask ventilation)</li> </ul>
Laryngeal mask airway	An inflatable silicone mask and rubber connecting tube that is inserted blindly into the airway, forming a seal	<ul style="list-style-type: none"> <li>• The airway is introduced into the pharynx and advanced until it meets resistance; balloon cuff is then inflated.</li> <li>• Easier insertion than a tracheal tube</li> <li>• Usually used in the unconscious child who benefits from bag-valve-mask ventilation but does not require intubation</li> <li>• Improvement in child comfort</li> </ul>
Tracheal intubation	A plastic tube inserted in the trachea to establish and maintain an airway when the airway cannot be maintained effectively using other measures (e.g., nasal trumpet or bag-valve-mask ventilation)	<ul style="list-style-type: none"> <li>• Skilled medical professional (physician, nurse practitioner, respiratory specialist, emergency medical technician, or physician’s assistant) necessary for insertion</li> <li>• The nurse acts as a valuable assistant during the intubation procedure.</li> </ul>

**FIGURE 53.5** The mask should form a seal over the nose and mouth, across the chin and nose bridge.

**FIGURE 53.6** Proper hand placement for maintaining airway and adequate mask seal using one-rescuer technique.

and mouth and excludes the eyes, thus preventing any pressure on the eyes (Fig. 53.5).

**Take Note!**

Face masks should be clear so that the nurse can see the child's lip color and identify any emesis during resuscitation.

Connect the BVM via the tubing to the oxygen source and turn on the oxygen. When resuscitating infants and children, set the flow rate at approximately 10 L/minute. For an adolescent who is adult sized, set the flow rate at 15 L/minute or higher to compensate for the larger-volume bag. Check to make sure that the oxygen is flowing through the tubing to the bag. Self-inflating bags do not provide free-flow oxygen out of the face mask; manual pumping of the bag is necessary. However, the bags have a corrugated plastic tail that allows oxygen to freely flow. Therefore, check over the tail for oxygen flow through the bag.

After opening the airway appropriately (see above), place the mask over the child's face. When one rescuer is providing ventilation (commonly referred to as "bagging"), the person must provide a seal with the mask over the child's face with one hand and use the other hand to manipulate the resuscitator bag. The hand used to provide the mask seal will simultaneously maintain the airway in an open position. Generally, use the left thumb and index finger to hold the mask on the child's face. While maintaining a good seal with the mask, use upward pressure on the jaw angle while pressing downward on the mask below the child's mouth to keep the

mouth open (Fig. 53.6). Take care not to put pressure on the neck with the fourth and fifth fingers.

If adequate personnel are available, a more desirable situation involves one person standing behind the child's head to maintain an open airway and to provide a seal of the mask over the face with a hand on each side (usually the thumbs and second fingers). A second rescuer stands on one side of the child and compresses the bag to ventilate the child using both hands. If the child is more difficult to ventilate, the two-rescuer method allows the ventilating nurse to provide better ventilation than with the one-rescuer method. In addition, the two-rescuer method ensures the best possible mask seal, as the rescuer holding the mask can use both hands to maintain the seal.

Regardless of the number of persons present, proper placement of the face mask is critical, and a good seal must be maintained throughout the resuscitation. In addition, during ventilation, use only the force and tidal volume necessary to cause a chest rise, no more. If a good chest rise is not observed, attempt to open the airway again. It may be necessary to adjust the position of the airway a few times to achieve a patency conducive to ventilation.

Compress the bag to deliver breaths at the amount recommended in infants and children. Initially, provide two rescue breaths and observe for a chest rise. Rescue breaths should not overinflate the lungs. Breathes should be delivered over 1 second. After the first two rescue ventilations, perform rescue breathing at a rate of one breath every 3 to 5 seconds, or about 12 to 20 breaths per minute. Delivering each breath should be a steady, one-inhalation-to-one-exhalation ratio. This means that the amount of time delivering the inspiratory ventilation

is equal to the amount of time that expiration is allowed. While ventilating the infant or child, work with, not against, any spontaneous respiratory effort; in other words, if the child is breathing out, do not attempt to force air in at the same time.

**Monitoring Effectiveness of Ventilation.** During the resuscitation, continually reassess the child's response to the resuscitative efforts, noting:

- Adequacy of chest rise
- Absence or minimal presence of abdominal distention
- Improved heart rate and pulse oximetry readings
- Improved color
- Capillary refill less than 3 seconds with strengthening pulses

If the child's status deteriorates and he or she becomes pulseless, then CPR must be started. In addition, periodically and briefly stop ventilating to evaluate for spontaneous respirations.

**Preventing Complications Related to Bag-Valve-Mask Ventilation.** During resuscitation, health care personnel usually exhibit high energy levels, a normal physiologic response that facilitates resuscitative efforts as the rescuers act quickly. However, this heightened state can lead to overzealousness while ventilating an infant or child. Health care providers may inadvertently ventilate the child too rapidly using too much tidal volume, leading to excessive ventilation volume and increased airway pressure. This poor technique can be detrimental to the child, causing:

- Reduced cardiac output (due to increased intrathoracic pressure and increased cardiac afterload)
- Air trapping
- **Barotrauma** (trauma caused by changes in pressure)
- Air leak (thus reducing the oxygen delivered to the child)

In addition, children with head injury who receive excessive ventilation volumes and high rates may develop:

- Decreased cerebral blood flow
- Cerebral edema
- Neurologic damage (Leon, Samson, Schexnayder, & Hazinski, 2011)

Thus, nurses must be mindful of their technique during bagging, not exceeding the recommended respiratory rate or providing too much tidal volume to the child. Ventilate the child in a controlled and uniform manner, providing just enough volume to result in a chest rise.

#### ASSISTING WITH VENTILATION USING TRACHEAL INTUBATION

Tracheal intubation is needed if the infant or child does not have a maintainable airway or will require artificial ventilation for a prolonged time (see Table 53.3). Intubation of infants and children is a procedure that requires great skill and therefore should be performed by only

### NURSING PROCEDURE 53.1

#### Assisting With Tracheal Intubation

1. Prepare equipment and supplies.
2. Draw up medications (for rapid sequence intubation).
3. Turn up the volume on the cardiac monitor so that members of the team can easily hear the audible QRS indication of the child's heart rate and note any bradycardia with the procedure.
4. Turn on the suction. Make sure that suction is working by placing your hand over the tubing before you attach the suction catheter.
5. Continue to ventilate the child with the bag-valve-mask (BVM) and 100% oxygen as the team prepares to intubate the child.
6. When there is no suspected cervical spine injury, in the child older than age 2 years, place a small pillow under the child's head to facilitate opening of the airway; this step is unnecessary in children younger than age 2 due to the prominence of their occiput.
7. When assisting with the intubation, stand beside the child's head and prepare to assist with suctioning of oral secretions, providing BVM ventilation as needed, and assisting with securing the tube with tape.
8. Before the initial intubation attempt and after each subsequent attempt to intubate, provide several inhalations of 100% oxygen via the BVM ventilation method (optimally for a few minutes).
9. Administer premedication and medications for sedation.
10. Administer paralyzing medication.
11. Observe as the health care professional who is intubating the child follows the recommended procedure for intubation using the laryngoscope to visualize the vocal cords.

the most qualified and experienced personnel. Children are most commonly intubated orally, rather than nasally, in acute situations.

Nurses are an essential part of the intubation team, usually assisting a physician, nurse practitioner, respiratory therapist, or physician's assistant during the intubation procedure (Nursing Procedure 53.1). The nurse may set up the equipment, prepare and administer intubation medications, or assist with suctioning the oral secretions and preparing the tape to secure the tracheal tube. In a child in full arrest, the nurse might be responsible

**TABLE 53.4** EQUIPMENT AND SUPPLIES FOR TRACHEAL INTUBATION

Laryngoscope blades	Straight blades (Miller) are usually used for infants and young children. A curved-blade laryngoscope (Macintosh) may be used for older children and adolescents. The blade has a little light bulb attached to it for visualization of the trachea. The light bulb should be bright and attached securely.
Tracheal tubes	Three sizes should be readily available: the estimated size, a size smaller, and a size larger. A stylet may be used to guide the tube through the child's vocal cords (it is then removed after the intubation procedure).
Oxygen	100% oxygen is provided using a bag-valve-mask before intubation and after unsuccessful intubation attempts.
Suction	Properly working wall or portable suction with appropriate-sized suction catheters (that fit the tracheal tube) should be prepared; the package is opened, leaving the sterile-tipped end inside the package and connecting the other end to the suction tubing. A Yankauer suction catheter (large catheter) should also be available if copious secretions are present in the mouth that interfere with the ability to visualize the airway.
Monitors	Pulse oximeter and cardiac monitor with an audible tone indicating the QRS complex should be in place. Exhaled CO <sub>2</sub> device is needed to detect increased CO <sub>2</sub> levels after the intubation.
Nasogastric tube	Placing a nasogastric (NG) tube will help to mitigate abdominal distention. Children who are manually ventilated typically have some abdominal distention as some air passes into the stomach.
Personal protective equipment	Usually just gloves, goggles, and a mask are necessary to protect health care workers. In the case of copious bleeding, health care workers should wear gowns also.
Tape, etc.	Tape should be prepared for securing the tube. Benzoin, a sticky substance, is usually applied under the tape for enhanced security of the tape. For children who have had multiple intubations, a protective barrier (as used to protect the skin around an ostomy) may be applied under the tape to protect the skin. Gauze pads should be available to clean up excess secretions that may interfere with taping the tracheal tube.

for performing ongoing chest compressions while other team members manage the child's airway.

**Setting Up Equipment.** Appropriate setup and preparation of equipment is essential (Table 53.4). The tracheal tube size used depends on the child's size. To calculate tracheal tube size, divide the child's age by 4 and add 4. The resulting number will indicate the size of the tracheal tube in millimeters. For example, if the child is 2 years old, the proper-sized tube would be 4.5 [(2/4) + 4 = 4.5]. Always have one size smaller ready also, so have a 4.0 and a 4.5 tracheal tube for this child.

**Administering Medications.** Several medications are often given to facilitate intubation of children. Premedicating a child before passing a tracheal tube aids in the following:

- Reducing pain and anxiety (consistent with the concept of atraumatic care)
- Minimizing the effects of passing the tracheal tube down the airway (vagal stimulation leading to **bradycardia** [decrease in heart rate])
- Preventing hypoxia
- Reducing intracranial pressure
- Preventing airway trauma and aspiration of stomach contents

The use of medications during the intubation process is known as rapid sequence intubation (Table 53.5). Typically, these medications are used in controlled settings such as the emergency department or the intensive care unit (ICU). Rapid sequence intubation is done only in children who are not experiencing cardiac arrest. If the intubation is expected to be particularly difficult, paralyzing medication should not be used.

The nurse must be aware of the differences in the various medication classes, their advantages, their disadvantages, and adverse effects. The nurse must also be able

TABLE 53.5

## MEDICATIONS FOR RAPID SEQUENCE INTUBATION

Medications	Desired Effects	Undesirable Effects
Anticholinergic: atropine	Decreases respiratory secretions and mitigates the vagal affects of intubation, thus decreasing the risk of bradycardia	Doses that are too low (<0.1 mg) can cause a paradoxical bradycardia. Young infants are more prone to the bradycardic effects of atropine, so its use is generally contraindicated in this population.
Sedatives: barbiturates—thiopental (short-acting barbiturate)	Has very rapid onset and short duration of action; reduces intracranial pressure and oxygen demand	Hypotensive effects of this drug are more severe in the dehydrated child. When given in combination with narcotics, respiratory depression is potentiated.
Sedatives: benzodiazepines—midazolam (Versed)	Has a slightly slower onset than thiopental but is associated with fewer adverse effects. Also causes amnesia. Can be titrated up or down (at lower doses it causes conscious sedation; at higher doses it can induce anesthesia)	When given in combination with narcotics, respiratory depression is potentiated.
Anesthetic agent: ketamine	Has a rapid onset with sedative, amnesic, and analgesic affects. Can be dissociative (child is awake but unaware). May improve BP and cause bronchodilation (helpful for children with status asthmaticus)	Ketamine can cause increased intracranial pressure and increased ocular pressure. Therefore, children who have suffered head trauma or globe injury should not receive this medication. Because of ketamine's sympathetic effects, hypertension can result from its use. Ketamine tends to cause increased secretions, often necessitating the concomitant use of atropine to counteract this adverse affect. May cause hallucinations and is therefore contraindicated in children with psychiatric problems
Anesthetic agent: lidocaine	Can decrease intracranial pressure at higher doses. Has an advantage when used in the management of hypovolemia because it is less likely to cause hypotension	Lidocaine can cause adverse cardiac effects (bradycardia, hypotension, dysrhythmias) in high doses. May be associated with CNS depression and seizures
Narcotic analgesic: fentanyl citrate (Sublimaze)	A highly concentrated opioid that causes fewer adverse effects (e.g., pruritus) than other opioids. Also exerts a less hypotensive effect	Constipation and urinary retention (as is common with opioids) may occur. Increases risk for respiratory depression, increased intracranial pressure, and hypotension. Chest wall rigidity is common with this drug and may cause difficulty with ventilation.
Paralyzing or neuromuscular blocking agents: rocuronium (Zemuron), succinylcholine (Anectine), vecuronium (Norcuron)	Used for short-term paralysis during the intubation process. May be used for extended paralysis in ICU for children in whom movement would be detrimental. For example, a child with epiglottitis has a very precarious airway and must remain intubated until the epiglottis decreases in size. In certain respiratory conditions, spontaneous respiratory effort would interfere with the ventilation of a child and therefore prolonged paralysis is desirable.	Succinylcholine (a depolarizing agent) has always been the gold standard for paralysis because it has a relatively rapid onset and is short acting. However, it has a greater risk of adverse effects (bradycardia, hyperkalemia, hypertension, increased intracranial and ocular pressure) and is contraindicated in a variety of clinical conditions. The contemporary approach to paralysis involves the use of longer-acting agents, such as rocuronium and vecuronium, because children have fewer adverse effects with these medications. In addition, rocuronium and vecuronium may be used for extended paralysis (not an option with succinylcholine).

CNS, central nervous system.

K., Hodding, J. H., & Kraus, D. M. (2011). *Pediatric and neonatal dosage handbook* (18th ed.). Hudson, OH: Lexi-comp.

to distinguish between medications that produce sedation and ones that produce analgesia. Children who are paralyzed and sedated may be suffering severe pain. The pain control needs of children who are acutely ill are of paramount importance and cannot be overstated. Do not mistake a child who is immobilized as a result of sedative and paralytic medications for a child who is pain-free.

### Take Note!

Attempts to insert a tracheal tube should last no longer than 20 to 30 seconds each. After each attempt, the child should receive multiple ventilations by the BVM method using 100% oxygen (Leon et al., 2011).

### Ensuring and Maintaining Correct Tube Placement.

To assess for correct placement once the tracheal tube is inserted, observe for symmetric chest rise and auscultate over the lung fields for equal breath sounds. Inspect the tracheal tube for the presence of water vapor on the inside, indicating that the tube is in the trachea. To rule out accidental esophageal intubation, auscultate over the abdomen while the child is being ventilated: there should not be breath sounds in the abdomen. Note improvement in the oxygen saturation level via pulse oximetry.

Once tracheal tube placement is verified, mark the tube with an indelible pen at the level of the child's lip and secure it with tape. Document the number on the tracheal tube at the level of the child's mouth. Anticipate a chest radiograph to confirm correct placement of the tracheal tube.

After placement is confirmed, the tracheal tube is connected to the ventilator by respiratory personnel. The ventilator will provide continuous artificial ventilation and oxygenation. Exhaled CO<sub>2</sub> monitoring is recommended as it provides an indication of appropriate ventilation (Box 53.1). If an exhaled CO<sub>2</sub> monitor is being used, the exhaled CO<sub>2</sub> should be yellow.

The nurse plays a key role in ensuring that the tracheal tube remains taped securely in place by doing the following:

- Using soft wrist restraints if necessary to prevent the child from removing the tracheal tube
- Providing sedative and/or paralyzing medications
- Using caution when moving the child for radiographs, changing linens, and performing other procedures

**Monitoring the Child Who Is Intubated.** Provide ongoing and frequent monitoring of the intubated child to determine adequacy of oxygenation and ventilation as noted earlier. Once the child is intubated, the ventilatory support being provided should result in improvement in oxygen saturation and vital signs. If the child begins to exhibit signs of poor oxygenation, perform a quick assessment. Auscultate the lungs for equal air entry and determine the heart rate. Are the breath sounds equal?

### BOX 53.1

#### EXHALED CO<sub>2</sub> MONITORING OR END-TIDAL CO<sub>2</sub> MONITORING

- Device that connects to the child's ventilator circuit to detect CO<sub>2</sub> in the tubing. CO<sub>2</sub> should be noted in the tubing after six ventilations.
- Devices are usually color coded. In the case of tracheal intubation, observe the color on the device change from purple to tan to yellow.
- The *Pediatric Advanced Life Support Provider Manual* (2011) suggests the following method to remember how the colors on the end-tidal CO<sub>2</sub> device correspond with tracheal tube placement:
  - Purple = Problem (little or no CO<sub>2</sub> detected)
  - Tan = Think about a problem.
  - Yellow = Yes, CO<sub>2</sub> is definitely detected and the tube is in the trachea.

Adapted from Leon, C., Samson, R. A., Schexnayder, S. M., & Hazinski, M. F. (2011). *Pediatric advanced life support provider manual*. Dallas, TX: American Heart Association.

Is the heart rate normal for age? Perform a quick survey of the equipment and look for any disconnected tubes or kinks in the tubing. Determine oxygen saturation levels via pulse oximeter and evaluate the end-tidal CO<sub>2</sub> color (see Box 53.1). Use the PALS mnemonic "DOPE" for troubleshooting when the status of a child who is intubated deteriorates:

D = Displacement. The tracheal tube is displaced from the trachea.

O = Obstruction. The tracheal tube is obstructed (e.g., with a mucous plug).

P = Pneumothorax. Usually a pneumothorax results in a sudden change in the child's assessment. The signs of a pneumothorax include decreased breath sounds and decreased chest expansion on the side of the pneumothorax. Subcutaneous emphysema may be noted over the chest. In the case of tension pneumothorax, there may be a sudden drop in heart rate and blood pressure.

E = Equipment failure. Relatively simple problems as previously discussed, such as a disconnected oxygen supply, can cause the child to deteriorate. Culprits such as a leak in the ventilator circuit or a loss of power are other types of equipment failure that may be responsible (Kleinman et al., 2010a).

Make sure all equipment is appropriately connected and functional. When obstruction with secretions is suspected, suction the tracheal tube. If the tracheal tube is displaced from the trachea, remove the tube if it remains in the child's mouth and begin BVM ventilation. In the case of pneumothorax, prepare to assist with needle thoracotomy.

**Preparing the Intubated Child for Transport.** Once the child is stabilized with a secure tracheal tube in place, prepare to transport the child. The child will be moved by stretcher to an intensive care unit in the acute care facility or by air or land ambulance to another facility that specializes in the care of acutely ill children. Make sure that all tubes are taped securely. During transport, use portable oxygen and ventilate manually with the BVM. As the sending nurse, ensure that all laboratory results are obtained and provided to the receiving nurse. If the child is going to another facility, complete a detailed summary of the resuscitation or provide a copy of the nurse's and/or progress notes. Complete the appropriate transfer forms as determined by the institution.

If the child is being transported by ambulance, the parents may not be able to accompany their child. In this case, find out as much as possible about the transport and assist the parents by giving directions to the receiving institution.

## SHOCK

Shock may be defined as an inability for blood flow and oxygen delivery to meet the metabolic demands of tissue (Kleinman et al., 2010b). If shock is left untreated, cardiopulmonary arrest will result. Shock, which may be classified as compensated or decompensated, is due to a variety of clinical problems. Compensated shock occurs when poor perfusion exists without a decrease in BP. In decompensated shock, inadequate perfusion is accompanied by a drop in BP. Unchecked decompensated shock leads to cardiac arrest and death. The principles of PALS stress the early evaluation and management of children in compensated shock with the goal of preventing decompensated shock (Kleinman et al., 2010b). Once the child in shock is hypotensive, organ perfusion is dramatically impaired and a dire clinical scenario ensues.

## Pathophysiology

Shock is the result of dramatic respiratory or hemodynamic compromise. Impaired cardiac output, impaired systemic vascular resistance (SVR), or a combination of both causes shock. Cardiac output (CO) is equal to heart rate (HR) times ventricular stroke volume (SV) ( $CO = HR \times SV$ ). Stroke volume is how much blood is ejected from the heart with each beat. Stroke volume is related to left ventricular filling pressure, the impedance to ventricular filling, and myocardial contractility. Left ventricular filling pressure is also known as preload, and the impedance to ventricular filling is commonly called afterload. Young children and infants have relatively small stroke volumes compared to older children and adults. Therefore, infants and young children differ from their adult counterparts in that their cardiac output depends on their heart rate, not their stroke volume. Clinically, in cases of circulatory

compromise and compensated shock in infants and children, the heart rate is increased. The exception to this is a paradoxical phenomenon in neonates, who may have bradycardia rather than tachycardia.

Systemic vascular resistance or afterload is the impediment to the heart's ventricular ejection. Increased SVR will result in a decrease in blood flow unless the ventricular pressure increases. Increased vascular resistance is a common problem in shock. In children who have shock-related increased SVR, cardiac output will fall unless the ventricle can compensate by increasing pressure. In cardiac insufficiency, the child's heart will have impaired ability to compensate for the increased afterload.

Altered microcirculatory status is common in all types of shock. Compensatory mechanisms are activated in response to decreased blood flow. Sympathetic nervous system response results in marked contraction of larger-vessel sphincters and arterioles. This compression results in dramatically impaired capillary blood flow. Blood is redirected away from less important body systems, such as the skin and the kidneys, to the vital organs (the heart and brain).

During compensated shock, the body can maintain some level of blood flow to the vital organs. Peripheral vasoconstriction, the body's compensatory response to diminished blood flow, often results in the child's ability to maintain a normal or near-normal BP. As shock continues, capillary beds become obstructed by cellular debris, and platelets and white blood cells aggregate. Endothelial damage occurs as a result of capillary congestion. Poor blood flow to the capillaries results in anaerobic metabolism. Lactic acid accumulates, and this can lead to acidosis. In addition, children with septic shock sustain marked endothelial damage as a result of exposure to bacterial toxins.

The cumulative effect of capillary obstruction and dramatically impaired blood flow is tissue ischemia. As tissue ischemia progresses, the child will show signs of altered perfusion to vital organs. For example, as blood flow to the brain is diminished, the child will demonstrate an altered level of consciousness. Altered blood flow to the kidneys will result in decreased urine output or absence of urine output (oliguria). Commonly, the heart rate will increase in the early stages of shock, but as the heart becomes compromised as a result of poor perfusion, the child will become bradycardic. The child will demonstrate an increased respiratory rate in the initial phase of shock. Tachypnea is seen in septic shock as well. In fact, the child may demonstrate marked hyperventilation in an effort to blow off carbon dioxide in response to the acidosis that is associated with septic shock.

## Types of Shock

The most common types of shock are hypovolemic, septic, cardiogenic, and distributive. Hypovolemic shock, the most common type of shock in children, occurs when

systemic perfusion decreases as a result of inadequate vascular volume (Kleinman et al., 2010b). Children commonly have hypovolemic shock that occurs in association with fluid losses. For example, hypovolemic shock may occur with gastroenteritis that results in vomiting and diarrhea, medications such as diuretics, and heat stroke. Other causes of hypovolemia in children include blood loss, such as from a major injury, and third spacing of fluid, such as with burns.

Septic shock is related to a systemic inflammatory response in which there may be increased cardiac output with a low SVR, known as warm shock. More commonly in children, septic shock results in a decrease in cardiac output with an increase in SVR, known as cold shock.

Cardiogenic shock results from an ineffective pump, the heart, with a resultant decrease in stroke volume. Children who have congenital or acquired cardiac abnormalities with a poorly functioning heart are at risk for cardiogenic shock (Fisher, Nelson, Beyersdorf, & Satkowiak, 2010).

Distributive shock is the result of a loss in the SVR. A relative hypovolemia occurs, most often with neurogenic injury–related shock and anaphylaxis. In relative hypovolemia, the vascular compartment expands due to systemic vasodilation. This results in a relatively larger vasculature requiring more fluid to maintain cardiac output despite no actual loss of fluid.

Lastly, toxic drug ingestions may also lead to shock.

## Nursing Assessment

Nursing assessment of the child in shock includes the health history and physical examination as well as laboratory and diagnostic testing. The nursing assessment must be performed quickly and accurately so that resuscitation can be expedited.

### Health History

In shock, the health history is based on the child's presentation. Children with shock are critically ill and require emergent intervention. Therefore, the history is obtained as life-saving interventions are provided. Determine when the child first became ill and treatments that have been given thus far. Inquire about sources of volume loss, such as:

- Vomiting
- Diarrhea
- Decreased oral intake
- Blood loss

Ask when the child last urinated. Investigate for other related symptoms such as behavioral changes or lethargy. Has the child had a fever or rash, complained of headache, or been exposed to anyone with similar symptoms? Inquire about day care attendance and

whether the family has recently traveled outside of the country. Determine if the child has a history of a congenital heart defect or other heart condition or if the child has severe allergies. Ask the parent about accidental ingestion of medications or other substances and, for the older child or adolescent, about the possibility of illicit substance use.

### Physical Examination

The key to successful shock management is early recognition of the signs and symptoms. Obtain vital signs, noting any alterations. Measure BP, although this is not a reliable method of evaluating for shock in children. Children tend to maintain a normal or slightly less than normal BP in compensated shock while sacrificing tissue perfusion until the child suffers a cardiopulmonary arrest. Therefore, other components of the circulatory evaluation will be more valuable when assessing a child.

#### Take Note!

Bradycardia is a serious sign in neonates and may occur with respiratory compromise, circulatory compromise, and/or overwhelming sepsis (Kattwinkel et al., 2010).

As with any emergency, evaluate the airway first. Is it patent? Then determine if the child is breathing. The child in shock will often demonstrate signs of respiratory distress, such as grunting, gasping, nasal flaring, tachypnea, and increased work of breathing. Auscultate breath sounds to determine the adequacy of air entry and airflow. If the child shows signs of respiratory distress, manage the airway and breathing problem first, as discussed earlier in the chapter.

Assess the skin color. Palpate the skin temperature and determine quality of pulses. Except in special cases, such as distributive shock, the child in shock will generally have darker and cooler extremities with delayed capillary refill. Note the line of demarcation if present. This refers to the point on the distal extremity where cool temperature begins (the proximal portion of the extremity may continue to be warm). In distributive shock, the initial assessment will reveal full and bounding pulses and warm, erythemic skin. Evaluate the pulse quality. Distal pulses will likely be weaker than central pulses.

Evaluate the child's hydration state and check skin turgor. Decreased elasticity is associated with hypovolemic states, though this is usually a late sign. Observe the child's face; in compensated shock the child may be awake but obtunded and demonstrate signs of distress. The child in decompensated shock may have his or her eyes closed and may be responsive only to voice or other stimulation. Evaluate pupillary responses. Determine urinary output, which will be decreased in the child with shock.

After having evaluated and provided initial life-saving management for airway, breathing, and circulation, evaluate the child's entire body for other disabilities. Injuries warrant vigilant evaluation for ongoing blood loss, although they may also produce internal blood loss (e.g., a femur fracture). Look for signs of malformation, swelling, redness, or pain of the extremities, which may suggest internal blood loss. Also inspect for any open wounds and active sites of bleeding. Children with abdominal injuries also may lose copious amounts of blood internally. Inspect the abdomen for redness, skin discoloration, or distention. Auscultate for bowel sounds in all four quadrants.

### Laboratory and Diagnostic Testing

As the child is being resuscitated, laboratory tests and radiographs will be ordered and obtained. However, no diagnostic test should replace the priority of respiratory support, vascular access, and fluid administration. Laboratory results will guide ongoing management. Common laboratory and diagnostic tests used for children with shock include:

- Blood glucose levels: usually performed at the bedside using a glucose meter (e.g., Chemstrip® or ACCU-CHEK®) to obtain a rapid result
- Electrolytes: to evaluate for electrolyte abnormalities
- CBC with differential: to assess for viral or bacterial infection (septic shock) and to evaluate for anemia and platelet abnormalities
- Blood culture: to evaluate for sepsis; preliminary results will not be available for 1 to 2 days
- C-reactive protein: to evaluate for infection
- Arterial blood gases: to assess oxygen and carbon dioxide levels and to provide information about acid-base balance
- Toxicology panel (if ingestion is suspected)
- Lumbar puncture: to evaluate the cerebrospinal fluid for meningitis
- Urinalysis: to evaluate for glucose, ketones, and protein; concentration (specific gravity) is increased in dehydration states
- Urine culture: to evaluate for urinary tract or kidney infection
- Radiographs: to evaluate heart size, to evaluate the lungs for pneumonia or pulmonary edema (present with cardiogenic shock)

## Nursing Management

Signs of shock in children warrant an emergent response.

### Managing the Child's ABCs

Always evaluate and manage the airway and breathing and check for pulses. Initiate CPR if the child is pulseless. All

children who have signs and symptoms of shock should receive 100% oxygen via mask. If the child has poor respiratory effort or is apneic, administer 100% oxygen via BVM or tracheal tube (refer to the section on respiratory emergencies for more specific information about management of airway and breathing). As part of ongoing monitoring, institute cardiac and apnea monitoring and assess oxygen saturation levels via pulse oximetry.

### Obtaining Vascular Access

Once the airway and breathing are addressed, nursing management of shock focuses on obtaining vascular access and restoring fluid volume. Children with signs of shock should receive generous amounts of isotonic IV fluids rapidly. However, obtaining vascular access in critically ill children can be challenging. Vascular access must be obtained using the quickest route possible in children whose condition is markedly deteriorated, such as those in decompensated shock.

Various forms of vascular access available for the management of the critically ill child include:

- Peripheral IV route: a large-bore catheter is used to give large amounts of fluid. This route may not be feasible in children with significant vascular compromise.
- Central IV route: central lines can be inserted into the jugular vein and threaded into the superior vena cava. The femoral route is best for obtaining central venous access while CPR is in progress because the insertion procedure will not interfere with life-saving interventions involving the airway and cardiac compressions. The subclavian vein, located under the clavicle, is an alternative route for central access.
- Saphenous vein: the saphenous vein (found in the ankle) is an alternative route for venous access that is obtained using a surgical incision.
- Intraosseous access: intraosseous access, obtained by cannulating the bone marrow, is recommended in cases of decompensated shock or cardiac arrest if IV access cannot be attained rapidly. The preferred site is the anterior tibia. Special intraosseous needles are used (generally a 15-gauge needle for older children, 18-gauge for younger children). The needle is inserted using a firm twisting motion slightly away from the growth plate. Any medications or fluids that can be administered using an IV site can be given using this route. Alternative sites include the femur, the iliac crest, the sternum, and the distal tibia.

### Restoring Fluid Volume

Administer IV isotonic fluids, such as Ringer's lactate or normal saline (the isotonic fluids of choice) rapidly. Administer 20 mL/kg of the prescribed fluid as a bolus, infusing the fluid as rapidly as possible. In general, a large-bore syringe, such as a 35- to 60-mL syringe attached to a

three-way stopcock, is the preferred method for rapid fluid delivery in children. Infusing the fluid via gravity is too slow. The fluid bolus may be repeated up to two times (for a total of three times) if required.

### Take Note!

Dextrose solutions are contraindicated in shock because of the risk of complications such as osmotic diuresis, hypokalemia, hyperglycemia, and worsening of ischemic brain injury (Leon et al., 2011).

Children in septic shock will often require larger volumes of fluid as a result of the increased capillary permeability. Children in shock due to trauma will usually receive a colloid, such as blood, when there is an inadequate response to crystalloid isotonic fluid. After each fluid bolus, reassess the child for signs of positive response to the fluid administration.

Insert an indwelling urinary catheter to allow for accurate and frequent measurement of urine output.

Indicators of improvement include:

- Improved cardiovascular status: the central and peripheral pulses are stronger. The line of demarcation of extremity coolness is diminishing and capillary refill is improved (time is decreased). BP is improved.
- Improved mental status: the child is more alert. For example, the child's eyes are open and watching personnel. If the child is younger, he or she may be pulling at the IV line.
- Improved urine output: this may not be noted initially but should be noted over the next few hours; the goal is 1 to 2 mL/kg/hour.

The process of fluid resuscitation involves giving the fluid, assessing and reassessing the child, and documenting findings. Children in shock may require as much as 100 to 200 mL/kg of resuscitative fluid during the initial hours of shock management. Most children in shock need and can tolerate this large volume of fluid. Continued reassessment will determine if the child is beginning to experience fluid overload in the form of pulmonary edema (this is rare but may occur in children with pre-existing cardiac conditions or severe chronic pulmonary disease) (Leon et al., 2011; Schwarz, 2012).

### Take Note!

Do not focus solely on the child's circulatory status; you may overlook signs and symptoms of respiratory deterioration.

## Administering Medications

In some circumstances, such as septic shock or distributive shock, fluid alone does not adequately improve the child's status and adjunctive medications may be ordered. Vasoactive medications are used either alone

or in combination to improve cardiac output, to increase SVR, or to decrease SVR. The selection of medications is dictated by the child's cardiac and vascular status. For example, dobutamine is a medication with significant  $\beta$ -adrenergic effects and thus can improve cardiac contractility. Epinephrine, which affects the heart muscle, is also a powerful vasoconstrictor. Dopamine affects the heart at lower doses but increasingly affects the vasculature with increased doses. These medications may be given as a loading dose, followed by a continuous infusion. When vasoactive drugs are administered, monitor for improvement in heart rate, BP, perfusion, and urine output.

## CARDIAC ARRHYTHMIAS AND ARREST

Unlike adults, in whom cardiopulmonary arrest is most often caused by a primary cardiac event, children typically have healthy hearts and thus rarely experience primary cardiac arrest. More commonly they experience cardiopulmonary arrest from gradual deterioration of respiration and/or circulation (Kleinman et al., 2010a). In particular, children experiencing a respiratory emergency or shock may deteriorate and eventually demonstrate cardiopulmonary arrest. Thus, the standard of care for managing a child in this situation is vastly different from that for an adult.

Nurses should be skilled in evaluating and managing respiratory alterations and shock in children, as discussed in previous sections. Overwhelming evidence suggests that if primary respiratory compromise or shock is identified and treated in the critically ill child, a secondary cardiac arrest can be prevented.

Rare exceptions do exist, however. For example, electrolyte abnormalities and toxic drug ingestions are primary insults to the cardiovascular system that may lead to a sudden cardiac arrest rather than a gradual progression. Other exceptions in which the child is at risk for a primary and sudden cardiac arrest include:

- History of a serious primary congenital or acquired cardiac defect
- Potentially lethal arrhythmias, such as prolonged QT syndrome
- Hyper- or hypotrophic cardiomyopathy
- Traumatic cardiac injury or a sharp blow to the chest, known as "commotio cordis" (e.g., when a high-velocity ball hits the chest)

The overwhelming majority of children rarely experience cardiac arrhythmias, so it is beyond the scope of this chapter to discuss the myriad possible complex rhythm disturbances. Therefore, this discussion will be limited to the management of emergent cardiac conditions that are more typically found in children.

## Pathophysiology

The AHA (2007) has simplified the nomenclature used to describe pediatric cardiac compromise and has established three major categories of cardiac rhythm disturbances:

- Slow: bradyarrhythmias
- Fast: tachyarrhythmias
- Absent: pulseless, cardiovascular collapse

The pathophysiology, causes, and therapeutic management of each of the categories of rhythm disturbances are discussed below.

### Bradyarrhythmias

Bradycardia is a heart rate significantly slower than the normal heart rate for age. Bradycardia in children is most commonly sinus bradycardia. In other words, there is not a cardiac nodal abnormality associated with the slowed heart rate. In sinus bradycardia, the P waves and QRS complex remain normal on the ECG. Brief dips in heart rates can be normal, such as when the child sleeps. Children are also susceptible to brief drops in heart rate that are associated with vagal stimulation. For example, passing an orogastric tube down the esophagus of a young infant may induce a temporary bradycardic response. These normal decreases in the child’s heart rate should recover with or without stimulation and are not normally associated with signs of altered perfusion.

Less commonly, children manifest bradycardia as a result of cardiac abnormalities and heart block. Infants with bradycardia related to heart block may exhibit poor feeding and tachypnea, whereas older children may demonstrate fatigue, dizziness, and syncope. Comparison Chart 53.2 compares the causes of sinus bradycardia and heart block in children.

In contrast, the child with a serious and possibly life-threatening bradyarrhythmia will have a heart rate below 60 bpm, with signs of altered perfusion. The most common causes of profound bradycardia in children are respiratory compromise, hypoxia, and shock. Sustained bradycardia is commonly associated with arrest. It is an ominous sign and should be taken seriously.

### Tachyarrhythmias

Children normally have faster heart rates than adults, and fever, fear, and pain are common explanations for significant increases in the heart rate of a child (**tachycardia**). This normal elevation in heart rate is known as sinus tachycardia. However, once the fever is reduced, the child is comforted, or the pain is managed, the heart rate should return close to the child’s baseline. Hypoxia and hypovolemia are pathologic reasons for tachycardia in the child. The signs, symptoms, and management of these concerns were discussed in previous sections. If the child has sinus tachycardia that results from any of these causes, the focus is on the underlying cause. It is inappropriate and dangerous to treat sinus tachycardia with medications aimed at decreasing the heart rate or with a defibrillation device.

Tachyarrhythmias in children that are associated with cardiac compromise have unique characteristics that present differently from sinus tachycardia. Examples of these include SVT and ventricular tachycardia. SVT is a cardiac conduction problem in which the heart rate is extremely rapid and the rhythm is very regular, often described as “no beat-to-beat variability.” Comparison Chart 53.3 explains the differences between SVT and sinus tachycardia. The most common cause of SVT is a reentry problem in the cardiac conduction system. Commonly, SVT is the result of a genetic cardiac conduction problem such as Wolff-Parkinson-White syndrome. SVT may also be associated with medications such as caffeine and theophylline. Children often can tolerate the characteristically higher heart rate that is associated with SVT for short periods of time. However, the increased demand that is placed on the cardiovascular system usually overtaxes the child and results in signs of congestive heart failure if the SVT continues unchecked for a prolonged time.

Ventricular tachycardia is a rhythm involving an elevation of the heart rate and a wide QRS (greater than 0.08 seconds) that is the result of an abnormal, rapid firing of one or both of the ventricles. Ventricular tachycardia is a rare arrhythmia in children and usually is associated with a congenital or acquired cardiac abnormality. In addition, prolonged QT syndrome is a conduction abnormality that can result in ventricular tachycardia and sudden

#### COMPARISON CHART 53.2

#### CAUSES OF SINUS BRADYCARDIA VERSUS HEART BLOCK

	Sinus Bradycardia	Heart Block
<i>Causes</i>	<ul style="list-style-type: none"> <li>• Pathologic: medications such as digoxin, hypoxia, hypothermia, head injury</li> <li>• Nonpathologic: well-conditioned athlete</li> </ul>	<ul style="list-style-type: none"> <li>• Congenital: associated with cardiac anomalies</li> <li>• Acquired: endocarditis, rheumatic fever, Kawasaki disease</li> </ul>

## COMPARISON CHART 53.3

## DISTINGUISHING SUPRAVENTRICULAR TACHYCARDIA (SVT) FROM SINUS TACHYCARDIA

	SVT	Sinus Tachycardia
Rate (bpm)	Infants >220, children >180	Infants <220, children <180
Rhythm	Abrupt onset and termination	Beat-to-beat variability
P waves	Flattened	Present and normal
QRS	Narrow (<0.08 seconds)	Normal
History	Usually no significant history	Fever, fluid loss, hypoxia, pain, fear

death in children. Less commonly, ingestion of medications and toxins, acidosis, hypocalcemia, abnormalities of potassium, and hypoxemia have been associated with the development of ventricular tachycardia in children.

### Collapsed Rhythms (Pulseless Rhythms)

A collapsed rhythm, as defined by PALS, is one that produces cardiac arrest with no palpable pulse and no signs of perfusion (cardiac arrest) (Leon et al., 2011). Typically, the most common pulseless arrest rhythms in children are asystole or pulseless electrical activity (PEA). **Asystole** occurs when there is no cardiac electrical activity, commonly referred to as “a straight line” on the ECG. The child with PEA has some appreciable rhythm on the ECG but no palpable pulses. PEA may be caused by hypoxemia, hypovolemia, hypothermia, electrolyte imbalance, tamponade, toxic ingestion, tension pneumothorax, or thromboembolism. Ventricular tachycardia may also present as pulseless. Ventricular fibrillation, once thought to be rare in children, occurs in serious cardiac conditions in which the ventricle is not pumping effectively. It may develop from ventricular tachycardia. Ventricular fibrillation (VF) is characterized by variable, high-amplitude waveforms (coarse VF) or a finer, lower-amplitude waveform with no discernible cardiac rhythm (fine VF). In either case, cardiac output is insufficient.

### Nursing Assessment

Nursing assessment of the child with a cardiac emergency includes the health history and physical examination as well as laboratory and diagnostic testing. The nursing assessment must be performed quickly and accurately so that resuscitation can be instituted if needed.

### Health History

Obtain a brief health history of the child with a cardiac emergency while simultaneously assessing the child and

providing life-saving interventions. Key areas to inquire about include:

- History of cardiac problems, asthma, chromosomal anomaly, delayed growth
- Symptoms such as syncope, dizziness, palpitations or racing heart, chest pain, coughing, wheezing, increased work of breathing
- Activity tolerance with play or feeding: Does the child get out of breath, turn blue, or squat during play? Can the child keep up with playmates? Does the infant tire with feedings?
- Precipitating illness, fever, unexplained joint pains, ingested medications
- Participation in a sport before the cardiac event occurred or injury to the chest
- Family history of cardiac problems, sudden death from a cardiac condition, heart attacks at a young age, chromosomal abnormalities
- Treatment measures performed at the scene: Was CPR initiated? Was an AED used?

### Physical Examination

Quickly establish the child's status. A child who is obviously in distress or is arresting must receive emergent life-saving interventions. Briefly perform the assessment while simultaneously providing life-saving interventions.

### INSPECTION AND OBSERVATION

Assess the child's airway patency and efficiency of breathing. Observe the child's color, noting circumoral pallor or duskiess or central pallor, mottling, duskiess, or cyanosis. Note any increased work of breathing, grunting, head bobbing, or apnea. Inspect the chest for barrel shape, which may be associated with chronic pulmonary or cardiac disease. Observe the pericardium for the presence of lifts or heaves. Note diaphoresis, anxious appearance, or dysmorphic features (40% to 50% of children with Down syndrome also have a congenital cardiac defect [Chen, 2012]). Determine if neck vein

distention is present. Inspect the fingertips for clubbing, which is indicative of chronic tissue hypoxemia.

### AUSCULTATION

Auscultate the breath sounds, noting any crackles or wheezes. Auscultate the heart rate. If the child does not have an adequate pulse, initiate CPR. If the child has a strong, perfusing pulse, complete the cardiac assessment. Auscultate with the diaphragm of the stethoscope first and then listen with the bell. Evaluate all of the auscultatory areas, listening first over the second right interspace (aortic valve) and then over the second left interspace (pulmonic valve); next move to the left lower sternal border (tricuspid area); and finally auscultate over the fifth interspace, midclavicular line (mitral area). Evaluate the rate and rhythm of the heart. Listen for any extra sounds or murmurs. Note and describe the quality, intensity, and location of any cardiac murmurs.

#### Take Note!

Murmurs are most often systolic and can be benign or associated with pathology. Murmurs that radiate to the back and are grade III or louder are more likely to be due to a cardiac defect. True diastolic murmurs are rare and almost always have a pathologic origin (Bernstein, 2011).

### PERCUSSION AND PALPATION

Percuss between the costal interspaces and note the heart's size. Palpate the heart to find the point of maximal impulse (PMI) and to evaluate for an associated thrill. A thrill feels like a fluttering under the fingers and is associated with cardiac pathology. Palpate and note the quality of the pulses. Evaluate each of the pulses bilaterally and note whether they are absent, faint, normal, or bounding. Compare the quality of pulses on each side of the body and also those of the upper and lower body. Note the skin temperature and evaluate the capillary refill.

### Laboratory and Diagnostic Testing

The major diagnostic test used is the ECG. Identify the arrhythmia according to the ECG reading (Fig. 53.7).

### Nursing Management

Provide oxygen at 100%. Institute cardiac monitoring and assess oxygen saturation levels via pulse oximetry. Obtain the child's preprinted code drug sheet or use the Broselow tape to obtain the child's height to estimate the tracheal tube sizes and medication dosages that are appropriate for the child. Always remember to intervene in this order: first airway, then breathing, then circulation. The remainder of this discussion will assume that the nurse has initiated interventions for airway and breathing as discussed earlier in the chapter.

#### Take Note!

Pay attention to the rhythm on the monitor, but continually monitor the child's pulse. If the child does not have a pulse or has a pulse of less than 60 bpm, perform cardiac compressions despite the monitor reading (Leon et al., 2011).

### Managing Bradyarrhythmias

The management of sinus bradycardia is focused on remedying the underlying cause of the slow heart rate. Since hypoxia is the most common cause of sustained bradycardia, oxygenation and ventilation are necessary. The newborn is particularly susceptible to bradycardia in relation to hypoxemia. Continue to reassess the child to determine if the bradycardia improves with adequate oxygenation and ventilation. If bradycardia persists, administer epinephrine and/or atropine as ordered. Epinephrine is the drug of choice for the treatment of persistent bradycardia.

Other causes of bradycardia such as hypothermia, head injury, and toxic ingestion are managed by addressing the underlying condition. Warming the hypothermic child may restore a normal sinus rhythm. Children with head injury may have bradycardia without any cardiac involvement, and with successful management of the head injury, the bradycardia will resolve. Antidotes to toxins may be necessary in children whose bradycardia is the result of a toxic ingestion.

### Managing Tachyarrhythmias

The tachyarrhythmias include SVT (stable or unstable) and ventricular tachycardia with a pulse. Examine the ECG to determine if the child is experiencing ventricular tachycardia or SVT. Clinically, determine whether the child in SVT is showing signs that require emergent intervention or if the child is stable. In compensated SVT, the child will appear to be alert, breathing comfortably, and well perfused. The child who is demonstrating signs of compromise, such as a change in consciousness, respiratory status, and perfusion, is considered to be in uncompensated SVT. Uncompensated SVT requires emergent intervention. The child who has ventricular tachycardia with a pulse will have poor perfusion and also requires immediate intervention. The evaluation and approaches to the tachyarrhythmias are discussed in Table 53.6.

#### Take Note!

Adenosine has a rapid onset of action and an extremely short half-life. Administer it extremely rapidly with a generous amount of IV flush; otherwise, it will be ineffective (Kleinman et al., 2010a).

**A****B****C****D**

**FIGURE 53.7** Arrhythmias. **(A)** Sinus tachycardia: normal QRS and P waves, mild beat-to-beat variability. **(B)** Supraventricular tachycardia: note rate above 220, abnormal P waves, no beat-to-beat variability. **(C)** Ventricular tachycardia: rapid and regular rhythm, wide QRS without P waves. **(D)** Coarse ventricular fibrillation: chaotic electrical activity.

**TABLE 53.6** MANAGING TACHYARRHYTHMIAS

Tachyarrhythmia	Signs and Symptoms	Management
Compensated SVT	<ul style="list-style-type: none"> <li>• Tachycardia, heart rate &gt;220</li> <li>• Abnormal P waves</li> <li>• Alert, well-perfused child</li> <li>• Possible complaints of headache and dizziness in older children</li> </ul>	<ul style="list-style-type: none"> <li>• Vagal maneuvers such as ice to face or blowing through a straw that is obstructed</li> <li>• Adenosine if vagal maneuvers fail</li> </ul>
Uncompensated SVT	<ul style="list-style-type: none"> <li>• Tachycardia, heart rate &gt;220</li> <li>• Abnormal P waves</li> <li>• Signs of shock: altered level of consciousness, poor perfusion, weak pulses</li> </ul>	<ul style="list-style-type: none"> <li>• Adenosine or synchronized cardioversion</li> </ul>
Ventricular tachycardia	<ul style="list-style-type: none"> <li>• Rate may range from normal to 200 bpm.</li> <li>• Wide QRS</li> <li>• No P waves</li> <li>• Pulse present, poor perfusion</li> </ul>	<ul style="list-style-type: none"> <li>• Synchronized cardioversion</li> <li>• IV amiodarone</li> <li>• Treatment of underlying causes</li> </ul>

Adapted from Kleinman, M. E., Chameides, L., Schexnayder, S. M., Samson, R. A., Hazinski, M. F., Atkins, D. L., et al. (2010). Pediatric advanced life support – 2010 American Heart Association guidelines for cardiopulmonary resuscitation and emergency cardiovascular care. *Pediatrics*, 126, e1361–e1399.

### Managing Collapsed Rhythms

As in any pediatric emergency, support the ABCs. Manage the airway, provide oxygen, and give fluids. In addition, if the child is pulseless or has a heart rate less than 60 bpm, initiate cardiac compressions (see the section on providing cardiopulmonary resuscitation earlier in the chapter). Additionally, some children may require medications and/or defibrillation or synchronized cardioversion. The pulseless rhythms include ventricular tachycardia, ventricular fibrillation, asystole, and PEA. ECG characteristics and management of these rhythms are summarized in Table 53.7. Also treat the underlying causes of the arrhythmia, if known.

The AHA emphasizes the importance of cardiac compressions in pulseless individuals with arrhythmias (Kleinman et al., 2010a). Give compressions before and immediately after defibrillation (see defibrillation section earlier in the chapter). Administer medications such as epinephrine, lidocaine, or amiodarone as ordered. In the past it was recommended that individuals who required defibrillation be given three shocks in a row, but recent research findings have shown that the individual should be defibrillated only once, followed by five cycles of CPR. For defibrillation to be most effective, cardiac compressions must be performed effectively with minimal interruptions (Kleinman et al., 2010a).

### NEAR DROWNING

Water can be a great source of fun and exercise for children and adolescents, but drowning is the second-leading cause of preventable death in children and

adolescents in the United States and worldwide (World Health Organization, 2010). In warm-weather states where swimming pools are more common, drowning is the primary cause of death in young people. Most drowning deaths are preventable, and the World Health Organization (2010) notes that “lapse in adult supervision is the single most important contributory cause for drowning.”

Near drowning is defined as a submersion injury in which the child survives. Survival and neurologic outcome of near drowning depend on early and appropriate resuscitation. In recent years, with appropriate resuscitation efforts and treatment, children have demonstrated better neurologic outcomes (Shepherd et al., 2011).

### Pathophysiology

Typically, a child who is drowning will struggle to breathe and eventually will aspirate water. Aspiration of relatively small amounts of water leads to poor oxygenation, with retention of carbon dioxide. Alveolar surfactant is depleted during the drowning event and pulmonary edema commonly occurs. Hypoxemia results in increased capillary permeability and resultant hypovolemia. Even small amounts of aspirated water may lead to pulmonary edema within a 24- to 48-hour period after the near-drowning episode (Shepherd et al., 2011). A near-drowning survivor is also at risk for renal complications due to altered renal perfusion during the hypoxic state.

**TABLE 53.7** ECG CHARACTERISTICS AND MANAGEMENT OF PULSELESS RHYTHMS

Pulseless Arrhythmia	ECG Characteristics	Management
Ventricular tachycardia	Wide QRS, no P waves	<ul style="list-style-type: none"> <li>• CPR</li> <li>• Defibrillation</li> <li>• Epinephrine; also possibly amiodarone, lidocaine, or magnesium</li> <li>• Treat underlying causes</li> </ul>
Ventricular fibrillation	<ul style="list-style-type: none"> <li>• Chaotic ventricular activity</li> <li>• No P waves, no QRS, no T waves</li> </ul>	<ul style="list-style-type: none"> <li>• CPR</li> <li>• Defibrillation</li> <li>• Epinephrine; also possibly amiodarone, lidocaine, or magnesium</li> <li>• Treat underlying causes</li> </ul>
Asystole	Flat line	<ul style="list-style-type: none"> <li>• Check lead placement</li> <li>• CPR if no pulse</li> <li>• Epinephrine</li> </ul>
Pulseless electrical activity	Electrical activity that is not consistent with ventricular tachycardia or ventricular fibrillation	<ul style="list-style-type: none"> <li>• Check lead placement</li> <li>• CPR if no pulse</li> <li>• Treat underlying cause</li> <li>• Epinephrine</li> </ul>

## Nursing Assessment

Nursing assessment of the near-drowning survivor is crucial and must take place quickly and accurately.

### Health History

Obtain the history rapidly while providing life-saving interventions. Ask about the circumstances of the event:

- Where did the incident occur? Was the child in a lake, river, ocean, or swimming pool? Was the child submerged in a toilet, bucket, or bathtub?
- Did someone witness the child's entry into the water?
- Was the water fresh or salty? Cold or warm?
- Is it likely the water was contaminated?
- Were there any extenuating circumstances, such as a diving or automobile accident, associated with the near drowning?
- What was the approximate length of time of the submersion? Was the child conscious or unconscious when rescued?
- What was done at the scene? Was CPR initiated? If so, when?
- If a cervical spine injury was suspected, was the cervical spine immobilized?
- Was an AED used?
- When did the child last eat (to prepare for possible intubation)?

### Physical Examination

Evaluate airway patency and breathing. Auscultate all lung fields for signs of pulmonary edema, such as coarseness or crackles. Evaluate the heart rate, pulses, and perfusion. Note the cardiac rhythm on the monitor and report evidence of arrhythmias. Evaluate the child's neurologic status. Use a pen light to determine pupillary reaction. Use the pediatric coma score to further assess the neurologic status. Does the child open the eyes spontaneously, to stimuli, or not at all? Is there any spontaneous movement? Is the younger child crying? Can the older child speak? Measure the child's temperature, as hypothermia often occurs with near drowning.

### Laboratory and Diagnostic Testing

While awaiting laboratory and diagnostic testing results, continue resuscitative efforts as addressed below. Laboratory and diagnostic tests typically include the following:

- Arterial blood gases: hypoxemia, acidosis
- ECG: cardiac arrhythmias
- Chest radiography: pulmonary edema, infiltrates
- Serum electrolytes: imbalance related to development of shock

## Nursing Management

Because of the potentially devastating effects that drowning-related hypoxia has on the child's brain, airway interventions must be initiated immediately after retrieving a child from the water. Every second counts. Initial interventions in a near-drowning event are always focused on the ABCs; commonly, resuscitative efforts have begun before the child arrives at the acute care facility.

If a cervical spine injury is suspected (as in the case of a diving accident), provide stabilization either manually or with a cervical collar. As with any suspected neck injury, do not remove the cervical collar until injury to the cervical spine has been ruled out through a radiograph and clinical evaluation. Suction the airway to ensure airway patency. The child may have aspirated particles from a contaminated water source or emesis, a relatively common complication associated with near drowning. A large-bore suction catheter (e.g., Yankauer) is an effective tool for clearing the upper airway. Administer supplemental oxygen at 100%. Children who have poor or absent respiratory effort most likely will require intubation. Insert a nasogastric tube to decompress the stomach and prevent aspiration of stomach contents. Initiate chest compressions if a pulse is not present.

Usually, the child exhibits some degree of hypothermia and will require warming. Generally, the core body temperature should be raised slowly, as warming a drowning victim too quickly may have deleterious effects. Remove any wet clothing, dry the child, and cover him or her with warmed blankets. Warm IV fluids and use other warming methods as prescribed.

### Consider This

Teva Dawson, a 2-year-old girl, is rushed to the emergency room by ambulance after experiencing a near drowning in the family swimming pool. Teva was resuscitated at the scene and is now breathing spontaneously. She is lethargic and coughs occasionally.

What health history information would you obtain from the parents or caregivers? What immediate management is necessary?

What education may be necessary for this family?

## POISONING

Emergency care of the pediatric poisoning victim consists of rapid nursing assessment and prompt management.

### Take Note!

If a normally healthy child (particularly a young child) suddenly deteriorates without a known cause, suspect a toxic ingestion.

## Nursing Assessment

Nursing assessment of the poisoning victim focuses on a thorough health history, followed by physical examination and laboratory and diagnostic testing.

### Health History

Obtain the health history from the parents or caregiver or, in the case of an older child or teenager, from the child. Inquire about the approximate time of poisoning and the nature of the toxin. Was the toxin ingested, inhaled, or applied to the skin? In the case of pill ingestion, does the caregiver have the medication bottle? Did the child experience nausea, vomiting, anorexia, abdominal pain, or neurologic changes such as disorientation, slurred speech, or altered gait? Determine the progression of the symptoms. Did the parent or caregiver call the National Poison Control Center Hotline? Has any treatment been given? In the case of older children and teens, inquire about any history of depression or threatened suicide.

### Take Note!

The National Poison Control Center Hotline number is 1-800-222-1222.

### Physical Examination

Ingestion of medications or chemicals may result in a wide variety of clinical manifestations. Perform a thorough physical examination, noting alterations that may occur with particular ingestions, such as:

- Hyper- or hypotension
- Hyper- or hypothermia
- Respiratory depression or hyperventilation
- Miosis (pupillary contraction) or mydriasis (pupillary dilatation)

Pay particular attention to the child's mental status, skin moisture and color, and bowel sounds (Penny & Moriarty, 2009).

### Laboratory and Diagnostic Testing

The suspected poison may direct the laboratory and diagnostic testing. A variety of blood tests may be performed:

- Chemistry panel: to detect hypoglycemia or metabolic acidosis and assess renal function
- ECG: to identify arrhythmias or conduction delay
- Liver function tests: to assess for liver injury
- Urine and blood toxicology screens (available for a limited number of medications; may vary per institution)
- Specific drug levels if the substance ingested is known or highly suspected

## Nursing Management

When poisoning occurs, give priority to the child's ABCs. Treat alterations as discussed earlier in this chapter. Monitor vital signs frequently and provide supportive care. Few specific antidotes are available for medications or other toxins. Ipecac is rarely used in the health care setting to induce vomiting and is no longer recommended for use in the home setting (Penny & Moriarty, 2009). Gastric lavage, administration of activated charcoal (binds with the chemical substance in the bowel), or whole bowel irrigation with polyethylene glycol electrolyte solutions may be used. Occasionally, dialysis is required to lower the level of toxin in the bloodstream. The intervention is based on the source of the ingestion. For example, activated charcoal is an effective method for preventing the absorption of many medications but is not effective in the case of an iron overdose.

If opiate or other narcotic ingestion is suspected, administer naloxone to reverse the respiratory depression or altered level of consciousness. Treatment of seizures and alterations in thermoregulation may also be needed.

Specific treatment of the poisoning will be determined when the toxin is identified and poison control is queried. Maintain ongoing assessment of the poisoned child because many toxins exhibit very late effects.

## TRAUMA

The leading cause of death in children and adolescents is unintentional injuries (Heron, 2010). Falls are the most common cause of pediatric injury and automobile accidents continue to cause the deaths of about five children daily, with significant numbers experiencing injury (National Highway Traffic Safety Administration, 2008). Childhood trauma also results from pedestrian accidents, sporting and bicycling injuries, and firearm use. Children of varying ages are susceptible to various forms of injury due to their developmental level as well as their environmental exposure. Young children rely on their caregivers to promote their safety. Young children also are not developmentally equipped to be able to recognize dangerous situations. Because pediatric injury is so common, nurses must become adept at assessment and intervention in the pediatric trauma victim.

## Nursing Assessment

The trauma survey includes a brief health history as the child is being assessed and life-saving measures are being instituted.

### Health History

Begin the health history by asking when the injury happened. If the child sustained a motor vehicle–related

injury, ask how fast the vehicle was going. Determine if the child was appropriately restrained in the automobile. If the child was riding a bicycle, skateboarding, or using in-line skates, was he or she wearing a helmet, knee pads, and wrist guards? Determine what interventions were performed at the scene. Was the child immobilized on a backboard to protect the cervical spine? If the child is bleeding, ask the person who transported the child to estimate the amount of blood lost.

If the child experienced a fall, ask if the fall was witnessed and the height from which the child fell. Did the child fall onto a hard surface such as concrete? How did the child land: on the head or back, or did the child catch himself or herself with the hands? Younger children and boys are at higher risk for injuring their head. Did the child lose consciousness at the scene? What kind of behavior did the child exhibit after the fall? Since the fall, has the child complained of a headache or been vomiting?

While obtaining a detailed history about the fall, think about the child's developmental stage. For example, does it seem plausible that a toddler might fall down the stairs? In contrast, what is the likelihood that a 2-month-old would suffer a fractured femur from a fall? Keep in mind the possibility of child abuse. Critically evaluate the reported circumstances and try to determine if the history, developmental stage of the child, and type of injury sustained match. In addition, evaluate the type of injury that the child sustained and the history given by the caregiver. For example, children who fall from significant heights often suffer skeletal fractures, but abdominal and chest injuries rarely result from falling from significant heights.

## Physical Examination

Physical examination of the child with a traumatic injury should be approached with an evaluation of the ABCs (primary survey) first. Assess the patency of the airway and establish the effectiveness of breathing (as discussed earlier in the chapter). Examine the child's respiratory effort, breath sounds, and color. Next, evaluate the circulation. Note the pulse rate and quality. Observe the color, skin temperature, and perfusion. If bleeding has occurred, the child's circulation may become compromised.

After assessing and intervening for the child's ABCs, proceed to the secondary survey. Assess for disability (D). Rapidly assess critical neurologic function. Determine the level of consciousness, pupillary reaction, and verbal and motor responses to auditory and painful stimuli. If the child is a young infant, palpate the anterior fontanel: a full and bulging fontanel signals increased intracranial pressure. The traumatized child's neurologic status may range from completely normal to comatose.

**Take Note!**

Unequal pupils or a fixed and dilated pupil is considered a neurosurgical emergency. Immediately report this finding.

Following the ABCs and D (disability) is E (exposure). Expose the child to observe the entire body for signs of injury, whether blunt or penetrating. Perform a systematic, thorough inspection of the child's body. Note active bleeding and extremity deformity, as well as any lacerations and abrasions. Observe for movement and any complaints of immobility or pain with movement. Inspect the abdomen for redness, skin discoloration, or distention. Auscultate for bowel sounds in all four quadrants. If the child is verbal, ask if he or she has any pain in the stomach. If the child is younger, ask, "Do you have a tummy ache?" If the child reports abdominal pain, ask the child to point to where it hurts. Note any guarding of the abdomen, which is an indication of abdominal pain. If bowel injury is a possibility, only light palpation is acceptable. Always assess the least tender areas first and palpate the more sensitive areas last.

### Laboratory and Diagnostic Testing

As in other pediatric emergencies, never delay life-saving measures to wait for laboratory or diagnostic test results. In addition to routine laboratory tests, common laboratory and diagnostic tests for the pediatric trauma victim include:

- Type and cross-match: to assess the child's blood type before blood products are given
- Prothrombin time and partial thromboplastin time: to evaluate for clotting dysfunction
- Amylase and lipase: to identify pancreatic injury
- Liver function tests: to assess for liver injury
- Pregnancy test (in any female who has reached puberty)
- CT scan, ultrasound, or MRI of the head, abdomen, or extremities: to evaluate the extent of the injury

### Nursing Management

Nursing management of the pediatric trauma victim focuses initially on the ABCs.

#### Providing Immediate Care

If head or spinal injury is suspected, open the airway using the jaw-thrust maneuver with cervical spine stabilization (see Fig. 53.4). The guidelines for basic life support recommend that if the airway cannot be opened using the jaw-thrust maneuver, it may be opened using the head tilt–chin lift maneuver since opening the airway is a priority (Berg et al., 2010). The head and neck of a trauma victim should be stabilized manually.

**Take Note!**

Infants and young children require unique cervical spine management because they have prominent occiputs that result in flexion of the neck in the supine position. To maintain the optimal neutral spinal position in the young child, use a special pediatric backboard with a head indentation, or use a folded towel to elevate the child's torso.

Clear the airway of obstruction using a large-bore suction device such as a Yankauer. If the child is breathing on his or her own, give oxygen at the highest flow possible (such as with a nonbreathing mask). If the child is not breathing on his or her own, intervene with basic life support discussed earlier in this chapter (Berg et al., 2010).

If a BVM device is available, connect it to the oxygen source and use the bag to ventilate the child. Observe the chest rise and be careful not to overventilate, as this results in abdominal distention. Deliver breaths at a rate of one breath every 3 seconds (Berg et al., 2010). Do not hyperventilate. In the not-too-distant past, head injury in children was managed using hyperventilation. This resulted in **hypocapnia** (decreased amounts of carbon dioxide in the blood). The physiologic effect of hypocapnia is the induction of vasoconstriction, which in turn results in tissue ischemia. Therefore, current management of head injury in children does not use hyperventilation. The only exception to this rule is in an acute situation, if the child is showing signs of a possible brain stem herniation, hyperventilation may be used initially and briefly.

Assess the child for a strong central pulse. If the child has no pulse, initiate CPR immediately. When perfusion is compromised, administer IV fluid resuscitation. Trauma victims are more likely to require colloids or blood products due to blood loss from the injury.

**Take Note!**

Children with head injury who have signs of shock such as poor perfusion and bradycardia should receive fluid volume resuscitation (Kleinman et al., 2010b).

### KEY CONCEPTS

- Young children's smaller airways and immature respiratory and immune systems place them at higher risk for respiratory distress than older children and adults. Children generally have healthy hearts and cardiovascular systems and thus rarely present with primary cardiac arrest. Younger children and adolescents are at higher risk for injury due to normal development at those ages.

- Children present with a variety of emergencies and injuries and must be evaluated and treated in an appropriate and timely fashion to achieve a positive outcome. The health history is obtained rapidly while life-saving measures are performed simultaneously.
- Assess the airway, then breathing, then circulation, providing interventions for alterations before moving on to the next assessment. Provide continuous reassessment, as children respond quickly to interventions and deteriorate quickly as well.
- Pulse oximetry and capnometry can be useful tools for evaluating respiratory status. Never delay intervention pending laboratory results if the child's clinical status warrants immediate action.
- Provide support and education to the child and family involved in an emergency. Teach families why certain procedures are being done, explaining technical medical interventions in simple terms and, for the child, at his or her developmental level.
- Small amounts of edema or secretions can contribute to significant respiratory effort in infants and young children.
- Children dehydrate more quickly than adults and experience alterations in perfusion related to hypovolemia.
- Children in respiratory distress and shock require supplemental oxygen. Intubation is necessary for the apneic child or the child whose airway is not maintainable.
- Accurate assessment of perfusion status and appropriate fluid resuscitation are critical in the prevention and treatment of shock in children.
- Life-threatening arrhythmias in children, though uncommon, often must be quickly treated with defibrillation or synchronized cardioversion in addition to CPR.
- In the case of near drowning, maintain ongoing assessment and intervention of pulmonary status.
- Maintain airway, breathing, and circulation in the child who has experienced an accidental ingestion and prepare for gastric lavage or administration of activated charcoal.
- In addition to intervening for airway, breathing, and circulation problems in the pediatric trauma victim, assess for altered neurologic status and extent of bleeding or injury.

## MULTIPLE CHOICE QUESTIONS

- An unresponsive toddler is brought to the emergency department. Assessment reveals mottled skin color, respiratory rate of 10 breaths per minute, and a brachial pulse of 52 bpm. What is the priority nursing action?
  - Prepare the defibrillator and draw up code medications.
  - Provide 100% oxygen with a bag-valve-mask and start chest compressions.
  - Start chest compressions and provide 100% oxygen via nonrebreather mask.
  - Begin an IV fluid infusion and administer epinephrine IV.
- A 10-year-old child in respiratory distress requires intubation. Which sizes of tracheal tubes will the nurse prepare?
  - 9.5 mm and 10.0 mm.
  - 8.5 mm and 9.0 mm.
  - 6.0 mm and 6.5 mm.
  - 6.5 mm and 7.0 mm.
- A preschooler presents to the emergency department with a history of vomiting, diarrhea, and fever over the past few days. She is receiving 100% oxygen via nonrebreather mask. Vital signs are temperature 104.5°F, pulse 144 bpm, respiratory rate 22 breaths per minute, and BP 70/50 mm Hg. She is listless and difficult to arouse and has weak peripheral pulses and prolonged capillary refill. What nursing intervention takes priority?
  - Administering acetaminophen rectally for the high fever.
  - Administering IV antibiotics for the infection.
  - Preparing the child for tracheal intubation.
  - Giving an IV bolus of normal saline 20 mL/kg.
- Assessment of a 12-year-old who crashed his bicycle without a helmet reveals the following: temperature 99.2°F, pulse 100 bpm, respiratory rate 24 breaths per minute with easy work of breathing, and BP 102/70 mm Hg. What is the priority action by the nurse?
  - Assess neurologic status while observing for obvious injuries.
  - Administer IV fluid bolus of normal saline at 20 mL/kg.
  - Remove the cervical collar if he complains that it bothers him.
  - Listen for bowel sounds while assessing for pain.
- An 18-month-old child is brought to the emergency department via ambulance after an accidental ingestion. What is the priority nursing action?
  - Take the child's vital signs.
  - Give oral syrup of ipecac.
  - Insert a nasogastric tube.
  - Start an IV line.

## CRITICAL THINKING EXERCISES

- A school-age child presents to the emergency department for evaluation. He had been feeling faint off and on and today fainted at school. On the cardiac monitor an abnormal cardiac rhythm is noted. At present the child is stable. What questions would be most appropriate for the nurse to ask when obtaining the child's health history? What objective assessments should the nurse make?
- Charlie is a 2-year-old who is admitted to the hospital after accidentally ingesting a medication. His mother, who brought Charlie to the hospital, is upset and crying. How does Charlie's age and stage of development affect his risk for accidental ingestion? How should the nurse respond to the mother's distress? Develop a discharge teaching plan for Charlie and his family related to poison prevention.
- A 7-month-old is brought to the acute care facility with a chief complaint of difficulty breathing. The infant's mother says that his cold has gotten worse and he won't eat. What additional questions should the nurse ask about the infant's health history? How would the nurse appropriately manage this infant's airway?

## STUDY ACTIVITIES

- Spend a day in the pediatric emergency department or urgent care center and document the role of the triage nurse.
- Observe the pediatric emergency medical team at work or observe a pediatric code in the hospital. Compare and contrast the measures performed for the child with those that would be performed for an adult in a similar emergency situation.

# CHAPTER WORKSHEET

3. Develop a teaching project related to injury prevention and present it at a local elementary, middle, or high school. Ensure that the education is geared toward the children's developmental level.
4. Interview the parents of a child who has experienced an emergency situation about how they felt during and after the emergency. Present the information to your classmates.
5. When providing care to a child in an emergency, the nurse performs the following assessments. Place them in the proper sequence.
  - a. Pupillary reaction
  - b. Presence of cough or sputum
  - c. Heart rate and capillary refill
  - d. Presence of bruises and abrasions
  - e. Work of breathing

# Appendix A

## Standard Laboratory Values

PREGNANT AND NONPREGNANT WOMEN		
Values	Nonpregnant	Pregnant
Hematologic		
Complete Blood Count (CBC)		
Hemoglobin, g/dL	12–16*	11.5–14*
Hematocrit, PCV, %	37–47	32–42
Red cell volume, mL	1,600	1,900
Plasma volume, mL	2,400	3,700
Red blood cell count, million/mm <sup>3</sup>	4–5.5	3.75–5.0
White blood cells, total per mm <sup>3</sup>	4,500–10,000	5,000–15,000
Polymorphonuclear cells, %	54–62	60–85
Lymphocytes, %	38–46	15–40
Erythrocyte sedimentation rate, mm/h	≤	30–90
MCHC, g/dL packed RBCs (mean corpuscular hemoglobin concentration)	30–36	No change
MCH (mean corpuscular hemoglobin per picogram)	29–32	No change
MCV/μm <sup>3</sup> (mean corpuscular volume per cubic micrometer)	82–96	No change
Blood Coagulation and Fibrinolytic Activity <sup>†</sup>		
Factors VII, VIII, IX, X		Increase in pregnancy, return to normal in early puerperium; factor VIII increases during and immediately after delivery
Factors XI, XIII		Decrease in pregnancy
Prothrombin time (protime), sec	60–70	Slight decrease in pregnancy
Partial thromboplastin time (PTT), sec	12–14	Slight decrease in pregnancy and again during second and third stage of labor (indicates clotting at placental site)
Bleeding time, min	1–3 (Duke)	No appreciable change
	2–4 (Ivy)	

(continued)

<b>PREGNANT AND NONPREGNANT WOMEN</b> (continued)		
<b>Values</b>	<b>Nonpregnant</b>	<b>Pregnant</b>
Coagulation time, min	6–10 (Lee/White)	No appreciable change
Platelets	150,000–350,000/mm <sup>3</sup>	No significant change until 3–5 days after childbirth, then marked increase (may predispose woman to thrombosis) and gradual return to normal
Fibrinolytic activity		Decreases in pregnancy, then abrupt return to normal (protection against thromboembolism)
Fibrinogen, mg/dL	250	400
Mineral and Vitamin Concentrations		
Serum iron, mcg	75–150	65–120
Total iron-binding capacity, mcg	250–450	300–500
Iron saturation, %	30–40	15–30
Vitamin B <sub>12</sub> , folic acid, ascorbic acid	Normal	Moderate decrease
Serum Protein		
Total, g/dL	6.7–8.3	5.5–7.5
Albumin, g/dL	3.5–5.5	3.0–5.0
Globulin, total, g/dL	2.3–3.5	3.0–4.0
Blood Sugar		
Fasting, mg/dL	70–80	65
2-hour postprandial, mg/dL	60–110	Under 140 after a 100-g carbohydrate meal is considered normal
Cardiovascular		
Blood pressure, mm Hg	120/80 <sup>‡</sup>	114/65
Peripheral resistance, dyne/s · cm <sup>-5</sup>	120	100
Venous Pressure, cm H <sub>2</sub> O		
Femoral	9	24
Antecubital	8	8
Pulse, rate/min	70	80
Stroke volume, mL	65	75
Cardiac output, L/min	4.5	6
Circulation time (arm-tongue), sec	15–16	12–14

<b>PREGNANT AND NONPREGNANT WOMEN</b> (continued)		
<b>Values</b>	<b>Nonpregnant</b>	<b>Pregnant</b>
Blood Volume, mL		
Whole blood	4,000	5,600
Plasma	2,400	3,700
Red blood cells	1,600	1,900
Plasma renin, units/L	3–10	10–80
Chest x-Ray Studies		
Transverse diameter of heart	–	1–2 cm increase
Left border of heart	–	Straightened
Cardiac volume	–	70-mL increase
Electrocardiogram	–	15° left axis deviation
V <sub>1</sub> and V <sub>2</sub>	–	Inverted T-wave
kV <sub>4</sub>	–	Low T
III	–	Q + inverted T
aVr	–	Small Q
Hepatic		
Bilirubin total	Not more than 1 mg/dL	Unchanged
Cephalin flocculation	Up to 2+ in 48 h	Positive in 10%
Serum cholesterol, mg/dL	110–300	↑ 60% from 16–32 wks of pregnancy; remains at this level until after delivery
Thymol turbidity	0–4 units	Positive in 15%
Serum alkaline phosphatase	2–4.5 units (Bodansky)	↑ from week 12 of pregnancy to 6 wks after childbirth
Serum lactate dehydrogenase		Unchanged
Serum glutamic-oxaloacetic trans- aminase		Unchanged
Serum globulin albumin, g/dL	1.5–3.0	↑ slight
	4.5–5.3	↓ 3.0 g by late pregnancy
A/G ratio		Decreased
α <sub>2</sub> -globulin		Increased
β-globulin		Increased
Serum cholinesterase		Decreased
Leucine aminopeptidase		Increased

(continued)

PREGNANT AND NONPREGNANT WOMEN (continued)		
Values	Nonpregnant	Pregnant
Sulfobromophthalein (5 mg/kg)	5% dye or less in 45 min	Somewhat decreased
Renal		
Bladder capacity, mL	1,300	1,500
Renal plasma flow (RPF), mL/min	490–700	Increase by 25%, to 612–875
Glomerular filtration rate (GFR), mL/min	105–132	Increase by 50%, to 160–198
Nonprotein nitrogen (NPN), mg/dL	25–40	Decreases
Blood urea nitrogen (BUN), mg/dL	20–25	Decreases
Serum creatinine, mg/kg/24 hr	20–22	Decreases
Serum uric acid, mg/kg/24 hr	257–750	Decreases
Urine glucose	Negative	Present in 20% of gravidas
Intravenous pyelogram (IVP)	Normal	Slight to moderate hydroureter and hydronephrosis; right kidney larger than left kidney
Miscellaneous		
Total thyroxine concentration	5–12 mcg/dL thyroxine	↑ 9–16 mcg/dL thyroxine (however, unbound thyroxine not greatly increased)
Ionized calcium		Relatively unchanged
Aldosterone		↑ 1 mg/24 hr by third trimester
Dehydroisoandrosterone	Plasma clearance 6–8 L/24 hr	↑ plasma clearance 10-fold to 20-fold
Adapted from Cunningham, F. G. (2012). Normal reference ranges for laboratory values in pregnancy. <i>UpToDate</i> . Retrieved from <a href="http://www.uptodate.com/contents/normal-reference-ranges-for-laboratory-values-in-pregnancy">http://www.uptodate.com/contents/normal-reference-ranges-for-laboratory-values-in-pregnancy</a> ; and Van Leeuwen, A. M., Poelhuis-Leth, D., & Bladh, M. L. (2011). <i>Davis's comprehensive handbook of laboratory &amp; diagnostic tests with nursing implications</i> (4th ed.), Philadelphia, PA: F. A. Davis.		

\* At sea level. Permanent residents of higher levels (e.g., Denver) require higher levels of hemoglobin.

† Pregnancy represents a hypercoagulable state.

‡ For the woman about 20 years of age.

10 years of age: 103/70.

30 years of age: 123/82.

40 years of age: 126/84.

# Appendix B Clinical Paths

## LABOR AND DELIVERY CLINICAL PATH—LABOR: EXPECTED OUTCOMES

	Active Phase	Expulsion/Pushing	Recovery 1st Hour Postpartum
CLIENT	<p>Client coping with labor support</p> <p>Client utilizing appropriate labor options</p> <p>Client verbalizes satisfaction with plan</p> <p>Management interventions</p>	<p>Client demonstrates effective pushing technique</p> <p>Client coping effectively with pushing</p> <p>Support person coping effectively with labor</p>	<p>Bonding appropriately with baby</p>
CLIENT'S STATUS	<p>Cervix dilated 5 cm—complete</p> <p>Contraction regularly with progressive cervical change</p> <p>Maternal/fetal well-being maintained</p> <p>Hydration maintained</p> <p>If indicated: FSE and/or IUPC placed</p> <p>Pitocin IV started</p> <p>Epidural placed/WE encouraged</p> <p>Medicate with PRN pain meds</p>	<p>Vaginal birth</p>	<p>Placenta delivered</p> <p>Fundus firm</p> <p>Lochia small—moderate</p> <p>Without clots</p> <p>Perineum intact/repaired</p> <p>Hemodynamically stable</p> <p>EBL &lt;500 mL</p>
CONTINUUM OF CARE	<p>Prenatal record available after 32 wks</p> <p>Prenatal labs WNL</p> <p>Preregistered to hospital</p> <p>Pediatrician identified</p> <p>Support after hospitalization identified</p> <p>Discharge plan discussed with client/family</p> <p>Communicates understanding of hospital and community resources</p>		
ASSESSMENT/TREATMENT	<p>Assess: Continuous EFM or auscultation</p> <p>Q 15 of 30 min as indicated</p> <p>Vital signs hourly/temp Q4 hr if intact membranes/Q 2 hr if membranes ruptured</p> <p>Uterine by monitor or palpation</p> <p>Bladder for distention</p> <p>Hydration status</p> <p>Cervical dilation, effacement, station</p>	<p>Assess: Q 15 min monitoring of fetal well-being (low risk) and Q 5 min (high risk)</p> <p>Vital signs hourly/temp. Q 2–4 hr depending on membrane status</p> <p>Bladder for distention</p> <p>Hydration status</p> <p>Pushing effectiveness</p> <p>Descent of presenting part</p> <p>Caput</p>	<p>Assess: Uterus—fundus</p> <p>Vital signs</p> <p>Lochia</p> <p>Bladder</p> <p>Perineum</p> <p>Placenta</p>
CLIENT EDUCATION	<p>Reinforce comfort measures</p> <p>Encourage use of labor options</p> <p>Inform client/support person of plan of care</p>	<p>Teaching of upright pushing positions</p> <p>Discourage prolonged maternal breath holding</p> <p>Encourage to assume position of choice</p> <p>Inform client of progress</p>	<p>Baby status</p> <p>Breast-feeding</p>

**LABOR AND DELIVERY CLINICAL PATH—LABOR: EXPECTED OUTCOMES** (continued)

Interventions			
TESTS/ PROCEDURES	Hgb or Hct (if not done recently) T & S (if ordered) VE as indicated IV therapy AROM by MD or CNM: assess for color, amount, and odor, as appropriate FSE/IUPC placement if indicated	AROM: assess for color, amount, and odor, as appropriate	Cord blood or RhoGAM workup if appropriate Cord blood if O+ mother
THERAPIES	Comfort measures/birthing ball/ ambulate/telemetry/shower IV therapy Amnio infusion for variable decelerations If appropriate, pain management reviewed	Perineal massage Warm soaks to perineal area Allow to rest until feels the urge to push Frequent position changes Cool cloth/ice chips	Ice pack to perineum Warm blankets
MEDS	Antibiotics as indicated for + GBS Pitocin if indicated PRN pain medication (encourage WE if requesting this)	Pitocin if indicated	Pitocin IV
ACTIVITY/ SAFETY	Labor option usage Position changes	Provide wedge if supine Promote effective position for pushing: i.e., squatting, side lying, upright Breathing technique client/support person most comfortable with	Assist with ambulate to bathroom Infant care Assist with positioning for breast-feeding Infant ID bands present
NUTRI- TION	Clear liquids Ice chips Others	Clear liquids Ice chips	Return to previous diet
UNIQUE CLIENT NEEDS			

## INTEGRATED PLAN OF CARE FOR CESAREAN DELIVERY

Expected Client Outcomes				
	Phase 1 Preadmission (Cesarean Delivery)	Phase 2 Surgery/ Immediate Postop/ Day of Surgery	Phase 3 Postop Day 1	
Usual time in phase Assessment/ potential complications	<b>N/A Date Started:</b> VS WNL for client Hgb or Hct/values within normal SLH antepartum range	Up to 23 hr VS WNL for client Systems assessment: Skin warm, dry Clear ⇒ Alert & oriented ⇒ Neg. Homans' sign ⇒ Breast soft/nipples intact ⇒ Lungs clear ⇒ Bowel sounds present ⇒ Fundus firm u/u or u 1-2 (-/+) Lochia sm—mod Dsg dry and intact No signs infiltration IV site Verbalizes comfort using pain rating scale 0-10	1 day VS WNL for client Afebrile Voiding without Foley ⇒ Passing flatus Incision without redness or drainage Lochia small amount Fundus firm u/1-2 Verbalizes comfort using pain scale 0-10 on oral pain meds	1-2 days Incision well approximated, without drainage or redness Passing flatus Lochia sm/mod amt Fundus firm u/1-2 Verbalizes comfort using pain medication as described
Client/family knowledge	<b>Date All Above Met</b> Verbalizes understanding of condition and need for surgery Verbalizes understanding of all preop teaching	<b>Date All Above Met</b> Verbalizes correct use of PCA/fentanyl pump and when to request pain medication Turn, cough, & deep breathe appropriately	<b>Date All Above Met</b> Can state criteria for when to call doctor for problems postdischarge ⇒ ↑ Bleeding ↑ Temperature ⇒ Incision redness, odor or drainage ⇒	<b>Date All Above Met</b> Verbalizes follow-up appointment date and time Verbalizes proper dosing of pain medication
ADLs/activity	<b>Date All Above Met</b> Verbalizes understanding of NPO status	<b>Date All Above Met</b> Able to ambulate with minimal assistance Tolerating clear/full liquid diet Bonding observed with newborn— taking-in phase ⇒	<b>Date All Above Met</b> Ambulating without assistance Tolerating soft to regular diet	<b>Date All Above Met</b> Ambulating in hall

## Breast-Feeding and Medication Use

### GENERAL CONSIDERATIONS

- Most medications are safe to use while breast-feeding; however, the woman should always check with the pediatrician, physician, or lactation specialist before taking any medications, including over-the-counter and herbal products.
- Inform the woman that she has the right to seek a second opinion if the physician does not perform a thoughtful risk-versus-benefit assessment before prescribing medications or advising against breast-feeding.
- Most medications pass from the woman's bloodstream into the breast milk. However, the amount is usually very small and unlikely to harm the baby.
- A preterm or other special needs neonate is more susceptible to the adverse effects of medications in breast milk. A woman who is taking medications and whose baby is in the neonatal intensive care unit or special care nursery should consult with the pediatrician or neonatologist before feeding her breast milk to the baby.
- If the woman is taking a prescribed medication, she should take the medication just after breast-feeding. This practice helps ensure that the lowest possible dose of medication reaches the baby through the breast milk.
- Some medications can cause changes in the amount of milk the woman produces. Teach the woman to report any changes in milk production.

### LACTATION RISK CATEGORIES (LRC)

Location Category	Risk	Rationale
L1	Safest	Clinical research or long-term observation of use in many breast-feeding women has not demonstrated risk to the infant.
L2	Safer	Limited clinical research has not demonstrated an increase in adverse effects in the infant.

Location Category	Risk	Rationale
L3	Moderately safe	There is possible risk to the infant; however, the risks are minimal or nonthreatening in nature. These medications should be given only when the potential benefit outweighs the risk to the infant.
L4	Possibly hazardous	There is positive evidence of risk to the infant; however, in life-threatening situations or for serious diseases, the benefit might outweigh the risk.
L5	Contraindicated	The risk of using the medication clearly outweighs any possible benefit from breast-feeding.

### POTENTIAL EFFECTS OF SELECTED MEDICATION CATEGORIES ON THE BREAST-FED INFANT

#### Narcotic Analgesics

- Codeine and hydrocodone appear to be safe in moderate doses. Rarely the neonate may experience sedation and/or apnea. (LRC: L3)
- Meperidine (Demerol) can lead to sedation of the neonate. (LRC: L3)
- Low to moderate doses of morphine appear to be safe. (LRC: L2)
- Trace-to-negligible amounts of fentanyl are found in human milk. (LRC: L2)

#### Nonnarcotic Analgesics and NSAIDs

- Acetaminophen and ibuprofen are approved for use. (LRC: L1)

- Naproxen may cause neonatal hemorrhage and anemia if used for prolonged periods. (LRC: L3 for short-term use and L4 for long-term use)
- The newer COX2 inhibitors, such as celecoxib (Celebrex), appear to be safe for use. (LRC: L2)

## Antibiotics

- Levels in breast milk are usually very low.
- The penicillins and cephalosporins are generally considered safe to use. (LRC: L1 and L2)
- Tetracyclines can be safely used for short periods but are not suitable for long-term therapy (e.g., for treatment of acne). (LRC: L2)
- Sulfonamides should not be used during the neonatal stage (the first month of life). (LRC: L3)

## Antihypertensives

- A high degree of caution is advised when antihypertensives are used during breast-feeding.
- Some beta blockers can be used.
- Hydralazine and methyl dopa are considered to be safe. (LRC: L2)
- Angiotensin-converting enzyme (ACE) inhibitors are not recommended in the early postpartum period.

## Sedatives and Hypnotics

- Neonatal withdrawal can occur when antianxiety medications, such as lorazepam, are taken. Fortunately withdrawal is generally mild.
- Phenothiazines, such as Phenergan and Thorazine, may lead to sleep apnea and increase the risk for sudden infant death syndrome.

## Antidepressants

- The risk to the baby is often higher if the woman is depressed and remains untreated, rather than taking the medication.
- The older tricyclics are considered to be safe; however they cause many bothersome side effects, such as weight gain and dry mouth, which may lead to non-compliance on the part of the woman.

- The selective serotonin uptake inhibitors (SSRIs) are also considered to be safe and have a lower side effect profile, which makes them more palatable to the woman. (LRC: L2 and L3)

## Mood Stabilizers (Antimanic Medication)

- Lithium is found in breast milk and is best not used in the breast-feeding woman. (LRC: L4)
- Valproic acid (Depakote) seems to be a more appropriate choice for the woman with bipolar disorder. The infant will need periodic lab studies to check platelets and liver function.

## Corticosteroids

- Corticosteroids do not pass into the milk in large quantities.
- Inhaled steroids are safe to use because they do not accumulate in the bloodstream.

## Thyroid Medication

- Thyroid medications, such as levothyroxine (Synthroid), can be taken while breast-feeding.
- Most are in LRC category L1.

## MEDICATIONS THAT USUALLY ARE CONTRAINDICATED FOR THE BREAST-FEEDING WOMAN

- Amiodarone
- Antineoplastic agents
- Chloramphenicol
- Doxepin
- Ergotamine and other ergot derivatives
- Iodides
- Methotrexate and immunosuppressants
- Lithium
- Radiopharmaceuticals
- Ribavirin
- Tetracycline (prolonged use—more than 3 weeks)
- Pseudoephedrine (found in many over-the-counter medications)

## Denver II Developmental Assessment

DA FORM 5694, MAY 1988  
**Denver II**

Examiner:  
 Date:

Name:  
 Birthdate:  
 ID No.:

FOR USE OF THIS FORM, SEE AR 600-75

©1969, 1989, 1990 W. K. Frankenburg and J. B. Dodds ©1978 W. K. Frankenburg

## DIRECTIONS FOR ADMINISTRATION

1. Try to get child to smile by smiling, talking or waving. Do not touch him/her.
2. Child must stare at hand several seconds.
3. Parent may help guide toothbrush and put toothpaste on brush.
4. Child does not have to be able to tie shoes or button/zip in the back.
5. Move yarn slowly in an arc from one side to the other, about 8" above child's face.
6. Pass if child grasps rattle when it is touched to the backs or tips of fingers.
7. Pass if child tries to see where yarn went. Yarn should be dropped quickly from sight from tester's hand without arm movement.
8. Child must transfer cube from hand to hand without help of body, mouth, or table.
9. Pass if child picks up raisin with any part of thumb and finger.
10. Line can vary only 30 degrees or less from tester's line. ✓/
11. Make a fist with thumb pointing upward and wiggle only the thumb. Pass if child imitates and does not move any fingers other than the thumb.

12. Pass any enclosed form. Fail continuous round motions.

13. Which line is longer? (Not bigger.) Turn paper upside down and repeat. (pass 3 of 3 or 5 of 6)

14. Pass any lines crossing near midpoint.

15. Have child copy first. If failed, demonstrate.

When giving items 12, 14, and 15, do not name the forms. Do not demonstrate 12 and 14.

16. When scoring, each pair (2 arms, 2 legs, etc.) counts as one part.
17. Place one cube in cup and shake gently near child's ear, but out of sight. Repeat for other ear.
18. Point to picture and have child name it. (No credit is given for sounds only.)  
If less than 4 pictures are named correctly, have child point to picture as each is named by tester.

19. Using doll, tell child: Show me the nose, eyes, ears, mouth, hands, feet, tummy, hair. Pass 6 of 8.
20. Using pictures, ask child: Which one flies?... says meow?... talks?... barks?... gallops? Pass 2 of 5, 4 of 5.
21. Ask child: What do you do when you are cold?... tired?... hungry? Pass 2 of 3, 3 of 3.
22. Ask child: What do you do with a cup? What is a chair used for? What is a pencil used for?  
Action words must be included in answers.
23. Pass if child correctly places and says how many blocks are on paper. (1, 5).
24. Tell child: Put block **on** table; **under** table; **in front of** me, **behind** me. Pass 4 of 4.  
(Do not help child by pointing, moving head or eyes.)
25. Ask child: What is a ball?... lake?... desk?... house?... banana?... curtain?... fence?... ceiling? Pass if defined in terms of use, shape, what it is made of, or general category (such as banana is fruit, not just yellow). Pass 5 of 8, 7 of 8.
26. Ask child: If a horse is big, a mouse is \_\_\_? If fire is hot, ice is \_\_\_? If the sun shines during the day, the moon shines during the \_\_\_? Pass 2 of 3.
27. Child may use wall or rail only, not person. May not crawl.
28. Child must throw ball overhand 3 feet to within arm's reach of tester.
29. Child must perform standing broad jump over width of test sheet (8 1/2 inches).
30. Tell child to walk forward,  heel within 1 inch of toe. Tester may demonstrate.  
Child must walk 4 consecutive steps.
31. In the second year, half of normal children are non-compliant.

## Down Syndrome

### Health Care Guidelines

TABLE I.1

DOWN SYNDROME HEALTH CARE GUIDELINES (1999 REVISION) RECORD SHEET

Sheet #1: Birth to Age 12 Years

Name: \_\_\_\_\_ Birthday: \_\_\_\_\_

Medical Issues	At Birth or at Diagnosis	Age, in years														
		6-mo	1	1½	2	2½	3	4	5	6	7	8	9	10	11	12
Karyotype & Genetic Counseling																
Usual Preventative Care																
Cardiology	Echo															
Audiologic Evaluation	ABR or OAE															
Ophthalmologic Evaluation	Red reflex															
Thyroid (TSH & T <sub>4</sub> )	State screening															
Nutrition																
Dental Exam <sup>1</sup>																
Celiac Screening <sup>2</sup>																
Parent Support																
Developmental & Educational Services	Early Intervention															
Neck X-rays & Neurological Exam <sup>3</sup>								X-ray								
Pneumococcal Conjugate Vaccine Series																

Instructions: Perform indicated exam/screening and record date in blank spaces. The grey or shaded boxes mean no action is to be taken for those ages.

<sup>1</sup>Begin Dental Exams at 2 years of age, and continue every 6 months thereafter.

<sup>2</sup>IgA antiendomysium antibodies and total IgA.

<sup>3</sup>Cervical spine x-rays: flexion, neutral and extension, between 3 and 5 years of age. Repeat as needed for Special Olympic participation. Neurological examination at each visit.

TABLE I.2

DOWN SYNDROME HEALTH CARE GUIDELINES (1999 REVISION) RECORD SHEET

Sheet #2: 13 Years to Adulthood

Name: \_\_\_\_\_ Birthday: \_\_\_\_\_

Medical Issues	Age, in years							
	13	14	15	16	17	18	19	20-29
Usual Preventative Care								
Audiologic Evaluation								
Ophthalmologic Evaluation								
Thyroid (TSH & T <sub>4</sub> )								
Nutrition								
Dental Exam <sup>1</sup>								
Parent Support								
Developmental & Educational Services								
Neck X-rays & Neurological Exam <sup>2</sup>								
Pelvic exam <sup>3</sup>								
Assess Contraceptive Need <sup>3</sup>								

Instructions: Perform indicated exam/screening and record date in blank spaces. The shaded boxes mean no action is to be taken for those ages.

<sup>1</sup>Begin Dental Exams at 2 years of age, and continue every 6 month thereafter.

<sup>2</sup>Cervical spine x-rays: flexion, neutral and extension, between 3 and 5 years of age. Repeat as needed for Special Olympics participation. Neurological examination at each visit.

<sup>3</sup>If sexually active.
